2022 ASCO ANNUAL MEETING PROCEEDINGS ABSTRACTS

Letter From the Editors

The 2022 *ASCO Annual Meeting Abstracts* (a supplement to *Journal of Clinical Oncology*) is an enduring record of the more than 2,400 abstracts selected by the ASCO Scientific Program Committee for presentation as part of the ASCO Annual Meeting.

Publication-only abstracts are included in the online supplement to the June 1 issue of *Journal of Clinical Oncology* at JCO.org. Abstracts can be also accessed online through the ASCO Meeting Experience (meetings.asco.org). Online abstracts include the full list of abstract authors and their disclosure information. All abstracts carry *Journal of Clinical Oncology* citations, for example:

J Clin Oncol 40:16s, 2022 (suppl; abstr 500)

We are also excited to share a new initiative to increase awareness of abstract publication through social media, specifically to increase awareness of less publicized, yet important, research. We will partner with *JCO* to curate abstract collections for publication on JCO.org and promote collections via Twitter. We will launch this initiative with the 2022 ASCO Annual Meeting and themes will include: diversity, equity and inclusion, global health, merit awardees, and health economics. Follow us on Twitter @JCO_ASCO, @ASCO, #ASCO22!

Should you have any questions or comments about this publication, we encourage you to provide feedback by contacting us at abstracts@asco.org.

Sincerely,

Pamela L. Kunz, MD
Consultant Editor for Meeting Abstracts, Journal of Clinical Oncology

Ryan D. Gentzler, MD, MS
Associate Consultant Editor for Meeting Abstracts, Journal of Clinical Oncology

ASCO Abstracts Policy

Public Release of Abstracts

The 2022 ASCO Annual Meeting Abstracts were publicly released by ASCO at 5:00 PM EDT on Thursday, May 26, 2022. Abstracts are publicly available online at meetings.asco.org. Late-Breaking Abstracts, which include all Plenary Abstracts, will be publicly released according to the following schedule:

- Late-Breaking Abstracts presented in a scientific presentation on Friday, June 3, will be publicly released Friday, June 3, at 8:00 AM EDT.
- Late-Breaking Abstracts presented in a scientific presentation on Saturday, June 4, will be publicly released Saturday, June 4, at 8:00 AM EDT.
- Late-Breaking Abstracts presented in a scientific presentation on Sunday, June 5, will be publicly released Sunday, June 5, at 8:00 AM EDT.
- Late-Breaking Abstracts presented in a scientific presentation on Monday, June 6, will be publicly released Monday, June 6, at 8:00 AM EDT.
- Late-Breaking Abstracts presented in a scientific presentation on Tuesday, June 7, will be publicly released Tuesday, June 7, at 8:00 AM EDT.

In the unlikely event that ASCO publicly releases an abstract in advance of the scheduled time, the release will be publicly announced on https://conferences.asco.org/am/abstract-policies-embargoes-exceptions.

Conflict of Interest Disclosure

All financial relationships reported by contributors to this activity are provided to learners prior to the start of the activity. During planning and development of the activity, relevant financial relationships were mitigated for all contributors. Relationships are considered self-held and compensated unless otherwise noted (I = Immediate family member; Inst = My Institution). Disclosures are submitted per the ASCO Policy for Relationships with Companies.

Please email coi@asco.org with specific questions or concerns.

LBA1 **Plenary Session**

Panitumumab (PAN) plus mFOLFOX6 versus bevacizumab (BEV) plus mFOLFOX6 as first-line treatment in patients with *RAS* wild-type (WT) metastatic colorectal cancer (mCRC): Results from the phase 3 PARADIGM trial. *First Author: Takayuki Yoshino, National Cancer Center Hospital East, Kashiwa, Japan*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

LBA2 **Plenary Session**

Phase III assessment of topotecan and cyclophosphamide and high-dose ifosfamide in rEECur: An international randomized controlled trial of chemotherapy for the treatment of recurrent and primary refractory Ewing sarcoma (RR-ES). *First Author: Martin McCabe, University of Manchester, Manchester, United Kingdom*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

LBA3 **Plenary Session**

Trastuzumab deruxtecan (T-DXd) versus treatment of physician's choice (TPC) in patients (pts) with HER2-low unresectable and/or metastatic breast cancer (mBC): Results of DESTINY-Breast04, a randomized, phase 3 study. *First Author: Shanu Modi, Memorial Sloan Kettering Cancer Center, New York, NY*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

LBA4 **Plenary Session**

Lenalidomide, bortezomib, and dexamethasone (RVd) ± autologous stem cell transplantation (ASCT) and R maintenance to progression for newly diagnosed multiple myeloma (NDMM): The phase 3 DETERMINATION trial. *First Author: Paul G. Richardson, Department of Medical Oncology, Dana-Farber Cancer Institute, Jerome Lipper Center for Multiple Myeloma Research, Harvard Medical School, Boston, MA*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

LBA100 **Clinical Science Symposium**

Adjuvant chemotherapy guided by circulating tumor DNA analysis in stage II colon cancer: The randomized DYNAMIC Trial. *First Author: Jeanne Tie, Peter MacCallum Cancer Centre, University of Melbourne, Walter and Eliza Hall Institute, Melbourne, VIC, Australia*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

101 **Clinical Science Symposium**

Circulating tumor DNA (ctDNA) analyses of the phase III VOYAGER trial: KIT mutational landscape and outcomes in patients with advanced gastrointestinal stromal tumor (GIST). *First Author: Cesar Serrano, Vall d'Hebron Institute of Oncology, Vall d' Hebron University Hospital, Barcelona, Spain*

Background: The genotype of primary mutations predicts imatinib response in untreated metastatic GIST. However, the sequence of salvage treatments in metastatic GIST is based solely on the chronological order of registration trials. ctDNA sequencing offers a powerful diagnostic tool to detect resistance mutations in GIST but has not been shown to correlate with outcomes in clinical trials of pretreated patients (pts). We analyzed ctDNA samples collected at baseline in the phase III VOYAGER trial (NCT03465722) to describe the landscape of KIT alterations and its association with outcomes of pts treated with avapritinib or regorafenib. **Methods**: In VOYAGER, 476 pts with advanced KIT-mutant GIST were randomly assigned to avapritinib (240 pts) or regorafenib (236 pts) in 3rd-4th line. Baseline plasma was collected and ctDNA analyzed with the Guardant 360 (G360), 74-gene panel. KIT molecular subgroups were determined and correlated with outcomes. PDGFRA-mutant GISTs were excluded from outcomes analysis. **Results**: Baseline ctDNA analysis was performed in 386/476 pts (81%). ctDNA was detected in 333 pts (86%), with 250 and 18 pts showing at least one KIT (75%) or PDGFRA (5%) variant, respectively. KIT primary mutations were detected in 71% pts (exon 11, 56%; exon 9, 14%; exon 13, 1%) and KIT secondary mutations in 55% of pts. Activation loop (AL, exons 17 and 18) was more commonly affected (44%) than the ATP-binding pocket (ABP, exons 13 and 14; 23%). Among KIT-mutant tumors, multiple KIT mutations were commonly detected within individual tumors (mean, 2.56; range, 1-14). Notably, 17% of pts had > 3 mutations (mean, 6.07; range, 4 to 14). Median PFS and OS were shorter for patients whose ctDNA was positive for V654A or T670I (ABP hot spots) when treated with avapritinib vs. regorafenib: mPFS, 1.9 mo vs. 7.4 mo; log-rank p < .001; mOS, 8.3 mo vs. 11.7 mo; log rank p = .0651. mPFS was shorter for patients with ctDNA positive for KIT exon 17 mutation if concurrently KIT V654A/T670I was absent when treated with avapritinib, with no difference in OS: mPFS, 4.7 mo vs. 6.7 mo; log-rank p = .03; mOS, 19.2 mo vs. NR; log-rank p = .628. mPFS on avapritinib was longer when ABP mutations were absent when compared to those with ABP present (5.6 vs. 1.9 mo; log-rank p < .001). There were no differences considering AL mutations vs. no AL mutations (3.8 vs. 3.9 mo; log-rank p = .622) when treated with avapritinib. Regorafenib showed similar activity regardless of KIT mutational status and the location of KIT mutation. **Conclusions**: Hybrid capture-based plasma sequencing detects ctDNA in the majority of patients with advanced TKI-resistant GIST, including heterogeneity of KIT mutations. This study is the first to show that ctDNA sequencing correlates with outcomes in pretreated GIST. Identification of ABP (exon13/14) KIT mutations negatively correlates with avapritinib activity. 102 **Clinical Science Symposium**

Largest evaluation of acquired resistance to sotorasib in *KRAS* p.G12C-mutated non–small cell lung cancer (NSCLC) and colorectal cancer (CRC): Plasma biomarker analysis of CodeBreaK100. *First Author: Bob T. Li, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Sotorasib, a specific, irreversible $KRAS^{G12C}$ inhibitor, has been approved in multiple countries for adults with *KRAS* p.G12C-mutated locally advanced or metastatic NSCLC who received prior systemic therapy based on the global phase 1/2 CodeBreaK100 trial. Here we describe putative mechanisms of acquired resistance to sotorasib from the largest single dataset evaluated to-date. **Methods:** Patients with advanced *KRAS* p.G12C-mutated NSCLC or CRC from the CodeBreaK100 Ph1/2 trial who received sotorasib monotherapy at 960 mg once daily were analyzed for efficacy. Primary endpoint was objective response rate (ORR) assessed by central review. To investigate biomarkers of resistance to sotorasib, an exploratory endpoint was defined to examine acquired genomic alterations at disease progression. Plasma samples collected at baseline and progression were analyzed for genomic alterations with the 23-gene Resolution Bioscience ctDx Lung test for NSCLC and the 74-gene Guardant 360 ctDNA test for CRC. Acquired genomic alterations were defined by their absence at baseline and presence at progression. **Results:** In 174 pts with NSCLC and 91 pts with CRC-treated with sotorasib, the ORR were 41% and 12% respectively. Median progression-free survival and median overall survival were 6.3 months (mos) and 12.5 mos for NSCLC pts and 4.2 mos and 13.4 mos for CRC pts (median follow-up: 22.5 mos NSCLC; 12.5 mos CRC). A total of 67 NSCLC pts and 45 CRC pts had a plasma sample sequenced both at baseline and at progression. At least one new acquired genomic alteration at progression was detected in 19 (28%) NSCLC pts and in 33 (73%) CRC pts (Table). The acquired genomic alterations were heterogeneous in both NSCLC and CRC, with variants detected across multiple genes and pathways. The most prevalent putative pathway of resistance in both NSCLC and CRC was the receptor tyrosine kinase (RTK) pathway. Secondary *RAS* alterations occurred more frequently in CRC versus NSCLC pts (16% vs. 3%). **Conclusions:** Based on the largest descriptive dataset to-date, diverse mechanisms of acquired resistance occur in *KRAS* p.G12C-mutated NSCLC and CRC pts treated with sotorasib. New RTK pathway alterations frequently emerged at progression, highlighting the potential role for combining sotorasib with upstream inhibitors of RTK, such as SHP2 or EGFR inhibitors. Serial plasma DNA analysis revealed acquired resistance patterns that support the development of $KRAS^{G12C}$ inhibitor combination therapies. Clinical trial information: NCT03600883. Research Sponsor: Amgen Inc.

Patients, n (%)	NSCLC (N = 67)	CRC (N = 45)
Acquired genomic alteration at progression	19 (28)	33 (73)
RTK pathway alteration	16 (24)	12 (27)
EGFR	6 (9)	7 (16)
2° *RAS* alteration	2 (3)	7 (16)
>1 alteration	8 (12)	27 (60)

103 **Clinical Science Symposium**

Circulating tumor DNA (ctDNA) and late recurrence in high-risk, hormone receptor–positive, HER2-negative breast cancer (CHiRP). *First Author: Marla Lipsyc-Sharf, Dana-Farber Cancer Institute, Boston, MA*

Background: Hormone receptor–positive breast cancer (HR+ BC) is the most common cause of BC-related death. Over half of metastatic recurrences occur ≥ 5 years (y) from diagnosis. Detection of minimal residual disease (MRD) via circulating tumor DNA (ctDNA) can identify cancer recurrence months to years in advance and may be an important tool to guide therapy. Little is known about ctDNA in the late adjuvant setting. We investigated ctDNA dynamics and clinical outcomes in pts ≥ 5 y from diagnosis of high-risk early-stage HR+ BC. **Methods:** Patients with high-risk HR+ BC (T3-4 or N2-3 or T1 with 3+ lymph nodes, or T2N1 [and Oncotype RS ≥ 26; grade 3; or Ki-67 ≥ 20%]) with no evidence of recurrence 5 y after diagnosis were prospectively identified and consented. Plasma samples were collected at time of consent and at routine visits every 6-12 mos. Whole-exome sequencing (WES) was performed on primary tumor tissue to identify somatic mutations and design for each patient a RaDaR assay, a tumor-informed liquid biopsy test to detect plasma ctDNA. Per current practice standards, pts did not undergo regular surveillance imaging. All pts were followed for development of local and/or distant metastatic recurrence, as determined by their clinical provider. **Results:** Of 103 pts enrolled, 85 had sufficient tumor tissue, and 83 pts had successful WES. Personalized RaDaR assays were designed targeting 12-51 variants (median, 36), and used to test 219 plasma samples from 83 pts. The number of plasma samples per patient ranged from 1-7 (median, 2). 57 pts (68.7%) had stage 3 disease, and most (75, 90.4%) received curative-intent chemotherapy. All pts received endocrine therapy (ET). 39 (47%) remained on adjuvant ET at time of last follow up. Of 44 pts who completed adjuvant ET, 41 (93.2%) received > 5 y of treatment. Time from diagnosis to first sample ranged from 4.9-20 y (median, 8.4 y). Median (range) follow up was 10.2 (6.7-22.3) y from diagnosis and 1.8 (0-3.6) y from first sample. 5 pts (6%) developed distant metastatic recurrence and 2 pts (2.4%) had locoregional recurrence. 4/83 (5%) pts were MRD+ at study entry and 8/83 (10%) pts were MRD+ at any time point. 5/5 (100%) pts with metastatic recurrence were MRD+, with ctDNA lead times up to 37.6 mos. ctDNA was detected at tumor fractions of 0.0027-26.84% (median, 0.396%). 2/8 (25%) MRD+ pts had not had clinical recurrence at latest follow up, one with no follow up since detection and one 15.4 mos from ctDNA detection (with ctDNA levels 0.045% and 26.84%). **Conclusions:** Here we report—to our knowledge—the first data on ctDNA detection in late adjuvant HR+ BC. 10% of pts had MRD at ≥ 5 y from diagnosis. ctDNA analysis identified MRD in all cases of distant recurrence. ctDNA was detected in 2 pts who have not yet experienced recurrence. Longer follow up is necessary for these pts at high risk. Additional studies will determine if ctDNA-guided intervention can alter clinical outcomes. Research Sponsor: AstraZeneca and Susan G. Komen Career Catalyst Research Grant to Dr. Heather Parsons (1K08CA252639-01A1), Inivata; Dana-Farber/Harvard Cancer Center (DF/HCC) Breast Cancer Specialized Program of Research Excellence (SPORE) grant (Grant 1P50CA168504), Susan G. Komen Leadership Grant to Dr. Eric Winer (SAB190001).

104 **Clinical Science Symposium**

Updated overall survival (OS) data from the phase 1b study of tebentafusp (tebe) as monotherapy or combination therapy with durvalumab (durva) and/or tremelimumab (treme) in metastatic cutaneous melanoma (mCM). *First Author: Mark R. Middleton, University of Oxford, Oxford, United Kingdom*

Background: Tebe is a T-cell receptor bispecific (gp100 x CD3) against gp100 peptide-HLA-A2 complexes that are overexpressed in uveal (UM)/cutaneous melanoma (CM). Tebe is the only therapy to show an OS benefit (HR 0.51) in a phase (Ph) 3 trial in previously untreated metastatic UM. In a prior Ph 1 trial, tebe demonstrated monotherapy activity in anti-PD1 naïve mCM (1-yr OS, approx. 74%). The safety and initial activity of tebe with dose escalation of durva and/or treme in previously treated mCM has been reported. Here, we present updated OS in the subset of mCM patients (pts) relapsed or refractory to prior anti-PD1, a population where recent reports suggest a benchmark 1-yr OS of approximately 55% and median OS of approximately 14 months (mos). **Methods:** Patients with HLA-A2+, pre-treated mCM received weekly tebe (IV) monotherapy in Arm 4a or in combination with dose escalation of durva and/or treme (IV) on day 15 of each cycle (Arms 1-3). Primary objective was RP2D, secondary objectives were safety and efficacy. Subgroup analyses were performed for durva doses ≥10 mg/kg, a threshold previously defined by Bavarel et al, 2018. Analysis performed on data cut-off 04 January 2022 with median follow up for 14.3 mos. [NCT02535078] **Results:** 112 pts were treated with median age 59, 23% were ECOG = 1, 37% were BRAFm (73% received prior BRAFi/MEKi), 55% had LDH > ULN. 92% of pts were 2L+ and 74% 3L+; median 3 prior lines. The safety profile of all therapy arms within this study therapy remains very favorable with no new safety signals identified. 97 of 112 pts were documented as relapsed or refractory to prior anti-PD1 (80% also received ipilimumab). Of these 97 pts, 32 received tebe + durva (Arm 1), 13 received tebe + treme (Arm 2), 26 received triplet therapy (Arm 3), and 20 received tebe monotherapy (Arm 4a). 33 of 97 pts in any arm received durva ≥ 10 mg/kg with 1-yr OS of 79%, 2-yr OS of 34%, and median OS of 20 mos. 64 of 97 pts received durva < 10 mg/kg with 1-yr OS of 53%, 2-yr OS of 24%, and median OS of 13 mos. Tebe + durva doublet therapy had similar OS to triplet therapy with tebe + durva + treme: 1-yr OS of 74% vs. 76%, and 2-yr OS of 32% vs. 27%, respectively. **Conclusions:** Promising OS is seen in mCM similar to mUM, with both tumor types overexpressing gp100. In mCM relapsed or refractory to prior anti-PD1, tebe with anti–PD-L1 continues to demonstrate promising OS (1-yr, approx. 75%) compared to recent benchmarks (1-yr, approx. 55%). These data provide rationale for a randomized study of tebe with anti-PD(L)1 in mCM. Clinical trial information: NCT02535078. Research Sponsor: Immunocore.

105 **Clinical Science Symposium**

Efficacy and safety of zenocutuzumab, a HER2 x HER3 bispecific antibody, across advanced NRG1 fusion (NRG1+) cancers. *First Author: Alison M. Schram, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: NRG1 fusions are rare oncogenic drivers that have been identified in a variety of solid tumors. These proteins bind HER3, leading to HER2/HER3 heterodimerization and oncogenic transformation. Zenocutuzumab (MCLA-128; Zeno) is a Biclonics antibody that overcomes HER3 mediated NRG1 (or NRG1 fusion) signaling in tumor cells. Zeno docks on HER2, then binds to and blocks the NRG1 fusion-HER3 interaction and HER3 heterodimerization with HER2. Zeno is being evaluated in patients (pts) with NRG1+ cancer in the ongoing pivotal phase 2 part of the eNRGy study and early access program (EAP). **Methods:** Pts with NRG1+ solid tumors previously treated with or not candidates for standard therapy, aged ≥ 18 years, with ECOG PS ≤ 2, and measurable (RECIST 1.1) or evaluable disease, were enrolled. *NRG1* fusions were determined by next generation sequencing (NGS) before enrollment. Zeno (750 mg IV Q2W) was administered until disease progression or unacceptable toxicity. Tumor imaging was conducted every 8 weeks. The primary endpoint is investigator (INV)-assessed objective response rate (ORR) and secondary endpoints include duration of response (DOR) and safety. **Results:** As of 12 Jan 2022, 99 pts with NRG1+ cancer (85 eNRGy, 14 EAP) were enrolled. Efficacy was assessed in 73 pts who received ≥ 1 dose of Zeno and who were enrolled as of 12 Jul 2021 to allow for the opportunity to have ≥ 6 months (mo) follow-up and met the criteria for the primary efficacy population. Median age was 59 y (range 22–84), 58% were female, 47%/53% pts had ECOG PS 0/1. Tumor types were non-small cell lung cancer (NSCLC; 41 pts), pancreas cancer (18 pts), breast cancer (5 pts), cholangiocarcinoma (3 pts), colorectal cancer (2 pts), and 4 other tumor types (1 pt each), with a median 2 prior systemic therapies (range 0-9). The most frequent fusion partners were CD74 (27%), SLC3A2 (18%), and ATP1B1 (15%). Among the 71 pts with measurable disease, the INV-assessed confirmed ORR was 34% (90% CI, 25;44), including responses in NSCLC (35%; 14/40 pts), pancreas cancer (39%; 7/18 pts), breast cancer (2/4 pts), and cholangiocarcinoma (1/3 pts). Responses occurred at the first tumor assessment in 20/24 responders, and are ongoing in 13 pts. Treatment is ongoing in 22 pts (13 NSCLC, 6 pancreas, 3 other solid tumors). Median DOR was 9.1 mo (95% CI, 5.2-12.0). Kaplan-Meier estimate of DOR rate at 6 mo was 70%. Among the 208 pts treated with Zeno monotherapy across all dosing schedules in the phase 2 setting, for individual adverse events irrespective of causality, grade ≥ 3 events were reported in <5% of pts. **Conclusions:** Zeno demonstrated robust and durable efficacy in pts with advanced NRG1+ cancer regardless of tumor histology. A well tolerated safety profile of Zeno was observed. Clinical trial information: NCT02912949. Research Sponsor: Merus NV.

106 **Clinical Science Symposium**

A study of AK104 (an anti-PD1 and anti-CTLA4 bispecific antibody) combined with standard therapy for the first-line treatment of persistent, recurrent, or metastatic cervical cancer (R/M CC). *First Author: Jing Wang, Hunan Cancer Hospital, Changsha, China*

Background: Current first-line standard therapy (SOC) for R/M CC is platinum-based chemotherapy +/- bevacizumab (bev). AK104 monotherapy has shown promising efficacy and tolerable toxicity in pretreated R/M CC (NCT04380805). In this study, we report the efficacy and safety of AK104 combined with SOC for the first-line treatment of R/M CC (NCT04868708). **Methods:** The multicenter, open-label, phase II study enrolled R/M CC pts without previous systemic therapy. Eligible pathological types were squamous cell carcinoma, adenocarcinoma, or adenosquamous cell carcinoma. Pts were assigned to 3 cohorts (A-15/A-10: AK104 15/10 mg/kg + PTX 175mg/m^2 + DDP 50 mg/m^2/CBP AUC 5, q3w; B-10: AK104 10 mg/kg + PTX 175 mg/m^2 + DDP 50 mg/m^2/CBP AUC 5 + bev 15 mg/kg, q3w). All pts received AK104 until PD or unacceptable toxicity. The primary endpoint was safety. Secondary endpoints included ORR, PFS per RECIST1.1, and OS, etc. **Results:** 45 pts were enrolled at 6 centers from Jun 3, 2021, to Nov 5, 2021. As of Jan 10, 2022, we assessed safety in all pts and efficacy in pts with at least one tumor assessment result. TRAEs of any grade occurred in 43 (95.6%) pts. Grade ≥3 TRAEs occurred in 23 (51.1%) pts. The most common TRAEs were anemia (55.6%), white blood cell count decreased (46.7%), rash (24.4%), and hypoesthesia (24.4%). The most common grade ≥ 3 TRAEs were anemia (15.6%), white blood cell count decreased (11.1%), neutrophil count decreased (8.9%), and platelet count decreased (8.9%). TRSAE occurred in 17 (37.8%) pts. IrAEs of any grade, assessed by INV, occurred in 24 (53.3%) pts. Grade ≥ 3 irAE occurred in 8 (17.8%) pts. One death due to hemorrhagic shock occurred in cohort B-10 and was judged as treatment-related. ORR were 73.3% (11/15) for A-15, 68.8% (11/16) for A-10, 92.3% (12/13) for B-10, respectively. The response to the treatment was favorable regardless of CPS (Table). PFS or OS data are not mature by cut-off date. **Conclusions:** AK104 combined with standard therapy was well tolerated, with encouraging antitumor activity in pts with R/M CC. Meanwhile, long-term safety evaluation still needs following up. A phase III trial is ongoing to evaluate the efficacy of AK104 plus standard therapy in first-line treatment for R/M CC (NCT04982237). Clinical trial information: NCT04868708. Research Sponsor: Akeso.

Summary of best overall response per investigator by CPS.

	Cohort A-15	Cohort A-15	Cohort A-10	Cohort A-10	Cohort B-10	Cohort B-10
	CPS>= 1 (N = 10)	Total (N = 15)	CPS>=1 (N = 8)	Total (N = 16)	CPS>= 1 (N = 9)	Total (N = 13)

Safety and clinical activity of MEDI5752, a PD-1/CTLA-4 bispecific checkpoint inhibitor, as monotherapy in patients (pts) with advanced renal cell carcinoma (RCC): Preliminary results from an FTIH trial. *First Author: Laurence Albiges, Institut Gustave Roussy, Villejuif, France*

Background: MEDI5752 is a monovalent bispecific antibody targeting PD-1 and CTLA-4. A phase I, open-label study (NCT03530397) of MEDI5752 monotherapy 2.25–2500 mg IV Q3W showed encouraging antitumor activity in advanced solid tumors. Maximum tolerated dose was not reached; doses <1500 mg were better tolerated than doses ≥1500 mg. Here we present preliminary results in pts with advanced RCC in the escalation (ESC) and expansion (EXP) cohorts. **Methods:** Eligible pts were ≥18 yrs old (ECOG PS 0–1). In ESC and EXP, pts could be treatment-naïve (1L) or refractory. Eligible EXP pts had clear cell component (ccRCC), were immunotherapy-naïve (IO-naïve) and limited to ≤2 prior lines of therapy. Pts were treated until progression or unacceptable toxicity. Primary objectives were safety and tolerability (ESC), and antitumor activity by objective response per RECIST v1.1 (EXP). **Results:** Overall, 46 RCC pts were treated: 19 ESC, 27 EXP. In ESC, pts (all IO-naïve, 73.7% prior nephrectomy, 26.3% 1L, 89.5% clear cell histology) were treated across 3 dose levels: 750 mg (n=1), 2000 mg (n=16) and 2500 mg (n=2). Seven pts (36.8%) had objective responses (all PRs); 4 of these were 1L, including 1 each with papillary and sarcomatoid histology. In EXP, pts (all IO-naïve, 63.0% prior nephrectomy, 48.1% 1L [of whom 69.2% had IMDC intermediate/poor risk], 96.3% clear cell histology) received MEDI5752 1500 mg IV Q3W. Ten (38.5%) had objective responses (2 CRs, 8 PRs). In 1L EXP pts, 58.3% had objective responses (1 CR and 6 PRs); disease control rate (DCR) was 91.7% (Table). Grade 3/4 treatment-related adverse events (TRAEs) were seen in 68.4% of ESC and 74.1% of EXP pts. In EXP, treatment-emergent AEs (TEAEs), particularly hepatotoxicity, were the most common cause of treatment discontinuation (D/C). At a median duration of follow-up of 14.6 mo, median duration of response (DOR; including in those who discontinued MEDI5752 due to AEs), median PFS and OS were NR in 1L EXP pts. **Conclusions:** MEDI5752 monotherapy showed deep and durable antitumor activity in pts with advanced RCC, despite high rates of treatment D/C, particularly in the 1L setting. To better characterize the risk-benefit profile, MEDI5752 is now being explored at doses <1500 mg in 1L ccRCC expansion cohorts. Clinical trial information: NCT03530397. Research Sponsor: AstraZeneca.

Prostate cancer risk in African American men evaluated via digital histopathology multi-modal deep learning models developed on NRG Oncology phase III clinical trials. *First Author: Mack Roach, University of California San Francisco, San Francisco, CA*

Background: Artificial intelligence (AI) tools can display racial bias as a result of existing systemic health inequities and biased datasets. We have previously developed multi-modal AI (MMAI) prognostic models based on digital pathology images from five phase III randomized radiotherapy prostate cancer trials that outperform NCCN risk groups for prediction of distant metastasis (DM), biochemical failure (BF), prostate cancer-specific mortality (PCSM) and all-cause mortality (OS). In this study, we assessed the algorithmic fairness of the locked MMAI models between African American (AA) and non-AA populations in the five randomized trials. **Methods**: Patients enrolled in NRG/RTOG 9202, 9408, 9413, 9910, and 0126 with digitized biopsy histopathology slides were included in this study. The locked MMAI models were applied, and subgroup analyses were conducted by comparing distributions of clinical variables and MMAI scores (medians for continuous variables and proportions for categorical variables reported), and evaluating MMAI models' prognostic ability among AA and non-AA men. The performance of the models were compared using DM as the primary endpoint and secondary endpoints of BF, PCSM, OS (death without an event as a competing risk) with Fine-Gray or Cox Proportional Hazards models. Either Kaplan Meier or cumulative incidence estimates were computed and compared using log-rank or Gray's test. **Results:** This study included 5,624 men: 932 (17%) AA, 4503 (80%) white, and 189 (3%) other races. AA had younger median age (69 vs 71 year [yr]), higher median baseline PSA (12 vs 10 ng/mL), more T1-T2a (62% vs 57%), more Gleason < 7 (42% vs 36%) and 8-10 (15% vs 12%), and more NCCN low and high risk (12% vs 10% and 41% vs 33%). AA and non-AA had estimated 5-yr BF rates 27% and 27%, 5-yr DM rates 5% and 5%, 10-yr PCSM 5% and 7%, and 10-yr OS 58% and 60%, respectively. The median (interquartile range) score of the model optimizing for 5-yr DM (5-yr DM MMAI) was 0.044 (0.037–0.059) in AA and 0.043 (0.036–0.057) in non-AA. Similarly, all other MMAI models had differences in the medians between AA and non-AA ranging from 0.001 to 0.02. For all endpoints, the 5-yr DM MMAI model showed strong prognostic signal (hazard ratio [HR] per one standard deviation increase: 1.6 for DM, 1.4 for BF, 1.6 for PCSM and 1.3 for OS, all p-values < 0.001) and had comparable trends within AA vs. non-AA in the entire cohort (e.g., HR for DM 1.4 vs 1.6). Similar results were observed for the MMAI model optimizing for 10-yr PCSM. **Conclusions**: To our knowledge, this represents the first comparative analyses of a digital pathology AI prognostic model in AA vs. non-AA prostate cancer patients. The prognostic performance of the AI models was found to be comparable between subgroups. Our data supports the use of these models across racial groups, though further validation in AA cohorts is ongoing. Research Sponsor: U.S. National Institutes of Health, Artera, Inc.

Long-term effect of machine learning–triggered behavioral nudges on serious illness communication and end-of-life outcomes among patients with cancer: A randomized clinical trial. *First Author: Ravi Bharat Parikh, University of Pennsylvania, Philadelphia, PA*

Background: Early serious illness conversations (SICs) between oncology clinicians and patients are associated with improved mood, quality of life, and quality of end-of-life (EOL) care. Yet, most patients with cancer die without a documented SIC. We report on pre-specified 40-week SIC and EOL outcomes from a stepped-wedge randomized clinical trial (NCT03984773) testing the impact of clinician-directed behavioral nudges to prompt SICs among patients with cancer at high risk of mortality based on a machine learning algorithm. **Methods:** Our sample consisted of patients with cancer receiving care at one of 9 tertiary or community-based medical oncology clinics between June 2019 and April 2020. We identified high-risk patients using a prospectively validated electronic health record machine learning algorithm to predict 6-month mortality. The intervention consisted of: (1) Weekly emails comparing individual oncologists' SIC rate relative to peers; (2) Weekly lists of forthcoming encounters with high-risk patients; and (3) Opt-out text messages to prompt SICs before high-risk patient encounters. Clinics were randomized in stepped-wedge fashion to receive the intervention in 4-week intervals through week 16, when all clinics received the intervention. Patients were followed through week 40. The primary outcome was SIC rates for all and high-risk patients. EOL outcomes among decedents were based on ASCO/NQF guidelines and included death in the hospital, intensive care unit admission within 30 days of death, receipt of systemic therapy within 14 days of death, hospice enrollment prior to death, and hospice length of stay. Intention-to-treat analyses were adjusted for clinic and wedge fixed effects and clustered at the oncologist-level. **Results:** The sample consisted of 20,506 patients and 41,021 encounters. 1,324 (6.5%) patients died by the end of follow-up. Among high-risk patients, the unadjusted SIC rate was 3.4% (59/1754) in the control period and 13.5% (510/3765) in the intervention period and remained >12% throughout follow-up. In adjusted analyses, the intervention was associated with an increase in SICs (adjusted odds ratio 2.09, 95% CI 1.53-2.87, p<0.001) and a decrease in systemic therapy at the end of life, relative to control (6.8% [72/1066]) vs 9.3% [24/258], adjusted odds ratio 0.27, 95% CI 0.12-0.63, p=0.002). There were no differences between control and intervention patients in hospice enrollment or length of stay, inpatient death, or EOL ICU utilization. **Conclusions:** In this randomized trial, a machine learning-based behavioral intervention led to a sustained increase in serious illness communication and reduction in EOL systemic therapy among outpatients with cancer. Machine learning and behavioral nudges can lead to long-lasting improvements in cancer care delivery. Clinical trial information: NCT03984773. Sarcopenia identified by computed tomography (CT) imaging using a machine learning–based convolutional neural network (CNN) algorithm impacts survival in patients with newly diagnosed multiple myeloma (NDMM). *First Author: Bharat Nayar Nandakumar, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Sarcopenia or a loss of muscle mass increases with aging and is associated with increased overall mortality in patients with cancer. Recent advances in machine learning–based CNN algorithms have allowed for the rapid processing of digital images to produce image classifications of body composition. Since incidence of MM is highly associated with aging, we sought to determine if the presence of sarcopenia, as determined by utilizing this machine learning–based CNN algorithm on CT images, had prognostic value in patients with NDMM. **Methods:** We identified all patients with NDMM from January 2003 to July 2019 who had a standard-dose CT scan that included the L3 vertebral level performed within 6 months of diagnosis. Using a machine learning–based CNN-algorithm, abdominal CT images were analyzed to measure muscle area. These measurements were normalized by dividing the area values by the height of the patient squared (m^2) to obtain skeletal muscle index (SMI) values. Patients were categorized as sarcopenic according to international gender-specific consensus cutoffs for SMI (male: < 55 cm^2/m^2 and female: < 39 cm^2/m^2). Patients with the following FISH cytogenetics were considered high risk (HR): t(4;14), t(14;16), t(14;20), and deletion 17p/monosomy 17 whereas the remainder were standard risk (SR). Survival analysis was performed using the Kaplan-Meier method and compared via the log-rank method. **Results:** The study cohort consisted of 344 patients. 68 (20%) were categorized as HR based on FISH cytogenetics.187 (54%) patients were sarcopenic based on their peri-diagnosis standard-dose CT scan. Sarcopenic patients were more likely to have ISS-3 disease (45% vs. 30%; p = .023), be male (73% vs. 48%; p < .001), and be ≥ age 75 (27% vs. 14%; p = .002) compared to non-sarcopenic patients. The median OS for patients with HR FISH and ISS 2 / 3 disease was 40 months and 57 months respectively compared to 90 months and 119 months for those with SR FISH and ISS-1 disease respectively (FISH: p < .004; ISS: p < .001). The median OS for sarcopenic patients was 44 months compared to 90 months for those not sarcopenic (p < .001). The time to next therapy (TTNT) for sarcopenic patients was 39 months compared to 45 months for those not sarcopenic (p = .05). In a multivariable model, the presence of sarcopenia (HR 1.64, 95% CI, 1.05–2.56; p = .03) retained significance in the presence of HR FISH, ISS 2 / 3 disease, and age ≥ 75. **Conclusions:** Gender-specific sarcopenia identified by a machine learning–based CNN algorithm significantly affects OS in patients with NDMM and is independent of age, ISS stage, and cytogenetic status. Future studies utilizing this machine learning–based methodology of assessing sarcopenia in larger prospective clinical trials are required to validate these findings. Single agent PD-1 blockade as curative-intent treatment in mismatch repair deficient locally advanced rectal cancer. *First Author: Andrea Cercek, Memorial Sloan Kettering Cancer Center, New York, NY*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

500 **Oral Abstract Session**

Final results from a phase III randomized clinical trial of adjuvant endocrine therapy ± chemotherapy in women ≥ 70 years old with ER+ HER2- breast cancer and a high genomic grade index: The Unicancer ASTER 70s trial. *First Author: Etienne Brain, Institut Curie, Saint-Cloud, France*

Background: Benefit of adjuvant chemotherapy (CT) in addition to endocrine therapy (ET) remains controversial for patients (pts) aged ≥ 70 years with oestrogen receptors-positive (ER+) HER2-negative (HER2-) breast cancer (BC). In a large prospective trial, we first assessed the tumour genomic grade index (GGI) in all pts, and second, randomized pts with a high GGI between CT + ET vs. ET alone. **Methods:** Eligible pts were women ≥ 70 years with ER+ HER2- primary BC or isolated local relapse, irrespective of other characteristics, for whom adjuvant systemic treatment was considered. G8 score, Charlson comorbidity index (CCI) and 4-year mortality Lee score were collected at baseline. GGI was centrally performed by RT-PCR on FFPE samples. Pts with low GGI were not recommended to receive CT and were followed in an observational cohort. Pts with high (+ equivocal) GGI were randomized 1:1 to CT + ET vs. ET alone, using G8, pN and centre for stratification. Investigators chose between 3 CT regimens: 4 cycles of doxorubicin/cyclophosphamide, non-pegylated liposomal doxorubicin/cyclophosphamide or docetaxel/cyclophosphamide, given q3w with G-CSF. Standard ET consisted of 5 years of aromatase inhibitor, tamoxifen or a sequence based on tolerance. Based on CALGB 49907 results, the primary objective was to demonstrate an overall survival (OS) benefit for CT (4-year assumptions 87.5 vs 80%, HR=0.60) in the intent to treat (ITT) population. With 171 events, the trial had 90% power to demonstrate a difference with a bilateral test α=0.05. Secondary objectives included BC specific survival (BCSS), invasive disease-free survival (iDFS), event-free survival (EFS), competing events, cost-effectiveness and Q-TWiST analysis, geriatric dimensions, willingness and quality of life. **Results:** Between 04/2012 and 05/2016, 1,969 pts from 61 French and 12 Belgian centres were enrolled. Of them, 1,089 (55%) were randomized between CT + ET and ET alone. Median follow-up was 5.8 years at the data cut-off (17/12/2021) with 180 OS events observed. Median age was 75 (70-92), G8 score, CCI and Lee score being >14, ≤ 2, and ≤ 8 in 60%, 62% and 84% of pts, respectively. Tumours were ≥ pT2, pN+, isolated local relapses, with histological grade III, in 56%, 46%, 11% and 39% of cases, respectively. No significant OS difference was observed between arms (HR 0.85 [0.64-1.13], p=0.2538); 4-year OS was 90.5% in the CT + ET arm and 89.7% in the ET alone arm. The forest plot could not identify any subgroup deriving significant benefit from CT. ITT and per protocol analysis of secondary objectives (BCSS, iDFS, EFS) showed similar results. **Conclusions:** In this large phase III trial, we did not find a statistically significant OS benefit with the addition of CT to ET after surgery for ER+ HER2- BC with a high GGI. Analysis of the other outcome measures will be presented. Clinical trial information: NCT0156405. Research Sponsor: PHRC 2011, Pharmaceutical/Biotech Company, LIGUE CONTRE LE CANCER, ARCS (AIDE A LA RECHERCHE CANCEROLOGIQUE DE SAINT-CLOUD).

Assessing the benefit of adjuvant endocrine therapy in patients following breast-conserving surgery with or without radiation stratified by a 7-gene predictive DCIS biosignature. *First Author: Pat W. Whitworth, Nashville Breast Center, Nashville, TN*

Background: Breast conserving surgery (BCS) followed by radiotherapy (RT) has been the mainstay for DCIS treatment. Adjuvant endocrine therapy (ET) has often been recommended based on multiple randomized clinical trials (RCT). However, these studies have failed to identify subsets of patients who did or did not benefit from adjuvant RT/ET therapy after BCS. We evaluated the association of a 7-gene predictive DCIS biosignature (PreludeDx, Laguna Hills, CA) to assess the impact of ET on 10-yr ipsilateral breast recurrence (IBR) risk after BCS alone or with RT. **Methods:** DCISionRT with integrated Residual Risk subtype (RRt) reported a decision score (DS) and three risk groups, a) Low Risk (DS≤2.8), b) Elevated Risk (DS > 2.8 without RRt) and c) Residual Risk (DS > 2.8 with RRt). DCISionRT/RRt was evaluated in 926 patients from 4 cohorts who were treated with BCS alone or with RT/ET. The three risk groups were assessed for 10-yr total (invasive and in situ) IBR risk by Kaplan Meier and Cox proportional hazards survival analysis. **Results:** DCISionRT/RRt classified 338 (37%) women as Low Risk, 399 (43%) as Elevated Risk, and 189 (20%) as Residual Risk. Overall, patients treated with ET had a significantly lower 10-yr IBR risk in multivariable analysis independent of RT (HR = 0.55, p = 0.033). In the Low Risk group treated with BCS without RT, the average 10-yr IBR risk was 5.6% (95% CI 2.5-12.1%, n = 124) and was not significantly different with vs without ET (p = 0.33). The 10-yr IBR risk after BCS alone was 22.6% in the Elevated Risk group and 50.3% in the Residual Risk group. Compared to BCS alone, the 10-year IBR risk tended to be lower in patients prescribed ET without RT in the Elevated (11.6%, 95% CI 3.9-32%) and Residual (15.4%, 95% CI 4.1-49%) Risk groups. 10-yr IBR risk was not significantly reduced by RT within the Low Risk group (p = 0.7) but was significantly reduced to 6.3% (95% CI 3.4-12%) by RT within the Elevated Risk (HR = 0.2, p < 0.001) and to 12.5% (95% CI 6.4-23%) within the Residual Risk (HR = 0.2, p < 0.001) groups. 10-yr IBR risk was significantly higher after RT in the Residual (HR = 2.5, p = 0.013) vs. Elevated Risk groups. After BCS and RT, there was no significant reduction in 10-yr IBR risk for those treated with vs without ET in the Elevated (p = 0.22) and Residual (p = 0.87) risk groups. **Conclusions:** The DCISionRT/RRt biosignature demonstrated prognostic and predictive RT response in Elevated and Residual Risk patients. Consistent with prior RCT data, ET was associated with lower 10-yr IBR risk overall, and within the DCISionRT Elevated and Residual Risk groups without RT. However, neither ET nor RT were asssociated with significant risk reduction in the Low Risk group. There was no added benefit of ET in the Elevated and Residual Risk groups after BCS+RT; the Residual Risk group patients still had a high IBR risk after RT. Research Sponsor: PreludeDx.

503 **Oral Abstract Session**

Event-free survival by residual cancer burden after neoadjuvant pembrolizumab + chemotherapy versus placebo + chemotherapy for early TNBC: Exploratory analysis from KEYNOTE-522. *First Author: Lajos Pusztai, Yale School of Medicine, Yale Cancer Center, New Haven, CT*

Background: KEYNOTE-522 (NCT03036488) tested the benefit from adding pembrolizumab (pembro) to chemotherapy (chemo) in patients (pts) with early TNBC. The primary results showed statistically significant and clinically meaningful improvements in pCR and EFS with pembro.Prior studies have shown the prognostic value of the residual cancer burden (RCB) method to quantify the extent of residual disease after neoadjuvant chemo. In this exploratory analysis, we assessed EFS by RCB in KEYNOTE-522. **Methods:** 1174 pts with previously untreated, nonmetastatic, stage T1c/N1-2 or T2-4/N0-2 TNBC were randomized 2:1 to pembro 200 mg Q3W or placebo (pbo) given with 4 cycles of paclitaxel + carboplatin, then 4 cycles of doxorubicin or epirubicin + cyclophosphamide. After definitive surgery, pts received pembro or pbo for 9 cycles or until recurrence or unacceptable toxicity. Dual primary endpoints are pCR and EFS. RCB was assessed by the local pathologist at the time of surgery. The association between RCB categories (RCB-0, -1, -2, -3, corresponding to increasingly larger residual cancer) and EFS was assessed based on a Cox regression model with treatment as a covariate. **Results:** Median follow-up was 39.1 months at data cutoff (23 MAR 2021). Pembro shifted RCB to lower categories across the entire spectrum (Table). The HRs (95% CI) for EFS were 0.70 (0.38 - 1.31) for RCB-0 (equivalent to pCR), 0.92 (0.39 - 2.20) for RCB-1, 0.52 (0.32 - 0.82) for RCB-2, and 1.24 (0.69 - 2.23) for RCB-3. The most common EFS event in both arms was distant recurrence, which occurred in fewer pts in the pembro arm in all RCB categories. **Conclusions:** Increased RCB score was associated with worse EFS. Pts with residual disease had lower RCB values in the pembro arm, including fewer pts with RCB-3. Pembro + chemo prolonged EFS vs chemo alone in the RCB-0, -1, and -2 categories; the small sample size limits interpretation in the RCB-3 category. The small subset of pts with extensive residual disease (RCB-3) in both arms, 5.1% and 6.7%, respectively, had a poor prognosis. These results highlight the importance of neoadjuvant treatment with pembro for improving survival in pts with early TNBC, and identified a subset of pts for whom additional therapies will be needed. Clinical trial information: NCT03036488. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Pathologic complete response (pCR) rates for HR+/HER2- breast cancer by molecular subtype in the I-SPY2 Trial. *First Author: Laura Ann Huppert, UCSF Helen Diller Comprehensive Cancer Center, San Francisco, CA*

Background: Hormone receptor positive (HR+), HER2- breast cancer (BC) is a heterogenous disease. We hypothesized that molecular subtypes capturing luminal, basal, and immune biology could predict response for patients (pts) with HR+/HER2- disease in the I-SPY2 trial. **Methods:** I-SPY2 trial is a phase II, randomized, adaptive study evaluating multiple investigational agents as neoadjuvant BC therapy; the primary endpoint is estimated pCR rate. Investigational agents are given with control weekly paclitaxel x 12, followed by AC x 4. Regimens graduate when the predicted pCR rate in any signature meets the pre-specified threshold of 85% probability of success in a hypothetical 300 pt randomized, phase 3 trial. We analyzed estimated pCR rates for the 1st 7 investigational agents in the HR+/HER- subset, analyzed by clinical/molecular features: BluePrint (BP) Luminal vs. Basal, Mammaprint High1 [MP1] vs. Mammaprint High2 [MP2], MP2 is < -0.57, Responsive Predictive Subtype-5 (RPS-5) (classification based on HR, HER2, immune, DNA-repair, and basal/luminal markers), histology, and stage/nodal status. **Results:** 38% (379/987) of pts had HR+/HER2- disease. Only pembrolizumab met the pre-specified graduation criteria for HR+/HER2- BC. pCR rates by treatment arm and molecular subtype are described in the Table. 28% were MP2; 72% were MP1. Overall, pCR rates were higher in pts with MP2 vs MP1 disease (30% vs 11%) including with pembrolizumab (55% vs. 21%). 29% were BP Basal, 71% were BP Luminal; BP Basal was more likely to be MP2 than BP Luminal (77% vs 8%). In all arms except MK2206, HR+/HER2- BP Basal pts were more likely to achieve pCR than BP Luminal pts. For MK2206, BP Luminal pts were more likely to achieve pCR. Immune+ by RPS-5 (39% of HR+/HER2-) predicted pCR to pembrolizumab irrespective of BP Basal or Luminal status (11 pCR/16 pts). Results by histology and stage/nodal status will also be reported. **Conclusions:** Our data suggest that MP2 and BP Basal signatures identify a subset of HR+/HER2- BC more likely to respond to neoadjuvant therapy; and that an immune signature can identify pts more likely to respond to pembrolizumab. These findings will aid in guiding prioritization of targeted agents with the goal to optimize pCR for all pts. Clinical trial information: NCT01042379. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Pharmaceutical/Biotech Company.

Measurement of endocrine activity (SET2,3) related to prognosis and prediction of benefit from dose-dense (DD) chemotherapy in estrogen receptor-positive (ER+) cancer: CALGB 9741 (Alliance). *First Author: Otto Metzger, Dana-Farber Cancer Institute, Alliance for Clinical Trials in Oncology, Boston, MA*

Background: We investigated the clinical utility of SET2,3, a novel biomarker designed to measure to endocrine sensitivity. SET2,3 measures nonproliferative hormone receptor-related transcription (SETER/PR) adjusted for a baseline prognosis index derived from tumor size, nodes involved and a 4-gene molecular subtype (RNA4). CALGB 9471 is a seminal phase III study that showed improved DFS and OS from 2-weekly dose-dense (DD) vs 3-weekly chemotherapy in ER-negative cancers. Risk of recurrence (ROR-PT) score (intrinsic subtype, proliferation score and tumor size) measured by Nanostring assay was reported to be prognostic in CALGB 9741, but did not predict benefit from DD chemotherapy. **Methods:** SET2,3 was performed using an aliquot of 200-300 ng RNA (residual from prior ROR-PT testing) from 682 ER+ tumor samples and tested using the QuantiGene Plex bead-based hybridization assay (ThermoFisher, Luminex). We report results for the primary and two secondary objectives of the NCI/CTEP-approved correlative science proposal CSC0154) to evaluate SET2,3 in CALGB 9741 for prognosis (primary endpoint: 95%CI for 5-year (yr) DFS > 75% for High SET2,3 using the predefined prognostic cutpoint 2.10), SET2,3 prognostic independence from ROR-PT, and prediction of outcome according to chemotherapy regimen. We used Cox models to estimate hazard ratios (HR) for prognosis and comparison with ROR-PT results (using c-indices) and for prediction according to chemotherapy schedule using an interaction term (prespecified significance level for interaction: $p < 0.10$). **Results:** The study met its primary endpoint with a 5-yr DFS of 85.6% (95%CI 81.3-90.2) in the High-SET subset (244/613, 40%). High-SET vs Low-SET was significantly associated with favorable outcomes at 5 yr (DFS 85.6% vs 69%, $p < .0001$; OS 95.3% vs 84.6%, $p < .0001$) and 10 yr (DFS 77.7% vs 58.2%, $p < .0001$; OS 86.9% vs 65.9%, $p < .0001$). PAM50 ROR-PT and SET classification were available for 596 tumors. In multivariate models for DFS and OS, SET2,3 remained an independent prognostic variable for DFS (SET high vs low HR = 0.46, 95% CI, 0.34 – 0.63, $p < 0.0001$; PAM50 ROR-PT high vs low HR = 1.22, 95% CI, 0.91 – 1.64, $p = 0.18$) and for OS (SET high vs low HR = 0.36, 95% CI, 0.25 – 0.53, $p < 0.0001$; PAM50 ROR-PT high vs low HR = 1.26, 95% CI, 0.91 – 1.75, $p = 0.16$). Similar observations were seen in models including SET and PAM50 ROR-PT as continuous variables. Lower SET2,3 values predicted improved outcomes from DD vs 3-weekly chemotherapy (interaction p=0.0998 for DFS, 0.042 for RFS and 0.027 for OS). This was unrelated to menopausal status and lower SET2,3 values favored DD concurrent treatments. **Conclusions:** SET2,3 index was strongly prognostic, independent of ROR-PT, and predicted survival benefit from DD chemotherapy in pre- and postmenopausal women with ER+ cancer. Clinical trial information: NCT00003088. Research Sponsor: https://acknowledgments.alliancefound.org Breast Cancer Research Foundation (BCRF-158), U10CA180821, U10CA180882, U24CA196171.

506 **Oral Abstract Session**

Adding ovarian function suppression to tamoxifen in young women with hormone-sensitive breast cancer who remain premenopausal or resume menstruation after chemotherapy: 8-year follow-up of the randomized ASTRRA trial. *First Author: Soo Yeon Baek, Division of Breast Surgery, Department of Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Addition of Ovarian Suppression to Tamoxifen in Young Women With Hormone-Sensitive Breast Cancer Who Remain Premenopausal or Regain Vaginal Bleeding After Chemotherapy (ASTRRA) trial, at 63 months median follow-up, showed that the addition of 2 years of ovarian function suppression (OFS) to Tamoxifen (TAM) significantly improved disease-free survival (DFS) compared with TAM alone in patients with hormone receptor–positive breast cancer who remain in a premenopausal state or resume ovarian function after chemotherapy. We report updated long-term outcomes from ASTRRA trial with 106.4 months median follow-up. **Methods:** This study is a post-trial follow-up of the ASTRRA trial, which randomly assigned 1,298 patients with breast cancer in a 1:1 ratio to receive TAM only (n = 647) or TAM + OFS (n = 635). The primary endpoint was DFS and secondary endpoint was overall survival (OS). We used Kaplan-Meier estimates for time to event endpoints and hazard ratios (HR) with 95% confidence interval (CI) from Cox-regression model. **Results:** At 106.4 months of median follow-up, there continues to be a statistically significant reduction in DFS event rate in favor of the TAM+OFS group. The estimated 8-year DFS rate was 85.4% in the TAM + OFS group and 80.2% in the TAM-only group (HR 0.67; 95% CI, 0.51 to 0.87). There were no significant differences in OS between two groups. The estimated 8-year OS rate was 96.5% in the TAM + OFS group and 95.3% in the TAM-only group (HR, 0.78; 95% CI, 0.49 to 1.25). The results of DFS and OS between the two groups defined from the time of random assignment to the time of events were also similar. **Conclusions:** These data demonstrate consistent survival advantages of adding OFS 2 years to TAM treatment over time, with the long-term follow-up reported to date. This study finding suggest that adding OFS to TAM should be considered for those who remain in a premenopausal state or resume ovarian function after chemotherapy. Longer follow-up is needed to fully evaluate the OS benefit. Research Sponsor: This research was supported by a grant of the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (grant number : HI19C0481, HC19C0147).

507 **Oral Abstract Session**

Long-term outcomes of adjuvant denosumab in breast cancer: Fracture reduction and survival results from 3,425 patients in the randomised, double-blind, placebo-controlled ABCSG-18 trial. *First Author: Michael Gnant, Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria*

Background: State-of-the-art adjuvant endocrine therapy with aromatase inhibitors (AI) compromises bone health in postmenopausal patients with hormone receptor-positive (HR+) breast cancer, increasing fracture incidence. Adjuvant treatment with the anti-RANK ligand denosumab (Dmab) counteracts these side effects and may improve outcomes. We here report the final long-term outcomes of the ABCSG-18 trial (ClinicalTrials.gov NCT00556374). **Methods:** In this prospective, double-blind, placebo-controlled, phase 3 trial, 3,425 postmenopausal patients with early HR+ breast cancer on AI therapy were randomised in 58 trial centers between 2006 and 2013 to receive either Dmab 60 mg or placebo s.c. every 6 months (q6m). The primary endpoint was time to first clinical fracture, secondary disease outcome-related endpoints were disease-free survival (DFS), bone-metastasis free survival (BMFS), and overall survival (OS). In addition to the main endpoint analyses reported previously, exploratory long-term follow-up was conducted in ABCSG-18. Main time-to-event analyses were based on stratified Cox models. Sensitivity analyses accounting for treatment cross-over associated with a late Dmab open-label phase, as well as for receiving any anti-resorptive agents were performed. **Results:** For this final protocol-defined analysis, median follow-up is 8 years (Q1,3: 6, 9.6), and all patients had ended their randomly assigned double-blind treatment (Dmab 60mg s.c. q6m n = 1711; placebo s.c. q6m n = 1709) for a median of 5 years. DFS was improved in the Dmab group versus the placebo group (309 versus 368 DFS events, hazard ratio (HR) 0.83, 95% CI 0.71-0.97, p = 0.016), resulting in an absolute 9-year DFS difference of 3.5% (79.4% vs 75.9%, respectively). When censoring for late cross-over and use of anti-resorptive agents, the DFS difference was confirmed (HR 0.82, p = 0.010). BMFS was improved by 19 per cent (HR 0.81, 95% CI 0.65-1.00, p = 0.047) in the Dmab group, and OS was improved by 20 per cent in the uncensored analysis (127 versus 158 OS events, HR 0.80, 95% CI 0.64-1.01, p = 0.065), and 26 per cent after censoring (HR 0.74, 95% CI 0.58-0.94, p = 0.013). The previously reported marked reduction in clinical fractures persisted even long-term, with 201 fractures in the Dmab and 255 fractures in the placebo group (HR 0.76, 95% CI 0.63-0.92, p = 0.004). No new toxicities for this (low) bone-protective dose of adjuvant Dmab were reported, particularly no ONJ occured.. **Conclusions:** Adjuvant Dmab 60mg every 6 months during AI therapy is safe, and markedly reduces treatment-induced clinical fractures even in the long-term. DFS, BMFS, and OS are improved in this descriptive final long-term analysis of ABCSG-18. Adjuvant denosumab should be considered for routine clinical use in postmenopausal patients with HR+ breast cancer. Clinical trial information: NCT00556374. Research Sponsor: Amgen.

508 **Oral Abstract Session**

Historical early treatment effects of adjuvant endocrine therapy for breast cancer in high-risk subgroups: Reanalysis of BIG 1-98, SOFT and TEXT. *First Author: Meredith M. Regan, Dana-Farber Cancer Institute and International Breast Cancer Study Group, Boston, MA*

Background: Clinical trials testing adjuvant endocrine therapy (ET) have not historically limited enrollment to patients with clinically high-risk breast cancer (BC), nor estimated treatment (trt) effects prior to 5 yrs. In light of recent trial results for adjuvant CDK4/6 inhibitors, we estimated early relative and absolute trt effects of aromatase inhibitor (AI) vs tamoxifen (T), with ovarian suppression (OFS) if premenopausal, in high risk subgroups. **Methods:** From pts enrolled in adjuvant phase 3 randomized clinical trials BIG 1-98 (postmenopausal, 5yr AI v T), TEXT (5yr AI+OFS v T+OFS) and SOFT (5yr AI+OFS v T+OFS v T), we identified subgroups with HR+/HER2- BC and high risk features (≥4 pLN; or 1-3 pLN with grade 3, pT≥5 cm and/or Ki-67≥20% [retrospectively centrally assessed]). TEXT randomized at start of adjuvant trt; BIG 1-98 and SOFT after chemotherapy. Disease-free survival (DFS) was defined from randomization to invasive recurrence at local, regional, distant or contralateral breast, second non-breast malignancy or death. We estimated trt effects as differences in 2, 3 and 5yr DFS Kaplan-Meier estimates (KM diffs at *t* yrs) and hazard ratios over time intervals of 0-2, 0-3 and 0-5 yrs (HRs over 0 to *t* yrs) to approximate the maturity of trial results with increasing follow-up. **Results:** The high-risk HR+/HER2- subgroups were 695/4922, 707/2660 and 526/3047 pts in BIG 1-98, TEXT and SOFT with 202, 122, 142 DFS events observed by 5 yrs since randomization. 60%, 46% and 44% of pts had ≥4 pLNs; 42%, 90% and 92% had chemotherapy. The table summarizes results. **Conclusions:** In re-analysis of clinical high risk HR+/HER2- subgroups of 3 trials each ~700 pts, 5 yrs AI vs T had similar magnitude of early trt effects after 2-3 yrs follow-up of all pts vs trt effects observed after 27 mos median follow-up in monarchE trial (HR=0.70; KM diffs 2.7% at 2 yrs, 5.4% at 3 yrs; n=5637). Relative and absolute trt effects sometimes diminished when estimated over 5 yrs rather than over 2 yrs, but meaningful absolute differences remained at 5 yrs in contrast to Penelope-B trial results. Design and interpretation of high risk HR+/HER2- early BC trials may depend on timing of randomization and selection of backbone adjuvant trts; follow-up >5 yrs must remain standard. Research Sponsor: None.

Prognostic and predictive implications of the intrinsic subtypes and gene expression signatures in early-stage HER2+ breast cancer: A pooled analysis of CALGB 40601, NeoALTTO, and NSABP B-41 trials. *First Author: Aranzazu Fernandez-Martinez, Lineberger Comprehensive Cancer Center, Department of Genetics, University of North Carolina, Chapel Hill, NC*

Background: Several biologic features are implicated in the differences in response and survival to dual (trastuzumab and lapatinib [HL]) vs. single (trastuzumab [H]) HER2-blockade across neoadjuvant trials in early-stage HER2+ breast cancer. We evaluated the association of intrinsic subtypes and gene expression signatures with pathologic complete response (pCR) and event-free survival (EFS) in a pooled analysis of three independent phase III neoadjuvant studies with similar designs: CALGB 40601 (Alliance), NeoALTTO, and NSABP B-41. **Methods:** Gene expression profiling by RNA sequencing was assessed on 761 pre-treatment samples (264 from CALGB 40601, 249 from NeoALTTO, 248 from NSABP B-41). Intrinsic subtypes and 759 gene expression signatures were calculated. We studied the association of pCR and the benefit of dual (HL) vs. single (H) HER2-blockade by tumor intrinsic subtype in the pooled set. The ability of multiple gene expression signatures to predict pCR and EFS across the three studies was also tested by logistic and Cox regression analyses. **Results:** pCR status was associated with EFS only in HER2-Enriched (HR 0.45, 95% CI 0.29-0.71, p-value < 0.001) and Basal-like (HR 0.19, 95% CI 0.04-0.86, p-value 0.031) intrinsic subtypes, but not in Luminal and/or ER+ tumors. The EFS benefit of dual vs. single HER2-blockade was limited to HER2-Enriched tumors (HR 0.47, 95% CI 0.27-0.81, p-value 0.007). When evaluating the three clinical trials separately, we found 89/759 (11.7%) gene expression signatures in common for the prediction of pCR across the three clinical trials, including HER2-amplicon and immune activation signatures. Luminal-related signatures were associated with lower pCR rates but better EFS outcomes, especially in patients with residual disease. Stratified Cox regression models by study showed a significant and strong association of NK, B and plasma cells, as well as Ig-related signatures with a better EFS outcome, while vascular, proliferation, and metastasis signatures were associated with poor EFS. **Conclusions:** In early-stage HER2+ breast cancer, the relationship between pCR and EFS differs by tumor intrinsic subtype, and the benefit of dual vs. single HER2-blockade seems to be limited to HER2-Enriched subtype tumors. Immune signatures were associated with higher pCR rates and better EFS, luminal signatures were associated with lower pCR rates but good EFS outcomes, and vascular/proliferation/metastasis signatures were associated with poor EFS across the three clinical trials. Clinical trial identification: CALGB 40601: NCT00770809. (CALGB is part of the Alliance for Clinical Trials in Oncology). Molecular subtype to predict pathologic complete response in HER2-positive breast cancer in the I-SPY2 trial. *First Author: Alexandra Thomas, Wake Forest Comprehensive Cancer Center, Winston-Salem, NC*

Background: HER2-positive breast cancer (bc) is a very heterogenous disease. We hypothesized that molecular subtype may predict disease response to investigational agents in HER2+ bc. Here, we report the pathologic complete response (pCR) rate in the first six agents tested in HER2+ bc in the I-SPY 2 trial for the full HER2+ cohort, by molecular subtype, and by disease receptor status. **Methods:** Women with HER2+ tumors which were > 2.5 cm were eligible. The I-SPY2 platform trial tests novel agents given neoadjuvantly with a backbone of taxol (T) and trastuzumab (H) followed by doxorubicin and cyclophosphamide. Agents investigated in HER2+ bc were TH (control), MK2206, AMG386, pertuzumab (P), neratinib (N (given in place of H), and TDM1+P (given in place of TH). An investigational arm graduated if there was >85% chance of success compared to control in a 300-person phase 3 neoadjuvant trial. Further details of the I-SPY2 methods have been previously published. Molecular subtyping based on gene expression was utilized to categorize tumors into 5 response predictive subtypes (RPS) (HER2-/Immune-/DRD (DNA repair deficiency)-, HER2-/Immune+, HER2-/Immune-/DRD+, HER2+/Her2_or_-Basal and HER2+/Luminal). **Results:** For the full HER2+ cohort (N=245) pCR rate was higher in all investigational arms than control (Table). By tumor receptor status, HER2+/HR- tumors (N=89) had a higher pCR rate than HER2+/HR+ tumors (N=156; 63% vs 37%, p = 0.0001). In HER2+/HR- tumors N, MK2206, P and TDM1/P graduated. In HER2+/HR+ tumors P and TDM1/P graduated. 76% (185/245) of I-SPY 2 HER2+ patients were classified as HER2+/Her2_or_Basal and 24% (60/245) were HER2+Luminal. pCR rate was significantly higher in the HER2+/Her2_or_Basal group than in the HER2+/Luminal group (57% vs 15%, p < 0.0001). All agents, except for MK2206, where numbers were small, showed greater efficacy in the HER2+/Her2_or_Basal group than in the HER2+/Luminal group. HER2+/Luminal appeared to be more sensitive to the AKT inhibitor MK2206 than to targeted HER2 agents, though numbers are small. **Conclusions:** pCR rates for patients with HER2+ bc treated with investigational agents, particularly dual HER2-blockade, were promising. Molecular response predictive subtype classification provides insight on how to better target therapy. The HER2+/Luminal group had low pCR rates with dual HER2-blockade but may have higher pCR rate with the addition of an AKT inhibitor and identifies a subgroup of HER2+ tumors in need of novel approaches. AKT inhibition for HER2/Luminal is being tested in I-SPY 2.2. Clinical trial information: NCT01042379. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Pharmaceutical/Biotech Company.

512 **Poster Discussion Session**

Phase 2 study of response-guided neoadjuvant sacituzumab govitecan (IMMU-132) in patients with localized triple-negative breast cancer: Results from the NeoSTAR trial.

First Author: Laura Spring, Massachusetts General Hospital Cancer Center, Boston, MA

Background: Sacituzumab govitecan (SG), a novel antibody-drug conjugate in which the topoisomerase 1 inhibitor SN-38 (active metabolite of irinotecan) is linked to a humanized monoclonal antibody targeting the tumor antigen Trop2, is currently approved for treatment of patients (pts) with pre-treated metastatic triple negative breast cancer (TNBC). We conducted a phase 2 study evaluating neoadjuvant (NA) SG as upfront therapy for pts with localized TNBC (NCT04230109). The primary objective was to assess pathological complete response (pCR) rate in breast and lymph nodes (ypT0/isN0) with SG. Secondary objectives included assessment of radiological response rate, evaluation of the safety and tolerability (CTCAE v5.0) and event-free survival (EFS). **Methods:** Patients with localized TNBC (tumor size ≥1cm, or any size if node positive) with no prior treatment were eligible. SG was administered IV on Days 1, 8 of each 21-day cycle at a starting dose of 10 mg/kg for 4 cycles. After 4 cycles, patients with biopsy-proven residual disease, considered as no pCR for primary endpoint, had the option to receive additional NA therapy at the discretion of the treating physician. Radiologic response (US or MRI) was defined by RECIST version 1.1 using a composite response of CR & PR. Standard descriptive statistics were utilized, including 95% binomial confidence intervals for all rates estimated. **Results:** From 7/14/20 – 8/31/21, 50 pts were enrolled (median age = 48.5; 11 stage I disease, 24 stage II, 11 stage III, 4 unknown; 62% node negative). The majority (98%; n = 49) of pts completed 4 cycles of SG. Overall, the radiological response rate with SG alone was 62% (n = 31, 95% CI 48%, 77%). 26 pts proceeded directly to surgery after SG. Overall, the pCR rate with SG alone was 30% (n = 15/50, 95% CI 18%, 45%). The other 11 pts had RCB-1 (n = 3), RCB-2 (n = 5), and RCB-3 (n = 3) disease, respectively. Of the 24 pts who received additional NA therapy, 6 had a pCR (3 received anthracycline-based regimen, 2 carboplatin/taxane, and 1 docetaxel/cyclophosphamide). Among pts with a germline BRCA mutation (n = 8), 7 proceeded directly to surgery after SG and 6 had a pCR (86%, 95% CI 42%, 99%). The most common AEs with SG were nausea (82%, n = 41), fatigue (78%, n = 39), alopecia (76%, n = 38), neutropenia (58%, n = 29), anemia (36%, n = 18), and rash (48%, n = 24). 6% of pts required dose-reduction. No pts discontinued SG therapy due to disease progression or AEs; 1 discontinued due to minimal response per investigator preference. At the time of data cut-off (1/18/22), no pts experienced disease recurrence. Updated biomarker and EFS results will be presented at the meeting. **Conclusions:** In the first neoadjuvant trial in TNBC with an ADC, SG demonstrated single agent efficacy in localized TNBC. Further research on optimal duration of SG as well as NA combination strategies, including immunotherapy, are needed. Clinical trial information: NCT04230109. Research Sponsor: Immunomedics.

513 **Poster Discussion Session**

Clinical and biomarker results of neoadjuvant phase II study of pembrolizumab and carboplatin plus docetaxel in triple-negative breast cancer (TNBC) (NeoPACT).

First Author: Priyanka Sharma, University of Kansas Medical Center, Westwood, KS

Background: Addition of pembrolizumab to anthracycline-taxane-platinum chemotherapy improves pathologic complete response (pCR) and event free survival (EFS) in TNBC. Aim of this study was to assess the efficacy of the anthracycline free neoadjuvant regimen of pembrolizumab plus carboplatin plus docetaxel (Cb+D) in TNBC. **Methods:** In this multicenter study, eligible patients with stage I-III TNBC received carboplatin (AUC 6) + docetaxel (75 mg/m^2) + pembrolizumab (200 mg) every 21 days x 6 cycles. The primary endpoint was pCR (no evidence of invasive tumor in breast and axilla). Secondary endpoints were residual cancer burden (RCB), EFS, toxicity, and immune response biomarkers. RNA isolated from pretreatment tumor tissue was subjected to next generation sequencing. Samples were classified as DNA Damage Immune Response (DDIR) signature and DetermaIO signature positive/negative using predefined cutoffs. Evaluation of stromal tumor infiltrating lymphocytes (sTILs) was performed using standard criteria. **Results:** 117 patients were enrolled from September 2018 to January 2022. 18% were African American, 39% had node positive disease, 88% had stage II/III disease and 15% had ER/PR 1-10%. Pathologic response information is available for 105 patients. pCR and RCB 0+1 rates were 60% (95% CI 51%-70%) and 71% (95% CI 62%-80%), respectively. Treatment related adverse events led to discontinuation of any trial drug in 12% of patients. Immune adverse events were observed in 28% of patients (Grade ≥3=6%). 47% of patients had sTILs ≥30%, 48% were DetermaIO positive, and 61% DDIR positive. The table describes the impact of these biomarkers on pCR and RCB. The areas under the prediction curve (AUC) for pCR were 0.660, 0.709, and 0.719 for DDIR, sTILs, and DetermaIO respectively. At a median follow up of 21 months, 2-year EFS is 88% in all patients; 98% in pCR group and 82% in no pCR group. **Conclusions:** Neoadjuvant pembrolizumab plus Cb+D regimen yields pCR of 60% and 2-year EFS of 88% in the absence of adjuvant pembrolizumab. The regimen was well tolerated, and no new toxicity signals were noted. Immune enrichment identified by sTILs or DetermaIO signature was associated with high pCR rates approaching or exceeding 80%. PD-L1 and additional biomarker analyses are ongoing. Clinical trial information: NCT03639948. Research Sponsor: Merck & Co, Inc.

The ImPrint immune signature to identify patients with high-risk early breast cancer who may benefit from PD1 checkpoint inhibition in I-SPY2.

First Author: Lorenza Mittempergher, Research and Development, Agendia NV, Amsterdam, Netherlands

Background: The remarkable increase of novel Immuno-Oncology drugs in many malignancies has led to the need for biomarkers to identify who would benefit. Various predictive biomarkers have been developed (PD-1/PD-L1 expression, mutations in mismatch repair genes and microsatellite instability, tumor mutational burden and immune infiltration), none have consistently predicted efficacy. The I-SPY2 consortium qualified several expression-based immune biology related signatures that predict response to PD1 checkpoint inhibition. Here we assessed whole transcriptome data of high-risk early-breast cancer (EBC) patients who received Pembrolizumab within the neoadjuvant biomarker-rich I-SPY2 trial (NCT01042379), aiming to migrate the I-SPY2 research findings to a robust clinical grade platform signature to predict sensitivity to PD1 checkpoint inhibition. **Methods**: Whole transcriptome microarray data were available from pre-treatment biopsies of 69 HER2- patients enrolled in the Pembrolizumab (4 cycles) arm of the I-SPY2 trial. All patients had a High-Risk 70-gene MammaPrint profile. Pathologic complete response (pCR) was defined as no residual invasive cancer in breast or nodes at the time of surgery. Of the 69 patients, 31 had a pCR (12 HR (hormonal receptor)+HER2-, 19 Triple Negative (TN)), while 38 (28 HR+HER2-, 10 TN) had residual disease (RD). To identify the most predictive genes associated with pCR, gene selection was performed comparing pCR and RD groups by iteratively splitting the dataset in training and test, balancing for HR status. Due to limited sample size, leave one out cross validation was used for performance assessment. Genes with effect size > 0.45 were considered significant. **Results**: A signature of 53 genes, named ImPrint, was identified with overall sensitivity and specificity > 90% and > 80% for predicting pCR to pembrolizumab in all patients. Sensitivity and specificity in TN were > 95% and ≥70%, and in HR+HER2- > 80% and > 85%, respectively. The Positive Predictive Value (PPV) is 77% for the HR+HER2- subgroup. Biological annotation of the 53 genes showed that over 90% of the genes have known immune system related functions, of which 63% were previously known to be involved in immune response (including genes coding PD-L1 and PD-1, as well as those identified in I-SPY2). **Conclusions**: In the signature development phase, ImPrint predicts pCR to Pembrolizumab in a set of 69 high risk EBC with high sensitivity and specificity. The signature features genes with immune-related functions known to be involved in immune response indicating that it might aid identifying patients with an immune-active phenotype. Importantly, ImPrint appears effective in identifying a subset of HR+HER2- patients who could benefit from immunotherapy. External validation in independent dataset(s) is ongoing and will be presented at the time of the meeting. Research Sponsor: None.

515 **Poster Discussion Session**

Racial/ethnic disparities in locoregional recurrence in hormone-receptor positive node-negative breast cancer patients enrolled in the TAILORx trial.

First Author: Olga Kantor, Dana-Farber Brigham Cancer Center, Boston, MA

Background: Whether racial/ethnic disparities in locoregional recurrence (LRR) exist in patients (pts) with similar access to care treated on clinical trials is uncertain. We examined racial/ethnic differences in LRR in hormone-receptor positive HER2-negative (HR+HER2-) node-negative pts enrolled in the TAILORx trial. **Methods:** 10,273 pts age 18-75 were enrolled in TAILORx, which assigned pts with an OncotypeDx Recurrence Score (RS) <11 to endocrine therapy (ET) alone, those with RS >25 to chemotherapy + ET (CET), and randomized pts with RS 11-25 to ET or CET. Pts with unknown race/ethnicity (n=323) or incomplete treatment adherence information (n=1,168) were excluded from this analysis. Race/ethnicity was self-reported. LRR was defined as ipsilateral invasive in-breast, chest wall, or regional nodal recurrence without distant recurrence. Kaplan-Meier curves were used to estimate 8-year LRR. Cox proportional hazards analysis adjusted for clinical and treatment factors was used to determine factors associated with LRR. **Results:** 8,782 pts with T1-2N0 HR+HER2- breast cancer were included. Race/ethnicity was non-Hispanic White (NHW) in 6,932 (78.9%), non-Hispanic Black (NHB) in 629 (7.2%), Hispanic in 818 (9.3%), and Asian in 403 (4.6%). Treatment adherence was high across groups over time, with a 9.1% crossover in treatment arms. Average duration of ET was 63.8 +/- 0.3 months. Radiation therapy was planned in 96.0% of pts after breast conservation and 12.7% after mastectomy. At a median follow-up of 8 years, LRR rates were 1.9% in NHW, 4.2% in in NHB, 3.2% in Hispanic, and 3.9% in Asian pts (p<0.01). LRR rates broken down by RS are shown in the Table. On adjusted analyses, NHB and Asian (vs. NHW) pts were more likely to have LRR (HR 1.94 for NHB, HR 2.04 for Asian, p<0.05 for both). Additional statistically significant factors associated with LRR included age <50 (HR 1.85), T2 tumors (HR 1.43), higher grade (HR 2.30 for grade 3), and high RS (HR 3.13 for RS>25). Treatment receipt (chemotherapy, ET duration, and radiation) was not associated with LRR in this population. **Conclusions:** Racial/ethnic differences in LRR were seen in T1-2N0 HR+HER2- breast cancer pts enrolled in the TAILORx trial despite high rates of treatment adherence in this clinical trial population, with highest LRR rates in NHB and Asian pts. Further study in needed to understand racial/ethnic patterns in LRR by breast cancer subtype and if failure to rescue after LRR may contribute to differences in breast cancer mortality. Research Sponsor: None.

Clinical outcomes and immune markers by race in a phase I/II clinical trial of durvalumab concomitant with neoadjuvant chemotherapy in early-stage TNBC. *First Author: Julia Foldi, Yale School of Medicine, New Haven, CT*

Background: The incidence of triple negative breast cancer (TNBC) is higher among Black or African American (AA) women, yet AA patients (pts) are underrepresented in clinical trials, exemplifying racial disparity in oncology. We conducted a phase I/II trial to assess the safety and efficacy of durvalumab concurrent with weekly nab-paclitaxel and dose dense doxorubicin/cyclophosphamide (ddAC) neoadjuvant therapy for stage I-III TNBC. The primary efficacy endpoint was pathologic complete response (pCR; ypT0/is,N0) rate. Given the unclear efficacy and safety of immunotherapy in AA pts with breast cancer, we extended our accrual to recruit AA pts, with the goal of evaluating the association between racial groups and PD-L1 expression, stromal tumor infiltrating lymphocytes (sTILs), toxicities, treatment response and survival. **Methods:** Our study population included 67 pts. PD-L1 immunohistochemistry results and sTIL counts were available on 59 and 60 pts, respectively. Chi-Squared test was used to evaluate associations between race and baseline characteristics. Cox proportional hazards model was used to assess association between AA race and overall survival (OS) and event free survival (EFS), adjusting for age, comorbidities and pCR status. Multivariate logistic regression analyses were used to evaluate the association between race and pCR, development of immune-related adverse events (irAEs) and breast cancer recurrence. **Results:** Twenty-one pts (31%) self-identified as AA. No significant associations between AA race and baseline body mass index (BMI; p=0.075), Charlson comorbidity index (p=0.32), tumor stage (p=0.40), grade (p=0.54), PD-L1 status (0.92) and sTIL count (p=0.57) were observed. pCR rates did not significantly differ between AA and non-AA pts: 9/21 (43%) AA vs. 22/48 (48%) non-AA (p=0.71). 3-yr OS was 87% in the non-AA versus 81% in the AA cohort (HR 1.72, 95% CI 0.481-6.136; p=0.405); 3 yr EFS were 78.3% and 71.4% in non-AA and AA pts respectively. (HR 1.451, 95% CI 0.524-4.017; p=0.474). Pts with pCR were more likely to remain event-free at 3 yrs, irrespective of race (HR 0.234, 95% CI 0.066-0.829; p=0.024). In multivariate logistic regression analyses, lack of pathologic response (OR for pCR 0.17, 95% CI 0.03-0.7; p=0.02) and node positive status (OR 4.13, 95% CI 1.05-19.88; p=0.05) were associated with recurrence. The incidence of irAEs was similar between AA and non-AA pts and no significant associations were found between irAEs and pathologic response. **Conclusions:** pCR rates after neoadjuvant immunotherapy and chemotherapy were similar in AA and non-AA pts. Stromal TILs, PD-L1 status, 3yr OS and EFS, and the frequency of irAEs were also similar. These results suggest that when patients receive identical treatment and are monitored closely, disparities in outcomes can be mitigated or abolished. Clinical trial information: NCT02489448. Whole transcriptomic analysis of HR+ breast cancer in Black women classified as basal-type by BluePrint. *First Author: Sonya A. Reid, Vanderbilt University Medical Center, Nahsville, TN*

Background: Breast cancer is the leading cause of cancer-associated death among Black women, and they are 41% more likely to die from breast cancer compared to White women. Few studies have evaluated if tumor biology differences contribute to this disparity in outcomes. Similar to triple negative breast cancer (TNBC), hormone receptor-positive (HR+) tumors classified as Basal-Type with BluePrint genomic analysis (HR+/Basal) are more aggressive, higher grade, are over-represented among young Black women and have worse clinical outcomes. TNBC is associated with low ACKR1 expression, which encodes the Duffy antigen and correlates with worse breast cancer outcomes. Given the over-representation and worse outcomes among Black women with HR+/Basal tumors, we compared differentially expressed genes (DEGs) by race and subtype. **Methods:** This study includes 2657 women with Stage I-III breast cancer who received BluePrint testing and are participants of the ongoing BEST study (5R01CA204819) at Vanderbilt University Medical Center or FLEX study (NCT03053193). Of 455 Black women, 315 had Luminal (HR+/Luminal) and 140 had Basal tumors (66 HR+/Basal and 74 HR-/Basal). White women within FLEX (n = 2202) were included as a reference group with HR+/Luminal (n = 1825), HR+/Basal (n = 158), or HR-/Basal (n = 219) tumors. Two-tailed proportional z-test was used to assess differences in subtype proportion by race. Limma R package was used to perform differential gene expression analysis (DGEA) of whole transcriptome data. Significant DEGs had an adjusted p-value < 0.05 and absolute log2 fold change > 1. **Results:** Black women had a significantly higher proportion of HR+/Basal (15%; p < 0.001) and HR-/Basal (16%; p < 0.001) tumors compared to White women (7% and 10%, respectively). In a multidimensional scaling analysis, HR+/Basal tumors cluster with TNBC rather than with HR+/Luminal tumors. While a DGEA comparing HR+/Basal with HR+/Luminal tumors resulted in over 700 DEGs within Black women, no DEGs were identified when comparing HR+/Basal tumors with TNBC. ACKR1 expression in HR+/Basal tumors was comparable to TNBC in Black women (p = 0.81) and White women (p = 0.46). In contrast, HR+/Basal tumors had significantly lower ACKR1 expression than HR+/Luminal tumors in Black (p < 0.01) and White women (p < 0.01). **Conclusions:** In this racially diverse cohort, transcriptomic analyses suggest that HR+/Basal tumors are biologically analogous to TNBC, independent of race. Molecular profiling identified racial disparities in the proportion of HR+/Basal tumors and underscores the need for diverse representation in clinical trials. With an over-representation of HR+/Basal tumors in Black women and evidence of worse outcomes, these data suggest that patients with HR+/Basal tumors should not be treated uniformly with HR+/Luminal tumors and highlight the importance of further genomic classification for patients with HR+ tumors. Clinical trial information: NCT03053193. Research Sponsor: Agendia Inc. , U.S. National Institutes of Health.

Impact of body mass index on treatment and outcomes in patients with early hormone receptor-positive breast cancer receiving endocrine therapy with or without palbociclib in the PALLAS trial. *First Author: Georg Pfeiler, Department of Obstetrics and Gynecology and Center for Breast Health, Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria*

Background: Body Mass Index (BMI) impacts breast cancer risk and prognosis. Conflicting results have been published regarding BMI as a predictive factor for endocrine therapy benefit. CDK4/6 inhibitors (CDK4/6i) in combination with endocrine treatment (ET) are standard-of-care treatments for metastatic hormone receptor-positive breast cancer. In contrast to cytotoxic chemotherapy, CDK4/6i are given at a fixed dose irrespective of BMI or weight. The PALLAS trial compared the combination of the CDK4/6i palbociclib and adjuvant ET to ET alone in the early breast cancer setting. This analysis investigates the impact of BMI on the efficacy and the side effect profile of palbociclib (P) in the PALLAS trial. **Methods:** In this pre-planned analysis, patients (pts) enrolled in PALLAS were categorized according to BMI as underweight (BMI <18.5 kg/m^2), normal weight (BMI 18.5-24.9 kg/m^2), overweight (BMI 25-29.9 kg/m^2) and obese (^{3}30 kg/m^2), respectively. Adverse event differences were assessed with Chi-squared tests. Time to early discontinuation of P was analyzed with Fine and Gray competing risk models. Cox models were used to investigate the association between BMI category and time to invasive disease-free survival (iDFS). **Results:** Of a total of 5698 pts included in this analysis, 68 (1.2%) were underweight, 2082 (36.5%) normal weight, 1818 (31.9%) overweight and 1730 (30.4%) obese at baseline. Significantly different rates of all grade neutropenia were observed in normal weight, overweight and obese pts with regard to total (88.5%, 85.7% and 74.7%), as well as grade 3 (64.1%, 62.0% and 43.9%) and grade 4 neutropenia (7.0%, 3.6% and 2.0%), respectively. The lower frequency and severity of neutropenia observed in overweight and obese pts was associated with a significant lower treatment discontinuation rate over time when compared to normal weight patients (overweight vs normal weight: HR 0.73 CI 0.63-0.84, p<0.0001, and obese vs normal weight: HR 0.65 CI 0.56-0.75, p<0.0001). In pts treated with P, neutropenia was the primary toxicity leading to treatment discontinuation in 21.1% of normal weight pts, 14.0% of overweight pts and 5.9% obese pts, respectively. Despite these observations, there was no statistically significant improvement in iDFS with the addition of P to ET in any weight category (normal weight HR 0.84 CI 0.63-1.12, overweight HR 1.10 CI 0.82-1.49 and obese HR 0.95 CI 0.69-1.30). **Conclusions:** This pre-planned analysis of outcomes by BMI in the PALLAS trial demonstrates significantly less frequent and less severe neutropenia in overweight and obese pts compared to those with normal weight, leading to significant lower treatment discontinuation rates. However, no difference in iDFS outcomes by BMI was observed. Additional long-term follow-up will further evaluate whether BMI ultimately impacts outcome. Clinical trial information: NCT02513394. Research Sponsor: Pfizer Inc.

A randomized presurgical trial of alternative dosing of exemestane in postmenopausal women with early-stage ER-positive breast cancer. *First Author: Andrea De Censi, EO Ospedali Galliera, Genoa, Italy*

Background: Successful therapeutic cancer prevention requires definition of the minimal effective dose of the proposed agent. Aromatase inhibitors substantially decreased breast cancer incidence in high risk postmenopausal women in phase III trials but their clinical use in prevention and adherence in adjuvant setting is limited by adverse events. We conducted a randomized presurgical phase IIb trial to evaluate two alternative doses of exemestane. **Methods:** We conducted a multi-center, pre-surgical, double-blind, 3-arm, non-inferiority phase IIb study in postmenopausal women with histologically confirmed estrogen receptor (ER)-positive breast cancer. Patients were randomized to receive either exemestane 25 mg/day (QD), or 25 mg/three times/week (TIW), or 25 mg once a week (QW) for 4-6 weeks before surgery. Blood and tissue biomarkers were collected at baseline and final visit. The primary aim was a non-inferiority percent change of circulating estradiol relative to the standard dose. Secondary endpoints were the change in Ki-67 and PgR expression in cancer tissue, blood sex hormones, lipid profile, toxicity and menopausal symptoms. For the power calculation we assumed a non-inferiority difference of 6% in the percentage change of estradiol among arms, using a one-sided, two-sample t-test. Assuming a 10% drop-out rate, a total sample size of 180 participants (60 per arm) had 80% power to detect a 6% margin of equivalence. The significance level for the main endpoint was 0.025 to account for multiple comparisons and 0.05 for secondary endpoints. **Results:** A total of 230 women were screened, 180 agreed to participate and 173 were evaluable for response. The median percent change of estradiol was -98%, -98%, and -70% for exemestane QD (n = 56), TIW (n = 57), and QW (n = 60), respectively, showing no significant difference between QD and TIW arms (p = 0.9). Similarly, no differences were observed for estrone, total estrone and estrone sulfate between QD and TIW arms. The QW arm showed some modulation in all hormones, even though less significantly so. Among the secondary endpoints, Ki-67 and PgR were reduced in all arms, with a median change of -5% vs -7.5% for Ki-67(p = 0.124), and -9 vs -17 for PgR (p = 0.246) in the TIW vs QD arms, respectively. SHBG and HDL-cholesterol had a more favorable profile with the TIW dose compared to the daily dose. Adverse events, measured according to the CTCAE (v4), and menopausal symptoms according to MENQOL were similar in all arms, but the short treatment time may not be representative. **Conclusions:** Exemestane 25 mg TIW retains a comparable activity than 25 mg QD. This activity was similar in both arms throughout the primary and the main secondary endpoints. This new schedule should be further assessed in prevention studies and in women on adjuvant treatment who do not tolerate the daily dose. Clinical trial information: NCT02598557. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Other Government Agency.

Chemotherapy refusal and subsequent survival in older women with high genomic risk, estrogen receptor–positive breast cancer. *First Author: McKenzie White, University of Minnesota, Minneapolis, MN*

Background: Patients with estrogen receptor (ER)- positive breast cancer and high-risk 21-gene recurrence score (RS) assay results benefit from chemotherapy, however some patients choose to decline chemotherapy. We evaluated factors associated with chemotherapy refusal by older women with high RS breast cancer and investigated the association of chemotherapy refusal with mortality. **Methods:** We used the National Cancer Database (2010-2017) to retrospectively identify women aged ≥65 years with ER-positive, HER2-negative, high RS (≥26) breast cancer. Women with Charlson Comorbidity Index ≥1, stage III or IV disease, or any unknown variables were excluded. Women with high RS who refused chemotherapy were compared to women with high RS who received chemotherapy. Refusal trends were analyzed using the Cochrane Armitage test. Factors associated with chemotherapy refusal were evaluated with a multivariable regression model. Overall survival (OS) by age and by treatment were evaluated with Kaplan-Meier and Cox proportional hazards modeling. **Results:** 6827 women met study criteria; 5449 (80%) received chemotherapy and 1378 (20%) refused. Relative to those who received chemotherapy, those who refused chemotherapy were older (median age 71 vs 69 years; $p < 0.05$), more often insured with Medicare (83% vs 80%; $p = 0.05$), were diagnosed more recently (2014-2017 vs 2010-2013, 67% vs 61%; $p < 0.05$), had lower grade tumors (grade 1 or 2 vs grade 3, 57% vs 48%; $p < 0.05$), more frequently had progesterone receptor-positive tumors (68% vs 63%; $p < 0.05$), and received radiation less frequently (67% vs 71%; $p < 0.05$). Chemotherapy refusal was significantly associated with increasing age (age 75-79 vs 65-74 OR 1.61, CI 1.4-1.85; age ≥80 vs 65-74 OR 3.24, CI 2.76-3.79) and more recent year of diagnosis (2014-2017 vs 2010-2013; OR 1.3 CI 1.14-1.48). Chemotherapy refusal was significantly associated with decreased 5-year OS for patients aged 65-74 years (92% vs 95%; $p < 0.05$) and patients aged 75-79 years (85% vs 92%; $p < 0.05$), but not for those aged ≥80 years (84% vs 91%; $p = 0.07$). Overall, when controlling for patient factors, hazard of death with chemotherapy refusal was significantly increased (HR 1.12, CI 1.04-1.2), but was not increased for women aged ≥80 years when stratified by age. **Conclusions:** Among healthy women aged ≥65 with high genomic risk ER-positive breast cancer, chemotherapy refusal increased with increasing age. Chemotherapy refusal was significantly associated with decreased OS in women aged 65-79, but did not impact OS in women aged ≥80. Lower use of chemotherapy in women ≥80 may demonstrate pragmatic decision-making between physicians and patients. Furthermore, the routine use of genomic assays may not be appropriate in this age group. More research is needed to determine why women aged 65-79 refuse chemotherapy, and whether patients remain satisfied with these choices. Research Sponsor: None.

Physician perspectives on extrapolating data from trials testing less-intense treatment to underrepresented populations. *First Author: Gabrielle Betty Rocque, University of Alabama at Birmingham, Birmingham, AL*

Background: Clinical trials provide the foundation for evidence-based practices, yet trial participants are often not representative of all patients. Historically, clinical trials involved adding novel agents to standard of care to improve survival. There has been a shift to an individualized approach with testing less intense treatment, yet vulnerable patient groups are at risk for underrepresentation. Little is known about physician perspectives on implementing less intense treatment approaches for patients who are not represented in sufficient number to draw conclusions on subpopulations. **Methods:** Open-ended, individual qualitative interviews with medical oncologists from different cancer centers exploring their perspectives on trials that test less intense treatment for patients with cancer. Interviews were audio-recorded and transcribed. Four independent coders utilized a content analysis approach to analyze transcripts using NVivo. Major themes and exemplary quotes were extracted. **Results:** Of the 39 participating physicians, 61.5% felt comfortable extrapolating, 30.8% were hesitant, and 7.7% would not feel comfortable extrapolating trial outcomes to underrepresented populations. One physician noted, "We've been extrapolating for as long as I can remember and certainly that I've been in practice; so we do need to do better there, but extrapolation is only natural with what we have." Facilitators of comfort included sentiment that "biology is biology", such that the cancer characteristics were what mattered; the strength of the evidence from the trial overall; inclusion of subset analysis on underrepresented populations; and prior experience making decisions with limited data. Barriers to extrapolation included the potential harm over the patient's lifetime; concerns about groups that had minimal participants; application specifically to younger patients; and extending findings to racially and ethnically diverse populations. Oncologists highlighted the need for shared decision-making when applying study results to underrepresented populations. They also expressed concerns about study findings being applied to patients who would have been ineligible in the original trials. Universally, broader inclusion in trials testing lowering chemotherapy is desired. **Conclusions:** The majority (92%) of physicians report that they would extrapolate clinical trial results to patients poorly represented in de-escalation trials, while expressing concerns about applicability to specific subpopulations based on tumor characteristics (e.g. stage, biology) and patient demographics (e.g. age, race). Further work is needed to increase clinical trial representation of diverse populations to safely and effectively optimize treatment for patients with cancer. Research Sponsor: Komen.

522 **Poster Session**

Effect of mevalonate pathway inhibitors on outcomes of patients (pts) with HER2-positive early breast cancer (BC) in the ALTTO trial. *First Author: Carmine De Angelis, Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy*

Background: Our preclinical findings suggest a role for the mevalonate pathway (MVA) in treatment resistance in HER2+ BC by providing alternative growth and survival signaling to bypass potent HER2 blockade, which could be overcome by the MVA inhibitors statins and nitrogen-containing bisphosphonates (NBs). Here we explored the effect of MVA inhibitors' use on pts' outcomes in the ALTTO trial (BIG2-06; NCT00490139). **Methods**: In the ALTTO trial, 8381 pts with HER2+ BC were randomized to 1 year of adjuvant lapatinib (L), trastuzumab (T), L+T, or T→L. All pts with documented treatment start with statins or NBs < 1 year after randomization were considered as MVA inhibitors users. Survival curves, with a median follow-up of 6.9 years, for disease-free survival (DFS), distant relapse-free interval (DRFI), BC-specific survival (BCSS), and overall survival (OS) according to MVA inhibitors use were estimated by the Kaplan Meier method and Log-rank test. All multivariate survival analyses employed a Cox proportional hazards regression model, adjusting for tumor size, nodal status, hormonal receptor (HoR), menopausal status, BMI, timing of chemo, and randomization arm. We considered interactions terms in Cox's model between MVA inhibitors use and randomization arm, hormonal status, and BMI group. **Results**: Among the 8381 pts included in this study, 493 and 299 were statins or NBs users, respectively. Table 1 summarizes the significant differences in pts' characteristics according to MVA inhibitors use ($P < .005$). In multivariate survival analyses, only NBs use was associated independently with better BCSS (HR, 0.44; 95% CI, 0.23 - 0.84; $P = 0.014$). Statin use was not independently associated with prognosis but only in interaction with pts characteristics: worse DFS, BCSS and OS in pts treated with L+T, worse DRFI and OS in pts treated with HoR+ BC (respective interaction P-values <0.05 in the Cox's model). **Conclusions**: NBs independently predicted improved BC-specific outcome in pts with HER2+ BC treated with adjuvant anti-HER2 therapy. Statin use was associated with an inferior outcome in pts with HoR+ disease and/or those treated with L+T. Whether this inferior association in statin users may reflect the underlying predisposition factors that can weaken the efficacy of anti-HER2 treatments and whether this effect was observed only in the L+T arm due to the more potent inhibition of the HER2 signaling pathway remain open questions. Further clinical investigations on the impact of MVA inhibitors on the outcome of pts with HER2+ BC are warranted. Research Sponsor: U.S. National Institutes of Health.

Socioeconomic disparities in supportive therapy use and tolerance of aromatase inhibitors in patients with early-stage, hormone-positive breast cancer. *First Author: Melanie Wain Kier, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Socioeconomic disparities impact breast cancer survival with significantly higher mortality among women of lower socioeconomic status. Little is known about how disparities affect patients with early-stage hormone receptor positive (HR+) breast cancer (BC) and patients' tolerance and adherence to standard of care adjuvant aromatase inhibitor (AI) therapy. AI-related adverse effects are common and can cause therapy intolerance and early discontinuation. Supportive therapies have been shown to improve symptom tolerability when utilized by patients. This study assessed socioeconomic disparities in utilization of supportive therapies and adherence to initial AI therapy. **Methods:** We performed a retrospective chart review of all female patients at our academic institution with early-stage, HR+, BC who were initiated on adjuvant AI between 2011-2020. We collected information on side effects, duration of first AI and use of supportive therapies. We linked median family income with zip codes based on national census data and sorted them based on the Pew Research Center categorization. Primary endpoints were the rate of discontinuation of AI at 1-year and utilization of supportive therapies in relation to income, insurance coverage and primary language. The Fisher's exact test, Pearson's Chi-squared test, and Wald test methods were used to compare rates of discontinuation of front-line AI therapy and use of supportive therapies for each group. **Results:** We identified 1006 patients of whom 95% (n = 954) had AI related side effects yet only 31% (n = 311) received supportive therapies in the first year of AI treatment. The majority (59%) of patients were in the middle-income range ($52,200-$156,000), followed by upper (24%) and lower (17%) income. Upper-income was associated with higher use of supportive therapies (OR 1.46, $p = 0.031$) but was not associated with lower 1-year discontinuation rate. Medicare was the most common insurance coverage (45%), followed by Commercial (32%) and Medicaid (23%). English was the primary language for 86% of patients. Neither insurance coverage nor primary language was associated with either endpoint. In evaluating race, Black patients had the least use of supportive therapies ($p < 0.001$), yet this group had the lowest 1-year discontinuation rate ($p = 0.005$). **Conclusions:** Our results demonstrate that income and race were associated with use of crucial supportive therapies that are proven to help patients mitigate AI toxicities. The etiology of these disparities is likely multifactorial and requires further study to ensure equitable care and access for all patients. Research Sponsor: None.

Estradiol (E2) levels in premenopausal women with hormone receptor-positive (HR+) breast cancer (BC) on ovarian function suppression (OFS) with gonadotropin-releasing hormone agonists (GnRHa).

First Author: Megan Elizabeth Tesch, Dana-Farber Cancer Institute, Boston, MA

Background: OFS is an important treatment component for premenopausal women with early and advanced HR+ BC and optimal efficacy may depend on complete E2 suppression with GnRHa, especially when combined with aromatase inhibitors (AI). However, standard assays lack sensitivity and accuracy at very low E2 concentrations, rendering detection of breakthrough ovarian function challenging. More informative data regarding endocrine effects of GnRHa are needed, particularly in young women who derive the most benefit from OFS yet more frequently had breakthrough E2 levels in the SOFT trial substudy, SOFT-EST. **Methods:** Using a prospective cohort study of women with BC diagnosed at age ≤ 40 years, we identified participants with stage I-IV HR+ BC on OFS treatment with leuprolide, goserelin or triptorelin and blood collected 1 year after diagnosis. Clinical data were obtained through surveys and medical records. Plasma estrogens were measured by liquid chromatography-tandem mass spectrometry, with a limit of detection of 0.2 pg/mL compared to 10 pg/mL with standard assays. We assessed the proportion of women on OFS with E2 > 2.72 pg/mL (10 pmol/L) and > 10 pg/mL. Patient characteristics, estrone (E1) and FSH levels, and disease-free (DFS) and overall survival (OS) were compared between those with and without elevated E2 using Fischer's exact, Wilcoxon rank sum and log rank tests, respectively. **Results:** Of 84 patients who met inclusion criteria, 72 (86%) had stage I-III and 12 (14%) had stage IV BC; 25 were on OFS plus AI and 59 were on OFS plus tamoxifen (TAM). Median E2 was 3.1 pg/mL (range 0.2-30.9). 46 patients (55%) had E2 > 2.72 pg/mL, including 8 on AI and 38 on TAM; 4 (5%) had E2 > 10 pg/mL, including 1 on AI and 3 on TAM. Factors associated with E2 > 2.72 pg/mL were no prior chemotherapy, TAM and high E1 ($P \leq .05$), but not age, BMI or GnRHa schedule (Table). After a median follow-up of 7 years, DFS events were seen in 6 patients with E2 > 2.72 pg/mL and 5 without ($P = .232$); OS events were seen in 7 patients with E2 > 2.72 pg/mL and 5 without ($P = .608$). **Conclusions:** More than half of young women with ER+ BC had E2 > 2.72 pg/mL on OFS, 91% of whom would not have been detected by standard assays. This may be an area amenable to intervention to improve outcomes in young women. However, larger studies are needed to elucidate the optimal E2 target on OFS and clinical implications of incomplete E2 suppression on ultrasensitive assays. Research Sponsor: Susan G. Komen, Breast Cancer Research Foundation.

Exploring homologous recombination deficiency thresholds for predicting response to platinum-based treatment in triple negative breast cancer.

First Author: Kirsten Timms, Myriad Genetics Inc., Salt Lake City, UT

Background: Homologous recombination deficiency (HRD) status can be used to identify patients who are eligible for treatment with DNA damaging agents. Using a 3-biomarker Genomic Instability Score (GIS) threshold of ≥42, studies have previously examined the association between HRD status and outcomes in patients with triple negative breast cancer (TNBC). However, evidence suggests that a GIS threshold of ≥33 may be more appropriate. Here, we conducted an exploratory analysis evaluating the ability of ≥33 and ≥42 GIS thresholds to predict response to platinum-based treatment in patients with TNBC. **Methods:** Patients across 5 cohorts (TBCRC030[1], TBCRC008[2], NCT01372579[3], PrECOG 0105[4], combined cisplatin cohort[4]) were included in this analysis if they had a primary TNBC diagnosis, received neoadjuvant platinum-based treatment, had a valid GIS, and had known pathologic complete response (pCR) status. GIS was determined by a combination of loss of heterozygosity, telomeric-allelic imbalance, and large-scale state transitions.[4,5] BRCA mutation status was defined by loss of function resulting from a pathogenic variant in *BRCA1* or *BRCA2*. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV), were calculated by comparing binary threshold status and binary pCR status. **Results:** A total of 204 tumors (158 BRCAwt; 33 BRCAm; 13 unknown) were included; pCR to platinum-based treatment occurred in 55 cases (39 BRCAwt; 14 BRCAm; 2 unknown). Sensitivity, specificity, PPV, and NPV were comparable between the ≥33 and ≥42 GIS thresholds, with the ≥33 threshold producing higher sensitivity values. This was true when thresholds were applied to all samples and to BRCAwt samples only (Table). Among patients who achieved pCR in response to platinum-based treatment, 5.5% of patients in the full cohort and 7.7% of those in the BRCAwt cohort had a GIS between 33-41. **Conclusions:** To ensure that the majority of patients likely to benefit from treatment are identified, a GIS of ≥33 may be the most appropriate threshold to predict response to platinum-based treatment in patients with TNBC; however, a prospective trial will be needed to confirm these findings. Additional studies will be important to determine whether this threshold may be appropriate to determine eligibility for other DNA-damaging agents such as PARP inhibitors. 1. Metformin, placebo, and endocrine therapy discontinuation among participants in a randomized double-blind trial of metformin versus placebo in hormone receptor–positive early-stage breast cancer (CCTG MA32).

First Author: Dawn L. Hershman, Columbia University College of Physicians and Surgeons, New York, NY

Background: The MA32 study (NCT01101438) investigated whether 5-years of metformin improves invasive disease-free survival in early-stage breast cancer (BC). Non-adherence to endocrine therapy (ET) and medications for chronic conditions is common, and increases with drug toxicity and polypharmacy. This secondary analysis evaluates rates and predictors of early discontinuation of metformin, placebo, and ET among participants with HR positive BC. **Methods:** Patients with high-risk non-metastatic BC were randomized to 60 months of metformin (850 mg BID) or placebo. Patients were administered bottles of metformin/placebo every 180 days. Metformin/placebo compliance was defined as a bottle dispensed at month 48 or later (i.e., medication supplied for 54 months). The ET compliance analysis included patients with HR positive BC who received adjuvant ET with start and stop date reported and was defined as > 48 months of use. Associations of baseline covariates with drug compliance and with ET adherence were examined using multivariable models. **Results:** Among the 2,521 HR-positive BC patients, 32.9% were non-compliant to study drug. Non-compliance was higher among patients on metformin vs. placebo (37.1% vs. 28.7%, p<0.001). Reassuringly, compliance to ET was similar between treatment arms (28.4% vs 28.0%, p=0.86). Patients who were non-compliant to endocrine therapy, were more likely to be non-compliant to study therapy (38.8% vs. 30.1%, p<0.0001). In a multivariable analysis, study drug non-compliance was increased with metformin vs. placebo (OR=1.43, 95% CI, 1.21-1.70; p<0.0001); grade 1 or greater GI toxicity during the first year (70.9% vs. 53.2%; OR=1.20, 95% CI, 1.01-1.44; p=0.044); lower age (age < 50 OR = 1.44, 95% CI, 1.21 – 1.71; p<0.01) and higher body mass index (BMI > 30, OR=1.49, 95% CI, 1.25 - 1.77; p<0.0001). Study drug non-compliance was decreased with prior receipt of chemotherapy (OR = 0.68, 95% CI, 0.50–0.84; p<0.001). Non-compliance with endocrine therapy was associated with increased non-compliance to study drug (OR: 1.47, 95% CI, 1.20, 1.70, p < 0.0001). Study drug (metformin vs placebo) non-compliance was not associated with endocrine therapy non-compliance (OR=0.97, 95% CI, 0.80-1.17; p=0.74). **Conclusions:** While non-compliance was higher among patients on metformin, it was still considerable among patients on placebo. Among other factors, development of GI toxicity and non-adherence to ET were associated with non-adherence to study drug. Many BC patients on ET are prescribed metformin and other oral medications for the treatment of chronic conditions. Reassuringly, non-adherence to study drug did not impact endocrine therapy adherence. Attention to global medication adherence is needed to improve BC and cardiovascular outcomes in cancer survivors. Clinical trial information: NCT0110143. Research Sponsor: U.S. National Institutes of Health.

Adjuvant abemaciclib for high-risk early breast cancer (EBC): Factors increasing the rate of treatment discontinuations in monarchE.

First Author: Sara M. Tolaney, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

Background: Adjuvant abemaciclib plus endocrine therapy (ET) demonstrated clinically meaningful improvement in reducing the risk of recurrence in patients (pts) with HR+, HER2– high risk EBC. In monarchE, 25.6% pts discontinued abemaciclib before completing the 2-year treatment period due to reasons other than recurrence. This exploratory analysis evaluates the impact of baseline factors on time to discontinuation for abemaciclib-treated patients with an aim to identify pts at higher risk of discontinuation. **Methods:** Time to discontinuation (TTD) was defined as time from first dose to the discontinuation of abemaciclib or all treatment due to reasons other than recurrence. These exploratory analyses evaluated the association between TTD and baseline demographics, disease characteristics, and the extent of pre-existing medical comorbidities. Factors with p-value <0.05 in the univariate Cox model were considered as potentially associated with TTD and then fitted into a multivariate Cox model with stepwise variable selection, with entry and retaining p-value threshold of 0.05. Discontinuation rates at selected timepoints (6-month, 12-month, 18-month, 24-month) within each subgroup were estimated using the Kaplan-Meier method. **Results:** The following variables were significantly associated with higher risk of discontinuation in the multivariate model: Age ≥65 yr, enrolled in North America or EU, ECOG PS=1, post-menopausal, 1-3 positive nodes, or 4 or more pre-existing comorbidities. The majority of discontinuations occurred within the first 6 months of the treatment period; thus, this timepoint was selected to estimate discontinuation rates for factors independently associated with TTD (Table). Complete results on discontinuation rates at other timepoints will be reported in the presentation. **Conclusions:** This exploratory analysis identified several factors associated with a greater risk of discontinuation. These results illustrate the importance of close monitoring and dose adjustments early on, particularly for patients with an increased risk of discontinuation prior to completing the 2-yr treatment period of abemaciclib. Clinical trial information: NCT03155997. Research Sponsor: Eli Lilly and Company.

AMEERA-4: A preoperative window-of-opportunity (WOO) study to assess the pharmacodynamic (PD) activity of amcenestrant or letrozole in postmenopausal patients with ER+/HER2− primary breast cancer. *First Author: Mario Campone, Institut de Cancérologie de l'Ouest, René Gauducheau, St Herblain, France*

Background: Amcenestrant is an optimized oral selective ER degrader (SERD) that antagonizes and degrades the ER and has demonstrated favorable preliminary safety and antitumor activity as monotherapy and in combination with palbociclib in postmenopausal patients with ER+/HER2− advanced breast cancer, irrespective of baseline (BL) *ESR1* mutation status. Here we present the final results of AMEERA-4 (NCT04191382), a Phase 2 preoperative WOO study that evaluated the PD activity of two dose levels of amcenestrant or letrozole using paired biopsies assessed for biomarkers. **Methods:** Postmenopausal women with operable stage I–III (tumor size ≥ 10 mm by ultrasound) ER+/HER2− breast cancer and Ki67 levels ≥ 15% by local assessment were randomized 1:1:1 to amcenestrant 400 mg once daily (QD), amcenestrant 200 mg QD or letrozole 2.5 mg QD for 14 days before surgery. Antiproliferative activity, as measured centrally by change from BL in Ki67 using paired biopsies before and after a 14-day treatment with 2 different doses of amcenestrant vs letrozole, was the planned primary endpoint. Main secondary endpoints included ER target engagement, assessed through the change in ER expression measured by change from BL in H-Score, and safety. **Results:** Trial enrollment was voluntarily stopped early, as informative data supporting adjuvant development became available; therefore, no formal statistical comparisons were conducted. Among 105 randomized patients (amcenestrant 400 mg: n = 34, amcenestrant 200 mg: n = 36, letrozole: n = 35), 95 were treated and had available pre- and post-treatment Ki67 per central review (modified ITT population). No major imbalances in BL patient and tumor characteristics were observed. The geometric least squares means (LSM) estimate (95% CI) of Ki67 reduction was 75.9% (67.9, 81.9) for amcenestrant 400 mg, 68.2% (58.4, 75.7) for amcenestrant 200 mg and 77.7% (70.0, 83.4) for letrozole. The LSM estimate (95% CI) of absolute change from BL in ER H-score was –176.7 (–201.4, –152.0) for amcenestrant 400 mg, –202.9 (–226.1, –179.7) for amcenestrant 200 mg and –32.5 (–57.2, –7.7) for letrozole, with median relative changes of –65.3%, –68.3% and –9.5%, respectively. The incidence of treatment-related adverse events (TRAEs) was 21.2% for amcenestrant 400 mg, 22.2% for amcenestrant 200 mg and 25.7% for letrozole. No Grade ≥ 3 TRAEs occurred in any treatment arm. **Conclusions:** Both doses of amcenestrant demonstrated robust Ki67 reductions, strongly engaged the ER target, and continued to show a favorable safety profile in an early breast cancer population, consistent with previous published reports. Based on PD activity and safety, and emerging results from other ongoing amcenestrant trials, the 200 mg QD dose of amcenestrant was selected for our ongoing study in the adjuvant setting; AMEERA-6 (NCT05128773). Clinical trial information: NCT04191382. Research Sponsor: The study was sponsored by Sanofi. Editorial support was provided by Amanda Sheldon, PhD, CMPP, of inScience Communications (Philadelphia, PA, USA), funded by Sanofi.

Association of progesterone receptor status with 21-gene recurrence score and survival among patients with estrogen receptor-positive breast cancer. *First Author: Sung Jun Ma, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Among patients with estrogen receptor (ER)-positive breast cancer, progesterone receptor (PR)-negative tumors were shown to have worse prognosis than PR-positive tumors. However, PR-negative tumors were underrepresented in trials such as TAILORx and RxPONDER, and the role of PR status in the setting of 21-gene recurrence score (RS) remains unclear. We performed an observational cohort study to evaluate the association of PR status with RS and the magnitude of chemotherapy benefits on survival. **Methods:** The National Cancer Database (NCDB) was queried for women diagnosed between 2010 and 2017 with ER-positive, human epidermal growth factor receptor 2 (HER2)-negative, pT1-3N0-1a breast cancer who underwent surgery and endocrine therapy. Logistic and Cox multivariable analyses (MVA) were used to identify variables associated with high RS (> 25) and overall survival (OS), respectively. Interaction test was performed among PR status, chemotherapy, and nodal staging. Propensity score matching was performed to reduce selection bias. Sensitivity analysis was performed after excluding those with postdiagnosis survival of less than 6 months to reduce immortal time bias. **Results:** A total of 143,828 patients met our criteria (n = 110,421 for PR-positive/pN0, n = 11,897 for PR-negative/pN0, n = 19,928 for PR-positive/pN1a, n = 1,582 for PR-negative/pN1a). Median follow up was 51.5 months (interquartile range 34.8-71.9). On logistic MVA, PR-negative tumors were more likely to have high RS (adjusted odds ratio [aOR] 6.68, 95% confidence interval [CI] 6.40-6.97, p < 0.001). On Cox MVA, PR-negative tumors were associated with worse OS (adjusted hazards ratio [aHR] 1.20, 95% CI 1.10-1.31, p < 0.001). Interaction among PR status, chemotherapy, and nodal staging was statistically significant (interaction p = 0.049). On subgroup analyses, the magnitude of chemotherapy benefit for OS was comparable among pN0 tumors (PR-positive: aHR 0.74, 95% CI 0.66-0.82; PR-negative: aHR 0.63, 95% CI 0.51-0.77) and was greater for PR-negative status among pN1a tumors (PR-positive: aHR 0.57, 95% CI 0.47-0.67; PR-negative: aHR 0.31, 95% CI 0.20-0.47). Similar findings were noted in 9,979, 1,822, 4,196, and 354 matched pairs for PR-positive/pN0 (HR 0.43, 95% CI 0.37-0.50), PR-negative/pN0 (HR 0.53, 95% CI 0.41-0.69), PR-positive/pN1a (HR 0.55, 95% CI 0.45-0.67), and PR-negative/pN1a (HR 0.25, 95% CI 0.14-0.45) tumors, respectively. On sensitivity analysis, our findings were consistent in Cox MVA using interaction and subgroup analyses. **Conclusions:** To our knowledge, this is the largest study using a nationwide oncology database suggesting that PR-negative status is an independent, adverse prognostic factor for survival associated with high RS, with greater chemotherapy benefits compared to PR-positive status among pN1a tumors even after adjusting for RS. Research Sponsor: None.

A prognostic model for distant recurrence-free survival in triple-negative breast cancer (TNBC) and the outcomes of initiation of adjuvant chemotherapy in the risk of relapse. *First Author: Zaida Morante, Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru*

Background: TNBC is a highly complex, heterogenous disease associated with poor outcomes, high incidence of distant metastases, and limited treatment options. With the purpose of identify patients at different risk of distant recurrence, we developed a prognostic model using clinicopathological characteristics that contribute to the risk of recurrence in TNBC patients and also evaluate its influence in the time of beginning of adjuvant therapy. **Methods:** We retrospectively analyzed 687 TNBC patients who received adjuvant chemotherapy between January 2000 to December 2014 at the Instituto Nacional de Enfermedades Neoplasicas (Lima, Peru). The database was randomly divided into two groups to create a discovery set (n = 344) and a validation set (n = 343). Univariate and multivariate Cox regression analysis was conducted to identify prognostic factors for distant recurrence-free survival (DRFS). We developed a linear risk score based on clinicopathologic characteristics. Under STEPP methodology we classified patients at high, intermediate or low-risk of distant recurrence and the absolute treatment effects of time to initiation of chemotherapy (TTC, ≤ 30 vs > 30 days) through risk subgroups was estimated. **Results:** The median of follow-up was 9.90 years. In total, 31.0% (n = 213/687) relapses were registered. Variables associated with DRFS in the multivariate analysis were: age, T-staging, and N-staging. A tumor staging of T3-T4 vs. T1/T2 (HR = 2.92, 95%CI: 1.39 - 6.17), followed by the number of positive lymph nodes (N2-N3 vs N0/N1; HR = 2.78, 95%CI: 1.74 - 4.45) and an older age (≥ 60 years vs. ≤ 40/41-59, HR = 2.66, 95%CI: 1.46 - 4.88) were the clinicopathologic characteristics contributing to a higher risk score according to the 3-variable model. Also, 3 risk groups were identified and corroborated in the validation group. In the discovery set, patients with a TTC > 30 days experienced an overall decreased of 17.5% (95%CI: 6.7 - 28.3) in 10-year DFRS vs. those who initiated adjuvant therapy before 30 days. The impact of TTC > 30 days was higher in patients classified as high-risk (Decreased 10-year DFRS: 53.3 ± 28.8 %), similar findings were found in the validation set. **Conclusions:** A prognostic model based in clinicopathological characteristics (age, pT and pN), was able to classify TNBC patients' candidates to adjuvant chemotherapy in 3 prognostics groups. We identified a subgroup of patients in which delaying of adjuvant chemotherapy (> 30 days) confers very high-risk of relapse. Research Sponsor: Own resources.

Breast density reduction as a predictor for prognosis in premenopausal women with hormone receptor–positive breast cancer: A retrospective analysis of the ASTRRA study. *First Author: Soong June Bae, Department of Surgery, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, South Korea*

Background: While the relationship between mammographic breast density (MD) decline and anti-hormone therapy efficacy has been reported in estrogen-receptor (ER)-positive breast cancer, it is still unclear in premenopausal women and in the case of adding ovarian function suppression (OFS) to anti-hormone therapy. We aimed to investigate the MD reduction (MDR) rate and impact of MDR on prognosis stratified by treatment from the updated result of the ASTRRA trial. **Methods:** ASTRRA trial, a randomized phase 3 study, showed that adding ovarian function suppression (OFS) to tamoxifen (TAM) improved survival in premenopausal women with ER+ breast cancer after chemotherapy. We updated survival outcomes with a median follow-up of 108 months. We assessed mammography taken before treatment and the follow-up mammography taken annually for up to five years after initiation of treatment. MD was classified into four categories based on the Breast Imaging Reporting and Data System. MDR positivity was defined as a downgrade in MD among follow-up mammography up to two years after randomization, with the pretreatment MD grade as a reference. **Results:** Among the 1,293 patients from ASTRRA trial, we successfully evaluated MDR in 947 patients, of which 796 (83.4%) belong to high MD (grade C or D). The patient characteristics were similar between the entire ASTRRA trial and the subgroup with available MDR. There was no difference in MDR-positive rate between two treatment groups (106 of 477 [22.2%] in TAM-only group vs. 87 of 470 [18.5%] in TAM + OFS group, $P = .156$). MDR-positivity was significantly associated with better disease-free survival (DFS) in TAM + OFS group (estimated 8-year DFS: 92.9% in MDR-positive vs. 82.2% in MDR-negative, $P = .013$), but did not in TAM-only group (estimated 8-year DFS: 80.3% in MDR-positive vs. 80.2% in MDR-negative, $P = .927$; $P_{interaction} = .025$). Simialr trends were observed in terms of recurrence-free survival, distant metastasis-free survival (DMFS), locoregional-free survival, and overall survival. In addition, MDR-positivity was an independent factor for favorable DFS (adjusted hazard ratio [HR], 0.37; 95% CI, 0.16 to 0.86; $P = .021$) and DMFS (adjusted HR, 0.35; 95% CI, 0.13 to 0.98; $P = .045$) in TAM + OFS group. **Conclusions:** Although the proportion of patients with MDR-positive was comparable between the two treatment groups, MDR-positive was independently associated with favorable outcomes only in TAM + OFS group. Future work is warranted to verify the mechanism by which the association between MDR and clinical benefit differs according to the treatment group. Clinical trial information: NCT00912548. Research Sponsor: This research was supported by a grant of the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (grant number: HI19C0481, HC19C0147).

The survival benefit of anti-HER2 treatment in the management of small (T1mic, T1a, T1b, T1c), node-negative HER2+ breast cancer. *First Author: Kai Conrad Cecil Johnson, Ohio State University - James Cancer Center, Columbus, OH*

Background: Limited compelling prospective and retrospective data regarding the added benefit of anti-HER2 therapy in the management of small, node-negative HER2-positive breast cancer (HER2+BC) exists, in part due to differences in outcome reporting, unmatched analyses, and a lack of head-to-head comparisons. As a result, national guideline committees find themselves unable to confidently recommend anti-HER2 therapy and clinicians are left to exercise clinical judgement on whether the use of anti-HER2 therapy should be considered for such patients. **Methods:** Our team performed a multi-institutional retrospective analysis using the ASCO CancerLinQ database, with a focus on clinical data from small, node-negative HER2+BC patients diagnosed between 2010 to 2021. We compared clinical outcomes between those who received adjuvant trastuzumab therapy, with or without chemotherapy, to those who did not, with our primary outcomes being invasive disease-free survival (iDFS) and overall survival (OS). We performed both a univariate and multivariate analysis, using a Cox proportional hazard model to control for factors including age, ethnicity, body mass index, hormone status, tumor grade, histology type, BRCA status, region, and smoking history. Additionally, a three-arm univariate analysis was performed comparing untreated patients to trastuzumab alone versus combination therapy. **Results:** In total, 1206 patients met inclusion criteria, including 779 patients who received trastuzumab with or without chemotherapy. We found a statistically significant improvement in both iDFS (HR 0.73, p = 0.01) and OS (HR 0.63, p = 0.027) on univariate analysis for those receiving anti-HER2 therapy. Similarly on multivariate analysis, iDFS (HR 0.75, p = 0.030) and OS (HR 0.61, p = 0.029) were improved in those who received therapy, regardless of tumor size. Our three-arm univariate analysis involving no treatment (n = 427), trastuzumab monotherapy (n = 169), and combination therapy (n = 578) found that iDFS was significantly improved for both treatment arms compared to observation alone (p = 0.006), whereas OS trended towards significance in the treatment arms but did not reach this target (p = 0.061). No significant difference was noted between treatment arms. **Conclusions:** Our analysis found a statistically significant improvement in iDFS and OS when patients with small, node negative, HER2+BC received adjuvant anti-HER2 therapy with or without chemotherapy as compared to observation. From our univariate three-arm comparison, it appears that trastuzumab provides the majority of benefit to patients in terms of DFS, but this result is exploratory. Further investigation is warranted, including meta-analyses to better characterize the degree of benefit seen with anti-HER2 treatment. For now, this data adds to evidence suggesting added benefit with therapy over observation. Research Sponsor: None.

Outcomes of patients with T1a,b N0 Her2-positive breast cancer treated with adjuvant trastuzumab in a prospective registry in Ontario, Canada. *First Author: Andrea Eisen, University of Toronto, Toronto, ON, Canada*

Background: Multiple randomized trials of chemo +/- tras in early stage, Her 2 positive BrCa demonstrated improvement in survival, but patients (pts) with T1a,b N0 disease were mostly excluded. Given the uncertainty of benefit in this group and the toxicities of chemo + tras, treatment in Ontario was funded for these patients conditional upon data collection for toxicity and survival endpoints. We report the outcomes for 483 patients enrolled in this Evidence Building Program (EBP). **Methods**: Between 2011 and 2018, 483 eligible pts with Her 2 pos disease and adequate cardiac function were treated with chemo + tras in the EBP. Cardiac toxicity, febrile neutropenia (FN), event-free (EFS), and overall survival (OS) were determined for this cohort from administrative datasets, and compared retrospectively to controls of similar stage selected from the Ontario Cancer Registry who did not receive tras and/or chemo. For the EBP cohort, clinicians also reported changes in left ventricular ejection fraction (LVEF). **Results**: Pt characteristics are shown in the Table. EBP patients had improved OS when compared to controls who received no chemo or tras. The 3-year OS in the EBP pts was 99.1%, versus 96.9% in the controls [adjusted HR 0.59 (95% CI 0.29-1.20)]. Patients receiving EBP tras had a significantly longer EFS than controls with or without chemo [adjusted HR 0.54 (0.36-0.83), p=0.005]. Use of chemo + tras in EBP pts was associated with an increased risk of clinical congestive heart disease (CHD) and febrile neutropenia (FN). About 3.5% of pts experienced CHD during treatment with chemo + tras. About 6% of pts had an absolute reduction of LVEF >10% or reached LVEF <50%. In an adjusted analysis, the risk of CHD was higher in older pts [HR 1.06 (1.03-1.08) per 1-yr increase in age, p<0.0001) and for pts who received anthracyclines [HR 5.00 (1.71-14.7). In a matched analysis, the crude frequency of FN during treatment was 20% in EBP pts vs. 3% among controls who did not receive chemo or tras (p<0.001). **Conclusions:** Analysis of the Ontario EBP for pts with, T1a,b N0 HER2 pos BrCa revealed that the prognosis is excellent and is improved with the use of chemo + tras. The safety profile was expected and tolerable, especially when non anthracycline chemo was used. These results led to a funding policy change where prospective data collection has been discontinued and chemo + tras is now routinely funded in this population. Research Sponsor: Ontario Ministry of Health.

Safety and tolerability of olaparib combined with breast radiotherapy in patients with triple-negative breast cancer: Final results of the RADIOPARP phase 1 trial. *First Author: Pierre Loap, Institute Curie, Department of Radiation Oncology, Paris, France*

Background: Preclinical studies have demonstrated that triple-negative breast cancer (TNBC) cells were sensitive to PARP inhibitors when used as radiosensitizers. Combining PARP-inhibitors with radiotherapy may consequently enhance the biological effectiveness of the irradiation, leading to improved locoregional control in TNBC patients. We aimed to establish the appropriate dosing and the safety profile of Olaparib used as a radiosensitizer in combination with radiotherapy in TNBC patients with residual disease after neoadjuvant chemotherapy. **Methods:** RADIOPARP (NCT03109080) was a prospective phase I dose-escalation trial establishing the tolerance profile of Olaparib combined with breast radiotherapy in high-risk early TNBC patients. Inclusion criteria were resected TNBC with non-complete pathological response after neoadjuvant chemotherapy, or unresectable TNBC despite prior neoadjuvant chemotherapy. Olaparib was started seven days before irradiation and continued during radiotherapy. A time-to-event continual reassessment method was used to increase Olaparib through four increasing dose levels (50mg, 100mg, 150mg or 200mg twice a day) with a 25% maximum probability rate of dose-limiting toxicities (DLT). Radiotherapy delivered 50 Gy to the breast or to the chest wall, with or without lymph node irradiation. Toxicities were graded according to CTCAE (version 4.03). Homologous recombination (HR) proficiency status was genetically determined based on shallow whole genome sequencing. **Results:** Twenty-four TNBC patients were enrolled between 09/2017 and 11/2019. Olaparib was escalated to 200 mg twice a day without DLT and the MTD was not reached. With a median follow-up of 34 months, no late treatment-related grade $\geq$ 3 toxicity was observed, and the maximum observed toxicities were limited to grade 2 breast pain (n=2), fibrosis (n=2), deformity (n=1) and telangiectasia (n=1). Three-year OS and EFS were 83% [95% CI: 70%-100%] and 65% [51%-91%], respectively. HR proficiency status was not associated with OS and EFS. **Conclusions:** Olaparib used as a radiosensitizer in combination with radiotherapy in TNBC patients was well-tolerated. The MTD was not reached, and no significant late toxicity was reported. For future trials evaluating the anti-tumor efficacy of this combination, an Olaparib dose of 200 mg twice a day should be considered. Clinical trial information: NCT03109080. Research Sponsor: AstraZaneca.

Efficacy and safety of initial five years of adjuvant endocrine therapy in postmenopausal hormone receptor-positive breast cancer: A systematic review and network meta-analysis. *First Author: Hao Liao, Peking University Cancer Hospital, Beijing, China*

Background: Endocrine therapy has greatly improved the clinical outcomes of hormone receptor-positive breast cancer patients. However, there was an unmet need to identify the potentially best regimen of initial adjuvant endocrine therapy. Therefore, in this network meta-analysis, we synthesized the latest evidence to indirectly compare the efficacy and safety among different 5 years of regimens of initial adjuvant endocrine therapy. **Methods:** We conducted a systematic search of the PubMed, Web of Science, and EMBASE in January 2022. Randomized clinical trials assessing the efficacy and safety of initial 5 years of adjuvant endocrine therapy were included. The primary outcomes were disease-free survival (DFS) and overall survival (OS) and the secondary outcome was severe adverse effects (SAEs). A Bayesian network meta-analysis was carried out to indirectly compare all regimens and the SUCRA values were used to obtain rankings. **Results:** Eleven studies with 49,987 subjects were included. For DFS, exemestane (EXE) (hazard ratio [HR] 0.91, 95% confidence interval [95%CI] 0.87-0.96), anastrozole (ANA) (0.94, 0.90-0.97), letrozole (LET) (0.93, 0.89-0.97), tamoxifen (TAM) followed by EXE (0.91, 0.87-0.96), and TAM followed by ANA (0.92, 0.87-0.98) were more favorable than TAM, with TAM followed by EXE ranking as the first of SUCRA. For OS, only TAM followed by ANA showed significant superiority than TAM (HR 0.91, 95%CI 0.86-0.97) and ranked as the first of SUCRA. For SAEs, EXE (HR 1.72, 95%CI 1.04-2.98), ANA (1.58, 1.03-2.43), and LET (1.63, 1.02-2.57) showed greater associations with bone fracture than TAM. However, no significant difference in the incidences of cardiac events, thromboembolic events, and cerebrovascular events was found among all comparisons. **Conclusions:** The sequential use of aromatase inhibitors may be the optimal treatment mode for hormone receptor-positive postmenopausal early breast cancer patients. In addition, the three kinds of aromatase inhibitors achieved roughly equal efficacy, but caused different types of SAEs. Research Sponsor: None.

Concordance and clinical impact of ER, PR, HER2 expression by local and central immunohistochemistry versus RT-PCR in HR+/HER2- early breast cancer (EBC): Results from the ADAPT trial. *First Author: Oleg Gluz, West German Study Group and Ev. Hospital Bethesda, Breast Center Niederrhein, Moenchengladbach, Germany and University Hospital Cologne, Cologne, Germany*

Background: We evaluated concordance of ER, PR and HER2 status between local, central, and RT-PCR/mRNA assessments and its clinical impact in the ADAPT trial collective in HR+ HER2- EBC (NCT01779206). Particularly, validity of borderline ER-positivity (expression level 1-10%) has great clinical relevance as treatment concepts between luminal-like and triple negative (TNBC) EBC differ substantially. **Methods**: Patients (pts) with clinically high-risk HR+/ HER2- EBC (ER and/or PR >1%) were initially treated by 3 (+/-1) weeks of endocrine therapy (ET) before surgery or sequential core biopsy (CB) and then allocated to an ET-alone or chemotherapy (ET) trial, depending on risk and endocrine response. OncotypeDX (incl. RT-PCR for ER, PR, HER2) and central IHC for ER, PR, HER2 were performed on the initial 1.CB. ER-low cohort was defined as 1-10% expression by local OR central lab (ASCO-CAP). Cox models were used to estimate hazard ratios. **Results**: In ADAPT, 5149 pts from 81 centers in Germany with locally ER and/or PR positive (known quantitative levels) EBC were screened 2012-2018. Median follow-up was 59 months. For ER (positive vs. negative), overall concordance measured as agreement (κ) was high between all three assessments: Local vs. central IHC: 99.3% (κ = 0.45), RT-PCR vs. central IHC: 99% (κ = 0.48). Concordance was lower for PR: RT-PCR vs. central IHC: 90.5% (κ = 0.58), local vs. central IHC: 93.1% (κ = 0.56). 3% were centrally found as HER2+ in 1.CB (73% of them were negative by RT-PCR) and/or 2. Sample. Regarding HER2-low status (1+ or 2+ but ISH negative), concordance between local and central IHC was only 53.8% (κ = 0.09). Of all pts, only 2% (n=109; n=85 with both measurements available) had low ER expression (1-10%) by either local or central pathology. Only 9 of them were concordantly identified as ER-low (11%); 8/58 (14%) ER-low by local lab had TNBC by central lab. 17/47 ER-low cases (36.2%) with known post-endocrine Ki67post had Ki67post <10% vs. 59.7% in ER>10%. 41.8% of ER-low cases had RS<25 vs. 76.7% in ER>10%. All cases with ER <10% by both assessments and those with Ki-67≥40% had RS >25. We observed worse iDFS (HR 1.91, p=0.034) in the ER-low group vs. ER>10%. **Conclusions**: Although we have confirmed high agreement between local and central IHC and RT-PCR for ER, PR, HER2 assessment in locally HR+/HER2- EBC, there are still a few clinically relevant discordances. Regarding HER2-low status, standardization and quality assurance are needed if this becomes clinically relevant. Treatment of the heterogeneous ER-low group as TNBC appears reasonable only if "ER-low" is confirmed by a second assessment and in cases with Ki-67>40%. Preoperative ET response assessment may be helpful if an endocrine-based therapy concept is intended. Clinical trial information: NCT01779206. Research Sponsor: Roche, Exact Sciences.

Adherence to EndoPredict test scores for extended endocrine therapy management in the prospective EndoPredict Extended Endocrine Trial (EXET). *First Author: Adam Brufsky, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: Current guidelines advise that individuals with estrogen receptor-positive (ER+) breast cancer (BC) undergo 5 years of endocrine therapy with consideration of up to 10 years of extended endocrine therapy (EET). The relative benefit of EET beyond 5 years is minimal for many patients, yet a significant group of patients at higher risk of late recurrence may benefit. EndoPredict is a gene expression assay to stratify those with high versus low BC recurrence risk and is validated to predict early and late distant metastasis up to 15 years using an EPclin score. In the prospective EXET study we evaluated adherence to EndoPredict test results when making decisions regarding EET. **Methods:** Patients with prior ER+, human epidermal growth factor 2 negative (HER2-) BC diagnosis and 4-6.5 years of endocrine therapy underwent EndoPredict testing. To evaluate the impact on decision making for EET, chart review was performed at or after test results were clinically disclosed. Univariable analysis was used for EPclin risk classification (high, low), multivariable analysis was used to evaluate the EPclin score with clinical variables and Firth logistic regression was used to assess the association of a given variable with the therapy decision. **Results:** The cohort consisted of 411 patients with an average age of 62 years (range 27, 90), 107 received adjuvant chemotherapy (26%), and 71 were lymph node positive (17.3%). The rate of EET was significantly different for those with low-risk scores (EPclin Score ≤ 3.3) compared to high-risk scores (EPclin Score > 3.3; OR 8.5×10^{-4} [95% CI 6.8×10^{-6}, 6.0×10^{-3}], p-value 5.7×10^{-68}). All patients with high-risk scores received EET. Within the low-risk group, those treated with adjuvant chemotherapy and those who were lymph node positive chose to extend endocrine therapy at higher rates. The EPclin score provided significant information in predicting EET status, even when accounting for clinical variables such as node status, tumor grade, age at diagnosis, adjuvant chemotherapy status and tumor stage (EPclin Score OR 20.2 [10.1, 44.0]; p-value=3.1×10^{-25}). **Conclusions:** Even after adjusting for other clinical factors, EndoPredict is a significant predictor of clinical decision on EET. High adherence to EndoPredict test results in EET decision making was noted in our study. Clinical trial information: NCT04016935. Research Sponsor: Myriad Genetics.

Rate of medical decision to extend endocrine therapy.

	N	EPclin High Risk (95% CI)	EPclin Low Risk (95% CI)	p-value

The real-world experience of adjuvant docetaxel and cyclophosphamide (TC) chemotherapy in HER-2 negative breast cancer. *First Author: Danilo Giffoni M. M. Mata, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Adjuvant chemotherapy in breast cancer (BC) substantially improves overall survival (OS) and the risk of recurrence. The short and long-term side effects of anthracycline, and its modest benefits in the adjuvant setting, led to controversy about its role in comparison with TC. We aim to compare the OS of TC with anthracycline-based regimens in Ontario, the most populous province in Canada. **Methods**: We conducted a retrospective population-based cohort study using the Institute for Clinical Evaluative Sciences (ICES) database, involving females with stage I-III BC HER2-negative. Patients were treated with adjuvant chemotherapy between January 2009 to December 2017. The anthracycline regimens for comparison were as follows, FEC-D: Fluorouracil, Epirubicin, Cyclophosphamide, followed by Docetaxel; and ACT: Doxorubicin, Cyclophosphamide, followed by Docetaxel or Paclitaxel. Exclusion criteria included missing baseline characteristics, a prior history of malignancy or chemotherapy starting more than 120 days from breast surgery. The end of follow-up was March 31st, 2018. Adjusted analyses to compare OS by positive axillary lymph nodes (LN) and chemotherapy regimens were conducted with Cox proportional hazards models. **Results**: Of a total 10634 female patients with BC, 60% were ≥ 50 years-old, with 19.6% stage I, 61.1% stage II, and 19.3% stage III and 7130 (67%) women were classified as ER+ and 2379 (22.4%) as ER-. Among 5764 (54.2%) patients with positive LN, 4300 (40.4%) had LN 1-3 and 1464 (13.8%) had LN ≥ 4. There were 4945 (46.5%) high-grade cases. There were 2487 (23.5%) patients treated with TC, 2981 (28%) with ACT, and 5166 (48.5%) with FEC-D. With a median follow-up of 5.5 years, the OS comparison for the entire study population showed hazard ratio (HR) of TC vs ACT was 1.47 (95% CI 1.14 – 1.90), p = 0.0027 and TC vs FEC-D HR was 1.48 (95% CI 1.18 – 1.86), p = 0.0007. For ER+ patients treated with TC, the OS comparison of LN 1-3 and LN ≥ 4 vs. LN 0 showed HR 1.34 (95% CI 0.81 – 2.21), p = 0.26, and HR 4.29 (95% CI 2.09 – 8.79), p < 0.0001, respectively. For ER+ LN 0 patients, the OS HR of TC vs. ACT was 1.15 (95% CI 0.58 – 2.35), p = 0.67, and TC vs. FEC-D HR was 1.38 (95% CI 0.81 – 2.33), p = 0.23. For ER- patients treated with TC, the OS comparison of LN 1-3 and LN ≥ 4 vs. LN 0 showed HR 1.12 (95% CI 0.42 – 3.01), p = 0.82 and HR 4.41 (95% CI 1.33 – 14.59), p = 0.015, respectively. For ER- LN 0 patients, the OS HR for TC vs. ACT was 2.04 (95% CI 1.09 – 3.81), p = 0.025, and TC vs. FEC-D HR was 2.05 (95% CI 1.08 – 3.90), p = 0.028. **Conclusions**: Patients treated with adjuvant TC who had four or more axillary LN had significantly lower OS when compared to patients with LN 0. For women with ER- disease, TC demonstrated a significant unfavourable survival outcome when compared to anthracycline-based treatments. Research Sponsor: The Department of Breast Cancer of Sunnybrook Health Sciences Centre, Odette Cancer Centre.

Ovarian function suppression is not indispensable in patients with early breast cancer who are older than age 40. *First Author: Jianqiao Xian, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Based on SOFT/TEXT studies, ovarian function suppression (OFS) has become the standard treatment for pre-menopausal breast cancer patients. However, a few studies reported more than 80% pre-menopausal breast cancer patients over 40 years old experienced permanent chemotherapy-induced amenorrhea (CIA) after chemotherapy, suggesting that these patients may not benefit from OFS. The purpose of this study was to evaluate the application value of OFS in early pre-menopausal hormonal receptor (HR)-positive breast cancer patients who experienced chemotherapy after 40 years old. **Methods:** 1386 pre-menopausal patients over 40 years of age with early HR-positive breast cancer underwent chemotherapy from 2010 to 2017 at the Sun Yat-Sen University Cancer Center. Serum hormone levels were used to define pre-menopausal status. OFS only referred to gonadotropin-releasing hormone agonist (GnRHa). Propensity score matching (PSM) was performed to reduce the selection bias between patients administrated with OFS and those without OFS. The prognostic value of OFS was determined using Kaplan-Meier and Cox proportional hazards analysis. **Results:** A total of 1386 patients (median age, 46 years; rang, 40-55 years) were enrolled in this study, 258 patients were treated with OFS and 1128 patients did not receive OFS treatment. After PSM, there were 258 patients allocated in Non-OFS group and 258 patients in OFS group. There had no statistically significant difference in terms of overall survival (OS) (p=0.5) and disease-free survival (DFS) (p=0.62) between Non-OFS group and OFS group. In Non-OFS group, 100 patients (8.86%) resumed menstruation after chemotherapy, and 1028 patients (91.14%) experienced permanent CIA. There also had no statistically significant difference in either OS (p=0.35) or DFS (p=0.79) between menstrual recovery group and permanent CIA group. In terms of the menstrual recovery duration time of the 100 patients who resumed menstruation, 37 patients (37%) were ≤ 6 months, 18 patients (18%) were 7 ~ 12 months, and 45 patients (45%) were > 12 months. In terms of the intervals from last time of chemotherapy to the beginning of menstrual recovery, 29 patients (29%) were ≤ 6 months, 16 patients (16%) were 7 ~ 12 months, and 55 patients (55%) were > 12 months. Finally, we analyzed the survival difference of different menstrual recovery durations and different intervals. We found that there still had no statistically significant difference in different recovery durations (OS, p=0.15; DFS, p=0.19) and different intervals (OS, p=0.11; DFS, p=0.24). **Conclusions:** In this study, early pre-menopausal HR-positive breast cancer patients who experienced chemotherapy after 40 years old did not benefit from OFS treatment in DFS and OS. These results suggest that OFS is not indispensable in early HR-positive breast cancer patients aged over 40 years. Research Sponsor: The National Natural Science Foundation of China (82172722).

540 **Poster Session**

Adjuvant chemotherapy is associated with an overall survival benefit regardless of age in patients with ER+/HER2-breast cancer with 1-3 positive nodes and Oncotype DX recurrence score 20 to 25: A National Cancer Database analysis. *First Author: Lifen Cao, University Hospitals at Cleveland Medical Center, Cleveland, OH*

Background: Based on the results of the RxPonder trial, post-menopausal women over age 50 with estrogen receptor (ER)+ breast cancer, 1-3+ nodes, and a 21-gene Oncotype DX recurrence score (RS) score of <25, did not benefit from receiving adjuvant chemotherapy. By contrast, adjuvant chemotherapy was beneficial in premenopausal women. We aimed to replicate the RxPonder trial using a larger sample sizes with real world data to determine whether a threshold with RS exists where adjuvant chemoendocrine therapy (CET) is beneficial regardless of age. **Methods:** The National Cancer Database (NCDB) was queried for women with ER+, human epidermal growth factor receptor 2 (HER2) negative breast cancer, 1-3 positive axillary nodes, and RS <25 who received endocrine therapy (ET) only or CET. Interaction was explored between CET and age as a surrogate for menopausal status in the Cox regression models. **Results:** The final analytic cohort included 28,427 eligible women: 7,487 (26.3%) received adjuvant CET and 20,940 (73.7%) ET. In the entire cohort, RS had a normal distribution, with a median score of 14. After correcting for demographic and clinical variables, a threshold effect was observed with RS >20 being associated with a significantly inferior overall survival (OS) (P value range: < 0.001-0.019). In women with RS of 20-25, CET was associated with a significant improvement in OS compared to ET alone, regardless of age (age < = 50: HR = 0.334, P = 0.002; age > 50: HR = 0.521, P = 0.019). **Conclusions:** Among women with ER+/HER2- breast cancer with 1–3 positive nodes, and RS of 20-25, in contrast to the RxPonder trial we observed that CET was associated with an OS benefit in women regardless of age. Predictive value of ectopic *HORMAD1* tumor expression for high-dose platinum-based chemotherapy benefit in patients with high-risk HER2-negative breast cancer. *First Author: Leonora Wijnandina De Boo, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: The meiotic DNA break regulator *HORMAD1* is aberrantly expressed in many cancers and is associated with increased genomic instability. The susceptibility of *HORMAD1* expressing tumors to agents targeting DNA damage repair (DDR) pathways is poorly understood since clinical data within the context of a randomized clinical trial (RCT) is lacking. Here, we retrospectively studied *HORMAD1* expression as a putative predictive biomarker in an RCT for benefit of adjuvant high-dose platinum-based chemotherapy (HDCT) with autologous stem cell support in patients with high-risk HER2-negative early breast cancer (BC). **Methods:** Patients with stage III BC participated in an RCT comparing HDCT to conventional chemotherapy (CDCT; Rodenhuis et all, NEJM, 2003; Steenbruggen et all, JAMA Oncol, 2020). We studied the subgroup with HER2-negative BC for whom tumor *BRCA1*-like classification was previously determined using a validated DNA comparative genomic hybridization algorithm (Vollebergh et all, BCR, 2014). Tumor *HORMAD1* expression was determined on FFPE samples using RNAscope, an RNA in situ hybridization method, and classified as negative (no expression) or positive (any expression detected). **Results:** For 195/246 (79.3%) HER2-negative patients treated according to protocol, *HORMAD1* RNAscope status was available; dropout was due to absence or insufficient quality of tumor specimens. *HORMAD1* positivity was enriched in triple-negative breast cancer (TNBC) (23/47; 48.9%). Furthermore, in all HER2-negative BCs, *HORMAD1* positivity (45/195; 23.1%) was associated with age ≤40 years, histological grade III, <10 positive lymph nodes, breast-conserving surgery, *BRCA1*-like profile, and tumor-infiltrating lymphocytes (TILs) >10%. Such association, although not significant, was also observed within TNBC. During a median follow-up of 20.3 years, 124 (63.6%) recurrences and 115 deaths (59.0%) occurred. The prognostic effect of *HORMAD1* positivity on overall survival (OS) varied with follow-up time and was borderline significant at 10 years and significant thereafter (10-year: adjusted (adj.) HR 0.47, 95% CI 0.21-1.04; 15-year: adj. HR 0.25, 95% CI 0.07-0.91). Benefit on RFS from HDCT over CDCT was stronger in patients with *HORMAD1*-positive tumors (adj. HR 0.18, 95% CI 0.06-0.54) than in patients with *HORMAD1*-negative tumors (adj. HR 0.69, 95% CI 0.46-1.02) (P-interaction = 0.02). Similar results were observed for OS. **Conclusions:** In this retrospective sub study of 195 patients with high-risk HER2-negative BC participating in an RCT, tumor *HORMAD1* expression is predictive for benefit of high-dose platinum-based chemotherapy. Our observations are consistent with the prior observations that *HORMAD1* expression is associated with genomic instability and impaired DDR pathways. Further research is warranted to validate our findings. Clinical trial information: NCT03087409. Research Sponsor: A Sister's Hope.

Adherence to adjuvant endocrine therapy assessed by data from prescription renewals and medical records from tamoxifen in Swedish patients with cytochrome P450 2D6 (CYP2D6) genotyped early breast cancer. *First Author: Linda Thoren, Department of Clinical Science and Education at Sodersjukhuset, Karolinska Institutet, Department of Oncology, Sodersjukhuset, Stockholm, Sweden*

Background: Suboptimal adherence to adjuvant endocrine treatment (AET) is an important clinical concern. A correlation between CYP2D6 activity and tamoxifen discontinuation has been suggested. The main aim of this study was to investigate the consistency between prescription refill data and reports from medical records on adherence to AET in early breast cancer. We also studied if there was an association between menopausal status, CYP2D6 activity, estimated risk for recurrence and adherence to AET. **Methods:** 1235 pre-and postmenopausal Swedish breast cancer patients operated 2006 – 2014, genotyped for CYP2D6, who initiated adjuvant tamoxifen treatment, were included in the study. Information on AET was retrospectively collected from both medical records and the Swedish Prescribed Drug Registry. Consistency was defined as dispensed doses of AET divided by AET intake documented in medical records. Adherence was calculated for patients with at least 4.5 years of follow up and was defined as Medical Possession Rate (MPR) ≥ 80 %. Subgroup analyses were performed based on menopausal status, recurrence-risk and CYP2D6 activity. **Results:** In 84% of the patients the consistency of AET between the sources of information was within 80-125%. Consistency < 80% was most frequent in premenopausal/high risk patients and CYP2D6 Poor Metabolizers (PM). Among 899 patients with at least 4.5 years follow up, adherence to tamoxifen was 72% according to prescription refill data, compared to 77% as reported by medical records. When including aromatase inhibitors adherence increased to 82% and 88%. Adherence did not differ by menopausal status or risk for recurrence. CYP2D6 PM had poorer adherence (54%) to tamoxifen compared to patients with the highest CYP2D6 activity (83%). **Conclusions:** Consistency between medical records and dispensing data on adherence was better than anticipated. Adherence to AET was good, 82% when including switch to aromatase inhibitors. Surprisingly, CYP2D6 PMs had low adherence to tamoxifen, despite a reduced risk of side effects according to previous studies. Further work is needed to clarify the impact of CYP2D6 activity on adherence to tamoxifen. Estimating survival benefit of adjuvant chemotherapy in postmenopausal women with pT1-2N0 early-stage breast cancer and Oncotype DX recurrence score > 26: A National Cancer Database (NCDB) analysis. *First Author: Lifen Cao, University Hospitals at Cleveland Medical Center, Cleveland, OH*

Background: Early validation studies using the Oncotype DX recurrence score (RS) in NSABP B20 demonstrated that women with node negative breast cancer and RS >31 had significant survival benefit from the addition of adjuvant chemotherapy to endocrine therapy (CET). Consequently, in the prospective TAILORx trial, node negative women with RS >26 received CET. These studies did not clearly delineate the magnitude of benefit of adjuvant chemotherapy for post-menopausal node negative women. A recently published well-designed adjuvant trial (RxPONDER) demonstrated that adjuvant chemotherapy was not beneficial in post-menopausal pts with ER+/HER2- breast cancer, 1-3 positive nodes, and RS <25. We hypothesized that CET would be associated with a modest but statistically significant overall survival (OS) in women with hormone receptor positive ER+/HER2- node negative breast cancer with RS >26 compared to endocrine therapy (ET) alone, given that CET is more beneficial in women <50 years of age. **Methods:** The National Cancer Database (NCDB) was queried to analyze women age > 50 with ER+/HER2- pT1-2N0M0 breast cancer with RS >26, to assess real world utilization. We separated women into two groups based on adjuvant treatment: ET alone or CET. Chi-square and logistic regression analysis determined difference between different systemic treatment groups. OS was analyzed using a multivariable Cox model. **Results:** A total of 16,745 eligible women who underwent surgery and received ET were identified in the NCDB—4,740 (28.3%) received ET alone and 12,005 (71.7%) received CET. We observed that CET use increased over time. Women were more likely to receive CET if their tumors were moderately differentiated (OR = 1.853, p < 0.001), poorly/undifferentiated tumors (OR = 3.875, p < 0.001), or associated with lymph-vascular invasion (OR = 1.206, p = 0.001). After accounting for demographic and oncologic factors, 5-year OS rates in this cohort were significantly superior in women receiving CET compared to ET alone (95.4% vs 92.0%, Hazard Ratio = 0.680, p < 0.001). **Conclusions:** Utilizing the NCDB to represent real world outcomes, we observed that women > 50 years with pT1-2N0M0 ER+/HER2- breast cancer, and RS > 26 had a significantly superior 5-year OS when receiving adjuvant chemotherapy provides a measurable OS benefit for post-menopausal women in this setting and should be discussed with patients. Comparison of predicted benefit using RS clin versus observed benefit in a U.S. registry of stage I ER-positive HER2-negative high oncotype DX RS breast cancer.

First Author: Christopher David Walden, Gundersen Lutheran Health System Inc., La Crosse, WI

Background: The 21-gene recurrence score assesses the risk of distant breast cancer recurrence and predicts the benefit of adjuvant chemotherapy in ER positive early-stage breast cancer. However, clinicopathologic risk factors continue to impact absolute benefit of adjuvant chemotherapy. Absolute benefit of adjuvant chemotherapy in low clinicopathologic risk Stage I ER positive breast cancer with high Oncotype RS is an important clinical component of shared decision making. The RSClin clinical tool, which integrates the 21-gene recurrence score (RS) and clinicopathologic features, was found to be more prognostic than RS result alone. We assessed RS Clin predicted benefit and compared to absolute benefit in low clinicopathologic risk Stage I ER positive breast cancer with high Oncotype RS as observed in the NCDB. **Methods:** Using the National Cancer Data Base (NCDB), we identified female patients age 18-75, ER positive and Her 2 negative, 21 gene signature high risk > 25 with negatives surgical margins, <2cm, lymph node negative breast cancers, who had received endocrine therapy with either Tam or AI diagnosed during 2010 - 2017. Clinicopathologic factors and RS were entered into the RSClin calculator, and a predicted benefit of chemotherapy was calculated for each patient. Using NCDB data, Cox proportional hazards regression models were used to project absolute survival benefit at 10 years from diagnosis for those who did vs those who did not receive chemotherapy. NCDB-derived absolute benefit of chemotherapy was compared to estimated absolute benefit as predicted by the RSClin tool. **Results:** 18,226 patients were identified. Stages T1a = 670(4%), T1b = 4,289(23%), and T1c = 13,267(73%). Median age 59 years (21-75). Race white 84% (15,365), black 10% (1840), and other 1021(6%). AI use 80% (14,711) was greater than Tam use 20% (3515). Chemotherapy was administered in 75% (13,827) of patients. Most patients had high or intermediate grade disease, G3 45% (8225), G2 46% (8328), and G1 9% (1672). Median duration of follow up was 57 months (2-160). Probability of death T1b at 10yrs with chemotherapy was 8.5%, and without chemotherapy was 15.1% with an absolute benefit of 6.6%. Predicted benefit in T1b using RS Clin at 10yrs was 10.8%. Probability of death for T1c at 10yrs with chemotherapy was 15.1%, and without chemotherapy was 23.5% with an absolute benefit of 8.4%. Predicted benefit in T1c using RS Clin at 10yrs was 14%. **Conclusions:** Patients with stage IB and IC hormone receptor positive HER2 negative breast cancers with high RS had a lower absolute benefit than predicted by RS Clin. The RSClin tool overestimated benefit of therapy in both IB and IC stages requiring caution when using this tool in patients with the lowest clinicopathologic risks. Predictive performance of breast cancer index (BCI) and clinical treatment score post-5 years (CTS5) in the IDEAL study.

First Author: Gerrit-Jan Liefers, Leiden University Medical Center, Leiden, Netherlands

Background: The Breast Cancer Index (BCI) is a gene expression–based signature that stratifies patients based on the risk of overall (0-10y) and late (post-5y) distant recurrence (DR) and predicted the likelihood of benefit from extended endocrine therapy in MA.17, Trans-aTTom, IDEAL, and B-42 trials. The Clinical Treatment Score post-5 years (CTS5) is an algorithm incorporating four clinicopathologic variables (nodes, age, tumor size and grade), which has been shown to be prognostic for late DR. Previous analysis of CTS5 in IDEAL showed that CTS5 was not predictive of extended endocrine therapy benefit. The current analysis compared the predictive performance of BCI (H/I) and CTS5 for the benefit of extended endocrine therapy in the same subset of patients from the IDEAL study. **Methods:** 818 patients from the IDEAL trial who remained recurrence free 2.5y after randomization and had both BCI (H/I) and CTS5 results available were included in this study. The primary endpoint was recurrence-free interval (RFI). Absolute benefit was measured as the difference in 10-year risk of recurrences between the two treatment arms. The likelihood ratio test from Cox regression models was used to test for interaction. **Results:** 818 IDEAL patients (68% ≥50y at surgery; 48% T2; 47% G2; 73% N+) were included in the analysis. CTS5 stratified 167, 346 and 305 patients into Low-, Intermediate-, and High-risk groups. The analysis revealed that no group derived significant benefit with CTS5-Low showing 6.4% absolute benefit (HR = 0.61, 95% CI: 0.20-1.86, P = 0.377), CTS5-Intermediate showing 6.7% absolute benefit (HR = 0.55, 95% CI: 0.27-1.09, P = 0.080), and CTS5-High showing 2.1% absolute benefit (HR = 0.80, 95% CI: 0.42-1.51, P = 0.482). BCI (H/I) stratified 428 and 390 patients into BCI (H/I)-Low and BCI (H/I)-High groups. Only BCI (H/I)-High patients derived a significant absolute benefit of 10.5% (HR = 0.38, 95% CI: 0.18-0.79, P = 0.007), while BCI (H/I)-Low patients did not show any absolute benefit (HR = 0.94, 95% CI: 0.55-1.60, P = 0.817). The treatment by biomarker interaction was significant for BCI (H/I) (P = 0.045), but not for CTS5 (P = 0.731). When re-stratifying CTS5 categories by BCI (H/I) or vice versa, only BCI (H/I)-High patients showed consistent absolute benefit regardless of CTS5 category (19.4%, 8.1% and 8.8% in CTS5-Low, -Intermediate and -High, respectively). In contrast, CTS5-High patients did not show any benefit (-4.4%) in the BCI (H/I)-Low group. **Conclusions:** These results demonstrate that CTS5 does not provide predictive information to support extended endocrine therapy decision-making. Only BCI (H/I) was a predictive biomarker of benefit from extended endocrine therapy. This study further highlights the clinical utility of BCI as an endocrine response biomarker and emphasizes that prognostic information does not equate to predictive information in guiding duration of endocrine therapy. Clinical utility of genomic recurrence risk stratification in early, hormone receptor–positive, human epidermal growth factor receptor 2–negative breast cancer.

First Author: Khalil Choucair, University of Kansas School of Medicine, Wichita, KS

Background: RNA-based genomic assessment of recurrence risk is used to estimate chemotherapy benefit in patients with hormone-receptor positive (HR+)/Human Epidermal Growth Factor 2-negative (*ERBB2*-) breast cancer (BC). While originally validated in patients who met established clinicopathologic guidelines for consideration of adjuvant chemotherapy, it is virtually used in all patients with early HR+/*ERBB2*- BC regardless of clinical recurrence risk. **Methods:** We conducted a retrospective chart review of adult patients with early-stage (T1-3; N0; M0) HR+/*ERBB2*- BC who underwent genomic risk assessment of recurrence using the Oncotype DX (Exact Sciences) 21-genes assay, between January 2015 and December 2020. Clinicopathologic features were collected to assess the clinical recurrence risk. A low clinical risk score (CRS) was defined as a tumor size ≤ 3 cm in diameter with histologic grade 1, or ≤ 2 cm with grade 2 or ≤ 1 cm with grade 3. A composite risk score of distant recurrent (RRS), derived from a COX model using data from the SOFT and TEXT trials (https://rconnect.dfci.harvard.edu/CompositeRiskSTEPP/), was also computed for 374 patients for whom clinical data was available. RRS > 1.42 was defined as high. High genomic risk of recurrence was defined as a score (GRS) ≥25. The data was collected under IRB approval. **Results:** A total of 517 patients with early-stage disease were referred for genomic testing, and clinical data was available for 501 of them. Median age was 69 years (IQR=13), median tumor size 1.03 cm (IQR=0.9), and grade 2 histology (57.49%) was the most common. Results of recurrence risk, using the 3 prognostication methods, are summarized in Table. Within patients with low CRS (n=349), 9.17% had a high GRS, compared to 8.93% in patients with low RRS (n=280). In patients with grade 1 histology (n=130), 3.85% had a high GRS and 68.46% had tumors > 1cm, of whom only 4.49% had a high GRS. Tumor size > 1cm did not associate with a high GRS (Fisher's Exact test; *P=1.00*). **Conclusions:** In patients with early HR+/*ERBB2*- BC, <10% of patients with low clinical risk, and <5% of patients with grade 1 tumors, had a high genomic recurrence risk, respectively. Given current NCCN recommendation for testing, our findings raise the question of whether genomic testing for patients with grade 1 tumors can be safely omitted, irrespective of size, and call for a better understanding of the need for routine genomic testing in patients with low grade/low clinical risk of recurrence. Research Sponsor: None.

Type of endocrine therapy and DFS in patients with early HER2+/HR+ BC: Analysis from the phase III randomized ShortHER trial.

First Author: Maria Vittoria Dieci, University of Padova, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy

Background: Optimal adjuvant endocrine therapy for HER2+/HR+ patients treated with chemotherapy and trastuzumab is still unclear. We evaluated the impact of the type of endocrine therapy on DFS in patients with HER2+/HR+ breast cancer enrolled in the phase III ShortHER trial. **Methods:** The Short-HER study randomized 1254 patients with HER2+ early breast cancer to receive 9 weeks vs 1 year of adjuvant trastuzumab combined with anthracycline-taxane chemotherapy. The type of adjuvant endocrine was collected every 6 months during the first 5 years of follow-up and was classified as: aromatase inhibitor (AI), tamoxifen and aromatase inhibitor (TAM-AI, in case of both drugs were administered for at least 1 year each), or tamoxifen (TAM). For premenopausal patients, the use of GnRH analogue was also collected. DFS was calculated from randomization to disease recurrence (locoregional or metastatic), second primary invasive cancer, or death. **Results:** 853 patients with HR+ BC (ER and/or PgR >10%) were included: 60% postmenopausal, 40% premenopausal. The pattern of endocrine therapy was: 55% AI, 22% TAM, 15% TAM-AI (8% missing data). Among premenopausal patients, 51% received GnRH. At a median follow up of 8.7 years (IQR 7.6-9.0), patients who received AI had a significantly better DFS as compared to patients who received TAM or TAM-AI: 7-yr DFS 87.3% vs 81.7%, log-rank P=0.017 (HR 1.46, 95%CI 1.05-2.03). In multivariate analysis including menopausal status, stage, and treatment arm, the type of endocrine therapy maintained a significant association with DFS (Table). In the subgroup of premenopausal patients, the use of GnRH was associated with numerically improved DFS: 86.6% vs 81.6%, log-rank P=0.168 (HR=0.70, 95%CI 0.43-1.16). **Conclusions:** In this post-hoc analysis of the ShortHER trial, adjuvant treatment with aromatase inhibitor was independently associated with improved DFS. Subgroup analysis in premenopausal patients suggests potential benefit with ovarian suppression. Clinical trial information: NCT00629278. Research Sponsor: ShortHER trial.

Multivariate analysis	HR	95%CI	P
TAM-AI or TAM vs AI	1.56	1.02-2.40	0.042
Stage I	Ref		
Stage II	1.49	1.00-2.22	0.051
Stage III	4.54	1.80-4.42	<0.001
Postmenopausal vs premenopausal	1.11	0.72-1.71	0.630
Short vs long treatment arm	1.10	0.79-1.54	0.564

Molecular diagnostics to reduce inequity in breast cancer diagnosis. *First Author: Clement Adebayo Adebamowo, Department of Epidemiology and Public Health and Greenebaum Comprehensive Cancer Center, University of Maryland School of Medicine, Baltimore, MD*

Background: Modern management of breast cancer requires proper subtyping of the breast tumor to guide appropriate treatment and prognostication. However, there are barriers to availability of this resource in low- and middle-income countries (LMIC) which contributes to global inequalities in breast cancer management and outcomes. The non-availability is due to high cost, and lack of personnel and infrastructure required for immunohistochemistry (IHC), the current gold standard for subtyping. IHC results are affected by pre-analytic and analytic handling and are subjective. Alternative methods that are more objective, cost less and require less infrastructure and skilled personnel will improve access and reduce disparities. **Methods:** In the AFBRECANE Project, we compared the results of ER and PR subtyping of 1,000 breast cancer tumors from patients recruited from 5 clinical sites in Nigeria using IHC and Cepheid GeneXpert RNA STRAT4 biomarker assay at ACCME Lab in Nigeria and University of Maryland. **Results:** For ER, the sensitivities, specificities, and agreement between IHC and STRAT4 ranged from 50.0%, 71.4% and 59.4% to 77.1%, 80.0% and 78.5% while for PR, they ranged from 58.1%, 66.7% and 62.5% to 84.6%, 84.2% and 84.4%. **Conclusions:** The wide range of sensitivities, specificities, and agreement between IHC and STRAT4 in this study confirms the challenges of molecular subtyping of breast cancer in LMICs like Nigeria. Sustainable objective methods are sorely needed to improve diagnosis, treatment and prognostication, and reduce global disparities. Establishment of a novel BRCAness score that predicts response to PARP inhibitors. *First Author: Masanori Oshi, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: BRCAness is a generic term used to describe characteristic features of homologous recombination deficiency (HRD) mimicking mutations in BRCA genes. Although clinical genetic testing has increased the detection of mutations in BRCA1 and BRCA2, we hypothesized that a measure to quantify BRCAness will identify the responders to PARP inhibitors that cause synthetic lethality in BRCA mutation tumors. **Methods:** The BRCAness score was established by using gene set variation analysis (GSVA) algorithm on 34 BRCA-mutation related genes. We investigated the clinical relevance of the score by performing silico analyses of 6245 breast cancer patients using multiple independent large cohorts in this study. **Results:** A score to quantify BRCAness was generated using gene set variation analysis algorithm on 34 BRCA1-mutation related genes selected by high AUC levels in ROC curve between BRCA1 mutation and wildtype breast cancer. The score was significantly associated with BRCA1 mutation, high overall mutation load and intratumoral heterogeneity as well as high HRD, DNA repair and MKI67 expression regardless of mutation in BRCA gene. High score tumor enriched not only DNA repair, but also five cell proliferation-related gene sets (E2F targets, G2M checkpoint, MYC targets v1 and v2, and MITOTIC signaling) in Hallmark collection (all false discovery rate < 0.10). Breast cancers with high score were significantly associated with higher infiltration of anti-cancerous immune cells and higher cytolytic activity. Not all breast cancer cell lines with BRCA-mutation showed high score and the other cells in human breast cancer tumor microenvironment were contributing to the score. We found that the BRCAness score was the highest in triple-negative among subtypes consistently in all cohorts (all $p < 0.001$). Finally, BRCAness was associated with response to chemotherapy and correlated strongly with response to PARP inhibitor in both triple-negative (AUC = 0.815) and ER-positive/HER2-negative breast cancer (AUC = 0.715). **Conclusions:** We established a novel BRCAness score using mRNA expression of BRCA-mutation-related genes and found that it associates with DNA repair and response to PARP inhibitor regardless of BRCA mutation. Research Sponsor: U.S. National Institutes of Health.

Predominance of BRCA2 mutation and estrogen receptor-positive breast cancer among BRCA1/2 mutation carriers. *First Author: Pascal Pujol, CREEC, UMR IRD 224-CNRS 5290 Université Montpellier, Montpellier, France*

Background: PARP inhibitor (PARPi) agents can improve progression-free survival of patients with breast cancer (BC) who carry a germline *BRCA1* or *BRCA2* pathogenic or likely pathogenic variant (gBRCA1/2) in both the metastatic and adjuvant setting. Therefore, we need to redefine the criteria of women and tumor phenotype that should be tested for gBRCA1/2. **Methods:** We studied the relative distribution of gBRCA1 and gBRCA2 in unselected populations of women with BC and in unaffected individuals. We also analyzed the proportion of estrogen receptor (ER)-positive (ER+) tumors in unselected BC patients with gBRCA1/2.We performed a meta-analysis of studies of unselected BC that analyzed the relative contribution of gBRCA1 versus gBRCA2 and ER+ tumors among gBRCA1/2 carriers. We then performed a meta-analysis of gBRCA1/2 carriage in unaffected individuals, from genome-wide population studies, the gnomAD databank, and case–control studies. **Results:** The *BRCA2* gene was involved in 54% of BC in unselected patients with gBRCA1/2 (n=108,699) and 59% of unaffected individuals (n=238,973) as compared with 38% of gBRCA1/2 family cohorts (n=29,700). The meta-analysis showed that 1.66% (95% CI 1.08-2.54) and 1.71% (95% CI 1.33-2.2) of unselected BC patients carried a gBRCA1 and gBRCA2, respectively. In unaffected individuals, the frequency of heterozygosity for gBRCA1 and gBRCA2 was estimated at 1/434 and 1/288, respectively. Nearly 0.5% of unaffected individuals in the studied populations carried a gBRCA1/2. Carriage of a gBRCA was 2.5% for patients with ER+ tumors (95% CI 1.5-4.1) and 5.7% (95% CI 5.1-6.2) for those with ER- tumors. Overall, 58% of breast tumors occurring in women carrying a gBRCA1/2 were ER+ (n=86,870). **Conclusions:** This meta-analysis showed that gBRCA2 carriage is predominant in unselected BC and in unaffected individuals. ER+ tumors among women with gBRCA1/2-related BC is predominant and has been underestimated. Because PARPi agents improve progression-free survival with ER+ gBRCA1/2 BC in both the adjuvant and metastatic setting, BC should be considered regardless of ER status for BRCA1/2 screening for therapeutic purposes. Research Sponsor: None.

Low baseline vitamin D levels correlate with adverse pathological features and clinical outcomes among patients with breast cancer. *First Author: Dina Barakat, Faculty of Medicine, Assiut University, Egypt, Assiut, Egypt*

Background: Serum vitamin D levels have been linked to breast cancer development; however, the impact on breast cancer features and outcomes remains unclear. The present study aimed at investigating the prognostic value of baseline vitamin D level among non-metastatic breast cancer patients. **Methods:** In this study; we prospectively assessed female patients presenting to our department with non-metastatic breast cancer during the period from October 2018 to December 2019 for their baseline serum vitamin D levels measured by ELISA test before starting systemic therapy, in addition to other clinicopathological factors. Low Vit-D was defined as Vit-D level less than 30 ng /l. Chi-square test (Fisher's exact test) was used to examine the relation between qualitative variables. Survival analysis was done using Kaplan-Meier method and comparison between two survival curves was done using log-rank test. Multivariate analysis was done using Cox-regression hazard model for the significant factors affecting survival on univariate analysis. **Results:** We enrolled 221 patients with non-metastatic breast cancer as they matched our eligibility criteria. Median age at diagnosis was (50.7± 10.9). About two thirds of the patients (64.7%) were post menopause. Median vitamin D level was (23.1 ng/l) with a range of (4-62.46 ng/liter). Around half of the patients (56.5%) had vitamin D level lower than 30 ng/liter, with higher numbers of low vitamin D levels among HER2 positive and triple negative (TNBC) patients compared to hormonal receptor positive (HR+ve) patients (P=<0.001). There was a significant negative correlation between vitamin D levels and tumor size, lymph node positivity and stage at diagnosis (the lower the vitamin D level, the larger the tumor size, and the higher the number of positive lymph nodes and the stage; r= -0.414, r= -0.586, r= -0.674; respectively; p<0.001). On follow up, the number of local recurrences, bone metastases and liver metastases were significantly higher among the low vitamin D level group, however; there was no significant difference between the two groups in terms of development of brain and lung metastases. Disease free survival (DFS) and overall survival (OS) was significantly worse among the low vitamin D level group (p<0.001). **Conclusions:** Low serum vitamin D in breast cancer patients negatively correlates with tumor size, lymph node positivity and stage at diagnosis. It is linked to HER-2 positive and TNBC, and is significantly associated with worse DFS and OS. Research Sponsor: None.

Correlation of Ki67 working group prognostic risk categories with oncotype DX recurrence score (RS) in early breast cancer (EBC). *First Author: Rima Patel, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: The 21-gene RS (Oncotype DX) provides prognostic information for distant recurrence risk and is predictive of adjuvant chemotherapy benefit in hormone receptor (HR)-positive, HER-2 negative EBC. Ki67 protein expression is a proliferation marker that is determined by immunohistochemistry (IHC). The International Ki67 Working Group (IKWG) has provided guidelines for clinical use of Ki67 for prognostic classification (PMID: 33369635). The objectives of this study were to determine the correlation between IHC-measured Ki67 with the 21-gene RS, and evaluate their association with other anatomic and biologic tumor features. **Methods:** We performed a retrospective chart review of women with HR-positive, HER-2 negative EBC with 0-3 positive lymph nodes who had both Ki67 (via IHC using MIB-1 antibody on surgical specimen at our institutional pathology CLIA laboratory) and 21-gene RS between 2013 to 2021. Patients were categorized into Ki67 low (≤ 5%), intermediate (6-29%), and high (≥30%) based on IKWG recommendations. Overall and risk stratified agreement between Ki67 and RS were assessed using the proportion of agreement and Kappa statistic. Linear regression was used to test for associations between tumor features of ER%, PR%, and tumor size and log transformed Ki67 and RS. A t-test was used to compare average log transformed Ki67 and RS by tumor differentiation and nodal status. **Results:** We identified 461 patients with HR-positive BC of whom 26.7% were ≤ 50 years at diagnosis, 30% pre-menopausal and 10% node-positive. Overall, 29% (n = 137) of patients had low Ki67, 49% (n = 227) intermediate, and 21% (n = 97) high Ki67. 18% (n = 85) had RS 0-10, 67% (n = 311) had RS 11-25 and 14% (n = 65) had RS ≥ 26. There was no significant agreement (kappa < 0) between Ki67 and RS (Kappa = -0.0035, p = 0.5406) in the overall population and fair agreement (kappa 0.21-0.40) between high Ki67 and RS (Kappa = 0.2510, p < 0.0001). Higher ER% was significantly associated with lower RS (p < 0.0001) and lower Ki67 (p = 0.0042). High tumor grade was associated with higher RS and higher Ki67 (p < 0.0001). Higher PR% was associated with lower RS (p > 0.0001) but not lower Ki67. Positive nodal status and larger tumor size were associated with higher Ki67 (p = 0.0081, p < 0.0001) but not RS. Among the 49% of patients with intermediate Ki67 of 6-29%, the distribution of low, intermediate, and high RS was 24%, 65%, and 11%, respectively. **Conclusions:** In this group of patients selected to have a 21-gene RS, there was no correlation between Ki67 and RS in the overall population, and fair agreement between high Ki67 and high RS. Among the approximately one-half with an intermediate Ki67 of 6-29%, 89% would be spared chemotherapy based on a low-intermediate RS. In patients with high Ki67, 68% might be spared chemotherapy based on the RS. In the low Ki67 group, 6% had a high RS. Ki67 has limited utility in identifying patients with high or low RS. Detection of early-stage breast cancer in women by plasma lipidomic profiling. *First Author: Cheka Kehelpannala, BCAL Dx, Sydney, NSW, Australia*

Background: Early detection of breast cancer provides the best opportunity for cure. Mammography is the benchmark for screening, but suffers technical, logistic, and diagnostic limitations. An effective and accurate blood test to detect early stages of the disease should increase the screening detection rate for breast cancer. We conducted a series of lipidomic studies in early-stage breast cancer patients and combined the datasets via a machine learning driven analysis to test if plasma lipidomic profiles can detect breast cancer. **Methods:** Blood samples were collected from women with stage 0-IV breast cancer (4 separate cohorts) with age and BMI matched breast cancer-free controls. Lipids from plasma enriched extracellular vesicles were extracted and analysed by high resolution accurate mass LC-MS. A commercially available software was used to annotate and quantify >400 manually curated lipid species. Following variable selection, a lipid signature was identified capable of distinguishing breast cancer samples from control. **Results:** Plasma samples from women with breast cancer were distinguished from controls with an average cross-validated accuracy of 0.81, and average AUC of 0.84 across 4 cohorts (Table 1). An optimised cross-cohort subset of early-stage IDC, DCIS and ILC were differentiated from controls with a cross-validated AUC of 0.90, sensitivity of 0.88 and specificity of 0.82 (201 early-stage breast cancer, 199 controls) (Table 1). For this optimised cohort our test achieved a sensitivity of 0.71 at a prescribed specificity of 0.90, or equivalently a sensitivity of 0.89 at a prescribed specificity of 0.80. **Conclusions:** Our study demonstrates the high sensitivity and specificity of a lipid biomarker signature with potential for early detection of breast cancer. Ongoing studies will prospectively compare the lipid-biomarker based test against mammographic and pathological diagnosis. Research Sponsor: BCAL Diagnostics.

Risk of contralateral breast and other cancers in patients with invasive lobular breast cancer. *First Author: Grace Mei Yee Choong, Mayo Clinic, Rochester, MN*

Background: Women with early-stage breast cancer (BCa) are living longer, and survivorship issues including second primary cancers (SPCs) are therefore increasingly important. This study seeks to determine the risk of SPCs, including contralateral breast cancer (CBCa), in women with early-stage invasive lobular carcinoma (ILC). **Methods:** The study population consisted of women with BCa diagnosis between 2000-2018 within the NCI Surveillance, Epidemiology, and End Results (SEER v 3.2.9) registry and between 2000-2021 in the Mayo Clinic Cancer Registry. In the SEER registry, the standardized incidence ratios (SIR) for SPCs were estimated for adult women with histologically confirmed early stage (I-III) ILC compared to the development of any primary cancer in the general population. For reference, SIRs for SPCs for a similar patient population with invasive ductal carcinoma (IDC) of the breast were also estimated. For comparison of CBCa between ILC and IDC, follow up records from the Mayo Clinic Cancer Registry were evaluated among adult women who underwent lumpectomy or unilateral mastectomy for early stage ILC or IDC. A multivariable Cox proportional hazards regression was performed to compare the risk of CBCa between ILC and IDC while adjusting for the age at diagnosis, race/ethnicity and estrogen receptor status of the primary tumor. **Results:** An increased incidence (p<0.05) of any SPCs and second BCa was noted for both ILC and IDC compared to the expected rate of primary cancer in the general population (Table). Interestingly, women with ILC were observed to have a significantly increased incidence of subsequent gastric cancer which was not seen for women with IDC. An SIR >1.5 was noted for subsequent risk of sarcoma, myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML) for both ILC and IDC (Table). In the Mayo Clinic Cancer Registry of 2,218 women with ILC and 14,629 women with IDC meeting the inclusion criteria, the 5-year risk of CBCa was 2.6% and 1.5% (log rank statistic p-value =0.001) for ILC and IDC respectively. A significantly increased risk of CBCa was noted in women with ILC (Hazard Ratio 1.82, 95% CI 1.34-2.47, p<0.001) compared to women with IDC in the multivariable analysis. **Conclusions:** Women with ILC may have an increased risk of SPC and second BCa compared to the risk of any primary cancer in the general population. The increased incidence of gastric cancer and the higher risk of CBCa in ILC survivors compared to women with IDC is intriguing and needs to be investigated further including evaluation of the role of germline genetic factors. Research Sponsor: Mayo Clinic Breast Cancer Spore.

Whole transcriptome analysis of tumors with discordant oncotype and MammaPrint results in the FLEX trial. *First Author: Matei P. Socoteanu, Texas Oncology-Longview Cancer Center, US Oncology, Longview, TX*

Background: Genomic tests, such as MammaPrint (MP) and Oncotype DX Breast Recurrence Score (RS), assess risk of recurrence in patients with early breast cancer (EBC). Using both assays may yield discordant results which leads to uncertainty in treatment recommendations. The assays differ in technology and genes analyzed. RS relies on RT-PCR to query 16 cancer-related genes and 5 controls. MP uses a microarray to query 70 cancer-related genes and 465 normalization controls. Here we explore the genetic basis for discordance by using the FLEX whole transcriptome database to examine differentially expressed genes among patients who received discordant RS and MP results. **Methods:** Patients with EBC enrolled in the FLEX study (NCT03053193) undergo standard of care MP and BluePrint (BP) tests, and consent to clinically annotated whole transcriptome data collection. MP stratifies risk of recurrence as Low risk and High. RS classifies patients as Low Risk (RS 0-10), Intermediate (RS 11-25), and High Risk (RS 26-100). Due to low representation of BP Basal and BP HER2-type tumors in this data set, we only examined BP Luminal-type tumors (N = 705). We used full genome transcriptomes to compare gene expression among discordant cases. Gene expression data were quantile normalized and analyzed using R package 'limma'. Genes were considered differentially expressed at a fold change of at least 1.7 and an adjusted p-value of lower than 0.05. To keep the analysis as unbiased as possible, comparisons between RS categories only included tumors within the same MP score range and similarly comparisons of MP categories only contained tumors within the same RS score range. **Results:** The comparisons between discordant cases, their numbers and the amount of differentially expressed genes (DEGs) are shown below. Sample sizes are shown in parentheses. Of the 49 DEGs found in the RS Intermediate group, several are associated with increased proliferation or increased metastatic potential. SCUBE2 and MMP9 were among the 49 genes and are among the 70-genes assayed by MP. **Conclusions:** The comparisons highlight the genomic diversity of the RS Intermediate (RS11-25) group, as seen with the high number of DEGs. MP separates cases into more genomically distinct categories, as reflected by fewer DEGs. Clinical trial information: NCT03053193. Research Sponsor: Agendia.

RS Intermediate (458)	MP High (213) vs MP Low (245)	49 DEGs
MP High (297)	RS High (85) vs RS Intermediate (212)	7 DEGs
MP Low (354)	RS Intermediate (245) vs RS Low (109)	12 DEGs

A breast cancer (BC) risk model incorporating Tyrer-Cuzick version 8 (TCv8) and a polygenic risk score (PRS) for diverse ancestries. *First Author: Elisha Hughes, Myriad Genetics, Inc., Salt Lake City, UT*

Background: BC risk assessment is important for guiding personalized screening and risk-reducing interventions. TCv8 is used to estimate BC risk based on age, breast density, family cancer history and other clinical factors. Accuracy may be improved by combining TCv8 with a PRS. We developed and validated a PRS for diverse ancestries based on 149 common genetic variants (PRS-149) comprised of 56 ancestry-informative and 93 BC-associated variants. Here, we describe a BC risk model that combines PRS-149 with TCv8. **Methods:** Subjects had multigene panel testing for hereditary cancer and were negative for pathogenic variants in known BC susceptibility genes. A combined risk score (CRS), incorporating PRS-149 and TCv8, was developed based on 189,230 women, including 43,444 (23%) with a history of BC. Breast Imaging Reporting and Data System (BI-RADS) breast density measurements were available for 12,363 women. We used multivariable logistic regression to test breast density and PRS-149 for association with risk of BC. An independent test cohort of 6,030 BC-unaffected women with BI-RADS assessment was used to evaluate the effect of PRS-149 on risk stratification. Relative contributions of family history, breast density, other clinical factors in TCv8 and PRS-149 were examined by adding terms sequentially to an ANOVA model. We compared differences in classification of women as high (20%) or low/moderate (20%) remaining lifetime risk according to TCv8 versus CRS. **Results:** In the development cohort, increased breast density was significantly associated with higher risk of BC ($p=3.0x10^{-6}$) with an effect size consistent with TCv8. PRS-149 improved BC risk prediction over age, breast density and family history (OR per unit standard deviation: 1.41, 95% CI: 1.37 – 1.46; p: $1.8x10^{-105}$). PRS-149 was weakly but significantly correlated with both family history (r=0.09) and breast density (r=0.01). After adjusting for multiple testing, no other factors were correlated with PRS-149. In the independent test cohort, PRS-149 explained 27% of CRS variability after accounting for family history, breast density and other clinical factors. Adding PRS-149 to TCv8 significantly altered risk estimates, with 16.3% (983/6,030) of patients classified differently by CRS versus TCv8. By TCv8 alone, 38.0% (2,289/6,030) of patients were classified as high-risk. Among patients who were high-risk by TCv8, 25.2% (576/2,289) were downgraded by CRS. **Conclusions:** This is the first BC risk model that includes breast density, family history, and a PRS based on genetically determined ancestry that is validated for diverse populations. Addition of PRS-149 improved risk prediction and substantially modified risk stratification compared to TCv8 alone. Implementation of CRS may therefore lead to improved identification of women who are likely to benefit from increased surveillance and preventive medications. Research Sponsor: Myriad Genetics, Inc.

Real-world clinical outcomes in patients with local/regional HER2-low breast cancer: An NCDB analysis. *First Author: Changchuan Jiang, Roswell Park Cancer Center, Buffalo, NY*

Background: The development of novel anti-HER2 drugs opens new treatment options, including women with lower expression of HER2. This study aimed to compare local/regional HER2-low and HER2-0 breast cancer outcomes in the real world. **Methods:** Women diagnosed between 2010 and 2017 with clinical stage I-III breast cancers with low HER2 expression or HER2-zero (0) expression were identified in the National Cancer Database (NCDB), a nationwide oncology outcomes database in the United States. HER2-Low was defined as IHC1+ or 2+/ISH negative, whereas HER2-zero was IHC-0. The primary outcome was overall survival (OS). We performed a multivariable Cox regression model to estimate hazard ratios and adjusted for the following factors: age, race/ethnicity, education, insurance, comorbidities, grade, stage, lymph nodes, type of surgery, the type of cancer center, and if any chemotherapy, any hormonal therapy, and any adjuvant radiation in the first treatment course. Stratification factors were hormone receptor status. Subgroup analyses for those who received neoadjuvant (NAC), adjuvant (AC), and no chemotherapy were performed, and the pathologic complete response (pCR) rates in NAC groups were estimated. **Results:** 376,199 (68%) women with HER2-low tumors and 177,298 (32%) with HER2-0 tumors were analyzed. 336,147 (89%) of the HER2-low tumors and 141,528 (79%) of the HER2-0 tumors were HR-positive. Low HER2 expression was associated with longer OS in both HR-positive (adjusted Hazard Ratio (aHR): 0.94, 95%CI 0.93-0.96, p<0.001) and HR-negative diseases (aHR: 0.88, 95%CI 0.85-0.91, p<0.001). HR-positive, HER2-low tumors had statistically significantly better survival than HR-positive, HER2-0 tumors in NAC (aHR 0.84, 95%CI 0.79-0.90, p<0.001) and AC (aHR 0.90, 95%CI 0.85-0.94, p<0.001) groups, but not in the no-chemo group (aHR 1.02, 95%CI 1.00-1.05, p=0.09, p interaction<0.001). In contrast, HR negative, HER2-low tumors had better OS than HR negative, HER2-0 tumors in all subgroups, regardless of receipt or timing of chemotherapy (NAC aHR 0.88, 95%CI 0.83-0.94, p<0.001, AC aHR 0.86, 95%CI 0.81-0.92, p<0.001, No chemo aHR 0.93, 95%CI 0.87-0.99, p=0.03, p interaction=0.06). In NAC groups, HER2-low expression was linked to lower pCR rates in both HR-positive (8.9% vs. 11.2%, p<0.001) and HR-negative (31.2% vs. 34.1%, p<0.001). **Conclusions:** Local/regional HER2-low breast cancer has better survival than HER2-0 breast cancer, irrespective of its hormone receptor status. The survival advantage was observed in HR-negative disease and only with receipt of chemotherapy in HR-positive breast cancer. Specific therapies, such as trastuzumab deruxtecan, have activity in HER2-low breast cancers, and other therapeutics for HER-2 low diseases should be sought. Research Sponsor: None.

Investigation of a genomic signature for transcription factor MAF gene amplification and lack of bisphosphonate benefit in early breast cancer. *First Author: Azadeh Nasrazadani, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: MAF amplification has been associated with increased bone metastases in breast cancer (BC). On the contrary, patients without MAF amplification in the primary tumor are more likely to benefit from adjuvant bisphosphonates as shown in a retrospective analysis of the AZURE trial and confirmed with a subset of NSABP-B34 specimens. A genomic signature could identify patients that lack MAF amplification as candidates for adjuvant bisphosphonates. Here we investigated the genes that could predict MAF amplification status. As MAF amplification is associated with high risk of bone metastases, 70-gene risk of distant recurrence signature (MammaPrint/MP) and 80-gene molecular subtyping signature (BluePrint/BP) were used to stratify the patient groups. **Methods:** A total of 166 BC patients from the UPMC were included in this pilot cohort. Fluorescence in situ hybridization was performed to detect MAF copy number. Signal-to-nucleus ratio (SNR) of ≥2.5 was used as the MAF-amplified (MAF+) cut-off. Differential gene expression analysis was performed with R limma using whole genome microarray data. MAF+ and MAF- (SNR<2.5) were compared within all patients and within patients matched by MP/BP to balance high risk groups. Differentially expressed genes (DEGs) were defined as absolute fold change ≥2 and adjusted p-value <0.05. Prediction of MAF amplification based on gene expression was performed using a correlation-based metric with training set, as well as with 1179 stage I-III BC patients from the FLEX Study (NCT03053193), which includes MP/BP testing and whole transcriptome data collection. **Results:** Of the 166 patients, 12% were MAF+ and 88% were MAF-. Among the MAF+ patients, 95% were MP High Risk, as expected from the association of MAF amplification and bone metastasis, as opposed to 29% of MAF- patients. Notably, there was no significant correlation between amplification and gene expression of MAF, which emphasizes the importance of utilizing other genes to predict MAF amplification. Comparing whole transcriptome of MAF+ and MAF- patients, 48 DEGs were found. From the MP/BP matched comparisons, genes ≥2-fold change were included in the final set of 57 genes, where C-X-C motif chemokine ligand and S100 calcium binding protein encoding genes were enriched. The 57-gene classifier of MAF status yielded 92% accuracy, 94% specificity, and 75% sensitivity on the training set. Interestingly, when the classifier was applied on the FLEX cohort, 12% MAF+ cases were identified, similar to the training set. **Conclusions:** Whole transcriptome analysis showed that BC tumors with MAF amplification are transcriptionally different than those without. Here we provide a set of 57 genes that could potentially predict MAF amplification status. Future work will expand the dataset and further explore the predictive value of such genomic signature in response to bisphosphonates. Clinical trial information: NCT03053193. Research Sponsor: University of Pittsburgh support, Pharmaceutical/Biotech Company.

Clinical implications for patients with discordant oncotype and MammaPrint results. *First Author: Matei P. Socoteanu, Texas Oncology-Longview Cancer Center, US Oncology, Longview, TX*

Background: Genomic tests provide critical information regarding risk of recurrence and inform treatment plans by identifying those patients who may safely forgo chemotherapy (CT) or shorten endocrine therapy (ET) duration. The IMPACT trial demonstrated that the 70 -gene risk of recurrence assay MammaPrint (MP) and 80-gene subtyping assay BluePrint (BP) inform treatment planning and increase physician confidence. However, not all genomic tests yield the same results. To examine consistency among genomic tests, we analyzed therapy implications for patients who received results from both MP/BP and Recurrence Score (RS). **Methods:** Using the FLEX cohort (NCT03053193), we examined 723 patients who received both MP/BP, and RS genomic assays. We assessed the potential clinical impact by examining the standardized reports of RS and MP/BP results. MP classified tumors as either ultralow, low, or high risk and BP further classified them as luminal, basal, or HER2. RS classified tumors as low (RS0-10), intermediate (RS11-25), or high (RS26-100). Clinical impact was defined as discordant genomic resulting in different treatment recommendations. Undertreatment indicates patients who may not have received CT based on RS but may have based on MP/BP and overtreatment those patients who would have received CT based on RS, but not based on MP/BP. ET duration too long is indicative of those patients that are ultralow risk by MP, regardless of RS classification, as those patients may have safely reduced the duration of their ET. Although outcomes are not available, treatment impacts are presuming a patient received both tests, but the treating physician opted to guide therapy according to the RS results rather than MP/BP. **Results:** We observed discordant results with a clinical impact in 49% (354) of patients, with 34% (244) who may be undertreated, 2% (11) potentially overtreated, and 14% (99) who may not be given the option to decrease ET to two years based on ultralow MP genomic risk. Of 114 concordant High-Risk tumors, 14% (16) were genomically Basal, and likely to require more aggressive CT than typically used in ER+ cancers. The table below summarizes the results. **Conclusions:** More than half of the patients in this cohort were at potential risk for undertreatment or overtreatment. The risk to patients is far more significant in the event of undertreatment, as this may result in incurable metastatic recurrence. Discordance between RS and MP/BP most often results in potential undertreatment if RS is used for treatment decision-making. Clinical trial information: NCT03053193. Research Sponsor: None.

Molecular characteristics and clinical outcomes of breast cancer with *HRAS* mutations. *First Author: Samuel Kareff, University of Miami/Jackson Memorial Hospital, Miami, FL*

Background: The RAS pathway regulates tumorigenesis and cell proliferation. HRAS is a RAS family member that activates via farnesylation. Indirectly targeting mutant HRAS with tipifarnib, a farnesyltransferase inhibitor (FTI), recently demonstrated efficacy in head and neck tumors. We aimed to investigate the molecular characteristics and clinical outcomes of HRAS mutations (HRASmut) for any potential role as a prognostic and therapeutic biomarker in breast cancer (BC). **Methods:** A total of 14,013 BC tissue samples had molecular profiling, including next generation DNA (592 Gene Panel, NextSeq, or WES, NovaSeq) or RNA sequencing (NovaSeq, WTS), and immunohistochemistry analyses, at Caris Life Sciences. MAP kinase (MAPK) activation and likelihood of a tumor's response to anti-PD1 therapy were evaluated via MAPK Pathway Activity Score (MAPS) and interferon (IFN) score, respectively. Wilcoxon, Fisher's exact, or Dunnett's tests were used to determine statistical significance. Overall survival (OS) was calculated from date of tissue collection to insurance claims last contact using the Kaplan-Meier method. HRAS mutations (HRASmut) were compared to the general BC cohort (GC). **Results:** HRASmut were significantly enriched in older patients (median 69 vs 60 yrs; $q<.0001$), and in primary compared to metastatic BC tumor samples (55.9% vs 41.9%, $p<.05$). There were 70 total HRASmut (0.5%): Q61 was the most frequent (41.4%), followed by G12 (28.6%) and G13 (24.3%). Patients with Q61 HRASmut had significantly worse OS compared to GC (HR 1.86, 95% CI [1.10-3.13]; $p<0.05$). HRASmut had significantly higher MPAS compared to GC (1.26, all; 1.31, Q61; 1.7, G12; -.39, GC, $q<.01$). HRASmut were found in HR+/HER2- (22.6%) and TNBC (77.4%) tumors, but no HR-/HER2+ BC. TNBC samples with HRASmut displayed more PIK3CA (62.5% VS. 18.9%, $q<.05$) but less TP53 mutations (50% vs 84.9%, $q<.05$), higher expression of PD-L1 (41.2% vs 10.8%, $p<.05$) and androgen receptor (AR, 45.8% vs 24.4%, $p<.05$), and more frequent ARv7 fusions (20.7% vs 4.3%, $p<.05$) compared to HR+/HER2- (Table 1). Q61 HRASmut had the highest MPAS (2.39 vs -0.28, p<.01) in TNBC, whereas G12 HRASmut displayed the highest MPAS (2.01 VS -0.47, $p<.05$) in HR+/HER2- BC. Conversely, Q61 had the lowest IFN score (-0.45 vs -0.3) in HR+/HER2- but the highest (-0.18 vs -0.3) in TNBC. **Conclusions:** HRASmut were mutually exclusive with HER2+ BC. The association of Q61 HRASmut with worse survival highlights the oncogenic role of these mutations and supports therapeutic investigation using FTI. PIK3CA was significantly co-mutated in HRASmut, highlighting a potential benefit of combining PIK3CA inhibitors with tipifarnib. Overall, HRASmut displayed a subtype-specific distinct genomic landscape and may represent a key therapeutic target in BC. Research Sponsor: None.

Percentage of co-alterations in HR+/HER2- BC.

	HRASmut	GC
PIK3CA	71.4	41.2
PTCH1	20	0.3
EPHA2	16.7	0.1

Serial postoperative ctDNA monitoring of breast cancer recurrence. *First Author: Jacqueline A. Shaw, University of Leicester, Leicester, United Kingdom*

Background: Up to 30% of patients with breast cancer relapse after primary treatment. There are no sensitive or reliable tests to monitor these patients and detect distant metastases before overt recurrence. Here, we demonstrate the use of personalized circulating tumour DNA (ctDNA) profiling performed postoperatively, postadjuvantly, and serially for detection of recurrence in breast cancer. **Methods:** Patients with primary breast cancer (n=188) were recruited following surgery and adjuvant therapy and were followed-up for up to 10 years with semi-annual blood sampling for ctDNA analysis. Patients (n=29) with insufficient residual tumour for whole exome sequencing (WES) were excluded from the analysis. Tumour WES profiles were generated for 159 patients; samples from 2 patients failed WES QC requirements and a personalised ctDNA panel could not be generated for 1 patient. In 156 patients, plasma samples (n=1141) were retrospectively tested for the presence of ctDNA using personalized Signatera assays (mPCR-NGS) targeting up to 16 somatic single nucleotide variants selected from primary tumour WES. **Results:** Plasma ctDNA was detected ahead of clinical or radiologic relapse in 30 of the 34 relapsed patients (sensitivity of 88%). Metastatic relapse was predicted with a lead interval of up to 2 years (median: 10 months, range: 0-39 months); median lead intervals for HR+/HER2- were 15 (2 - 39); for HR-/HER2+ 6 (0.5 – 12) for HR+/HER2+ 8 (5 – 14) and 9 (0-20) for TNBC. Patients with a positive ctDNA test had poorer relapse-free-survival (RFS) (HR=47.5; 95% CI 18.5-161.4; p <0.001) from surgery and all four breast cancer subgroups showed a similarly reduced RFS. Overall survival was also significantly reduced for patients who were ctDNA positive (HR=84.15; 95%CI 16.43-1538; p <0.001). The number of variants, mean VAF and MTM/mL varied between patients, with significantly higher values at the time closest to relapse than in the first ctDNA positive sample (p =0.0002). Among the 4 relapsed patients not detected in the study all were HR+/HER2-, 1 had a local recurrence, 2 had bone recurrence (1 with axillary LN involvement) and 1 had cancer cells in pleural fluid. Of the remaining 122 patients, only 5 developed ctDNA-positivity, all with low VAF, none of them have relapsed by the follow-up census date (31 December 2021). However, follow-up for some of these patients limits definitive assessment. Lastly, 4 patients developed a second primary cancer (2 breast, 2 lung) all of whom were ctDNA-negative. **Conclusions:** This study demonstrates that serial post-operative ctDNA analysis has strong prognostic value. More importantly, earlier detection of metastatic disease provides a possible window for therapeutic intervention, while repeated negative ctDNA tests can provide reassurance to patients. Future interventional studies may assess the clinical utility of ctDNA-based risk-stratification. Research Sponsor: Cancer Research UK, Astrazeneca.

Associations of a breast cancer polygenic risk score with tumor characteristics and survival. *First Author: Josephine Lopes Cardozo, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: A polygenic risk score (PRS) consisting of 313 single nucleotide polymorphisms (PRS_{313}) is associated with risk of breast cancer and contralateral breast cancer. One of the most promising clinical applications for the use of PRS is to provide a personalized risk assessment to individualize breast cancer screening programs. This study aimed to evaluate the association of the PRS_{313} with clinical-pathological characteristics and survival of breast cancer. **Methods:** Women of European ancestry with invasive breast cancer were included, 98,397 women from the Breast Cancer Association Consortium (BCAC) and 683 women from the MINDACT trial. Associations between PRS_{313} (continuous, per SD) and clinical-pathological characteristics, including the 70-gene signature for patients included in MINDACT, were evaluated with logistic regression analyses. Associations of PRS_{313} with overall survival (OS), breast cancer-specific survival (BCSS) and distant metastasis-free interval (DMFI) were evaluated with Cox regression analyses, adjusted for clinical-pathological characteristics and treatment. **Results:** The PRS_{313} was associated with favorable tumor characteristics. In BCAC, increasing PRS_{313} was mostly associated with lower grade, hormone receptor-positive tumors, and with smaller tumor size. In MINDACT, PRS_{313} was associated with a low risk 70-gene signature, but the association was attenuated after adjustment for clinical-pathological characteristics. In BCAC, univariable analyses showed an association of PRS_{313} with better survival, hazard ratio (HR) per unit SD increase of PRS_{313} for OS: 0.96 (95% confidence interval (CI): 0.94-0.97), for BCSS HR: 0.96 (95% CI: 0.94-0.98) and for DMFI HR: 0.98 (95% CI: 0.96-1.00). The association in the unadjusted analysis was explained by differences in clinical-pathological characteristics (and treatment) and disappeared after adjustment: OS HR: 1.01 (95% CI: 0.98-1.05), BCSS HR: 1.02 (95% CI: 0.98-1.07) and DMFI HR: 1.03 (95% CI: 0.99-1.07). **Conclusions:** An increased PRS_{313} is associated with favorable tumor characteristics but was not independently associated with prognosis. This information is crucial input for modelling effective stratified screening programs, especially in the current era of optimized (systemic) treatments. Given the significant increase in breast cancer risk associated with increasing PRS_{313}, absolute breast cancer mortality will still be higher for women with higher PRS_{313}. Is there a role for the oncotype DX breast recurrence score genomic assay in estrogen receptor-low positive breast cancer? *First Author: Julia Giordano, Dana-Farber Brigham Cancer Center, Boston, MA*

Background: The Oncotype DX Breast Recurrence Score assay is widely used in estrogen receptor (ER)-positive breast cancer patients to help determine the potential benefit of chemotherapy. However, little is known about the value of the test in breast cancer patients who have ER-low positive (1-10%) cancers. The purpose of this study was to determine the potential utility of the Oncotype test for these patients by describing the range of Recurrence Score (RS) results and patient outcomes. **Methods**: Patients treated between 8/2011-8/2020 for primary non-metastatic breast cancer that was ER-low positive (10%) and HER2-negative in whom tissue from their surgical excision specimen was available to perform the Oncotype DX assay were identified. Clinicopathologic characteristics were abstracted from patient charts, and the RS result was determined. **Results**: 38 women with ER-low positive breast cancer and available tissue were identified. The median age was 56.5 (range 36-94); 34 patients were Caucasian, 2 Black, 1 Asian and 1 Hispanic. Thirty-seven patients underwent surgery as their initial intervention and 1 received neoadjuvant chemotherapy. The final pathologic anatomic stage was IA in 26 (68.4%), IB in 10 (26.3%) and IIA in 2 (5.3%); the pathologic nodal status was pN0 in 24 (63.2%), pN0i+ in 3 (7.9%), pN1mi in 1 (2.6%), pN1 in 6 (15.8%) and pNx in 4 (10.5%). The average and median RS was 49 with a range of 23-72; only 2 patients had a RS 25. One patient with RS = 24 was a 64yo with pT1cN0 disease who received chemotherapy + endocrine therapy therefore could potentially have been spared chemotherapy based on the RS result and the TAILORx trial data. Six patients had previously had a RS determined on their diagnostic core biopsy (RS = 46, 58, 45, 47, 51 and 52); the RS on their surgical specimen was concordant (RS = 45, 54, 47, 48, 47, and 50). The ER status as determined by the Oncotype DX assay was positive for 8 (21%) patients. Adjuvant therapy included: chemotherapy and endocrine therapy in 13 (34.2%), chemotherapy alone in 13 (34.2%) and endocrine therapy alone in 4 (10.5%). 8 (21.1%) received no adjuvant therapy. After a median follow-up of 40 months (range 3-106), 3 patients have experienced a recurrence; all 3 had received chemotherapy. The 3-year recurrence free survival rate was 97.0% (95% CI: 96.9-97.1%). All 3 of these patients had a local recurrence; 2 also had a distant recurrence which they ultimately succumbed to. The 3-year disease-specific survival rate was also 97.0% (95% CI: 96.9-97.1%). **Conclusions**: The majority of the patients with low ER+/HER2- breast cancer had RS > 25 suggesting these tumors are high-risk, more similar to ER- disease. The RS result is of limited utility in ER-low positive patients, as these data indicate that most would benefit from chemotherapy. Recurrence Score (RS) results, clinicopathologic characteristics, treatments, and outcomes in primary versus subsequent breast cancer (BC): Exploratory analysis of the Clalit Health Services (CHS) registry. *First Author: Shlomit Strulov Shachar, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel*

Background: In this exploratory analysis of the CHS registry we investigated differences in RS results and clinicopathologic characteristics between a primary and subsequent BC as well as the association with treatments received (after the first BC) and clinical outcomes. **Methods:** The analysis included all ER+ HER2-negative BC pts who were RS-tested through CHS between 1/2006 and 12/2020, had ≤3 positive lymph nodes in their first BC, and ≥2 RS results > 1 yr apart. **Results:** The analysis included 60 pts (all had second BC, 2 also had a third BC). All were female; the median age at diagnosis of the first BC was 56 (IQR, 44-62) yrs and at the subsequent diagnosis, 61 (50-67) yrs. In the first diagnosis, 46/14 pts (77%/23%) were N0/node-positive; in the subsequent BC, it was 50/9 pts (81%/15%), (missing data for 3 pts [5%]). Of the 46 N0 pts at the first BC, 37 (80%) were N0 in the subsequent BC. Tumor characteristics were similar between the first and the subsequent BC tumors. No statistically significant differences were observed between the first and subsequent tumors with respect to tumor size, grade, histology, and the proportion of N0 vs N1/N1mi pts. The RS results were statistically significantly higher in the subsequent BC vs the first (mean [SD] of 24 [12]) vs 19 [10]; $P = .00062$, Mann-Whitney test). In the first BC, 7 (12%), 44 (73%), and 9 (15%) had RS 0-10, 11-25, and 26-100, respectively. In the subsequent BC, the distribution shifted with more pts in the higher RS category (5 [8%], 32 [52%], and 25 [40%], respectively; $P = .0072$, χ^2-test). The differences in the RS between the first and subsequent BC varied considerably between pts (median difference, 6; IQR, -0.25 to 11.0; range, -50 to 56). Of the 46 pts with N0 at the first BC, 36 (78%) received endocrine therapy (ET), 34 (74%) received radiation therapy (RT), and 5 (11%) received CT after the first BC diagnosis; of the 14 N1mi/N1 pts, 12 (86%) received ET, 12 (86%) RT, and 4 (29%) CT after the first BC diagnosis. In 45 N0 pts with available information, higher RS in the subsequent BC was observed more often in irradiated breasts (pts who received RT to the breast that was subsequently diagnosed with second/third BC, n = 23) vs non-irradiated breast (pts with no RT or pts with subsequent BC in the opposite breast, n = 22): 83% vs 55%, $P = .042$; χ^2-test. No other statistically significant associations were observed between treatments received after the first diagnosis and RS differences between the first and subsequent BC diagnoses. With a median (IQR) follow up of 4.2 (1.6-8.2) yrs from the latest diagnosis, 5 distant recurrences were reported: 2 in pts with RS≤25 in their second BC (of whom one had N1 BC), and 3 in pts with RS > 25 in their second BC. **Conclusions:** In ER+ HER2-negative BC pts, the RS in a second/third BC is generally higher than the first, particularly if the breast involved was irradiated. Immune landscape of breast tumors with low and intermediate estrogen receptor (ER) expression. *First Author: Leonie Voorwerk, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Immune checkpoint blockade (ICB) is currently only approved for patients with triple-negative breast cancer (TNBC). However, the cut-off used for ER expression (<1% and in some countries <10%) has been developed as a biomarker for endocrine treatment response and not for selection for likelihood of response to ICB. While stromal tumor-infiltrating lymphocytes (sTILs) and PD-L1 expression are higher in TNBC compared to ER-positive tumors, the distribution of these and other key immune parameters in tumors with very low (1-9%), low (10-50%), intermediate (51-99%) and high (100%) ER levels is unknown. **Methods:** We collected a consecutive series of treatment-naïve tumor blocks of ER+/HER2- breast tumors diagnosed between 2010 and 2019. All available tumor blocks were used from the groups with ER expression between 1-9% and 10-50%. For the other groups, we randomly selected tumor blocks aiming for similar group sizes. This resulted in the following subgroups: ER 0% (n=46), 1-9% (n=17), 10-50% (n=22), 51-99% (n=37) and 100% (n=51). sTILs were scored using H&E slides. Immunohistochemistry was performed for CD8 and PD-L1 (22C3, scored on immune cells, cut-off ≥1%). Gene expression analysis was performed using the NanoString nCounter Breast Cancer 360 panel. **Results:** We found the highest levels of sTILs and stromal CD8+ cells in tumors with ER0% with comparable levels in tumors with ER1-9% and ER10-50% (Table). The proportion of PD-L1 positive tumors was 86% in tumors with ER0%, 81% in tumors with ER1-9%, 76% in tumors with ER 10-50% and 59% and 50% in tumors with ER51-99% and 100% respectively. As expected, a higher differentiation grade correlated with lower levels of ER expression. Differential gene expression demonstrated that expression of immune-related signatures, such as *IDO1*, antigen presenting machinery, CD8+ T cells and IFNγ, was comparable in tumors with ER1-50% as compared to ER0%, but statistically significantly higher as compared to tumors with ER100%. **Conclusions:** Our data suggest that breast tumors with low levels of ER expression (1-9%, 10-50%) comprise a separate entity within ER-positive breast cancer regarding their immune landscape. Here we show that not only tumors with very low ER levels (1-9%) mimic TNBC in terms of immune landscape but also that tumors with low ER levels (10-50%) might be more likely to respond to ICB than tumors with high levels of ER expression. Research Sponsor: None.

ER expression subgroup	Median % sTILs (range)	Median % stromal CD8+ cells (range)
ER 0%	20 (1-90)	10 (1-70)
ER 1-9%	10 (1-80)	10 (1-60)
ER 10-50%	20 (5-80)	10 (1-60)
ER 51-99%	10 (1-30)	5 (1-30)
ER 100%	10 (1-80)	5 (1-60)

Disparity between Ki67 measurements and tumor gene expression tests in patients with hormone-sensitive early breast cancer from the OPTIMA preliminary trial. *First Author: Robert C. Stein, National Institute for Health Research University College London Hospitals Biomedical Research Centre, London, United Kingdom*

Background: Tumor gene expression tests are increasingly used in breast cancer management. The Ki67 biomarker has been proposed as an inexpensive alternative for making chemotherapy decisions, has demonstrated utility for determination of endocrine therapy responsiveness and is included in the FDA license for adjuvant abemaciclib. We have compared Ki67 measurements with tumor gene expression test results for patients included in the OPTIMA prelim trial. **Methods:** We compared Ki67 %staining with the results of Oncotype DX, Prosigna and MammaPrint performed by the test vendor. Ki67 was determined in a single laboratory on triplicate tissue micro-arrays using quantitative image analysis including a 10% manual quality control check. We used kappa statistics to measure agreement between tests, divided into groups using the pre-defined test score boundaries for high vs. not high risk. **Results:** Data were available for 259 patients. Using ≥20% staining to define a high Ki67 score, kappa values (95% CI) for agreement with Prosigna were: 0.39 (0.28-0.49); Oncotype DX: 0.27 (0.18-0.36); and MammaPrint: 0.38 (0.27-0.49). Kappa values <0.2 are conventionally interpreted as showing slight agreement and 0.21-0.4 as fair agreement. A detailed breakdown of the comparisons of Ki67 with Prosigna and Oncotype DX is tabulated. **Conclusions:** Agreement between Ki67 and tumor gene expression tests is limited. Therefore, Ki67 values cannot accurately be used to reflect any of the molecular scores assessed here, all of which are well validated prognostic biomarkers. The use of Ki67 to determine suitability for adjuvant chemotherapy requires validation before it can replace the existing tests. Tumor gene expression tests may prove superior to Ki67 for the identification of patients likely to benefit from adjuvant abemaciclib. OPTIMA prelim is registered as ISRCTN42400492 and funded by the UK NIHR Health Technology Assessment Programme, award number 10/34/01. Clinical trial information: ISRCTN42400492. Research Sponsor: National Institute for Health Research.

		Ki67 <20%	Ki67 ≥20%
Prosigna	Median score (IQR)	40 (28-55)	64 (45-75)
	Prosigna score >60	23%	77%
	Prosigna score ≤60	64%	36%
Oncotype DX	Median score (IQR)	13 (10-18)	20 (16-28)
	Recurrence Score >25	12%	88%
	Recurrence Score ≤25	57%	43%

Impact of neighborhood disadvantage on biological and clinical indicators of anxiety among newly diagnosed patients with breast cancer. *First Author: Neha Goel, University of Miami Miller School of Medicine/Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Women living in disadvantaged neighborhoods consistently having worse breast cancer (BC) survival. Recent studies have identified that disparities by neighborhood disadvantage persist after controlling for patient, tumor, and National Comprehensive Cancer Network-guideline concordant treatment. This persistent disparity suggests unaccounted mechanisms by which neighborhood disadvantage "gets under the skin" to impact to shorter BC survival. **Methods:** Women with stage 0-3 BC between 1998-2005 were enrolled in a clinical trial for stress management 2-10 weeks post-surgery and before initiating adjuvant treatment. At baseline, women provided an evening-time serum cortisol sample and were administered a structured clinical interview of anxiety symptoms (Hamilton Anxiety Rating Scale; HAM-A). Of the 240 women who enrolled in the study and completed baseline procedures, home addresses were provided by 225 women (93.8%). The addresses were used to determine the Area Deprivation Index (ADI), a validated measure of neighborhood disadvantage, using the University of Wisconsin Neighborhood Atlas. Women were categorized as low (1-3) versus high (4-10) ADI. Linear regression analyses was used to assess the relationship between ADI and serum cortisol and logistic regression to assess whether ADI group predicted the presence of clinically significant anxiety per the HAM-A. **Results:** The average age of our population was 50.4 years old (range 23-70 years) and the majority were non-Hispanic White (63.6%). Most patients had stage 1 (37.8%) or 2 (38.2%) disease. The majority lived in advantaged neighborhoods (low ADI, 77.8%). On the HAM-A, 46.8% of women reported clinically significant anxiety symptoms. When controlling for age, stage, and type of surgery, women with a high ADI had higher cortisol levels than women in with a low ADI (Beta = .19, $t(117) = 2.18$, $p = .031$). Moreover, accounting for age, stage, and type of surgery, women with a high ADI were nearly two times as likely to have clinically significant anxiety symptoms in the HAM-A clinical interview (OR 1.99, 95%CI 1.01, 3.90, p = .046). **Conclusions:** This study identified that neighborhood disadvantage is significantly associated with higher levels of cortisol and clinical anxiety. Future studies need to evaluate stress pathways as a potential mechanism by which neighborhood disadvantage "gets under the skin" to impact BC-specific survival. Research Sponsor: U.S. National Institutes of Health.

Assessment of FOXC1 expression as a predictor of response to neoadjuvant taxane plus platinum regimens in primary triple-negative breast cancer: Retrospective analysis of three clinical trial cohorts. *First Author: Partha Ray, Onconostic Technologies, Evanston, IL*

Background: Taxane and platinum (TP) NAC regimens, e.g. Carboplatin and Docetaxel (CbD), in TNBC are currently of great interest, having good pathologic complete response (pCR) rates but with a significantly more manageable toxicity profile compared to anthracycline-based NAC regimens. Forkhead Box C1 (FOXC1), a transcriptional driver of cell plasticity/partial EMT/metastasis is an established mesenchymal marker diagnostic of basal-like breast cancer having proven prognostic value, but of uncertain predictive value. We sought to evaluate the potential of FOXC1 in predicting pCR to neoadjuvant TP regimens in patients diagnosed with TNBC. **Methods:** Pre-NAC tumor biopsy FOXC1 mRNA expression status was correlated with rate of pCR in a pooled, ambispective cohort (prospective cohort GEICAM/2006-03, NCT00432172 pooled with multi-institutional retrospective cohort, n = 119). A specific FOXC1 mRNA expression cutoff value was derived to maximize Negative Predictive Value (NPV) and Sensitivity for pCR prediction. The pCR-predictive ability of FOXC1 mRNA expression was then assessed in two validation cohorts of evaluable patients who had been enrolled in prospective clinical trials (UCONN/FIOCRUZ, n = 222, HGUGM, NCT01560663, n = 221). All evaluated patients had been diagnosed with TNBC and had received a Taxane plus Platinum-based NAC regimen. **Results:** FOXC1 mRNA expression was associated with pCR in CbD/TP treated TNBC patients with pCR rates of 43.48%, 47.89% and 52.73% observed in the discovery and two validation cohorts (two tailed T-test p-values of 0.0005, 0.002, 0.009, respectively). FOXC1 expression above the pre-determined cutoff value was associated with pCR to CbD/TP NAC in patients diagnosed with TNBC in both validation cohorts (OR 4.894, 1.504-15.924; p = 0.004 and OR 2.293, 1.208-4.352; p = 0.006). **Conclusions:** We report the retrospective validation of pre-NAC breast cancer biopsy FOXC1 mRNA expression for predicting efficacy of CbD/TP NAC in two independent, prospectively accrued TNBC patient cohorts. The described strategy may be acceptable for patient stratification to guide CbD/TP NAC recommendations in TNBC. FOXC1 mRNA or protein expression, assessed using qRT-PCR or routine immunohistochemistry (IHC), respectively, could potentially be utilized in future fixed-arm/adaptive clinical trials to further optimize NAC efficacy, in terms of achieved pCR rates, and to extend disease-free survival in patients diagnosed with TNBC. Research Sponsor: None.

miR-150 expression in breast cancer attracts and activates immune cells, and is associated with better patient outcome. *First Author: Masanori Oshi, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: MicroRNA (miRNA) epigenetically regulate a large number of cancer-related genes and is known as a key player in cancer biology. MiR-150 promote cancer cell proliferation, migration, and invasion. However, there has been no study that investigated the role of miR-150 in the tumor microenvironment (TME) of breast cancer patients. **Methods:** Total of 1,961 breast cancer patients from multiple independent large cohorts were analyzed. These observational results were validated by in vitro experiments. Lymphocyte attraction was assessed using Transwell system. **Results:** miR-150 expression was the highest in triple negative breast cancer (TNBC) among subtypes and correlated with Nottingham histological grade (all $p<0.001$). A high miR-150 was significantly associated with better overall survival (OS) in both METABRIC and TCGA cohorts regardless of subtypes (all $p<0.05$ except for TNBC in TCGA). MiR-150 expression was strongly correlated with Hallmark immune-related gene sets (Allograft rejection, IL6 signaling, IFN-γ response, Inflammatory response, IL2 signaling, and apoptosis), with cytolytic activity, with infiltration of CD8+ T cells, CD4+ memory T cells, and dendritic cells, as well as with gene expressions of major immune checkpoint molecules (PD-1, CTLA4, IDO1, TIGIT, BTLA, and LAG3), consistently in both METABRIC and TCGA cohorts (all $r>0.65$, $p<0.01$). Unexpectedly, overexpression of miR-150 by mimic did not increase growth, migration, nor invasion of neither MDA-MB231 or BT-549 breast cancer cell lines. On the other hand, overexpression of miR-150 in either MDA-MB231 or BT-549 significantly increased attraction of lymphocyte cell line (Jurkart cells), which was abolished by addition of miR-150 inhibitor. By comparing the gene expression profile between miR-150 overexpressed and control cells, we found that many inflammation related gene sets including NF-kB signaling that enhance cell migration was enriched to miR-150 overexpressed cells, implicating that is how miR-150 high cells attract lymphocytes to TME. **Conclusions:** miR-150 expression is associated with immune cell infiltration and immune response, as well as with better survival in breast cancer patients. Overexpression of miR-150 in breast cancer cells did not promote cancer cell proliferation, migration, nor invasion; however, increased attraction of lymphocytes. Multiple inflammation-related genes were expressed higher in miR150 overexpressed MDA-MB231. Research Sponsor: U.S. National Institutes of Health.

Mode of detection of second breast cancers in patients undergoing surveillance after treatment of ductal carcinoma in situ. *First Author: Bethany Waites, Department of Obstetrics and Gynecology, Kaiser Permanente San Francisco, San Francisco, CA*

Background: The incidence of ductal carcinoma in situ (DCIS) has increased, resulting in more women undergoing post-treatment surveillance for second breast cancers. National Comprehensive Cancer Network (NCCN) guidelines recommend annual breast imaging and physical exam every 6-12 months for five years, and then annually. We assessed mode of detection (imaging, patient-reported, or physical exam) of secondary DCIS and/or invasive breast cancer in a large cohort of DCIS patients undergoing surveillance after treatment of primary DCIS. **Methods**: We performed a retrospective cohort study of DCIS patients treated between 1/1/2008 and 1/1/2011 within a large integrated health care system. Patients had a minimum of 5 years of follow up. Patient demographics, treatment for primary DCIS, and tumor characteristics (of both primary DCIS and secondary cancer) were obtained from the electronic health record or from manual chart review. Chart review also included mode of detection of secondary breast cancers. **Results**: Our study cohort consisted of 1561 women with DCIS, with a median age of 59 years (range 32-92) at time of diagnosis. Among initial DCIS tumors, tumor grade was low/intermediate in 942 (60.3%) and high in 619 (39.7%); 1274 (81.6%) were estrogen receptor positive, and 988 (63.3%) progesterone receptor positive. Surgical treatment for the initial DCIS included lumpectomy (n=1134, 72.6%), unilateral mastectomy (n=320, 20.5%), or bilateral mastectomy (n=61, 3.9%), and included sentinel lymph node biopsy in 211 (14%) of patients. Additionally, 691 (44.3%) received radiation therapy and 440 (28.2%) received endocrine therapy. The cohort was followed for a median of 120 months, during which we identified 179 women (11.5%) with a secondary cancer detected at a median time of 57 months. Of the second breast cancers, 77 (43.0%) were ipsilateral, 98 (54.8%) contralateral, and 4 (2.2%) presented with distant metastases; 110 (61.5%) were invasive, 65 (36.3%) were DCIS, and 4 (2.2%) Paget's disease. See table for mode of detection of second breast cancers. **Conclusions**: In our cohort of patients undergoing surveillance following initial diagnosis and treatment of DCIS, 2% of secondary breast cancers were detected by clinical breast exam, a rate similar to incidental detection at time of plastic surgery. These results can help inform future recommendations for surveillance of second breast cancers in DCIS patients. Research Sponsor: None.

Mode of detection of second breast cancers.

Primary results of ANZ 1002: Post-operative radiotherapy omission in selected patients with early breast cancer trial (PROSPECT) following pre-operative breast MRI. *First Author: Bruce Mann, The Royal Melbourne and Royal Women's Hospital, Parkville, Australia*

Background: Selective use of radiotherapy (RT) after surgery for early breast cancer (EBC) has been an elusive goal. The role of breast MRI in localised EBC is controversial. We aimed to determine if preoperative MRI could identify patients with EBC in whom the ipsilateral invasive recurrence (IIR) rate was sufficiently low without RT, such that RT might be safely omitted. Here we report primary and secondary outcomes, and imaging/biopsy findings for occult lesions. **Methods:** PROSPECT is a prospective single-arm study. Criteria for omission of RT included age at least 50, nil/minimal or mild Background Parenchymal Enhancement (BPE) on MRI, unifocal pT1N0 cancer, not Triple Negative (TNBC), no LVI. All patients who underwent PROSPECT MRI were included in the analysis. Imaging findings on MMG, US and MRI were documented and all biopsies were recorded. Pathology of lesions identified by MRI was described. The primary outcome was the IIR at 5 years of those treated without RT. An IIR rate of 5% or less was considered acceptable. The protocol specified primary analysis occurred after the 100th patient reached 5 years follow up in May 2021. **Results:** Between 9/2011 and 5/2019, 443 patients had MRI after diagnosis. BPE was nil/minimal or mild in 344 patients. MRI detected 194 occult lesions in 144 (33%) patients; 139 (72%) were ipsilateral. 61 MMG/US occult malignant lesions - 36 invasive and 25 DCIS - were identified in 48 patients (11% of total cohort). Of 38 ipsilateral lesions in 32 patients (7% of total cohort), 23 were DCIS, 4 were T1a, 7 T1b and 4 T1c. 201 patients were treated on trial without RT. The median age was 63 years (range: 50 to 84), median tumour size 11 mm (range: 2 to 20), grade 1 (104), grade 2 (86) or grade 3 (11). The rate of IIR at 5 years was 1% (1/101). There were 2 IIRs at 4.6 and 7.7 years follow up, 1 regional recurrence, and 1 patient with both a regional and distant recurrence with 1 breast cancer death. There was 1 contralateral (CL) breast cancer, 1 CL DCIS, 2 other cancer diagnoses and 1 death from other causes. Of 242 patients undergoing MRI but not in the main study, median age was 63 range: 50-80, median tumour size, 13mm (range: 4-145). 9 underwent mastectomy (2% of total cohort). Followup is complete for 235. There was 3 IIR, 3 CL primary and no distant metastases or breast cancer deaths. **Conclusions:** Breast MRI in selected, low risk patients identified occult malignancy in 11% of patients. At a median of 5 years follow up the IIR and other breast cancer events was very low. This suggests that local recurrences may be due to occult breast cancers, and MRI may allow the identification of truly localised cancers for which radiation may be safely omitted. The event rate for the entire cohort was very low, suggesting that identification of occult malignancy in apparently unifocal EBC is beneficial. Confirmatory trials are needed. The percentage of unnecessary mastectomy due to false size prediction by preoperative imaging studies in patients with breast cancer who underwent neoadjuvant chemotherapy. *First Author: Yireh Han, Seoul National University Hospital, Seoul, South Korea*

Background: It was shown that, with neoadjuvant chemotherapy (NCT), about 40-50% of breast conserving surgery (BCS) ineligible breast cancer converted to BCS-eligible. Because the estimated tumor extent with imaging after NCT tend to be discordant with pathologic extent, we assumed that proportion of unnecessary total mastectomy (TM) might be greater in NCT patients compared with non-NCT patients. We aimed to determine the proportion of TM for potential BCS candidate due to false size prediction after NCT and factors affecting that. **Methods:** We prospectively enrolled patients with invasive breast cancer (Stage II or III) who were scheduled for TM from 2018 to 2021 at Seoul National University Hospital (SNUH). Patients who were determined to undergo TM by only patient's preference, who had BRCA1/2 mutation, multicentric cancer, diffuse malignant calcification over more than a quadrant, and inflammatory cancer were excluded. The decision of TM was done by operating surgeon considering the tumor extent, location, and breast size. Breast imaging including mammography, ultrasonography (USG), and MRI were done in patients. Before surgery, each surgeon recorded a hypothetic maximum tumor size (HMS) that the surgeon would have been able to try BCS if the patient had actually less than that size of tumor at that location in the patient. After operation, the HMS was compared with final pathologic total extent of the tumor including invasive and in situ cancer. In SNUH, decisions and tries of BCS led to eventual BCS with negative margin in 97.4% of patients during same period with this study. **Results:** Among 360 patients enrolled, 130 were patients who underwent NCT, and 230 were chemotherapy naïve as a control group. 62 of 130 (52.3%) in the NCT group and 49 of 230 (21.3%) in the non-NCT group were found to have smaller tumor extent than the pre-recorded HMS, respectively (NCT vs non-NCT p-value <0.001). Further analyses were done only for NCT group. In an analysis according to subtype, the proportion of TM with false size prediction were more in HER2-positve (63.3%) and triple-negative breast cancer (TNBC) (57.6%) than in ER-positive/HER2-negative breast cancer (25.0%) (p-value <0.001). In an imaging analysis, MRI size were larger than HMS in 73.8% of all patients. Both MRI-pathology size and USG-pathology size discrepancies were significantly associated with false decision of TM (both p<0.001), but not with mammography. Without MRI, the false decision would have been reduced by 26.1%. **Conclusions:** We found that 52.3% of patients who received TM after NCT were actually BCS eligible, which was significantly higher than non-NCT patients. The proportion of false prediction were more in HER2-positive and TNBC. MRI imaging contributed to false size prediction and subsequent TM for BCS eligible patients. Clinical trial information: NCT04689529. Research Sponsor: None.

A prospective ultrasonographic surveillance study on the incidence and recovery period of COVID-19 vaccination-related axillary lymphadenopathy following a booster shot. *First Author: Kumiko Kida, Department of Breast Surgical Oncology, St. Luke's International Hospital, Tokyo, Japan*

Background: COVID-19 vaccination-related lymphadenopathy is a frequent imaging finding that may be indistinguishable from malignant nodes and can lead to diagnostic difficulties in patients with cancer or healthy individuals on cancer screening. However, no prospective trials regarding COVID-19 vaccination-related lymphadenopathy following a booster shot have been conducted. The purpose of this study was to determine the incidence and imaging characteristics of COVID-19 vaccination-related axillary lymphadenopathy and assess the recovery period following a booster shot. **Methods**: We prospectively enrolled healthy women working at St. Luke's International Hospital, who would receive the third shot of the Pfizer-BioNTech COVID-19 vaccine between December 6 and 28, 2021. Women with a history of cancer, atopic dermatitis, auto-immune disease, or axillary surgery were excluded. All participants underwent ultrasound (US) examinations for the bilateral axilla at baseline (prior to the third shot), early phase (1–3 days after the shot), and late phase (6 weeks after the shot) if lymphadenopathy was detected at the early phase. We evaluated the incidence and US characteristics of lymphadenopathy. As for US characteristics mimicking a malignant node, focal cortical thickening, absence of the echogenic hilus, and vascularity were examined. In this study, abnormal lymphadenopathy was defined as [1] an increase in the short-axis size by more than 2 mm compared with the baseline, [2] an increase in the number of nodes with short-axis diameter more than 5 mm, and [3] demonstrating US characteristics mimicking malignant nodes. **Results**: A total of 100 women were enrolled in this study. The median age was 41 years (range 23–63). Abnormal axillary lymphadenopathy on the vaccinated side was observed in 59% of participants in the early phase and 8% in the late phase. In the contralateral axilla, abnormal lymphadenopathy was observed in 1% of participants in the early phase and 2% in the late phase. The median short-axis size of ipsilateral abnormal lymphadenopathy was 7.6 mm in the early phase and 5.7 mm in the late phase. In the early phase, US characteristics mimicking malignant nodes were observed, including focal cortical thickening in 54% of participants, absence of the echogenic hilus in 16%, and hypervascularity in 33%. **Conclusions**: COVID-19 vaccination-related axillary lymphadenopathy indistinguishable from malignant nodes was observed in more than half of the participants compared with the baseline, which improved in most cases within 6 weeks after the latest booster shot. To avoid a diagnostic conundrum, patients with breast cancer should be vaccinated on the arm contralateral to the cancer side. It is recommended that non-urgent imaging screening for the axilla should be scheduled after 6 weeks following the latest vaccination. Research Sponsor: None.

A randomized, prospective, multicenter trial of 3D printing, a patient-specific surgical guide for breast-conserving surgery after neoadjuvant chemotherapy: Comparative evaluation according to the presence or absence of surgical guide. *First Author: Hong-Kyu Kim, Seoul National University Hospital, Seoul, South Korea*

Background: To obtain a clear resection margin during breast-conserving surgery (BCS) after neoadjuvant chemotherapy (NCT), accurate targeting of the location and assessment extent of the tumor are essential. However, conventional targeting methods such as USG/MMG guided hook wire insertion have disadvantages in that they could only localize the tumor, not reflecting its extent. To assess this problem, we developed an MRI-based 3D printed breast surgical guide (3DP-BSG) and conducted a multicenter randomized clinical study to prove its clinical effectiveness. **Methods:** In this multicenter, randomized (1:1), controlled trial (KCT0004469), we assigned 566 patients who underwent NCT and planned to undergo BCS, to use customized 3DP-BSG for lumpectomy, or not to use 3DP-BSG for lumpectomy. We assumed that 3DP-BSG group achieve non-inferior outcomes compared with control group with conventional targeting method. The primary endpoint was the margin positivity of the first resected margin. Under the assumption that the proportion of margin positivity would be 23% in both groups, a total of 438 patients were calculated to have 80% power to establish non-inferiority with a margin of 10% at a one-sided significance level of 0.05. Efficacy was assessed in the intention-to-treat (ITT) population. **Results:** Between 2019 and 2021, 282 (49.8%) patients were assigned to 3DP-BSG group, and 284 (50.2%) patients were assigned to control group with conventional targeting method. The median age was 51 years. In the ITT analysis, first resected margin was positivity in 5 (2.1%) of 235 patients in 3DP-BSG group and 7 (2.9%) of 244 patients in control group (difference -1.15 [95% CI -3.58 to -1.28], pnon-inferiority < .0001). In the analysis of population excluding patients assessed as complete response (CR), first resected margin was positivity in 5 (3.40%) of 147 patients in 3DP-BSG group and 7 (4.8%) of 145 patients in control group (difference -1.43 [95% CI -5.25 to -2.40], pnon-inferiority < .0001). Most of the cases, marked areas with 3DP-BSG were partially different from those with conventional targeting method, and there were some cases where completely different areas were marked. In most of these cases, pathological CR made it difficult to compare the accuracy of the targeting methods, but in one case, a malignant tumor was diagnosed only in the 3DP-BSG targeting region. Even lesions that have been incorrectly targeted by conventional methods can be properly removed using 3DP-BSG, which is believed to be helpful in surgery. **Conclusions:** Lumpectomy using 3DP-BSG showed non-inferiority compared to the conventional targeting group, and the surgeon's satisfaction was higher by quantitatively presenting the extent of initial tumor. Clinical trial information: KCT0004469. Associations between axillary staging, adjuvant treatment, and survival in older women with early-stage breast cancer: A population-based study. *First Author: Matthew Castelo, Institute of Health Policy, Management and Evaluation, Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada*

Background: The Choosing Wisely guidelines recommend against surgical axillary staging (AS) in women ≥70 years with ER+/HER2- early stage breast cancer (BC). However, there has been little change in practice patterns, which may be influenced by observational studies reporting worse survival among women not receiving AS. Previous analyses did not take into account comorbidities, specific adjuvant treatments and HER2 status which may confound the association between AS omission and survival. This study examined the impact of AS omission on survival in older patients with Stage I/II BC, and secondarily emulated the Choosing Wisely population in a subgroup of those ≥70 years undergoing sentinel node biopsy (SLNB) vs. no AS for ER+/HER2- tumors. **Methods:** This was a population-based cohort study using linked health administrative data in Ontario, Canada. From the Ontario Cancer Registry, we identified women aged 65-95 years who underwent surgery for Stage I/II BC between 2010 and 2016. We excluded women who received neoadjuvant chemotherapy. To address confounding between those who did and did not receive AS, we built a propensity score model including patient and disease characteristics. Patients were weighted by propensity scores using overlap weights. Association with overall survival (OS) was calculated using weighted Cox proportional hazards models, and breast cancer-specific survival (BCSS) was calculated using weighted Fine and Gray models, adjusting for biomarkers and adjuvant treatments. Adjuvant treatment receipt was modelled with weighted log-binomial models. **Results:** Among 17,546 older women, 1,807 (10.3%) did not undergo AS, who were older, more comorbid, less likely to undergo mastectomy, and more likely to have tumors ≥ 2 cm. After propensity score weighting, baseline characteristics including comorbidity were balanced between the two groups. Women who did not undergo AS were less likely to receive adjuvant chemotherapy (adjusted RR 0.70. 95% CI 0.58-0.84), endocrine therapy (adjusted RR 0.85, 95% CI 0.82-0.89) and radiotherapy (adjusted RR 0.69, 95% CI 0.65-0.73). Unadjusted 5-year survival was lower for women who did not undergo AS (68.1%, 95% CI 65.8-70.2 vs. 87.6%, 95% CI 87.0-88.1; $p< 0.001$), and there was a higher 5-year incidence of BC deaths (7.6%, 95% CI 6.2-9.2 vs. 4.3%, 95% CI 3.9-4.7; $p< 0.001$). After weighting and adjustment, women who did not undergo AS continued to have worse OS (adjusted HR 1.13, 95% CI 1.03-1.24), however, there was no significant difference in BCSS (adjusted HR 1.00, 95% CI 0.78-1.26). The results among 6,286 ER+/HER2- women ≥70 years undergoing SLNB vs. no AS were similar for OS (adjusted HR 1.22, 95% CI 1.05-1.42) and BCSS (adjusted HR 1.08, 95% CI 0.67-1.76). **Conclusions:** The omission of AS in older women with early stage BC was associated with worse OS, reflecting selection bias, but no significant difference in BCSS. Patient interest in exploring nonsurgical treatment approaches for early-stage breast cancer: A qualitative study. *First Author: Maya Guhan, UT MD Anderson Cancer Center, Houston, TX*

Background: Advances in radiotherapy allow the ability to deliver ablative treatments without compromising outcomes, but there has been limited application of these treatments to early-stage breast cancers. The purpose of this study was to explore patients' interest in pursuing nonsurgical treatment approaches for their early-stage breast cancer. **Methods:** Investigators conducted a qualitative descriptive study involving semi-structured interviews with 21 early-stage breast cancer patients eligible for participation in a phase 2 trial offering omission of surgery. Interviews were transcribed, and three independent reviewers performed an inductive, thematic analysis to generate themes and subthemes. **Results:** Data analysis revealed the following factors that impacted patients' willingness and desire to explore nonsurgical treatment options: Perceptions and feelings about their cancer; Current quality of life and the level of support available in their daily life; External conversations focusing on family members' and friends' experiences with cancer and/or cancer treatments; Personal healthcare experiences, including with their current breast cancer diagnosis; Perceptions and feelings about their physicians; Conversations with their physicians about their treatment options; and Self-identified desire to direct care decisions. Specifically, patients described fearing surgery and surgical recovery and wanting to avoid negative surgery-related events previously experienced by friends, family, and themselves. Participants also expressed a desire to preserve their breast(s), receive treatment per the latest research, match the level of treatment with the severity of their cancer, and avoid other comorbidities as reasons for omitting surgery. Patient reasons for pursuing surgery included the desire to remove their cancer immediately, prior positive experiences of friends, family, and themselves with surgery, lack of concern about preserving their breast(s), and prior negative experiences of friends, family, and themselves with radiation. **Conclusions:** The results of this study highlight that there is patient interest in nonsurgical options for biologically favorable early stage breast cancers. A key factor hindering patient education and awareness of nonsurgical options is how the physician frames the discussion and presents treatment options. In addition, patients' self-identity and the prior experiences of friends, family, and self with cancer treatment and surgery in general appear to be key factors in their decision-making. The findings from this study demonstrate an unmet need to explore nonsurgical options for early-stage breast cancer. Study results can help shape conversations around shared decision making and clinical trial design and result in more personalized treatment options for women with early-stage breast cancer. Three-year disease-free survival in randomized trials of chemotherapy and HER2-targeted therapy: A meta-analysis. *First Author: Abhenil Mittal, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: The Katherine trial reported a 3-year invasive disease-free survival (DFS) of 77% in patients not achieving pathological complete response (pCR) and continuing on adjuvant trastuzumab. Case series suggest better outcomes and data support that some patients with residual disease have similar outcomes to those with pCR (Steenbruggen et al). The absolute benefit of adjuvant trastuzumab emtansine (T-DM1) would be smaller in patients with favourable outcomes despite residual disease. As such, a more precise estimate of 3-year DFS is needed for treatment planning. **Methods:** We reviewed reports of randomized trials of neoadjuvant chemotherapy and HER2-directed therapy and extracted the 3-year DFS, a validated surrogate endpoint in HER2-positive early-stage breast cancer. Data were extracted for patients with residual disease and with pCR. The mean 3-year DFS weighted by study sample size was calculated. Meta-regression comprising linear regression weighted by sample size (mixed effects) was performed to explore associations between 3-year DFS and trial-level patient, disease and treatment factors and changes in 3-year DFS over time. Quantitative significance was explored using methods described by Burnand et al. **Results:** Eleven studies comprising 3908 patients were included in the analysis. The mean 3-year DFS for patients with pCR and for residual disease was 90.1% and 80.0%, respectively. DFS improved over time. For trials whose final year of accrual was after 2010, mean 3-year DFS for residual disease was 84.7% compared to 78.0% for trials completing accrual before that time (p<0.001). In a subgroup analysis of patients with residual disease, those receiving dual HER2-targeted therapy in the neoadjuvant setting had a 3-year DFS of 85.3% compared to 73.3% for those receiving only trastuzumab (p<0.001). Meta-regression results for residual disease are shown in the Table. Positive quantitative significance was observed for final year of accrual, ER-expression, dual anti-HER2 therapy and concurrent vs sequential anti-HER2 therapy. Negative quantitative significance was observed for larger clinical tumor size and nodal involvement. **Conclusions:** 3-year DFS for patients with residual disease and HER2-targeted therapy is better than reported in the Katherine trial and has improved over time, possibly due to increased use of dual HER2-targeted therapy in the neoadjuvant setting. In this context, the absolute benefit of adjuvant T-DM1 may be smaller than anticipated. Research Sponsor: None.

Variable	Beta coefficient	p
Final year of accrual	0.57	0.11
ER positivity	0.675	0.046
Median age	0.155	0.71
≥T3	-0.696	0.19
Lymph node positive	-0.54	0.35
Dual HER2-targeted therapy	0.431	0.25
Anthracycline-containing regimen received	-0.288	0.45
Concurrent/sequential Trastuzumab	0.343	0.37

NOHA: A sensitive, low-cost, and accessible blood-based biomarker to determine breast cancer estrogen receptor status in low-resource settings. *First Author: Srinidi Mohan, University of New England, Portland, ME*

Background: Significant challenges to breast cancer control in low- and middle-income countries (LMICs) include late-stage disease presentation because of few/no early detection programs, inadequately staffed and equipped pathology laboratories, and constrained treatment options. Estrogen receptor (ER) expression is critical to determining candidacy for cost efficient and accessible hormonal agents in LMICs; however, access to standard immunohistochemistry (IHC)-based ER analysis is grossly limited/nonexistent due to cost and technical requirements. We have identified N^{ω}-hydroxy-L-Arginine (NOHA) as a low cost and accessible blood-based biomarker to distinguish estrogen-receptor negative (ER^-) from estrogen-receptor positive (ER^+) breast cancer, differentiate ER^- high grade versus low grade tumors, and correlate ER^- molecular phenotype with ethnic variation. Our studies with US patients suggest the NOHA threshold of <4nM as a reliable indicator of ER^- versus ER^+ disease (Table 1). Here we examine the clinical utility of NOHA as an alternative to IHC in distinguishing ER^- from ER^+ breast tumors in Tanzanian patients. **Methods:** Following informed consent, 70 newly diagnosed breast cancer patients were recruited at Kilimanjaro Christian Medical Center (KCMC; Moshi, Tanzania). Prior to any treatment, a needle prick amount of blood was collected from each patient on a Noviplex plasma card (Shimadsu, U.S.) and stored at -80˚C. Plasma cards and unstained tumor pathology slides were shipped at 2-3 months intervals to US labs for NOHA and immunohistochemistry (IHC) ER testing. Statistical difference was set at p<0.01, with NOHA and IHC assay operators blinded to patient clinical status. **Results:** Our early data show correlation between NOHA levels and ER IHC results, providing a means to distinguish ER^- from ER^+ breast cancer in the low-resource setting. Plasma cards stored at -80˚C for up to 3 months retained NOHA stability in assays involving a proprietary antibody-based ELISA, and by LC-MS. **Conclusions:** This study suggests the clinical utility of NOHA as a cost-effective, accessible replacement for standard IHC testing in determining ER status among breast cancer patients in LMICs, promising to extend access to cost efficient and available hormonal agents and improving outcomes and quality of life. The present study provides foundational knowledge for broader studies of NOHA utility in global breast cancer control, as well as in ongoing development of NOHA rapid-testing technologies. Research Sponsor: UNiversity of New England Seed, and Research Infrastructure Funds.

Distinction in plasma NOHA between ER^- and ER^+ breast cancer patients diagnosed with stage I, low-grade tumors, at n = 65/group.

Tested conditions	NOHA (nM) Mean ± Standard Deviation
ER^- patients, low-grade, stage I	2.51 ± 1.03*
ER^+ patients, low-grade, stage I	6.28 ± 0.72
Healthy controls	7.04 ± 0.49

*Represents significance from ER+/healthy controls, p < 0.01.

Low TMB as predictor for additional benefit from neoadjuvant immune checkpoint inhibition in triple-negative breast cancer. *First Author: Thomas Karn, Goethe-Universität Frankfurt, UCT-Frankfurt-Marburg, Frankfurt, Germany*

Background: It is commonly anticipated that a high tumor mutational burden (TMB) is a predictor of response to immune checkpoint blockade (ICB). We previously showed that triple-negative breast cancer (TNBC) from the GeparNuevo study with high TMB displayed increased response both to neoadjuvant chemo-ICB with durvalumab but also to chemotherapy alone, with no significant interaction with treatment arm (Karn et al. Ann Oncol 2020). In contrast, we also observed that cases with very low TMB more often displayed a pCR after treatment with chemo-ICB than with chemotherapy alone. This may in fact suggest a benefit of ICB to those TNBC with rather low TMB. **Methods:** We have analyzed the distant disease-free survival (DDFS) of GeparNuevo patients according to TMB and treatment arm (neoadjuvant chemotherapy plus durvalumab or chemotherapy plus placebo). For TMB (mut/Mb) we applied the identical cutoff of the upper tertile as in our previous analysis. **Results:** The median follow-up of the time-to-event data was 43.7 months. Data of TMB was available in 149 of 174 patients. We found that within the high-TMB tumors (durvalumab: n=27; placebo: n=23), DDFS was similar between both arms of the trial (durvalumab vs. placebo: HR (hazard ratio) 0.95 [95%CI 0.19-4.69], p=0.95). Strikingly however, within the low-TMB group (durvalumab: n=47; placebo: n=52) we observed a significantly better DDFS in the durvalumab-chemotherapy combination arm, in contrast to the arm treated only with chemotherapy (durvalumab vs. placebo: HR 0.23 [95%CI 0.06-0.79], p=0.02; interaction test for TMB and treatment arm p=0.17). The observation was also robust to alternative TMB cutoffs. Similar results were obtained for invasive disease-free survival. **Conclusions:** Our results show, in contrast to other published data, that patients with early TNBC and low TMB/neoantigen counts may benefit from short-term neoadjuvant durvalumab treatment, while for those with high TMB, durvalumab plus chemotherapy does not improve efficacy over chemotherapy alone. Peripheral lipidomics analyses with ensemble machine learning predict response to neoadjuvant therapy in breast cancer. *First Author: Jiani Wang, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Neoadjuvant therapy (NAT) is critical in the therapeutic strategy for locally advanced breast cancer (BC) patients. Biomarkers to predict the pathologic complete response (pCR) and to screen beneficial responders need to be urgently explored. Lipidomics is a high-throughput analysis technique, which has potential applications for peripheral biomarkers' detection to overcome the difficulty in serial pathological biopsies and tumor heterogeneity. Machine learning is a method for mining high-dimensional information with high group and low intermolecular correlation. Here we construct multidimensional models with machine learning approach combining clinical clinicopathological and lipidomics data to predict NAT response. **Methods:** Plasma samples were collected from 119 BC patients before after two cycles of NAT. Peripheral lipidomic profiles at multiple levels of lipid composition, concentration, chain length, and saturation were dynamically monitored by using absolute quantitative lipidomics. Responders (pCR) and non-responders (non-pCR) groups were randomly sampled in a 1:1.5 ratio for subsequent analysis. Screening of candidate lipidomic biomarkers were performed according to the criteria "VIP>1, FC>2 or FC<0.5 and p<0.05". Above feature screening were validated by using ensemble machine learning algorithms (Logistic regression, Random forest and Support vector machine). Pearson correlation coefficients were calculated for the expressions of candidate biomarkers. Multidimensional prediction models with the logistic regression algorithm were constructed by correlating candidate lipidomics features with clinicopathologic phenotypes prospectively collected with baseline and dynamic changes. The performance of the models constructed above were assessed by ROC analysis. **Results:** A total of 8 major classes, 39 subclasses, and 2292 molecules of lipid metabolites were identified in the 235 plasma samples. Most of the candidate biomarkers had lower correlations, indicating lower overlapping and more optimal combination of panels. The prediction models constructed by baseline correlating candidate lipidomics features with ensemble machine learning achieved an Area under the Curve (AUC) of 0.84 for the training set and 0.72 for the validation set with the accuracy 0.84, the specificity 0.92, and the sensitivity 0.71 when the cutoff value is 0.57.The prediction models constructed with lipidomics dynamic changes also achieved good performance. **Conclusions:** The study suggested a possibility that peripheral lipidomics provided a potential tool to develop multidimensional models with ensemble machine learning for predicting response to NAT for BC patients with good discrimination power, which might guide individual optimal NAT strategies and avoid unnecessary treatment. Research Sponsor: Chinese Society of Clinical Oncology (CSCO) Roche Oncology Research Fund Program(Y-Roche2019/2-0046) and Chinese Society of Gerontology and Geriatrics Clinical Oncology Research Program (YXJL-2018-0067-0058).

Biomarkers for response to immunotherapy in triple-negative breast cancer: Differences between survival and pCR biomarkers. *First Author: Carsten Denkert, Institute of Pathology, Philipps-University Marburg and University Hospital Marburg, Marburg, Germany*

Background: Immunotherapy is entering clinical practice as a promising new neoadjuvant therapeutic approach in triple-negative breast cancer, and it is important to identify biomarkers to focus this therapy on those patients that have the highest benefit. Interestingly, an improved survival outcome is observed in pCR and non-pCR patients, which raises the hypothesis that biomarkers might also be different for pCR prediction as well as prognosis. In this study, we investigated this hypothesis in the neoadjuvant GeparNuevo trial. **Methods:** A total of 174 patients were randomized to receive neoadjuvant chemotherapy with durvalumab vs. placebo. HTG EdgeSeq mRNA analysis was performed for a total of 2549 genes in 162 pretherapeutic core biopsies. In addition, tumor-infiltrating lymphocytes (stromal and intratumoural) as well as PD-L1 protein expression was evaluated by IHC. We systematically compared the distant disease-free survival (DDFS) of 5 predefined gene signatures (including the GeparSixto immune signature) as well as 12 single mRNA markers identified in previous projects between treatment arms using univariate Cox proportional-hazard regression analyses. In addition, exploratory biomarker analyses were performed. **Results:** The PSIP1 gene expression (per 1 unit hazard ratio [HR]: 0.58 95%CI 0.41-0.83; p=0.002), TAP1 (per 1 unit HR: 0.68 95%CI 0.48-0.95; p=0.025) as well as stromal TILs (sTILs) (per 10% HR: 0.73 95%CI 0.56-0.95; p=0.019) were significant for improved DDFS in the complete cohort. In the placebo arm PSIP1 (HR 0.50 95%CI 0.29-0.87; p=0.014) as well as sTILs (HR 0.73 95%CI 0.53-0.99; p=0.044) were significant for improved DDFS. In the durvalumab arm, the gene expression of PSIP1 (HR 0.54 95%CI 0.31-0.94; p=0.029), PD-L1/CD274 (per 1 unit HR: 0.41 95%CI 0.21-0.77; p=0.006), CD38 (per 1 unit: HR 0.52 95%CI 0.29-0.92; p=0.026) as well as the GeparSixto immune signature (per 1 unit HR: 0.51 95%CI 0.27-0.97; p=0.041) were significant for improved DDFS, with a positive test for interaction with treatment arm for PD-L1/CD274 (interaction p=0.020). Additional analyses, including multivariate Cox regressions for DDFS as well as systematic comparisons for biomarkers for DDFS and for pCR, will be presented. **Conclusions:** Our analysis suggests that biomarkers for immune response are linked to improved survival with neoadjuvant durvalumab therapy and that in this setting, survival biomarkers are not identical to pCR biomarkers. The results are a basis for a further dissection of the contribution of pCR to survival effects of immunotherapy. Real-world outcomes of patients with human epidermal growth factor 2 (HER2)–positive breast cancer receiving neoadjuvant therapy without adjuvant ado-trastuzumab emtansine (T-DM1). *First Author: Massimo Di Iorio, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: HER2-positive early-stage breast cancer (EBC) treated with neoadjuvant chemotherapy and HER2-targeted therapy has favourable outcomes, especially for those attaining pathologic complete response (pCR). Among those with residual invasive disease (RD), outcomes are variable. Replacing adjuvant trastuzumab with ado-trastuzumab emtansine (T-DM1) reduces the risk of recurrence, but increases toxicity and cost. The magnitude of benefit of T-DM1 may be small among patients with RD and favourable prognostic features. Here we report on real-world outcomes of patients with HER2-positive EBC treated with neoadjuvant therapy without adjuvant T-DM1. **Methods:** We performed a single institution, retrospective review of HER2-positive EBC treated with neoadjuvant chemotherapy and trastuzumab between January 1st, 2012 and February 1, 2021. We excluded patients who received adjuvant T-DM1. We collected clinical and pathologic characteristics, treatment data, and outcomes events. We estimated 3-year disease-free survival (DFS), a validated endpoint in HER2-positive EBC, using Kaplan-Meier with recurrence and/or death as events. Outcomes were reported in subgroups based on known prognostic factors. The study was approved by the University Health Network Research Ethics Board. **Results:** The study comprised 193 patients with a median follow-up of 30 months. The majority (n=160, 83%) received neoadjuvant anthracycline and taxane-based chemotherapy; 42 (22%) received neoadjuvant pertuzumab. All received adjuvant trastuzumab. Median age was 53 years (range 25-87), 113 (59%) patients had estrogen receptor (ER) positive disease, and 82 (42%) had pCR. In total, 16 events were observed, of which 13 (81%) were distant recurrences (including 5 (31%) in the brain) and 3 (19%) were locoregional. Of these, 14 (88%) occurred in the first 3 years of follow-up. Estimated 3-year DFS was 98.6% in patients with pCR, and 85.4% in patients with RD. Patients with ER positive disease had excellent outcomes, regardless of pathologic nodal (ypN) status. The highest risk of recurrence was in ER negative and ypN positive disease (Table). **Conclusions:** Real-world outcomes of patients with HER2-positive EBC treated with neoadjuvant therapy without adjuvant T-DM1 are favorable, including those with RD if ER positive. The expected benefit of adjuvant T-DM1 in this group is therefore likely to be small. Patients with ER- disease had poorer outcomes irrespective of nodal status. Further research to identify patients with RD for whom the benefit of T-DM1 is unlikely to merit its added toxicity and cost is warranted. Research Sponsor: None.

Identification of transcriptional changes with MammaPrint and BluePrint in early-stage breast cancer after neoadjuvant chemotherapy. *First Author: Alice P. Chung, Cedar-Sinai Medical Center, Los Angeles, CA*

Background: The use of neoadjuvant chemotherapy (NAC) in patients with early-stage breast cancer (EBC) increases the opportunity for genomic testing which can help predict treatment response and optimize outcomes. MammaPrint (MP) classifies tumors as having a Low Risk (LR) or High Risk (HR) of distant recurrence. MP with BluePrint (BP), a molecular subtyping assay, categorize tumors as Luminal A (MP LR), Luminal B (MP HR), HER2, or Basal-Type. Our recent analysis comparing matched pre- and post-NAC tumors found 25% of pre-NAC Luminal B tumors changed to Luminal A post-NAC, which corresponded with improved 5-year outcomes compared with patients who remained Luminal B. Here, we report differential gene expression (DGE) and pathway analyses in these matched tumors that may distinguish the different responses. **Methods:** Among the patients with EBC who received NAC at Cedars Sinai Medical Center between 2007-2016, 38 with residual disease (RD) had paired pre- and post-NAC tissues. In patients with Luminal tumors, 8 were Luminal B pre- and post-NAC (HR/HR), and 7 were Luminal B pre-NAC but changed to Luminal A post-NAC (HR/LR). Limma R package was used for quantile normalization and DGE analyses. Differentially expressed genes (DEG) with < 0.05 false discovery rate and > 2-fold change were considered significant. Functional pathway enrichment was performed using Metascape. **Results:** Within HR/LR tumors, a DGE analysis identified 104 DEGs in post-NAC tissues relative to pre-NAC, with changes in cell cycle/proliferation pathways. Interestingly, there was a more robust transcriptional change in HR/HR tumors, with 956 DEGs between post- and pre-NAC samples, with enrichment of extracellular matrix organization, angiogenesis, and wound healing pathways. Notably, immune pathway enrichment was in both HR/LR and HR/HR groups, although the nature of enrichment differed. Immune deconvolution identified significant increases in activated myeloid dendritic cells (DC) and CD8+ T cells in HR/LR but not in HR/HR post-NAC tumors, suggestive of a host immune response. **Conclusions:** Although post-NAC RD correlates with poor prognosis, even in Luminal tumors, these data suggest gene expression profiling may distinguish a subset with good prognosis. Using matched samples, we assessed the transcriptional differences in tumors that changed MP risk (HR/LR) with tumors that stayed MP HR post-NAC (HR/HR). Overall, HR/HR tumors had a larger transcriptional response with metastatic-related pathway enrichment. Given these patients with HR/HR tumors displayed worse outcomes, pathway changes may indicate resistance and patients may need additional therapy. Differential changes in immune cells between HR/HR and HR/LR tumors were also observed. The activated immune response in HR/LR tumors may be a biomarker for therapy response and improved outcome and will be the focus of further evaluation. Research Sponsor: Agendia Inc.

Association of facility volume with pathologic complete response and overall survival in patients with non-metastatic breast cancer. *First Author: Sung Jun Ma, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: High facility volume has been previously shown to be associated with a higher likelihood of pCR among patients with breast cancer following neoadjuvant chemotherapy. However, factors underlying the association of high facility volume with pCR and the impact of facility volume on survival remain unclear. We performed an observational cohort study to investigate the association of overall survival (OS) with facility volume and identify variables associated with high facility volume. **Methods:** The National Cancer Database (NCDB) was queried for women diagnosed between 2010 and 2017 with non-metastatic breast cancer treated with neoadjuvant chemotherapy followed by surgery. Facility volume was stratified by tertiles of low, intermediate, and high. Logistic and Cox multivariable analyses (MVA) were performed to evaluate factors associated with facility volume and OS, respectively. Propensity score matching was used to reduce selection bias. **Results:** A total of 105,804 women met our inclusion criteria (low facility volume: n=6,172; intermediate facility volume: n=20,199; high facility volume: n=79,433). The median follow up was 49.2 months (IQR 32.7-71.3). On logistic MVA, both intermediate (adjusted odds ratio [aOR] 1.24, 95% confidence interval [CI] 1.14-1.35, p<0.001) and high (aOR 1.53, 95% CI 1.42-1.65, p<0.001) facility volumes were associated with pCR. On Cox MVA, high (adjusted hazards ratio [aHR] 0.89, 95% CI 0.83-0.96, p=0.001), but not intermediate (aHR 0.97, 95% CI 0.90-1.04, p=0.40), facility volume was associated with improved OS. Similar findings were noted in 18,671 matched pairs between high versus low or intermediate facility volumes (HR 0.90, 95% CI 0.85-0.94, p<0.001). On logistic MVA, patients were more likely to receive treatments at high volume facilities if they were academic (adjusted odds ratio [aOR] 5.47, 95% CI 5.24-5.71, p<0.001), African American (aOR 1.25, 95% CI 1.20-1.30, p<0.001) with private insurance (aOR 1.13, 95% CI 1.04-1.22, p=0.005), and higher tumor grades (grade 2: aOR 1.10, 95% CI 1.03-1.18, p=0.008; grade 3: aOR 1.12, 95% CI 1.05-1.20, p=0.001). Patients were less likely to undergo treatments at high volume facilities if they reside in urban (aOR 0.63, 95% CI 0.60-0.66, p<0.001) or rural (aOR 0.75, 95% CI 0.67-0.85, p<0.001) areas with limited education (aOR 0.90, 95% CI 0.87-0.93, p<0.001), had government-led insurance (aOR 0.87, 95% CI 0.80-0.94, p=0.001), and had time interval of <180 or >240 days between diagnosis and surgery (aOR 0.92, 95% CI 0.90-0.95, p<0.001). **Conclusions:** To our knowledge, this is the largest study using a nationwide oncology database to report the association of high facility volume with pCR and improved OS, with various patient demographics associated with high facility volume. Our findings suggest an integral role of facility volume on pCR and survival for breast cancer. Research Sponsor: None.

Dapagliflozin associated to sacubitril/valsartan and relationship with cardioprotection in human cardiac cells exposed to doxorubicin and HER2-blocking agents through MyD88, NLRP3 mediated pathways. *First Author: Nicola Maurea, Istituto Nazionale per lo Studio e la Cura dei Tumori "Fondazione G. Pascale"-IRCCS, Naples, Division of Cardiology, Naples, Italy*

Background: The cumulative incidence of cardiac events in breast cancer patients treated with anthracycline and trastuzumab at 1 year after the diagnosis of cancer was 16.4%, at 2 years 23.8 %, and at 3 years 28.2%. Sodium glucose co-transporter 2 inhibitors, a new class of antidiabetic drugs, has shown measurable benefits in reduction of HF hospitalization and cardiovascular mortality. LCZ696 (neprilysin inhibitor + valsartan) as able to lower the risk of cardiovascular events in chronic heart failure. We hypothesize that dapagliflozin associated to LCZ696 could exerts cardioprotective effects in cellular models of doxorubicin and trastuzumab-induced cardiotoxicity. **Methods:** Human cardiomyocytes (HL-1 cells) were exposed to subclinical concentration of doxorubicin and trastuzumab (100 nM) alone or in combination with dapagliflozin (50 nM) or LCZ696 (at 100 mM) or both in combination for 48h. Cell viability, apoptosis and necrosis were performed. Quantification of malondialdehyde, 4-hydroxynonenal and intracellular Ca2+ were performed through spectrophotometric methods. Anti-inflammatory studies were also performed (expression of NLRP3 inflammasome, TLR4/MyD88 pathways, nuclear expression of NF-kB). Intracellular concentration of IL-1α, IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, IL17-α, IL-18, IFN-γ, TNF-α, G-CSF, and GM-CSF were also performed. **Results:** Dapagliflozin and LCZ696 increased synergistically the cell viability during exposure to doxorubicin and trastuzumab. Combination of dapagliflozin and LCZ696 reduces intracellular Ca2+ overload (-68,4% vs cells treated only to anticancer drugs; p<0,001), lipid peroxidation (mean reduction of 57-63,4 % compared to cells exposed only to anticancer drugs; p<0,05). The expression of MyD88, NLRP3 and NF-kB were strongly reduced after treatment with dapagliflozin and LCZ-696 (-52,5, -43,7 and -57,3 % vs cells exposed only to anticancer drugs, respectively; p<0.05). Notably, combination of dapagliflozin and LCZ-696 enhanced the expression Of IL-10; contrary, pro-inflammatory cytokines were reduced, such as IL-1α, IL-1β, IL-6, IL-8, IL17-α and IL-18 (p<0.05). **Conclusions:** During exposure to doxorubicin and trastuzumab, dapagliflozin associated to LCZ-696 exerts additive cardioprotective and anti-inflammatory effects compared to each drug alone. Their properties are mediated by the reduction of iCa2+ content that consequently reduces peroxidation and NLRP3- MyD88 expression. These results indicating the potential use of SGLT-2 inhibitors associated to LCZ696 in preclinical models of cardiotoxicity. Research Sponsor: Ricerca Corrente.

Primary analysis of MUKDEN 01: A multicenter, single-arm, prospective, phase 2 study of neoadjuvant treatment with pyrotinib and letrozole plus dalpiciclib in triple-positive breast cancer. *First Author: Nan Niu, Shengjing Hospital of China Medical University, Shenyang, China*

Background: Despite the use of multiple lines of targeted therapy has revolutionized treatment for HER2-positive breast cancer, these methods still have limited efficacy for triple-positive breast cancer (TPBC), which calls for persistent exploration for optimized treatment strategy. This MUKDEN-01 prospective trial aimed to evaluate the efficacy of oral, chemo-sparing neoadjuvant therapy with pyrotinib, letrozole and dalpiciclib, which also meet the need for treatment convenience under COVID-19 pandemic, for patients with TPBC. **Methods:** The MUKDEN 01 was an investigator-initiated, multicentre, single arm, prospective phase II trial, which was performed at twelve hospitals in China(NCT04486911). Treatment-naïve patients with stage II-III tumors that according to the AJCC 8th edition criteria were eligible. Patients were treated with each cycle of 4 weeks with oral administration of pyrotinib 320 mg, and letrozole 2.5mg once daily for 4 weeks, and dalpiciclib 125 mg once daily for three weeks, followed by one week off, for five cycles. The primary endpoint was pathological complete response (pCR) in the breast and axilla (ypT0/is ypN0). Secondary endpoints included pCR in the breast (ypT0/is). residual cancer burden (RCB) score, Ki67 index change at surgery compared with baseline, and safety. Safety was analyzed in all patients, who received treatment. The study is still ongoing, and the enrollment has been completed. **Results:** Between June 20, 2020 and Sep. 6, 2021, 68 patients were screened for eligibility and 61 patients were recruited into this first stage of study. After surgery, 18 (29.5%, 95% CI 18.5-42.6) out of 61 patients achieving tpCR(ypT0/is ypN0), 21 (34.4%, 95% CI 22.7-47.7) patients achieved bpCR(ypT0/is). The patients with excellent pathologic response (RCB 0-1) to the combined therapy accounted for 54.1% (33/61, 95% CI 40.9-66.9). Mean Ki67 expression was reduced from 38.7% (95%CI: 31.3-46.0) at baseline to 19.3% (95% CI:13.6-25.0; p=0.0001) in the surgical samples. The most frequent grade 3 AE were neutropenia (35 [57%]), leukopenia (13 [21%]), diarrhea (9 [15%]) and oral mucositis (4 [7%]). There were five grade 4 neutropenia (8%) and one grade 4 increased AST (2%), but without other SAE and death throughout the study. **Conclusions:** Neoadjuvant therapy with pyrotinib, letrozole and dalpiciclib yielded a pCR rate comparable to standard chemotherapy plus dual HER2 blockade in TPBC patients. The combined therapy was also well-tolerated and provided a chemo-sparing neoadjuvant approach for TPBC patients. To our knowledge, this is the first study to evaluate the therapeutic efficacy of a chemo-free neoadjuvant treatment with HER2 TKI pyrotinib and letrozole plus CDK4/6 inhibitor dalpiciclib for TPBC patients. Further validation in a large-scale randomized controlled trial is warranted. Clinical trial information: NCT04486911. Research Sponsor: None.

Neoadjuvant giredestrant (GDC-9545) plus palbociclib (P) versus anastrozole (A) plus P in postmenopausal women with estrogen receptor–positive, HER2-negative, untreated early breast cancer (ER+/HER2– eBC): Final analysis of the randomized, open-label, international phase 2 coopERA BC study. *First Author: Peter A. Fasching, University Hospital Erlangen, Comprehensive Cancer Center (CCC) Erlangen-EMN, Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany*

Background: Endocrine therapy (ET) is the therapeutic mainstay for ER+ BC. Giredestrant is a highly potent, nonsteroidal, oral, selective ER antagonist and degrader (SERD) which has demonstrated robust ER occupancy, is well tolerated, and has previously shown encouraging antitumor activity as monotherapy and in combination with P in metastatic BC. coopERA BC (NCT04436744) evaluated giredestrant in eBC and met its primary endpoint, highlighting superior Ki67 suppression with single-agent giredestrant vs A at Week 2. Giredestrant was well tolerated. Here, we report the final analysis. **Methods:** Eligible patients (pts) with measurable ER+/HER2– untreated eBC and baseline Ki67 score ≥5% (202 planned) were randomized 1:1 to receive, on Days 1–14 of a neoadjuvant window-of-opportunity phase, 30 mg oral daily (PO QD) giredestrant or 1 mg PO QD A followed by a 16-week neoadjuvant phase of QD giredestrant or A for four 28-day cycles with 125 mg PO P on Days 1–21. Randomization was stratified by tumor size, baseline Ki67 score, and progesterone receptor status. Endpoints assessed here included Ki67 suppression from baseline to surgery, complete cell cycle arrest (CCCA; Ki67 ≤2.7%) at surgery, objective response rate (ORR), and safety. **Results:** At final analysis (cutoff: Nov 24, 2021), 112 and 109 pts were randomized to the giredestrant and A arms, respectively (median age: 62 years each; stage I/IIa disease: 60% vs 54%). Consistent with the primary analysis, greater suppression of Ki67 was observed at surgery with giredestrant + P (–81% [95% confidence interval (CI): –86%, –75%]) vs A + P (–74% [95% CI: –80%, –67%]). Similarly, greater CCCA was achieved at surgery with giredestrant + P (20%) vs A + P (14%). ORR was similar between the two arms (giredestrant + P: 50% [95% CI: 40%, 60%]; A + P: 49% [95% CI: 39%, 59%]). ET-related adverse events (AEs) were non-serious and occurred at similar rates between the two arms. Related Grade ≥3 AE rates were also similar at 6% each. Interruption/withdrawal of ET due to AEs was low and similar for both arms. **Conclusions:** In this final analysis of coopERA BC, the greater suppression of Ki67 with giredestrant vs A observed at Week 2 in the primary analysis was maintained at surgery, and safety data remained consistent with the known safety profile of giredestrant. coopERA BC is the first randomized study to show superior antiproliferative activity of an oral SERD (giredestrant) over an aromatase inhibitor (A) in ER+/HER2– eBC; studies are ongoing to further assess giredestrant's clinical benefit. Clinical trial information: NCT04436744. Research Sponsor: F. Hoffmann-La Roche Ltd.

Collaborative federated learning behind hospitals' firewalls for predicting histological complete response to neoadjuvant chemotherapy in triple-negative breast cancer. *First Author: Jean Ogier du Terrail, Owkin, Paris, France*

Background: Triple-Negative Breast Cancer (TNBC) is characterized by high metastatic potential and poor prognosis with limited treatment options. Neoadjuvant chemotherapy (NACT) is the standard of care in non-metastastic setting due to the ability to assess pathologic responses providing important prognostic information and guidance in adjuvant therapy decisions. However, the histological response heterogeneity is still poorly understood. We investigate the use of Machine Learning (ML) to predict from diagnosis Whole-Slide Images (WSI) of early TNBC the positive histological Complete Response (pCR) to NACT on surgical specimens. To overcome the known biases of small scale studies while respecting data privacy, we conduct a study in a multi-centric fashion behind hospitals' firewalls using collaborative Federated Learning (FL). Thereby allowing access to enough TNBC data to sustain a complete response heterogeneity investigation. **Methods:** We collected in both comprehensive cancer centers: Centre Léon Bérard (A)(n=99) and Institut Curie (B) (n=420), WSI of biopsies performed at diagnosis and relevant clinical variables. We use traditional Multiple Instance Learning pipelines by tiling the matter on each WSI with a pre-trained Neural Network (NN). We train a second NN to predict the NACT pCR using the mean feature of each WSI. ML trainings are performed using either one cohort in isolation (NN Local) or both cohorts using FL. We compare the performance of this federated WSI based model to the best clinical model (Clin.) simulating clinical practice (using grade and Tumor-Infiltrating Lymphocytes (TILs) percentage) on both centers. **Results:** Performance of models to predict NACT pCR (AUC). All results are evaluated in 5 repeated 4-folds cross validations. **Conclusions:** The final ML model, that was trained in a privacy preserving fashion on both hospitals, provides better prediction of NACT pCR than current clinical standards. This study shows that 1. Not all relevant information is routinely extracted from WSI and 2. Non simulated FL is possible in Healthcare and gives better results than siloed studies on open medical questions. Additional interpretability results of the model show that it has rediscovered known biomarkers such as TILs and apocrine tumor cells without any tile-level annotation, and hints at potential new biomarkers. Research Sponsor: Owkin, French Public Investment Bank (BPI France).

Methods	A (n=79)	B (n=360)
NN FL	75.3, 95% CI [71.6, 78.9]	60.2, 95% CI [57.7, 62.7]
NN Local A	70.4, 95% CI [66.9, 73.9]	58.1, 95% CI [55.4, 60.8]
NN Local B	68.9, 95% CI [64.5, 73.2]	56.9, 95% CI [54.6, 59.3]
Grade + TILs	68.5, 95% CI [65.0, 72.0]	56.9, 95% CI [54.8, 59.0]

The remaining WSI are used to test the final models. On A (n=20), NN FL performs on par with Clin. 61.5 vs 66.7 AUC (comparison p-value > 0.05 with z-test), on B (n=60) NN FL performs significantly better than Clin. 78.0 vs 63.2 AUC (p-value 3.38e-2).

Improved pathologic complete response rates for triple-negative breast cancer in the I-SPY2 Trial. *First Author: Douglas Yee, Masonic Cancer Center, University of Minnesota, Minneapolis, MN*

Background: The I-SPY2 Trial evaluates multiple investigative agents in neoadjuvant breast cancer therapy with the primary endpoint of estimated pathologic complete response (pCR) rate. As a platform phase 2 trial it utilizes an adaptive design to compare new regimens with control chemotherapy (weekly paclitaxel followed by AC). **Methods:** Specific regimens are assigned based on clinically relevant signatures, including triple negative breast cancer (TNBC). Drug regimens graduate from the trial when the predicted pCR rate in any signature meets the prespecified threshold of 85% probability of success in a hypothetical 300-patient, 1:1 randomized, phase 3 trial. The strong correlation between pCR rate and event free survival has been reported. To establish the benefit of administering investigational agents in combination with control weekly paclitaxel x 12 in TNBC, we report estimated pCR rates for the first 7 investigational agents. **Results:** TNBC accounted for 37% (363/987) of enrolled patients. Only veliparib and carboplatin (VC) and pembrolizumab (Pembro) met the graduation criteria for TNBC. However, compared to control chemotherapy, each drug tested in TNBC resulted in a numerically superior pCR rate compared to control. These findings imply that stratification of TNBC by response-predictive biomarkers may lead to improved pCR rates. For example, we have used gene expression profiling to further refine TNBC classification into Immune enhanced (Immune+), Immune-/DNA Repair Deficient (DRD)+, and Immune-/DRD- classes. TNBC identified as immune enhanced (63%) have an 89% pCR rate to pembrolizumab, while VC is less effective with pCR rate of 71%. Similarly, Immune-/DRD+ (11%) identifies TNBCs with a 80% pCR rate to VC, while pembrolizumab's pCR rate in this group is only 33%. For tumors that are neither immune enhanced or DRD-positive (Immune-/DRD-; 25%) show numerically improved pCR rates for neratinib (20%), MK2206 (25%), ganitumab (24%), and ganetespib (22%) compared to control (12%). pCR rates for VC (10%) and pembrolizumab (20%) in this group were similar to drugs that did not graduate. For TNBC, many agents in I-SPY2 showed numerically improved pCR rates compared to conventional chemotherapy even when they did not meet our specified definition of graduation. **Conclusions:** Further refinement of TNBC signatures should yield improved therapeutic strategies while also sparing women unnecessary systemic therapy. Clinical trial information: NCT01042379. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Pharmaceutical/Biotech Company.

Distribution of breast cancer molecular subtypes within receptor classifications: Lessons from the I-SPY2 Trial and FLEX Registry. *First Author: Jaeyoon Cha, University of California San Francisco, San Francisco, CA*

Background: Expression-based molecular subtypes of breast cancer (BC) predict tumor behavior and therapeutic response. Subtype distributions by age and sociodemographics can inform strategies for BC screening, treatment, and prognosis. The conventional approach, adopted by NCI's Surveillance, Epidemiology, and End Results (SEER) Program, uses HR and HER2 to label: "triple negative" (HR-HER2-), "HER2-enriched" (HR-HER2+), "luminal A" (HR+HER2-), and "luminal B" (HR+HER2+). However, immunohistochemical (IHC)-based receptor labels may not reflect clinically and epidemiologically relevant molecular subtypes that share the same nomenclature, e.g., luminal B. **Methods:** We compared IHC labels by HR/HER2 to molecular subtypes by MammaPrint (MP) and BluePrint (BP) for patients in the phase II neoadjuvant I-SPY2 TRIAL for high-risk, stage II-III BC (NCT01042379, n = 981) and in the multicenter, prospective FLEX Registry for stage I-III BC (NCT03053193, n = 5,679). **Results:** IHC labels were discordant with MP/BP in 52% of I-SPY2 and 43% of FLEX cases (Table 1). HR-HER2- had the highest concordance with basal-type (99% in I-SPY2, 88% in FLEX). HR+ labels had the least agreement with MP/BP: HR+HER2- tumors were molecularly luminal B and basal in 71% and 29% of I-SPY2 and 40% and 4% of FLEX cases, respectively. HR+HER2+ tumors were molecularly luminal A and HER2-type in 10% and 60% of I-SPY2 and 15% and 36% of FLEX cases, respectively. Of molecularly luminal B cases, only 14% in I-SPY2 and 7% in FLEX were HR+HER2+. **Conclusions:** IHC markers collected by population-based registries (SEER) enable BC surveillance. However, IHC labels cannot be used as surrogates for molecular subtypes by MP/BP, especially for luminal B tumors. Given the unmet need to improve management of luminal B BC, we anticipate the growing importance of molecular subtyping to inform treatment and epidemiological research. We propose that the BC research community work with SEER to update its IHC labels to avoid overlap with molecular subtype nomenclature and incorporate such modern classifications when available. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Pharmaceutical/Biotech Company.

Combined assessment of metabolic response and tumor infiltrating lymphocytes as a predictor of outcomes following neoadjuvant therapy for HER2-positive breast cancer: Results from the randomized PREDIX HER2 trial.

First Author: Alexios Matikas, Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden

Background: Abundance of tumor infiltrating lymphocytes (TIL) is prognostic in early HER2-positive breast cancer (BC). Response to neoadjuvant therapy (NAT) according to positron emission tomography combined with computed tomography (PET-CT) has been shown to predict pathologic complete response (pCR). There is paucity of data regarding long-term prognostication using PET-CT and the potential value of the combined assessment of both these biomarkers. **Methods:** PREDIX HER2 (NCT02568839) is a prospective randomized phase 2 trial that compared standard NAT (docetaxel, trastuzumab, pertuzumab) with trastuzumab emtansine, in patients with HER2-positive BC. Overall, 202 patients were included (197 evaluable) and the primary efficacy analysis showed no difference in pCR or event-free survival (EFS) between the two groups (Hatschek, JAMA Oncology 2021). Assessment with fluorine 18–labeled fluorodeoxyglucose PET-CT was performed at baseline and after 2 and 6 treatment cycles, and SUVmax was evaluated as a continuous variable. TILs were assessed at baseline biopsies according to guidelines from the International TIL Working Group (J.H.). The aim of this secondary analysis was to investigate the combined assessment of TIL and PET-CT as an early predictor of response to NAT. **Results:** Overall, 112 patients underwent baseline PET-CT and 109 after C2, whereas 173 had baseline TIL. In multivariable analysis, baseline SUVmax did not predict pCR (OR_{adj}= 1.04, 95% CI 0.97-1.12, p = 0.259) or EFS (HR_{adj}= 1.07, 95% CI 0.98-1.17, p = 0.117). In contrast, higher SUVmax at C2 predicted lower pCR (OR_{adj}= 0.65, 95% CI 0.48-0.87, p = 0.005) and worse EFS (HR_{adj}= 1.18, 95% CI 1.04-1.34, p = 0.01). Baseline TIL > 10% (median cut-off) provided additional prognostic information to clinical parameters (stage and hormone receptor expression) and C2 SUVmax (LR-$\Delta\chi^2$ = 7.19, p = 0.007; OR_{adj}= 3.52, 95% CI 1.37 – 9.06, p = 0.009). 75% of patients with high TIL and C2 SUVmax < 2.49 achieved pCR, compared with 13.8% of those with low TIL and high C2 SUVmax and 39.1%-41.3% for the intermediate groups (p = 0.001). **Conclusions:** SUVmax after two cycles of NAT for HER2-positive BC is an independent predictor of both short- and long-term outcomes. A combined assessment with TIL may facilitate early selection of good responders for de-escalation and poor responders for alternative treatment strategies. Clinical trial information: NCT02568839. Prediction of pathologic complete response to neoadjuvant chemotherapy in breast cancer (SWOG S0800) using image analysis-based tumor infiltrating lymphocyte measurements.

First Author: Kim Blenman, Yale University, New Haven, CT

Background: Image analysis-based tumor infiltrating lymphocyte (TIL) quantitation methods are being developed to eliminate reader-to-reader variation in TIL assessment that hinders its clinical adoption as prognostic and chemotherapy response predictive marker. We evaluated the ability of an image analysis-based TIL score to predict pathologic complete response (pCR) and event free survival (EFS) in breast cancer. **Methods:** 113 pretreatment samples were analyzed from the SWOG S0800 trial that randomized stage IIB-IIIC HER-2-negative breast cancers to neoadjuvant chemotherapy with or without bevacizumab. TIL quantitation was performed on H&E sections using QuPath open-source software and a convolutional neural network cell classifier (CNN11). The digital easTILs% score was calculated as [sum of TIL Area (mm^2) / Stromal Area (mm^2)] x 100. Pathologist-read stromal TIL score (sTILs%) was defined using international guidelines. A previously validated threshold of easTILs% > 19.9% defined high easTILs% status. **Results:** Pretreatment easTILs% was significantly higher in cases with pCR compared to residual disease (RD) (means, 31% vs. 17%, p < 0.001). easTILs% high and low cases had pCR rates of 41% and 21% (p = 0.019), respectively. In logistic regression adjusting for other factors, easTILs% was prognostic for pCR as continuous score (p < 0.001) and as high *vs* low categories (p = 0.035). There was strong positive correlation between easTILs% and sTILs% (r = 0.606, p < 0.0001), and sTILs% was also predictive of pCR. The areas under the prediction curve (AUC) were 0.709 and 0.627 for easTILs% and sTILs%, respectively. There was no statistically significant interaction between easTILs% and bevacizumab benefit (p = 0.26), and higher easTILs% or sTILs were not associated with better EFS. **Conclusions:** Image analysis-based TIL quantification is predictive of pCR in breast cancer and had better pCR outcome discrimination than pathologist-read sTIL count. Artificial intelligence (AI)–powered spatial analysis of tumor-infiltrating lymphocytes (TIL) for prediction of response to neoadjuvant chemotherapy (NAC) in triple-negative breast cancer (TNBC).

First Author: Hee Jin Lee, Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

Background: Stromal TIL are a well-recognized prognostic and predictive biomarker in breast cancer. There is a need for tools assisting visual assessment of TIL, to improve reproducibility as well as for convenience. This study aims to assess the clinical significance of AI-powered spatial TIL analysis in the prediction of pathologic complete response (pCR) after NAC in TNBC patients. **Methods:** H&E stained slides and clinical outcomes data were obtained from stage I – III TNBC patients treated with NAC in two centers in Korea. For spatial TIL analysis, we used Lunit SCOPE IO, an AI-powered H&E Whole-Slide Image (WSI) analyzer, which identifies and quantifies TIL within the cancer or stroma area. Lunit SCOPE IO was developed with a 13.5 x 109 micrometer2 area and 6.2 x 106 TIL from 17,849 H&E WSI of multiple cancer types, annotated by 104 board-certified pathologists. iTIL score and sTIL score were defined as area occupied by TIL in the intratumoral area (%) and the surrounding stroma (%), respectively. Immune phenotype (IP) of each slide was defined from spatial TIL calculation, as inflamed (high TIL density in tumor area), immune-excluded (high TIL density in stroma), or desert (low TIL density overall). **Results:** A total of 954 TNBC patients treated from 2006 to 2019 were included in this analysis. pCR (ypT0N0) was confirmed in 261 (27.4%) patients. The neoadjuvant regimens used were mostly anthracycline (97.8%) and taxane (75.1%) -based, with 116 (12.1%) patients receiving additional platinum and 41 (4.3%) patients treated as part of immune checkpoint inhibitor or PARP inhibitor clinical trials. The median iTIL score and sTIL score were 4.3% (IQR 3.2 – 5.8) and 8.1% (IQR 6.3 – 13.4), respectively. The mean iTIL score was significantly higher in patients who achieved pCR after NAC (5.8% vs. 4.5%, p < 0.001), and a similar difference was observed with sTIL score (12.1%.1 vs. 9.4%, p < 0.001). iTIL score was found to remain as an independent predictor of pCR along with cT stage and Ki-67 in the multivariable analysis (adjusted odds ratio 1.211 (95% CI 1.125 – 1.304) per 1 point (%) change in the score, p <0.001). By IP groups, 291 (30.5%) patients were classified as inflamed, 502 (52.6%) as excluded, and 161 (16.9%) as desert phenotype. The patients with inflamed phenotype were more likely to achieve pCR (44.7%) than other phenotypes (19.8%, p < 0.001). **Conclusions:** AI-powered spatial TIL analysis could assess TIL densities in the cancer area and surrounding stroma of TNBC, and TIL density scores and IP classification could predict pCR after NAC. Final result for SAFIA trial for neoadjuvant palbociclib in patients with operable luminal breast cancer responding to fulvestrant.

First Author: Khalid A. Al-Saleh, Mcmaster University LTCC, Ancaster, ON, Saudi Arabia

Background: Luminal, human epidermal growth factor receptor 2 (HER2)-negative breast cancer (BC) encompasses the most common subtype of breast malignancies. Neoadjuvant strategies of operable BC are primarily based upon chemotherapy (CT), while neoadjuvant hormone therapy (NAHT) has not been well studied in the Middle East and North Africa (MENA) region. However, these tumors might respond poorly to neoadjuvant CT with significant side effects, emphasizing the need to identify patients who could be candidates for NAHT. **Methods:** The SAFIA trial is a prospective multicentre, international, double-blind, neoadjuvant phase-III trial using upfront 21-gene Oncotype DX Breast Recurrence Score assay (RS) <31) to select operable Luminal HER2-negative patients for induction hormonal therapy with Fulvestrant 500 mg +/– Goserelin (F/G) before randomizing responding patients to F/G + Palbociclib (Cyclin-Dependent Kinase 4/6 inhibitor / CDK 4/6) versus F/G + Placebo. The primary endpoint of this study was the complete pathologic response (pCR) rate. **Results:** A total of 354 patients were enrolled, leading to 277 patients treated with induction F/G. Of these, 253 responding patients were randomized to F/G fulvestrant with palbociclib or Placebo. Two hundred and thirty patients were evaluable for pathologic response. No statistically significant differences were identified in terms of pCR rates between F/G with palbociclib or placebo: 2% versus 7%, respectively. According to the radiologic responses post- induction F/G, the hormone sensitivity rate was 89.8%, while the clinical benefit of 8–9 months of neoadjuvant F/G was 96%. Safety in the MENA population was acceptable with a grade 3-4 neutropenia rate of 25% in the F/G plus palbociclib arm. The feasibility of performing the 21-gene breast recurrence score assay on core biopsy specimens was optimal in 96.4% of cases. **Conclusions:** The addition of palbociclib to neoadjuvant F/G did not show any additional benefit in terms of pathologic response, including pCR in neoadjuvant therapy of Luminal HER2-negative BC responding to induction F/G. The use of an upfront 21-gene assay appeared feasible on biopsy specimens, and the identification of tumors with RS<31 allowed to select endocrine sensitive patients, leading ultimately to a 96% clinical benefit with 8–9 months of F/G neoadjuvant therapy. Clinical trial information: NCT03447132. Research Sponsor: AstraZeneca, Pfizer, King Saud University.

Radiological response to induction F/G, according to hormone sensitivity (response > 0%) and RS levels (n = 266).

Radiological Response	RS [0 -10] N=34	RS [11 – 25] N=147	RS [26 – 30] N=25	Without RS N=60	Total

Harnessing artificial intelligence to automate delineation of volumetric breast cancers from magnetic resonance imaging to improve tumor characterization. *First Author: Ryle Zhou, Stanford University, Stanford, CA*

Background: Automated breast tumor identification and segmentation in magnetic resonance imaging (MRI) is a difficult and crucial area of study in breast cancer research. Artificial intelligence (AI) models are increasingly being developed for automated localization of lesions in imaging studies to facilitate quantitative assessment of features for improved diagnostic, prognostic and predictive performance. Such models have had success in detecting breast cancers in mammography, ultrasound and CT, but few have achieved three-dimensional (3D) volumetric tumor segmentation from breast MRI. The purpose of this study was to apply two state-of-the-art AI – specifically, deep learning (DL) - algorithms to 3D MRI breast cancer data and identify the higher performing algorithm for precise segmentation of breast tumors. **Methods:** We evaluated pre-treatment, T1 post-gadolinium contrast enhanced breast MRI from 222 patients with known breast cancers (n = 262). Images were split into training (n = 142), validation (n = 36), and hold-out test (n = 44) datasets. Two DL algorithms, U-Net and VAE-UNet, were trained to classify tumors on the training dataset across 1000 epochs. The output for each is a precise localization and segmentation of each tumor at the pixel level from every MRI image. We evaluated the performance of each algorithm using 5-fold cross-validation and testing on the validation and test sets. We calculated a dice accuracy score for each model as the performance comparison metric. **Results:** The highest dice accuracy score achieved on the validation dataset by generic U-Net was 83.38%, with an average across 1000 epochs of 62.41%. The highest dice accuracy achieved on the validation dataset by VAE-UNet was 82.62%, with an average across epochs of 61.28%. On our test dataset, the highest dice accuracy score achieved by U-Net was 93.09%, with an average across epochs of 66.31%, and the highest accuracy score for VAE-UNet was 90.98%, with average across epochs of 50.47%. Although U-Net appeared to perform slightly better than VAE-Unet for most cases, there were distinct cases where VAE-UNet outperformed U-Net (dice score up to 59% better than U-Net). Subsequent analysis indicated that VAE-UNet preferentially outperforms U-Net for tumors with low sphericity (p = 0.001). **Conclusions:** Our results suggest that U-Net is well suited for segmenting breast tumors from breast MRI in most cases, but that VAE-UNet outperforms U-Net when the tumor shapes are less spherical. Our findings could inform the choice of DL algorithms in research and clinical endeavors that rely on accurate breast cancer tumor segmentation. In particular, these two tools could be configured to facilitate tumor assessment from breast MRI in the clinical setting for: breast cancer screening in high-risk patient populations, pre-surgical planning, and monitoring of treatment response. Prediction of response to neoadjuvant therapy (NAT) in early breast cancer (EBC) at community hospitals: SimBioSys TumorScope Validation Study. *First Author: John R. Pfeiffer, SimBioSys, Inc., Chicago, IL*

Background: While most cancer patients are treated at community hospitals, specialized equipment, diagnostic tests, and therapeutic regimens are generally validated at academic settings. Here we present a novel approach to precision medicine to improve outcomes in breast cancer care in the community setting. TumorScope (TS) is a biophysical modelling platform that uses only pretreatment standard of care (SoC) diagnostic data (demographics, drug regimen, imaging (DCE MRI) & pathology) to construct a 3D model of the tumor. TS integrates models for tumor morphology, metabolism, vascularity, and drug behavior and simulates predicted tumor response longitudinally to NAT. With this information TS predicts the reduction in tumor volume and the pathological complete response (pCR), a surrogate marker of long-term outcome, to anticipated NAT in EBC. **Methods:** We performed a single center validation study to show the clinical applicability of TS. Patients at Northwest Community Healthcare that received NAT with corresponding pretreatment MRI were identified in a chart review. A validation set, independent from the training set, was generated from this list and data processed through TS (n=50). Pretreatment patient SoC diagnostic data was loaded into TS. TS predicted the weekly volumetric response throughout the treatment, and it simulated residual volume to predict pCR. The validation was performed using ground truth from post treatment assessment of pCR, radiographic volumes extracted from MRIs. **Results:** TS predicted pCR, prospectively defined as a simulated residual tumor volume <0.01 cm^3 or a 99.9% or greater reduction in tumor volume. Performance metrics of TS were calculated. TS tumor volume prediction accuracy had an area under the curve (AUC)=0.947 with sensitivity and specificity of 93.3% and 94.3% respectively. Performance was robust across all subtypes (See Table 1). TS predicted the reduction in tumor volume with a median absolute volumetric error of 3.4% as compared to radiographic volume from pre-surgery MRIs (n=50). **Conclusions:** In summary, TS accurately predicts patient-specific tumor volume reduction and pCR prior to NAT in EBC using only SoC pretreatment data, which could lead to a more personalized cancer care for the patient. Moreover, we demonstrate the feasibility of implementing TS at community hospitals. Research Sponsor: None.

Real-world effectiveness of prophylactic granulocyte colony-stimulating factor (G-CSF) early (week 1) and late (weeks 2-3) in the cycle for the prevention of febrile neutropenia (FN) among patients (pts) with breast cancer (BC) after high FN–risk chemotherapy (chemo). *First Author: Douglas W. Blayney, Stanford University, Stanford, CA*

Background: G-CSF mitigates chemotherapy-induced neutropenia (CIN) and reduces FN risk. G-CSF moves the nadir of absolute neutrophil count (ANC) earlier (to week 1) in the chemo cycle and shortens nadir duration (Crawford, NEJM 1991), suggesting the potential for suboptimal CIN protection early (week 1) in the chemo cycle. The relative FN risk in week 1 vs. weeks 2-3 of the cycle with G-CSF is unknown and was analyzed compared with no G-CSF in the real-world setting with high FN risk chemo. **Methods**: Using a database of administrative claims representing 100% of fee-for-service Medicare, we analyzed BC pts who initiated docetaxel (T), doxorubicin (A), or cyclophosphamide (C) monotherapy or combination therapy between 01/01/2015 – 12/31/2019. Sample pts included adults aged ≥ 65 years with continuous coverage in Medicare Parts A, B, and D for 6 months before and 20 days after chemo initiation. Pts were categorized as receiving vs. not receiving G-CSF therapy within 3 days after chemo. Rate of FN events starting in week 1 vs. weeks 2-3 in cycle 1 was calculated. We defined FN as an inpatient admission with a primary or secondary diagnosis of neutropenia and measured the interval between chemo initiation and FN admission. **Results**: Among 18,788 Medicare beneficiaries with BC treated with T, A, and/or C, 72% received G-CSF therapy. More pts receiving G-CSF were treated with ≥ 2 of T, A, and/or C compared to pts who did not receive G-CSF (71% vs. 51%). Overall FN incidence in cycle 1 was significantly lower among pts receiving G-CSF (4.0%; n=546) compared to pts not receiving G-CSF (8.8%; n=462) (p<0.0001). In pts with G-CSF, 81% (440/546) of all 1st-cycle FN events started in week 1 vs. 19% (106/546) in weeks 2-3. In pts not receiving G-CSF, the start of 1st-cycle FN events was more equally distributed: 41% (190/462) started in week 1 vs. 59% (272/462) in weeks 2-3. Results were robust to sensitivity analyses restricted to pts receiving ≥ 2 of T, A, and/or C. The rates of 1st-cycle FN events starting in weeks 1 and 2-3 with and without G-CSF following chemo initiation is shown below. **Conclusions**: Prophylactic G-CSF was highly effective for the prevention of FN in weeks 2-3, but relatively ineffective in week 1 of cycle 1 in the real-world setting, leaving pts largely unprotected during the first week. This represents an unmet medical need in week 1 of the cycle, despite use of G-CSF. Clinical trial information: NCT03294577. Research Sponsor: BeyondSpring Pharmaceuticals Inc.

	Pts receiving G-CSF (N=13,544)	Pts not receiving G-CSF (N=5,244)	p-value
Rate of FN events starting in week 1 of cycle 1	3.2% (n=440)	3.6% (n=190)	0.20
Rate of FN events starting in weeks 2-3 of cycle 1	0.8% (n=106)	5.2% (n=272)	<0.0001

Deep learning algorithm to predict pathologic complete response to neoadjuvant chemotherapy for breast cancer prior to treatment. *First Author: Rachel Choi, Dept. of Therapeutic Radiology, Yale School of Medicine, New Haven, CT*

Background: Pathologic complete response (PCR) to neoadjuvant chemotherapy (NAC) is associated with improved disease-free survival and overall survival in patients with breast cancer. Predicting PCR at the patient level prior to treatment initiation would allow physicians and patients to focus on therapies with the highest likelihood of success and minimize unnecessary toxicities from chemotherapy. We hypothesize that pre-treatment prediction of PCR is possible through a deep neural network algorithm trained on breast MRI imaging obtained prior to treatment. **Methods:** 126 tumors from patients treated with neoadjuvant chemotherapy for T3 stage breast cancer at a single institution from 2002 to 2006 were analyzed. In total, 3780 MRI slices were included. 3 MRI contrast phases (pre, immediate post, delayed post) from each slice were used as individual inputs to create separate model predictions of PCR. The 2-D CNN was trained over 50 epochs on the training set. The model was tested on the isolated test set (30% of samples). **Results:** Average model prediction accuracy over the total test set using a single phase of contrast (pre-, immediate post-, or delayed post-) was 90.4%. Concordance adjustment was conducted, with exclusion of slices that had produced discordant predictions across different contrast phase inputs. This resulted in an increase of overall model accuracy to 97.6%. Model accuracy was similar across subsets of age and tumor size despite differences in PCR rates. However, model accuracy was significantly lower in the triple-negative disease group. **Conclusions:** We demonstrate a deep neural network that accurately predicts PCR based on breast MRI imaging taken prior to NAC initiation. Our findings represent the promise of deep learning algorithms in providing personalized prognostic data for physicians and patients. Research Sponsor: Radiological Society of North America, U.S. National Institutes of Health, Yale School of Medicine.

Multimodal machine learning model prediction of complete pathological response to neoadjuvant chemotherapy in triple-negative breast cancer. *First Author: David Groheux, Hôpital Saint Louis, AP-HP, Paris, France*

Background: Triple negative breast cancer (TNBC) is a biologically and clinically heterogenous disease, associated with poorer outcomes when compared with other subtypes of breast cancer. In early-stage TNBC, surgery with curative intent remains the mainstay of therapy. Neoadjuvant chemotherapy is often given prior to surgery and achieving pathological complete response (pCR) has been associated with improved long-term outcomes in terms of progression-free survival (PFS) and overall survival (OS). There is thus high clinical interest in the ability to accurately predict pCR status using baseline data. **Methods:** A retrospective cohort of 57 patients with early-stage TNBC treated with neoadjuvant chemotherapy was analyzed to develop a machine learning-based algorithm predictive of pCR likelihood at the individual patient level. Multimodal baseline data were collected including clinical, biological (e.g., histology, genomic profile including CDC2, CDC20, KPNA2, MYBL2, complete blood count, Ki67), imaging data (baseline PET/CT scan), the radiology report and clinical outcomes data (pCR, PFS, OS). For each patient, tumors were segmented in 3D by an experimented nuclear physician using the SOPHiA Radiomics platform. Radiomics features were then extracted following the IBSI standards and then combined with the other data modalities. A filter-based variable selection method was applied before training several machine learning algorithms. The optimization criterion was the Area Under the ROC Curve (AUC). Due to the small size of the cohort, a nested leave-pair-out cross-validation approach was used to properly estimate the model performance. **Results:** The best result was obtained with the SVM algorithm with a linear kernel, reaching an AUC of 0.82, a precision of 71%, a sensitivity of 71% and a specificity of 70%. The features with highest weight in the algorithm were a mix of radiological, radiomics, biological and clinical features, highlighting the importance of a truly multimodal analysis. Indeed, withdrawing a specific data modality (e.g., radiomics features or biological features), led to a decrease of ~10% of the AUC. Patients were then stratified into two groups based upon their predicted pCR status. These two groups displayed a statistically significant difference in PFS ($p<0.001$), suggesting that baseline multimodal data analysis could help predict long-term outcomes. **Conclusions:** This proof of concept study suggests that machine learning applied to baseline multimodal data can help predict pCR status after neoadjuvant chemotherapy for TNBC at the individual patient level, as well as stratify patients to inform long-term outcomes. Patients that would be predicted as non-pCR could benefit from concomitant treatment with immunotherapy, or dose intensification. This algorithm will be further validated in a larger, multicentric cohort. Research Sponsor: None.

Neoadjuvant ipilimumab and nivolumab in combination with paclitaxel following anthracycline-based chemotherapy in patients with treatment resistant early-stage triple-negative breast cancer (TNBC): A single-arm phase 2 trial. *First Author: Sherene Loi, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: We examined the efficacy and safety of neoadjuvant ipilimumab and nivolumab combined with paclitaxel following suboptimal response to anthracycline-based chemotherapy in patients with early-stage TNBC. **Methods:** This single arm multicentre phase 2 study enrolled 34 patients in 8 sites. Patients were aged ≥18 years with previously untreated stage 3 TNBC and were required to have ≥15mm of tumor remaining or 10mm of tumor with one positive lymph node after 4 cycles of anthracycline-based therapy. A suboptimal response subset at baseline was defined as < 50% reduction in tumor volume after initial anthracycline-based chemotherapy. Patients received neoadjuvant ipilimumab 1mg/kg IV 6 weekly for 2 doses and nivolumab 240mg every 2 weeks for 6 doses, with weekly paclitaxel at 80mg/m^2 for 12 weeks, followed by surgery. Nivolumab (480mg 4-weekly) continued post operatively for further 9 months. Primary endpoint was pathological complete response (pCR) in breast and axilla, with secondary endpoints pCR in the suboptimal responders, pCR in PD-L1 positive patients (≥1% by SP142 assay), clinical response in the breast (ORR by RECIST), event-free (EFS) and overall survival (OS). **Results:** Between December 2018 and April 2020, 34 patients were enrolled, 33 were evaluable for the primary endpoint. Median age was 46.6yrs. At diagnosis, all patients were clinical stage III (AJCC v8), 16/34 (47%) were node positive, 8/31 (26%) were PD-L1 positive. At study entry (following anthracycline-based chemo), the median tumor size by ultrasound was 28mm (12-62). 16/33 (48%) were considered suboptimal responders. The pCR rate (ypT0ypN0) was 24.2% (95% CI, 11.09-42.26) in all evaluable, 37.5% [3/11] in PD-L1+ and 23% [5/22] in PD-L1- patients. In patients with suboptimal anthracycline response (< 50% tumor reduction), the pCR rate was 18.8% (95% CI, 8.52-75.51) (3/16). ORR in the breast was 57.6% (19/33) in all evaluable patients and 43.7% (8/20) in the suboptimal responders. The number of patients with residual cancer burden (RCB) class 0,1,2,3 was 8 (24%), 1 (3%), 19 (57.5%) and 5 (15%) respectively. With 14 months median follow up, 12-months EFS was estimated at 85% and OS 94%. For patients with pCR vs non-pCR, the hazard ratio (HR) for EFS was 0.62, 12 mo EFS was 100% vs 75%. In the neoadjuvant phase, 15/33 (45%) patients experienced at least one grade 3-4 adverse event. Most common immune-related event was grade 1 or 2 pneumonitis 9/33 (27%), which generally occurred with fever after the first dose of ipilimumab, and resolved. There was one case of grade 3 colitis. **Conclusions:** In these high risk patients, the addition of ipilimumab and nivolumab to neoadjuvant paclitaxel resulted in promising ORR and pCR rates, regardless of PD-L1 status. Rates of low grade pneumonitis were high. Follow up continues. Clinical trial information: ACTRN12617000651381. Research Sponsor: Bristol-Myers Squibb, Other Foundation.

603 **Poster Session**

Copy number aberration burden on circulating tumor DNA predicts recurrence risk after neoadjuvant chemotherapy in patients with triple-negative breast cancer: Post-hoc analysis of phase III PEARLY trial. *First Author: Min Hwan Kim, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: Our previous study reported prognostic significance of copy number aberration (CNA) burden on low-pass whole genome sequencing (LP-WGS) based circulating tumor DNA (ctDNA) analysis in metastatic breast cancer patients. Here, we report the prognostic value of ctDNA CNA burden measured before neoadjuvant chemotherapy in stage II-III triple-negative breast cancer (TNBC) patients enrolled in phase III PEARLY trial (NCT02441933, BIG Supporter Study BIG 19-01, KCSG BR15-01). **Methods:** The PEARLY trial was performed as a randomized, open-label, multicenter, phase III study to test the efficacy and safety of adding carboplatin to (neo)adjuvant chemotherapy in patients with stage II-III TNBC. Patients were randomized in a 1:1 ratio to receive 4 cycles of AC followed by the taxane or taxane plus carboplatin (AUC 5, tri-weekly 4 cycles) as neoadjuvant or adjuvant therapy. This post-hoc baseline ctDNA analysis (before neoadjuvant chemotherapy) included only the neoadjuvant patient cohort with available baseline ctDNA results (n = 465, median follow-up 16.8 months), while it was blinded for randomization information (carboplatin or not). We used "l-score" method to estimate CNA burden of ctDNA by LP-WGS to be matched with disease-free survival (DFS) after primary surgery. **Results:** The baseline ctDNA l-score level was positively associated with clinical T and N stage, while baseline l-score was not different between patients with pathologic complete response (pCR) and non-pCR. We listed 465 patients in the order in which they underwent primary surgery, and then alternated patients to be assigned to exploratory cohort (n =232) and validation cohort (n = 233). The DFS was significantly shorter in high l-score (l-score ≥ 7.81) patients compared with low l-score (l-score < 7.81) patients in exploratory cohort. The high l-score independently predicted poor DFS adjusted for clinical T stage, clinical N stage, and pCR status (hazard ratio [HR] 3.88, $p = 0.003$). In the validation cohort, high l-score was validated to be associated poorer DFS, and multivariate Cox analysis validated the independent prognostic impact of l-score on DFS (HR 2.04, $p = 0.050$). The high baseline l-score patients showed shorter DFS both in pCR-positive and pCR-negative patients. The 12-month DFS rate for pCR (+)/Low l-score patients was 98%, whereas that of pCR(-)/High l-score patients was 61.3 % in the validation cohort. **Conclusions:** The baseline ctDNA CNA burden on LP-WGS before neoadjuvant chemotherapy robustly predicts recurrence risk in stage II-III TNBC patients. The ctDNA l-score showed prognostic value independently from pCR status, suggesting ctDNA l-score can serve as a useful clinical determinant for escalating or de-escalating (neo)adjuvant strategy in TNBC patients. Clinical trial information: NCT02441933. Research Sponsor: Ministry of Trade, Industry & Energy (MOTIE, Korea), Other Government Agency.

604 **Poster Session**

Effect of neoadjuvant versus adjuvant chemotherapy on ipsilateral breast tumor recurrence after breast-conserving surgery and whole-breast irradiation. *First Author: Jong-Ho Cheun, Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul, South Korea*

Background: Early Breast Cancer Trialists' Collaborative Group conducted a large meta-analysis and reported that patients who underwent neoadjuvant chemotherapy (NAC) had higher ipsilateral breast tumor recurrence (IBTR) rate than those with adjuvant chemotherapy. However, since the study was conducted with patients treated two decades ago, the results could not reflect the advance in treatments and IBTR rate was much higher than in recent studies, Thus, we investigated the association between chemotherapy settings and IBTR rates in breast cancer patients. **Methods:** We retrospectively reviewed the data of 5,307 patients who underwent breast conserving surgery followed by whole breast irradiation between January 2004 and December 2018 in a single institution. Patients who underwent mastectomy or omitted chemotherapy were excluded. **Results:** The 1,473 patients who underwent NAC showed significantly higher IBTR rate than the 3,564 patients who underwent adjuvant chemotherapy (10-year risk: 4.5% vs. 4.0%; log-rank p=0.045, hazard ratio 1.42 [95%CI,1.01-1.99]). The difference was more evident for patients with hormone receptor (HR) positive and human epidermal growth factor receptor-2 (HER2) negative tumor (unadjusted p=0.001, hazard ratio 2.27 [95%CI,1.37-3.74; adjusted p=0.002, hazard ratio 2.80 [95%CI,1.45-5.42]], and the statistical significance was still remained after 1:1 propensity score matching (p=0.026). In contrast, patients with other subtypes did not show significant differences between two groups. **Conclusions:** Patients who underwent NAC for HR+/HER2- tumors carry increased risk of IBTR than those who underwent adjuvant chemotherapy. Our observation supports the need for considering tumor subtypes in initial treatment. In addition, more intensive surveillance would be needed for patients with HR+/HER2- tumors after NAC. Research Sponsor: None.

Intratumoral (IT) INT230-6 can cause tumor necrosis in vivo: Preliminary results of a phase II randomized presurgical window-of-opportunity study in early breast cancers (the INVINCIBLE study). *First Author: Angel Arnaout, Department of Surgery, The Ottawa Hospital, University of Ottawa & The Ottawa Hospital Research Institute, Ottawa, ON, Canada*

Background: The INVINCIBLE study is a randomized, Phase 2 presurgical Window-Of-Opportunity trial for IT INT230-6 (comprising VINblastine (VIN) Cisplatin (VIN)) evaluating clinical and BioLogical Effects in patients with early-stage operable Breast Cancer. INT230-6 also contains a dispersion enhancer molecule designed to facilitate diffusion of the cytotoxic agents into cancer cells and cause tumor necrosis. We have previously demonstrated that INT230-6 halts cancer cell replication and induces apoptosis while maturing dendritic cells and recruiting T-cells to the tumor microenvironment. In this trial, IT injections of INT230-6 are conducted to 1) exploit the potential of regional cytotoxic chemotherapy on breast cancer *in vivo* and 2) assess the potential for an immune response in the tumor microenvironment and host prior to surgical resection. **Methods:** Up to 90 women with newly diagnosed operable early-stage intermediate or high-grade T1-T2 invasive breast cancers are randomly allocated (2:1) prior to resection to IT injections of INT230-6, no treatment or saline sham. This study has two parts. Part I (N=29) was a randomized trial comparing 1-3 doses of INT230-6 injected weekly vs no treatment prior to surgery to evaluate safety, feasibility, and optimal drug dosing. Part II is a double-blinded randomized trial of up to 60 patients where patients will receive one IT dose of INT230-6 vs saline injection (2:1). The primary endpoint is to estimate the proportion of patients who achieve a complete cell cycle arrest post-surgery compared to the diagnosis biopsy. Secondary endpoints include an evaluation of the rate of pathological complete response, the percent of residual cancer, and safety. The study will also profile changes in CD4/CD8 and the T-cell repertoire. **Results:** Part I demonstrated feasibility, safety and tolerability of presurgical IT injections in breast cancer patients. Twenty patients with tumors ranging from 1-4.4cm were injected with at least one dose up to 48 hours prior to surgery. No surgeries were delayed or altered and the most common (>10%) AEs were injection site pain (100%), infusion site extravasation, injection site reaction and vomiting (10% each). Preliminary data show histologic evidence of up to 95% tumor necrosis in varying biologic subtypes and an increase in intratumoral TILs in injected tumors compared to controls. Part II is ongoing. **Conclusions:** Preliminary evidence shows that a single dose of INT230-6 can cause intratumoral necrosis and stimulate an immune response in breast cancers prior to surgery with minimal adverse effects and good tolerability. The results of Part II of the study will further evaluate the potential cytotoxic, immunomodulatory and other biologic effects of INT230-6 and its role as a potential cancer therapy in breast cancer patients awaiting surgery. Clinical trial information: NCT04781725. Research Sponsor: Intensity Therapeutics, Inc.

Does race influence long-term outcomes after neoadjuvant chemotherapy in breast cancer: A National Cancer Database analysis. *First Author: Arya Mariam Roy, Roswell Park Cancer Institute, Buffalo, NY*

Background: Pathologic complete response (pCR) after neoadjuvant chemotherapy (NACT) is a surrogate predictor for long-term survival in breast cancer (BC). Patients who attain pCR have improved relapse-free and overall survival (OS) when compared to patients with residual disease (RD). We examined the pCR in Black and White BC patients who received NACT and their OS after attaining pCR and RD. **Methods:** The National Cancer Database (NCDB) was queried for Black and White females with non-metastatic BC from the years 2010 – 2016 who received NACT. Logistic regression was used to analyze pCR/RD and Cox proportional hazards regression to analyze OS, with adjustment for age, race, stage, grade, body mass index, treatments received, insurance status and comorbidities. STATA/IC 16.0 was used for analysis and a two-sided p-value < 0.05 was considered significant. **Results:** A total of 101,014 White and Black BC patients were identified, including 24,852 (Whites - 74.43%, Black - 25.57%) triple negative breast cancer (TNBC), 51,043 (Whites - 84%, Blacks - 16%) hormone receptor positive HER2 negative (HR+HER2-) and 17,818 (Whites - 83%, Blacks - 17%) HER2 positive. Whites had a slightly higher odds of attaining pCR compared to Blacks (adjusted Odds Ratio (aOR) = 1.040, 95% Confidence Interval (CI) = 1.02 - 1.19, $p = 0.02$). The difference was largest in TNBC subtype (TNBC: aOR = 1.34, 95% CI = 1.20 - 1.56, $p < 0.001$; HR+HER2-: aOR = 1.1; 95% CI = 1.02 - 1.32, $p = 0.038$; HER2+: aOR = 1.13, 95% CI = 1.08 - 1.27, $p < 0.001$). Among those who attained pCR, Blacks had worse OS when compared to Whites in HER2+ subtype (adjusted Hazard Ratio (aHR) = 1.41, 95% CI = 1.04 - 1.93, $p = 0.028$) but not in TNBC or HR+HER2- subtypes. Among those with RD, Blacks had worse OS in the whole cohort compared to Whites (aHR = 1.43, 95% CI = 1.26 - 1.58, $p < 0.001$), and in all subtypes: TNBC (aHR = 1.17, 95% CI = 1.11 - 1.23, $p < 0.001$), HR+HER2- (aHR = 1.38, 95% CI = 1.31 - 1.45, $p < 0.001$) and HER2+ (aHR = 1.45, 95% CI = 1.32 - 1.59, $p < 0.001$). **Conclusions:** Black BC patients with TNBC were less likely to achieve pCR than Whites after NACT. When Black patients with HER2+ subtype did attain pCR, they still had worse OS than Whites. The same racial difference in OS was observed in all BC subtypes - TNBC, HR+HER2- and HER2+ among patients with RD. This highlights the importance to investigate novel personalized treatment strategies for Black patients. Research Sponsor: None.

TPS607 **Poster Session**

Adjuvant study of amcenestrant (SAR439859) versus tamoxifen for patients with hormone receptor-positive (HR+) early breast cancer (EBC), who have discontinued adjuvant aromatase inhibitor therapy due to treatment-related toxicity (AMEERA-6). *First Author: Thomas Meyskens, European Organisation for Research and Treatment of Cancer (EORTC), Brussels, Belgium*

Background: There are currently limited treatment options for patients with HR+ EBC who have discontinued adjuvant treatment with aromatase inhibitors (AIs) due to treatment-related toxicity. Amcenestrant is an optimized oral selective estrogen receptor degrader (SERD) with potent dual activity which antagonizes and degrades the ER resulting in inhibition of the ER signalling pathway. Preliminary clinical evidence from the phase 1/2 AMEERA-1 trial has demonstrated meaningful antitumour activity and a favourable safety profile of amcenestrant in the treatment of HR+ advanced breast cancer (Linden HM, Campone M, Bardia A, et al: Abstract PD8-08: A phase 1/2 study of SAR439859, an oral selective estrogen receptor (ER) degrader (SERD), as monotherapy and in combination with other anti-cancer therapies in postmenopausal women with ER-positive (ER+)/human epidermal growth factor receptor 2-negative (HER2-) metastatic breast cancer (mBC): AMEERA-1. SABCS 2020 PD8-08). **Methods:** AMEERA-6 is a prospective, randomized, international, double-blind, double-dummy, phase 3 study. 3738 patients will be randomized 1:1 to receive either amcenestrant 200 mg daily or tamoxifen 20 mg daily. Eligible patients are pre-or postmenopausal women or men with HR+ EBC (stage IIB-III) who have received at least 6 months of adjuvant AIs (at least 3 months in the adjuvant setting if they have received prior neoadjuvant AI therapy) and discontinued them within 30 months of initiation due to treatment-related toxicity. Participants will be centrally assessed to have ER+ and/or PgR+ (≥10% positive stained cells) status by immunohistochemistry assay. Prior use of adjuvant CDK4/6 inhibitors are allowed. Patients are eligible irrespective of HER2 status; for patients with HER2-positive disease adjuvant anti-HER2 treatment and chemotherapy must be completed prior to randomization. Stratification factors include: duration of AI therapy, HER2 status, prior chemotherapy, prior CDK4/6 inhibitors, geographic region, and menopausal status. Planned treatment duration is 5 years. Patients will be followed-up for 10 years from randomization. The primary endpoint is invasive breast cancer-free survival (IBCFS). Invasive disease-free survival is a key secondary endpoint, while other secondary endpoints include distant relapse-free survival (RFS), locoregional RFS, overall survival, breast-cancer specific survival, safety, patient reported outcomes and pharmacokinetics. Adherence to treatment is an exploratory endpoint. AMEERA-6 opened for recruitment in January 2022. Clinical trial information: NCT05128773. Research Sponsor: Sanofi.

TPS608 **Poster Session**

A phase 3, single arm, open-label study evaluating ovarian suppression following 3-month leuprolide acetate for injectable suspension in combination with endocrine therapy in premenopausal subjects with HR+, HER2-negative breast cancer (OVELIA). *First Author: Ryan Tooker, Tolmar, Inc, Fort Collins, CO*

Background: In US clinical practice, GnRH agonists are widely used to suppress ovarian function in pre/perimenopausal patients with breast cancer that is moderate-to high-risk for recurrence. Despite extensive use of leuprolide acetate (LA) for ovarian suppression, regulatory approval for this indication has not been established in the US. Additionally, existing three month formulations may not reliably provide ovarian suppression, as demonstrated by escapes in estradiol (E2). An extended-release LA product with a 3-month dosing period specifically developed for ovarian suppression in patients with breast cancer could fill this unmet need. TOL2506 is a 3-month, extended-release formulation of 30 mg of LA. This combination of active drug and in situ polymeric extended release technology is expected to deliver higher exposure to drug than the currently available 3-month (22.5 mg) formulations of LA marketed for advanced prostate cancer and potentially reduce escapes in E2 over the dosing period. **Methods:** TOL2506A (OVELIA) is a phase 3, single arm, open-label study evaluating the effectiveness of TOL2506 to suppress ovarian function in premenopausal women with HR+, HER2-negative breast cancer. Approximately 250 subjects will be enrolled, with 30% aged 40 years or younger. Subjects must be premenopausal women, age 18-49, with a diagnosis of Stage I, II, or III HR+, HER2-negative breast cancer (ER > 1% and/or, PR > 1%, HER2-negative per ASCO CAP guidelines), who are candidates for ovarian suppression with endocrine therapy. For subjects receiving chemotherapy, premenopausal status will be determined, and confirmed by central lab hormone testing, prior to initiating chemotherapy. Male subjects with HR+, HER2-negative breast cancer may also be eligible, but will be evaluated for safety analyses only. Eligible subjects will enter the 48 week treatment period in 2 groups: those receiving tamoxifen concurrently with TOL2506 or those who initiate therapy with an aromatase inhibitor (AI; letrozole, anastrozole, or exemestane) beginning 6 weeks after the first administration of TOL2506, if E2 < 20 pg/mL has been achieved. After Week 12, subjects will be allowed to switch from receiving an AI to receiving tamoxifen or from tamoxifen to AI at the Investigator's discretion. Subjects will receive 4 doses of TOL2506 every 12 weeks over the 48 week study duration. Achievement of ovarian suppression will be defined as ≥ 90% of subjects with luteinizing hormone (LH) levels < 4 IU/L at Week 6. Secondary endpoints include suppression of LH, E2 (< 20 pg/mL for tamoxifen cohort and < 2.72 pg/mL for AI cohort) and absence of menses at weeks 6, 12, 24, 36, and 48. Clinical trial information: NCT04906395. Research Sponsor: Tolmar, Inc.

TPS609 **Poster Session**

Adjuvant dynamic marker-adjusted personalized therapy comparing endocrine therapy plus ribociclib versus chemotherapy in intermediate-risk HR+/HER2- early breast cancer: ADAPTcycle. *First Author: Nadia Harbeck, Breast Center, Dept. Obstetrics & Gynecology, University of Munich (LMU) and CCCLMU and West German Study Group, Munich, Germany*

Background: The WSG ADAPT trial program focusses on individualization of (neo)-adjuvant decision-making in EBC in a subtype-specific manner. Clinical feasibility of the WSG ADAPT trial goals - early response assessment and subtype-specific therapy tailoring to those patients (pts) who are most likely to benefit - has recently been confirmed by the 5-years survival data of the ADAPT HR+/HER2- clinical trial. **Methods:** WSG-ADAPTcycle is a prospective, multi-center, interventional, two-arm, (neo)adjuvant, non-blinded, randomized, controlled phase III trial (NCT04055493) investigating whether treatment with the CDK4/6 inhibitor ribociclib (600mg/day) together with ET is superior to standard-chemotherapy (CT) in intermediate-risk HR+/HER2- EBC. Definition of intermediate-risk is either based on Oncotype DX and endocrine responder status (measured by Ki67-response after 2-4 weeks of induction endocrine therapy (ET)) or on low-intermediate baseline Ki67 and high estrogen receptor (ER)/progesterone receptor (PR)-expression (Dowsett et al. NPJ Breast Cancer 2020). Co-primary endpoints are DFS and dDFS. It is planned to screen 5600 pts and to randomize 1670 pts (1002 to ribociclib + ET; 668 to standard CT followed by ET). Study start was in July 2019 (88 sites, enrollment period 42 months) and until date of submission, 3079 pts have been screened and 811 randomized (490 ribociclib / 321 CT). Pre-/postmenopausal pts with histologically confirmed invasive HR+/HER2- EBC with high clinical risk (cT2-4 or Ki-67 20% or G3 or cN+) are eligible if they fulfil the ADAPT intermediate-risk criteria: Recurrence Score (RS) ≤25 plus several risk factors and poor ET responder, RS >25 and ET-responder in p/cN0-1 pts, or RS ≤25 with c/pN2-3 in ET-responder. Direct randomization of premenopausal patients (irrespective of ET-response) with c/pN0 and RS 16-25 or c/pN1 with RS 0-25 is allowed according to investigator's decision; however, based on the ADAPT results, ET+ovarian function suppression alone is strongly recommended in ET-responders. Treatment duration is 2 years for the ribociclib + aromatase inhibitor (AI) (premenopausal: AI + GnRH)-arm and 16-24 weeks for the CT-arm; neoadjuvant or adjuvant treatment is allowed. The minimum 5-year follow-up phase includes standard adjuvant ET. ePROs are collected using CANKADO; ECG monitoring is performed using a novel eHealth method. Translational analyses: Tumor tissue will be collected prior to ET, after at least 3 weeks of ET, if residual tumor is diagnosed (neoadjuvant treatment), and at recurrence, to identify potential resistance markers. Exploratory tissue biomarker research will be conducted to assess alterations in molecular markers. In addition, ctDNA/ctRNA from optional blood samples will be assessed for mutations and gene expression relevant for HR+/HER2- EBC. Clinical trial information: NCT04055493. Research Sponsor: Novartis, Exact Sciences.

TPS610 **Poster Session**

Phase II trial to evaluate immune-related biomarkers for pathological response in stage II-III HER2-positive breast cancer receiving neoadjuvant chemotherapy with subsequent randomization to multi-epitope HER2 vaccine versus placebo in patients with residual disease post-neoadjuvant chemotherapy. *First Author: Saranya Chumsri, Mayo Clinic, Jacksonville, FL*

Background: Several studies demonstrated worsening disease-free survival in patients who failed to achieve complete pathological response after neoadjuvant chemotherapy (NAC), particularly in HER2-positive (HER2+) breast cancer. Despite the recent approval of trastuzumab emtansine (T-DM1) in patients with residual disease after NAC approximately 12% of patients still develop recurrent and metastatic disease. TPIV100 is a multi-epitope vaccine that includes a pool of 4 degenerate HER2-derived HLA-DR epitopes, which activate CD4 helper T cells, admixed with GM-CSF. In our previous phase I trial this vaccine was shown to be safe in combination with trastuzumab in stage II-III HER2+ breast cancer after completion of standard of care chemotherapy. Furthermore, this vaccine also generated robust long-lasting T-cell immune responses and antibody immunity against HER2. **Methods**: This trial is a multi-center, randomized, placebo-controlled, phase II trial of TPIV100 in combination with T-DM1 in stage II-III HER2+ breast cancer patients with residual disease after NAC. This trial is currently opened through the ACCRU consortium. Eligible patients include those with stage II-III HER2+ with residual disease, in the breast and/or lymph nodes, after trastuzumab ± pertuzumab-based NAC, with ECOG PS ≤ 2 and adequate organ function. Patients with baseline left ventricular ejection fraction < 50%, history of trastuzumab-related cardiac toxicity, myocardial infarction or stroke < 6 months, history of congestive heart failure, autoimmune disease, immunocompromised patients with known HIV or those on chronic steroid, hypersensitivity to GM-CSF, and other active malignancy < 3 years are excluded. TPIV100 or placebo, in combination with GM-CSF, will be given concurrently with T-DM1. To ensure that TPIV100 in combination with T-DM1 is safe, there is a run-in phase with 20 patients treated with the combination. If there is no significant dose-limiting toxicity observed in the run-in phase, the trial will be expanded to the randomized phase II portion, which will include 240 patients. Eligible patients will be randomized in a 2:1 fashion with ER/PR as a stratification factor. The primary endpoint is invasive disease-free survival, and the secondary endpoint includes immunogenicity of TPIV100 as assessed by IFN-g ELIspot analysis. Correlative studies include assessment of helper T-cell response distribution (including Th1, Th2, Th17, Tfh), HER2-specific antibody immunity, and HLA genotype. Currently, 20 patients in the run-in phase have been enrolled. Enrollment to the randomized phase II portion is expected to begin in March 2022. Clinical trial information: NCT04197687. Research Sponsor: Department of Defense.

TPS611 **Poster Session**

A phase 3, randomized, open-label study of the anti-Globo H vaccine adagloxad simolenin/obi-821 in the adjuvant treatment of high-risk, early-stage, Globo H-positive triple-negative breast cancer. *First Author: Hope S. Rugo, Department of Medicine, University of California San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: Adagloxad simolenin (A-S) is an anti-Globo H immunogen comprised of the carbohydrate tumor antigen Globo H, covalently linked to keyhole limpet hemocyanin, a carrier protein that deploys T cells to enhance the humoral response. Administration of A-S in combination with the immune adjuvant OBI-821 serves as an anti-tumor associated carbohydrate antigen vaccine intended to generate anti-Globo H humoral responses in patients with Globo H-expressing tumors. **Methods:** Study OBI-822-011, a phase 3 study, was initiated in 2018. Following feedback from investigators and advisors the study design was changed from a double-blind, placebo-controlled study to an open-label, standard of care (SOC) study. The revised protocol includes patients who have recovered from surgery and completed all planned neoadjuvant and/or adjuvant multiagent chemotherapy and/or radiation therapy. SOC in the A-S/OBI-821 arm is concomitant therapy of capecitabine or immune checkpoint inhibitor. In the SOC arm patients will receive SOC therapy consisting of observation alone, or adjuvant capecitabine alone, or immune checkpoint inhibitor alone. The key protocol changes included a change from open-label to standard of care, providing unblinding and reconsent guidelines for patients enrolled into the study prior to the protocol amendment, allowing concurrent adjuvant single agent chemotherapy, revising the stratification algorithm from a non-hierarchical to a hierarchical structure and aligning the stratification factors with prognostic factors more representative of the study population, revising the eligibility criteria, number and frequency of assessments to reduce patient burden, revising the interim analysis timepoints for futility, and removed an interim analysis for superiority. Study Objectives: Primary Objective: To determine the effect of A-S/OBI-821 treatment on improving IDFS in the study population. Secondary Objectives: To determine the impact of A-S/OBI-821 treatment on Overall survival (OS), Quality of life (QoL), Breast cancer-free interval (BCFI), Distant disease-free survival (DDFS) in the study population; To determine the safety and tolerability of A-S/OBI-821 in the study population. Key Exploratory Objectives: Beyond the safety, efficacy, and QoL endpoints of this trial, exploratory endpoints will evaluate the relationship between aberrant Globo H expression and baseline characteristics, including tumor pathology and immune factors. Conclusion: An estimated 668 subjects will be enrolled, treated for up to 2 years, and followed until occurrence of 187 events (invasive disease recurrence or death) or 3 years from last subject randomized. Survival follow-up is for 5 years from randomization of last subject. Clinical trial information: NCT03562637. Research Sponsor: OBI Pharma Inc.

TPS612 **Poster Session**

FLEX, the 30,000 breast cancer transcriptome project: A platform for early breast cancer research using full-genome arrays paired with clinical data. *First Author: Cynthia X. Ma, Washington University School of Medicine, St. Louis, MO*

Background: The ongoing, multi-center FLEX trial (NCT03053193) began in the United States in 2017, with the ultimate goal of 30,000 patients enrolled. The primary objective is to create a large-scale collaborative registry of early-stage breast cancer patients that links comprehensive clinical and full genome expression data to reveal new prognostic and/or predictive gene signatures. A key secondary objective of the trial is to enable investigator-initiated studies to explore early-stage breast cancer at a relatively low cost to the investigator. **Methods:** The prospective FLEX trial enrolls patients aged ≥ 18 years with histologically proven stage I-III breast cancer, with negative or 1-3 positive lymph nodes. Eligible patients have received MammaPrint, with or without BluePrint testing as standard of care, and consent to clinically annotated full transcriptome data collection. The FLEX base study protocol permits investigators to submit their own concept proposal, and upon review and approval by the Research and Scientific Review Committees, investigators interrogate clinical and genomic data from the FLEX database. The 10-year enrollment goal is a minimum of 30,000 patients. Since April 2017, 9,170 patients have been enrolled at over 109 sites in the United States. To date, 38 investigator-initiated substudies have been approved and are in progress, and 28 abstracts have been published in the US scientific congresses. To ensure inclusion of diverse populations, patients from local communities and 11 National Cancer Institute-designated Comprehensive Cancer Centers were included. Our diverse data set is helping meet the needs of historically under-represented patients with breast cancer. Of the self-reported ethnicities within the FLEX database, 65% are White or Caucasian, 8% Black or African American, 4% Latin American, and 2% Asian. There are 5 ongoing FLEX sub studies investigating racial disparities. The molecular profiling and differential gene expression analysis in early-stage breast cancer patients of African American, Asian, Hispanic ancestries helps to provide critical insights that correlate tumor biology with treatment outcomes. FLEX is expanding globally with sites anticipated in multiple European countries. The FLEX trial continues to expedite the discovery and development of novel genomic profiles, bringing precision oncology into the clinic to improve breast cancer management. Clinical trial information: NCT03053193. Research Sponsor: Agendia.

TPS613 **Poster Session**

NRG-BR007: A phase III trial evaluating de-escalation of breast radiation (DEBRA) following breast-conserving surgery (BCS) of stage 1, hormone receptor+, HER2-, RS ≤18 breast cancer. *First Author: Julia R. White, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Approximately 50% of newly diagnosed breast cancers are stage 1, with the majority being ER/PR-positive, HER2-negative. Genomic assays such as the Oncotype DX® have identified patients (pts) with reduced risk of distant metastasis and without benefit from chemotherapy added to endocrine therapy, freeing them from excess toxicity. Genomic assays are also recognized as prognostic for in-breast recurrence (IBR) after BCS and could similarly allow de-escalation of adjuvant radiotherapy (RT). Reducing overtreatment is of interest to pts, providers, and payers. **Methods:** We hypothesize that BCS alone is non-inferior to BCS plus RT for in-breast recurrence and breast preservation in women intending endocrine therapy (ET) for stage 1 breast cancer (ER &/or PR positive, HER2-negative with an Oncotype DX Recurrence Score [RS] of ≤18). Stratification is by age (<60; ≥60), tumor size (≤1 cm; >1-2cm), & (RS <11, RS 11-18). Pts are randomized post-BCS to Arm 1 with breast RT using standard methods (hypo- or conventional-fractionated whole breast RT with/without boost, APBI) with ≥5 yrs of ET (tamoxifen or AI) or Arm 2 with ≥5 yrs of ET (tamoxifen or AI) alone. The specific regimen of ET in both arms is at the treating physician's discretion. Eligible pts are stage 1: pT1 (2 cm), pN0, age ≥50 to <70 yrs, s/p BCS with negative margins (no ink on tumor), s/p axillary nodal staging (SNB or ALND), ER &/or PR positive (ASCO/CAP), HER2-negative (ASCO/CAP), and Oncotype DX RS of ≤18 (diagnostic core biopsy or resected specimen). Primary endpoint is in-breast recurrence. Secondary endpoints are breast conservation rate, invasive in-breast recurrence, relapse-free interval, distant disease-free survival, overall survival, patient-reported breast pain, patient-reported worry about recurrence, and adherence to ET. We assume a clinically acceptable difference in of 4% at 10 yrs to judge omission of RT as non-inferior (10-yr event-free survival for RT group is 95.6% *vs* 91.6% for the omission of RT group). The study is powered to detect a non-inferiority with 80% power and a one-sided α=0.025, assuming that there would be a ramp-up in accrual in the first two years (leveling off in Yrs 3-5); 1,670 (835 per arm) pts are required to be randomized. Conservative loss to follow-up is 1% per yr. Some of the T1a pts screened may have Oncotype DX scores >18, making them ineligible for the study. In the accrual process, pts will be required to register (1,714 pts) to ensure that our final randomized cohort is 1,670 pts. Current accrual (2-2-2022) is 52 screened and 45 randomized. Support: U10CA180868, -180822, NCT04852887. Clinical trial information: NCT04852887. Research Sponsor: U.S. National Institutes of Health.

TPS614 **Poster Session**

SMALL: Open surgery versus minimally invasive vacuum-assisted excision for small screen-detected breast cancers. *First Author: Stuart McIntosh, Queens University Belfast, Belfast, United Kingdom*

Background: Mammographic screening programmes reduce breast cancer mortality but detect many small tumours with favourable biology which may not progress. These are treated with surgery and adjuvant therapies, but associated morbidities mean there is a need to reduce overtreatment. Minimally invasive treatments such as vacuum-assisted excision (VAE) have been described but there is no prospective randomised evidence to support their routine use. SMALL (ISRCTN 12240119) is designed to establish the feasibility of using VAE to treat small tumours detected within the UK NHS Breast Screening Programme (BSP). **Methods:** Phase III multicenter randomized trial comparing surgery with VAE for screen-detected good prognosis cancers. Eligibility criteria are age ≥47 years, unifocal grade 1 tumors (maximum diameter 15mm), strongly ER/PR+ve and HER2-ve, with negative axillary staging. Patients are randomized 2:1 to VAE or surgery, with no axillary surgery in the VAE arm. Excision is assessed radiologically, and if incomplete, patients undergo surgery. Adjuvant radiotherapy and endocrine therapy are mandated in the VAE arm. Coprimary end-points are: (1) Non-inferiority comparison of the requirement for a second procedure. (2) Single-arm analysis of local recurrence (LR) at 5 years after VAE. Recruitment of 800 patients will permit demonstration of 10% non-inferiority of VAE for requirement of a second procedure, ensuring sufficient patients for single arm analysis of LR rates, where expected LR free survival is 99% at 5 years, with an undesirable survival probability after VAE of 97%. The DMC will monitor LR events to ensure these do not exceed 3% per year. Secondary outcome measures include time to ipsilateral recurrence, overall survival, complications, quality of life and health economic analysis. A QuinteT Recruitment Intervention (QRI) is integrated throughout SMALL to optimize recruitment and informed consent. Recruitment challenges are identified by analyzing recruiter/patient interviews, audio-recordings of trial discussions, and by review of screening, eligibility and recruitment data and study documentation. Solutions are developed collaboratively, including recruiter feedback and recruitment tips documents. Results: SMALL opened in December 2019, but recruitment halted for 5 months due to COVID-19. At 11th February 2022, 91 patients had been recruited from 22 centers, with an approached/consented ration of 50%. Drawing from preliminary QRI findings, a recruitment tips document has been circulated (on discussing SMALL, providing balanced information on treatment options and explaining randomization). Individual recruiter feedback has commenced, with wider feedback planned shortly. Conclusion: Despite pandemic-related challenges, SMALL has excellent recruitment to date and is expected to have a global impact on treatment of screen-detected breast cancer. Clinical trial information: 12240119. Research Sponsor: UK National INstitute for Health Research Health Technology Assessment Programme.

TPS615 **Poster Session**

ATNEC: A multicenter, randomized trial investigating whether axillary treatment can be avoided in patients with T1-3N1M0 breast cancer with no residual cancer in the lymph glands after neoadjuvant chemotherapy. *First Author: Amit Goyal, Royal Derby Hospital, Derby, United Kingdom*

Background: Neoadjuvant chemotherapy (NACT) results in eradication of cancer in the axillary nodes in 40-70% of patients. This raises questions about the benefit of further axillary treatment in patients with no evidence of residual nodal disease (ypN0) post NACT. **Methods:** Design: ATNEC is a phase 3, randomized (1:1), multi-center UK trial, with embedded economic evaluation. Patients with proven axillary node metastases on needle biopsy receive NACT followed by sentinel node biopsy (SNB). If the sentinel nodes have converted to benign (ypN0), ATNEC randomly assigns patients to axillary treatment (nodal radiotherapy [ART] or axillary nodal clearance [ALND]) vs no further axillary treatment. Stratification: Institution, type of surgery (breast conserving surgery vs mastectomy), receptor status (triple negative vs HER2 positive vs ER positive and/or PR positive and HER2 negative).Inclusion criteria: Age ≥ 18; Male or female; T1-3N1M0 breast cancer at diagnosis (pre-NACT); FNA or core biopsy confirmed axillary nodal metastases at presentation; ER and HER2 status evaluated on primary tumor; Received standard NACT as per local guidelines; Imaging of the axilla to assess response to NACT;Dual tracer SNB post-NACT and at least 3 nodes removed (sentinel nodes and marked node): If a single tracer is used, the patient is eligible if the involved node is marked pre-NACT and at least 3 nodes removed (including the marked node), If axillary node sampling is performed following failed localization of sentinel nodes, patient is eligible if at least 3 nodes removed (including the marked node), If node is not marked, or marked node is not removed, patient is eligible if the histology report shows evidence of down-staging with complete pathological response in at least one node and at least 3 nodes removed; No evidence of nodal metastases post NACT (ypN0). Exclusion criteria: Bilateral invasive breast cancer; SNB prior to NACT; Previous ipsilateral axillary nodal surgery; Previous cancer within last 5 years or concomitant malignancy. Aims: To assess whether omitting further axillary treatment (ALND & ART) for patients with early-stage breast cancer and axillary nodal metastases on needle biopsy - who after NACT have no residual nodal disease on SNB (ypN0) - is non-inferior to axillary treatment in terms of disease-free survival, and reduces lymphoedema at 5 years. Statistical methods: All analyses will be carried out on an intention-to-treat basis to preserve randomization, avoid bias from exclusions and preserve statistical power. Radiotherapy Quality Assurance: Study has in-built radiotherapy QA program that will be coordinated by National Radiotherapy Trials QA (RTTQA) group. Target accrual: 1,900 Status: Recruiting. As of 11-Feb-2022, 39 sites open, 87 patients enrolled, 31 randomized. Clinical trial information: NCT04109079. Research Sponsor: UK National Institute for Health Research - Health Technology Assessment Programme (NIHR128311).

TPS616 **Poster Session**

Comparing an operation to monitoring, with or without endocrine therapy (COMET), for low-risk ductal carcinoma in situ (DCIS). *First Author: Thomas Lynch, Duke University, Durham, NC*

Background: Approximately 50,000 women in the U.S. are diagnosed with ductal carcinoma *in situ* (DCIS) each year. Without treatment, it is estimated that only 20-30% of DCIS will lead to invasive breast cancer (IBC). However, over 97% of women are currently treated with surgery +/- radiation. An alternative to surgery is active monitoring (AM), a management approach in which mammograms/physical exams are used to monitor breast changes and determine when, or *if*, surgery is needed. The COMET Study will compare risks and benefits of AM versus surgery for low-risk DCIS in the setting of a Phase III multicenter prospective randomized trial. The study is funded by the Patient-Centered Outcomes Research Institute. The COMET trial opened in the U.S. in June 2017 (Clinicaltrials.gov reference: NCT02926911). In November 2021, the Data Safety Monitoring Board reviewed the trial and suggested that it continue as planned. Patient accrual will continue until 12/31/2022. **Methods:** The primary objective is to assess whether the 2-year ipsilateral IBC rate for AM is non-inferior to that for surgery. Secondary objectives include determining whether AM is non-inferior to surgery for 2-year mastectomy rate; breast conservation rate; contralateral breast cancer rate; overall and breast cancer-specific survival. Patient reported outcomes will enable comparison of health-related quality of life and psychosocial outcomes between surgery and AM groups at baseline, 6-months, and years 1-5. Eligibility criteria include: age > 40 at diagnosis; pathologic confirmation of grade I/II DCIS or atypia verging on DCIS without invasion by two pathologists; ER and/or PR ≥ 10%; no mass on physical exam or imaging. The accrual goal is 1200 randomized patients across 100 Alliance for Clinical Trials in Oncology sites. Sample size is estimated using a 2-group test of non-inferiority of proportions, with the 2-year IBC rate in the surgery group assumed to be 0.10 based on published studies and non-inferiority margin of 0.05. Based on a 1-sided un-pooled z-test, with alpha = 0.05, a sample size of n = 446 per group will have 80% power to detect the specified non-inferiority margin. Final analysis plan will include a per protocol component as well as a pragmatic component for patients who are randomized and decline participation in their assigned arm. Primary analyses will adjust for dropout, non-compliance and contamination by utilizing instrumental variable methods. Clinical trial information: NCT02926911. Research Sponsor: Patient-Centered Outcomes Research Institute (PCORI).

TPS617 **Poster Session**

A single-arm, phase 2 study of perioperative ipilimumab, nivolumab, and cryoablation in women with hormone receptor-negative, HER2-negative, early-stage/resectable breast cancer. *First Author: Heather L. McArthur, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Local tumor destruction with cryoablation (cryo) induces inflammation and releases antigens that can activate tumor-specific immune responses. Pre-clinically, cryo with checkpoint inhibition augmented tumor-specific immune responses and prevented recurrence. Clinically, we established that peri-operative (peri-op) cryo with ipilimumab (ipi) +/- nivolumab (nivo) was not only safe in patients (pts) with operable, early stage breast cancer (ESBC) but also generated robust intra-tumoral and systemic immune responses. In this phase 2 study, we evaluate the disease specific impact of peri-op ipi/nivo/cryo in women with residual triple negative breast cancer (TNBC) after neoadjuvant chemotherapy (NAC), a subset at high risk of early relapse. **Methods:** Eligible pts are ≥18y, with ER < 10%, PR < 10%, HER2 negative (per ASCO/CAP definition), ≥ 1.0 cm, residual operable disease after taxane-based NAC. Approximately 80 pts will be enrolled and treated with ipi/nivo/cryo followed by breast surgery and adjuvant nivo. Pts undergo percutaneous, image-guided cryo with concurrent research core biopsy 7-10 days prior to surgery and will receive ipi (1mg/kg IV) with nivo (240mg IV) 1 to 5 days prior to cryo. After surgery, pts will receive 3 additional doses of nivo at 240mg IV Q2 weeks. Adjuvant capecitabine is recommended for all patients per local standard-of-care. Patients will be stratified by NAC platinum administration, NAC anthracycline administration, and clinical nodal status (positive versus negative). The primary endpoint is 3-year Event Free Survival (EFS). Secondary endpoints include Invasive Disease-Free Survival (IDFS), Distant Disease-Free Survival (DDFS), overall survival (OS) and safety. Exploratory correlative studies will be performed on tumor and serum to characterize the immunologic impact of the intervention and to explore predictors of efficacy and toxicity. Clinical trial information: NCT03546686. Research Sponsor: BMS, Conquer Cancer Foundation of the American Society of Clinical Oncology, Other Foundation, BTG.

TPS618 **Poster Session**

Anlotinib plus tislelizumab combined with chemotherapy as neoadjuvant treatment in triple-negative breast cancer: A prospective, single-arm, open-label phase II study. *First Author: Jing Luo, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, China*

Background: Neoadjuvant anti-PD-(L)1 therapy confers an improvement in pathological complete response (pCR) rate in unselected triple-negative breast cancer (TNBC). Combination of antiangiogenic agent plus immune checkpoint inhibitor and chemotherapy therapy for advanced TNBC is reported as a promising anti-tumor strategy presented in the FUTURE-C-PLUS study. Tislelizumab is a humanized immunoglobulin G4 anti-PD-1 monoclonal antibody engineered to minimize binding to $Fc\gamma R$ on macrophages. Anlotinib is a novel multi-target tyrosine kinase inhibitor that effectively inhibit VEGFR, FGFR, c-KIT, c-MET and RET. Previous studies have proven the efficacy of both anlotinib monotherapy and combination with immune checkpoint inhibitor in advanced breast cancer. This phase II study aims to evaluate the efficacy and safety of anlotinib plus tislelizumab combined with chemotherapy as neoadjuvant treatment in TNBC. **Methods:** This is a prospective, single-arm, open-label, phase II trial. Eligible patients (pts) were women, aged 18-75 years, ECOG status 0-1, previously untreated invasive TNBC with histologically confirmed (cT1N1-2M0 or cT2-4N0-2M0). 32 pts will be enrolled and received 5 cycles of anlotinib (8 mg qd, d1-14; 21 days per cycle) with 6 cycles of tislelizumab (200 mg, once every 3 weeks) plus nab-paclitaxel (260 mg/m^2, once every 3 weeks) and anthracycline (epirubicin 75 mg/m^2 or doxorubicin 60 mg/m^2), followed by surgery. The primary endpoint is pathological complete response rate (pCR, ypT0/Tis ypN0) and the secondary endpoints include invasive disease-free survival (iDFS), event-free survival (EFS), overall survival (OS), and safety. A sample size of 32 patients was estimated to provide a 80% power to detect a difference of 25% in pCR at a significance level of $\alpha = 0.05$. The study was initiated in August 2021. Clinical trial information: NCT04914390. Research Sponsor: BeiGene, Ltd. and Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

TPS619 **Poster Session**

PARTNER: A randomized, phase II/III trial to evaluate the safety and efficacy of the addition of olaparib to platinum-based neoadjuvant chemotherapy in patients with triple-negative and/or germline BRCA-mutated breast cancer. *First Author: Lynsey Drewett, Department of Oncology, University of Cambridge and Cambridge Breast Cancer Research Unit, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom*

Background: Triple negative breast cancers (TNBCs) are a biologically diverse and aggressive subgroup lacking targeted therapy. TNBC and germline BRCA (gBRCA) breast cancer share certain phenotypic and molecular similarities, with gBRCA mutations seen in 10% to 20% of TNBC patients. Homologous recombination-deficient tumors, especially those caused by germline or somatic BRCA mutations, are thought to be particularly sensitive to PARP inhibitors. **Methods:** This is a 3-stage open-label randomized phase II/III trial of neoadjuvant paclitaxel and carboplatin +/- olaparib, followed by clinicians' choice of anthracycline regimen. The aim is to establish whether the addition of olaparib to neoadjuvant platinum-based chemotherapy in the treatment of basal TNBC and/or gBRCA breast cancer is safe and increases efficacy. In stages 1 and 2, all patients receive 4 cycles of 3-weekly carboplatin AUC5/weekly paclitaxel 80mg/m^2. They are randomly assigned 1:1:1 to a control arm, or to one of two research arms. These research arms include different treatment schedules of olaparib 150 mg BD for 12 days. In stage 3, patients are randomly assigned 1:1 to either the control or research arm chosen following stage 2. The primary endpoints are: Stage 1: Safety; Stage 2: Schedule selection based on pCR rate and olaparib completion rate using a "pick-the-winner" design. Stage 3: pCR rate. Key eligibility criteria are age 16-70; histologically confirmed invasive breast cancer; ER-negative, HER2-negative with TNBC basal phenotype or gBRCA positive, HER2-negative irrespective of hormone status; stage T1-4 N0-2; performance status 0-1; treatment within 6 weeks of diagnostic biopsy; biomarker scores: TILs, CK 5/6, EGFR +/- AR. The recruitment of TNBC non-gBRCA and gBRCA patients is independent. Enrichment design is applied with an overall significance level 0.05(α) and 80% power. A minimum of 780 patients will be included to detect an absolute improvement of 15% (all patients) and 20% (gBRCA patients) by combining olaparib with platinum-based chemotherapy. This trial includes an optional pathway called PARTNERING for patients with residual disease after six chemotherapy cycles. This aims to establish if adding new agents (ATR inhibitor and PD-L1 inhibitor) improves treatment response. Each cohort will consist of 15 patients. Since May 2016, 756 patients from 30 sites have been enrolled. An IDSMC review following stages 1 and 2 identified no safety concerns and Research Arm 2 was selected (olaparib administration on days 3-14). Stage 3 phase I (recruitment of non-gBRCA and gBRCA patients) completed December 2021. Stage 3 phase II (recruitment of gBRCA patients) remains open to patients in the U.K. and internationally. 5 patients have enrolled in PARTNERING. Follow-up duration is 10 years. Clinical trial information: NCT03150576. Research Sponsor: Sponsored by Cambridge University Hospitals NHS Foundation Trust and the University of Cambridge, Other Foundation, Pharmaceutical/Biotech Company.

TPS620 **Poster Session**

Phase II neoadjuvant pyrotinib combined with epirubicin and cyclophosphamide followed by docetaxel in HER2-low–expressing and HR-positive early or locally advanced breast cancer (PILHLE-001): A single-arm trial. *First Author: Yuan Xia, Breast Tumor Center, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*

Background: As a latent new subtype, HER2-low-expressing breast cancer has attracted increasing attention. However, HER2-low-expressing/HR-positive early or locally advanced breast cancer (E/LABC) has the lowest pathological complete response (pCR) rate among all types of breast cancer. Pyrotinib, a small-molecule HER1/HER2/HER4 tyrosine kinase inhibitor, combined with chemotherapy regimen showed excellent efficacy and safety in the treatment of patients with HER2-positive early, locally advanced and metastatic breast cancer. In-vitro experiment showed pyrotinib can significantly inhibit colony formation in breast cancer cell lines with different HER2 expression levels including HER2-positive and HER2-low-expressimg [immunohistochemistry (IHC) 2+/in situ hybridization (ISH) negative]. Therefore, the investigator-driven, ongoing PILHLE-001 trial has been conducted to evaluate the potential role of neoadjuvant pyrotinib plus chemotherapy in the treatment of HER2-low-expressing/HR-positive E/LABC, which may provide a novel neoadjuvant therapeutic strategy for these patients. **Methods:** PILHLE-001, as a single-arm, phase II study, is the first trial to evaluate the efficacy and safety of neoadjuvant pyrotinib combine with chemotherapy in HER2-low-expressing (defined as IHC 2+ with ISH negative) and HR-positive (ER or PR > 1% stained cells) E/LABC (cT1c with histologically involved lymph nodes or ≥cT2). Patients who have HER2 IHC 1+, or severe heart diseases or basic gastrointestinal diseases are excluded. The trial has 80% power to detect true difference from previous reported pCR rate of 17.5%, to an expected pCR rate of 35% at two-sided alpha level of 0.05. Considering a drop rate of 10%, a total of 46 patients will be needed. Since May 19, 2021 until now, 19 patients have been enrolled. All eligible patients will receive pyrotinib 320mg orally daily with all chemotherapy cycles (epirubicin 90 mg/m^2 intravenously plus cyclophosphamide 600 mg/m^2 intravenously on day 1 for four 3-week cycles followed by docetaxel 100 mg/m^2 intravenously on day 1 for four 3-week cycle). The primary outcome is the rate of total pCR, defined as no residual invasive tumor cells in the breast and axillary nodes, regardless of ductal carcinoma in situ (ypT0/is ypN0) after neoadjuvant treatment. The secondary outcomes include Miller-Payne grade, residual cancer burden score, overall response rate, breast conservation rate, disease-free survival, overall survival, exploratory biomarkers and drug related safety. Primary efficacy outcomes will be analyzed in the intention-to-treat population and safety outcomes in the safety set population. Long-term efficacy outcomes will be assessed later with enough follow-up. Clinical trial information: NCT05165225. Research Sponsor: None.

TPS621 **Poster Session**

DECRESCENDO: De-escalation of adjuvant chemotherapy in patients with HER2+/HR-/node-negative early breast cancer who achieve pCR after neoadjuvant taxane and subcutaneous dual anti-HER2 blockade. *First Author: Veronique Debien, Institut Jules Bordet, Université Libre de Bruxelles (U.L.B.), Brussels, Belgium*

Background: Human Epidermal growth factor Receptor-2 positive (HER2+) breast cancer (BC) heterogeneity can be captured at the mRNA level by the PAM50 classification. The HER2 "Enriched" (HER2-E) intrinsic subtype is encountered more often in HER2+ Hormone Receptor negative (HR-) tumors compared to HER2+ HR+ tumors and is particularly sensitive to HER2 blockade. HER2+ HR- and HER2-E achieve high pathological complete response (pCR) rates with neoadjuvant chemotherapy (CT) and dual anti-HER2 blockade with trastuzumab and pertuzumab. Additionally, the patients with pCR have improved outcomes. However, standard CT with common drugs such as anthracyclines has significant short and long-term toxicities, including cardiac events and secondary leukemias. Thus, tailoring the neoadjuvant treatment among carefully selected patients in order to reduce toxicity while preserving efficacy is a priority in early HER2-positive BC. **Methods:** DECRESCENDO is a large, multicentric, single-arm, phase 2 de-escalation study evaluating the efficacy of neoadjuvant CT with paclitaxel 80mg/m2 weekly or docetaxel 75mg/m2 every 3 weeks (Q3W) with pertuzumab and trastuzumab (P+T) 600/600mg fixed-dose combination (FDC) for subcutaneous (SC) injection Q3W for patients with early HER2+, HR- (ER<1% and PR<1%) BC. After surgery, the patients with pCR (defined as Residual Cancer Burden (RCB)=0, per local assessment) will receive 14 additional cycles of P+T FDC SC. Patients with RCB≥1 will receive adjuvant T-DM1 (preceded by anthracycline-based CT if RCB≥2). Eligible patients must be candidates for neoadjuvant treatment, with a tumor between 15 and 50mm, N0, ECOG PS 0-1, with LVEF ≥55%. 1,065 patients will be enrolled in 12 countries. A baseline tumor sample is required to retrospectively assess the intrinsic tumor subtype. The primary objective is to evaluate 3-year recurrence-free survival (RFS) in patients with HER2-E tumors who achieve pCR after neoadjuvant treatment. The key secondary objective is to evaluate 3-year RFS in all patients with pCR. If a 3-year RFS ≥94% with the lower boundary of a 1-sided 95% CI ≥92% is observed in the target group, the study treatment will be considered an acceptable alternative to strategies that include the addition of other chemotherapies such as anthracyclines, alkylating agents and platinum salts. A flexible care sub-study will enroll 121 patients with pCR in Belgium, France, Ireland, Israel and Italy to receive adjuvant P+T FDC SC in a location outside the hospital, such as at home or workplace. The aim is to compare patient preference for administration of P+T FDC SC outside the hospital vs in the hospital. The first patient was enrolled in January 2022. The trial is co-led by the Breast International Group (BIG) and Institut Jules Bordet. Clinical trial information: NCT04675827. Research Sponsor: Research grant from Pharmaceutical Compagny (Roche).

TPS622 **Poster Session**

Assessing response to neoadjuvant docetaxel and trastuzumab in Nigerian women with HER2-positive breast cancer (ARETTA). *First Author: Atara Isaiah Ntekim, Department of Radiation Oncology, Oyo, Nigeria*

Background: Breast cancer rates are increasing in Nigeria and across sub-Sahara Africa without the necessary infrastructure to manage the disease. Adequate clinical trial resources are needed to address the growing need for high quality, patient centered cancer care on the Continent. The ARETTA clinical trial was initiated by the Nigerian Breast Cancer Study Team in partnership with the University of Chicago Comprehensive Cancer Center. To build local capacity for biomarker informed clinical trials and translational research. Clinical investigators receive extensive training and local facilities at four University-based Cancer Centers in Southwest Nigeria were upgraded. The study is a pragmatic single-arm, phase II clinical trial to determine the safety and efficacy of neoadjuvant taxotere and trastuzumab in women with HER2-positive breast cancer. The study sought to 1) determine the pathological complete response (pCR) rate of patients with early stage breast cancer to neoadjuvant docetaxel and subcutaneous trastusumab 2) assess the feasibility of conducting oncology clinical trials using upgraded facilities and trained personnel and 3) determine accrual rate of participants. **Methods:** The study is currently open to accrual. Inclusion criteria include treatment naïve women aged 18 years to 70 years with Her-2 positive breast cancer stages II-IIIC (AJCC). Eligible participants receive four cycles of docetaxel 75mg/m^2 and trastuzumab every 3 weeks. Those with incomplete clinical response by breast ultrasound volume measurements receive 3 additional cycles of chemotherapy; cyclophosphamide 600mg/m^2, epirubicin 90mg/m^2 and 5-fluorouracil 600mg/m^2 every 3 weeks before re-evaluation for surgery. All participants receive a fixed dose of sub-cutaneous Herceptin (600mg) every 3 weeks (total of 18 doses). The primary endpoint is pCR rate. Secondary objectives are to evaluate invasive disease-free survival (iDFS), the pattern of response and mechanisms of resistance to treatment based on genomic markers, the pharmacokinetics of Herceptin SC, quality of life, and adverse event rates, including cardiac toxicity. Planned enrollment is 47 evaluable patients, which will provide 90% power to test the null hypothesis that the pCR rate is 20% versus a 40% alternative (one-sided alpha=0.05). More protocol details can be found at ClinicalTRial.gov NCT03879577 and JCO Glob Oncol2020 doi: 10.1200/GO.20.00043. *Progress:* Accrual commenced on 3rd April 2020 and is 75% completed. To date, monitoring, regulatory, as well as Data Safety and Monitoring Board progress evaluation did not identify any logistical or safety issues such as underdeveloped infrastructure, unacceptable rate of non-compliance with study protocol, poor informed consent procedure or serious adverse events to warrant stopping the trial. Clinical trial information: NCT03879577. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Pharmaceutical/Biotech Company.

TPS623 **Poster Session**

TRIO-US B-12 TALENT: Phase II neoadjuvant trial evaluating trastuzumab deruxtecan with or without anastrozole for HER2-low, HR+ early-stage breast cancer. *First Author: Sara A. Hurvitz, Department of Medicine, Division of Hematology/Oncology, David Geffen School of Medicine, University of California-Los Angeles, Jonsson Comprehensive Cancer Center, Los Angeles, CA*

Background: Although patients with hormone receptor-positive (HR+)/HER2-negative breast cancer (BC) frequently experience disease response to neoadjuvant therapy, fewer than 10% achieve a pathologic complete response (pCR) with standard chemotherapy or endocrine therapy, even in combination with CDK4/6 inhibitors. Thus, finding more effective therapies for this disease remains an area of unmet need. HER2 amplification is a known driver of endocrine resistance and HER2 may be expressed at a low level (IHC 1+ or 2+) in approximately 60% of HR+ BC. Trastuzumab deruxtecan (DS-8201a, T-DXd) is a novel HER2-targeting antibody drug conjugate (ADC) that is FDA approved in the US for HER2-positive (with boxed warnings for interstitial lung disease) and has demonstrated promising clinical efficacy in HER2-low BC with an objective response rate of ~37%. The aim of TALENT (TRIO-US B-12, NCT04553770) is to evaluate the clinical activity and safety of neoadjuvant T-DXd alone or in combination with endocrine therapy in patients with HR+/HER2-low early BC. **Methods:** This is an ongoing randomized, multicenter, open-label, two-stage, phase II neoadjuvant trial for participants with early stage, HR+, HER2-low (1+ or 2+/ISH- by IHC) BC. Eligible participants include men and women with previously untreated, operable invasive BC greater than 2.0 cm (cT2). Pts with recurrent, metastatic, or inflammatory BC are excluded. Pts are randomized 1:1 to receive six to eight cycles of T-DXd (5.4 mg/kg IV q21 days) alone or in combination with anastrozole AI (1 mg PO QD). Men and pre/peri menopausal women randomized to the AI arm also receive routine care GnRH agonist. Stratification factors include HER2 expression and menopausal status (men stratified as postmenopausal). Tumor tissue is taken at baseline, cycle 1 day 17-21, and at surgery. Blood samples are taken at 4 time points for biomarker analysis. The primary endpoint is pCR rate (breast and lymph node) at definitive surgery. In stage I, 58 participants will be randomized (29/arm). If >2 participants in an arm achieve pCR, that arm will expand (stage II) to enroll an additional 15 participants (total of 44/arm). A pCR rate of > 10% (5/44) would be considered favorable, warranting further evaluation in a larger trial. Other endpoints include safety, changes in Ki67 expression, Residual Cancer Burden index, biomarker analysis (including serial cfDNA analysis), and health-related quality of life. As of January 2022, 37 participants have enrolled, 24 have completed treatment, and 14 have had surgery. To our knowledge this is the first and only ongoing study evaluating T-DXd with or without endocrine therapy for HR+, HER2-low BC in the neoadjuvant setting. The study will shed light on clinical activity and biomarkers, which may guide larger confirmatory studies for this population. Clinical trial information: NCT04553770. Research Sponsor: Daiichi Sankyo.

TPS624 **Poster Session**

Neoadjuvant HER2-targeted therapy +/- immunotherapy with pembrolizumab (neoHIP): An open-label randomized phase II trial. *First Author: Heather L. McArthur, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Immune checkpoint inhibition (ICI) is synergistic with HER2-directed therapy in pre-clinical models. Clinically, pembrolizumab (K)-mediated ICI plus HER2-directed therapy with trastuzumab (H) was safe and demonstrated modest activity in H-resistant HER2-positive (HER2+) metastatic breast cancer. Because ICI may confer more robust activity when administered earlier in the course of disease, H and K administered in the curative-intent, treatment-naive setting may allow for de-escalation of cytotoxics; confer life-long, tumor-specific immunity; and ultimately, improve cure rates. Moreover, the synergy of H and K with paclitaxel (T) may overcome the need for dual HER2-blockade with H plus pertuzumab (P). In this randomized, multicenter, phase II, open-label trial the efficacy and safety of neoadjuvant THP vs THP-K vs TH-K are explored. **Methods:** 174 patients (pts) ≥18y with previously untreated, stage II-III, HER2+ breast cancer will be randomized and stratified by clinical nodal status (positive vs. negative) and hormone receptor status (positive vs. negative). In arm A, pts receive T at 80mg/m2 weekly for 12 weeks, H at 8mg/Kg (loading dose) and then 6mg/Kg every 3 weeks x 3 doses, P at 840 mg (loading dose) and then 420mg/Kg every 3 weeks x 3 doses (THP). In arm B, pts receive THP plus K at 200mg every 3 weeks x 4 doses (THP-K). In arm C, pts receive TH-K. Definitive surgery is 3-6 weeks after the last dose. After surgery, pts are treated per the treating physician's discretion including radiotherapy per local clinical standard. Pts whose tumors are hormone-receptor positive will receive hormone therapy per local standard-of-care. The primary end point is pathologic complete response (pCR) rate in the breast and axilla (ypT0/Tis ypN0). Secondary end points include pCR rate by ypT0ypN0 and ypT0/Tis, residual cancer burden index, event free survival, breast conserving surgery rate, safety and overall survival. Exploratory correlative studies will characterize potential immune biomarkers predictive of efficacy and/or toxicity. Clinical trial information: NCT03747120. Research Sponsor: Merck, Other Foundation.

1000 **Oral Abstract Session**

Trastuzumab deruxtecan (T-DXd) versus trastuzumab emtansine (T-DM1) in patients (pts) with HER2-positive (HER2+) unresectable and/or metastatic breast cancer (mBC): Safety follow-up of the randomized, phase 3 study DESTINY-Breast03. *First Author: Erika P. Hamilton, Sarah Cannon Research Institute/Tennessee Oncology, Nashville, TN*

Background: In the DESTINY-Breast03 (NCT03529110) primary analysis (data cutoff [DCO], May 21, 2021), T-DXd showed superiority over T-DM1 in pts with HER2+ mBC, with a significant improvement of progression-free survival by blinded independent central review (HR, 0.284; 95% CI, 0.217-0.373; $P < 0.001$), and a safety profile consistent with prior studies. This analysis provides updated safety data with longer follow-up. **Methods:** Pts were randomized 1:1 to T-DXd or T-DM1. Prespecified safety analysis of treatment-emergent adverse events (TEAEs) was conducted; endpoints included time to event, duration of event, and resolution. **Results:** At DCO (September 7, 2021), 116 (45.1%) pts vs 39 (14.9%) pts remained on treatment in the T-DXd vs T-DM1 arms; median treatment duration was 16.1 mo (range, 0.7-33.0) for T-DXd vs 6.9 mo (range, 0.7-28.5) for T-DM1. Any-grade (G), G≥3, and serious AE (SAE) rates were similar for T-DXd vs T-DM1 (99.6% vs 95.4%; 53.3% vs 49.8%; and 21.0% vs 19.2%), while exposure-adjusted incidence rates (EAIRs; per pt-year) for G≥3 and SAEs were lower for T-DXd vs T-DM1 (0.42 vs 0.70 and 0.17 vs 0.27). Median time to TEAE associated with drug discontinuation or dose reduction was longer with T-DXd vs T-DM1 (224.0 vs 147.0 d and 96.0 v 19.0 d, respectively). Most TEAEs in ≥20% of pts were hematologic or gastrointestinal. Median time to first onset of select any-G TEAEs was 70.0 vs 42.0 d for anemia, 196.0 vs 168.0 d for lymphopenia, 132.0 vs 8.0 d for thrombocytopenia, 22.0 vs 24.0 d for fatigue, 74.5 vs 92.0 d for leukopenia, and 64.0 vs 105.0 d for neutropenia, with T-DXd vs T-DM1, respectively. In both arms, most nausea and vomiting events were G1/2; while G≥3 events with T-DXd vs T-DM1 were 6.6% vs 0.4% for nausea and 1.6% vs 0.8% for vomiting, respectively. Rates of nausea, vomiting, and alopecia were highest in cycle 1 and lower in subsequent cycles for T-DXd. Rates of hematologic events were generally lower in earlier cycles vs cycle ≥8 in both arms. Rates of adjudicated, drug-related ILD/pneumonitis were 10.9% (1 G2 event since previous DCO) with T-DXd vs 1.9% with T-DM1, with no G4/5 events. Median time to first adjudicated, drug-related ILD/pneumonitis event was 5.9 vs 9.5 mo for T-DXd vs T-DM1, respectively; at DCO, most events resolved (57.1% vs 80.0%), and follow-up is ongoing. **Conclusions:** In this updated safety analysis, T-DXd demonstrated a tolerable safety profile consistent with prior studies. Despite longer treatment duration with T-DXd, EAIRs of G≥3 and SAEs were lower for T-DXd vs T-DM1. Rates of ILD/pneumonitis for T-DXd were similar to those in the previous DCO. Nausea, vomiting, and alopecia rates decreased over time. This longer safety update reinforces the consistent safety profile of T-DXd, supporting the clinical benefit of T-DXd over T-DM1 in patients with HER2+ mBC. Clinical trial information: NCT03529110. Research Sponsor: Daiichi Sankyo Inc. and AstraZeneca.

Primary results from TROPiCS-02: A randomized phase 3 study of sacituzumab govitecan (SG) versus treatment of physician's choice (TPC) in patients (Pts) with hormone receptor–positive/HER2-negative (HR+/HER2-) advanced breast cancer. *First Author: Hope S. Rugo, Department of Medicine, University of California San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

1002 **Oral Abstract Session**

Results from the phase 1/2 study of patritumab deruxtecan, a HER3-directed antibody-drug conjugate (ADC), in patients with HER3-expressing metastatic breast cancer (MBC). *First Author: Ian E. Krop, Dana-Farber Cancer Institute, Boston, MA*

Background: Patritumab deruxtecan (HER3-DXd) is a novel, investigational ADC composed of a human anti-HER3 monoclonal antibody covalently bound to a topoisomerase I inhibitor payload via a stable tetrapeptide-based cleavable linker. Here we report updated safety and efficacy data from this ongoing study (U31402-A-J101; NCT02980341; JapicCTI-163401) of HER3-DXd in pts with previously treated MBC. **Methods:** U31402-A-J101 is a phase 1/2, multicenter, open-label, first-in-human study of HER3-DXd in pts with HER3-expressing MBC (N = 182). The study enrolled pts in dose-escalation (3.2-8.0 mg/kg IV Q3W) and dose-finding portions across molecular subtypes (n = 66; including HER2+ MBC, n = 14) followed by dose expansion in the following subtypes: HER3 high (4.8 mg/kg [n = 33] or 6.4 mg/kg [n = 31]), HER3 low (6.4 mg/kg [n = 21]) HR+/HER2– MBC or HER3-high TNBC (6.4 mg/kg [n = 31]). HER3-high and -low were defined as ≥75% and 25% – < 75% membrane positivity. The primary objective was to assess safety and efficacy; secondary objectives included determining the relationship between efficacy and HER3 expression. **Results:** At data cutoff (16 Aug 2021), median study duration was 31.9 mo (range, 15-56). Median age was 57 y (range, 30-83); 132 (72.5%) and 50 (27.5%) pts had an ECOG PS of 0 or 1. Pts had a median of 5 (range, 1-13) prior lines of therapy for locally advanced/metastatic disease. Median treatment duration with HER3-DXd was 5.9 mo (range, 0.7-30.6). In a pooled evaluation of dose escalation/finding and expansion, efficacy is shown in pts with HR+/HER2– MBC, TNBC, and HER2+ MBC in the Table. Overall, 130 pts (71.4%) had grade ≥3 TEAEs; the most common (≥15%) were decreased neutrophil count (39.6%), decreased platelet count (30.8%), anemia (18.7%), and decreased white blood cell count (18.1%). 12 pts (6.6%) experienced treatment-related interstitial lung disease according to central adjudication, including 1 grade 5 event. **Conclusions:** A pooled analysis in this heavily pretreated population showed promising efficacy in pts with HR+/HER2– and HER2+ MBC as well as TNBC. The safety profile with longer follow-up is consistent with previous reports and showed adequate safety and tolerability. Studies are ongoing in MBC tumor types, with a focus on biomarkers associated with efficacy. Clinical trial information: NCT02980341. Research Sponsor: Daiichi Sankyo, Co., Ltd.

1005 **Oral Abstract Session**

Fulvestrant plus capivasertib versus fulvestrant plus placebo after relapse or progression on an aromatase inhibitor in metastatic, estrogen receptor–positive breast cancer (FAKTION): Overall survival and updated progression-free survival data with enhanced biomarker analysis. *First Author: Robert Hugh Jones, Velindre Cancer Centre and School of Medicine Cardiff University, Cardiff, United Kingdom*

Background: Previous results from the Phase 2 FAKTION trial (NCT01992952) showed progression free survival (PFS) in patients with aromatase inhibitor (AI) resistant ER+/HER2– advanced breast cancer was significantly longer with fulvestrant plus capivasertib vs fulvestrant plus placebo. At the time of analysis, PFS benefit associated with capivasertib was not restricted to patients with activating mutations in PIK3CA (E542K, E545K, H1047R or H1047L) or PTEN protein null. We report now mature overall survival (OS) data with enhanced biomarker analysis. **Methods:** For the enhanced analysis, available tissue and plasma samples were sent for targeted next generation sequencing (NGS) with Foundation One CDx and GuardantOMNI assays. 'Pathway altered' (PA) was defined as any activating mutation in PIK3CA (exons 1,4,7,9,20) or AKT1 (E17K only) or inactivating alterations in PTEN. For samples not tested by targeted NGS, previously reported digital droplet PCR (ddPCR) results for PIK3CA were used, in addition to tissue AKT1 ddPCR analysis performed after the initial publication. Concordance between mutations identified by ddPCR and subsequent NGS was 97%. **Results:** In January 2022, 108 OS events were reported (77% maturity) in the intention to treat (ITT) population. The median OS was 29.3 vs 23.4 months (mo) in the capivasertib (n = 69) vs placebo (n = 71) arms respectively (HR 0.66, 95% CI 0.45–0.97; p = 0.035). In the enhanced biomarker analysis, 76 participants were classified as PA compared to 59 in the original analysis. In the PA group, OS was 39.0 vs 20.0 mo in the capivasertib vs placebo arms respectively (HR 0.46, 95% CI: 0.27–0.79; p = 0.005). Within the pathway non-altered (PNA) group, median OS was 26.0 vs 25.2 mo in the capivasertib vs placebo arms respectively (HR 0.86, 95% CI: 0.49–1.52; p = 0.60). In the updated PFS analysis, the advantage in the ITT population persisted with capivasertib vs placebo (median 10.3 vs 4.8 mo, HR 0.56, 95% CI: 0.38–0.81; p = 0.002). PFS analysis against the updated biomarker subgroups shows a significant improvement in PFS in the PA group: 12.8 vs 4.6 mo in the capivasertib vs placebo arms respectively (HR 0.44, 95% CI: 0.26–0.72; p = 0.001). In the PNA group, median PFS was 7.7 vs 4.9 mo in the capivasertib vs placebo arms respectively (HR 0.70, 95% CI: 0.40–1.25; p = 0.23). **Conclusions:** Updated analysis of the FAKTION trial data show a significant improvement in OS in the ITT population. Enhanced subgroup analysis suggests that the benefit of capivasertib in both PFS and OS may be predominantly in patients with PIK3CA/AKT1/PTEN pathway altered tumours, but further elucidation will be forthcoming from the ongoing Phase 3 CAPItello-291 study in which participants with PA and PNA tumours have been recruited. Clinical trial information: NCT01992952. Research Sponsor: AstraZeneca, Cancer Research UK.

1006 **Oral Abstract Session**

Alpelisib (ALP) + fulvestrant (FUL) in patients (pts) with hormone receptor–positive (HR+), human epidermal growth factor receptor 2–negative (HER2−) advanced breast cancer (ABC): Biomarker (BM) analyses by next-generation sequencing (NGS) from the SOLAR-1 study. *First Author: Dejan Juric, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: *PIK3CA* mutations (mut; ~ 40% of HR+, HER2– ABC) are linked to poor prognosis. In SOLAR-1, ALP (PI3Kα-selective inhibitor and degrader) + FUL improved progression-free survival (PFS) vs placebo (PBO) + FUL in pts with *PIK3CA*-mutated HR+, HER2– ABC. Here, we focus on efficacy data by gene alterations in SOLAR-1 *PIK3CA*-altered (alt) cohort. **Methods:** SOLAR-1 was a phase 3, randomized, double-blind study of ALP (or PBO) + FUL in HR+, HER2– ABC progressing on/after an aromatase inhibitor. Baseline tissue samples with enough quantity/quality (N = 398) were retrospectively tested by NGS (FoundationOne CDx 324-gene panel) and pts grouped by *PIK3CA*-alteration status. Clinical benefit was assessed using PFS and hazard ratio (HR) based on tumor mutational burden (TMB) and gene alteration status in the *PIK3CA*-alt cohort. No multiplicity adjustment was made. **Results:** *PIK3CA*-alt (ALP, n = 120; PBO, n = 117) and *PI3KCA*-non-alt (ALP, n = 81; PBO, n = 80) cohorts had differential gene alteration landscapes. In the *PIK3CA*-alt cohort, ALP + FUL clinical benefit was seen across TMB quartiles (Q1: 0 -<2.52, Q2: 2.52 -<3.78, Q3: 3.78 -<5.04, Q4: ≥ 5.04 mut/megabase). ALP + FUL had greater benefit in pts with alt vs non-alt *FGFR1/2* (Table). ALP + FUL benefit was independent of alterations in *TP53, ESR1, CCND1, MAP3K1*, and *ARID1A* and limited in *MYC*- and *RAD21*-alt cohorts. ALP + FUL benefit was seen in pts with alt genes in the MAPK (HR [95% CI] vs PBO: alt 0.43 [0.23 - 0.80]; non-alt 0.56 [0.40 - 0.79]) and PI3K (in addition to *PIK3CA*; alt 0.68 [0.38 - 1.23]; non-alt 0.48 [0.34 - 0.68]) pathways, and implicated in CDK4/6i resistance (alt 0.52 [0.30 - 0.89]; non-alt 0.53 [0.37 - 0.76]). **Conclusions:** The unique mut profile of *PIK3CA*-alt tumors did not affect ALP + FUL benefit in pts with HR+, HER2– ABC. Clinical benefit was maintained regardless of alterations in most BMs, including *ESR1* and genes implicated in CDK4/6i resistance, consistent with ALP targeting the *PIK3CA* driver oncogene. Clinical trial information: NCT#02437318; EUDRA CT#2015-000340-42. Research Sponsor: Novartis Pharmaceuticals Corporation.

mPFS and HR in pts receiving ALP + FUL (*PIK3CA*-alt cohort).

1007 **Oral Abstract Session**

NRG-BR002: A phase IIR/III trial of standard of care systemic therapy with or without stereotactic body radiotherapy (SBRT) and/or surgical resection (SR) for newly oligometastatic breast cancer (NCT02364557). *First Author: Steven J. Chmura, The University of Chicago Medicine, Chicago, IL*

Background: Prospective and retrospective studies of patients (pts) with oligometastatic (OM) disease have supported that metastases (mets) directed treatment (MDT) with SBRT or SR in addition to standard of care systemic therapy (SOC ST) can improve progression-free (PFS) and overall survival (OS) compared with SOC ST alone. However, randomized evidence in oligometastatic breast cancer (OMBC) are lacking. NRG-BR002, a randomized Phase IIR/III trial, sought to determine the efficacy of SOC ST + MDT (SBRT or SR) as first line treatment of OMBC. **Methods:** OMBC pts with ≤ 4 extracranial mets on standard imaging with controlled primary disease were eligible if on first line SOC ST for ≤ 12 months without progression. Pts were randomized (1:1) to ARM 1 – SOC ST (mainly chemotherapy, endocrine therapy, anti-HER2) or ARM 2 – SOC ST with MDT of all mets. Stratification included mets number (1 vs > 1), ER/PR and Her2 status, and chemotherapy use. Phase IIR targeted sample size was 128 total/116 eligible pts, for 92% power and 1-sided significance level = 0.15 to determine if adding MDT shows a signal for improved PFS (hazard ratio [HR] = 0.55, corresponding to median PFS (mPFS) from 10.5 to 19 months), in order to continue to the full phase III trial for OS. PFS and OS were estimated by Kaplan-Meier and arms compared with log-rank. **Results:** 125 of the 129 pts randomized were eligible (ARM 1 = 65, ARM 2 = 60). Key characteristics included median age 54, 79% ER+ or PR+/HER2-, 13% HER2+, 8% triple negative. 60% had 1 metastasis and 20% presented synchronously with primary disease. Following randomization, systemic therapy was delivered to 95% in ARM 1 and 93% in ARM 2; ablation: SBRT 93%, SR 2%, and 5% none. The median follow-up was 30 mo. The mPFS (70% CI) in ARM 1 was 23 mo (18, 29) and 19.5 mo (17, 36) in ARM 2; 24 and 36-mo PFS (70% CI) for ARM 1 were 45.7% (38.9, 52.5) and 32.8% (26.0, 39.5) compared with 46.8 (39.2, 54.3) and 38.1 (29.7, 46.6) in ARM 2; HR (70% CI): 0.92 (0.71, 1.17); and 1-sided log-rank p = 0.36. As PFS did not show signal, OS reporting is included: median OS was not reached in either arm; 36-mo OS (95% CI) in ARM 1 71.8% (58.9, 84.7) and ARM 2 68.9% (55.1, 82.6; 2-sided log-rank p = 0.54). Analysis of first failure showed new mets outside index area (Arm 1) /RT field (Arm 2) developed similarly in both arms at 40%. There were fewer new mets inside treated/index area for Arm 2 6.7% vs ARM 1 29.2%, respectively. There were no grade 5 treatment-related adverse events (AEs), 1 grade 4 AE in ARM 1, and 9.7% and 5.3% grade 3 AEs in ARMS 1 and 2, respectively. Circulating tumor cell counts (0 vs ≥1) at baseline were similar in both arms and were not prognostic HR (95% CI): 1.04 (0.54, 2.02). **Conclusions:** The addition of MDT to SOC ST did not show signal for improved PFS, nor OS difference in patients with OMBC. The trial will not proceed to the Phase III component. Clinical trial information: NCT02364557. Research Sponsor: National Cancer Institute (NCI).

1008 **Oral Abstract Session**

Contributions of screening, early-stage treatment, and metastatic treatment to breast cancer mortality reduction by molecular subtype in U.S. women, 2000-2017. *First Author: Jennifer Lee Caswell-Jin, Stanford University, Stanford, CA*

Background: Treatment for metastatic breast cancer has advanced since 2000, but we do not know if those advances have reduced mortality in the general population. **Methods**: Four Cancer Intervention and Surveillance Network (CISNET) models simulated US breast cancer mortality from 2000 to 2017 using national data on mammography use and performance, efficacy and dissemination of estrogen receptor (ER) and HER2-specific treatments of early-stage (stages I-III) and metastatic (stage IV or distant recurrence) disease, and competing mortality. Models compared overall and ER/HER2-specific breast cancer mortality rates from 2000 to 2017 relative to estimated rates with no screening or treatment, and attributed mortality reductions to screening, early-stage or metastatic treatment. Results of an exemplar model are shown. **Results**: The mortality reduction attributable to early-stage treatment increased from 35.8% in 2000 to 48.2% in 2017, while the proportion attributable to metastatic treatment decreased slightly from 23.9% to 20.6%. The increasing contribution of early-stage treatment reflects the transition of effective metastatic treatments to early-stage disease: accordingly, ten-year distant recurrence-free survival improved (82.5% in 2000, 87.3% in 2017; for ER+HER2+, 78.2% to 90.9%). Survival time after metastatic diagnosis also increased, doubling from 1.48 years in 2000 to 2.80 years in 2017, with the best survival for women with ER+HER2+ cancers (4.08 years) and worst for ER-HER2- (1.22 years). **Conclusions**: Advances in metastatic breast cancer treatment are reflected in lower population mortality, both through transition to early-stage treatment and gains for women with metastatic disease. These results may inform patient/physician discussions about breast cancer prognosis and expected benefits of treatment. Research Sponsor: U.S. National Institutes of Health.

	Year	All Subtypes	ER+HER2+	ER+HER2-	ER-HER2+	ER-HER2-

***ESR1* F404 mutations and acquired resistance to fulvestrant in the plasmaMATCH study.** *First Author: Belinda Kingston, Breast Cancer Now Toby Robins Research Centre, Institute of Cancer Research, London, United Kingdom*

Background: The selective estrogen receptor modulator (SERD) fulvestrant is commonly used to treat patients with hormone receptor positive advanced breast cancer, although potential mechanisms of acquired resistance are poorly understood. plasmaMATCH cohort A (NCT03182634) investigated the activity of fulvestrant in patients with activating *ESR1* mutations in circulating tumor DNA (ctDNA). Here we present analysis of baseline and end-of-treatment (EOT) ctDNA to identify potential resistance mutations to fulvestrant. **Methods:** Paired baseline and EOT plasma samples from patients enrolled into plasmaMATCH underwent ctDNA sequencing (Guardant360, Guardant Health) to identify acquired mutations. For F404 analysis, MCF-7 cells were transiently transfected with estrogen receptor expression constructs containing either wildtype *ESR1* (WT), single *ESR1* mutations (D538G, E380Q, F404L), or compound mutations (D538G_F404L, E380Q_F404L), alongside an estrogen response element (ERE)-luciferase reporter construct. Transfected cells were treated with or without fulvestrant and ERE-luciferase activity compared. **Results:** Of 84 patients enrolled in cohort A, 69 had paired baseline and EOT sequencing. Patients with baseline *ESR1* Y537S had shorter progression free survival (PFS), and Y537C longer PFS, than those wild-type for each respective mutation ($p = 0.03$ and $p = 0.04$). Patients frequently acquired mutations at EOT (n = 35, 51%), including potentially targetable mutations in 25% (including 3 *PTEN*, 3 *BRCA1/2*, 2 *PIK3CA*, 2 *HER2*, 1 *BRAF*). Three (4%) patients acquired *ESR1* p.F404 mutations (F404L, F404I, F404V), with 7 mutations in total. Of 26 patients with PFS of ≥16 weeks, 3 patients (12%) acquired *ESR1* F404. In 800 patients screened for entry to plasmaMATCH, one harbored a F404 mutation (0.13%), with a prior history of fulvestrant. F404 mutations resided in *cis* with E380Q in 6/7 assessable mutations. *In vitro* structural modelling revealed that *ESR1* p.F404 resides within the *ESR1* ligand binding domain, and contributes to estrogen and fulvestrant binding through a pi-stacking bond between the aromatic ring of phenylalanine and estrogen/fulvestrant, with all F404 mutations disrupting this bond. Transient transfection demonstrated that single mutations D538G, E380Q, F404L and wild-type *ESR1* were sensitive to fulvestrant ($p < 0.0001$, $p = 0.0006$, $p = 0.04$ and $p = 0.0001$), whereas compound mutations D538G_F404L and E380Q_F404L were resistant. Further investigation of relative sensitivity of the F404 mutant *ESR1* to other anti-estrogens will be presented. **Conclusions:** We have identified a novel resistance mechanism to fulvestrant, with F404 mutations acquired in patients with pre-existing activating *ESR1* mutations. F404 confers fulvestrant resistance through the loss of a pi-stacking bond and likely reduced fulvestrant binding affinity, identifying a new potential target to overcome endocrine therapy resistance. Allelic dosage of *RB1* drives CDK4/6 inhibitor treatment resistance in metastatic breast cancer. *First Author: Anton Mikhailovich Safonov, Hospital of University of Pennsylvania, Philadelphia, PA*

Background: We recently reported inferior outcomes to CDK4/6 inhibitors and endocrine therapy (CDK4/6i-ET) associated with germline *BRCA2* (g*BRCA2)* in a cohort of estrogen receptor (ER) positive breast cancers. Co-occurrence of *gBRCA2* with loss of heterozygosity (LOH) of neighboring *RB1* was found to portend particularly poor outcomes. Here, we sought to define the effects of pre-treatment *RB1* allelic copy number status on outcomes of CDK4/6i-ET and the likelihood of developing *RB1* loss-of-function (LOF) mutations on CDK4/6i through the analysis of an expanded cohort of metastatic ER+ breast cancer patients. **Methods:** Patients who underwent sequencing on MSK-IMPACT from April 2014 to May 2021 were included. For every sample preceding CDK4/6i-ET, we performed FACETS to infer *RB1* allele specific copy number, ploidy, tumor purity and fraction genome altered (FGA). Patients were categorized based on *RB1* allelic status: HetLoss (total of one allelic copy), copy neutral LOH (CNLOH), other allelic imbalance including all other aneuploidy states, and diploid. Progression free survival (PFS) was assessed using univariate and multivariate Cox proportional hazard models adjusted for ET partner and FGA. Firth penalized logistic regression was used to study association of pre-treatment *RB1* status with acquired *RB1* LOF variants in paired post-CDK4/6i samples. **Results:** Of 2,630 potentially eligible patients, 279 patients had genomic sequencing performed prior to 1st line CDK4/6i-ET. Of these, 75 (26.8%) exhibited *RB1* HetLoss, 39 (14.0%) had CNLOH of *RB1*, 111 (39.7%) exhibited diploid *RB1* state, while 54 (19.4%) had other patterns of *RB1* allelic imbalance. All non-diploid *RB1* states were associated with significantly shortened PFS relative to diploid (univariate HetLoss HR: 2.05, 95% CI: 1.42, 2.97; CNLOH HR: 2.08, 95% CI: 1.32, 3.25; other imbalance HR: 1.70, 95% CI: 1.11, 2.58). Only HetLoss remained significant when adjusted for FGA (HR 1.61, 95% CI: 1.09, 2.38, $p = 0.017$). *RB1* LOF was rare in pre-CDK4/6i tumors (< 1%); excluding these cases did not change our results. Of the 176 patients with paired pre- and post-CDK4/6i samples, only *RB1* HetLoss in pre-CDK4/6i sample was significantly associated with development of *RB1* LOF mutations in post-CDK4/6i sample (18.4%) as compared to diploid (4.2%, OR 4.25, 95% CI 1.02, 17.7, $p = 0.047$). These results indicate that tumors with one functional copy of *RB1* are more likely to acquire *RB1* LOF on CDK4/6i to achieve biallelic RB1 loss as a mechanism of CDK4/6i resistance. **Conclusions:** We demonstrate that LOH and allelic imbalance of *RB1* are associated with shorter PFS on CDK4/6-ET. We postulate this may occur partly as a result of more frequent acquired *RB1* LOF mutations under selective pressure of CDK4/6i. These data supports the implementation of more refined allele-specific copy number methods and identifies a high-risk population for escalated monitoring and treatment approaches. Use of real-world data (RWD) to assess the utility of cell-free circulating tumor DNA (cfDNA) in identifying resistance to early treatment in advanced breast cancer (aBC). *First Author: Seth Andrew Wander, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: The approvals of CDK4/6 inhibitors (CDK4/6i) and alpelisib (a PI3Ka inhibitor, PI3Ki) have overhauled early treatment of hormone positive aBC. While some clinical trials have investigated mechanisms of resistance to these drugs, their impact on tumor evolution requires further exploration. Here we use cfDNA to examine molecular changes pre- and post-CDK4/6i or PI3Ki treatment and use RWD to assess the impact of putative resistance alterations on response to treatment. **Methods:** Patients (pts) with aBC were identified via the Guardant INFORM database and included if they had a cfDNA test within 90 days prior to therapy initiation and/or 90 days after therapy discontinuation with CDK4/6i or PI3Ki. Pts with *RB1* loss of function (LOF) alterations (alts) who received CDK4/6i and pts with *PTEN* LOF alts who received PI3Ki were separately identified, and these cohorts were matched 1:3 with a *RB1/PTEN* negative population respectively, by age (+/- 5 years), sex, year of cfDNA test, and line of therapy. Log-rank tests were used to assess differences in time to discontinuation (TTD) and time to next treatment (TTNT). **Results:** Differences in the frequencies of certain alts detected in pts pre- and post-CDK4/6i or PI3Ki treatment are shown (Table). Pts with *RB1* LOF alts prior to the start of CDK4/6i had significantly worse TTD and numerically worse TTNT versus controls (TTD = 3 mos vs 4.7 mos, p=0.018; TTNT = 7.3 mos vs 8 mos, p=0.082). Pts with *PTEN* LOF alts prior to start of PI3Ki had no significant difference in TTD or TTNT versus controls (TTD = 4.1 mos vs 4.1 mos, p=0.92; TTNT = 7.4 mos vs 7 mos, p=0.32). Notably, 54% of pts receiving CDK4/6i and 84% of pts receiving PI3Ki were on their third or later line of therapy. **Conclusions:** Using cfDNA, we were able to further characterize the resistance landscape of both CDK4/6i and PI3Ki, and identified specific *ESR1, RB1* and *PTEN* alterations that appear likely to occur under the pressure of therapy. Our real-world analysis examining *RB1* LOF alts added further evidence to suggest it may be both a primary and acquired resistance mechanism to CDK4/6i. As a non-invasive alternative to tissue biopsies, this data further illustrates that cfDNA can provide unique insight into tumor evolution and disease progression in the aBC setting. Circulating tumor DNA (ctDNA) and serum thymidine kinase 1 activity (TKa) matched dynamics in patients (pts) with hormone receptor–positive (HR+), human epidermal growth factor 2–negative (HER2-) advanced breast cancer (ABC) treated in first-line (1L) with ribociclib (RIB) and letrozole (LET) in the BioItaLEE trial. *First Author: Grazia Arpino, Department of Medical Clinics and Surgery, Universitàa Federico II, Napoli, Italy*

Background: Independent early dynamic assessment (baseline [D0] and day 15 of first cycle [D15]) of both TKa and ctDNA was prognostic and predictive in pts with HR+, HER2– ABC treated with RIB+LET enrolled in the BioItaLEE trial (NCT03439046). Here we performed a combined analysis of these two biomarkers. **Methods:** 287 pts were enrolled in the study. Overall, early dynamics were assessable for both biomarkers in 241/287 pts (84.0%). Methods applied for ctDNA and TKa evaluation were previously reported. For ctDNA, samples were defined as wild type (WT) if no mutations were observed at D0 and D15, ctDNA positive (+) if with or negative (-) if without a primary target mutation at D15. Samples were TKa+ or TKa- if TKa levels were above or below the limit of detection at D15. According to ctDNA and TKa pts were classified as: WT/TKa-, WT/TKa+, ctDNA-/TKa-, ctDNA-/TKa+, ctDNA+/TKa- and ctDNA+/TKa+ and then divided into 3 main study groups (GRs) WT/TKa- (GR1, n = 126), WT/TKa+, ctDNA-/TKa-, ctDNA-/TKa+, ctDNA+/TKa- (GR2, n = 96) and ctDNA+/TKa+ (GR3, n = 19). The association between biomarkers and PFS (progression-free survival) was estimated using Kaplan-Meier analysis and multivariate Cox models with 95% confidence intervals (CIs) adjusted for clinical variables. **Results**: Median follow-up was 26.9 months. In multivariate Cox models both TKa dynamics and mutational tumor burden at D15 were independently predictive of PFS. Hazard ratios (HRs) were 0.37 (95% CI: 0.23-0.60; p < 0.0001) for WT vs ctDNA+ and 0.56 (95% CI: 0.32-1.00; p = 0.0506) for ctDNA- vs ctDNA+. For TKa, HR was 0.49 (95% CI: 0.30-0.80; p = 0.0040) in TKa- vs TKa+. Interestingly combining the two variables further improve prediction of outcome. HRs for TKa- vs TKa+ were 0.17 (95% CI: 0.09-0.32; p < 0.0001), 0.28 (95% CI: 0.13-0.59; p = 0.0009) and 0.44 (95% CI: 0.23-0.86; p = 0.0169) in WT, ctDNA- and ctDNA+ pts, respectively. Considering the 3 study GRs, median PFSs (95% CI) were not reached (27.89, NE), 19.58 (13.83, 23.39) and 6.65 (2.83, 12.16) months in GR1, GR2 and GR3, respectively, p < 0.001. At multivariate Cox models, HRs of GR1 and GR2 compared with GR3 were 0.17 (95% CI: 0.09-0.32; p < 0.0001) and 0.37 (95% CI: 0.20-0.67; p = 0.001) respectively. **Conclusions**: These findings suggest that combining the early dynamic assessment of both ctDNA and TKa may improve outcome prediction in pts treated with RIB+LET. Pts with ctDNA+/TKa+ are strongly enriched for non-responders. TKa and ctDNA capture different features of tumor biological activity and their combination warrants further evaluation in relation to other treatments, settings, and diseases. Clinical trial information: NCT03439046. Research Sponsor: Novartis Farma SpA.

Effect of socioeconomic status as measured by Neighborhood Deprivation Index on survival in metastatic breast cancer. *First Author: Susrutha Puthanmadhom Narayanan, University of Pittsburgh Medical Center Cancer Center, Pittsburgh, PA*

Background: Socioeconomic status (SES) and race are major determinants of health outcomes in the United States. We aim to assess the effect of SES as measured by the Neighborhood Deprivation Index (NDI) and race on outcomes in metastatic breast cancer patients at our center. **Methods:** The NDI scores for patients with metastatic breast cancer who were treated at our center between 2000 and 2017 were obtained from the Neighborhood Atlas using their Zip-Code (N = 1246). The SES groups were defined as low deprivation with an NDI score in the bottom tertile and high deprivation with NDI in the top or middle tertiles. Baseline characteristics were compared between the SES groups with Bonferroni correction. Univariate and multivariate survival analysis were performed using the R packages "survival" and "survminer". **Results:** Race was the only baseline characteristic that was significantly different between the SES groups, the high deprivation group had a higher proportion of African Americans (10.5%) than the low deprivation group (3.7%, P = 9.3e-05). In univariate Kaplan-Meier survival analysis, both SES and race had significant effect on overall survival such that the high deprivation group had worse survival than low deprivation (Log Rank P = 0.01) and African Americans had worse survival than Caucasians (P = 0.008). In multivariate Cox proportional hazard model, SES, but not race, had a significant effect on overall survival (hazard ratio for high deprivation was 1.19 [95% Confidence interval 1.04 - 1.37], P = 0.01; Table). Progression-free survival on first-line chemotherapy was not different between the SES groups or racial groups in both univariate and multivariate analysis. **Conclusions:** The current study shows that patients from the high deprivation group (i.e., low SES), have worse survival in metastatic breast cancer. Race was no longer a significant predictor of survival when SES was accounted for in the analysis. This possibly suggests that poor outcomes in the African American population is explained by the association between low SES and African American race. Based on these results, there is an urgent need for healthcare investments in the low SES neighborhoods. Research Sponsor: None.

Cox proportional hazard model for survival in metastatic breast cancer.

	Hazard ratio [95% confidence interval]	P value
Race = Caucasian	0.8145 [0.6430 - 1.0318]	0.09
SES group = High deprivation (i.e., low SES)	1.1911 [1.0367 - 1.368]	0.01
Age at metastatic diagnosis	1.0095 [1.0045 - 1.0145]	0.0002
Subtype = ER+/HER2-	0.9685 [0.7702 - 1.2178]	0.78
Subtype = ER+/HER2+	0.8140 [0.6196 - 1.0692]	0.14
Subtype = Triple negative	2.0315 [1.5827 - 2.6077]	2.64e-08

Increasing Black patient participation in metastatic breast cancer clinical trials: The BECOME (Black Experience of Clinical Trials and Opportunities for Meaningful Engagement) project. *First Author: Stephanie Walker, Metastatic Breast Cancer Alliance, New York, NY*

Background: Among U.S. racial/ethnic groups, Black people with breast cancer have the highest death rate and shortest survival. Although ~15% of cancer patients in the U.S. are Black, only 4-6% of clinical trial participants are Black. Only when trial participants reflect the diversity of the general population can oncologists understand how a drug works across subpopulations. The objectives of the BECOME initiative are to understand barriers to trial participation by Black patients with metastatic breast cancer (MBC) and to identify actions to increase participation. **Methods**: BECOME is sponsored by the Metastatic Breast Cancer Alliance, a consortium of representatives from nonprofit organizations, pharmaceutical/biotech companies, and patient advocates, many of whom are living with MBC. Findings from a literature review and Key Informant interviews informed a survey of U.S. adults living with MBC. **Results**: Of 424 survey respondents, 102 (24%) self-identified as Black. Black respondents' trust and satisfaction with their oncology care team were high (> 90%), and 83% of Black respondents were somewhat or very likely to consider trial participation. However, 40% of Black respondents reported no one on their care team had discussed trials. Black respondents' reasons to not participate in a trial included concerns about side effects (73%) and effectiveness (63%). Black respondents were more likely than non-Black respondents to believe unstudied treatments may be harmful (57% vs 31%). Black respondents were less likely than non-Black respondents to indicate they trust trials (73% vs 91%) and trust that people of all races/ethnicities get fair treatment in trials (32% vs 56%). Black respondents were more likely than non-Black respondents to value receiving trial information from someone with the same racial/ethnic identity (67% vs 10%), who has had breast cancer (73% vs 44%) or MBC (73% vs 51%), or who has been in a trial (72% vs 48%). Black respondents were also more likely to be motivated to participate to ensure people with their racial or ethnic identity will benefit (83% vs 51%). **Conclusions**: Black patients with MBC are willing to consider participating in clinical trials. Actionable steps to increase Black patient participation include: 1) enhancing awareness about trials by informing patients, increasing education, training healthcare providers to deliver patient-friendly information in an unbiased manner, and providing messaging from people of shared racial/ethnic identity and health experience; 2) building trust through clear communication; 3) addressing concerns about side effects, effectiveness, harm, and fair treatment; and 4) helping patients find and access trials. All stakeholder groups have a role to play in increasing Black patient participation in MBC clinical trials. Research Sponsor: Metastatic Breast Cancer Alliance.

1015 **Poster Discussion Session**

Quality of life (QOL) with ribociclib (RIB) plus aromatase inhibitor (AI) versus abemaciclib (ABE) plus AI as first-line (1L) treatment (tx) of hormone receptor-positive/human epidermal growth factor receptor–negative (HR+/HER2−) advanced breast cancer (ABC), assessed via matching-adjusted indirect comparison (MAIC). *First Author: Hope S. Rugo, Department of Medicine, University of California San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: The combination of a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) + endocrine therapy is the recommended 1L tx for HR+/HER2– ABC. A statistically significant overall survival (OS) benefit with RIB + AI was recently reported for MONALEESA-2 (ML-2); final OS results for the MONARCH 3 (MON-3) trial of ABE + AI are pending. QoL is an important end point that affects tx decisions. Understanding the impact of CDK4/6i on QoL is of increasing importance given use in earlier tx lines for ABC and an emerging role in treating early breast cancer, where QoL considerations may be more relevant. MAIC analysis allows for comparative effectiveness in the absence of head-to-head trial data. In this analysis, patient (pt)-reported QoL for the Phase III ML-2 (RIB + AI) and MON-3 (ABE + AI) trials were compared using MAIC with a focus on individual domains; the PALOMA-2 trial could not be considered for this analysis because of the different pt-reported outcome measures evaluated in the trial compared to ML-2 and MON-3. **Methods:** An anchored MAIC of QoL with RIB + AI vs ABE + AI was performed using data from EORTC QLQ-C30 and BR-23 questionnaires, individual participant data from ML-2 (data cutoff: 6/10/2021), and published data from MON-3 (data cutoff: 11/3/2017). All available QoL data were used in this analysis; the median follow-up for ML-2 was 79.7 months, and the median duration of follow-up at which QoL data were reported for MON-3 was 26.73 months. Inclusion and exclusion criteria were generally similar. Pts in both arms of ML-2 were weighted to match baseline characteristics in the corresponding arms of MON-3. Cox proportional hazards model was used to generate hazard ratios (HRs); anchored HRs were calculated using the Bucher method. Time to sustained deterioration (TTSD) was calculated as the time from randomization to a ≥ 10-point deterioration with no later improvement above this threshold. **Results:** 205 and 149 pts from the ML-2 arms of RIB/PBO were matched to 328 and 165 pts from the ABE/PBO arms of MON-3. After weighting, pt characteristics were well balanced. TTSD significantly favored RIB vs ABE in appetite loss (HR, 0.46; 95% CI, 0.27-0.81), diarrhea (HR, 0.42; 95% CI, 0.23-0.79), and fatigue (HR, 0.63; 95% CI, 0.41-0.96) as measured by QLQ-C30 and arm symptoms (HR, 0.49; 95% CI, 0.30-0.79) as assessed by BR-23. TTSD did not significantly favor ABE vs RIB in any functional or symptom scale of the QLQ-C30 or BR-23. **Conclusions:** This MAIC suggests that RIB + AI is associated with better symptom-related QoL vs ABE + AI for postmenopausal pts with HR+/HER2– ABC in the 1L setting. QoL differences between CDK4/6i and their associated adverse event profiles may impact clinical decisions in HR+/HER2– ABC. Research Sponsor: Novartis Pharmaceuticals.

1016 **Poster Discussion Session**

Characterization of alpelisib-associated hyperglycemia in metastatic breast cancer. *First Author: Sherry Shen, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: For women with metastatic hormone receptor (HR)-positive, human epidermal growth factor 2 (HER2)-negative breast cancer, the combination of alpelisib and fulvestrant improves progression-free survival in those with *PIK3CA* mutations. Hyperglycemia is a major toxicity of PI3K inhibitors including alpelisib, which limits the clinical efficacy of these drugs due to interrupted/reduced dosing and discontinuation. In the SOLAR-1 trial that led to the Food and Drug Administration (FDA) approval of alpelisib, over 60% of patients developed hyperglycemia of any grade, and over 36% developed grade 3-4 hyperglycemia. Here we describe the incidence and treatment of alpelisib-associated hyperglycemia in a single center cohort. **Methods:** Patients with metastatic breast cancer who received alpelisib on a clinical trial or as part of standard care from 2013-2021 at Memorial Sloan Kettering Cancer Center were included in this retrospective study. Patient and tumor characteristics and pre-treatment body mass index (BMI), hemoglobin A1c, and serum glucose levels were abstracted from medical records. Alpelisib dose interruptions, reductions, or discontinuation was recorded as well as endocrinology consultation and use of anti-hyperglycemic agents. Date of progression and/or death were recorded where applicable. **Results:** 247 patients were included in this study, among whom 245 (99.1%) were female and 198 (80.1%) were white. 100 (40.5%) were treated on a clinical trial. Median baseline BMI was 25.4 kg/m^2. Among 164 patients with baseline hemoglobin A1c levels available, 93 (56.7%) patients had normal hemoglobin A1c, 54 (32.9%) had prediabetes, and 17 (10.4%) had diabetes. 152 patients (61.5%) developed hyperglycemia of any grade; 56 (22.7%) developed grade 3 and 16 (6.5%) developed grade 4 hyperglycemia. The median time to onset of hyperglycemia was 16 days. BMI ≥25 kg/m^2 or hemoglobin A1c ≥5.7% were strongly predictive of development of any-grade hyperglycemia (p= 0.036 and p< 0.001, respectively) and grade 3-4 hyperglycemia (p< 0.001 for both). Among those who developed hyperglycemia, 101 (40.9%) received treatment; 69 patients (27.9%) required only 1 anti-hyperglycemic agent whereas 9 (3.6%) required ≥3 anti-hyperglycemic agents. 49 (19.8%) were referred for endocrinology consult. In 66 patients (26.7%), alpelisib was held until resolution of hyperglycemia; 42 patients (17%) required dose reductions, and 11 (4.5%) discontinued alpelisib due to hyperglycemia. There was no significant difference in progression-free survival by hyperglycemia status or severity of hyperglycemia. **Conclusions:** Overweight BMI and hemoglobin A1c in the prediabetes or diabetes range were strongly predictive of developing alpelisib-associated hyperglycemia. Management of these co-morbidities prior to alpelisib treatment should be strongly considered. Research Sponsor: None.

1017 **Poster Discussion Session**

Impact of ribociclib (RIB) dose modifications (mod) on overall survival (OS) in patients (pts) with HR+/HER2- advanced breast cancer (ABC) in MONALEESA(ML)-2. *First Author: Lowell L. Hart, Florida Cancer Specialists and Research Institute, Fort Myers, FL*

Background: The phase 3 ML-2, -3, and -7 trials all demonstrated consistent and statistically significant OS benefit with RIB (starting dose: 600 mg/d 3 wk on/1 wk off) vs PBO in pts with HR+/HER2– ABC. RIB dose mod (reductions and/or interruptions) when needed did not impact OS benefit with RIB + endocrine therapy (ET) in previous analyses of ML-3/-7. Here we present data on the effect of RIB dose mod on OS in postmenopausal pts with HR+/HER2– ABC in ML-2. **Methods:** ML-2 (NCT01958021) enrolled postmenopausal pts randomized 1:1 to first-line RIB + letrozole (LET) or PBO + LET. Landmark (LM) analyses of OS were performed to evaluate the association between dose reductions (yes vs no) and OS. Multiple LM times were considered to determine the sensitivity of the findings. As an alternative to LM analysis, a Cox proportional hazards model with a time-varying covariate was performed. Two time-dependent variables, dose reduction (with/without mod from 600 mg starting dose) and relative dose intensity 2 (RDI2), were included in the respective model as covariates to explore the association with OS. To account for differences in time to first dose mod, RDI2 reflects the post–dose mod period. Median (m) OS was obtained using a modified Kaplan-Meier method. **Results:** At data cutoff (June 10, 2021; m follow-up, 49.35 [range, 0-86.7] mo), 209 of 334 pts (62.6%) had ≥ 1 RIB dose reduction and 125 of 334 (37.4%) had 0 RIB dose reduction. LM analyses by dose reduction are presented (Table). mOS was 66.0 (95% CI, 57.6-75.7) mo in pts with ≥ 1 RIB dose reduction vs 60.6 (95% CI, 42.5-79.2) mo in pts with no RIB dose reductions (HR, 0.87 [95% CI, 0.65-1.18]). RDI2 was classified according to tertile: low (< 64.27%), medium (64.27%-95.86%), and high (> 95.86%). In pts with low, medium, and high RDI2, mOS was 62.6 (95% CI, 50.0-80.7) mo, 63.9 (95% CI, 48.8-not reached [NR]) mo, and 65.3 (95% CI, 50.5-NR) mo, respectively (HR low vs high, 0.99 [95% CI, 0.69-1.42]; HR medium vs high, 0.97 [95% CI, 0.62-1.38]). **Conclusions:** In this exploratory analysis of ML-2, OS benefit was maintained in pts with HR+/HER2– ABC who required mod from the recommended starting dose of RIB (600 mg/d 3 wk on/1 wk off). No relationship was observed between OS and RIB dose reduction or RDI2; OS benefit with RIB was observed in all groups. Clinical trial information: NCT01958021. Research Sponsor: Novartis Pharmaceuticals.

Alpelisib (ALP) + endocrine therapy (ET) in patients (pts) with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2–), *PIK3CA*-mutated (mut) advanced breast cancer (ABC): Baseline biomarker analysis and progression-free survival (PFS) by duration of prior cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) therapy in the BYLieve study. *First Author: Dejan Juric, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: ALP (PI3K-α selective inhibitor and degrader) + fulvestrant (FUL) is approved for pts with HR+, HER2– ABC and a tumor mutation in *PIK3CA* (~ 40% of these pts). Primary analyses from the Phase 2 BYLieve study demonstrated efficacy and safety of ALP + ET in pts with *PIK3CA*-mut, HR+, HER2– ABC in the post-CDK4/6i setting. Post hoc analyses, including pts with disease progression within 6 mo of CDK4/6i + ET treatment (Tx), confirmed ALP benefit regardless of duration of prior CDK4/6i. Here we assess baseline biomarkers in circulating tumor DNA (ctDNA) by duration of prior CDK4/6i Tx and PFS in pts from BYLieve Cohorts A and B. **Methods:** In the BYLieve study, pts with *PIK3CA*-mut, HR+, HER2– ABC had CDK4/6i + aromatase inhibitor (Cohort A) or + FUL (Cohort B) as immediate prior Tx to receiving ALP + FUL and ALP + letrozole (LET), respectively. At data cutoff dates, pts had ≥ 18-mo follow-up in Cohort A and ≥ 6-mo in Cohort B. In each cohort, pts were grouped based on duration of prior CDK4/6i Tx (≤ 6 mo or >6 mo). Alterations were detected on ctDNA using next-generation sequencing (PanCancer V2 Panel). PFS was assessed in each cohort and by duration of prior CDK4/6i Tx. **Results:** Of 127 and 126 pts enrolled in Cohorts A and B, respectively, 98 (≤ 6-mo: 24; >6-mo: 74) and 94 (≤ 6-mo: 28; >6-mo: 66) were included in this analysis based on availability of ctDNA samples, data on duration of prior CDK4/6i, and centrally confirmed *PIK3CA*-mut disease. In this population, median (m) PFS (95% CI) was 8.2 mo (5.6 - 9.5) and 5.6 mo (3.7 - 7.1) in Cohorts A and B, respectively. In Cohort A, mPFS (95% CI) was 12.0 mo (5.5-non estimable) and 6.2 mo (5.4 - 8.5) in the ≤ 6-mo and >6-mo groups, respectively. The OncoPrint genomic profiles showed that pts in the ≤ 6-mo vs >6-mo group had a lower median ctDNA fraction and fewer detected gene alterations, including in genes associated with ET and/or CDK4/6i resistance, and fewer chromosomes 8/11 amplifications (linked to early relapse). In Cohort B, mPFS was 5.9 mo (3.5 - 11.0) and 5.6 mo (3.7 - 7.1) in the ≤ 6-mo and >6-mo groups, respectively. Both groups had high median ctDNA fractions and complex tumor mutation profiles reflecting more extensive treatment history. **Conclusions:** Lower median ctDNA fraction and lower mutational complexity observed in Cohort A ≤ 6-mo vs >6-mo group was associated with numerically longer mPFS, potentially indicating increased dependence on the mutant PI3K-α. In Cohort B, both ≤ 6-mo and >6-mo groups had high median ctDNA fractions and similar tumor mutation profiles. Additional ctDNA and tissue analyses are needed to elucidate the correlation between ALP + ET efficacy and treatment timing and baseline genomic complexity. Research Sponsor: Novartis Pharmaceuticals Corporation.

1019 **Poster Discussion Session**

Baseline and longitudinal ctDNA biomarkers in GEICAM/2013-02 (PEARL) trial cohort 2 comparing palbociclib and fulvestrant (PAL + FUL) versus capecitabine (CAPE). *First Author: Javier Pascual, Royal Marsden Hospital and The Institute of Cancer Research, London, United Kingdom*

Background: The randomized PEARL trial found no superiority of PAL plus endocrine therapy over CAPE in patients (pts) with metastatic HR-positive, HER2-negative breast cancer resistant to aromatase inhibitors (Martin M, Ann Oncol 2020). We investigated associations between baseline genomic landscape and on-treatment plasma ctDNA dynamics with progression free survival, in pts from cohort 2 of the trial. **Methods:** Plasma was collected for ctDNA analysis from -7 days to cycle 1-day 1 (C1D1) for baseline prognostic analysis and cycle 1-day 15 (C1D15) when available, and sequenced with an in-house error-corrected targeted capture panel encompassing 21 genes commonly altered in breast cancer. For predictive ctDNA dynamics analysis, a pre-specified criteria of 14 minimum days of treatment in first cycle was required and variants with VAF <0.5% in C1D1, set as limit of detection, were excluded. The circulating DNA ratio (CDR) was calculated as a weighted mean for potentially clonal mutations at C1D1. The optimal cut-off for predicting PFS was assessed by fitting a range of cut-offs, identifying the one with lower p-value on the log-rank test. Adjusted p-values, potential overestimation corrected by a shrinkage factor and bootstrapping techniques to calculate the CI95% were used in the cutpoint Cox regression model. **Results:** A total of 201 pts had a C1D1 sample sequenced for baseline prognostic analysis, 146 (73%) had baseline mutations identified and 55 (27%) had no mutations. 187 (93%) pts had a paired C1D15 sample for CDR calculations. Of these, 134 (72%) had baseline mutations detected, 120 of them (90%) above 0.5%, 14 (10%) had no calls, 1 pair failed sequencing. Both baseline and CDR subsets were representative of the overall study population. Pts with *TP53* mutations had worse PFS in the overall population (4.4 vs 9.3 months, logrank p= 0.04), with no differences between treatments. For on-treatment ctDNA dynamic analysis, median CDR (suppression) was lower in the CAPE arm (0.07 vs 0.21, p<0.01). There was an association between optimal cut-offs predicting PFS both in CAPE (suppressed 16.6 months vs high ctDNA 4.2 months, HR 2.37, CI95% 0.96-5.83, p=0.05) and PAL + FUL arms (suppressed 15.7 months vs high ctDNA 5.5 months, HR 2.14, CI95% 0.92-5, p=0.06). More ctDNA suppression associated with likelihood of objective responses (median CDR 0.1 in objective responders vs median CDR 0.2 in progressive disease p=0.03), with no statistical significance when stratified per treatment. **Conclusions:** In PEARL cohort 2, *TP53* mutations associated with poor outcome regardless of treatment allocation, suggesting aggressive behaviour not specifically linked to endocrine resistance. Lack of ctDNA suppression associated with worse outcome in both patient groups. Capecitabine resulted in greater ctDNA suppression at C1D15, likely reflecting faster ctDNA suppression. Research Sponsor: Pfizer and AstraZeneca.

1020 **Poster Discussion Session**

Survival in patients with breast cancer and history of autoimmune disease. *First Author: Demitrios Dedousis, University Hospitals, Case Medical Center - Cleveland VA Hospital, Cleveland, OH*

Background: Patients with autoimmune disease, specifically systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), and Sjogren syndrome, are at reduced risk of developing breast cancer compared to those without a prior history of autoimmune disease. Despite this, little is known about the survival of patients with concurrent autoimmune disease and breast cancer. This study compared outcomes in patients with breast cancer with and without autoimmune disease. **Methods:** This study was a retrospective analysis of patients from SEER-Medicare databases from 2007-2014 with breast cancer. Patients with a history of autoimmune disease were identified using ICD-9 codes. The effects of autoimmune disease on overall survival (OS) and cancer-specific survival (CSS) were estimated using multivariable Cox regression and Gray's method respectively controlling the effects of age, race and chronic kidney disease (CKD). The cumulative CSS was estimated taking death as a competing risk. **Results:** The overall prevalence of investigated autoimmune diseases among the 137,324 patients with breast cancer was 26.69%. The most common autoimmune diseases identified were RA (23.35%), psoriasis (2.41%) and SLE (1.12%). In stage IV breast cancer patients the OS and CSS were significantly higher in patients with autoimmune disease (p values < 0.0001), with a median OS of 36 months compared to 30 months in patients without autoimmune disease. After adjusting for the effects of age, race, and CKD, autoimmune disease was still predictive of higher OS (HR: 1.46, 95% CI: 1.37 – 1.57, p < 0.0001) and CSS (HR: 1.39, 95% CI: 1.29 – 1.5, p < 0.0001). Patients with autoimmune disease and stage I-III breast cancer, had lower OS (p < 0.0001, p < 0.0001, and p = 0.026 respectively) compared to patients without autoimmune disease. **Conclusions:** We found a higher prevalence of RA, Crohn disease, ulcerative colitis, and SLE in patients with breast cancer compared to cohorts of similar age ranges in the general population. History of autoimmune disease resulted in significantly improved OS and CSS in patients with stage IV breast cancer even when controlling for age, race and CKD, in this pre-immunotherapy cohort. These results suggest that that anti-tumor immunity plays an important role in late-stage breast cancer, and could be potentially exploited to improve the effectiveness of immunotherapy. Further research into the relationship between autoimmunity and breast cancer is warranted. Research Sponsor: Department of Hematology and Oncology at University Hospitals Cleveland Medical Center.

1021 **Poster Discussion Session**

A phase 1a/b trial of imlunestrant (LY3484356), an oral selective estrogen receptor degrader (SERD) in ER-positive (ER+) advanced breast cancer (aBC) and endometrial endometrioid cancer (EEC): Monotherapy results from EMBER. *First Author: Komal L. Jhaveri, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Imlunestrant is a novel, orally bioavailable SERD with pure antagonistic properties that result in sustained inhibition of ER-dependent gene transcription and cell growth. In dose escalation, imlunestrant showed favorable safety, pharmacokinetics (PK) and preliminary efficacy in patients with ER+, HER2- aBC and ER+ EEC (Phase 1a EMBER, Jhaveri 2021). Here we present updated data from the dose escalation (Phase 1a) and dose expansion (Phase 1b) of imlunestrant monotherapy in EMBER (NCT04188548). **Methods:** Phase 1a/1b enrolled patients with ER+ aBC (prior ET sensitivity; ≤3 prior therapies for aBC in Phase 1a following protocol amendment and ≤2 in Phase 1b) and ER+ EEC (prior platinum therapy; no prior fulvestrant or aromatase inhibitor). Premenopausal women received a concomitant GnRH agonist. Serial plasma samples were obtained for PK and ctDNA analysis. Key endpoints included recommended phase 2 dose (RP2D) determination, safety and tolerability, PK, objective response rate per RECIST v1.1 (ORR: complete response [CR] or partial response [PR]) in patients with measurable disease and ≥1 post-baseline tumor assessment or discontinued prior to tumor assessment, and clinical benefit rate (CBR: CR or PR, or stable disease ≥24 weeks) in patients enrolled ≥24 weeks prior to data cut. **Results:** As of January 14, 2022, 138 patients (n = 114 aBC, n = 24 EEC) received imlunestrant monotherapy at doses ranging from 200-1200 mg QD. Median age was 62.0 years (range 32-95). Median number of prior therapies for aBC and EEC was 2 (range 0-8) and 1 (0-5), respectively. aBC patients had received a prior ET (94.7%), CDK4/6 inhibitor (92.1%), fulvestrant (50.9%) and chemotherapy (26.3%). No dose-limiting toxicities were observed. Most treatment-emergent adverse events (TEAEs) were grade 1. At the RP2D (400 mg QD, n= 69), the most common all grade TEAE's were nausea (33.3%), fatigue (27.5%), and diarrhea (23.2%). Across all doses, the incidence of treatment-related grade 3 AEs was low (3.6%). No patient discontinued due to a TEAE. In evaluable aBC patients, ORR was 8.0% (6/75) and CBR was 40.4% (42/104). In evaluable EEC patients, ORR was 5.0% (1/20 had a PR- ongoing pending confirmation) and CBR was 47.1% (8/17). Clinical benefit was observed regardless of baseline *ESR1* mutation status as determined by ctDNA sequencing. Additional biomarker analyses will be presented at the meeting. **Conclusions:** Imlunestrant continues to demonstrate a favorable side effect profile, with no cardiac or opthalmic safety signals, and has continued evidence of clinical activity in heavily pre-treated ER+ aBC and EEC patients. Clinical trial information: NCT04188548. Research Sponsor: Eli Lilly and Company.

1022 **Poster Discussion Session**

Open-label, phase 2, multicenter study of lasofoxifene (LAS) combined with abemaciclib (Abema) for treating pre- and postmenopausal women with locally advanced or metastatic ER+/HER2− breast cancer and an *ESR1* mutation after progression on prior therapies. *First Author: Senthil Damodaran, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Resistance to endocrine therapy can develop when treating estrogen receptor positive (ER+), metastatic breast cancer (mBC). Treatment with aromatase inhibitors can lead to acquired mutations in the estrogen receptor 1 (*ESR1*), which can constitutively activate the ER, leading to endocrine resistance and worse disease prognosis. Treatment options for mBC patients with an *ESR1* mutation are limited. Further, data suggest that patients could derive clinical benefit from Abema after progression on prior cyclin-dependent kinase 4/6 inhibitor (CDK4/6i). LAS, a third-generation selective estrogen receptor modulator, as monotherapy or combined with a CDK4/6i, was shown to have superior efficacy over fulvestrant (FVT) in preclinical breast cancer models expressing *ESR1* mutations. Based on these results, a phase 2 clinical trial of LAS combined with Abema was initiated in mBC patients with *ESR1* mutations. **Methods:** ELAINE 2 is an open-label, phase 2, multicenter trial evaluating the safety and efficacy of LAS combined with the CDK4/6i, Abema. Study participants were pre- and postmenopausal women with ER+/HER2- mBC with acquired *ESR1* mutation (identified by ctDNA testing), whose disease had progressed on one or two lines of hormonal therapy for metastatic disease with or without a CDK4/6i (including Abema). Patients took oral LAS 5 mg/day and Abema 150 mg BID. Treatment continued until evidence of disease progression, death, unacceptable toxicity, or withdrawal from the study. The primary endpoint was safety, and secondary endpoints were progression free survival (PFS), objective response rate (ORR), and clinical benefit rate (CBR). **Results:** 29 patients were enrolled at 16 US sites (Oct 2020 to June 2021). Mean age was 58.3 y (35-79 y); 86% were Caucasian. Most had progressed with at least 2 previous hormonal treatments (80%). All except 1 patient received a prior CDK4/6i and 72% had received prior FVT; 48% had chemotherapy in the metastatic setting. Four patients discontinued the trial due to adverse events (AEs, n = 2), consent withdrawal (n = 1), or investigator withdrawal (n = 1). No deaths occurred during the study and few Grade 3/4 AEs were observed. Most common AEs were diarrhea, nausea, and leukopenia. Five patients had an Abema dose reduction from 150 mg to 100 mg BID. To date, 11 patients have progressed and 14 continue treatment. The censored median PFS was 13.9 mos (95% CI, 8.0–NE), the ORR 33.3% (95% CI, 16.3–56.3) with 6 confirmed partial responses, and the CBR 62.1% (95% CI, 44.0–77.3). **Conclusions:** LAS combined with Abema in the ELAINE 2 trial was well tolerated and demonstrated robust and meaningful efficacy in women with ER+/HER2- mBC and an *ESR1* mutation who had progressed on previous CDK4/6i therapies. Clinical trial information: NCT04432454. Research Sponsor: Sermonix Pharmaceuticals.

1023 **Poster Discussion Session**

A phase 1b/2 study of the BET inhibitor ZEN-3694 in combination with talazoparib for treatment of patients with TNBC without gBRCA1/2 mutations. *First Author: Philippe Georges Aftimos, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium*

Background: Metastatic triple negative breast cancer (mTNBC) is an aggressive and heterogeneous cancer with limited therapeutic options. PARP inhibitors (PARPi), approved to treat patients with HER2- breast cancer with a germline BRCA1/2 (gBRCA1/2) mutation, have not shown efficacy in homologous recombination repair (HRR) proficient tumors. In pre-clinical models, the BET inhibitor (BETi) ZEN-3694 sensitizes wild-type (WT) BRCA1/2 tumors to PARPi through downregulation of HRR gene expression, providing a rationale for combination therapy. We previously reported results from the Ph 1b portion of the trial evaluating the combination of ZEN-3694 plus talazoparib, in TNBC patients without gBRCA1/2 mutations; here we present results from the completed Ph 1b/2 study. **Methods:** A Ph 1b dose finding portion (n = 15) was followed by a single arm Ph 2 Simon 2-stage portion (n = 17+20 (37)). The primary endpoint of the Ph 1b portion of the study was safety and recommended Ph 2 dose (RP2D). The secondary endpoints were pharmacokinetics (PK), pharmacodynamics (PD), and clinical benefit rate (CBR = confirmed objective response rate (ORR) + stable disease > 16 weeks). Ph 2 measured CBR as the primary endpoint, ORR and duration of response (DOR) as key secondary endpoints. Eligibility criteria for Ph 1b included TNBC (ER/PR < 10%, HER2-), WT gBRCA1/2, and > 1 prior cytotoxic regimen for mTNBC, and in the Ph2 portion ER/PR < 1% and < 2 prior cytotoxic regimens for mTNBC. Patients were dosed daily in continuous 28 day cycles until disease progression or unacceptable toxicity. Adverse events, PK, and PD in whole blood and tissue biopsies were assessed. Response endpoints were assessed per RECIST 1.1 every 2 cycles. **Results:** RP2D was determined to be 48mg qd ZEN-3694 plus 0.75mg qd talazoparib. The most common AE for the Ph 1b/2 study was thrombocytopenia (TCP) (55% any grade, 34% G3/4), which was managed with dose holds and reductions. Dose intensity analysis showed average daily doses of ZEN-3694 and talazoparib could be maintained above 40mg and 0.5mg, respectively, over 8 cycles. Robust target engagement was demonstrated using BET-dependent and HRR transcripts assessed in paired tumor biopsies. Ph 2 portion of the trial met its primary endpoint with a CBR of 30% (11/37). For the Ph 1b/2 trial, investgator assessed ORR was 22% (11/50), including 2 CR, CBR was 35% (18/51) and the median DOR was 24 weeks. For the subset of TNBC at diagnosis patients (no history of HR+ disease) , ORR was 32% (11/34), and CBR was 44% (15/34). **Conclusions:** Combination of ZEN-3694 and talazoparib demonstrated anti-cancer activity in pretreated mTNBC WT gBRCA1/2 patients. All confirmed responses were observed in TNBC at diagnosis patients, whose tumors are expected to be more sensitive to the combination due to their basal-like properties. The trial is being expanded to Ph. 2b to accrue an additional 80 TNBC at diagnosis patients. Clinical trial information: NCT03901469. Research Sponsor: Zenith Epigenetics.

1024 **Poster Discussion Session**

Results from plasmaMATCH trial cohort E: A phase II trial of olaparib and ceralasertib in patients with triple-negative advanced breast cancer (CRUK/15/010). *First Author: Alistair E. Ring, The Royal Marsden NHS Foundation Trust, Surrey, United Kingdom*

Background: The plasmaMATCH trial was an open label platform trial, consisting of circulating tumour DNA (ctDNA) testing in ~1000 patients with advanced breast cancer (ABC) linked to parallel treatment cohorts with therapies matched to mutations identified in ctDNA. Cohorts A-D have already reported (Turner N et al, Lancet Oncol 2020). Cohort E recruited patients with triple negative breast cancer (TNBC) without a targetable mutation identified at ctDNA screening, treating with olaparib (PARP inhibitor) plus ceralasertib (ATR inhibitor). **Methods:** Patients with TNBC who had received 1 or 2 lines of chemotherapy for advanced disease or relapsed within 12 months of (neo)adjuvant chemotherapy were eligible. Treatment was olaparib 300mg b.i.d continuously and ceralasertib 160mg qd on days 1–7 on a 28 day cycle, until disease progression. The primary endpoint was confirmed objective response rate by RECIST v1.1. Secondary endpoints included clinical benefit rate, progression-free survival (PFS) and safety. Biomarker analysis included response according to *BRCA* and somatic DNA repair gene status and ATM loss. Using a two-stage design with a target response rate of 25%, unacceptable response rate of 10%, alpha=2% and power=90%, ≥13 responses out of 69 evaluable stage 2 patients were required to infer efficacy (5/37 stage 1). **Results:** Between 17/09/18 and 5/10/20 75 patients enrolled in Cohort E of whom 70 were evaluable for response. The median age was 55.6 years. 42 (56%) patients had 1 and 13 (17.3%) had 2 prior line(s) of chemotherapy for metastatic disease. Efficacy is shown in Table. The most common grade ≥3 adverse events were: hypertension 12 (17%) and anaemia 9 (13%). Dose reductions and interruptions occurred in 19 (26.4%) and 34 (47.2%) patients respectively. **Conclusions:** The response rate to olaparib and ceralasertib did not meet pre-specified criteria for efficacy in the overall evaluable population. Responses were observed in patients without germline or somatic BRCA1/2 mutations. Translational analyses are underway to identify potential biomarkers of response in this population and will be presented at the meeting. Clinical trial information: ISRCTN16945804. Research Sponsor: Cancer Research UK and Stand Up To Cancer, Pharmaceutical/Biotech Company.

Response rates and median PFS.

Population	N	Number of confirmed responses	Confirmed response rate, % (95%CI)	Median PFS (IQR), months
All evaluable patients	70	12	17.1 (9.2, 28.0)	4.3 (1.9, 10.0)
***BRCA1/2* germline mutation**	10	3	30 (6.7, 65.2)	8.4 (6.1, 25.4)
***BRCA1/2* germline or somatic mutation**	13	3	23.1 (5.0, 53.8)	7.3 (4.5, 25.4)
No germline or somatic *BRCA1/2* mutation ^	55	9	16.4 (7.8, 28.8)	3.7 (1.9, 10.0)
ATM loss*	14	3	21.4 (4.7, 50.8)	3.4 (1.4, 10.2)
No ATM loss*	29	4	13.8 (3.9, 31.7)	2.5 (1.9, 10.0)

*ATM loss defined as H score ≤10. ATM loss subgroup analysis was restricted to those with no *BRCA1/2* germline or somatic mutation. 12 patients had either a missing or inadequate sample.
^2 patients did not have somatic BRCA testing.

1025 **Poster Session**

The mutational profile of ER-, PR+, HER2- metastatic breast cancer. *First Author: Neal A. Fischbach, Yale Cancer Center, New Haven, CT*

Background: ER-PR+Her2- breast cancer is a rare subtype occurring at approximately 1% of all breast carcinomas. Most of these cancers behave in an aggressive fashion with limited benefit from anti estrogen therapy, similar to triple negative breast cancer (TNBC). Better characterization of these tumors is needed for predicting clinical behavior, response to endocrine therapy, and eligibility for clinical trials. Here we sought to evaluate the mutational profile of a well curated set of ER-PR+HER2- metastatic breast cancers and compare to other receptor phenotypes. **Methods:** 2049 consecutive breast cancers submitted to Foundation Medicine for comprehensive genomic profiling (CGP) were included. ER, PR and HER2 expression were abstracted from submitted pathology reports. Cases without complete ER, PR and HER2 information in pathology reports were excluded. CGP was performed as previously described (Frampton, 2013). **Results:** Patient ages were similar across subgroups. Generally, ER-PR+HER2- tumors were rare (n = 23, 1.1%) and most similar to TNBC in their genomic profiles. These tumors harbored high rates of *TP53* and *BRCA1* alterations and low rates of *PIK3CA, ESR1,* and *CDH1* alterations. Genomic loss of heterozygosity (gLOH) was similar in the ER-PR+HER2- and ER+PR+HER2-subtypes (8.18% and 8.66% respectively), and lower than TNBC (17.19%). Notably, a high rate of *RB1* alterations were identified in the ER-PR+HER2- patients (13%, 3/23), numerically higher than the other subtypes. *EGFR*, *MET*, *PTEN*, *CDKN2A* and *KRAS* alterations were also observed at a higher frequency in ER-PR+Her2- cancers (8.7, 4.2, 39.1, 13.0 and 13.0% respectively) relative to the other subtypes. IO drug biomarkers including MSI, TMB and PD-L1 IHC were similar among the groups. **Conclusions:** The mutational profile for ER-PR+Her2- metastatic breast cancer more closely resembles TNBC than ER+ breast cancer. These data suggest molecular profiling may be a useful adjunct to optimize treatment strategies for this rare subset of cancers. Based on molecular characteristics, we recommend including ER-PR+Her2- patients in clinical trials for TNBC. Finally, genes including RB1, *CKDN2A*, *PTEN*, *EGFR* and *MET* are mutated at higher frequency in ER-PR+Her2- cancers than other subsets, suggesting unique biology with potential therapeutic implications. Research Sponsor: None.

	Overall cohort	ER+ PR+ HER2-	ER+ PR- HER2-	ER- PR+ HER2-	HER2+	TNBC

A phase II, single-arm, open label, Simon two-stage study of pembrolizumab in patients with metastatic HER2-negative breast cancer: Evaluation of impact of germline variants in APOBEC3B (AUROR). *First Author: Gwo Fuang Ho, Department of Clinical Oncology, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia*

Background: A germline deletion in the *APOBEC3B* cytosine deaminase gene [A3Bdel] occurs more frequently in Asian women (45% heterozygous deletion (hetD) and 15% homozygous deletion (homD)) compared to in Caucasian women (15% hetD and 4% homD). Carriers are more likely to develop breast cancer, and cancers in carriers are more likely to have a hypermutator phenotype (with C > T transitions) and to be immune-enriched. In this clinical trial, we aim to evaluate whether the immune activation increases response to checkpoint immunotherapy. **Methods:** In this open label, single arm Phase II study of single agent pembrolizumab in metastatic HER2-receptor negative breast cancer patients with germline deletion in A3B, 40 evaluable subjects who have received > = 1 but < = 3 lines of therapy in a metastatic setting will be enrolled and given pembrolizumab 200 mg intravenously (IV) every 3 weeks (Q3W) for up to 35 administrations (2 years), with Objective Response Rate (ORR) using RECIST 1.1 as the primary study endpoint. The study applies a Simon two-stage design, where if at least 3 out of 22 evaluable patients achieve CR/PR in stage I, the study will proceed to stage II. **Results:** To date, 84 breast cancer patients were screened for germline A3Bdel, of whom 46 (54.8%) were heterozygous carriers and 12 (14.3%) were homozygous carriers. The study enrolled 22 female A3Bdel carriers with a median age of 59.4 years (range: 32.1, 82.9 years) between September 2020 and September 2021 for stage I analysis. On average, patients received 2 prior lines of chemotherapy in a metastatic setting [6 with 1, 8 with 2 and 8 with 3 lines of prior chemotherapy]. Complete response (CR) was observed in one patient, while partial response (PR) was observed in 4 patients, with an ORR of 22.7% (5 over 22 subjects) in stage I, meeting the predefined criteria to proceed to stage II. Notably, the patient with complete response had received 2 prior lines of chemotherapy, whereas of the patients with partial response, 1 had received 1 prior line and 3 had received 3 prior lines of chemotherapy in a metastatic setting. As the observed ORR was greater than the value of r_1 (13.6%), the study has met the statistical criteria to proceed to the stage II enrolment with an additional 18 patients required to complete the entire study. **Conclusions:** Single agent pembrolizumab demonstrates promising efficacy in germline A3Bdel carriers, who constitute almost two-thirds of Asian patients. Clinical trial information: NCT03989089. Research Sponsor: Cancer Research Malaysia, Other Foundation.

1027 **Poster Session**

Targetable genomic mutations in young women with advanced breast cancer. *First Author: Norin Ansari, Yale New Haven Hospital, New Haven, CT*

Background: Advanced breast cancer in women < 40 years is more aggressive, with worse prognosis and disease-free survival, compared to older women with the disease. With increasing availability of targeted and immune therapies, we aimed to compare genomic alterations (GA) using comprehensive genomic profiling (CGP) of tumor tissue. **Methods:** We analyzed 2,049 breast cancers submitted to Foundation Medicine for CGP. Hybrid-capture based CGP was performed to evaluate all classes of GA. Tumor mutational burden (TMB) was determined on at least 0.8 Mbp of sequenced DNA and microsatellite instability was determined on at least 95 loci. Tumor cell PD-L1 expression (defined as tumor proportion score >/= 1) was determined by IHC (Dako 22C3). We identified 28 (1.37%) patients <30 years, 159 (7.76%) between 30-39 years, and 1862 (90.87%) >/= 40 years. Breast tissue was used for CGP in 69.5% of cases and remainder of specimens were lymph node, metastatic, or unspecified. **Results:** Breast tumors were less likely to be estrogen receptor positive in younger women (54% of those <30 years, 60% of those 30-39 years, 69.4% of those >/= 40 years) and more likely to be triple negative (43%, 33%, 26.1% in the same respective groups). There was no clear pattern in HER2+ status by age (0%, 15.1%, 7.2%). Younger women had higher rates of *BRCA1* (17.9%, 10.1%, 2.6%), *BRCA2* mutations (7.10%, 5.70%, 4.1%), and *RB1* mutations (14.3%, 9.4%, 6.1%), and lower rates of *CDH1* (7.1%, 5%, 15.4%) and *PIK3CA* mutations (17.9%, 17.6%, 40.0%). Younger women were more likely to have PD-L1 expression (55.6%, 54.4%, 51.5%) but had lower frequencies of TMB >10 (0.0%, 5.0%, 8.7%). Differences are statistically significant in *BRCA1*, *CDH1*, and *PIK3CA*. **Conclusions:** These findings confirm that young women with breast cancer have actionable GA. Different mutational profiles may support differential use of targeted and immune therapies. Statistically and clinically significant differences include higher *BRCA1* mutations which may lend to PARP inhibitor use and lower *PIK3CA* mutations which may reduce alpelisib use. Higher *RB1* mutations and immunotherapy biomarker differences were not statistically significant. However, these may clinically translate into CDK4/6 resistance and reduced immunotherapy options, respectively. Research Sponsor: None.

Neratinib plus fulvestrant plus trastuzumab (N+F+T) for hormone receptor-positive (HR+), HER2-negative, *HER2*-mutant metastatic breast cancer (MBC): Outcomes and biomarker analysis from the SUMMIT trial. *First Author: Komal L. Jhaveri, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: N is an oral, irreversible pan-HER TKI with activity against *HER2* mutations. Genomic analyses from the SUMMIT MBC cohort following N±F suggest that resistance to N may occur via mutant allele amplification or secondary *HER2* mutations. Adding T to N+F in SUMMIT showed encouraging durable responses in patients (pts) with HR+, *HER2*-mutant MBC and prior CDK4/6 inhibitors (CDK4/6i). **Methods:** SUMMIT (NCT01953926) enrolled pts with HR+, HER2-negative MBC with activating *HER2* mutation(s) and prior CDK4/6i. Pts received N+F+T (oral N 240 mg/d with loperamide prophylaxis, im F 500 mg d1&15 of cycle 1 then q4w, iv T 8 mg/kg initially then 6 mg/kg q3w). During the small, randomized portion of the trial, pts received N+F+T, F+T or F (1:1:1 ratio). Pts randomized to F+T or F could crossover to N+F+T at progression. Efficacy endpoints: investigator-assessed ORR and CBR (RECIST v1.1); DOR; best overall response. Pre-treatment tumor tissue was centrally assessed retrospectively by next-generation sequencing. ctDNA from patient samples was assessed by NGS. **Results:** SUMMIT has completed enrolment; we report efficacy from 45 pts in the N+F+T cohort, plus 10 pts who progressed on F (n=6) or F+T (n=4) and crossed over to N+F+T (Table). *HER2* allelic variants in the 45 N+F+T pts and ORR (%) (pts may have >1 mutation) were: V777L (n=6, 50%), L755S/P (n=15, 40%), S310F (n=4, 50%), exon 20 insertion (n=11, 36%), other KD missense (n=6, 33%), TMD missense (n=2, 0%), exon 19 deletion (n=1, 0%). **Conclusions:** N+F+T is a promising combination for HR+, *HER2*-mutated MBC with prior exposure to CDK4/6i, across a range of activating *HER2* mutations. Results from the upcoming Apr 2022 data cut, including biomarkers, safety, mechanisms of acquired resistance, and preclinical mechanism of N+T, will be presented. Clinical trial information: NCT01953926. Research Sponsor: Puma Biotechnology, Inc.

Detection of presumed germline pathogenic variants of hereditary breast cancer predisposition genes in circulating tumor DNA: SCRUM-Japan MONSTAR-SCREEN. *First Author: Masaya Hattori, Department of Breast Oncology, Aichi Cancer Center, Nagoya, Japan*

Background: Approximately 5-10% of breast cancer are hereditary. Variant allele frequency (VAF) of hereditary breast cancer predisposition genes in circulating tumor DNA (ctDNA) may be useful for detecting presumed germline pathogenic variants. **Methods:** One hundred and sixty-eight patients with advanced breast cancer (ABC) who underwent ctDNA and tumor tissue sequencing analyses in the SCRUM-Japan MONSTAR-SCREEN, a cancer genome screening project in Japan, from December 2019 to November 2021 were included. The patients were tested and monitored for their genomic alterations by FoundationOne Liquid assay or FoundationOne Liquid CDx assay. The pathogenic variants (PV) of hereditary breast cancer predisposition genes with VAF of 30% or higher in ctDNA were defined as PGPV. The VAF of *BRCA1/2* on ctDNA analyses in *BRCA1/2* germline pathogenic variant (GPV) carriers and the prevalence of PGPV in five hereditary breast cancer predisposition genes, including *ATM*, *BRCA1*, *BRCA2*, *CHEK2*, and *PALB2*, were investigated. **Results:** From 168 patients with ABC, including 115 Luminal, 32 HER2-positive, and 21 triple negative breast cancer, with a median age of 58 years, 39 PVs in 5 genes were identified with a median VAF of 0.62% (range: 0.1-84.77). ctDNA identified GPV of known *BRCA1/2* GPV carriers (1 with *BRCA1* and 6 with *BRCA2*), with a median VAF of 51.4% (range: 48.2-77.5). The VAF of GPV on ctDNA were higher than 30% in subsequent consecutive samples. Among 161 patients with ABC, excluding 7 known *BRCA1/2* GPV carriers, 6 PGPV (1 with *BRCA1,* 3 with *BRCA2,* and 2 with *PALB2*) were detected, with a median VAF of 65.5% (range: 51.2-84.8). Subsequent confirmatory tests were performed for two PGPV, and the variants were confirmed to be of germline origin. **Conclusions:** VAF on ctDNA analysis can help to easily detect PGPV of hereditary breast cancer predisposition genes. The PGPV detected in ctDNA analysis should be validated by established germline tests, and the results could provide opportunities for targeted therapies, as well as cancer risk assessment of patients and their relatives. Research Sponsor: None.

Association of interleukin-enhanced factor 2 (ILF2) expression with prognosis and clinico-genomic features in breast cancer (BC). *First Author: Matias A. Bustos, Saint John's Cancer Institute at Providence Saint John's Health Center, Santa Monica, CA*

Background: Novel prognostic and predictive biomarkers beyond traditional histological subtypes are needed to better inform outcomes and enhance therapy guidance in breast cancer (BC). We have previously reported that ILF2 was overexpressed in TNBC cell lines and has a functional role in DNA and RNA metabolism, making it a promising biomarker for risk assessment and treatment decisions. Herein, we aim to leverage a large clinico-genomic dataset to further characterize ILF2 in BC patients (pts). **Methods:** A total of 9456 BC tissue samples underwent molecular profiling at Caris Life Sciences (Phoenix, AZ). Analyses included next generation sequencing of DNA (592 Gene Panel, or Whole Exome Sequencing), and RNA (Whole Transcriptome Sequencing), and immunohistochemistry (IHC). Wilcoxon and Fisher's exact were used to determine statistical significance. Overall survival (OS) was obtained from insurance claims and Kaplan-Meier estimates were calculated. Spearman correlation was used to identify highly correlated genes (ρ>0.6) with ILF2 and significant genes that were subsequently analyzed via pathway analysis using STRING. **Results:** BC pts were grouped into ILF2-High (H, top quartile) and ILF2-Low (L, bottom quartile) based on mRNA expression (TPM). ILF2-H pts were significantly younger (73 vs 80% for pts >50), enriched in ductal histology (90.9 vs 77.7%), TNBC subtype (48.9 vs 18.9%), and had a higher CNS metastases rate (4.3 vs 1.4%) compared to ILF2-L pts (all q<0.0001). ILF2 overexpression was associated with significantly inferior OS in all BC pts (HR 3.38, 95%CI: 2.97 – 3.84); when stratified into known BC hormonal receptor (HR) subtypes, ILF2 was prognostic in both HR+ BC (HR 1.7, 95 CI: 1.34-2.19) and TNBC (HR 3.8, 95 CI: 3.1-4.7), all p<0.0001. In TNBC (n=2468), ILF2-H was associated with a higher frequency of TP53 mutations(mt), lower rate of PIK3CA mt and higher amplification of CCNE1 and FGF23; in HR+/HER2- BC (n = 5071), an association with a higher rate of TP53 mt, PD-L1 expression, NOTCH2 and CCND2 amplification was seen (Table). No significant molecular correlation with ILF2 was seen in HR-/HER2+ BC (n=682). In TNBC, ILF2 expression was significantly correlated with genes involved in spliceosome, cell cycle and RNA transport pathways. In HR+/HER2- BC, ILF2-correlated genes were significantly enriched in mismatch repair and DNA replication pathways (p<0.05 for all factors individually). **Conclusions:** High expression of ILF2 is associated with a poorer prognosis independent of subtype in BC and our study warrants further investigation on ILF2 as a diagnostic and therapeutic target. Research Sponsor: None.

Zanidatamab (zani), a HER2-targeted bispecific antibody, in combination with docetaxel as first-line (1L) therapy for patients (pts) with advanced HER2-positive breast cancer: Preliminary results from a phase 1b/2 study. *First Author: Keun Seok Lee, National Cancer Center, Center for Breast Cancer, Goyang, South Korea*

Background: HER2-targeted agents have improved outcomes in HER2-positive breast cancer, but some pts develop resistance, relapse, or do not respond to current 1L therapies. Zani, also known as ZW25, is a novel HER2-targeted bispecific antibody that binds to two distinct extracellular domains of HER2. In a Phase 1 trial (NCT02892123) zani was well tolerated and demonstrated preliminary antitumor activity as monotherapy/with chemotherapy in pts with pre-treated advanced HER2+ breast cancer. **Methods:** Cohort 1 of this ongoing open-label, Phase 1b/2 study (NCT04276493) is evaluating zani in combination with docetaxel as a 1L therapy in adult females with advanced HER2+ breast cancer who may have received prior neoadjuvant/adjuvant treatment. Cohort A pts received zani 30 mg/kg IV, Cohort B pts received zani 1800 mg IV, both with docetaxel 75 mg/m^2 IV Q3W. Primary endpoints were safety and investigator (INV)-assessed objective response rate (ORR) per RECIST v1.1. Secondary endpoints included INV-assessed duration of response (DoR), disease control rate (DCR) and progression-free survival (PFS). **Results:** As of Nov 26, 2021, 25 pts with a median age of 57.0 years (range: 33.0–80.0) were assigned to Cohort A (n=11) or B (n=14). Median study follow-up was 7.0 months (range: 1.1–17.4) and the median number of treatment cycles was 10 (range: 2–20), 16 (64.0%) pts remained on treatment. Of the 22-efficacy evaluable (EE) pts, confirmed ORR was 86.4% (95% CI: 65.1, 97.1). The 6 months PFS rate was 90.9% (95% CI: 68.3, 97.7). Efficacy data are summarized in Table 1. All pts experienced ≥ 1 treatment emergent adverse event (TEAE) and 17 (68.0%) pts experienced ≥ Grade 3 TEAEs. In total, 23 (92.0%) pts experienced treatment related TEAEs (trTEAEs), and 17 (68.0%) pts experienced ≥ Grade 3 trTEAEs. The most common trTEAEs were diarrhea (56.0%) and decreased neutrophil count (52.0%). Serious trTEAEs occurred in two (8.0%) pts, trTEAEs leading to treatment discontinuation occurred in one (4.0%) pt and no trTEAEs led to death. **Conclusions:** Zani and docetaxel combination demonstrated antitumor activity in 1L therapy for advanced HER2+ breast cancer, with a manageable safety profile. Clinical trial information: NCT04276493. Research Sponsor: This study was sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Victoria Dagwell, MSc, of Ashfield MedComms, an Ashfield Health company, and funded by BeiGene, Ltd.

Summary of efficacy results (EE analysis set*).

	Cohort A (n=9)	Cohort B (n=13)	Total (n=22)
Confirmed best overall response, n (%)			
Complete response	1 (11.1)	0 (0)	1 (4.5)
Partial response	7 (77.8)	11 (84.6)	18 (81.8)
Stable disease	0 (0)	1 (7.7)	1 (4.5)
Progressive disease	1 (11.1)	1 (7.7)	2 (9.1)
Confirmed ORR, n (%) 95% CI	8 (88.9) 51.8, 99.7	11 (84.6) 54.6, 98.1	19 (86.4) 65.1, 97.1
Confirmed DCR, n (%) 95% CI	8 (88.9) 51.8, 99.7	12 (92.3) 64.0, 99.8	20 (90.9) 70.8, 98.9
Confirmed DoR, range	1.4–12.4	1.5–5.6	1.4–12.4

*Three pts without any post-baseline tumor assessments were excluded from EE analysis set.
Data cut-off: Nov 26, 2021.

1032 **Poster Session**

Serena-1: Updated analyses from a phase 1 study (parts C/D) of the next-generation oral SERD camizestrant (AZD9833) in combination with palbociclib, in women with ER-positive, HER2-negative advanced breast cancer. *First Author: Mafalda Oliveira, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: SERENA-1 (NCT03616587) is a Phase 1, multi-part, open-label study of camizestrant in women with ER+, HER2– advanced breast cancer (ABC). Parts A/B (escalation/expansion) assessed camizestrant monotherapy and have been presented previously. Parts C/D examine camizestrant in combination with palbociclib; here we present mature data from camizestrant 75 mg in combination with palbociclib; 75 mg being the camizestrant dose currently under investigation in the Phase 3 studies SERENA-4 (NCT04711252) and SERENA-6 (NCT04964934). **Methods:** The primary objective was to determine the safety and tolerability of camizestrant once daily (QD) with palbociclib. Secondary objectives included anti-tumor response and pharmacokinetics (PK). Prior treatment with < 2 lines of chemotherapy in the advanced setting was permitted. There was no limit on the number of lines of prior endocrine treatment in the advanced setting; prior treatment with CDK4/6 inhibitors and fulvestrant (F) was permitted. **Results:** As of 9 September 2021, 25 patients had received camizestrant 75 mg QD in combination with palbociclib. Tolerability of the combination of camizestrant 75 mg and palbociclib was consistent with that of each drug individually. No patient required camizestrant dose interruption/reduction/discontinuation due to a camizestrant-related adverse event (AE); moreover, none experienced a Grade ≥3 camizestrant-related AE. All camizestrant-related heart rate reductions were Grade 1 (asymptomatic). All camizestrant-related visual effects were Grade 1 (mild), apart from one patient who experienced transient Grade 2 (moderate) visual effects that resolved to Grade 1 without dose modification. Camizestrant-related gastrointestinal disorders were all Grade 1, except one instance of Grade 2 nausea lasting one day. PK data for camizestrant 75 mg QD and palbociclib combined were broadly consistent with camizestrant as monotherapy and published palbociclib steady-state PK data, further supporting the use of camizestrant 75 mg QD (Phase 3 dose) in combination with the approved palbociclib doses. In these heavily pre-treated patients (48% prior chemotherapy, 80% prior CDK4/6i, 68% prior F; all in advanced disease setting) and of whom 60% had visceral metastases, the clinical benefit rate at 24 weeks was 7/25 (28%). **Conclusions:** The PK and safety profile of camizestrant 75 mg QD in combination with palbociclib is favorable in this mature Phase 1 dataset. Despite extensive pre-treatment - including chemotherapies, CDK4/6i, and F - camizestrant 75 mg QD in combination with palbociclib exhibits encouraging clinical activity. The results from the ongoing Phase 3 studies, SERENA-4 and SERENA-6, will further elucidate the role of this combination in the treatment of patients with HR+/HER2– ABC. Clinical trial information: NCT03616587. Research Sponsor: AstraZeneca.

Pyrotinib in combination with metronomic oral vinorelbine in patients with HER2-positive advanced breast cancer who had failed prior trastuzumab-based therapy: A single-center, single-arm, prospective phase 2 study. *First Author: Chunfang Hao, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*

Background: In 15% to 30% of breast cancers, human epidermal growth factor receptor 2 (HER2) is overexpressed, this is related to aggressive disease and poor prognosis. Although important clinical benefits for patients have been achieved by the use of the HER2 antibody trastuzumab, 50% to 74% of patients with metastatic disease have no response to treatment, and approximately 75% progress within one year. The purpose of this study was to evaluate the efficacy and safety of oral pyrotinib in combination with oral metronomic vinorelbine in patients with HER2-positive advanced breast cancer who had failed prior trastuzumab-based therapy. **Methods:** This prospective phase 2 study enrolled patients aged 18-75 years with HER2-positive advanced breast cancer who had failed prior trastuzumab-based therapy, and had an Eastern Cooperative Oncology Group performance score of 0-2. Patients received pyrotinib 400 mg once daily and vinorelbine 40 mg once on Monday, Wednesday, Friday of each week until disease progression or unacceptable toxicity. Both pyrotinib and vinorelbine were orally administered 30 min after meals. The primary endpoint was progression-free survival (PFS). The secondary endpoints were objective response rate (ORR), disease remission rate (DCR), overall survival (OS), quality of life (QoL) and safety (CTCAE 5.0). The follow-up of this study is ongoing, but enrolment is closed. This study is registered on Clinical Trials.gov, number NCT04903652. **Results:** Between Oct 21, 2019, and Jan 21, 2022, 36 patients were enrolled and all of them were included in the intent-to-treat (ITT) population. 20 of 36 patients had disease progress or death. Median follow-up was 16.23 months. The median PFS (mPFS) was 14.23 months (95% CI 8.13-20.33). The ORR and DCR were 38.9% and 83.3%, respectively. The median OS was not reached. Grade 3 adverse events (AEs) occurred in 17 of 36 patients, the most common were diarrhea 27.8% and stomachache 5.6%. No grade 4 AEs were observed. **Conclusions:** Pyrotinib combined with metronomic oral vinorelbine showed promising efficacy and manageable safety in patients with HER2-positive advanced breast cancer who had failed prior trastuzumab-based therapy. This study might represent a potential treatment option for these patients. Clinical trial information: NCT04903652.. Research Sponsor: CSCO-Hengrui Cancer Research Fund (Y-HR2018-075).

1034 **Poster Session**

Pyrotinib monotherapy or pyrotinib in combination with capecitabine could significantly prolong progression-free survival and overall survival in patients with HER2-positive metastatic breast cancer. *First Author: Xiuwen Guan, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: In the NALA phase III trial, irreversible pan-ErbB tyrosine kinase inhibitor (TKI) neratinib plus capecitabine demonstrated significant improvement in the progression-free survival (PFS), but no significant benefit in overall survival (OS) compared to lapatinib plus capecitabine. However, another TKI pyrotinib plus capecitabine showed significant benefits in PFS and a trend of OS benefits in the PHOEBE phase III study. But in general, current data on survival of irreversible TKIs in patients with HER2-positive metastatic breast cancer (MBC) was limited. Thus, we performed a pooled analysis of individual patient data from the phase I to III trials in HER2-positive MBC patients receiving pyrotinib or pyrotinib combined with capecitabine, to provide a cumulative assessment on long-term outcomes of irreversible TKI. **Methods:** Individual patient data was collected and analyzed from the phase I trial for pyrotinib and pyrotinib plus capecitabine, the Pivotal phase II trial and the PHOEBE phase III trials that enrolled patients in China National Cancer Center. Next-generation sequencing was performed on circulating tumor DNA for predictive biomarkers in the phase I trial. **Results:** Between August 2013 and October 2018, a total of 120 patients were assigned to received pyrotinib (n = 38), pyrotinib plus capecitabine (n = 53) and lapatinib plus capecitabine (n = 29) across the above four trials. The median follow-up duration for OS was 73.6 months (95% CI:69.9-77.3 months). The estimated median PFS was 8.2 months (95% CI:5.6-10.9 months) in the pyrotinib monotherapy group and 22.0 months (95% CI:13.2-30.8 months) in the pyrotinib plus capecitabine group (P= 0.002), while the median OS was 27.1 months (95% CI: 21.6-32.5 months) in the pyrotinib monotherapy group and 44.5 months (95% CI: 30.8-58.1 months) in the pyrotinib plus capecitabine group (P= 0.065). In this pooled analysis, pyrotinib 400mg in combination with capecitabine, recommended for phase II and III trials, had significantly longer PFS (22.0 vs 6.9 months, P< 0.001) and OS (59.9 vs 31.2 months, P= 0.035) than lapatinib plus capecitabine. Analysis of all genetic alterations in baseline blood samples suggested that the patients harbored concomitant mutations in HER2-related signaling network (including HER2 bypass signaling pathway, PI3K/Akt/mTOR pathway and TP53) were observed with significantly poorer PFS and OS compared to none or one genetic alteration (median PFS, 7.3 vs. 26.1 months, P= 0.003; median OS, 25.1 vs. 48.0 months, P= 0.013). **Conclusions:** This pooled analysis based on phase I to III trials revealed promising PFS and OS was achieved in pyrotinib and pyrotinib plus capecitabine. Concomitant mutations in HER2-related signaling network may be a potential efficacy and prognosis biomarker for pyrotinib in HER2-positive MBC. Clinical trial information: NCT01937689,NCT02361112,NCT02422199,NCT03080805. Research Sponsor: National Nature Science Foundation of China(82103634).

Pyrotinib plus nab-paclitaxel in patients with HER2-positive advanced or metastatic breast cancer: A multicenter, single-arm, open-label phase 2 trial. *First Author: Huan Li, Department of Breast internal medicine, Liaoning Cancer Hospital and Institute, Shenyang, China*

Background: For human epidermal growth factor receptor 2 (HER2) positive advanced or metastatic breast cancer, the standard therapeutic strategy is HER2-targeted agents combined with a taxane. This multicenter, single-arm phase 2 trial was designed to assess the efficacy and safety of pyrotinib (a brand-new generation, irreversible anti-HER2 tyrosine kinase inhibitor) plus nab-paclitaxel in patients with HER2-positive advanced or metastatic breast cancer. **Methods:** This was a multicenter, single-arm, open-label phase 2 trial conducted at seven centers in China (ChiCTR1900023653). Women aged 18-75 years, with histologically or cytologically confirmed HER-2 positive (immunohistochemistry [IHC] 3+ or positive confirmed by fluorescence in situ hybridization) advanced or metastatic breast cancer and with Eastern Cooperative Oncology Group performance score (ECOG PS) of 0-1 were enrolled. Patients with primary resistance to trastuzumab and bone-only metastases were excluded. Eligible patients received pyrotinib (400 mg, po, qd) plus nab-paclitaxel (125 mg/m^2, iv, day 1/8/15) for each 28-day cycle until disease progression, unacceptable toxicity, consent withdrawal or death. The primary endpoint was objective response rate (ORR), defined as the proportion of patients with complete response (CR) or partial response (PR) according to Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1. Secondary endpoints included progression-free survival (PFS), overall survival, safety and quality of life. **Results:** Between December 2019 and December 2021, 51 patients were enrolled. The median age was 55 years (range 35–72). Twenty-three patients (45.1%) had ECOG PS of 0. Ten patients (19.6%) with metastatic disease had previously received first-line treatment and 28 (54.9%) had received prior treatment with trastuzumab. More than half (29 of 51, 56.9%) had hormone receptor-positive disease. Visceral metastases occurred in 56.9% of the patients (29 of 51) and 26 patients (51.0%) were menopausal. The data cutoff for the present analysis was January 21, 2022. Among 38 evaluable patients, four patients (10.5%) had CR, 27 (71.1%) had PR, six (15.8%) had stable disease, and one (2.6%) had progressive disease. The confirmed ORR was 81.6% (95% CI 65.1-91.7%). The PFS data were still immature. The most common grade ≥3 treatment-emergent adverse events included neutropenia (14 of 51, 27.5%), diarrhea (10 of 51, 19.6%), fatigue (5 of 51, 9.8%) and peripheral neuropathy (4 of 51, 7.8%). **Conclusions:** Pyrotinib combined with nab-paclitaxel showed a promising antitumor activity with good tolerance in patients with HER2-positive advanced or metastatic breast cancer. Clinical trial information: ChiCTR1900023653. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

1036 **Poster Session**

Monitoring and management of interstitial lung disease/pneumonitis among patients with metastatic breast cancer treated with trastuzumab deruxtecan. *First Author: Jonathan K. Kish, Cardinal Health, Dublin, OH*

Background: Trastuzumab Deruxtecan (T-DXd) was associated with an increased risk of interstitial lung disease (ILD)/pneumonitis (P) in metastatic breast cancer (mBC) patients (pts) in clinical trials, leading to ILD/P monitoring and management guidelines in the product label. This study aims to describe the monitoring and management of ILD/P during T-DXd therapy among US community oncology practices. **Methods:** Oncologists in the Cardinal Health Oncology Provider Extended Network (OPEN) participated in a cross-sectional survey on monitoring approaches for ILD/P among mBC pts. Participating physicians provided data from medical charts of up to 10 pts who were treated with T-DXd regarding presence of ILD/P symptoms, management, and outcomes of ILD/P symptoms. **Results:** Twenty-eight physicians from across the U.S participated and provided data on 149 T-DXd pts. Nearly all physicians reported they were monitoring ILD/P after T-DXd initiation by physical examination (n = 27), symptoms checklist (n = 25) and pulse oximetry (n = 23) at every visit, whereas fewer reported performing lung CT scan (n = 18), echocardiogram (n = 13), chest X-ray (n = 12), lung PET scan (n = 10), pulmonary function tests (n = 8) and diffusion testing (n = 7) on a less frequent basis. Among 149 T-DXd pts, 4 pts were diagnosed with ILD/P over an average T-DXd treatment duration of 5.5 months. All 4 cases initiated T-DXd treatment at 5.4mg/kg every 3 weeks, experienced ILD/P within the first 5 cycles of T-DXd, were diagnosed with lung CT scan and initially presented with Grade 2 symptomology (2 cases progressed to Grade 3). For both cases that remained as Grade 2, ILD/P completely resolved within 23 days. One case received IV methylprednisolone (1000mg daily; duration of therapy (DOT): 3 days) during hospitalization, oxygen therapy and T-DXd was permanently discontinued; whereas the other one received oral prednisone (started at 40mg daily and tapered to 5mg daily; DOT: 7 days) and T-DXd dose was held. For the two grade 3 cases, one received IV methylprednisolone (125mg daily; DOT: 7 days) during hospitalization, T-DXd dose was held, and ILD/P completely resolved within 11 days; whereas the other case received oral prednisone (started at 80mg daily and tapered to 5mg daily; DOT: 63 days), oxygen therapy, T-DXd was permanently discontinued, and ILD/P resolved with sequela within 46 days. **Conclusions:** ILD/P incidence in this small study sample of patients receiving T-DXd treatment was 2.7%. Although general awareness of ILD and routine screening by pulse oximetry and physical exam were common, management approaches for ILD/P were not always consistent with T-DXd prescribing information. Further physician education may be needed to improve appropriate management of ILD/P and outcomes for T-DXd pts. Research Sponsor: Daiichi Sankyo.

Updated results and biomarker analyses from the phase I trial of A166 in patients with HER2-expressing locally advanced or metastatic solid tumors. *First Author: Xichun Hu, Department of Medical Oncology, Fudan University Cancer Hospital, Shanghai, China*

Background: A166, an antibody-drug conjugate, with an anti-HER2 antibody site-specifically conjugated to Duo-5 (anti-microtubule agent), via a stable protease-cleavable valine citrulline linker, has proved its safety and efficacy in patients with HER2 positive breast cancer (Xichun Hu et al. ASCO 2021). Here, we report updated data and biomarker analyses from this single-arm, multi-center, open-label, phase I trial (CTR20181301). **Methods:** This study has two parts: dose escalation and dose expansion. In the expansion part, dose cohorts were expanded at 4.8 and 6.0 mg/kg Q3W, and the primary endpoint was ORR, as assessed according to the RECIST 1.1. Next-generation sequencing was performed on tissue-derived DNA and blood-derived circulating tumor DNA (ctDNA). **Results:** As of Dec 10, 2021, in total 58 female pts were enrolled in the expansion dose cohorts. Median age was 53.5 years (range 26-71), 58 pts (100%) had prior HER2-targeted therapy with the median lines of 4, including 100% received trastuzumab ± pertuzumab, 94.8% received anti-HER2 TKIs, and 20.7% received anti-HER2 ADCs in the metastatic setting. Any grade treatment-related AEs (TRAEs) were documented in 100.0% (58/58) of pts. Common TRAEs were corneal epitheliopathy (98.3%), blurred vision (89.7%), peripheral sensory neuropathy (67.2%), muscular weakness (36.2%) and dry eyes (32.8%). Most common grade ≥3 TRAEs were corneal epitheliopathy (34.5%), blurred vision (22.4%) and ulcerative keratitis (10.3%). 7 pts had serious AEs, 3 of whom were possibly related to the study drug, including thrombosis, peripheral motor neuropathy and muscular weakness. TRAEs led to 39.7% (23/58) dose reduction and 1.7% (1/58) treatment discontinuation. All patients were evaluable for efficacy with the best ORR being 73.91% (17/23; 95% CI, 51.59 to 89.77) and 68.57% (24/35; 95% CI, 50.71 to 83.15), mPFS being 12.30 months (95% CI, 6.00 to not reached) and 9.40 months (95% CI, 4.00 to 10.40) in 4.8 and 6.0 mg/kg cohort, respectively. Of 23 pts treated at 4.8 mg/kg dose level, one had a confirmed and sustained complete response lasting 7+ months. At the time of the data cutoff, 24 pts (41.4%) continued to receive A166 treatment.NGS of 520 genes was performed on tissue-derived DNA and ctDNA of baseline tumor tissue samples (n = 42) and blood samples (n = 53), respectively, and post-treatment blood samples (n = 8). Univariate and multivariate analysis showed that baseline PIK3CA/PTEN status had no influence on the PFS, and gave an idea of FGFR1 amplification as a potential negative predictor of A166 efficacy in HER2-positive breast cancer. **Conclusions:** The previously demonstrated preliminary clinical benefit of A166-ADC was maintained with no new safety signals, which demonstrated manageable toxicity and encouraging anti-tumor activity in heavily pretreated HER2-positive metastatic breast cancer patients. Clinical trial information: CTR20181301. Research Sponsor: Sichuan Kelun-Biotech Biopharmaceutical Co., Ltd.

1038 **Poster Session**

Early clinical safety and pharmacokinetics data of DZD1516, an BBB-penetrant selective HER2 inhibitor for the treatment of HER2-positive metastatic breast cancer. *First Author: Xichun Hu, Department of Medical Oncology, Fudan University Cancer Hospital, Shanghai, China*

Background: Patients with HER2+ metastatic breast cancer (MBC) are at high risk of developing central nervous system metastases. DZD1516 is a reversible HER2-specific tyrosine kinase inhibitor (TKI) with full blood-brain barrier (BBB) penetration. Here we report the preliminary safety and PK data from the ongoing phase 1 study (NCT04509596) in patients with HER2+ MBC who relapsed from multiple prior treatments. **Methods:** Eligible patients received single oral dosing of DZD1516 on C0D1 and then twice daily (BID) oral dosing from C1D1 in a continuous 21-day cycle until disease progression, unacceptable toxicity or withdrawal of consent. The primary objective is to investigate the safety and PK of DZD1516 as a single agent. **Results:** As of 17 January 2022, DZD1516 was explored in 21 HER2+ MBC patients from the USA and China. DZD1516 was well tolerated at doses < 300 mg, BID. Two DLT events were reported in the 300 mg cohort. In all cohorts, 20 (95.2%) patients reported treatment-emergent adverse events (TEAEs), and 3 (14.3%) patients reported grade 3 drug-related TEAE. Two patients had dose interruption and one patient had dose reduction due to TEAE, all in the 300 mg cohort. Majority of TEAEs were reversible. The longest treatment duration was > 3 months. In all cohorts, the most common (> 20%) TEAEs included headache (42.9%), vomiting (38.1%), nausea (23.8%) and hemoglobin decreased (23.8%). At doses < 300 mg, there is no diarrhea or rash reported. PK data showed that combined exposure of DZD1516 and its active metabolite DZ2678 increased in a dose-proportional manner across the dose ranges. Elimination half-life was about 15-19 hrs. About 2-fold accumulation of DZD1516 in AUC was observed on multiple doses. *In vitro*, both DZD1516 and DZ2678 showed good permeability, and were not substrates of P-gp and BCRP. In patients, $K_{puu,CSF}$ of DZD1516 and DZ2678 was around 2.13 and 0.66, respectively, suggesting good CNS penetration. At the time of data cutoff, 16 patients had at least one post treatment anti-tumor assessment. With a median of 7 lines of prior treatment, the best anti-tumor response was stable disease. **Conclusions:** Preliminary clinical data showed that DZD1516 is a full BBB-penetrant HER2 TKI, with good safety profile. Consistent with its high selectivity, no wide type EGFR related AEs have been reported. Further evaluation of its safety and efficacy is ongoing. Clinical trial information: NCT04509596. Research Sponsor: Dizal Pharmaceutical.

Survival of elderly patients with HER2+/HR- metastatic breast cancer in clinical practice: SEER-Medicare data 2012-2016. *First Author: Zhonghui Ou, MCPHS University, Boston, MA*

Background: Older patients with human epidermal growth factor 2-positive (HER2+) metastatic breast cancer(mBC) are underrepresented in clinical trials. We aim to assess the overall survival (OS) and breast cancer-specific survival of elderly women with de novo HER2+/hormone receptor-negative (HR-) mBC in a real-world setting. **Methods:** Elderly women with HER2+/HR- mBC treated with chemotherapy and/or HER2-targeted agents and with continuous Medicare Part A, B, and D coverage 1-year before diagnosis were identified from the SEER-MEDICARE database 2012-2016. Patients were retrospectively followed from metastatic diagnosis until death, disenrollment from Medicare A, B, or D, or end of the observation period. Patients' year and month of diagnosis and death were retrieved from SEER. Death dates were verified with Medicare records reported by the Social Security Administration (SSA). For all-cause deaths, Kaplan-Meier analysis was used to estimate overall survival. The cumulative incidence competing risk (CICR) method based on cumulative incidence function (CIF) was used to estimate breast cancer-specific death incidence. **Results:** Seventy-three patients (mean age at diagnosis, 75.0±7.7 years) met the inclusion criteria. Among them, 56 were treated with trastuzumab ± pertuzumab /chemotherapy as first-line treatment, and 17 were treated with chemotherapy only. The median time to initiate trastuzumab-based treatment from diagnosis was 2.5 months, and the longest trastuzumab treatment length was over 44 months. The median follow-up for OS was 13 months. One patient developed stomach cancer 6 months after breast cancer diagnosis. In Kaplan-Meier analysis, censoring or not censoring this patient after second cancer development resulted in a median OS of 19 months (95% CI, 9-24 months) and 18 months (95% CI, 9-22 months). The OS at the end of 46 months was approximately 25%. Five patients died from other causes, including lung cancer, cerebrovascular diseases, aortic aneurysm and dissection, pneumonia and influenza, and heart diseases during treatment. Considering these competing risks, 50% (95% CI, 36%-64%) of patients specifically died from breast cancer between 21 and 22 months, estimated by the CICR method. **Conclusions:** Our study observed a shorter OS among HER2+/HR- mBC elderly patients in clinical practice than the OS of 40.8 and 56.5 months among younger patients in the CLEOPATRA trial, suggesting that age is an important prognostic factor for breast cancer survival. The presence of second cancer and other competing risks led to overestimating the probabilities of breast cancer-specific death and resulted in a shorter OS using the Kaplan-Meier method. The CICR method is more relevant to estimate the breast-cancer-specific death incidence. Research Sponsor: None.

Pyrotinib-based therapy for patients with HER2-positive breast cancer: A multicenter, real-world study. *First Author: Haoqi Wang, Fourth Hospital of Hebei Medical University, Shijiazhuang, China*

Background: Pyrotinib, an irreversible pan-ErbB inhibitor, has been approved for the treatment of HER2-positive advanced breast cancer in China. Real-world data is instructive for effect evaluation and application of the drug in clinical practice. Herein, this study was conducted to evaluate the effectiveness and safety of pyrotinib-based therapy in patients with HER2-positive breast cancer in the real-world setting. **Methods:** In this retrospective, multicenter, real-world study, data of patients with HER2-positive breast cancer who received pyrotinib-based therapy from 19 sites were reviewed. Disease characteristics, prior therapies, and treatment patterns were summarized. Progression-free survival (PFS) and the incidence of diarrhea were analyzed. **Results:** Between September 2018 and June 2021, a total of 378 patients with HER2-positive advanced breast cancer were included. Of 378 patients, 47.4% had hormone receptor (HR)-positive disease, 41.3% had HR-negative disease, and 11.4% had unknown HR status. Brain, lung, liver, and bone metastases were found in 24.9%, 35.7%, 31.7%, and 33.1% of all cases, respectively. Most of patients (83.1%) were trastuzumab-exposed, 12.7% were pertuzumab-exposed, and 8.2% had been treated with lapatinib or neratinib before receiving pyrotinib. Pyrotinib plus chemotherapy (211 [55.8%]) was the most commonly used regimen, followed by pyrotinib monotherapy (115 [30.4%]), pyrotinib plus trastuzumab and chemotherapy (29 [7.7%]), other regimens (18 [4.8%]), and unknown regimen (5 [1.3%]). Standard dose (400 mg once daily) was used in 256 (67.7%) patients. With a median follow-up duration of 20.5 months, the median PFS was 13.0 months (95%CI, 12.0-14.0). Further analyses showed that the median PFS did not differ in subgroups by age (≥65 or < 65 years), HR status (positive or negative), brain metastasis (yes or no), lung metastasis (yes or no), liver metastasis (yes or no), bone metastasis (yes or no), prior exposure to trastuzumab (yes or no), treatment regimen (pyrotinib monotherapy or combination therapy). Significant variance was discovered between sufficient dosage group and non-sufficient group (13.2 months vs 10.93 months, p= 0.028). The survival advantage of sufficient dosage was also evident in brain metastasis cases (14.4 months vs 8.3 months, p= 0.043).The most common adverse event was diarrhea (85.7%), and grade ≥3 diarrhea occurred in 18.5% of patients. Diarrhea was the leading cause for does reduction of pyrotinib. **Conclusions:** The PFS data in our study was similar to previous clinical trials referring to HER2-positive advanced breast cancer treated with pyrotinib. Cases with brain metastasis also displayed a satisfactory survival result. Sufficient dosage is of great importance for prolonged survival, prevention of diarrhea may efficiently avoid does reduction and guarantee the drug efficacy. Research Sponsor: None.

HER2 alterations and prognostic implications in all subtypes of breast cancer. *First Author: Kaitlyn O'Keefe, Atrium Health Levine Cancer Institute, Charlotte, NC*

Background: Amplification or overexpression of human epidermal growth factor receptor 2 (HER2) oncogene is present in about 15-20% of breast cancers & is a prognostic & predictive biomarker. Additional *ERBB2*/HER2 alterations have become apparent on tumor next generation sequencing (NGS), including activating kinase domain mutations & fusions. **Methods:** DNA NGS (592 gene panel or whole exome) data from 12,153 breast samples retrospectively reviewed for *ERBB2* alterations with RNA whole-transcriptome sequencing (WTS) data available for 7289 (60%) samples. Gene fusions detected using the ArcherDx fusion assay or WTS. Clinicopathologic features were described including breast cancer subtype, age, & biopsy site. HER2 status determined according to 2018 ASCO-CAP guideline. Overall survival obtained from insurance claims & Kaplan-Meier estimates were calculated for defined patient (pt) cohorts. Statistical significance was determined using Chi-square & Wilcoxon rank sum tests. **Results:** ERBB2 mutations (*ERBB2mts*) were identified in 3.2% (n = 388) of tumors overall & most common in liver metastases (113/1972, 5.7%). *ERBB2mts* were found more in breast lobular tumors compared to ductal tumors (10 vs 2.1%, p < 0.001). HER2+ tumors had higher frequency of *ERBB2mts* compared to HER2- (4.3 vs 3%, p = 0.028). Tumors with score of 0 by immunohistochemistry demonstrated lower rate of *ERBB2mts* (0+ 2.2%, 1+ 3.5%, 2+ 4.5%, 3+ 3.45%, p < 0.05). Among HER2- tumors, *ERBB2mts* were present in 3.6% of hormone receptor (HR)+/HER2- & 1.9% of TNBC. Metastatic tumors had a higher rate of *ERBB2mts* compared to locoregional breast tumors (3.8 vs 2%, p < 0.001), with increased rates of activating mutations S310F (0.1 vs 0.0%, p < 0.05) & D769H (0.3 vs 0.1%, p < 0.05), & the resistance mutation L755S (1.2 vs 0.6%, p < 0.01). Compared to *ERBB2*-WT, *ERRB2mts* were associated with decreased *ERBB2* transcripts levels in HER2+ samples (222 vs 441 transcripts per million [TPM], p < 0.001) & increased levels in HER2- samples (73 vs 35 TPM, p < 0.001). High tumor mutational burden (≥ 10 mut/Mb) & *ERBB3* mutations were more common in *ERBB2mts* compared to *ERRB2*-WT (16.7 vs 7.7%, p < 0.001; 10.6 vs 0.8%, p < 0.001). *ERBB2* fusions were rare (0.49%) with 97% occurring in HER2+ tumors. Of 8358 pts with outcome data, prognosis (HR 1.2, P = 0.06) & response to chemotherapy (HR 1.1, P = 0.42) was similar between pts with HER2- *ERBB2mt* & *ERBB2*-WT. **Conclusions:** *ERBB2mts* & fusions were observed in all breast cancer subtypes - more commonly in HER2+, metastatic, & lobular histology tumors - & did not influence prognosis. These alterations may reflect response to treatment pressures in HER2+ disease to reactivate HER2-mediated growth pathways following anti-HER2 therapy & may represent a targetable upregulated oncogenic pathway in HER2- disease. Ongoing identification of *ERBB2* alterations may augment treatment options for breast cancer pts & clinical outcomes from this approach are under investigation. Research Sponsor: Caris Life Sciences.

Matched FES and FDG PET imaging in patients with hormone receptor-positive, HER2+ advanced breast cancer. *First Author: Natasha Hunter, University of Washington, Seattle, WA*

Background: The recently FDA approved ^{18}F-Fluoroestradiol (FES) is a PET imaging tracer for characterizing disease in patients with ER+ breast cancer. As FES PET enters clinical practice it will be important to establish its utility in the full population of hormone-receptor positive patients, including those with HER2+ tumors. Historically the consensus around ER+/HER+ disease has been that these tumors are primarily driven by HER2, with therapies focused on targeting this pathway. Emerging research suggests that ER+ and HER2+ tumors represent a distinct phenotype, with bidirectional crosstalk between ER and HER2 pathways contributing to resistance to therapies targeting these critical pathways. **Methods:** Our cross-sectional database of patients with one or more FES scans stretches back to 1996. We selected all patients with HER2+ advanced breast cancer to determine whether ER is functional in the ER+/HER2+ subset. We examined paired FDG and FES scans and recorded SUVmax in matched lesions between the FDG and FES scans. We also looked at a subset of patients who underwent scans at more than one time-points and examined the clinical characteristics of these cases over time. **Results:** 36 patients with metastatic ER+, HER2+ breast cancer underwent concurrent FDG and FES PET scans between 1996 and 2013. 34 subjects (94%) were female; 32 (89%) were Caucasian, and 4 (11%) were Asian. Eight patients underwent serial scans. A total of 200 metastatic sites were recorded with the majority (67%) being bony lesions. No difference in quantitative FES avidity was observed between soft tissue and osseous sites. Six patients (16%) had negative FES scans despite displaying FDG avid lesions; three patients had at least one negative FES scan on serial scans, and two demonstrated FES-avid lesions with no FDG activity. Average FES SUVmax for positive scans was 3.5, with a range of 0.8 to 10.7. Among eight patients with multiple scans, half had 2 scans, three had 3 scans, and one had 4 scans. In 7/8 patients (88%) FES avidity increased over time even as FDG decreased or stayed stable with treatment; in one, both FES and FDG decreased on follow up scan. **Conclusions:** In a cohort of ER+, HER2+ patients undergoing FDG and FES PET scans, robust concordance between FDG and FES uptake was observed. FES avidity increased in patients with multiple scans, suggesting that the ER pathway remained active during treatment. The strong FES positivity in many HER2+ patients in this cohort suggests that FES PET could be used to guide patient selection for trials examining deescalated regimens employing a non-chemotherapy partner for HER2-directed therapy or emphasizing more ER-directed therapies such as CDK4/6 inhibitors, which are not currently approved in this population. With the ongoing development of HER2- PET imaging, combination scans could carry the potential for discrimination between sites, possibly serving as a tool to guide biopsy. Treatment patterns and their impact on the outcome of patients with HR+/HER2+ metastatic breast cancer in a large real-world cohort. *First Author: Marcela Carausu, Institut Curie, Saint-Cloud, France*

Background: The place of endocrine therapy (ET) in the treatment of hormone receptor-positive (HR+), HER2+ metastatic breast cancer (MBC) is still not clearly defined. Data suggest that blocking both HR and HER2 signaling pathways could be an efficacious strategy to overcome secondary resistance. **Methods:** We aimed to retrospectively evaluate the impact of first line (L1) therapy for HR+/HER2+ MBC patients (pts) included between 2008- 2017 in the French real-world ESME MBC database (NCT03275311). Our primary endpoints were median overall survival (mOS) and median first progression-free survival (mPFS1). We used descriptive statistics and the Kaplan-Meier method to report patient characteristics and outcomes. Cox proportional hazards models and a propensity score were constructed to report and adjust for prognostic factors. **Results:** From the 23,501 female pts in the ESME MBC cohort, 1,790 pts had HR+/HER2+ MBC treated with Trastuzumab (T, n=1,089) or Trastuzumab-Pertuzumab (TP, n=701) during L1. Among them, 1,584 pts received antiHER2 therapy+CT+/-ET and 206 pts, antiHER2+ET only. Pts with antiHER2+CT+/-ET had more often ECOG performance status 0 (29.5% vs 15.8%, p<0.001), grade III tumors (36.6% vs 25.6%, p=0.007), time to MBC < 6 mo (51.6% vs 29.1%, p<0.001), TP as antiHER2 therapy (43.2% vs 9.4%, p<0.001), ≥3 metastatic sites (23.2% vs 14.8%, p=0.007), visceral metastasis (56.5% vs 42.4%, p<0.001), and less often bone-only disease (18.4% vs 35%, p<0.001) than pts with antiHER2+ET. In multivariable analysis, antiHER2+CT+/-ET was not superior to antiHER2+ET (Table), while TP was superior to Trastuzumab, and this result was confirmed by matching pts using a propensity score (p=0.76 for mOS and p=0.85 for mPFS1). Using the time-dependent ET variable among pts with antiHER2+CT, pts with maintenance ET had significantly better PFS1 and OS than those without (adjusted HR for PFS1=0.70 [95%CI 0.60-0.82], adjusted HR for OS=0.47 [95%CI 0.39-0.57], p<0.001). **Conclusions:** These data suggest that endocrine therapy could be an interesting less toxic alternative to chemotherapy in combination with antiHER2 therapy as first line treatment for HR+/HER2+ MBC pts. Research Sponsor: Roche, Pfizer, AstraZeneca, MSD, Eisai, Daiichi Sankyo.

Univariate and multivariable analysis for OS and PFS1 for pts treated with T or TP.

Univariate	N	OS			PFS1		
		median	95% CI	*p* value	median	95% CI	*p* value
Trastuzumab							
antiHER2+CT+/-ET	902	58.6	54.9-63.3	0.13	13.8	12.6-15.5	0.05

Prognostic implications of HER2Neu-low in metastatic breast cancer. *First Author: Shaakir Hasan, New York Proton Center, New York, NY*

Background: HER2-Low (or HER2-equivocal, FISH negative) breast cancer has historically been treated as HER2-negative; however, recent evidence suggests that there may be prognostic and/or predictive differences between the two. We explore demographic characteristics and clinical outcomes of HER2-negative and HER2-low metastatic breast cancer (MBC) patients using real world data. **Methods:** We queried the National Cancer Database to identify MBC patients that were HER2 0, HER2 1+, or HER2 2+ per immunohistochemical staining, with the latter two defined as HER2-low and the former HER2-negative. A multivariable binomial regression analysis identified demographic and clinical correlates of each subtype. A Cox multivariable regression analysis (MVA), propensity matched to HER2 status, was performed to identify correlates of survival. **Results:** After excluding missing data, 24,636 MBC patients diagnosed between 2008-2015 were identified, 6,865 (27.9%) of whom were HER2-negative and 17,771(72.1%) of whom were HER2-low. There were no differences between the two groups with respect to age, race, year treated, location, income, insurance status, Charles Deyo comorbidity score, laterality, T stage, N stage, or use of systemic therapy. HER2-low tumors were half as likely to have concomitant hormone receptor-negative status (OR = 0.49, 95% CI 0.46-0.53). The 3-year survival rate among hormone receptor-negative patients was 33.8% for HER2-low and 32.2% for HER2-negative, and 60.9% and 55.6% in HER2-low and HER2-negative cases among hormone receptor-positive patients, respectively. HER2-low cases were associated with better survival on MVA (HR = 0.91, 95% CI 0.87-0.95), and remained superior with propensity-matching (HR = 0.92, 95% CI 0.89-0.96). In a subset analysis isolated to hormone receptor-positive cases, HER2-low remained correlated with improved survival (HR = 0.93, 95% CI 0.89-0.98) with propensity-matched MVA. Correlates of worse survival include older age as a continuous variable (HR = 1.02), Black race (HR = 1.13), uninsured (HR = 1.18), comorbidity score > 0 (HR = 1.28), higher T stage (HR = 1.17 to 2.34), node positivity (HR = 1.17) and, as the most influential, hormone receptor-negative status (HR = 1.94) [all P < 0.01]. **Conclusions:** Consistent with recent data in non-MBC, our study demonstrates a small but statistically significant association with improved survival for HER2-low tumors compared to HER2-negative tumors in MBC. Randomized data are necessary to further validate this discrepancy and determine if different management is warranted for each subtype. Research Sponsor: None.

Brain metastasis as first and only metastatic relapse site portends poor outcomes in patients with advanced HER2+ breast cancer. *First Author: Laura Noteware, Duke University School of Medicine, Durham, NC*

Background: In patients (pts) with stable or no extracranial disease (ECD) presenting with breast cancer brain metastases (BCBrMs), current guidelines recommend pts receive local therapy with radiation +/- surgery, without changing systemic therapy. However, preliminary studies suggest that pts with isolated HER2+ BCBrM without ECD have inferior overall survival (OS) compared to pts with concurrent ECD. Our study further explores the implications of ECD status on intracranial progression free survival (iPFS) and OS. **Methods:** Retrospective analysis was performed on data from 153 pts diagnosed with initial HER2+ BCBrM who received CNS radiation at Duke between 2008 and 2020. Demographics, dates of metastatic and BCBrM diagnosis, ECD status at first CNS event, systemic therapy, and outcomes were collected. The primary endpoint was iPFS defined as the time from first CNS radiation to the subsequent documentation of intracranial progression (RANO-BM). OS was defined as time from first CNS radiation and first metastatic disease to date of death or last known contact. ECD status was defined by RECIST1.1 from systemic staging scans within 30 days of first CNS event. **Results:** In this cohort of 153 pts with HER2+ BCBrMs undergoing CNS radiation, > 70% of pts with known ECD status had controlled systemic disease: either no ECD (27%) or stable/responding disease (44%). 64% of pts' tumors were ER+. Median age was 50 years (range 24 – 75). Most pts (59%) developed first CNS event during adjuvant or $1^{st}/2^{nd}$ line metastatic therapy. CNS radiation treatment included 48% of pts receiving SRS only, 9% WBRT only, and 43% SRS and WBRT. All pts with no ECD presented with isolated BCBrMs as first metastatic disease. Among pts with known ECD status, OS from initial metastatic disease to death was markedly worse for pts with isolated brain metastases or no ECD (median = 28.4m, 95% CI: 18.1 to not reached) compared to those with progressive or stable/responding ECD (48.8m, 95% CI: 40.5 to 65.0; and 68.1m, 95% CI: 55.2 to 85.7, respectively; log-rank p = 0.004). OS from first CNS involvement to death was significantly worse for pts with progressive ECD (17.8m, 95% CI: 13.7 to 28.8) versus stable/responding (36.6m, 95% CI: 29.7 to 45.2) or no ECD (28.4m, 95% CI: 18.1 to not reached; log-rank p = 0.008). iPFS did not differ statistically among subgroups of pts with known ECD status: progressive ECD (median = 7.7m), no ECD (8.3m), or stable/responding ECD (11.2m) (log-rank p = 0.15). **Conclusions:** Overall survival in pts with HER2+ isolated BCBrM was markedly inferior to that of pts with progressive or stable/responding ECD. Studies investigating initiation of brain penetrable HER2-targeted therapies earlier in the disease course of isolated HER2+ BCBrMs pts are warranted. Research Sponsor: None.

Dynamic circulating tumor DNA (ctDNA) in monitoring trastuzumab deruxtecan (TDXd) activity for patients (pts) with advanced breast cancer: Preliminary results of a feasibility study. *First Author: Elena Giordani, Regina Elena National Cancer Institute, Rome, Italy*

Background: Trastuzumab Deruxtecan (TDXd), a novel antibody-drug conjugate (ADC) that combines trastuzumab with a topoisomerase I inhibitor, has recently demonstrated high efficacy in HER2-overexpressing breast cancer after trastuzumab failure. Resistance to TDM1 have recently suggested to be dynamically associated with distinct circulating ctDNA species (*Allegretti et al, Mol Cancer 2021*). A prospective study aiming to evaluate the feasibility of Liquid Biobsy (LB) in monitoring ctDNA in pts receiving TDXd in the national Expanded Access Program was conducted. **Methods:** In this prospective study, LB for ctDNA analysis (evaluating '*per pt*' ctDNA species and Variant Allelic Frequencies, VAF) was performed using 52-gene targeted NGS panel, in patients who progressed after two or more prior anti-HER2-based regimens and candidates to TDXd (3-weekly 5.4 mg/kg). This preliminary analysis reports data referring to Time-0 (T0) and T6 (cycle 6) assays. **Results:** From April 2021, LBs were collected for 14 pts and to date 8 are evaluable for LB. Median pts' age was 59 yrs (range 38-72) and median number of previous anti-HER2 lines was 6 (2-11); 4 pts had Pertuzumab/Trastuzumab plus taxane as first-line and all pts received TDM-1. Median cycles of TDXd administered was 7.5 (1-10). At T0, 5/8 pts had at least one detectable ctDNA specie, and the remaining 3 developed at least one ctDNA at T6. ctDNA species and VAFs ranged from 1 to 5, and A0.1% to 68.94%, respectively. Decreases and increases were observed simultaneously in the same pt. The former varied from marginal to drastic, whereas the latter were invariably below 0.5% in VAFs. ctDNA monitoring was possible in 8/8 pts and at T6 ctDNA progression was detectable in 5/8 pts. Two pts displayed multiple HER2 copy number variations. **Conclusions:** The early results of this study suggest that considerable ctDNA burden, marked clonal complexity, and variable clonal response to TDXd can be found in pretreated HER2 positive patients, who progressed after antiHER2 therapies. Although the very small sample, this complex tumor evolution is surprising in light of the bystander payload effect of TDXd. Research Sponsor: None.

Factors associated with short- and long-term survival in metastatic HER2+ breast cancer. *First Author: Jose Pablo Leone, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA*

Background: There have been significant therapeutic advances for HER2+ metastatic breast cancer (MBC) over the past decade. The aim of this study was to evaluate prognostic factors in metastatic HER2+ disease and their relationship with short- and long-term overall survival (OS) in the modern era. **Methods:** We evaluated patients (pts) with de novo metastatic HER2+ breast cancer diagnosed between years (y) 2010 and 2018, reported in SEER. Univariate analyses were performed to determine the effect of each variable on OS. Significant variables were included in a multivariate Cox model for OS that evaluated all pts diagnosed 2010 – 2018. Univariate and multivariate logistic regression was used to evaluate the association of each variable with short (< 2 y) and long (≥ 5 y) term OS. To allow sufficient follow up, only pts diagnosed 2010 – 2016 were included in the logistic regression for OS < 2 y, and only those diagnosed 2010 – 2014 were included for OS ≥ 5 y. **Results:** We included 5,576 pts with a median follow up of 48 months (IQR 25 – 73 months). Median OS was 41 months. The proportion alive at 2 y, 5 y, and 8 y, was 63.3% (95% CI 62.0% - 64.7%), 37.8% (95% CI 36.2% - 39.4%) and 26.8% (95% CI 24.8% - 28.9%), respectively. In multivariate analysis for OS, older vs younger age (HR 2.5), black vs white pts (HR 1.4), non-ductal non-lobular vs ductal (HR 2.7), bone metastases vs not (HR 1.2), brain metastases vs not (HR 1.8), liver metastases vs not (HR 1.6), lung metastases vs not (HR 1.3), 6 metastatic organ sites vs 1 (HR 3.6), ER/PR- vs + (HR 1.3), < $35k income vs ≥ $75k (HR 1.8), and being diagnosed in earlier years (HR 1.06 per each prior year) had significantly worse OS (all p≤0.044). Similar results were seen for breast cancer-specific survival. Factors associated with < 2 y OS in adjusted models were older age (OR 3.8), black race (OR 1.5), non-ductal non-lobular (OR 4.6), brain metastases (OR 3.0), liver metastases (OR 2.0), lung metastases (OR 1.6), ER/PR- (OR 1.7) and lower income (OR 1.6), all p < 0.04. Number of metastatic organ sites was not significant in this model. Factors associated with ≥ 5 y OS in adjusted models were younger age (OR 2.9), white vs black race (OR 1.7), fewer metastatic organ sites (OR 2.6), ER/PR+ (OR 1.3), and higher income (OR 3.3), all p < 0.02. Specific organ sites (bone, brain, liver and lung) were not significant in this model. **Conclusions:** In this cohort of pts with de novo HER2+ MBC, OS improved significantly over the study period, and a considerable proportion of pts were still alive at 8 y. Factors associated with shorter survival included older age, black race, lower income, and the presence of visceral or brain metastases. Long-term (≥ 5 y) survival was associated with both demographic (younger age, white race, higher income) and tumor-related (fewer metastatic sites, ER/PR positivity) factors. Research Sponsor: None.

HER2-targeted immunoconjugates for breast cancer: Ancestry and dose adjustment for thrombocytopenia. *First Author: Michael Rainone, City of Hope, Duarte, CA*

Background: Thrombocytopenia (TCP) is a common toxicity of HER2-targeted agents, trastuzumab emtansine (TDM1) and trastuzumab deruxtecan (TDXd). A high incidence of this toxicity was observed in pivotal trials that led to approval of these agents. We investigated whether Asian ancestry increases risk of dose adjustment for TCP on TDM1/TDXd and its impact on dosing in the real-world setting. **Methods:** Females with HER2+ breast cancer who initiated TDM1/TDXd between 1/16/17-10/26/21 were identified by retrospective review. Primary endpoint was number of chemotherapy cycles until adjustment of TDM1/TDXd dose for TCP; competing endpoints included discontinuation for other toxicity, disease progression, and completion of treatment. Individuals who were switched from TDM1 to TDXd contributed an additional observation post-switch. Recurrent events analysis evaluated Asian ancestry (p<0.05) using a proportional means model, with robust sandwich estimate recognizing correlation between repeated observations per individual. Covariates (age, metastatic disease, drug, prior adjustment) were retained if they improved the model. **Results:** The study excluded individuals who declined to self-identify (n=23), self-identified as other than Asian or White (n=28), and/or dissented to research (n=24). The study included n=181 individuals (mean age 55.1+12.8 years), of whom n=48 (26.5%) identified as Asian and n=124 (68.5%) had metastatic disease. Overall, 33 individuals received TDXd exclusively, leaving 148 (81.8%) individuals who received TDM1, including 45 individuals who later switched to TDXd after development of TCP while on TDM1 (n=9) or other toxicity (n=36) on TDM1. For n=226 observations (total 2551 cycles), the endpoint was dose adjustment for TCP (n=32), discontinuation for other toxicity or disease progression (n=112), completion of treatment (n=27), or censoring (n=55). Taking into account history of switching drug for TCP, Asian ancestry was associated with increased risk of dose adjustment for TCP (Table). Neither age, metastatic disease, nor specific drug improved the model (data not shown). **Conclusions:** Among individuals taking TDM1 and/or TDXd for HER2+ breast cancer, we observed that those with Asian ancestry are at greater risk of dose reduction for TCP than their non-Asian counterparts. Upon confirmation in additional individuals with HER2+ cancers of the breast and other sites, this heightened susceptibility to TCP among Asian individuals should be further investigated to elucidate the underlying mechanism and optimize clinical guidelines for prevention and management. Research Sponsor: None.

Predictors of dose adjustment for thrombocytopenia among individuals with breast cancer on HER2-targeted agents.

Independent Risk Factors	Hazards Ratio (95% Confidence Interval)	p
Asian Ancestry	2.84 (1.39-5.82)	0.0044
Prior Discontinuation for Thrombocytopenia	6.96 (2.80-17.30)	<0.0001

Post-recurrence survival in asymptomatic compared with symptomatic metastatic breast cancer: A multicenter retrospective study. *First Author: Sayaka Kuba, Nagasaki University Graduate school of biomedical Science, Nagasaki, Japan*

Background: Asymptomatic metastatic breast cancer (mBC) is often detected using tumor marker or imaging tests in Japan. At the ASCO 2019, we reported on mBC detection, the distribution of symptomatic and asymptomatic disease by subtype (abstract e12568). We aimed to determine whether there are differences in post-recurrence survival (PRS), and treatment between asymptomatic and symptomatic MBCs, and identify factors associated with PRS. **Methods:** We performed a multicenter, retrospective analysis of patients with mBC treated in our hospitals from 2008 to 2018. Patients were divided into asymptomatic and symptomatic MBCs to compare their prognosis by breast cancer (BC) subtypes: luminal (hormone receptor positive/human epidermal growth factor 2 [HER2] negative), HER2 (any hormone receptor/HER2 positive), and triple-negative (TN) (hormone receptor negative/HER2 negative). **Results:** Of 204 patients with mBC (114 asymptomatic, 90 symptomatic), PRS was longer in asymptomatic mBC than in symptomatic mBC (median survival: 55 months vs. 29 months; $p < 0.001$) and tended to have longer overall survival (OS) (110 months vs 72 months, respectively; $p = 0.09$). In multivariate analysis, TN, recurrence-free survival (RFS), multiple metastasis sites, and symptomatic disease were independently predictive of PRS (Table). In luminal and HER2, PRS trended higher in the asymptomatic group than in the symptomatic group (luminal: 54 months vs. 41 months; $p = 0.08$, HER2: 71 months vs. 27 months; $p = 0.09$), but without significant difference in OS (luminal: 112 months vs. 124 months; $p = 0.91$, HER2: 113 months vs. 72 months; $p = 0.40$). In the luminal group, 13 patients (11%) were treated with cyclin-dependent kinase 4/6 (CDK4/6) inhibitors. The median PRS was 80 months for luminal patients with three factors — longer than 4 years of RFS, a single metastasis site, and asymptomatic disease. The duration of endocrine therapy did not differ between groups; however, the patients with luminal BC in the asymptomatic group had longer chemotherapy than those in the symptomatic group. In TN, PRS was very short (asymptomatic, 28 months; symptomatic, 10.5 months; p = 0.01). **Conclusions:** We demonstrated that asymptomatic MBC and symptomatic MBC differed in terms of subtypes, prognosis, and duration of chemotherapy in the luminal group. Therefore, unique treatment strategy for asymptomatic or symptomatic MBC should be developed. Research Sponsor: None.

Variable	HR	95% CI	*p* Value
TN vs no-TN	2.56	1.69 to 3.90	<0.001
RFS, year	0.91	0.87 to 0.96	<0.001
Multiple sites of metastasis vs single sites of metastasis	1.86	1.32 to 2.61	<0.001
Symptomatic vs asymptomatic	1.76	1.26 to 2.45	<0.001

HR = hazard ratio; CI = confidence interval; TN = triple-negative; RFS = recurrence-free survival.

Chemotherapy shows better efficacy than endocrine therapy in patients with metastatic breast cancer with heterogeneous estrogen receptor expression. *First Author: Yizhao Xie, Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Heterogeneity of estrogen receptor (ER) expression has long been challenges for diagnosis and treatment strategy of metastatic breast cancer (MBC). A novel convenient way of ER detection using ^{18}F-fluoroestradiol positron emission tomography/computed tomography (^{18}F-FES PET/CT) offers a chance to screen and analyze MBC patients with ER uncertainty. **Methods:** MBC patients who received ^{18}F-FES PET/CT were screened and patients with both FES positive (FES+) and negative (FES-) lesions were enrolled in this study. Progression-free survival (PFS) was estimated by Kaplan-Meier method and compared by log-rank test. **Results:** A total of 635 patients were screened and 75 of 635 (11.8%) patients showed ER uncertainty. 51 patients received further treatment and were enrolled in this study. Among them, 20 (39.2%) patients received chemotherapy (CT), 21 (41.2%) patients received endocrine-based therapy (ET) and 10 (19.6%) patients received combined therapy (CT+ET). CT showed better progression-free survival (PFS) compared to ET (mPFS 7.1 vs 4.6 months, HR 0.44, 95% CI 0.20-0.93, P = 0.03). CT+ET did not improve PFS compared to either CT or ET alone (mPFS 4.4 months, P > 0.2). **Conclusions:** ^{18}F-FES PET/CT could identify patients with ER heterogeneity. Patients with ER uncertainty showed better sensitivity to CT rather than ET. Combined therapy of CT+ET did not improve treatment outcome. Research Sponsor: None.

Aromatase inhibitors for breast cancer therapy: Analysis of real-world FAERS data. *First Author: Dawood Findakly, Louisiana State University (Shreveport) Program, Shreveport, LA*

Background: Aromatase inhibitors (AIs) are extremely effective adjuvant treatment in postmenopausal women with hormone receptor-positive breast cancer (HRPBC). We utilized the Food and Drug Administration Adverse Event Reporting System (FAERS) database to evaluate the musculoskeletal (MSK), fractures, and ischemic heart disease (IHD) adverse events (AEs) caused by AIs. **Methods:** We conducted a retrospective FAERS public database review to assess the MSK, fracture, and IHD AEs for the three AIs (anastrozole, letrozole, and exemestane) from 2001 through 2021. Chi-square was used to compare categorical variables. **Results:** A total of 31,683 AEs reports were identified, out of which, 15,140 (47.8%) were MSK, 13,311 (42.0%) were fracture, and 3,232 (10.2%) were IHD. The differences in AEs distributions among the three drug classes were statistically significant for MSK and fracture AEs (P < 0.001) but not reached statistical significance for IHD AEs (P = 0.140). MSK AEs were mostly reported with anastrozole, followed by exemestane, and letrozole in 35.23%, 33.97%, and 32.06%, respectively (P < 0.001). Compared to older individuals, younger adults (≤65 years) had higher rates of MSK AEs—mostly with anastrozole (38.43%, P < 0.001), followed by exemestane (36.37%, P = 0.006) and letrozole (34.28%, P < 0.001). Fracture AEs were mostly reported, in descending order, with letrozole, exemestane, and anastrozole in 12.07%, 11.41%, and 9.34% respectively (P < 0.001). Older adults (> 65 years) had higher rates of fracture AEs with letrozole (16.77%, P < 0.001) and anastrozole (10.37%, P < 0.001), while unable to demonstrate statistical significance with exemestane (13.48%, P = 0.108). Among older adults (> 65 years), IHD AEs were significantly reported with anastrozole (21.56%, P < 0.001) and exemestane (14.18%, P = 0.016) but no statistical significance reached for letrozole (14.12%, P = 0.528). **Conclusions:** The findings in this study highlight trends for selected AEs with various AI regimens, provide further insights, and help guide therapeutic decisions for patients with HRPBC. Research Sponsor: None.

Long-term safety of inavolisib (GDC-0077) in an ongoing phase 1/1b study evaluating monotherapy and in combination (combo) with palbociclib and/or endocrine therapy in patients (pts) with *PIK3CA*-mutated, hormone receptor-positive/HER2-negative (HR+/HER2-) metastatic breast cancer (BC). *First Author: Philippe L. Bedard, University of Toronto, Toronto, ON, Canada*

Background: Dysregulating mutations in *PIK3CA*, encoding the PI3K p110α subunit, occur in ~40% of HR+/HER2– BCs. Inavolisib is a PI3Kα-specific inhibitor that also promotes degradation of mutant p110α. It has demonstrated encouraging preliminary antitumor activity in pts with *PIK3CA*-mutated HR+ BC as a monotherapy, and in combo with other anticancer agents. **Methods:** We included pts from NCT03006172 on treatment ≥1 year with inavolisib alone (Arm A), or in combo with palbo + letrozole (letro) (B), letro (C), fulvestrant (fulv) (D), or palbo + fulv (E; + metformin in Arm F for pts with body mass index ≥30 and/or HbA1c ≥5.7%). Inavolisib was administered orally daily (PO QD) at 3, 6, 9, or 12 mg (3+3 dose-escalation design); letro at 2.5 mg PO QD; palbo at 125 mg PO QD for 21/28 days; and fulv at 500 mg intramuscularly every 4 weeks, in 28-day cycles until intolerable toxicity/disease progression. Safety was assessed by NCI-CTCAE v4. **Results:** 57 female pts were included (cutoff 07/26/21; N = 1, 18, 6, 12, 15, 5 in Arms A–F); median age: 57 years (range 33–80); median lines of prior therapy: 2 (1–7). All but 2 pts, both in Arm B (3 mg), were assigned the 9 mg inavolisib recommended phase 3 dose. Overall median treatment duration: 19 months (range 12–45); median inavolisib cumulative dose intensity, 95%. The most frequent treatment-related adverse events (AEs; in ≥20 pts/35%) were hyperglycemia (68%), stomatitis (68%; grouped terms), neutropenia (58%), diarrhea (51%), nausea (39%), alopecia (35%), and rash (35%; grouped terms). The most frequent treatment-related Grade (G) 3–4 AEs (≥2 pts/4%) were neutropenia (47%), hyperglycemia (16%), leukopenia (9%), thrombocytopenia (9%), lymphopenia (7%), weight decreased, and hypokalemia (4% each). G3–4 neutropenia, leukopenia, thrombocytopenia, and lymphopenia were all reported in palbo arms. One G5 AE of pleural effusion was reported (disease progression-related). 39 pts (68%) had ≥1 AE resulting in study treatment modification (drug interruption/dose reduction/treatment withdrawal); 11 (19%) had an inavolisib dose reduction and 2 (4%) discontinued treatment due to an AE (1 related G2 diarrhea, 1 unrelated G3 cerebrovascular disorder). AEs typically occurred during the first 6 months and tended to be less frequent in later cycles. No new safety signals were observed with long-term inavolisib use. **Conclusions:** These data indicate acceptable long-term tolerability. The safety profile of pts on study treatment with inavolisib alone or in combo with endocrine-based anticancer therapies for ≥1 year was similar to that reported for the overall study population. Updated data will be presented. A phase 3 study of inavolisib + palbo + fulv is enrolling (NCT04191499; INAVO120). Clinical trial information: NCT03006172. Research Sponsor: Genentech, Inc.

1053 **Poster Session**

Phase I study combining pembrolizumab and aromatase inhibitor in patients with metastatic hormone receptor–positive breast cancer. *First Author: Xuan Ge, City of Hope, Duarte, CA*

Background: Aromatase inhibitor (AI) is standard of care for patients with hormone receptor positive (HR^+) human epidermal growth factor receptor 2-negative ($HER2^-$) metastatic breast cancer (MBC). The current phase I trial was designed to test the safety and efficacy of AI and the immune checkpoint inhibitor pembrolizumab (NCT 02648477). **Methods:** Key eligibility criteria were HR^+ $HER2^-$ MBC per ASCO/CAP; RECIST 1.1 measurable disease; adequate organ function; and ECOG 0-1. Eligible patients received 200 mg pembrolizumab IV every 3 weeks plus AI until progression or unacceptable toxicity. Primary objectives were to evaluate the safety and efficacy of this combination. This study employed a 3-at-risk design with a lead-in at the standard dosing of both AI and pembrolizumab with a targeted accrual of 20 patients. **Results:** A total of 20 patients were accrued between March 2016 and April 2017. Median age was 62 (range 34-79), with 75% white, 15% Asian and 10% unknown. Median lines of therapy were 3 (0, 9). All but one patient received aromatase inhibitor and/or fulvestrant prior to enrollment. The combination was well tolerated, and the most common adverse events were grade 2 fatigue (35%), rash (15%), and hot flashes (10%). Grade 3 adverse events were elevated AST/ALT (5%), rash (5%), and lymphopenia (5%). Responses were 10% partial response and 15% stable disease, resulting in a clinical benefit rate (CBR) of 20% at 6 months. Median follow-up time was 40.1 months (range 31.3 – 46.8 months). Median progression free survival was 1.8 months (95% CI 1.6, 2.6) and median overall survival was 17.2 months (95% CI 9.4, NA). 14 tumor specimens had programmed death ligand 1–positive (PD-L1) by 22C3 testing, including 3 PD-L1-positive and 11 PD-L1 negative. No association between PD-L1 and response was found. **Conclusions:** The combination of pembrolizumab and AI is well tolerated in patients with HR^+ $HER2^-$ MBC who were not pre-selected for PD-L1. There was minimal overall clinical activity observed beyond what was to be expected with AI alone in this group of patients. Clinical trial information: NCT 02648477. Research Sponsor: Merck.

Molecular alterations associated with rapid progression following CDK4/6 inhibitors (CDKi) in metastatic hormone receptor–positive breast cancer (mHRBC). *First Author: Malinda T West, OHSU Knight Cancer Institute, Portland, OR*

Background: Combination of CDKi with endocrine therapy is a key treatment for mHRBC due to survival benefit and favorable safety profile. However, progressive disease inevitably develops and outcomes after CDKi discontinuation (dc) are not well-described. Within our institution, we previously reported clinical characteristics and outcomes for a cohort of 140 mHRBC patients who received CDKi therapy. Median progression-free survival (PFS) and overall survival (OS) post-CDKi dc were 7.0 and 15.4 months, respectively. However, 29% experienced rapid progression or death within 4 months following CDKi dc. Molecular predictors of rapid progression after CDKi are unknown and may help define therapies to improve outcomes. In this study, we sought to identify molecular predictors for rapid disease progression after CDKi dc in mHRBC. **Methods:** We identified within our cohort 34 patients with mHRBC who progressed on CDKi with next-generation sequencing (NGS) performed on pre-CDKi tissue samples. PFS and OS, measured from CDKi dc, were analyzed with the Kaplan-Meier estimator and log-rank test. Rapid progression was analyzed with logistic regression and Fisher's exact test to evaluate association between pre-CDKi tumor mutation and rapid progression post-CDKi. **Results:** NGS of pre-CDKi tumor biopsies found 12 genes (*FGF3, FGF4, FGFR, PIK3CA, PTEN, AKT, RB1, CDKN2A, MYC, CCND1, ESR1, TP53*) that were altered in ≥3 of the 34 patients. The six patients (18%) with a *PTEN mutation (mut)* had a median PFS of 3 months and median OS of 4 mo. In comparison, median PFS and OS of *PTEN wild-type (wt)* patients were 7 mo. (log-rank p=0.008) and 21 mo. (log-rank p<0.001), respectively. Moreover, those with *PTENmut* tumors were more likely to experience rapid progression compared to *PTENwt* (odds ratio = 7.0, 95% CI: 1.1 – 60.5, p=0.048). Notably, in the 10 rapid progression patients with pre-CDKi NGS results, alterations to PI3K pathway constituents were prevalent: *PTENmut* (40%), *FGFRmut* (50%), *AKTmut (*20%) and *PIK3CAmut* (40%). **Conclusions:** PI3K pathway alterations are prevalent in mHRBC patients who develop rapid progression post-CDKi dc, with *PTENmut* being the most significant predictor. These hypothesis-generating findings provide the basis for ongoing investigations to find clinical and molecular biomarkers that can help improve outcomes for mHRBC at risk of rapid progression post-CDKi therapy. Research Sponsor: None.

Relationship of *PTENmut* and other PI3K pathway mutations on post-CDKi outcomes.

Clinical outcomes with alpelisib (ALP) plus fulvestrant (FUL) after prior treatment (tx) with FUL in patients (pts) with advanced breast cancer (ABC): A real-world (RW) analysis. *First Author: Joyce O'Shaughnessy, Baylor University Medical Center, Texas Oncology, US Oncology Network, Dallas, TX*

Background: ALP (α-selective PI3K inhibitor and degrader) + FUL was FDA approved and reflected in the NCCN guidelines in 2019 for pts with hormone receptor–positive/human epidermal growth factor receptor 2–negative (HR+/HER2–) ABC with *PIK3CA* mutations following progression on or after endocrine-based therapy (ET). The Phase III SOLAR-1 trial excluded prior FUL, and data on ALP + FUL after FUL are limited. As cyclin-dependent kinase 4/6 inhibitor (CDK4/6i) + ET (including FUL) is the standard in the first line (1L) or second line (2L) for pts with HR+/HER2– ABC, more data on ALP + FUL post-FUL are needed. Here we report patterns and clinical outcomes on RW use of ALP + FUL in pts with HR+/HER2– ABC with prior FUL exposure. **Methods:** This retrospective study used de-identified electronic health record data from the ConcertAI Patient360 Breast Cancer data product sourced from US oncology centers. Adults with HR+/HER2– ABC treated with ALP + FUL (index tx) who received prior FUL (monotherapy or in combination) in the metastatic setting were included; pts with a *PIK3CA* negative test on or prior to the index were excluded. Pts were followed until date of death or last activity. RW progression-free survival (rwPFS), defined as first documented progression/death from ALP + FUL start date, was assessed. **Results:** This analysis included 157 pts (median age, 63 y [57-71 y]) who received ALP + FUL from 2019 to 2021, with 11.5% pts in 1L, 17.8% in 2L, 26.8% in third line (3L), and 43.9% in fourth line and beyond (4L+). Prior FUL tx included CDK4/6i + FUL (74.5%), FUL alone (33.8%), and non-CDK4/6i + FUL (21.0%). In pts who received ALP + FUL in 1L (n = 18), prior FUL exposure was in the same line without documented progression. In the metastatic setting, 28.0% of pts received > 1 FUL-containing regimen and/or 72.0% received prior chemotherapy (CT). At the median duration of follow-up (8.7 mo [4.1-12.5 mo]), the median rwPFS was 5.7 mo (4.0-7.3 mo) in the overall population. The median rwPFS was also analyzed by line of therapy (Table). In pts with CDK4/6i + FUL as immediate prior therapy (n = 39), the median rwPFS was 6.2 mo (3.0-9.1 mo); 79.5% of these pts received ALP in ≤ 3L. At the time of analysis, 107 pts (68.2%) had discontinued ALP + FUL; the median time to discontinuation was 4.7 mo (3.7-6.1 mo). Following discontinuation of ALP + FUL, CT was the most common subsequent therapy (33.8%). **Conclusions:** This analysis on RW data from early years of ALP access in the US shows clinical benefit of ALP + FUL in pts with HR+/HER2– ABC with *PIK3CA* mutation even when exposed to prior FUL, confirming the oncogenic dependence of the tumor on the *PIK3CA* mutation. Research Sponsor: Novartis Pharmaceuticals.

CDK4/6 inhibitors outcomes in patients with advanced breast cancer based on HER2-low expression. *First Author: Laura Sabina Lapuchesky, Cramer 1180, CABA, Argentina*

Background: HER2-low expression, defined as HER2 immunohistochemistry (IHC) score of 1+ or 2+ with negative in situ hybridization assay (FISH), accounts for 50% of breast cancers. There is limited and conflicting evidence regarding the efficacy of cyclin-dependent kinase (CDK) 4 and 6 inhibitors in patients with ER+ and HER2-low tumors. This study aimed to investigate the prognostic value of HER2-low expression in patients with ER+/HER2-negative advanced breast cancer treated with CDK 4/6 inhibitors. **Methods:** We retrospectively selected consecutive patients with ER+/HER2-negative advanced breast cancer treated with CDK 4/6 inhibitors plus endocrine therapy in our institution from May 2015 to Feb 2020. Two cohorts were compared, including HER2-0 (IHC score) and HER2-low (HER2 IHC score 1+ and 2+ [negative FISH]) tumors. Comparisons in progression-free survival (PFS) and overall survival (OS) were performed using a log-rank test. The prognostic value of HER2-low was investigated by the Cox regression model. **Results:** Among the 186 patients included, median age at treatment was 55 (r 27-84), and majority had ECOG 0 (126, 67.8%). Progesterone receptor was positive in 155 (83.3%) tumors. Of note, most patients received CDK4/6 inhibitors and endocrine therapy as first-line setting (131, 70.4%). Mostly received palbociclib (161, 86.6%), while ribociclib and abemaciclib were used in 23 (12.4%) and 2 (1.08%) patients, respectively. Overall, 27 patients (14.5%) had de novo metastatic disease, 68 (36.6%) had only bone metastases, and 69 (37.1%) had visceral disease. Of the total population, 64 (34.4%) tumors were HER2-low (43 [23.1%] HER2-1+, and 21 [11.3%] HER2-2+), and 122 (65.6%) were HER2-0. Median PFS among patients with HER2-0 and HER-low were 19 mo. (95% CI, 13.9-24.1), and 15.6 mo. (95% CI, 11.1-20.0), p = 0.074, respectively. In patients treated with CDK 4/6 in the first-line setting, no statistically significant differences were observed in terms of PFS and OS between HER2-0 and HER2-low (PFS HR 0.73 [95% CI, 0.47-1.13; p = 0.160], and OS HR 1.04 [95% CI, 0.51-2.14; p = 0.909]). **Conclusions:** In our study, HER2-low expression did not show a statistically significant impact on patients with ER+/HER2-negative advanced breast cancer treated with CDK 4/6 inhibitors. Our study supports the necessity of real-world evidence and the design of pooled analysis to understand the real implication of this biomarker in patients with ER+/HER2-negative tumors. Research Sponsor: None.

***ESR1* mutations in circulating tumor DNA (ctDNA) are associated with CTCs and increased hormone receptors in metastatic tumor tissues of patients with metastatic breast cancer (MBC).** *First Author: Qiang Zhang, Northwestern University, Department of Medicine, Division of Hematology/Oncology, CTC Core Facility, Lurie Cancer Center, Chicago, IL*

Background: The monitoring of ctDNA and circulating tumor cells (CTCs) in patients with MBC predicts metastasis and prognosis. We previously reported that HER2 and *ESR1* alterations in ctDNA were associated with predicted metastasis in MBC (2019 ASCO#1036). Furthermore, ctDNA can be used to evaluate tumor heterogeneity (2020 ASCO #1028). Here, we report that baseline ctDNA *ESR1* mutation is a key point associated with tumor tissue characteristics and CTCs, which may help to elucidate disease resistance in MBC. **Methods:** This study included 288 hormone receptors positive MBC patients who received systemic treatment under an IRB-approved clinical trial (NU16B06) at NU Lurie Cancer Center (2016-2021). Baseline plasma ctDNA was analyzed by Guardant360 NGS for ESR1 mutations. CTC enumerations were performed by using 7.5ml blood in CELLTRACKS (Menarini). Estrogen receptor (ER), progesterone receptor (PR), HER2 and Ki67 in each patient's biopsy tumor tissue before surgery, surgical tumor tissue and metastatic tumor tissue were evaluated by NU PathCore. Kruskal-Wallis was used for statistics. **Results:** Of the 288 patients, *ESR1* mutations were found in 18 hotspots from 38 patients ($ESR1^{Mut}$, 13.19%) and there were 250 patients without any mutation ($ESR1^{WT}$, 86.81%). Median of Total CTCs (/7.5ml) and $HER2^+$ CTCs (/7.5ml) were significantly increased in $ESR1^{Mut}$ group compared to $ESR1^{WT}$ group, total CTCs were 8.0 vs 1.0 (P=0.006) and $HER2^+$ CTCs were 1.5 vs 0 (P=0.014), respectively. There were significant differences on hormone receptors expression (positive cells %) in tumor tissues between $ESR1^{Mut}$ group and $ESR1^{WT}$ group: 1) $ESR1^{Mut}$ group has significant higher expression in ER and PR in biopsy tumor tissues. The mean of ER in $ESR1^+$group was 90.48% vs 48.18% in $ESR1^{WT}$ group (p<0.001). The mean of PR in $ESR1^{Mut}$ group was 40.86% vs 25.60% in $ESR1^{WT}$ group (p<0.001). Meanwhile, there is not significant difference on HER2 expression in $ESR1^{Mut}$ group compared $ESR1^{WT}$group; 2) In the surgical tumor tissues, the mean ER was 97.64% in $ESR1^{Mut}$ group which was significantly higher than 47.90% in $ESR1^{WT}$ group (p<0.001), while the PR was 45.33% and 24.32%, respectively; 3) In metastatic tumor tissues, the mean of ER in $ESR1^{Mut}$ group was 84.75% vs 34.89% in $ESR1^{WT}$group (p<0.001) and the mean of PR in $ESR1^{Mut}$ group was 32.25% vs 9.33% in $ESR1^{WT}$ group (p<0.001). Furthermore, median of Ki67 in $ESR1^{Mut}$ group is 28.33% which was significantly higher than 18.75% in $ESR1^{WT}$ group (p<0.01). **Conclusions:** Baseline ctDNA ESR1 mutations not only had higher total CTCs and $HER2^+$ CTCs but also significantly correlated with high hormone receptors and proliferation in tumor metastatic tumor tissues. The synergy of ctDNA *ESR1* mutation and tissue pathological characteristics expands the early predictive role of ctDNA monitoring metastatic prognosis for clinical decision-making. Research Sponsor: U.S. National Institutes of Health.

Longitudinal circulating tumor DNA (ctDNA) whole-exome sequencing (WES) in the phase Ib/II trial of palbociclib and bazedoxifene reveals genomic dynamics and clonal evolution with the acquisition of treatment resistance in hormone receptor-positive, HER2-negative (HR+ HER2-), advanced breast cancer (ABC). *First Author: Albert Grinshpun, Dana-Farber Cancer Institute, Boston, MA*

Background: Patients (pts) with HR+ HER2- ABC ultimately develop endocrine resistance. To gain insights into the genetic mechanisms of resistance we performed WES on serial plasma samples from endocrine resistant pts treated on a clinical trial (NCT02448771). **Methods:** Plasma samples were collected at baseline (n=36), day 1 of cycle 2 (n=33), and at the end of treatment (EOT, n=33). Samples were subjected to ultra-low passage (ULP, 0.19-0.57X) WGS to determine ctDNA tumor fraction (TF) for the selection of samples (TF>0.03) for subsequent WES (193X). Somatic single nucleotide variations, somatic copy number alteration (SCNA), phylogeny, tumor mutational burden, mutational signatures, and germline analyses were performed. **Results:** All 102 samples underwent successful ULP and 68 WES. Overall, most frequent pathogenic mutations were in *ESR1* and *PIK3CA*. At baseline, 32% of pts had *ESR1* mutation and 21% *PIK3CA* mutation. There was no association between *ESR1* mutations and PFS. In contrast, baseline *PIK3CA* mutations were detected only in pts who did not have a clinical benefit, and were associated with worse PFS compared to pts with wild-type *PIK3CA* (1.8 vs. 3.9 months, respectively, HR=0.2, 95% CI 0.06-0.6, *P=0.0019*, log-rank test). Additionally, pts with a baseline truncating mutation, mostly in tumor suppressor genes (*TP53, MEN1, RB1, CDKN1B, NF1, TP53BP1, TP63, SMAD2/4, ARID1A, KMT2C*), also had a significantly worse PFS (1.7 vs 3.8 months, HR=0.3, 95% CI 0.1-0.7, *P=0.006*, log-rank test). At EOT, 20% (4/20) of pts with matched baseline samples had newly acquired mutations that are suggestive of mechanisms of acquired resistance and offer potential therapeutic targets (e.g. *ERBB2, PIK3CA).* SCNA analysis showed that in all pts there were at least 2 SCNAs in cancer-related driver genes, most common in *CCND1* and *ELF3*. Moreover, in all samples we identified at least 1 SCNA related to a potential mechanism of resistance. To better understand tumor heterogeneity and sub-clonal architecture we performed an evolutionary analysis (sufficient TF≥0.15, available in n=7). Phylogenetic analysis revealed sub-clonal dynamics that could explain the acquisition of resistance in at least three pts (3/7), and identified novel genes which might have role in endocrine resistance (e.g. *DCAF13, ZFHX3*). **Conclusions:** Our results demonstrate the feasibility and utility of serial WES in a clinical trial. Serial ctDNA WES and evolutionary studies enabled us to discover novel potential genomic mechanisms of tumor progression, and identified *PIK3CA* mutations as a candidate biomarker of resistance to the combination of palbociclib and bazedoxifene, which may apply to other next generation endocrine treatments. Clinical trial information: NCT02448771. Research Sponsor: Pfizer.

Efficacy and safety of tenalisib, a PI3K δ/γ and SIK3 inhibitor in patients with locally advanced or metastatic breast cancer: Initial results from a phase II study. *First Author: Tamta Makharadze, LTD High Technology Hospital Medcenter, Batumi, Georgia*

Background: Hyperactivation of the PI3K pathway in breast cancer is implicated in malignant transformation, cancer progression, and resistance to endocrine therapy. Salt Inducible Kinase-3 (SIK3) is highly expressed in breast cancer and elevated SIK3 expressions are shown to contribute to tumorigenesis. Tenalisib (RP6530), a highly selective PI3K δ/γ and SIK3 inhibitor has been evaluated in > 150 patients with haematological malignancies and demonstrated encouraging activity in T-cell lymphoma with a differentiated safety profile. Tenalisib has a major metabolite (IN0385) which shows potent SIK3 inhibition. Preclinical studies in breast cancer cell lines have demonstrated that Tenalisib potentiated the activity of taxol and doxorubicin. The aim of this phase II study was to investigate the efficacy and safety of single-agent tenalisib in patients (pts) with HR+ HER2- locally advanced or metastatic breast cancer (MBC). **Methods:** This randomized, open-label study was designed to evaluate two doses (800 mg BID and 1200 mg BID) of Tenalisib in HR+/HER2- locally advanced or MBC patients including TNBC patients whose disease had progressed following at least one line of therapy. Tenalisib was given orally in a 28-days cycle until disease progression. Forty pts (20 pts at each dose level) were planned to be enrolled with the primary outcome being the percentage of pts without disease progression at the end of 6 months. The investigator-assessed ORR, PFS, and Clinical Benefit Rate (CBR = CR+PR+SD), using RECIST v1.1 were secondary outcomes. **Results:** All forty pts have been enrolled in the study. Pts had a median of 3 (range 1-7) lines of prior therapy; of these, 87% pts had prior endocrine therapy, and 40% and 30% pts had aromatase inhibitor or fulvestrant as their last prior therapy respectively. The median age was 63.8 (31-71) years, 52.5% of pts had PS 1, 77.5% had visceral disease, and 95.0% had ≥ 2 metastatic lesions at the time of enrollment. As of 07-Feb 2022, twenty-eight pts were efficacy evaluable. Of the 28, 2 pts had a PR (7%), 17 pts had SD (61%) and 6 pts had PD (21%) at the first efficacy assessment after completion of 2 cycles. Three pts discontinued from the study due to adverse events (11%) before the first efficacy assessment. The CBR was 68%. On safety, the most common TEAEs (≥5%) of any grade were transaminitis (All: 22%, ≥G3: 10%), GGT elevation (All: 7%, ≥G3: 5%), fatigue (All: 7%, ≥G3: 0%), rash (All: 7%, ≥G3: 2.5%). Discontinuations due to related TEAEs were infrequent (7%). There were no unexpected TEAEs. Two pts were discontinued due to related TEAEs (rash and GGT elevation). **Conclusions:** Based on the data from the ongoing study, Tenalisib showed encouraging preliminary efficacy as a single agent in patients with advanced MBC. Updated efficacy and tolerability data will be provided at the time of presentation. Clinical trial information: NCT05021900. Research Sponsor: None.

Predicting hyperglycemia among patients receiving alpelisib plus fulvestrant for metastatic breast cancer. *First Author: Xuan Ge, City of Hope, Duarte, CA*

Background: Although hyperglycemia is recognized as a common adverse event (AE) on alpelisib (ALP), this AE has been little studied outside clinical trials. We report the frequency of ALP-associated hyperglycemia in a real-world setting and evaluate proposed risk factors. **Methods:** We retrospectively identified patients with PIK3CA-mutated, hormone receptor-positive, metastatic breast cancer who initiated treatment with ALP+fulvestrant (FUL) between August 2019 and December 2021. Five primary characteristics (diabetes, prediabetes, body mass index (BMI), age, Asian ancestry) were evaluated as independent risk factors for ALP-associated hyperglycemia using ordinal logistic regression that considered 3 glycemic levels: normoglycemia, grade 2, and grade 3-4 hyperglycemia. Overall risk of error from multiple hypothesis testing was kept below 5% using the False Discovery Rate method. **Results:** The study included n = 92 subjects, all but 1 female, mean age 59.9 (+11.9) years, 13.0% with Asian ancestry. One third (33.7%) of patients had pre-existing diabetes, another 9.8% had pre-diabetes only. One third (32.6%) were obese, another third (31.5%) were overweight. Hypertension and hyperlipidemia were present in 53.3% and 41.3%, respectively. On ALP+FUL, 59 (64.1%) current subjects developed hyperglycemia of grade 1-4, a rate no different than the 181/284 (63.7%) reported in the ALP+FUL arm of the SOLAR-1 trial. Among our subjects, risk of grade 2-4 hyperglycemia was independently increased by 4 of 5 hypothesized risk factors, specifically pre-existing diabetes (Odds Ratio 3.75, 95% Confidence Interval: 1.40-10.01), pre-diabetes (6.22, 1.12-34.47), Asian ancestry (7.10, 1.75-28.84), each unit of BMI above 20 (1.17, 1.07-1.28), but not by additional year of age (1.01, 0.97-1.05). Exploratory analysis detected no association with pre-existing hypertension or hyperlipidemia. **Conclusions:** These findings suggest that Asian ancestry merits further study as a predisposing factor for ALP-associated hyperglycemia. Our study of this AE also demonstrates that pre-existing hyperglycemia and greater BMI are independent risk factors; diabetes and pre-diabetes confer similar degrees of risk; risk from BMI begins after BMI 20 and rises incrementally; and age is not a contributing factor. Research Sponsor: U.S. National Institutes of Health.

Utility of liquid biopsy for identifying emerging mutations (mut) and novel treatment options in luminal metastatic breast cancer (LMBC). *First Author: Alberto Gonzalez-Medina, Cancer Genomics Group, Vall dHebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Molecular characterization of LMBC for the choice of therapy and inclusion in clinical trials is frequently performed in archival biopsies procured several years before. Emerging mut secondary to therapeutic pressure are hence frequently missed but could be detected by real-time analysis of circulating tumor DNA. Aim: 1) To assess the emergence of *ERBB2* and other mut upon therapeutic pressure; 2) To compare the concordance of mut in tumor and plasma samples between patients (pts) with metachronous and synchronous sample acquisition. **Methods:** Pts with LMBC and available tumor biopsy and plasma samples were identified and divided in two groups: 1) Cohort 1 (metachronous) if the time between tissue and plasma acquisition was > 3 months and systemic treatment was given between the sampling; 2) Cohort 2 (synchronous) if sampling occurred with < 3 months interval in the absence of systemic treatment. Tumor and plasma were analyzed using MiSeq Amplicon-based NGS (custom panel of 60 cancer-related genes). The emergent mut in plasma in Cohort 1 and the concordance of ESCAT Tier I and II mut (*PIK3CA, AKT1, ERBB2, ESR1, PTEN*) in both Cohorts were determined and correlated with clinical features. **Results:** 176 pts were included, 112 in Cohort 1 and 64 in Cohort 2. In Cohort 1, emerging mut in *PIK3CA* were identified in 5 cases (14% of total cases with *PIK3CA* mut), *ESR1* in 22 cases (85% of cases with *ESR1* mut) and *PTEN* in 3 cases (43% of cases with *PTEN* mut). No emerging *ERBB2* or *AKT1* mut were seen in plasma. In Cohort 1 *ERBB2* mut were identified in 10 pts (8.9%), 5 both in plasma and tissue and 5 only in tissue. Concordance between tumor and plasma was 53% in Cohort 1 and 66% in Cohort 2 (95% CI of the difference -2% to 38%, P = .09). In Cohort 1, concordance was not associated with (neo)adjuvant treatment, number of lines for MBC, presence of visceral metastasis, location of biopsy (primary tumor or metastasis), interval between sampling (range 3.6 – 288 months) or type of systemic treatment before plasma sampling. In Cohort 2, higher concordance associated with shorter interval between primary diagnosis and sampling (p = 0.02). *PI3KCA* and *ESR1* were the two genes most frequently altered in both cohorts. *PI3KCA* mut had the highest degree of concordance in both groups (70% in Cohort 1 and 76% in Cohort 2). Concordance for *ESR1* mut was low in both cohorts (20% and 48%, respectively). **Conclusions:** A significant number of *ESR1* mut emerged upon therapeutic pressure in LMBC. Plasma analysis could also detect the emergence of *PIK3CA* and *PTEN*, but not *ERBB2* mut. The trend towards lower concordance between metachronous and synchronous tumor and plasma sampling is probably due to increased tumor heterogeneity and clonal diversity secondary to systemic treatment. Our findings confirm that liquid biopsies provide complementary information respect to tumor tissue that may be potentially useful for clinical decisions. Research Sponsor: Puma Biotechnology.

Clinical value of next-generation sequencing in endocrine therapy for advanced hormone receptor–positive/HER2-negative breast cancer. *First Author: Dan Lv, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Acquired gene mutation is a major mechanism of resistance to endocrine therapy in hormone receptor (HR)-positive advanced breast cancer. Circulating tumor DNA (ctDNA) facilitates the current assessment of the genomic profile in patients with advanced cancer. We performed this clinical trial to determine the landscape of gene mutation before endocrine therapy, to search for molecular markers of endocrine therapy efficacy, and to explore the clinical value of ctDNA to guide precise endocrine therapy in patients with advanced breast cancer. **Methods:** We conducted an open-label, single-center, multicohort, prospective study. Patients were women with pathologically and immunohistochemically confirmed HR-positive/HER-2-negative patients with advanced breast cancer. Patients relapsed during or after adjuvant endocrine therapy or progressed after completing at least one previous line of treatment for advanced breast cancer. Patients were assigned to four parallel treatment cohortsmatched to mutations identified in ctDNA: 1) cohort A comprised patients with abnormal activation of PI3K/Akt/mTOR pathway signal, preferred mTOR inhibitor combined with endocrine therapy; 2) cohort B comprised patients with ESR1 mutation and who did not use fulvestrant before, preferred fulvestrant; 3) cohort C comprised patients with HER2 mutations, preferred pyrotinib combined with endocrine therapy; 4) cohort D comprised patients with no significant gene mutation, making treatment plan according to the actual clinical situation. If more than one mutation was identified, the priority of entry is cohorts C, cohorts A and cohort B. In the A-D cohort, patients who obey the treatment plan are the compliance group, and patients who do not obey the treatment plan are the violation group. The primary endpoints were progression-free survival (PFS), and the secondary endpoints included overall survival time (OS). **Results:** A total of 113 patients underwent NGS detection of ctDNA, and 84 patients were enrolled in the study. In all cohorts, combined median PFS was 4.9 months, and the median PFS in the compliance group was 3.0 months longer than in the violation group (6.03 vs 3.03 months, p = 0.0222, HR = 0.5743, 95%CI 0.3273-1.007). In cohort C, the median PFS was 11.1 months in the compliance group and 2.22 months in the violation group (p = 0.0067, HR = 0.1980, 95%CI 0.032-1.22). There was no significant difference in the median PFS between patients with and without compliance with the treatment protocol in cohort A and cohort B (p = 0.5054 and 0.7325, respectively). **Conclusions:** The study suggested that ctDNA detection may guide the optimal endocrine therapy strategy for patients with advanced breast cancer and achieve the benefit of progression free survival. NGS detection might distinguish patients with HER2 mutation and provide new treatment strategies. Clinical trial information: NCT03786575. Research Sponsor: None.

Ribociclib-induced acute kidney injury: Uncover the MONALEESA's dark face. *First Author: Maissoune Hajir, King Hussein Cancer Center, Amman, Jordan*

Background: The phase-3 MONALEESA-2,-3 and -7 randomized trials showed improved progression-free survival (PFS) and overall survival (OS) with the addition of cyclin D-cyclin-dependent kinase 4/6 (CDK4/6) inhibitor ribociclib to endocrine therapy in women with advanced-stage breast cancer. However, ribociclib induced acute renal injury is not recognized in these studies. In this report, we explore ribociclib-induced acute kidney injury (AKI) in breast cancer patients receiving ribociclib. **Methods:** We performed a retrospective chart review of all breast cancer patients who received ribociclib at our institution between April 2019 and September 2021. Patients and disease characteristics were collected, details of creatinine kinetics in relation to administration of ribociclib and other nephrotoxic drugs were obtained. Acute kidney injury grades (AKI-KDIGO classification) were captured. **Results:** 145 females, median age 60.0 years, all with advanced-stage breast cancer treated with aromatase inhibitors (AI) or fulvestrant plus ribociclib were reviewed. A total of 26 (17.9%) patients developed AKI; 3 were grade-I, 21 grade-II and 2 were grade-III. Rate of AKI was significantly higher (n = 15, 48.4%) among 31 patients on other concomitant nephrotoxic drugs, compared to 11 (9.6%) of 114 other patients, p = 0.001. Nephrotoxic drugs include non-steroidal anti-inflammatory (38%), metformin (30%), angiotensin-II receptor blockers (26%), and angiotensin-converting enzyme inhibitors (11%). Median time to develop AKI was 54 (range, 21-168) days, while the median time for creatinine recovery was 5 (range, 4-7) days after holding the drugs. Average creatinine increment for affected patients was 2.28 times the baseline level. Time to AKI was shorter, but not statistically significant, among patients on nephrotoxic drugs and recovery was faster after stopping these drugs (Table). **Conclusions:** Ribociclib-induced AKI is not uncommon and not adequately addressed. Though reversable in majority of patients, some patients may develop grade-III AKI or require treatment interruption. Nephrotoxic medications seem to significantly enhance ribociclib-associated renal injury. Withhold these medications with periodical assessment by nephrologist is strongly recommended in these patients. Larger studies are warranted to validate our findings. Research Sponsor: None.

	Without other nephrotoxic drugs	With Other nephrotoxic drugs	P-Value

Identifying genetic factors of response and resistance to CDK4/6 inhibitors in metastatic HR+/HER2-breast cancer using real-world data. *First Author: Smita Agrawal, ConcertAI, Bengaluru, India*

Background: CDK4/6 inhibitors plus endocrine therapy are approved for treatment of HR+/HER2- metastatic breast cancer (MBC) and have shown to provide a significant progression free survival benefit over endocrine therapy alone. But not all patients benefit from this treatment and some develop resistance over time. The molecular mechanisms governing this resistance are poorly understood. We have developed a real world dataset that includes data elements from structured EMR tables as well as deeply curated unstructured data from BC patients (ConcertAI Genome360 BC Dataset) who have been treated with CDK4/6 inhibitors and have undergone DNA sequencing to identify somatic mutations. We have leveraged this linked clinical-genomics dataset to identify genetic drivers of resistance and response to CDK4/6 inhibitors. **Methods:** This retrospective study uses the Genome360 BC Dataset (N = 1249). The patient's eligibility to be included in this study (N = 456) was HR+/HER2- MBC patients with age > 18 years treated with at least one of the CDK4/6 inhibitors and have response data based on RECIST criteria (responders = 231, non-responders = 225). For each patient in both cohorts, all pathogenic gene mutations and copy number changes were identified and enrichment analysis was performed. Biomarkers with Z value > 1.96 (p value < 0.05) were considered for further analysis. Pathway analysis was performed using these biomarkers and the CDK4/6 pathway to identify pathways and genes that can potentially be targeted to overcome resistance based on the mutational landscape of the patients receiving therapy. **Results:** We identified 7 potential segments (similar groups of genes) which predicted response or resistance to CDK4/6 inhibitors. Here we present data on 3 such segments which are closely related. Loss of function mutations in RB1 were enriched in the non-responder population (Z value = 2.33; p value = 0.026; N = 31). This is consistent with previously reported findings. In addition, amplifications and gain of function mutations in MYC and associated genes were also significantly enriched in the non-responder population (Z value = 2.71; P value = 0.01; N = 44). Interestingly, loss of function mutations in TSC1/2 genes which are downstream of MYC were predictors of good response to CDK4/6 inhibitors (Z value = 2.19; P value = 0.036; N = 30), strengthening the role of the parallel MYC signaling pathway in resistance to CDK4/6 inhibitors. **Conclusions:** Using our Genome360 BC Dataset, we have identified genetic markers affecting response to CDK4/6 inhibitors. In addition to the known role of RB1 in resistance to CDK4/6 inhibitors, the MYC signaling pathway emerged as a strong candidate. Based on these results, patients with mutations in these pathways may benefit from addition of mTOR or PKL1 inhibitors to CDK4/6 inhibitors to overcome resistance and prolong their effect. Real-world efficacy of ribociclib (RIB) plus aromatase inhibitor (AI)/fulvestrant (FUL), or endocrine monotherapy (ET), or chemotherapy (CT) as first-line (1L) treatment (tx) in patients (pts) with hormone receptor–positive (HR+), human epidermal growth factor receptor-2–negative (HER2–) advanced breast cancer (ABC): Results of fourth interim analysis (IA) from RIBANNA. *First Author: Diana Lüftner, Charité University Hospital, Berlin, Germany*

Background: RIBANNA is a real-world, noninterventional study conducted in Germany evaluating efficacy, safety, and tolerability of RIB in combination with AI/FUL aiming to gain insights into routine clinical practice for pts with HR+, HER2– ABC. Here, we present results of the fourth IA from RIBANNA. **Methods:** Pre-, peri- and postmenopausal pts who received 1L tx with RIB+AI/FUL, or ET or CT for HR+, HER2– ABC were included in accordance with the German tx guideline. The effect of baseline demographic characteristics, including histological grade, age, previous adjuvant tx, Eastern Cooperative Oncology Group-performance score (ECOG-PS), and metastatic sites on progression-free survival was evaluated using Cox regression model. **Results:** At data cutoff October 11, 2021, 2598 pts were enrolled in the study (RIB+AI/FUL, n = 2177; ET, n = 239; CT, n = 182). Data from 1L tx were available for 2492 pts (95.9%), second-line tx for 689 pts (26.5%), third-line tx for 263 pts (10.1%), and fourth-line tx for 94 pts (3.6%). Significant differences were observed in baseline mean age and metastatic sites for pts in RIB+AI/FUL cohort vs ET and CT cohorts (both < 0.001). At baseline, the mean (SD) ages of pts were 65.5 (11.6), 70.7 (11.5) and 61.6 (11.6) years in RIB+AI/FUL, ET, and CT cohorts, respectively. While comparing the performance status, 44.2% of pts in RIB+AI/FUL, 34.7% of pts in ET and 42.1% of pts in CT cohort were fully active with ECOG-PS = 0. CNS, liver, or lung metastases were recorded in 42.6% of pts in RIB+AI/FUL, 26.8% of pts in ET and 67.1% of pts in CT cohort. Bone only metastases were reported in 30.8%, 47.9% and 15.0% of pts in RIB+AI/FUL, ET, and CT cohorts, respectively. Overall, 32.1%, 37.7%, and 52.7% of pts discontinued the study in RIB+AI/FUL, ET, and CT cohorts, respectively, the most common reasons being deaths (16.1%,17.2%, and 31.9%, respectively) and lost to follow-up (5.9%, 8.8%, and 9.3%, respectively). The most common tx-emergent adverse event (grade 3 or 4) observed in RIB+AI/FUL cohort was neutropenia (14.8%), while 6.6% and 6.9% of pts in ET and CT cohorts, respectively, experienced neutropenia. The efficacy results from all 3 cohorts, including Kaplan-Meier curves, will be presented during ASCO 2022. **Conclusions:** RIBANNA study showed diverse population characteristics among pts who received RIB tx in a real-world setting. Overall higher number of pts were treated in 1L with RIB+AI/FUL followed by ET and CT. The differences in baseline characteristics on metastatic pattern, age, and ECOG-PS reflect different selection strategies for 1L tx decision. No new safety signals were identified. Clinical trial information: CLEE011ADE03. Research Sponsor: Novartis Pharma GmbH, Germany.

Dalpiciclib in combination with letrozole/anastrozole or fulvestrant in HR+/HER2- advanced breast cancer: A phase Ib study. *First Author: Qingyuan Zhang, Department of Medical Oncology, Harbin Medical University Cancer Hospital, Harbin, China*

Background: Dalpiciclib (Dalp; SHR6390) is a novel cyclin-dependent kinase 4/6 inhibitor which showed tolerability and preliminary clinical activity as monotherapy for pretreated advanced breast cancer (ABC). Here we conducted a multicenter, phase 1b trial to further assess the safety, pharmacokinetics and efficacy of Dalp in combination with endocrine therapy (ET) in HR+/HER2- ABC. **Methods:** 5 cohorts of patients with HR+/HER2- locally recurrent or metastatic BC and any menopausal status were enrolled (~15 patients/combination regimen). Patients without prior treatment for ABC (cohort1/2) were given Dalp (125 or 150 mg po qd, d1-21, q4w) plus letrozole (LTZ; 2.5 mg po qd) or anastrozole (ATZ; 1 mg po qd); patients who progressed after ET (cohort 3-5) were given Dalp (125, 150, or 175 mg po qd, d1-21, q4w) plus fulvestrant (Fulv; 500 mg im, cycle 1 d1, d15, then d1 q4w). The primary endpoint was safety. The data cutoff date was Sep. 20, 2021. **Results:** 58 patients received Dalp plus LTZ/ATZ and 46 received Dalp plus Fulv. No maximum tolerated dose of Dalp was reached with LTZ/ATZ or Fulv. Across all cohorts, 75.0%-93.8% of patients had a grade ≥3 treatment-related adverse event (TRAE), with the most common being neutropenia (grade 3, 40.0%-87.5%; grade 4, 4.2%-46.7%) and leukopenia (grade 3, 33.3%-80.0%; grade 4, 0%; Table). Treatment-related serious AEs occurred in 2 (3.4%) patients with Dalp plus LTZ/ATZ and none with Dalp plus Fulv. At the tested dose levels, steady-state areas under the concentration curve and peak concentration of Dalp increased with dose in combination with LTZ/ATZ or Fulv. Dalp 150 mg was associated with a numerically higher objective response rate in both ET-untreated (67.6%, 95% CI 49.5-82.6) and ET-pretreated (53.3%, 95% CI 26.6-78.7) patients per investigator. The median progression-free survival with Dalp 150 mg was 20.3 mo (95% CI 16.9-not reached [NR]) and 16.7 mo (95% CI 1.9-24.1) in ET-untreated and ET-pretreated patients respectively. **Conclusions:** Dalpiciclib plus letrozole/anastrozole or fulvestrant showed an acceptable safety profile, with hematological toxicities as the most common TRAEs. The recommended phase 3 dose of dalpiciclib was 150 mg. Together with the promising anti-tumor activity observed with the combination therapy in HR+/HER2- ABC, further trials are warranted. Clinical trial information: NCT03481998. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co. LTD.

Grade ≥3 TRAEs occurring in ≥10% of patients in any cohort.

Survival outcomes in metastatic HR-positive, HER2-negative invasive ductal carcinoma compared to invasive lobular carcinoma and mixed ductal/lobular treated with endocrine therapy in combination with CDK4/6 inhibitors, mTOR inhibitor, or PI3K inhibitor. *First Author: Jason A Mouabbi, MD Anderson Cancer Center, Houston, TX*

Background: The majority of invasive lobular breast cancers (ILC) are hormone receptor (HR)-positive, HER2-negative and are clinically treated similarly to HR+ HER2-negative invasive ductal cancers (IDC). However, ILC differs distinctly from IDC in its clinicopathologic characteristics and molecular alterations. ILC also differs in response to systemic therapy, with studies showing ILC as less sensitive to chemotherapy. It is currently unknown if patients with ILC or mixed ductal/lobular (MDL) histologies derive similar benefits as IDC from endocrine therapy (ET) in combination with cyclin-dependent kinase 4/6 inhibitors (CDK4/6is), mTOR inhibitor everolimus or PI3K inhibitor alpelisib. **Methods:** We retrospectively searched for patients treated at MD Anderson Cancer Center with a diagnosis of HR+, HER2-negative metastatic breast cancer (MBC) with ET in combination with CDK4/6is, everolimus or alpelisib. Patients were divided into 3 groups based on their histology: ILC, IDC and mixed. We obtained data on demographics, estrogen (ER) and progesterone (PR) receptor status, menopausal status, treatment duration and survival status. The Kaplan-Meier product-limit method was used to compare progression-free survival (PFS) and overall survival (OS) between the three different groups stratified by the treatment received. **Results:** We identified 2,971 patients (2,432 IDC [82%], 427 ILC [14%], 112 Mixed [4%]) with HR+ HER2-negative MBC treated with ET in combination with CDK4/6is, everolimus and/or alpelisib between 2010 and 2021. Median age was around 50 years in all groups. Around 80% of patients were white, 10% Hispanic and 5% black. Around 55% of patients were post-menopausal, 99% had ER+ and 88% PR+ tumors; 1,895 patients (81% IDC, 15% ILC, 4% mixed) received CDK4/6is, 1,027 (82% IDC, 14% ILC, 4% mixed) received everolimus and 49 (81% IDC, 19% ILC) received alpelisib. PFS and OS were not statistically different between the 3 groups (Table). **Conclusions:** HR+ HER2-negative MBC patients with IDC, ILC and MDL benefited from ET in combination with CDK4/6is, everolimus or alpelisib similarly with no significant differences in PFS and OS. Research Sponsor: None.

	CDK4/6i + ET N = 1,895			Everolimus + ET N = 1,027			Alpelisib + ET N = 49

Hormone therapy (HT) or capecitabine (CAP) as maintenance therapy following the first-line chemotherapy in HR+/HER2-ABC/MBC: Secondary endpoint adverse effects (AEs) and toxicity report of OVERSTEP Trial (ZJCH15001/CBCSG 035). *First Author: Jian Huang, Department of Breast Medical Oncology, Cancer Hospital of the University of Chinese Academy of Sciences, Zhejiang Cancer Hospital, Hangzhou, China*

Background: OVERSTEP (NCT02597868) is a multicenter, randomized clinical trial of capecitabine (CAP) versus endocrine therapy (HT) as maintenance therapy after 1st-line CAP-based combination chemotherapy in HR+/HER2- ABC/MBC. At 2020 SABCS conference, we reported the primary endpoint (progression-free survival, PFS) at follow-up of 24.3 months, at 2021 SABCS, repoted the PFS and OS at follow-up of 41.4 months. Here, we reported the secondary endpoint Adverse effects (AEs) . **Methods:** Total of 181 patients with HR+ and HER2- MBC were enrolled in this study from Jun, 2013 to Jan, 2019. All the patients received at least 4 cycles of CAP-based combination regimen as 1st-line salvage chemotherapy. The patients who achieved CR, PR or durable SD by RECIST criteria entered into the maintenance therapy setting (MT), and randomly (1:1 ratio) assigned to either CAP single or HT group. Randomization was done centrally with stratification by endocrine sensitive or resistance and visceral or non-visceral metastasis. After combined chemotherapy, 75.14% (n=136) cases entered into the maintenance therapy setting, and 24.86% case were disease progressed (PD) during combined chemotherapy. After a median follow-up of 41.4 months (IQR 21.57-79.23), we reported the secondary endpoint Adverse effects (AEs) . **Results:** In PPS, hematologic toxicities in ET group and CT group were as follows, anemia (69.6% vs 64.2%), leukopenia (60.8% vs 50.8%), neutropenia (66.7% vs 31.2%), thrombocytopenia (26.1% vs 26.9%). The non-hematologic toxicities were hand-foot syndrome (HFS) (33.3 vs 41.8%) , increased ALT (50.7 % vs 37.3%), increased AST (53.6% vs 37.3%), hyperbilirubinemia (32.2% vs 25.4%), fatigue (14.5% vs 10.4%), hypokalemia (5.8% vs 4.5%), pneumonia (0.0% vs 6.0%), peripheral neuropathy (4.8% vs 0.0%) ,etc. Duration of maintenance, the AEs in the ET group were significantly lighter, just like anemia (0.0% vs 28.4%), leukopenia (5.8% vs 17.8%), neutropenia (5.8% vs 16.4%), thrombocytopenia (2.9% vs 22.4%) et al., the non-hematologic toxicities were HFS (0.0% vs 23.9%), increased ALT (4.3% vs 16.4%), increased AST (5 .8% vs 16.4%), increased bilirubin (0.0% vs 10.4%), peripheral neuropathy (5.8% vs 0.0%). Moreover, the toxicities of grade 3/4 were in the CT maintenance group, anemia was 1 case (1.5%), neutropenia 2 cases (2.99%), HFS 5 Case (7.5%) and increased AST in 1 case (1.5%). The ET maintenance group had not any grade 3/4 AEs. **Conclusions:** For HR+ and HER2- MBC, after 1st-line salvage combined chemotherapy, HT maintenance therapy is superior to chemotherapy (capecitabine) maintenance in terms of efficacy and safety. But, if toxicity is well managed, the safety is still tolerated during chemotherapy maintenance. Therefore, in the post-CDK4/6 period, chemotherapy is still an option. Clinical trial information: NCT02597868. Research Sponsor: China breast cancer clinical research collaboration group.

A novel analysis of data from the PALOMA-3 trial confirms the efficacy of palbociclib and provides an option for efficacy assessments that could accelerate drug approvals. *First Author: Celine Yeh, Columbia University College of Physicians and Surgeons, New York, NY*

Background: Advances in breast cancer (BC) therapy the past few decades have led to higher survival rates. Beginning with palbociclib, cyclin-dependent kinase 4 and 6 (CDK4/6) inhibitors have emerged as a treatment option for BC. We analyzed data from PALOMA 3 that could release a biomarker of OS in patients that receive palbociclib. **Methods:** We estimated concurrent rates of growth (g) and regression (d) from the 393 women with advanced BC enrolled in PALOMA-3 who had radiographic tumor measurement data including 261 treated with fulvestrant + palbociclib, and 132 with fulvestrant + placebo. We analyzed data using a model defined as SLD (t) = exp ($-d$ x t) + exp (g x t) – 1, where SLD = sum of longest diameters and t = time. We examined the relationship between g and overall survival (OS) and compared the median growth rates (g) of various cohorts. **Results:** g values associate highly with OS (p<0.0001). Emulating results in the clinical trial, palbociclib slowed the median g values of the entire population and those with sensitivity to previous endocrine therapy but not those deemed resistant. Further cohort analyses found greater benefit with palbociclib in those with visceral metastases, and longer disease-free interval, and benefit independent of ECOG PS, menopausal status, prior lines of therapy, and age. With only the baseline and two additional scans obtained, the median g values of the palbociclib and placebo arms were statistically different: p=0.038 after 28 (19/9) patients and p=0.0043 after 40 (26/14) patients. **Conclusions:** Estimates of palbociclib's impact on tumor growth rates (g) confirm its efficacy in PALOMA 3. Our ability to discern differences in g, a value associated with OS, after only two follow up scans in as few as 28 patients merits considering g an early biomarker of OS benefit that could bring effective drugs to patients as rapidly as possible. Research Sponsor: Pfizer Inc.

The safety, tolerability, and preliminary antitumor activity of sitravatinib plus tislelizumab in patients with locally recurrent or metastatic triple-negative breast cancer. *First Author: Lei Fan, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Anti-PD-1 antibody plus chemotherapy has been demonstrated promising anti-tumor activity in patients with locally recurrent or metastatic triple negative breast cancer (TNBC). However, this regime only limited to TNBC patients with PD-L1 positive. As antiangiogenic agents could enhance the response to immune checkpoint inhibitors, we conducted this phase 2 study to assess the efficacy and safety of novel chemotherapy-free regimen of sitravatinib (targets receptor TKI against TYRO3, AXL, MERTK and VEGF family of receptors) in combination with tislelizumab (anti-PD-1 antibody) in patients with locally recurrent or metastatic TNBC regardless of PD-L1 status. **Methods:** Patients with locally recurrent or metastatic TNBC were included and divided into two cohorts. Patients received 70 mg (cohort A) or 100 mg (cohort B) sitravatinib QD PO and 200 mg tislelizumab IV Q3W until disease progression or intolerable toxicity. The primary endpoints included overall response rate (ORR) (cohort A and B) and rate of grade ≥3 treatment-related adverse events (AEs) (cohort B). Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), duration of response (DOR), 1-year overall survival rate and safety/tolerability. In cohort A, the first statistical analysis would be performed when 12 patients were enrolled; if ≥1 of 12 patients were with confirmed response during the first stage, additional 9 patients would be enrolled to the second stage based on Simon's two-stage design. We would deem cohort A to be statistically superior to a historical control of 8% under the settings if > 3 of 21 patients responded (one-sided a = 0.1 and power of 80%). Patients' recruitment in cohort B would begin after completing the recruitment in cohort A. **Results:** Herein we reported the preliminary results in cohort A. Four patients were with confirmed response during the first stage, and additional nine patients were enrolled to the second stage. A total of 21 patients with 0-3 lines of prior chemotherapy were included from April 2021 to September 2021. The median age was 51 (32-66) years and 20 (95%) patients had ECOG PS 0. At data cut off 13 Jan 2022, 19 patients were alive, 11 are still on treatment. The confirmed ORR was 38.1% (95% CI, 18.1%-61.6%) based on current 21 efficacy evaluable patients. DCR was 95.2% (95% CI, 76.2%-99.9%), and median PFS was 7.0 (95% CI, 3.7 - not reached) months. 4/21 (19%) of patients experienced grade 3 treatment-related AEs. Grade 3 AEs reported in ≥5% of patients were aspartate aminotransferase increased (9.5%) and palmar-plantar erythrodysaesthesia syndrome (9.5%). No patients experienced grade 4 AEs. **Conclusions:** Sitravatinib combined with tislelizumab demonstrated clinically meaningful anti-tumor activity and had a manageable safety profile. Clinical trial information: NCT04734262. Research Sponsor: BeiGene (Beijing) Co., Ltd.

Sacituzumab govitecan (SG) versus treatment of physician's choice (TPC) in patients (pts) with previously treated, metastatic triple-negative breast cancer (mTNBC): Final results from the phase 3 ASCENT study. *First Author: Aditya Bardia, Department of Hematology/Oncology, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: Treatment goals for pts with metastatic breast cancer include extended survival and improved quality of life (QoL). SG is an antibody-drug conjugate composed of an anti–Trop-2 antibody coupled to the cytotoxic SN-38 payload via a proprietary, hydrolyzable linker. SG received FDA approval for pts with mTNBC who received ≥2 prior chemotherapies (at least 1 in the metastatic setting). In the pivotal phase 3 ASCENT study (NCT02574455), SG demonstrated a significant survival benefit over single-agent chemotherapy TPC in the primary analysis population of pts with second line or greater (2L+) mTNBC without known brain metastases at baseline (Bardia A et al. *NEJM* 2021) and QoL (Loibl S. et al. ESMO 2021). With additional follow up, we present the final data on efficacy, including overall survival (OS), safety, and QoL. **Methods:** Pts with mTNBC refractory or relapsing after ≥2 prior chemotherapies with at least 1 in the metastatic setting were randomized 1:1 to receive SG (10 mg/kg IV on days 1 and 8, every 21 days) or TPC (capecitabine, eribulin, vinorelbine, or gemcitabine) until disease progression or unacceptable toxicity. Primary endpoint was progression-free survival (PFS) per RECIST 1.1 by independent review in pts without known brain metastases at baseline. Key secondary endpoints included OS, safety, and health-related QoL. Safety was analyzed in pts who received ≥1 dose of study drug. **Results:** Of 529 pts enrolled, 468 did not have known brain metastases at baseline (median age: 54 y [range, 27-82]; median prior lines: 4 [range, 2-17]). As of Feb 25, 2021 (final database lock), SG (n = 235) vs TPC (n = 233) significantly improved median PFS (5.6 vs 1.7 mo; HR: 0.39; P< 0.0001) and median OS (12.1 vs 6.7 mo; HR: 0.48; P< 0.0001). The OS rate at 24 months was 22.4% (95% CI, 16.8-28.5) in the SG arm and 5.2% (95% CI, 2.5-9.4) in the TPC arm. In the safety population (n = 482), key treatment-related grade ≥3 adverse events with SG (n = 258) vs TPC (n = 224) were diarrhea (11% vs 0.4%), neutropenia (52% vs 33%), anemia (8% vs 5%), and febrile neutropenia (6% vs 2%). There was no grade ≥3 neuropathy and 1 case of grade 3 interstitial lung disease reported with SG. No patient experienced a treatment-related death with SG, and there was 1 treatment-related death with TPC due to neutropenic sepsis. Treatment discontinuations due to AEs were ≤3% in both arms. SG arm showed clinically meaningful and statistically significant improvements than the TPC arm in scores for all five primary focus health-related QoL domains. **Conclusions:** The analysis based on the final database lock of ASCENT confirms the superior survival outcomes of SG over single-agent chemotherapy, with a manageable safety profile and improvement in QoL for pts with mTNBC in the 2L+ setting. These findings reinforce SG as an effective treatment option for this pt population. Clinical trial information: NCT02574455. Research Sponsor: Gilead Sciences, Inc.

Apatinib combined with chemotherapy versus single chemotherapy in HER-2 negative advanced breast cancer: A randomized, controlled, open-label phase II study. *First Author: Zhanhong Chen, Department of Breast Medical Oncology, Cancer Hospital of the University of Chinese Academy of Sciences, Zhejiang Cancer Hospital, Hangzhou, China*

Background: Apatinib is an oral, highly potent tyrosine-kinase inhibitor targeting VEGFR2. A series of clinical studies have shown that anti-angiogenic drugs combined with chemotherapy enable to improve the efficacy of HER2-negative advanced/metastatic breast cancer(MBC). **Methods:** Patients with HER2-negative MBC with less than two lines of systemic therapy were enrolled in this open-label, controlled, phase II trial. Patients with measurable disease were randomly assigned, in a 1:1 ratio, to receive oral apatinib (250 mg once daily) combined with chemotherapy(A+CT) or chemotherapy(CT) alone (the physician's choice) until disease progression or intolerable toxicity. The primary end point was progression-free survival(PFS), which was assessed by investigator and was analyzed on an intention-to-treat basis. **Results:** Between August 2017 and January 2021, of the 80 patients who underwent randomization, 40 were assigned to receive apatinib plus chemotherapy(A+CT) and 40 were assigned to receive standard therapy(CT). As of January 2022, 10 patient had not undergone response evaluation or dropout, 70 patients(36 patients in A+CT, 34 patients in CT were finally included with PFS events and 72 patients were included in safety set. Median PFS was significantly longer in A+CT than in CT (182 days vs 63 days; P = 0.043);The median PFS of TNBC subgroup (11 in A+CT group, 14 in CT) was longer in the aptinib group than in CT group (167 days vs 63 days; P = 0.637);The median PFS of HR+ subgroup(25 in apatinib group, 20 in chemotherapy group) was longer in the aptinib group than in CT group (259 days vs 56 days; P = 0.054);The median PFS of patients with liver metastases(19 in apatinib group, 17 in chemotherapy group) was longer in the aptinib group than in the CT group (151 days vs 54 days; P = 0.191); The severe adverse reactions (grade 3/4) were neutropenia(22.2% vs 13.9%), hypertension(11.1% vs 0.0%), leukopenia(8.3% vs 8,3%), hypokalemia(8.3% vs 2.8%), anemia(5.6% vs 11.1%), ALT(2.8% vs 8.3%), AST(0.0% vs 5.6%) in the apatinib group and the CT, respectively. Proteinuria did not occur in both groups. Treatment delay or dose reduction owing to adverse event was 16.7% and 11.1%, respectively. Treatment discontinuation owing to adverse event was 23.5% and 8.8%, respectively. **Conclusions:** Apatinib combined with chemotherapy showed a significant improvements in PFS and a manageable safety profile in HER2 negative MBC. Research Sponsor: None.

Leveraging patient engagement to optimize a phase 3 clinical trial design, study participation and recruitment for women diagnosed with triple-negative breast cancer (TNBC). *First Author: Mary E. Elmer, Merck & Co., Inc, North Wales, PA*

Background: The importance of Patient Engagement (PE) on clinical trial design is well established. PE in oncology medicines development can serve many purposes including obtaining input on trial design/procedures, identifying recruitment challenges and barriers to participation, and understanding retention strategies. Designing a clinical trial with procedures that have been confirmed as acceptable to participants is also likely to improve patient adherence to treatments. Triple-Negative Breast Cancer (TNBC) is a virulent subtype associated with early onset and increased risk of early recurrence and accounts for 15% to 20% of breast cancers. In addition, a higher risk exists in premenopausal and Black women. Chemotherapy is the mainstay of curative therapy recommended by guidelines. The aim was to obtain insights from patients to inform key aspects of a clinical study design including choice of chemotherapy regimen, study feasibility and recruitment strategies. **Methods:** Two groups of US women (N = 20) ages 28-54; (race 55% Caucasian, 30% African American, 10% Hispanic, 5% Native American) diagnosed with Stage IIb-IV TNBC and in active or completed treatment were recruited to participate in two in person IRB approved sessions. Trained 3rd party facilitators used qualitative methods to elicit patient feedback. Preliminary research included interviews with key stakeholders, including TNBC advocacy group leaders and a review of online patient communities. Patients reviewed a study design with an investigational agent every 3 weeks plus chemotherapy (nab-paclitaxel; paclitaxel) or placebo plus chemotherapy. **Results:** Patient reaction to the choice of taxane chemotherapy in the standard of care arm was neutral to negative. Approximately 50% of the patients identified taxane treatment as a barrier to participation. All patients requested flexibility in treatment choices, clear information about required tests and visits, and more diversity in recruitment materials. Black and Hispanic women impacted by TNBC did not feel they had equal access to clinical trials due to race, rural location, and other factors. Patient insights reinforced the decision to add another standard-of-care option (carboplatin plus gemcitabine) as a treatment arm to the trial design and was confirmed with investigators. Patient feedback was incorporated into the trial along with additional strategies to support recruitment of diverse patients in the clinical study. **Conclusions:** On November 13, 2020 the FDA approved this regimen in the label for pembrolizumab in combination with chemotherapy, as the 1st line treatment in women with locally recurrent or metastatic TNBC. Both patients and physicians perceived that a flexible chemotherapy backbone was a benefit. Research Sponsor: Merck & Co., Inc.

Real-world outcomes of Black women versus non-Hispanic White women with advanced triple-negative breast cancer treated with immune checkpoint inhibitors at an urban cancer center. *First Author: Jeffrey Aldrich, Department of Hematology and Medical Oncology, Winship Cancer Institute, Emory University, Atlanta, GA*

Background: Black women (BW) are disproportionately diagnosed with metastatic triple negative breast cancer (mTNBC) compared to Non-Hispanic White women (NHW). Median overall survival (OS) in mTNBC remains poor at 12-18 months. While immune checkpoint inhibitors (ICIs) are a promising treatment strategy, BW were significantly underrepresented in pivotal clinical trials that led to the approval of ICIs in mTNBC. Therefore, the efficacy, safety, and optimal biomarkers of ICI response in BW remain unknown. We sought to compare baseline characteristics and outcomes between BW and NHW with mTNBC treated with an ICI and chemotherapy at an urban tertiary care institution. **Methods:** BW and NHW with advanced unresectable or mTNBC treated with an ICI plus chemotherapy at Emory University between 2019 and 2021 were retrospectively evaluated. Baseline characteristics, including next generation sequencing (NGS), as well as clinical outcomes between BW and NHW were compared using Kruskal-Wallis tests and Fisher's exact tests. Progression free survival (PFS) and OS were analyzed with the Kaplan-Meir method. **Results:** Forty-one women with PDL-1 positive mTNBC treated with an ICI and chemotherapy were identified [BW, n = 26 (63%) and NHW, n = 15 (37%)]. A majority of patients had relapsed disease (73%); however BW were more likely to have de novo metastatic disease compared to NHW (38% vs 7%, p = 0.03). Twenty-seven (66%) patients received atezolizumab and 14 (34%) were treated with pembrolizumab. Of the 23 (56%) patients with NGS testing, alterations in TP53, PIK3CA, and BRCA were seen in 23 (100%), 5 (31%), and 1 (6%) patient, respectively. Median tumor mutational burden was similar between BW and NHW (5 vs 7, p = 0.8). BW had numerically lower median PDL-1 (SP142) compared to NHW (1% vs 2%, p = 0.5). Rates of immune and dose-limiting chemotherapy-related adverse events were similar between BW and NHW (Table). There were no differences in ICI response between groups, though BW had fewer complete responses and a shorter median PFS compared to NHW. Median OS was 12 months in BW compared to 28 months in NHW (p = 0.1). **Conclusions:** Our experience with real-world use of this regimen showed that BW had fewer complete responses and a trend towards worse OS compared to NHW. BW had numerically lower median PDL-1 expression compared to NHW, suggesting further investigation of biomarkers, potentially by Race, are needed to better identify responders to ICI in mTNBC. Research Sponsor: None.

Characteristics N(%)/months [95% CI]	BW (N = 26)	NHW (N = 15)	*P* value
Immune-related adverse events	3 (12)	4 (27)	0.4
Chemotherapy-related adverse events	9 (35)	3 (20)	0.5
Response	16 (64)	11 (73)	0.7
Partial	14 (88)	5 (45)	
Complete	2 (13)	6 (55)	
Progressive or stable disease	9 (36)	4 (27)	0.7
Median PFS	4 [2, 7]	8 [2, not reached]	0.2
Median OS	12 [8, 27]	28 [4, not reached]	0.1

Real-world treatment patterns and outcomes among patients (pts) with second-line (2L) and third-line (3L) metastatic triple-negative breast cancer (mTNBC) in England using the Cancer Analysis System (CAS). *First Author: Lawrence Chang, Gilead Sciences, Inc., Foster City, CA*

Background: TNBC is the most aggressive type of breast cancer due to rapid growth, metastasis, and recurrence post-treatment. This study aimed to assess real-world treatment patterns and survival of pts with mTNBC who received 2L and 3L therapy in England and report OS and PFS of pts receiving 2L therapies stratified by treatment-free interval from the curative setting. **Methods:** This retrospective study using the CAS database, included pts with mTNBC who received at least three systemic treatments (at least two in metastatic setting) for TNBC during the years 2012 to 2020. $Cohort_{2L}$ included pts with initial early-stage BC diagnosis and treatment (at least two systemic treatments prior to 2L). $Cohort_{3L}$ included pts initially diagnosed with either early-stage TNBC, or de novo advanced TNBC (at least two systemic treatments prior to 3L). The two cohorts are not mutually exclusive. The study outcomes were stratified by cohort ($Cohort_{2L}$ and $Cohort_{3L}$) and treatment-free interval (<12 m versus ≥12 m from end of curative treatment to start of 1L treatment, $Cohort_{2L}$ only). Kaplan-Meier methods estimated progression-free survival (PFS) and overall survival (OS). PFS was proxied by 'Time to treatment discontinuation or death' (TTDD). Log-rank tests compared the distribution of OS and PFS for 2L stratified by treatment-free interval (<12 m versus ≥12 m). **Results:** $Cohort_{2L}$ included 606 pts and $Cohort_{3L}$ included 374 pts. Tumor morphology was similar across Cohorts. Pts at 3L had worse ECOG performance score compared to 2L, and more pts with de novo advanced TNBC had brain metastasis at any point after diagnosis than pts diagnosed with early-stage TNBC. Regimens at 2L for $Cohort_{2L}$ included capecitabine (32%), eribulin (16%), carboplatin and gemcitabine in combination (12%), and paclitaxel (10%). A similar distribution was seen for $Cohort_{3L}$. Regimens at 3L ($Cohort_{3L}$ only), included eribulin (38%), capecitabine (16%), and paclitaxel (13%). Stratifying $Cohort_{2L}$ by treatment-free interval did not exhibit significant differences in PFS nor OS by log rank tests (Table). **Conclusions:** This nationwide study, in England, accentuates the significant unmet need in 2L and 3L therapy for mTNBC highlighted by the poor prognosis. The stratification by prior treatment-free interval from curative setting did not show a difference in OS or PFS for patients receiving 2L treatment. Research Sponsor: Gilead Sciences.

mTNBC PFS and OS from commencement of treatment line.

Survival outcome	Median PFS_{TTDD} (*in months*)	Median OS (*in months*)
By cohort:		
$Cohort_{2L}$ (n=606)	2.53 (2.30–2.76)	6.70 (6.14-7.62)
$Cohort_{3L}$ (n=374)	2.43 (2.20–2.76)	5.54 (4.90-6.14)
By treatment-free interval ($Cohort_{2L}$):		
<12m (n=255)	2.30 (2.07-2.76)	5.72 (5.06-6.64)

Exposure-response analyses of sacituzumab govitecan (SG) efficacy and safety in patients (pts) with metastatic triple-negative breast cancer (mTNBC). *First Author: Indrajeet Singh, Gilead Sciences Inc., Foster City, CA*

Background: SG is an antibody-drug conjugate composed of an anti–Trop-2 antibody coupled to the cytotoxic SN-38 payload via a proprietary, hydrolyzable linker. SG is approved for pts with mTNBC who received ≥2 prior chemotherapies (> 1 in the metastatic setting). The relationships between exposure of SG, free SN-38, and total antibody (tAB) following SG administration and its efficacy and safety outcomes were evaluated in pts with mTNBC. **Methods:** Available exposure efficacy and safety outcomes from the mTNBC cohort of the phase 1/2 IMMU-132-01 study (relapsed/refractory pts; n = 24) and mTNBC pts from the phase 3 ASCENT study who had received ≥2 prior therapies (> 1 in the metastatic setting; n = 253) were analyzed. Pts in IMMU-132-01 received 8 or 10 mg/kg SG and pts in ASCENT received 10 mg/kg SG on d1 and d8, of every 21d cycle. Effect of exposure on CR, ORR and the evaluated adverse events (AEs) of vomiting, diarrhea, hypersensitivity reactions, nausea, and neutropenia were analyzed using logistic (CR, ORR) or ordinal logistic (AE) regression models while OS, PFS, time to first dose reduction and time to first dose delay were analyzed using Cox PH models. Several exposure metrics related to the PK of SG, free SN-38, and tAB were evaluated as predictors of SG efficacy and safety and the most statistically significant exposure metric was retained in the model; effect of other covariates was characterized within the modeling framework. **Results:** Higher values of the average exposure over the treatment duration (CAVG) for SG ($CAVG_{SG}$) were significantly associated with an increase in the probability of CR and ORR and higher CAVG values for tAB ($CAVG_{tAB}$) were significantly associated with longer OS and PFS. The probability of Grade ≥1 evaluated AEs, the risk of dose reductions and dose delays were found to increase significantly with increasing $CAVG_{SG}$. Neutropenia was the only AE where the effect of exposure was significantly associated with the probability of Grade ≥3 evaluated AEs. No statistically significant associations between exposure and the probability of Grade 4 AEs were observed for any of the evaluated endpoints. The developed models were used to estimate the efficacy and safety outcomes for the 8 mg/kg vs 10 mg/kg SG dose levels and the results indicated a more favorable risk/benefit profile for the 10 mg/kg dose level driven by the higher estimated efficacy. Baseline Trop-2 expression level was not statistically correlated with magnitude of clinical response based on the limited available Trop-2 data. **Conclusions:** Exposure-response relationships were observed for all evaluated efficacy and safety endpoints for SG in patients with mTNBC, and the higher efficacy (as assessed by CR, ORR, OS and PFS) achieved with the exposures associated with the 10 mg/kg SG dose regimen and its manageable safety profile support the appropriateness of the approved regimen of SG. Clinical trial information: NCT02574455, NCT01631552. Research Sponsor: Gilead Sciences, Inc.

1077 **Poster Session**

A phase 3, multicenter, open, randomized controlled clinical study of gemcitabine plus capecitabine versus gemcitabine plus carboplatin in the first-line treatment for advanced triple-negative breast cancer. *First Author: Xiaodong Liu, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*

Background: Gemcitabine plus capecitabine (GX) regimen is still lack of phase III clinical trial evidence for the first-line treatment of advanced triple-negative breast cancer (TNBC). We designed this phase III trial to compare the efficacy and safety of GX with gemcitabine plus carboplatin (GC) in patients with advanced TNBC. We also explored the correlation between tumor infiltrating lymphocytes (TILs) and the prognosis in TNBC treated with different chemotherapy regimen. **Methods:** Patients with advanced TNBC were randomly assigned to receive gemcitabine (1,000 mg/m^2) on days 1 and 8 plus oral capecitabine (1,000 mg/m^2 twice a day) on days 1 through14; or, to receive gemcitabine (1,000 mg/m^2) on days 1 and 8 plus carboplatin (AUC = 2) on days 1 and 8. The primary end point was progression free survival (PFS), and secondary end points were objective response rate (ORR), clinical benefit rate (CBR), overall survival (OS) and safety. Immunohistochemistry was performed with antibodies against CD3, CD4, CD8, and CD 19 antigens on tissue sections of 52 TNBC patients. The margin used to establish non-inferiority was 1.2. This study is registered on Clinical Trials.gov, number NCT02207335. **Results:** From Jan 2014, to Dec 2020, 187 patients underwent eligibility assessment and were randomly assigned (93 in GX and 94 in GC). The ORRs in GX arm and GC arm were 37.6%, and 39.4%, respectively (P = 0.808). The CBRs in GX arm and GC arm were 78.5% and 79.8%, respectively (P = 0.828). Median PFS was 6.1 months for GX arm compared with 6.3months for GC arm (log-rank P = 0.348; HR = 1.148, 95% CI: 0.856 to 1.539, P = 0.357). The median OS in GX arm and GC arm was 21.0 months and 21.5 months, respectively (log-rank P = 0.992; HR = 1.002, 95% CI: 0.717 to 1.400, P = 0.992). Hematologic adverse events (AEs) were commonly observed in both arms, especially in GC arm. Non-hematological AEs such as hand-foot syndrome, diarrhea, and peripheral sensory neuropathy were more common observed in GX arm, while alopecia, nausea, vomiting, fatigue, decreased appetite, infusion related reaction, and hyperglycemia were more common in GC arm. Patients with high $CD8^+$ TILs had a significantly longer PFS (HR = 0.559; 95% CI: 0.314 to 0.993, P = 0.047) and OS (HR = 0.436; 95% CI: 0.226 to 0.843, P = 0.014) compared with patients with low $CD8^+$ TILs. In the high $CD8^+$ group，patients treated with GC had prolonged PFS (HR = 0.322; 95% CI: 0.127 to 0.816, P = 0.017) and OS (HR = 0.300; 95% CI: 0.094 to 0.957, P = 0.042) compared with GX. **Conclusions:** The trial did not meet the prespecified criteria for the primary end point of PFS in the ITT population. Compared with GC, GX demonstrated lower toxicity. Compared to patients with low $CD8^+$ TILs, patients with high $CD8^+$ TILs showed better outcomes, and in these patients, GC regimen could improve survival compared with GX regimen. Clinical trial information: NCT02207335. Mechanisms of action and acquired resistance to atezolizumab plus *nab*-paclitaxel in metastatic triple-negative breast cancer (mTNBC). *First Author: Luciana Molinero, Genentech, Inc., South San Francisco, CA*

Background: In the IMpassion130 study (NCT02425891) first-line atezolizumab plus *nab*-paclitaxel (A+nP) provided clinical benefit compared with placebo plus nP (P+nP) in patients with mTNBC whose tumors were PD-L1+ (Schmid NEJM 2018). However, in many patients, disease that was initially controlled eventually progressed. The mechanism of action of A+nP and nP in the mTNBC tumor microenvironment (TME) and the biological changes associated with tumor progression with these therapies remain largely unknown. The goal of the current study was to evaluate biological changes in the TME induced by atezolizumab and nP early on treatment (OT) and at the time of progressive disease (PD) in IMpassion130. **Methods:** Paired tumor biopsies from IMpassion130 collected pre-treatment at baseline (BL), after 4 weeks OT, and at clinical PD were evaluated histologically for PD-L1 expression, CD8 content, stromal tumor infiltrating lymphocytes and immune phenotypes. RNA sequencing was also used to evaluate TNBC molecular subtypes and gene expression (hallmark gene sets, and immune cell and stromal gene signatures). Matched tumor pair samples from BL and PD were further analyzed by next-generation sequencing for genomic changes using the FoundationOne gene panel. Wilcoxon, Fisher, and McNemar's tests were used for statistical analysis. **Results:** OT A+nP (n = 24 pairs), but not P+nP (n = 18 pairs) increased PD-L1 in both tumor-infiltrating immune cells and tumor cells, and increased frequency of immune-inflamed tumors. RNA-based signatures for A+nP showed an increase in lymphocytes (T-, B-, and NK cell), as well as IFN-α and IFN-γ responses, driven mainly by responders. While P+nP increased RNA-based stromal signatures (cancer-associated fibroblasts, pericytes, and angiogenesis) and epithelial mesenchymal transition, these changes were not observed with A+nP. OT A+nP and P+nP both reduced cell proliferation but only A+nP reduced metabolic pathways. At PD there was a significant reduction of RNA-based immune and stromal signatures in both A+nP (n = 59) and P+nP (n = 55) arms. Cell proliferation and DNA repair signatures were increased with A+nP but not P+nP. Evaluation of genomic changes suggested that both A+nP and P+nP increased tumor mutational burden (TMB), but only A+nP increased genomic scarring. At PD, the tumor immune phenotypes changed at PD with no directionality, while TNBC subtypes remained stable. **Conclusions:** A+nP boosted tumor immune inflammation and decreased tumor cell proliferation and metabolism in mTNBC patients, particularly in responders. Addition of atezolizumab prevented early stromal recruitment induced by nP. While decreased immune and stromal components and increased TMB were observed with both nP and A+nP, A+nP tumor escape was characterized by increased cell proliferation and DNA scarring. Clinical trial information: NCT02425891. Research Sponsor: F. Hoffmann-La Roche Ltd.

Comprehensive immune profiling unravels evolution of spatial distribution and immune repertoire in tumor microenvironment from primary to metastatic triple-negative breast cancer. *First Author: Weihua Guo, City of Hope National Medical Center, Duarte, CA*

Background: Immune checkpoint inhibitors (ICI) have improved PFS and OS in metastatic triple-negative breast cancer (mTNBC), but benefit is limited to PD-L1 positive tumors. Metastatic tumors are notorious for deficient immune cell infiltration and immunosuppressive features that may limit responses to ICI in mTNBC. However, the underlying mechanisms for the weak immunogenicity of the metastatic tumor immune microenvironment (TIME) and related poor ICI responses are still not well understood. The current study was designed to investigate the evolution of the TIME between paired primary and metastatic TNBCs. **Methods:** Spatial distribution of 37 key immune regulators using the NanoString digital spatial profiling (DSP) platform was analyzed. 452 regions of interests (ROIs) from 33 primary tumors (PT) and 29 metastatic tumors (MT) including 28 paired specimens, were selected based on CD45+ immune hotspots, and the protein expression levels of the key immune regulators were quantified within pan-cytokeratin (panCK) and CD45 masked regions, respectively. In parallel, we examined the clonality of tumor infiltrating B cell receptors by reconstructing the immune repertoire from bulk RNA-seq data. **Results:** Using the DSP platform, we confirmed reduced immune infiltration (e.g., CD3 and CD20) in both panCK and CD45 masked regions of MT, while CD8A and CD11c ($p_{adj} = 2.8\times10^{-7}$ and 2.1×10^{-6}) expression was only observed in panCK masked regions of MT compared with PT. A significant shift in myeloid composition between PT and MT as evidenced by increased CD68 signal ($p_{adj} = 5.8\times10^{-4}$) in CD45 masked regions of MT was identified. Within MT, PD-L1 signal was substantially higher ($p_{adj} = 0.030$) in CD45 masked regions only, while PD1 counts were lower ($p_{adj} = 0.035$) in panCK masked regions. This suggests the limited responses to ICI for MT may stem from relatively low expression of activated and targetable T cell subsets in MT islands. In support of the lower CD20 counts in MT, immune repertoire analysis revealed B cell receptor (BCR) repertoire diversity (represented by Gini index) was substantially lower in MT than PT (p = 0.041) suggesting that the ability of B cells to recognize a wide variety of tumor antigens in MT is greatly reduced in contrast to PT. **Conclusions:** Through comprehensive analysis of the TIME spatial organization within paired PT and MT, a significant reduction in dendritic cell/macrophage ratios (CD11c/CD68), reduced tumor localized T cell activation (CD8, PD1, PD-L1), and reduced B cell diversity (BCR clonality) are key features of the reduced immunogenicity of the metastatic TIME in TNBC. Further work to understand key mechanistic features driving the evolution of these differences in TIME between primary and metastatic tumors are ongoing. Research Sponsor: Genentech.

Genomic landscape and peripheral blood biomarkers of advanced triple-negative breast cancer treated with immune checkpoint blockade: An exploratory analysis of the TQB2450-Ib-07 trial. *First Author: Yiqun Han, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China*

Background: Immune checkpoint inhibitor (ICI) has emerged as a novel therapeutic option for advanced triple-negative breast cancer (aTNBC). However, no robust biomarker indicative of clinical outcomes has been identified. Herein, we portraited the genomic landscape and explored the biomarkers for patients with aTNBC receiving ICI-based therapy. **Methods:** This is a prospective, multicenter, phase 1b clinical trial (NCT03855358) to assess the efficacy and safety profiles of TQB2450, a humanized monoclonal PD-L1 antibody, plus anlotinib in pretreated TNBC. Eligible patients undergo liquid biopsy at baseline and the timepoint of disease progression. NGS-based assay was performed based on circulating tumor DNA (ctDNA) in the bloodstream. Meanwhile, results of laboratory blood tests were dynamically collected and blood markers, including neutrophil to lymphocyte ratio (NLR), lymphocyte to monocyte ratio (LMR), and platelet to lymphocyte ratio (PLR), were successively evaluated. The primary endpoints were progression-free survival (PFS) and clinical efficacy assigned via guidelines for response criteria for use in trials testing immunotherapies (iRECIST). **Results:** Between May 29, 2019, and December 31, 2020, 34 patients with aTNBC were enrolled. Gene alternations primarily comprised mutation, amplification, or deletion of *TP53*, *MLL3*, *DNMT3A*, *PI3KCA*, *EP300*, *PTEN*, *LRP1B*, *MDM2*, and *NCOR1*. The median maximum somatic allele frequency (MSAF) was 9.97% significantly indicative of PFS, which was 3.58 months for the MSAF-high group and 13.34 months for the MSAF-low group (P = 3e-04), respectively. Else, a strong association was also signified between MSAF and tumor shrinkage (CR/PR vs. SD/PD, P = 0.012). For blood tumor mutation burden (bTMB), the median was 6.72 muts/Mb, which the bTMB-low group was suggestive of a better PFS (11.09 months vs. 5.52 months, P = 0.007), yet no obvious association existing in terms of clinical response. Dynamic analysis revealed that a decline in MSAF was significantly associated with a better PFS (7.10 months vs. 2.74 months, P = 0.018), while no correlations were detected between bTMB and PFS. Based on NLR week 2/0 of 0.95, PFS was significantly worse in the NLR-low group (11.0 months vs. 3.5 months, P = 0.006) and likely distinguished the clinical response (CR/PR vs. SD vs. PD, P = 0.049; non-PD vs. PD, P = 0.022). Moreover, NLR week 2/0 could notably foretell the clinical response for patients with aTNBC with the AUC of 0.82 (0.61-1.00). No comparable utilities were identified regarding LMR and PLR. **Conclusions:** For aTNBC treated with ICI, MSAF tended to be a robust indicator for both PFS and clinical response. NLR week 2/0 presented a favorable profile indicative of PFS as well as a strong predictor for clinical responsiveness of patients with aTNBC receiving immune checkpoint blockade. Clinical trial information: NCT03855358. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

1081 **Poster Session**

Phase 1b/2 study of GX-I7 plus pembrolizumab in patients with refractory or recurrent (R/R) metastatic triple-negative breast cancer (mTNBC): The KEYNOTE-899 Study. *First Author: Joohyuk Sohn, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: GX-I7 (efineptakin alfa) is a hybrid Fc-fused long-acting recombinant human IL-7 which plays an essential role in the development and homeostasis of T-cells. GX-I7 can potentially enhance the anti-tumor effect of pembrolizumab via induction of T-cell activity. Here, we report results of phase 1b/2 study of GX-I7 plus pembrolizumab in patients with R/R mTNBC. **Methods**: Eligible patients had R/R mTNBC that failed up to 3rd lines of chemotherapy in the metastatic setting. Phase 1b patients received GX-I7 in 5 dose levels ranging from 360 μg/kg to 1,440 μg/kg every 9 (Q9W) or 12 (Q12W) weeks plus pembrolizumab 200 mg Q3W (n=51). Phase 2 is an expansion cohort where 33 patients were treated with the recommended phase 2 dose (RP2D). The primary objective was to determine the RP2D for phase 1b and to assess the objective response rate (ORR) for phase 2. **Results**: The study included 84 patients (phase 1b, n=51; phase 2, n=33) and 53.6% (45/84) of patients have received 2nd to 3rd lines of previous therapy. In phase 1b, one dose-limiting toxicity (DLT; grade 3 skin rash) was reported in the 1,440 μg/kg cohort and GX-I7 1,200 μg/kg Q9W was selected as RP2D. The ORRs were 15.7% [95% confidence interval (CI): 7.0 – 28.6] for phase 1b (n=51) and 21.2% [95% CI: 9.0 – 38.9] for phase 2 (n=33). Median PFS was 2.4 months (95% CI: 2.1 – 2.7) at the median follow-up of 10.4 months for all patients combined (n=84). GX-I7 induced up to 3.6-fold (range 1.2 – 8.1) increase in absolute lymphocyte counts (including CD4+ and CD8+ T cell) in all dose levels. The most common treatment-related adverse events (AEs) of any grade were injection site reaction (50.0%), ALT increased (39.3%), pyrexia (38.1%) and rash (35.7%). The additional correlative study data will be presented. **Conclusions**: GX-I7 in combination with pembrolizumab demonstrated a manageable safety profile with promising anti-tumor activity in patients with R/R metastatic TNBC. Clinical trial information: NCT03752723. Research Sponsor: Korea Drug Development Fund.

Association of 27-gene IO score with outcome in a phase Ib trial of pembrolizumab (pembro) plus chemotherapy (CT) in metastatic triple-negative breast cancer (mTNBC). *First Author: David B. Page, Earle A. Chiles Research Institute at the Robert W. Franz Cancer Center, Portland, OR*

Background: The IO score is a is a 27-gene signature developed to classify the tumor immune microenvironment derived from the 101-gene TNBCtype genomic classifications. The IO score predicts clinical outcome following immune checkpoint inhibitor therapy in NSCLC and bladder cancer, and recently was shown to predict benefit by pCR of atezolizumab plus CT over neoadjuvant CT alone in early stage TNBC (NeoTRIPaPDL1 trial). The IO score has not yet been evaluated in mTNBC or with pembro in breast cancer. **Methods:** We report preliminary associations of IO score with response from a phase Ib trial (NCT02734290). mTNBC subjects received 1st/2nd line pembro (200mg IV q3wk) plus investigator's choice paclitaxel (80mg/m2 IV q1wk, n = 15) or capecitabine (2000mg PO BID x 7d, q2wk, n = 14). Baseline (n = 23) and on-treatment (at wk 6, n = 10) biopsies were analyzed for IO score and genomic subtype by RNA exome sequencing. Objective response rate (ORR, partial or complete response, 12 weeks) and survival was determined among response-evaluable subjects (n= 21). Tumor PD-L1 was assessed by IHC (combined positive score, CPS > 10%). The IO signature was analyzed as a binary classifier (IO+/IO-) and as a continuous variable (IO score). **Results:** 39% of evaluable subjects were IO+ (n =9/23). IO+ was associated with improved clinical outcome, including ORR (IO+ 43%, IO- 29%), median progression free survival (mPFS, IO+ 138d, IO- 79d), and median overall survival (mOS, IO+ 687d, IO- 305d). IO+/IO- classification and IO scores were stable across serial biopsies (Cohen's kappa = 0.74, r = 0.84). IO score was not strongly correlated with PD-L1 CPS (r = 0.27) or sTILs (r = .09). PD-L1-/IO+ tumors constituted 31% (n = 5/16) of PD-L1- cases and exhibited favorable outcome (ORR 40%, mPFS 162d, mOS 556d). IO score and ORR varied across TNBCtype classifications (BL1 subtype: 50% ORR, 66% IO+; BL2 subtype: 0% ORR, 66% IO+; LAR subtype: 50% ORR, 0% IO+, MSL subtype: 33% ORR, 60% IO+). **Conclusions:** IO score is associated with favorable outcome following pembro + CT, and may identify PD-L1-negative cases that respond to pembro + CT. Further investigation in larger datasets is warranted to ascertain the clinical utility of IO score in this setting. Funding: Drug support and funding provided by Merck Sharpe & Dohme as part of the Merck Investigator Studies Program. Clinical trial information: NCT02734290. Impact of steroid premedication on atezolizumab (atezo)-induced immune cell activation: A comparative analysis of IMpassion130 and IMpassion131 peripheral blood mononuclear cells (PBMCs). *First Author: Luciana Molinero, Genentech, Inc., South San Francisco, CA*

Background: The immune checkpoint inhibitor (ICI) atezo showed disparate outcomes as first-line therapy for metastatic TNBC when combined with nab-paclitaxel (nPac) in IMpassion130 [Schmid 2018] vs solvent-based paclitaxel (Pac) in IMpassion131 [Miles 2021]. A key difference between the trials was use of steroid premedication for Pac in IMpassion131 but not for nPac in IMpassion130. In patients (pts) receiving ICIs, prior steroid exposure has been linked to worse outcome [Drakaki 2020]. Further, IMpassion130 and IMpassion131 subgroup analyses suggested reduced atezo treatment effect in taxane-pretreated pts. This post hoc biomarker study explored the impact of: 1) steroids on systemic immune cell activation with atezo+taxane; 2) prior taxane exposure on atezo-induced immune cell activation. **Methods:** PBMCs collected at baseline and at day 1, cycle 2 (wk 4) were selected from matched pts (RECIST responders, PD-L1+, no liver metastases) from IMpassion130 and IMpassion131. Single-cell RNAseq was performed and the transcriptomic profile of immune cells was analyzed using GSEA pathway analyses, cell proportion and TCR clonality. **Results:** CITEseq from 695,851 single cells was generated from 39 IMpassion130 PBMC pairs (29 atezo+nPac; 10 placebo [Pla]+nPac) and 35 IMpassion131 pairs (26 atezo+Pac; 9 Pla+Pac). At wk 4, atezo+nPac resulted in increased IFNα and IFNγ responses across multiple cell types (CD4+ and CD8+ T cells, B cells, NK cells and monocytes) and proliferation in NK cells, but reduced TNF signaling across multiple cell types. In contrast, 4 wks of Pla+nPac increased TNF signaling but decreased IFNα and IFNγ responses. In the presence of steroids, 4 wks of atezo+Pac also increased IFNα and IFNγ responses mainly in NK cells and monocytes, but not T cells, and reduced proliferative pathways across B and T cells and TNF signaling. Pla+Pac increased TNF signaling only in NK cells, but reduced proliferative signatures across cell types. The only on-treatment change differing significantly between atezo+nPac vs atezo+Pac was the increase in proliferation pathways in NK, T and B cells with atezo+nPac. There were no significant changes in proportions of cell subsets or TCR clonality. PBMCs from taxane-pretreated pts had higher RNA-based metabolic profile (OxPhos, DNA repair and IFNα). Taxane-naive but not taxane-pretreated immune cells had increased IFNγ and IFNα response after atezo+taxane. **Conclusions:** Our results suggest that atezo+taxane promotes IFNα and IFNγ responses and that steroid co-administration reduces proliferation pathways across immune cells. Prior taxane exposure was associated with an increased metabolic status, possibly rendering immune cells less sensitive to atezo-induced activation. The immune context of taxane-naive TNBC may result in more potent immune activation with atezo. Clinical trial information: NCT02425891 and NCT03125902. Research Sponsor: F. Hoffmann-La Roche Ltd.

Safety interim analysis (SIA) of atractib: A phase 2 trial of first-line (1L) atezolizumab (A) in combination with paclitaxel (P) and bevacizumab (B) in metastatic triple-negative breast cancer (mTNBC). *First Author: Maria Cortes, Hospital Ramon y Cajal, Madrid, Spain*

Background: A substantial benefit from adding an immune checkpoint inhibitor to chemotherapy (CT) was reported in mTNBC patients (pts) with PD-L1+ tumors. However, many pts still have a poor outcome. ATRACTIB is exploring the synergism between A (anti-PD-L1 antibody) and B (a VEGF-targeted antibody) with P in mTNBC irrespective of PD-L1 status. We report results from protocol-specified SIA. **Methods:** ATRACTIB is an open-label, single-arm, phase 2 trial (NCT04408118). Pts aged ≥18 years, with unresectable locally advanced or mTNBC, ECOG performance status of 0–1, who had received no prior systemic therapy or ≥12 months since (neo)adjuvant taxane-based CT are eligible. Pts receive A (840 mg IV, days 1, 15) with P (90 mg/m^2 IV, days 1, 8, 15), and B (10 mg/kg IV, days 1, 15) on each 28-day cycle until disease progression, unacceptable toxicity, or patient withdrawal. Primary endpoint is investigator-assessed progression-free survival (PFS) as per RECIST v.1.1. Secondary endpoints include objective response and clinical benefit rates, overall survival, and safety. The trial was designed to detect a treatment effect in terms of median PFS (H_0: ≤7 months; H_1: ≥9.5 months) and 100 pts are needed to attain 80% power at a nominal one-sided α level of 5%. One SIA was planned for evaluating safety as per CTCAE v.5.0 on the first 20 pts who had completed a 3-month follow-up or reached the end of study. **Results:** From Oct 5, 2020, through Nov 21, 2021, 34 pts were enrolled at 13 sites in Spain and Germany and received at least 1 dose of study treatment. Median age was 57.5 (range 40–84) years, 23 (67.6%) pts had received prior CT for early disease, and 19 (56.0%) had visceral disease. At data cutoff (Sep 30, 2021), 25 (71.4%) pts were still receiving the drug regimen. Adverse events (AEs) led to drug discontinuation in 3 (8.8%) pts. Mean relative dose intensity was 90.2% for A, 96.5% for P, and 95.7% for B. P dose reduction was reported in 7 (20.6%) pts. Five (14.7) pts required a dose delay due to AEs (11.8% for A, 11.8% for P, and 8.8% for B). The most common AEs of any grade (G) were fatigue (47.1%; 8.8% G≥3), diarrhea (38.2%; 0% G≥3), and neurotoxicity (35.3%; 8.8% G≥3). Anemia (20.6%; 0% G≥3) and neutropenia (17.6%; 8.8% G≥3) were the most frequent hematological AEs. AEs of clinical interest (AECI) for B were hypertension (17.6%; 5.9% G≥3) and pulmonary embolism (2.9%; 0% G≥3). AECI for A were pneumonitis (2.9%; 0% G≥3), autoimmune hepatitis (2.9%; 2.9% G≥3), and alanine aminotransferase increased (2.9%; 2.9% G≥3). No treatment-related deaths were reported. **Conclusions:** The addition of A to P and B as 1L therapy for mTNBC shows a tolerable safety profile which is consistent with known safety profile of each agent without a significant synergistic toxicity. Based on the independent data monitoring committee recommendation, patient recruitment is ongoing. Clinical trial information: NCT04408118. Research Sponsor: F. Hoffmann-La Roche Ltd.

Targeting kinome reprogramming in ESR1 fusion-driven metastatic breast cancer. *First Author: Xuxu Gou, Baylor College of Medicine, Houston, TX*

Background: Genomic analysis has recently identified multiple *ESR1* gene translocations in estrogen receptor-alpha positive (ERα+) metastatic breast cancer (MBC) that encode chimeric proteins whereby the ESR1 ligand binding domain is replaced by C-terminal sequences from many different gene partners. Transcriptionally active ESR1 fusions promoted hormone-independent cell growth, motility and resistance to endocrine therapy. The diversity of partner genes creates a considerable diagnostic challenge and no targeted treatments exist for *ESR1* translocated tumors. Thus, we have established a transcriptional signature to diagnose the presence of an active ESR1 fusion (PMID: 34711608) and developed novel targeted therapies against ESR1 fusion-driven biology. **Methods:** Fifteen *ESR1* fusion cDNA constructs were expressed in ER+ breast cancer cell lines by lentiviral transduction. Cell growth was assayed by Alamar blue assay. A mass spectrometry (MS)-based Kinase Inhibitor Pulldown Assay (KIPA) and tandem mass tag-based proteomics were performed to identify ESR1 fusion-driven druggable kinases for subsequent pharmacological inhibition. **Results:** KIPA profiling demonstrated an increase of multiple receptor tyrosine kinases including RET in T47D cells expressing active ESR1 fusions. Inhibition of RET by repurposing an FDA-approved drug significantly suppressed ESR1 fusion-driven cell growth *in vitro*, suggesting that despite marked diversity in the 3' partners, common kinase activities were elevated and targetable. Proteogenomic profiling, including whole exome sequencing, RNA sequencing, and MS-based proteomics and phosphoproteomics were further performed on 22 ER+ patient-derived xenograft (PDX) tumors, which demonstrated different degrees of estradiol dependence. These integrated "omic" profiles defined targetable genes/pathways and predict tumor subsets that could be responsive to kinase inhibition therapy from this biologically heterogeneous panel of PDX tumors. WHIM18, a PDX naturally harboring the ESR1-YAP1 fusion showed elevated level of RET and CDK4/6 pathways. The tumor volumes were significantly reduced by the RET inhibitor. CDK4/6 inhibitor treatment showed similar tumor reductions to RET inhibition. Interestingly, WHIM9 PDX that expressed wild-type ESR1 conferred a comparable kinome profile to WHIM18. The tumor growth was significantly suppressed by RET or CDK4/6 inhibition. Therefore, pharmacological experiments validated proteogenomics-predicted drug response in two tested ER+ PDX models. **Conclusions:** Proteogenomics characterization of PDX tumors can drive clinical trial hypotheses. Here, we reveal therapeutic kinase vulnerabilities in ESR1 fusion-driven tumors as exemplified by RET inhibition, which will lay the framework for future clinical trials. Research Sponsor: Department of Defense, Other Foundation.

1086 **Poster Session**

Shedding of ctDNA, radiomics assessment of tumor disease volume (TDV), and concordance of mutations (mut) in synchronous liquid and tumor biopsies in metastatic breast cancer (MBC). *First Author: Andri Papakonstantinou, Department of Oncology-Pathology, Karolinska Institutet and Breast Cancer Group, Vall DHebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Genomic alterations driving MBC progression may be better captured by ctDNA reflecting clonal evolution, but it is currently unknow whether ctDNA analysis can replace tumor sequencing for clinical decision purposes. Aim: to study the concordance between mut in synchronous plasma and tumor samples prospectively collected from patients (pts) with MBC progressing on their last systemic therapy. **Methods:** MiSeq Amplicon-based NGS (custom panel of 60 cancer-related genes; *BRCA1/2* and *PALB2* not included) was performed in both tumor biopsy and plasma. The concordance of ESCAT Tier I and II mut (*PIK3CA, AKT1, ERBB2, ESR1, PTEN*) was determined and correlated with mutant allele fraction (MAF), TDV, and clinical features. Findings from liquid biopsies were classified as true positive (TP-ctDNA) if a given mut was detected in both tumor and plasma and false negative (FN-ctDNA) if only in the tumor. TDV: all metastasis volume assessed by CT scan (excluding sclerotic bone metastasis), and analyzed by an experienced radiologist using the 3DSlicer semiautomatic segmentation tool (TDV = pixel size x number of pixels). Non-shedding cases were those where any mut was detected in tumor but none in plasma. **Results:** 88 cases were collected (luminal 64, HER2+ 17, triple negative 7). Median age at diagnosis 49 years (range 28-80). Radiomics assessment could be performed in 78/88 cases. The plasma/tissue concordance at case level was 74%. Discordance came from 23 cases; in 15 cases mut was only found in tissue and in 8 cases it was only detected in plasma. At gene level, *PIK3CA* had the highest concordance (79%); in *ESR1* it was 52%. Higher concordance associated with non-luminal subtype (OR 0.08, 95%CI 0.002 – 0.59) and shorter interval between primary diagnosis and metastatic relapse (20.3 vs 51 months; p = .02), but not with MAF. FN-ctDNA occurred in 15/49 cases (31%) and associated with luminal subtype (p = .02), but not with other clinical variables. Non-shedding cases associated with older age (p = .03), luminal subtype (p = .007), low TDV (p = .0006) and < 3 metastatic sites (p = .05). In patients with visceral metastasis (n = 45), higher TDV associated with lower probability of FN-ctDNA (p = .03). All non-luminal subtypes were shedders and all but one were TP-ctDNA. In multivariate analysis, higher probability of TP-ctDNA in luminal tumors associated with tumor sampling from a progressing lesion (OR 10.8; 95% 1.5 – 122; p = .03) and shorter interval between diagnosis of metastatic disease and biopsy (OR 0.96, 95% CI 0.92 – 0.99; p = .03). **Conclusions:** Our results suggest that ctDNA can detect a significant proportion of clinically relevant mut in MBC. Patients' characteristics, tumor subtype, type of gene, and tumor volume should be integrated with ctDNA results to better inform clinical decisions. Retrospective study to estimate the prevalence of HER2-low breast cancer (BC) and describe its clinicopathological characteristics. *First Author: Giuseppe Viale, European Institute of Oncology, University of Milan, Milan, Italy*

Background: Approximately 50% of BCs traditionally categorized as HER2 negative (HER2-neg) express low levels of HER2 (IHC 1+ or IHC 2+/ISH-; Miglietta, *NPJ Breast Cancer* 2021). HER2-targeted therapies for HER2-low metastatic BC (mBC) are under investigation (eg, T-DXd in the phase 3 DESTINY-Breast04 study; NCT03734029), but HER2 assays currently used to select patients (pts) for approved anti-HER2 therapies are optimized for high HER2 expression and are not validated for HER2-low detection. A recent study found relatively poor agreement (<70% interrater agreement) in evaluation of IHC scores of 0 and 1+ using current HER2 assays (Fernandez, *JAMA Oncol* 2022). Our objectives were to assess the prevalence of HER2-low among HER2-neg based on rescored HER2 IHC slides after training on low-end expression scoring and to describe pt characteristics of HER2-low vs HER2 IHC 0 mBC. Preliminary results are reported for 233 of 1000 planned pts. **Methods:** This multicenter, retrospective study (NCT04807595) included pts with confirmed HER2-neg unresectable/mBC diagnosed between 2015 and 2017. Local laboratories, blinded to historical HER2 scores, rescored HER2 IHC-stained slides. HER2 was assessed using Ventana 4B5 and other assays. BCs were categorized as HER2-low or HER2 IHC 0. The prevalence of HER2-low BC among pts originally scored as HER2-neg was measured. Demographics (eg, age, country, race) and clinicopathological characteristics were examined via medical charts/electronic health records. Concordance between historical HER2 scores and rescores was assessed. **Results:** HER2 rescores were obtained for 233 pts (mean age, 54 y). HER2-low prevalence was 63.2% overall and numerically greater in hormone receptor (HR)–positive vs HR-negative subgroups (66.1% vs 54.8%; Table). No notable differences in prevalence were seen among different HER2 assays or in demographic/baseline disease characteristics between the HER2-low and HER2 IHC 0 groups. Concordance rate between historical and rescored slides for HER2-status classification was 82.3%. The presentation will include an expanded data set (≈400 pts) with additional results. **Conclusions:** Data on HER2-low prevalence in BC is limited. Preliminary data from this study of mBC samples suggest a somewhat higher prevalence estimate (≈63%) than a previous study of primary BC samples (≈50%). Concordance was 82%; ongoing analyses with updated data will clarify the concordance between rescored and historical HER2 slides. These data can support development of best practices for identifying pts with HER2-low expression who may benefit from HER2-targeted therapies. Clinical trial information: NCT04807595. Research Sponsor: This study is funded by AstraZeneca Pharmaceuticals and Daiichi Sankyo Inc. In March 2019, AstraZeneca entered into a global development and commercialization collaboration agreement with Daiichi Sankyo for trastuzumab deruxtecan (T-DXd; DS-8201).

Prevalence of HER2-low in HER2-neg mBC population.

Assay, %	HR positive (n=167)	HR negative (n=62)	All pts (N=233)[a]
All (N=233)[b]	66.1	54.8	63.2
Ventana 4B5 (n=90)	67.6	50.0	64.4

Survival and prognostic factors in oligometastatic breast cancer. *First Author: Annemiek Van Ommen - Nijhof, The Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Clinical guidelines for the treatment of oligometastatic breast cancer (OMBC) propagate multimodality treatment including polychemotherapy and ablative local therapy for all detected disease. The aim of this aggressive approach is prolonged disease remission, or even cure, but randomized data to support this strategy lack and long-term outcomes are not well known. We report prognostic factors, and event-free survival (EFS) and overall survival (OS) in a real world, single center cohort of patients with OMBC with long-term follow-up. **Methods:** Patients with breast cancer and 1-3 distant metastatic lesions who underwent treatment in the Netherlands Cancer Institute were identified via text mining of medical files. We collected patient, tumor and treatment characteristics as well as recurrence and survival data from the medical records. The Kaplan-Meier method was used to calculate EFS and OS estimates, and Cox regression analyses to assess potential prognostic factors. **Results:** The cohort included 239 patients (of whom two males), diagnosed between 1997 and 2020. Median follow-up was 75.0 months. Fifty-one percent had hormone receptor (HR)-positive/ human epidermal growth factor receptor 2 (HER2)-negative disease, 20.1% had HER2-positive disease, and 19.2% had triple negative (TN) disease. Median age at OMBC diagnosis was 49.0 years and 47.3% of patients had synchronous disease (metastases ≤6 months of primary diagnosis). Most patients (81.2%) received chemotherapy and local therapy (surgery, radiotherapy and/or radiofrequency ablation) of all metastatic lesions (83.7%). Of 239 patients, 134 experienced disease recurrence with a median EFS of 40.0 months (95% confidence interval (CI): 28.6-51.4); 97/239 died and median OS was 93.0 months (95% CI 74.5-111.5). The table shows factors associated with favorable OS in multivariable analysis. Cox regression analysis for EFS showed similar results. **Conclusions:** In this large real world cohort of OMBC patients, EFS and OS compare favorably to survival in the general MBC population. HR-positive and/or HER2-positive subtypes, synchronous disease or long DFI, favorable response to first-line systemic therapy and local therapy of all distant lesions are independently associated with better survival. Future studies should be directed at optimizing patient selection and therapy choices in this population with the potential for cure. Research Sponsor: None.

Quantitative proteomics landscape and association with BASP1 and breast cancer metastasis. *First Author: Jaspreet Kaur, Georgia State University, Atlanta, GA*

Background: Tumor recurrence and metastatic progression remain the leading cause for breast cancer related mortalities. The study aimed to identify differences in proteomics landscape in serum between (i) healthy controls and breast cancer patients, (ii) baseline samples at time of diagnosis from patients that later developed metastases versus those that did not and, (iii) baseline samples presented after completed treatment versus the samples collected before patients developed metastasis. **Methods:** We performed mass spectrometery-based proteome profiling of 100 serum samples from 51 breast cancer patients and 27 healthy donors. Of the 51-breast cancer patients, 29 patients did not metastasize, and 22 patients had a metastatic recurrence. Each of the 22 breast cancer patients with metastasis had 2 samples-one collected within a year of diagnosis and second one collected within a year before the patient developed metastases. Intensity-based absolute quantification (iBAQ) method was employed to convert recovered peptide information to quantificational gene protein product and then normalized to final quantificational value using an in-housed software. Protein values were normalized using z-score before differential expression analyses. FDR < 0.1 and a p-value < 0.05 was used as the cutoff to identify differentially expressed proteins. **Results:** We identified 1177 proteins in total from 100 serum samples of healthy women and breast cancer patients. PCA analysis revealed a complete separation of the breast cancer and healthy control samples. However, we found overlapping but distinct groups of metastatic and non-metastatic samples. We found 179 proteins to be differentially expressed between normal healthy control samples and baseline breast cancer samples irrespective of their metastatic status. Upon comparing baseline breast cancer samples that metastasized with breast cancer samples that did not metastasize, we found BASP1 as the top-ranked gene that was significantly upregulated in metastatic samples. We did not find any significant differences between paired baseline samples collected at diagnosis and pre-metastatic samples collected before the patient developed metastasis. **Conclusions:** Our results show distinct proteomic profiles exist between breast cancer and normal healthy control samples. Further studies are required to confirm if serum BASP1 can be used as a putative biomarker for predicting metastatic risk in breast cancer patients. Efficacy and impact of SARS-CoV-2 vaccination on cancer treatment for patients with breast cancer: A multicenter, prospective, observational study. *First Author: Mitsuo Terada, Department of Breast Surgery, Nagoya City University Graduate School of Medical Sciences, Aichi, Japan*

Background: Vaccination is an essential strategy to prevent infection in the SARS-CoV-2 pandemic. However, there are concerns about vaccine efficacy and the impact of vaccination on cancer treatment. Additionally, the emergence of novel variants may affect vaccination efficacy. This multi-center, prospective, observational study investigated the efficacy and impact of vaccination against SARS-CoV-2 variants on treatment among breast cancer patients in Japan. **Methods:** Breast cancer patients scheduled to be vaccinated with the SARS-CoV-2 vaccine from May to November 2021 were included. They were stratified into five groups according to their cancer treatment: no treatment, endocrine therapy, CDK4/6 inhibitor, chemotherapy, anti-HER2 therapy. Serum samples were collected before the first vaccination and after the second vaccination. Immunoglobulin (Ig)G levels against the SARS-CoV-2 S protein and neutralizing antibody titers against wild-type (WT), alpha (α), delta (δ), kappa (κ), and omicron (o) variants were measured by ELISA assay. The effect of vaccination on cancer treatment was also investigated. **Results:** There were 85 eligible patients (no treatment, n = 5; endocrine therapy, n = 30; CDK4/6 inhibitor, n = 14; chemotherapy, n = 21; and anti-HER2 therapy, n = 15) with a median age of 65 years. The overall seroconversion rate of anti-SARS-CoV-2 IgG was 95.3%. The seroconversion rate of the chemotherapy group was 81.8%. The anti-SARS-CoV-2 IgG antibody concentration was positively correlated with the lymphocyte count before vaccination (r = 0.232, p = 0.039). Overall neutralizing antibody titers against each variant were significantly lower than for WT. Overall positive rates of neutralizing antibodies against WT, α, δ, κ, and o variants were 90.2%, 81.7%, 96.3%, 84.1%, and 8.5%, respectively. A downward trend of neutralizing antibody titers against each variant was seen in chemotherapy and CDK4/6 inhibitor groups compared with other groups. Significant decreases were detected in neutralizing antibody titers against WT, α, and κ variants in the chemotherapy group, and WT and α variants in the CDK4/6 inhibitor group compared with the no treatment group. Withdrawal or postponement of systemic therapy because of vaccination was only observed in one patient. **Conclusions:** Our data support SARS-CoV-2 vaccination for cancer patients being treated with systemic therapy. However, neutralizing antibody titers against the o variant were very low even after two vaccinations among patients with or without cancer treatment. Further, a decrease in neutralizing antibody titer was suggested during chemotherapy and CDK4/6 inhibitor, raising concerns about the impact on long-term infection prevention. For these patients, infection-preventive behaviors should be recommended even after vaccination. They will also be good candidates for booster vaccinations. Clinical trial information: UMIN000045527. Lurbinectedin in patients with pretreated *BRCA*1/2-associated metastatic breast cancer: Results from a phase II basket study. *First Author: Valentina Boni, NEXT Madrid, Universitario Hospital Quirónsalud Madrid (at the time of the study: START Madrid-CIOCC, Centro Integral Oncológico Clara Campal), Madrid, Spain*

Background: Lurbinectedin (L) is a selective inhibitor of oncogenic transcription that leads to cell apoptosis and shows antitumor activity against homologous recombination repair-deficient cell lines. A previous phase II study (Cruz *et al.* JCO 2018;36:3134-3143) demonstrated antitumor activity in patients (pts) with pretreated metastatic breast cancer (median of 1 prior advanced chemotherapy line) and *BRCA*1/2-mutated tumors with L 3.5 mg/m^2 or 7.0 mg flat dose (equivalent to 4.0 mg/m^2) every three weeks [q3wk]). This report focuses on the outcomes in the *BRCA*1/2-associated breast cancer cohort of a phase II Basket multitumor trial. **Methods:** This phase II study evaluated L 3.2 mg/m^2 1-hour intravenous (i.v.) infusion q3wk in a cohort of 21 female pts with pretreated *BRCA*1/2-associated breast cancer. The primary efficacy endpoint was ORR according to RECIST v1.1. Secondary endpoints included duration of response (DoR), progression-free survival (PFS), OS and safety. **Results:** Median age was 45 years (range, 29-73 years). Hormone receptor (HR)+ disease was observed in 76.2% of pts, triple negative disease in 19.0% and HER2+ in 9.5%. *BRCA1* and *BRCA*2 were reported in 47.6% and 52.4% of pts, respectively. Median number of prior lines of chemotherapy for advanced disease was 2 (range, 0-3 lines). Prior poly(ADP-ribose) polymerase inhibitors and platinum compounds had been administered to 23.8% and 47.6% of pts, respectively. Confirmed partial response (PR) was observed in six pts (ORR = 28.6%; 95% CI, 11.3-52.2%). Lurbinectedin was active in both BRCA mutations: four PRs in 11 pts (36.4%) in *BRCA*2 and two PRs in 10 pts (20.0%) in *BRCA*1. Median DoR was 8.6 months, median PFS was 4.1 months and median OS was 16.1 months. Stable disease (SD) was observed in ten pts (47.6%), including three pts with unconfirmed response in a subsequent tumor assessment (ORR unconfirmed = 42.9% [95%CI, 21.8-66.0]). Clinical benefit rate (PR + SD≥4 months) was 76.2% (95% CI, 52.8-91.8%). The most common grade 3/4 toxicity was neutropenia (42.9%; grade 4, 23.8%; with no febrile neutropenia). **Conclusions:** This phase II study met its primary endpoint and confirmed the activity of L in pretreated *BRCA*1/2-associated breast cancer pts. L 3.2 mg/m^2 1-hour i.v. infusion q3wk showed an acceptable, predictable and manageable safety profile. Considering the exploratory aim of this trial as well as previous results in other phase II study, further development of L in this indication is warranted. Clinical trial information: NCT02454972. CK+/CD45+ (dual-positive) circulating cells are associated with prognosis in patients with advanced breast cancer.

First Author: Carolina Reduzzi, Northwestern University - Feinberg School of Medicine, Chicago, IL

Background: Circulating tumor cells (CTCs) expressing epithelial markers (EPCAM, cytokeratin (CK)) and lacking CD45 (a leukocyte marker) have been associated with poor outcome in many cancer types. Nonetheless, the presence of cells expressing both CK and CD45 (CK+/CD45+), circulating in the blood of cancer patients (pts) have also been reported, but not widely investigated. Early evidence indicates that circulating dual-positive cells (DPcells) are hybrids deriving from the fusion of tumor cells and macrophages. We previously reported that it is possible to detect DPcells in the blood of pts with metastatic breast cancer (BC) and that they are associated with shorter progression-free survival (PFS), in pts with <5 CK+/CD45- CTCs. Here, we investigated the impact of DPcells on overall survival (OS) in pts with advanced BC (aBC). **Methods:** Blood samples (7.5 ml) were collected from aBC pts before starting a new therapy and processed with the FDA-approved CellSearch platform for CTCs and DPcells enumeration. The prognostic role of CTCs and DPcells was assessed through the Kaplan-Meier method using the log-rank test. Single DPcells were isolated using the DEPArray platform and underwent whole genome amplification and lowpass whole genome sequencing (Ampli1 WGA and Ampli1 Lowpass kits). **Results:** Blood samples from 341 pts with luminal (n=168), HER2+ (n=76) and triple negative (n=88) BC were analyzed. Of these, 131 samples (38.4%) contained ≥5 CTCs (CTC^{pos}), whereas DPcell were detected in 152 samples (44.6%, range 0-53), of which 66 (43.4%) were CTC^{pos} and 86 (56.6%) CTC^{neg}. Overall, DPcells were associated with a shorter OS: median OS 24.5 vs 35.0 months, p=0.046. However, when analyzing CTC^{pos} and CTC^{neg} separately, only the latter group showed a difference in OS according to DPcells presence. In particular, among CTC^{neg} pts, those with ≥4 DPcells showed a 2.3-fold shorter OS (26.7 vs 60.6 months, p=0.025). Moreover, pts with ≥4 DPcells were less likely to experience a 6-months PFS clinical benefit (p=0.015). Interestingly, in the analysis by BC subtype, DPcells were confirmed to be associated with worse OS only in pts with triple negative BC (median OS 11.5 vs 16.9, p=0.048). To explore the exiology of DPcells, 2 out of 3 cells analyzed after single-cell isolation from 1 patient were confirmed to have copy number alterations (CNA) consistent with malignant cells. CNA and mutational profiling of additional single DPcells and CTCs are ongoing. **Conclusions:** DPcells are associated with worse OS in aBC pts, with the prognostic impact primarily in pts with <5 CTCs and triple negative BC. This suggests that DPcells might be an alternative way of tumor dissemination in specific pts, in which CK+/CD45- CTCs are less prevalent. More studies are needed to better elucidate DPcell clinical significance in BC, and to confirm their fusion-hybrid origin. Eribulin mesylate versus eribulin plus anlotinib in patients with advanced or metastatic breast cancer: Results of a phase II study.

First Author: Liping Liu, Department of Breast Cancer Medical Oncology, Hunan Cancer Hospital / The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, China

Background: Eribulin mesylate is a structurally simplified, synthetic, macrocyclic ketone analogue of Halichondrin B. We investigated the efficacy and safety of eribulin monotherapy versus eribulin plus the oral anti-angiogenesis inhibitor anlotinib in patients with advanced or metastatic breast cancer. **Methods:** This Phase II study included adult Chinese patients with locally advanced or metastatic breast cancer previously treated with at least two chemotherapy regimens, including both anthracycline- and taxane-based therapy (NCT05206656). Patients were randomized (1:1) to receive eribulin (1.4 mg/m^2, intravenously, on days 1–8), alone or in combination with anlotinib (12 mg orally once daily), in 21-day cycles. The primary endpoint was investigator-assessed disease control rate (DCR), per RECIST version 1.1. Key secondary endpoints included objective response rate (ORR), progression-free survival (PFS) and safety. **Results:** Between February 12, 2020, and July 22, 2021, 56 patients were randomized to eribulin (n=32) or eribulin plus anlotinib (n=24) (Table). Sites of metastasis were: bone (60.7%), lung (52.7%), liver (53.6%), lymph nodes (73.2%) and soft tissue (7.1%). Among all patients, the DCR was 66.7% versus 100% (treatment difference, 33.3%; P=0.007), the ORR was 37.0% versus 38.9%, and the median PFS was 3.7 months versus 9.7 months (adjusted hazard ratio, 0.20; 95% CI, 0.04 to 0.91; P=0.04) for patients receiving eribulin versus eribulin plus anlotinib, respectively. Among 36 (64.3%) patients with triple-negative breast cancer, the DCR was 55.6% versus 72.2% (treatment difference, 16.7%; P=0.300) and the median PFS was 3.6 months versus 9.7 months (log rank P=0.030) with eribulin alone versus eribulin plus anlotinib, respectively. The most frequent grade 3-4 adverse events in the eribulin and eribulin plus anlotinib groups were decreased neutrophil count (25.0% [n=8] vs. 29.2% [n=7]) elevated transaminase (6.3% [n=2] vs. 0.0%) and decreased thrombocyte count (3.1% [n=1] vs. 0.0%), respectively. **Conclusions:** Eribulin plus anlotinib was associated with a significantly better DCR, ORR and PFS than eribulin monotherapy in patients with locally advanced or metastatic breast cancer previously treated with anthracyclines and taxanes. Clinical trial information: NCT05206656. Research Sponsor: None.

Patient clinical characteristics.

Variable	All patients (N=56)	Eribulin (n=32)	Eribulin plus anlotinib (n=24)
Mean age at eribulin usage ± SD (years)	48.9 ± 8.1	49.0 ± 8.2	48.8 ± 8.0
Time from diagnosis to relapse or metastasis ± SD (months)	28.2 ± 35.3	31.8 ± 40.3	23.5 ± 27.3
Surgery, n (%)	49 (87.5)	29 (90.6)	20 (83.3)

Historical redlining and breast cancer survival in the United States: Evidence from the 2010-2017 SEER Medicare linked dataset.

First Author: Jean C. Bikomeye, PhD Program in Public and Community Health, Division of Epidemiology and Social Sciences, Institute for Health and Equity, Medical College of Wisconsin, Milwaukee, WI

Background: Cancer is the second leading cause of morbidity and mortality in the US. Systemic racism is a critical cause of health disparities and historically disadvantaged people experience poor outcomes including poor breast cancer (BC) survival. This study aims to investigate the impact of historical redlining on all-cause and BC-specific survival among older women in the US. **Methods:** Historic 1930's Homeowner's Loan Corporation (HOLC) boundaries and grades were linked to 2010 Census tracts and the 2010-2017 SEER Medicare BC cohort. Women were included if they were 66+ years old at diagnosis, diagnosed with invasive BC, enrolled in Medicare Part A and Part B for 12 months prior to diagnosis to calculate comorbidity, and a Census tract match for HOLC grade. The independent variable was HOLC grade in two categories: A and B(not redlined), and C and D(redlined). The outcomes were all-cause and BC-specific survival, determined by Kaplan Meier Survival curves and both unadjusted and adjusted Cox regression models. End point for censoring was 12/31/2019 (all-cause) and 12/31/2018 (BC-specific). The final models were stratified by age and tumor stage at diagnosis; and adjusted for comorbidity, race and ethnicity, hormone receptor (HR) and human epidermal growth factor receptor 2 (HER2) status, and interaction term between comorbidity and race. **Results:** Among 10,113 women, 62.8% resided in historically redlined Census tracts. At a mean (+SD) follow-up time of 48.5 (+28.8) months, 28.9% were deceased; 41.6% of which died of BC. Women residing in historically redlined census tracts experienced poorer BC survival (49.8 +28.2 months) than those residing in non-redlined Census tracts (57.8 +30.7 months). After controlling for covariates, residing in a historically redlined Census tract remained an independent predictor of higher mortality: HR (95%CI) = 1.11 (1.02, 1.20) and 1.24 (1.011, 1.39) for all-cause mortality and BC-specific mortality, respectively. **Conclusions:** Residing in a formerly redlined Census tract at the time of BC diagnosis is associated with worse all-cause and BC-specific mortality, even after stratifying/adjusting for important patient and tumor characteristics. Public health and government agencies stakeholders should consider historical contexts when designing and implementing equity-focused community and clinical interventions targeted at mitigating and reducing BC disparities and improving health equity. Research Sponsor: This study is part of the National Cancer Institute (NCI)–funded R01 research project (R01CA214805) led by Dr. Beyer at the Medical College of Wisconsin.

Comprehensive whole-exome and transcriptome profiling to identify actionable alterations associated with response to PARP inhibitors in breast cancer.

First Author: Susan M. Dombrowski, Exact Sciences, Phoenix, AZ

Background: The use of targeted therapies identified using genetic and genomic approaches is now routine in breast cancer (BC). In this clinical lab experience study the frequency of actionable somatic alterations in DNA repair pathway genes associated with the use of PARP inhibitors (PARPi) is described. **Methods:** BC samples were sequenced with the Oncomap ExTra assay, which uses whole-exome DNA sequencing with germline subtraction to detect somatic single base substitutions, indels, and copy number alterations, and RNA sequencing to detect gene fusions. Clinically actionable alterations were defined as associated with FDA approved drugs or clinical trial enrollment. Here, the focus is on 49 repair genes associated with PARPi response: *ARID1A, ATM, ATR, ATRX, BAP1, BARD1, BLM, BRCA1/2, BRIP1, CDK12, CHEK1/2, EPCAM, ERCC1/2/3/4/5, FANCA/C/D2/E/F/G/I/L/M, MLH1, MRE11A, MSH2/6, MUTYH, NBN, PALB2, PMS2, PPP2R2A, PTEN, RAD21/50/51/51B/51C/51D/52/54L, XRCC1/2/3*. **Results:** Of 1103 BCs, 246 (22.3%) had mutations in repair genes; 69 (6.3%) were in *BRCA1/2*. Repair gene mutations were less common in $HER2^+$ cancers (n=27, 14.3%) compared to HR^+HER2^- (n=156, 23.9%) or TN cancers (n=49, 26.1%) (p<0.01). Across subtypes, the top four most commonly mutated of the repair genes were *PTEN* (27.2%), *ARID1A* (22.8%), *BRCA2* (14.2%), and *BRCA1* (14.2%); 33 cancers (13.4%) had mutations in multiple (≥2) repair genes. For the 69 cancers with *BRCA1/2* mutations, 11 (15.9%) carried other repair gene mutations (9 of 35 *BRCA1*; 3 of 35 *BRCA2*). RNA sequencing found 19 fusions in repair genes in 17 patients (1.5%); *CDK12* was involved in 13 (68.4%), and *RAD51C* in 3 (15.8%). Fusion incidence was more frequent in $HER2^+$ cancers (p<0.01) (Table). **Conclusions:** PARPi therapy is FDA approved for $HER2^-$ germline *BRCA1/2* mutated BC patients. Recent evidence suggests somatic *BRCA1/2* mutations predict PARPi benefit (Tung, NM. J Clin Oncol 2020). In addition to BRCA1/2 alterations, our study also highlights the importance of alterations in other DNA repair genes associated with response to PARPi. Trials are ongoing to determine if these genes predict for PARPi benefit. Research Sponsor: Exact Sciences Corporation.

Interplay between B cell and GABA metabolism (GABAm) and association with immune evasion in breast carcinoma (BC). *First Author: Frances Elaine Chow, Department of Neurosurgery, University of Southern California, Norris Cancer Center, Los Angeles, CA*

Background: GABAergic signaling has been reported to play a pivotal role in breast cancer (BC) tumorigenesis and metastasis, however, its role in immune modulation remains unclear. Recent *in vitro* and *in vivo* studies (Zhang et al., Nature, 2021) report the role of B cell-derived GABA metabolites in promoting anti-inflammatory macrophages (MM), thus limiting anti-tumor immunity. In this study, we aim to characterize the interplay between B cells and the GABAm pathway, as well as their associated immune infiltrates and cytokines. **Methods:** BC tumors (n = 9455) were analyzed by next generation sequencing (NextSeq, 592 Genes and WES, NovaSEQ) and whole transcriptome sequencing (WTS, NovaSeq) at Caris Life Sciences. Gene set variation analysis (GSVA) scores were used for GABAm pathway activity (GMPA). IFN score to test the likelihood of a tumor's response to anti PD1 therapy and Immune cell fraction (quanTIseq) were assessed by mRNA analysis. Wilcoxon-Mann-Whitney test was applied (p without, q with multiple comparison correction). Correlation coefficients were calculated using spearman correlation. **Results:** GMPA demonstrated a statistically significant positive correlation with B cells fraction ($r = 0.24$, $p < 0.0001$). When stratified by classical molecular subtypes, the positive correlations were exclusive to HR+ and HER2+ BC, and absent in TNBC. GMPA was the most enriched in HR+ BC, followed by HER2+ and TNBC. BC tumors with high B cell infiltration were then grouped into GMPA-high (B+G+, cutoff > median for both) or GMPA-low (B+/G-), which likely represented tumors with B cell-derived high and low GMPA group, respectively. The GMPA-high group demonstrated significantly less fractions of MM1 (2.8 vs 3.7) and CD8+ T cells (0.8 vs 1.2) but greater MM2 (5.3 vs 4.9). mRNA levels of the MM2 marker IL10, a proposed marker of immune evasion, was significantly overexpressed in the B+/G+ group compared to the B+/G- group (fold change, FC = 1.39). mRNA levels of GAD1, a GABA-generating enzyme, were higher in B+/G+ than B+/G- (FC = 7.19). B+/G+ group had notably less IFN score than B+/G- group (-0.37 vs -0.27). When further stratified into molecular subtypes, concurrent more MM2 (5.4 vs 5.2) and less CD8+ T cell (0.74 vs 0.91) fractions were found in B+/G+ compared to B+/G- in HR+ tumors, but not in HER2+ or TNBC tumors. B+/G+ group also demonstrated a lower IFN score (-0.38 vs -0.32) in HR+ tumors. Additionally, IL10 and GAD1 were consistently overexpressed in B+/G+ regardless of subtype, reaching FC 7.9 in HR+ tumors. $q < 0.0001$ for all comparisons. **Conclusions:** Our study is the largest clinical dataset to demonstrate the association of interplay between B cell and GABAm with immunogenicity. Our results support the potential role of B cell-derived GABAm metabolites in immune modulation in BC in a subtype-specific manner. Targeting small metabolites to modulate immune evasion in BC warrants further investigation. Research Sponsor: None.

A phase IB/II study of nivolumab in combination with eribulin in HER2-negative metastatic breast cancer (KCSG BR18-16). *First Author: Se Hyun Kim, Division of Hematology and Medical Oncology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam, South Korea*

Background: Combining immune checkpoint inhibitors with chemotherapy has become a promising therapeutic strategy in metastatic breast cancer. Eribulin is a potent microtubule inhibitor and modulates the immune microenvironment of tumor cells. Therefore, combining eribulin to nivolumab may synergize antitumor efficacy in metastatic breast cancer. **Methods:** Adult patients with histologically confirmed recurrent/metastatic HER2- breast cancer were enrolled prospectively from 10 academic hospitals in Korea (ClinicalTrials.gov Identifier: NCT04061863). Key eligibility criteria included prior treatment with taxanes and/or anthracyclines, ≥1 measurable disease, and ≤2 prior cytotoxic chemotherapies in the metastatic setting. Patients received nivolumab 200 mg intravenously (IV) on day 1 plus eribulin 1.4 mg/m^2 IV on day 1 and 8 of every 3 weeks until disease progression or intolerable toxicity. The dose level was determined from safety profile of three patients in run-in phase. The primary endpoint was investigator-assessed progression-free survival (PFS) rate at 6 months. Secondary endpoints included investigator-assessed objective response rate (ORR) per RECIST v1.1, disease control rate (DCR), overall survival (OS), and toxicity profile of the combination treatment. The association between PD-L1 expression by SP142 Ab and efficacy was analyzed. **Results:** From August 2019 to June 2021, 90 patients (HR+HER2- 45 pts/TNBC 45 pts), with a median age of 51 (range 31–71), were enrolled in the study. With a median study follow-up time of 16.3 months, 68 (75.6%) patients experienced progressive disease. PFS rate at 6-months was 49.6% and 24.1% in patients with HR+HER2- and TNBC group, respectively. Median PFS was 5.6 months (95% CI: 4.3-6.8) and 3.0 months (95% CI: 1.3-4.7) for HR+HER2- and TNBC group, respectively. ORRs were 53.3% (CR:0, PR: 24) for HR+HER2- and 21.8% (CR1, PR: 12) for TNBC. Patients with PD-L1+ tumors (PD-L1 expression ≥ 1% on TC or IC) had similar ORR compared to PD-L1- tumors (ORR 50% vs. 53.8% in HR+HER2-, 30.8% vs. 29.0% in TNBC). The most common grade 3/4 adverse event was neutropenia (15/90, 16.7%), and the most common immune-related adverse events were grade 1/2 hypothyroidism (19/90, 21.1%) and grade 1/2 pruritus (16/90, 17.8%). Five patients had discontinued study treatment due to immune-related adverse events (3 pneumonitis, 1 hepatitis, 1 skin rash). **Conclusions:** In this parallel phase II clinical trial, the addition of nivolumab to eribulin showed promising efficacy and tolerable safety profile in previously treated HER2- MBC. Further survival and exploratory analyses to find predictive markers will be followed. Clinical trial information: NCT04061863. Research Sponsor: Ono Pharma (Nivolumab), Pharmaceutical/Biotech Company.

Objective response according to RECIST v1.1.

	ER+ (n)	(%)	TNBC (n)	(%)	Total (n)	(%)

Is cure possible for breast cancer metastatic to the liver? *First Author: Rene Adam, AP-HP Hôpital Paul Brousse, Université Paris-Saclay, Villejuif, France*

Background: Metastatic breast cancer (MBC) is a lethal disease and is generally only amenable to systemic treatment. Although increasingly recommended on selected patients, local treatments, and particularly surgery, are seldom used in the therapeutic armamentarium for MBC and their long-term survival benefit is unknown. We hypothesized that combining surgery to systemic treatment for selected patients with breast cancer liver metastases could lead to long-term survival or even an option of cure. **Methods:** A retrospective study of prospectively gathered data from a surgical series of liver resections for MBC was conducted. Patients with no or limited and stable extra-hepatic disease were offered surgery after multidisciplinary discussion, if the liver metastases were responding to systemic treatment and were amenable to complete macroscopic resection. Five- and ten-year actual survivors were identified and their characteristics were explored. **Results:** From 1984 to 2020, 207 female patients underwent liver resections for MBC in our institution. There was no postoperative mortality. Postoperative complication rate was 23.3% and liver-specific complication rate was 19.0%. There was a total of 48 repeat hepatectomies. Median disease-free interval between initial breast cancer and liver metastasis was 36 ± 90.1 months. There was a median of 2 ± 1.8 liver metastases at diagnosis with a median size of 33.0 ± 18.3 mm and 73.1% of patients had radiological response before resection. Five- and ten-year overall survivals (OS) as well as 5- and 10-year disease-free survivals (DFS) were 39.6% and 12.7% as well as 14.2% and 6.4%, respectively. Median OS was 44.0 ± 47.2 months in the whole series. Focusing on the 5- and 10-year survivors, median OS were 89.5 ± 44.7 months and 144.0 ±42.6 months, respectively. In the 10-year survivors' group, median DFS was 98 ±62.3 months. Observed survivals in this study underestimate true actual survivals owing to censoring of patients lost to follow-up. **Conclusions:** Long-term survival (≥ 5 years) as well as a curative perspective (≥ 10 years survival) are achievable for selected patients with breast cancer liver metastases by combining surgery to systemic treatment. Considering the recent improvements in the results of systemic treatments, introducing surgical resection in the treatment sequences of MBC could play an even more beneficial role. Subgroup analysis of patients with no prior chemotherapy in EMERALD: A phase 3 trial evaluating elacestrant, an oral selective estrogen receptor degrader (SERD), versus investigator's choice of endocrine monotherapy for ER+/HER2-advanced/metastatic breast cancer (mBC). *First Author: Virginia G. Kaklamani, University of Texas Health Sciences Center, Houston, TX*

Background: EMERALD demonstrated significantly prolonged progression-free survival (PFS) and a manageable toxicity profile for elacestrant vs standard of care endocrine therapy (SOC) in patients with ER+/HER2- mBC following progression on prior endocrine and CDK4/6 inhibitor therapy. Benefit was observed in the overall study population and in patients with *ESR1* mutations *(mESR1)*. Here, we report a subgroup analysis from EMERALD in patients with no prior chemotherapy. **Methods:** EMERALD (NCT03778931) is a randomized, open-label, phase 3 trial that enrolled patients with ER+/HER2– mBC who had 1–2 lines of endocrine therapy, mandatory pretreatment with a CDK4/6 inhibitor, and ≤1 chemotherapy. Patients were randomized 1:1 to elacestrant (400 mg orally daily) or SOC (investigator's choice of fulvestrant or aromatase inhibitor). Primary endpoints were PFS in all patients and patients with *mESR1*. In this analysis, we compared PFS between elacestrant and SOC in patients without prior chemotherapy. **Results:** Among the 477 patients enrolled in the trial, 77.8% (n = 371) had not received prior chemotherapy for mBC (median age = 64). Among patients without prior chemotherapy, treatment with elacestrant was associated with significantly prolonged PFS compared to SOC in both the overall population (hazard ratio [HR] = 0.68 [95% CI, 0.52-0.89] P = 0.004; median PFS 3.7 vs 2.0; 6-mo PFS 38% vs 23%; 12-mo PFS 27% vs 12%), and patients with *mESR1* (HR = 0.54 [95% CI, 0.36-0.80] P = 0.002; median PFS 5.3 vs 1.9; 6-mo PFS 44% vs 24%; 12-mo PFS 31% vs 12%). Key treatment-related adverse events (AEs) in the no prior chemotherapy elacestrant group were nausea (25.9%), fatigue (12.7%), and hot flush (11.1%). There were no treatment-related deaths in either group. **Conclusions:** Among patients with ER+/HER2– mBC without prior chemotherapy, elacestrant significantly prolonged PFS compared to SOC endocrine therapy and showed favorable outcomes in this subgroup. Clinical trial information: NCT03778931. Research Sponsor: Radius Health, Inc and the Menarini Group.

Clinical and radiographic characteristics of patients with metastatic breast cancer and pseudocirrhosis: A single-center retrospective cohort study. *First Author: Laura Ann Huppert, UCSF Helen Diller Comprehensive Cancer Center, San Francisco, CA*

Background: Pseudocirrhosis is a term used to describe changes in hepatic contour that mimic cirrhosis radiographically, but lack the classic pathologic features of cirrhosis. This radiographic finding is frequently found in patients with metastatic breast cancer (MBC); the pathophysiology and clinical consequences are poorly understood. The objective of this study is to describe the patient, tumor, and treatment characteristics associated with pseudocirrhosis, and to assess associated clinical outcomes. **Methods:** In this retrospective study, we identified patients with MBC and imaging findings consistent with pseudocirrhosis (diffuse liver contour abnormalities) who were treated at the University of California San Francisco from 2002-2021. We used chart extraction and radiology review to determine demographic characteristics, treatment history, response to treatment, imaging features, and complications of pseudocirrhosis. Comparisons between groups were made using the unpaired t-test or two-sided Fisher's exact test. **Results:** 120 patients with MBC and radiographic evidence of pseudocirrhosis were identified with the following BC subtypes: Hormone receptor (HR) positive, HER2 negative (n = 99, 82.5%), HR+/HER2+ (n = 14, 11.7%), HR-/HER2+ (n = 3, 2.5%), and triple negative (TNBC; n = 4, 3.3%). All patients with pseudocirrhosis had liver metastases (n = 120, 100.0%) and 82.5% (n = 99) had > 15 lesions. Median time from diagnosis of MBC to radiographic evidence of pseudocirrhosis was 29.2 months. Most patients received chemotherapy for MBC prior to the finding of pseudocirrhosis (n = 111, 92.5%) with median 2.0 lines. Pseudocirrhosis was observed in the setting of stable or responding disease in 50% of patients (n = 60). Patients received a median of 1.0 line of additional therapy after pseudocirrhosis diagnosis, with a median overall survival of 7.9 months from pseudocirrhosis to death. Sequelae of pseudocirrhosis included the radiographic finding of ascites (n = 97, 80.8%), gastric/esophageal varices (n = 68, 56.7%), splenomegaly (n = 26, 21.7%), GI bleeding (n = 12, 10.0%), or hepatic encephalopathy (n = 11, 9.2%). Radiographic evidence of ascites was associated with a shorter survival from MBC diagnosis compared to no ascites (42.8 vs. 76.2 months, p = < 0.001). GI/Hepatology consultation was uncommon (n = 9, 7.5%). **Conclusions:** To our knowledge, this is the largest reported case series of patients with MBC and pseudocirrhosis. Nearly all patients had HR+ disease and extensive liver metastases. Pseudocirrhosis was frequently observed in the setting of responding or stable disease, creating complexity in management. Survival was short in all patients, particularly patients with radiographic evidence of ascites. Further understanding of the pathogenesis of and risk factors for pseudocirrhosis could help improve outcomes for this condition. Research Sponsor: None.

A multiple center, open-label, single-arm, phase II clinical trial of MRG002, an HER2-targeted antibody-drug conjugate, in patients with HER2-low expressing advanced or metastatic breast cancer. *First Author: Zefei Jiang, The Fifth Medical Center of Chinese PLA General Hospital, Beijing, China*

Background: MRG002 is a novel HER2-targeted ADC, composed of a sugar-modified trastuzumab, MMAE payload and a cleavable vc-linker. MRG002 was effective in HER2-low expressing breast cancer in preclinical studies. Hence, we conducted the phase II study to evaluate the safety and anti-tumor efficacy of MRG002 in HER-low breast cancer. **Methods:** HER2 low tumor expression was determined by a central lab and had to be immunohistochemistry (IHC)1+ or 2+/ISH-. Eligible patients had advanced/metastatic HER2-low expressing breast cancer that failed standard therapies. MRG002 was administered intravenously once every 3 weeks at the dose of 2.6 mg/kg, until disease progression or unacceptable toxicity which ever occurred first. The primary endpoint was objective response rate (ORR) assessed by independent review committee (IRC). The secondary endpoints were progression-free survival (PFS), disease control rate (DCR), and safety. **Results:** A total of 56 female patients with HER2-low advanced or metastatic breast cancer were enrolled at the time of data cut-off (Dec 31, 2021) and had received at least one cycle of MRG002. The median age was 55 (30-72) years. Most patients were HER2 IHC1+ (83.9%), hormone receptor positive (HR+) (85.7%), and with a ECOG PS of 1 (57.1%). Twenty-eight patients (50.0%) had received at least 2 lines of chemotherapy and the median treatment was 3. Forty-one patients (73.2%) had visceral metastasis and 31 patients (55.4%) had bone metastasis. The ORR and DCR in 49 evaluable patients were 34.7% and 75.5%, with 17 PR, 20 SD and 12 PD. Subgroup analysis indicated that the ORR was 39.5% (15/38) and DCR was 76.3% (29/38) among the evaluable patients with visceral metastasis. The tumor responses were similar in both the HER2 IHC 1+ and IHC 2+ subgroups, as is 34.1% and 37.5% respectively, which might be attributed to fewer IHC 2+ enrollment in this trial. Although only 8 HR- subjects enrolled in our study, the ORR (37.5%) and DCR (62.5%) is promising in these triple negative BC patients post to ≥2 line therapies. Most common treatment related adverse events (TRAEs) were grade 1 or 2. The most common TRAEs (≥20%) were neutrophil count decreased (53.6%), white blood cell count decreased (48.2%), AST increased (46.4%), alopecia and ALT increased (39.3%), blood lactate dehydrogenase increased(33.9%), GGT increased (32.1%), nausea (32.1%), vomiting (23.2%), constipation (23.2%), diarrhea(23.2%) and hyperglycemia (21.4%). Most common grade ≥3 TRAE(≥10%) was neutrophil count decreased(14.3%). No patients died due to MRG002. **Conclusions:** MRG002 shows promising efficacyand well tolerated in patients with HER2-low breast cancer. Further evaluation is underway. Clinical trial information: NCT04742153. Research Sponsor: Shanghai Miracogen Inc.

Patient-reported outcomes for measuring the quality of life in advanced breast cancer treated with third-line and beyond chemotherapy-based regimens: A national cross-sectional study. *First Author: Xiuwen Guan, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Prolongation of survival and maintenance of quality of life (QoL) are the primary therapeutic goals in advanced breast cancer. Around 10% of adverse events (AEs) in the CTCAE are symptomatic AEs (e.g., nausea, sensory neuropathy), which can severely and directly affect the QoL of patients. However, seldom evidence mapped the QoL and symptomatic AEs utilizing patient-reported outcomes (PROs) in heavily pretreated breast cancer patients. This study aimed to investigate the PROs for measuring the QoL and symptomatic AEs of advanced breast cancer treated with third-line and beyond chemotherapy-based regimens in China. **Methods:** This national survey enrolled patients with advanced breast cancer receiving third-line and beyond chemotherapy-based regimens in 59 centers all over China from March to April in 2021. Each patient filled out a questionnaire containing demographic information, medical history, EORTC-QLQ-C30, and symptomatic AEs. The symptomatic AEs included fatigue, nausea/vomiting, pain, dyspnea, insomnia, appetite loss, constipation, diarrhea, alopecia, fever, and limb numbness. The range method was used for the linear conversion of the PRO scores, which were converted into standardized scores of 0 to 100. **Results:** This study enrolled 1015 patients with the median age of 52 years. The QoL of all patients were poor, with the global health status score of 52.4±17.7 (Table). All the symptomatic AE scores were low among the patients. However, no significant differences were observed in global health status and symptomatic AEs between mono-chemotherapy and multi-agent chemotherapy (All P>0.05). **Conclusions:** The QoL of advanced breast cancer patients treated with third-line and beyond chemotherapy were poor, especially in symptomatic AEs. In addition, the EOTRC-QLQ-C30 scale appears to underestimate the differences in symptomatic AEs between mono-chemotherapy and multi-agent chemotherapy, probably due to a lack of sensitivity of the scale, which fails to match the actual clinical observations of the PROs and QoL. Therefore, new scales need to be developed for the evaluation of symptomatic AEs and QoL in advanced breast cancer. Research Sponsor: Nature Science Foundation of China (82103634).

The comparation of the scores of QoL and symptomatic AEs between mono-chemotherapy and multi-agent chemotherapy.

Symptomatic AEs	All (n=1015)	Mono-chemotherapy (n=784)	Multi-agent chemotherapy (n=231)	*P* value
Global Health Status	52.4±17.7	52.0±17.8	53.8±17.4	0.319
Fatigue	43.0±25.8	42.8±26.3	43.8±24.2	0.622
Nausea and vomiting	47.7±28.7	48.4±28.9	45.4±27.9	0.155
Pain	48.2±27.8	47.9±28.2	49.5±26.3	0.503
Insomnia	42.8±30.7	43.1±30.4	42.0±31.6	0.518
Appetite loss	45.4±29.4	45.9±29.5	43.7±29.1	0.330
Diarrhea	55.9±32.6	55.6±32.4	57.0±33.6	0.567
Alopecia	37.0±31.6	36.5±31.1	38.4±33.3	0.534
Limb numbness	47.5±30.8	47.3±30.9	48.3±30.7	0.654

A novel oral paclitaxel and HM10381 (oraxel)-treated metastatic breast cancer: A phase I study (KX-ORAX-CN-007). *First Author: Tao Qin, Sun Yat-sen University Sun Yat-sen Memorial Hospital, Guangzhou, China*

Background: This phase I study assessed the pharmacokinetics, safety, antitumor activity of oral paclitaxel and HM10381 (Oraxel) in patients with metastatic breast cancer. **Methods:** Oraxol (oral paclitaxel 205 mg/m^2 plus HM30181A 15 mg) daily for 3 consecutive days weekly for up to 16 weeks was administered to patients. The primary objective endpoint was pharmacokinetic analysis. The secondary endpoint were objective response rate (ORR) and safety. For pharmacokinetic analysis, timed blood samples were collected. **Results:** Twenty-four female patients were enrolled from Apr 2019 to Aug 2019. The median age was 53 years (range: 35 to 70 years). The mean lines and median line of treatment were 2.5 and 2, respectively. Previous breast cancer treatments included chemotherapy in 23 (96%) patients, hormonal therapy in 20 (83%) patients. Prior taxanes therapy was reported in 20 (83%) patients. There were 15 patients in efficacy dataset. The best ORR (Investigator) was PR in 40%, SD in 53%, and PD in 7%. The best overall response rate (ICRRC) was PR in 36%, SD in 57%, and PD in 7% of patients. There were no hypersensitivity-type reactions. Adverse events of interest neutropenia, neurotoxicity, and diarrhea were reported as 20 (83%) , 7 (29%) and 11 (46%), retrospectively. A total of 15 (63%) patients experienced Grade ≥3 TEAEs, including neutrophil count decreased in 11 (46%) patients, WBC count decreased in 8 (33%) patients. Treatment related SAE was reported in 1 (4.17%) patient experienced febrile neutropenia, pneumonia, and septic shock. The PK data indicated that the efficacy response is not associated with oral paclitaxel exposure parameters AUC or Cmax. **Conclusions:** The study showed that Oraxol as novel oral chemotherapy agent shows promising antitumor activity in patients with metastatic breast cancer, manageable toxicity, and no hypersensitivity-type reactions. Clinical trial information: NCT04993040. Research Sponsor: Athenex Pharmaceuticals (Chong Qing) Limited.

Impact of an individualized counseling program on weight loss and quality of life in breast cancer survivors. *First Author: Iktej Singh Jabbal, Cleveland Clinic Florida, Weston, FL*

Background: Survivors of breast cancer who are obese have a greater than two-fold increase in mortality compared to their counterparts. We assessed the feasibility of an individualized nutrition counseling and exercise program with the goal of helping participants achieve a loss of 10% body weight. Secondary endpoints included impact on multiple metabolic parameters, cardiovascular health, and quality of life. **Methods:** We present preliminary data from a single-arm pilot trial (NCT04365569) whereby survivors of breast cancer with BMI ≥ 25 kg/m^2 participated in a 6-month, individualized counseling program. A registered dietitian (RD) counseled patients based upon recommendations by the American Cancer Society. The intervention included in-person (baseline, months 3 and 6) and telephone visits (months 1, 2, 4, and 5). The nutrition component included weight and body composition measures and blood work, including lipid panel and hemoglobin A1c. Cardiovascular fitness and extrapolated VO2 max were measured using SHAPE study. Quality of life was evaluated using: the Functional Assessment of Cancer Therapy – Breast Cancer (FACT-B), the Brief Pain Inventory (BPI), the Generalized Anxiety Disorder-7 (GAD-7), the Patient Health Questionnaire-9 (PHQ-9), and the NCCN Distress Thermometer. Paired statistics were used to compare changes in these aforementioned outcomes pre-and post-intervention. **Results:** A total of n=55 female breast cancer survivors (mean age 58.1± 9.13) were enrolled. N=28 completed the trial to date. While 14.3% of participants lost >10% of their baseline weight, 21.4% lost 5-10 % of their weight. Patients had a mean 45.30% drop in body fat composition overall (p<0.001). There was no statistically significant difference in lipids and hemoglobin A1c. In terms of cardiovascular function, a decline in mean VO_2 max of -4.71 (SD 4.71, p <0.001) was observed, accompanied by a decline in mean METS of -1.09 (SD 0.84, p <0.001). Higher compliance with the intervention was associated with losing weight (p 0.001). FACT-B scoring revealed improvements in Physical (mean +1.92, SD 3.82), Emotional (mean +1.03, SD 2.71), and Functional well-being (mean +2.70, SD 4.34) (p <0.05). This trial was also associated with lower indicators of depression, as evaluated by PHQ-9 scoring (mean -1.32, SD 3.19, p 0.038). Even in patients with weight gain, improvements in QoL surveys were observed, although not statistically significant, likely due to the small sample size in this subpopulation (n = 7). **Conclusions:** An individualized counseling program benefits survivors of breast cancer who are overweight by helping them reduce weight and improve their overall quality of life. While no improvements in VO2 max levels were observed, this may be partially explained by a decrease in effort on the part of participants. Further investigation into the utility of extrapolated VO2 max using the SHAPE study is ongoing. Clinical trial information: NCT04365569. Research Sponsor: Weston, Florida Internal Research.

Optimal timing and interval of imaging for metastatic breast cancer. *First Author: Shruti Rajesh Patel, Stanford University, Stanford, CA*

Background: Breast cancer is a family of diseases with varying disease trajectories based on intrinsic biology of the tumor. The time of progression varies across & within subtypes, and with increasing rates of drug resistance depending on prior therapeutic exposure. There is no strong consensus about optimal surveillance and routine imaging in patients with metastatic breast cancer (mBC), but many oncologists report that monitoring strategies are based on strategies used in clinical trials. **Methods:** We reviewed 17 prior Phase III studies that led to FDA approval in mBC. We reviewed 8 studies for ER+ mBC, 5 studies for HER2+ mBC, 2 studies for triple negative (TNBC) mBC, and 2 studies for BRCA+ mBC. We calculated rates of progression or death (POD) per month for the first year on therapy using data from survival analysis tables and compared them across the different types and lines of therapy. **Results:** Risk of progression in mBC varies based on receptor status and line of therapy (Table). There was a significant difference in POD rates between ER+ therapies compared with all other disease types (HER2+, TNBC, BRCA) (p = 0.012). Patients with TNBC or receiving PARP inhibitors or later line HER2 therapies had higher POD rates than those with ER+ breast cancer or receiving first line HER2 therapy (6.9% vs 4.1% per month; p = 0.0004). No significant difference was seen in the monitoring frequency between ER+ and HER2+ disease (p = 0.39). **Conclusions:** These data suggest that shorter interval imaging should be performed for patients with TNBC or receiving PARP inhibitors or later line HER2 therapies. Surveillance imaging for patients with mBC should be based on disease biology, number of prior regimens, time since initiation of therapy, and regimen efficacy. Current imaging recommendations are not data-based and do not adjust for new agents that have been approved. Oncologists should integrate these into individualized estimates to determine optimum frequency of imaging in clinical practice and research. Research Sponsor: None.

Disease Type	Trial Name	Line of Therapy	Treatment	Treatment Arm: Risk of progression or death/month	Control	Control Arm: Risk of progression or death/month	Monitoring frequency (Every X Weeks)	Median PFS (months)
ER+	PALOMA2	First	Palbociclib + AI	3.10%	AI	4.20%	12	24.8

EPIK-B4: A phase 2, randomized study of metformin (MET) extended release (XR) +/- dapagliflozin (DAPA) to prevent hyperglycemia (HG) in patients (pts) with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-), *PIK3CA*-mutated (mut) advanced breast cancer (ABC) treated with alpelisib (ALP) and fulvestrant (FUL). *First Author: William John Gradishar, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: ALP (α-selective PI3K inhibitor and degrader) is approved with FUL for pts with *PIK3CA*-mut HR+, HER2– ABC. HG is a known on-target effect of PI3K inhibition, manageable with oral anti-HG agents such as MET and dose interruptions/modifications of ALP and reversible upon discontinuation of ALP. Although HG management guidelines were refined throughout the SOLAR-1 and BYLieve studies evaluating ALP + FUL/letrozole, there remains a need for optimized strategies beyond initial MET therapy that offers earlier and more sustained improvement of HG, particularly for pts at an increased risk for severe HG. In preclinical models, the addition of a SGLT2 inhibitor to ALP (+/– MET) reduced HG while maintaining ALP efficacy. The aim of this study is to evaluate the safety and efficacy of prophylactic MET XR +/– the SGLT2 inhibitor DAPA in reducing severe HG in pts with *PIK3CA*-mut HR+, HER2– ABC on ALP + FUL with an increased risk for severe HG (grade ≥ 3) on ALP. **Methods:** EPIK-B4 is a Phase II, randomized (1:1), open-label, active-controlled study assessing the efficacy and safety of MET XR +/– DAPA (starting at Cycle 1 Day 1 [C1D1]) with ALP (300 mg orally [PO], once daily [QD], starting at C1D8) + FUL (500 mg intramuscularly on C1D1, C1D15, and D1 of subsequent cycles) in pts (N ≈ 132) with HR+, HER2–, *PIK3CA*-mut ABC after progression on/after endocrine-based treatment (Tx). MET XR is administered PO starting at 500 mg QD (titrated up to 2 g QD) and MET XR + DAPA starting at 500 mg and 5 mg QD (titrated up to 2 g and 10 mg QD), respectively. Eligible pts include adult men or postmenopausal women with confirmed HR+, HER2–, *PIK3CA*-mut ABC and ≥ 1 risk factor for severe HG (diabetes [fasting plasma glucose (FPG) ≥ 126 mg/dL and/or HbA1c ≥ 6.5%], prediabetes [FPG ≥ 100 to < 126 mg/dL and/or HbA1c 5.7% to < 6.5%], obesity [BMI ≥ 30], age ≥ 75 years); prior endocrine-based Tx (eg, FUL or oral SERD) was permitted. Randomization is stratified by baseline diabetes status. Key exclusion criteria include > 1 line of Tx in the metastatic setting; prior chemotherapy (metastatic setting) or PI3K, mTOR, or AKT inhibitor; type I or II diabetes requiring Tx; or antecedent of pancreatitis or severe cutaneous reaction. The primary endpoint is the occurrence of severe HG (grade ≥ 3 [glucose > 250 mg/dL] based on laboratory assessments) over the first 8 weeks of ALP + FUL. Secondary endpoints include progression-free survival, overall response and clinical benefit rates with confirmed response, safety, and tolerability. A biomarker analysis is planned as an exploratory objective. Recruitment is ongoing with enrollment planned in 56 sites across 8 countries; completion of primary data collection is anticipated in 2023. Clinical trial information: NCT04899349; EUDRACT#2021-001908-15. Research Sponsor: Novartis Pharmaceuticals Corporation.

TPS1108 **Poster Session**

Phase 3 study of tucatinib or placebo in combination with trastuzumab and pertuzumab as maintenance therapy for HER2+ metastatic breast cancer (HER2CLIMB-05, trial in progress). *First Author: Erika P. Hamilton, Sarah Cannon Research Institute at Tennessee Oncology, Nashville, TN*

Background: The current first-line (1L) standard of care (SOC) for human epidermal growth factor receptor 2-positive (HER2+) metastatic breast cancer (MBC) is trastuzumab (T) plus pertuzumab (P) and a taxane. Despite advances in 1L SOC, most patients (pts) progress during maintenance therapy with T+P. Tucatinib is a tyrosine kinase inhibitor (TKI) approved in combination with T and capecitabine for adults with HER2+ MBC, with and without brain metastases (BM). In HER2CLIMB, the addition of tucatinib significantly prolonged progression-free survival (PFS) and overall survival (OS) in pts with HER2+ MBC and was well tolerated. Adding tucatinib also reduced the risk of disease progression or death in pts with untreated and/or active BM (Murthy et al. 2020, Curigliano et al. 2021). HER2CLIMB-05 investigates whether adding tucatinib to 1L SOC as maintenance therapy will extend PFS while maintaining quality of life (QOL). **Methods:** HER2CLIMB-05 (NCT05132582) is a phase 3, randomized, double-blind study evaluating tucatinib plus T+P as maintenance therapy for HER2+ MBC. Approximately 650 pts will be enrolled. Eligible pts will have advanced HER2+ disease, no progression on 4–8 cycles of prior 1L SOC, ECOG Performance Status of 0 or 1, and no or asymptomatic BM. Exclusion criteria include prior treatment with anti-HER2 and/or anti-epidermal growth factor receptor TKI (prior SOC for early BC is permitted) or inability to undergo contrast magnetic resonance imaging of the brain. Pts will be randomized 1:1 to receive either tucatinib or placebo twice daily, with T+P once every 21 days. Pts with HR+ disease may receive endocrine therapy. The primary endpoint is investigator-assessed PFS. Secondary endpoints include OS (key endpoint), time to deterioration of health-related QOL, central nervous system PFS, safety, and pharmacokinetic (PK) parameters. PFS and OS will be compared using a 2-sided stratified log-rank test between treatment groups. Time-to-event endpoints will be summarized using the Kaplan–Meier method. PK and safety data will be summarized using descriptive statistics. Enrollment is ongoing in the US, with additional sites planned. Clinical trial information: NCT05132582. Research Sponsor: Seagen.

TPS1109 **Poster Session**

EPIK-B5: A phase III, randomized study of alpelisib (ALP) plus fulvestrant (FUL) in patients with hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-), *PIK3CA*-mutated advanced breast cancer (ABC) progressing on/after an aromatase inhibitor (AI) with a cyclin-dependent kinase 4/6 inhibitor (CDK4/6i). *First Author: Michelino De Laurentiis, Istituto Nazionale Tumori IRCCS "Fondazione G. Pascale"-Breast Oncology Unit, Naples, Italy*

Background: Endocrine therapy (ET) + CDK4/6i is standard of care for HR+, HER2– ABC; however, CDK4/6i resistance, in which the phosphatidylinositol-3-kinase (PI3K) pathway has a key role, remains challenging. Progression-free survival (PFS) for ≥ 2nd-line ET monotherapy post CDK4/6i is poor; prognosis may be worse in patients with a *PI3KCA* mutation. ALP (PI3K-α selective inhibitor and degrader) + FUL is approved by the European Medicines Agency (EMA) for HR+, HER2–, *PIK3CA*-mutated ABC after ET monotherapy. Outside the EMA, ALP + FUL approval includes post-CDK4/6i use. ALP + FUL has shown clinical activity and consistent safety in a small subpopulation in SOLAR-1 with prior CDK4/6i treatment (n = 9) and in BYLieve Cohort A (CDK4/6i + AI as immediate prior treatment; n = 121). The EPIK-B5 study aims to confirm the efficacy and safety of ALP + FUL in a larger population with HR+, HER2–, *PIK3CA*-mutated ABC with prior CDK4/6i + AI treatment. **Methods:** EPIK-B5 is a Phase III, randomized (1:1), double-blind, placebo-controlled study assessing the efficacy and safety of ALP (300 mg/d orally starting Cycle 1 Day 1 [C1D1]) + FUL (500 mg intramuscularly on C1D1 and C1D15, and D1 of subsequent cycles) in patients (N ≈ 234) with HR+, HER2–, *PIK3CA*-mutated ABC progressing on/after CDK4/6i + AI. Patients randomized to placebo + FUL can cross over to ALP + FUL after progression. Randomization is stratified by presence of lung and/or liver metastasis and prior CDK4/6i setting. Adult men or postmenopausal women with confirmed HR+, HER2–, *PIK3CA*-mutated ABC and ≥ 1 measurable lesion are eligible. The primary endpoint is PFS per blinded independent review committee assessment. Secondary endpoints include overall survival, overall response and clinical benefit rates, duration of and time to response, PFS by *PIK3CA*-mutation status in circulating tumor DNA, PFS on next-line treatment, time to definitive deterioration of ECOG status, quality of life (QoL), and safety and tolerability. Exploratory endpoints include biomarker analyses, additional QoL endpoints, and time to subsequent chemotherapy. Recruitment is ongoing, with enrollment planned over 2 years in 18 countries; completion of primary data collection is anticipated in 2026. Clinical trial information: NCT05038735; EUDRACT2021-001966-39. Research Sponsor: Novartis Pharmaceuticals Corporation.

TPS1110 **Poster Session**

A randomized, multicenter, placebo-controlled, phase III study to evaluate the efficacy and safety of HER2/neu peptide GLSI-100 (GP2 + GM-CSF) in patients with residual disease or high-risk PCR after both neo-adjuvant and postoperative adjuvant anti-HER2 therapy, Flamingo-01. *First Author: Snehal Patel, Greenwich LifeSciences, Stafford, TX*

Background: GP2 is a biologic nine amino acid peptide of the HER2/*neu* protein delivered in combination with Granulocyte-Macrophage Colony Stimulating Factor (GM-CSF) that stimulates an immune response targeting HER2/neu expressing cancers, the combination known as GLSI-100. In a prospective, randomized, single-blinded, placebo-controlled, multicenter Phase IIb study, no recurrences were observed in the HER2+ population after 5 years of follow-up, if the patient was treated with GLSI-100, survived and was followed from more than 6 months ($p = 0.0338$). Immunotherapy elicited a potent response measured by skin tests and immunological assays. Of the 146 patients that have been treated with GLSI-100 over 4 clinical trials, GLSI-100 was well-tolerated and no serious adverse events were observed considered related to the immunotherapy. **Methods:** This Phase 3 trial is a prospective, randomized, double-blinded, multi-center study. After 1 year of trastuzumab-based therapy, 6 intradermal injections of GLSI-100 or placebo will be administered over the first 6 months and 5 subsequent boosters will be administered over the next 2.5 years for a total of 11 injections over 3 years. The participant duration of the trial will be 3 years treatment plus 1 additional year follow-up for a total of 4 years following the first year of treatment with trastuzumab-based therapy. Patients will be stratified based on residual disease status at surgery, hormone receptor status and region. Approximately 498 patients will be enrolled. To detect a hazard ratio of 0.3 in invasive breast cancer free survival (IBCFS), 28 events will be required. An interim analysis for superiority and futility will be conducted when at least 14 events have occurred. This sample size provides 80% power if the annual rate of events in placebo patients is 2.4% or greater. Up to 100 non-HLA-A*02 subjects will be enrolled in an open-label arm. Eligibility Criteria: The patient population is defined by these key eligibility criteria: HER2/neu positive and HLA-A*02; Residual disease or High risk pCR (Stage III at presentation) post neo-adjuvant therapy; Exclude Stage IV; Completed at least 90% of planned trastuzumab-based therapy. Trial Objectives: To determine if GP2 therapy increases IBCFS; To assess the safety profile of GP2; To monitor immunologic responses to treatment and assess relationship to efficacy and safety. Accrual: Site selection and study start-up is in progress at multiple sites. Target enrollment is 598 subjects. Clinical trial information: 05232916. Research Sponsor: Greenwich LifeSciences, Inc.

TPS1111 **Poster Session**

Phase 2 trial of tucatinib plus trastuzumab deruxtecan in patients with HER2+ locally advanced or metastatic breast cancer with and without brain metastases (HER2CLIMB-04, trial in progress). *First Author: Ian E. Krop, Dana-Farber Cancer Institute, Boston, MA*

Background: Tucatinib is an oral reversible small-molecule tyrosine kinase inhibitor highly selective for human epidermal growth factor receptor 2 (HER2). Tucatinib is approved in the US for use in combination with trastuzumab and capecitabine in adult patients with HER2+ metastatic breast cancer (MBC), with and without brain metastases, who have received ≥1 prior anti–HER2-based regimens in the metastatic setting. Trastuzumab deruxtecan (T-DXd), an antibody–drug conjugate (ADC) comprising a HER2-directed monoclonal antibody conjugated to a topoisomerase I inhibitor payload, is also approved in the US for patients with HER2+ MBC. In HER2+ breast cancer (BC) xenograft models, tucatinib increased the antitumor activity of a HER2-directed ADC comprising a HER2-directed monoclonal antibody conjugated with 8 exatecan moieties (T-Ex) when compared to T-Ex alone (Kulukian et al 2019). While significant advances have been made in the treatment of patients with HER2+ BC, treatment of metastatic disease remains a clinical challenge due to limited treatment options. **Methods:** HER2CLIMB-04 (NCT04539938) is a single-arm, open-label, multicenter, phase 2 study evaluating the efficacy and safety of tucatinib plus T-DXd in previously treated patients aged ≥18 years with unresectable, locally advanced, or metastatic (LA/M) HER2+ BC. Patients must have prior treatment with a taxane and trastuzumab (with or without pertuzumab) in the LA/M setting or progressed within 6 months after neoadjuvant or adjuvant treatment involving a regimen including a taxane and trastuzumab (with or without pertuzumab). Patients with brain metastases, including active brain metastases, may be enrolled. A safety lead-in portion of the study with 10 patients who were followed for at least 1 cycle has been completed. This portion of the study demonstrated a manageable safety profile so the trial will enroll approximately 60 response-evaluable patients (including the 10 patients from the safety lead-in), evenly distributed between patients with and without brain metastases. The primary endpoint is confirmed objective response rate (cORR) by investigator assessment per RECIST 1.1. Secondary endpoints are progression-free survival (PFS), duration of response (DOR), disease control rate (DCR) by investigator assessment per RECIST 1.1, overall survival, and safety. Exploratory endpoints will include cORR, PFS, DCR, and DOR by independent central review per RECIST 1.1, pharmacokinetic analyses, biomarker analyses, and changes in patient-reported outcomes. Efficacy and safety will be summarized with descriptive statistics. Enrollment in the US began in late 2020. Clinical trial information: NCT04539938. Research Sponsor: Seagen.

TPS1112 **Poster Session**

Targeting HER2-positive metastatic breast cancer with ARX788, a novel anti-HER2 antibody-drug conjugate in patients whose disease is resistant or refractory to T-DM1, and/or T-DXd, and/or tucatinib-containing regimens. *First Author: Janice M. Lu, University of Southern California, Los Angeles, CA*

Background: The overexpression and/or amplification of human epidermal growth factor receptor 2 (HER2) occurs in approximately 20% of breast cancers (BC) and is a major driver of tumor development and progression. This HER2 subtype confers aggressive tumor behavior and the HER2 receptor remains a valuable target for antibodies, bi-specifics, and antibody drug conjugates (ADC). With advances in targeted therapy, patients with HER2-positive breast cancer (HER2+ BC) may experience an improved prognosis, including survival. Novel HER2-targeted therapies are being investigated to overcome drug resistance and to help mitigate adverse events (e.g., cardiotoxicity). ARX788 is a next-generation ADC using a technology platform whereby a HER2 specific monoclonal antibody is conjugated with Amberstatin269 (AS269), a potent cytotoxic tubulin inhibitor. Site-specificity, high homogeneity, and stable covalent conjugation of ARX788 leads to its slow release and prolonged peak of serum pAF-AS269, which may contribute to the lower systemic toxicity and increased targeted delivery of payload to tumor cells at a lower effective dose compared to other HER2 ADCs. Clinical activity has been seen in Phase I HER2 breast and pan-tumor studies. **Methods:** Trial Design: ACE-Breast-03 (NCT04829604) is a global, phase 2 study designed to assess anticancer activity and safety of ARX788 in patients with metastatic HER2 positive breast cancer. Patients whose disease is resistant or refractory to T-DM1, and/or T-DXd, and/or tucatinib-containing regimens are eligible. Patients must have adequate organ function. Any brain metastases must be radiographically stable without steroid dependence. Efficacy will be assessed using Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 by imaging every 6 weeks on study. Endpoints include objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), best overall response (BOR), duration of response (DOR), and time to response (TTR). The safety and tolerability profile will be evaluated. Blood samples will be collected at specified time points to determine serum concentrations of ARX788, total antibody, and metabolite pAF-AS269. Potential predictive and/or prognostic biomarkers at baseline and on-treatment will be analyzed for exploratory purposes. Descriptive statistics will be used to evaluate anticancer activity, safety, and tolerability. The study is currently recruiting patients. Please contact breast03trialinquiry@ambrx.com for additional information. Clinical trial information: NCT04829604. Research Sponsor: Ambrx, Inc.

TPS1113 **Poster Session**

Targeting insulin feedback to enhance alpelisib (TIFA): A phase II randomized trial in metastatic, *PIK3CA*-mutant, hormone receptor–positive breast cancer. *First Author: Sherry Shen, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Breast cancer is the most common malignancy among women in the U.S. and is a leading cause of cancer-related death. Among women with hormone receptor (HR)-positive, human epidermal growth factor receptor 2 (HER2)-negative breast cancer, 45% harbor activating mutations in the *PIK3CA* gene, which induces hyperactivation of phosphatidylinositol 3-kinase (PI3K) and drives cell growth and survival. The SOLAR-1 trial found that the combination of alpelisib, a PI3K inhibitor, and fulvestrant, an endocrine therapy, significantly improved progression-free survival compared to fulvestrant alone, leading to Food and Drug Administration approval in *PIK3CA*-mutated metastatic breast cancer. While PI3K inhibition induces apoptosis of cancer cells, inhibition of this pathway in the liver and skeletal muscle impairs physiologic insulin signaling leading to hyperglycemia. This affects > 60% of patients, results in grade 3-4 hyperglycemia in 36% of patients, and is a major cause of interrupted/reduced dosing or discontinuation. In preclinical models, application of a very low carbohydrate (ketogenic) diet or a sodium-glucose cotransporter 2 inhibitor (SGLT2i), a commonly used diabetes medication, minimized hyperglycemia and improved the anti-tumor efficacy of PI3K inhibition. These interventions are safe and feasible in cancer patients but have not been studied for the prevention of PI3K inhibitor-associated hyperglycemia. **Methods:** We are conducting a multicenter phase II clinical trial (NCT05090358) in patients receiving standard-of-care alpelisib plus fulvestrant to test the efficacy of three interventions (n = 106): 1) ketogenic diet, 2) low-carbohydrate diet, or 3) canagliflozin (a SGLT2i) in preventing alpelisib-associated hyperglycemia. The goal of this study is to mitigate a major toxicity of PI3K inhibitors and maximize their clinical efficacy. Eligible patients must be postmenopausal and have histologically confirmed HR-positive, HER2-negative metastatic breast cancer, ≥1 activating *PIK3CA* mutations, measurable disease per RECIST v1.1 or at least one predominantly lytic bone lesion, recurrence or progression during or after endocrine-based therapy, ECOG performance status of 0-1, hemoglobin A1c < 8%, and fasting blood glucose < = 140mg/dL. Prior CDK4/6 inhibitor use is allowed. The primary endpoint is the grade 3-4 hyperglycemia-free rate at 12 weeks. Secondary endpoints include the 6- and 12-month overall response rate, 6- and 12-month progression-free survival, alpelisib adherence, changes in systemic hormones and metabolites related to glucose homeostasis, changes in body composition, and quality of life. The first patient was enrolled on October 15, 2021. Participating sites include Memorial Sloan Kettering Cancer Center, Weill Cornell Medical Center, and the Ohio State University Wexner Medical Center. Clinical trial information: NCT05090358. Research Sponsor: Novartis.

TPS1114 **Poster Session**

A phase II, single-arm, non-randomized study of alpelisib (BYL719) in combination with continued endocrine therapy following progression on endocrine therapy in hormone receptor–positive, HER2-negative, *PIK3CA*-mutant metastatic breast cancer: A Big Ten Cancer Research Consortium Study (btcrc-BRE19-409). *First Author: Cristina I. Truica, Penn State Health Milton S. Hershey Medical Center, Hershey, PA*

Background: The PI3K pathway is frequently altered in hormone receptor positive (HR+) breast cancer (BC) and 40% of patients have *PIK3CA* mutations. The PI3Kα-specific inihibitor, Alpelisib, is FDA-approved in combination with fulvestrant for treatment of patients with HR+ HER2 negative (HER2-) *PIK3CA* mutated, advanced BC following progression on or after a non-fulvestrant endocrine therapy (ET) based regimen. We hypothesized that the benefit seen in the seminal SOLAR-1 study that compared alpelisib plus fulvestrant to placebo with fulvestrant, was due to the addition of alpelisib, rather than the change to fulvestrant, such that addition of alpelisib to ongoing ET at time of progression could lead to similar outcomes. Unlike SOLAR-1, our study continues prior ET at time of progression and requires prior CDK4/6 inhibitor therapy. **Methods:** We designed a phase II single arm study that tests the efficacy of adding alpelisib to ongoing ET at time of progression on ET. The primary objective is to estimate the progression–free survival (PFS) of alpelisib with continued ET (aromatase inhibitor or fulvestrant) following progression in patients with HR+ HER2-, *PIK3CA* mutant advanced BC. Secondary objectives are to estimate overall response rate, clinical benefit rate, duration of response, overall survival and safety/tolerability. Correlative studies include evaluation of PIK3-CA activity in circulating tumor cell liquid biopsy at baseline, C1D15, C2D1, C4D1 and at progression and correlation with primary and secondary objectives. Eligibility: Men and postmenopausal female patients with histologically confirmed ER and/or PR ≥1%, HER2- metastatic or unresectable BC with *PIK3CA* mutation and either measurable disease or at least one predominantly lytic bone lesion. No more than two lines of ET and no chemotherapy in the metastatic setting is allowed and patients must have received treatment with a CDK4/6 inhibitor and have progressed on ET as last line of therapy. Exclusions include prior *PIK3CA, mTOR* or *AKT* inhibitors in the metastatic setting, symptomatic active CNS metastases or CNS metastases that require therapeutic interventions. Statistical Analysis. The sample size calculation is based on testing the null hypothesis that the median PFS is at most 5 months against the alternative that the PFS is greater than 5 months (based on data from SOLAR-1). An increase of at least 3 months in the median PFS will be considered a sufficient efficacy signal. A sample size of 44 subjects is required to detect an anticipated increase in the median PFS from 5 to 8 months at the one-sided 0.10 significance level with 90% power, assuming a uniform accrual period of 24 months. Clinical trial information: NCT04762979. Research Sponsor: NOVARTIS, The Kerry Taylor Memorial fund.

TPS1115 **Poster Session**

A multicenter, open-label, phase 2 study of odetiglucan (IMPRIME PGG) and pembrolizumab in patients with metastatic breast cancer (mBCA) who have progressed through prior hormonal therapy. *First Author: Alison Stopeck, Stony Brook Cancer Center, Stony Brook University, Stony Brook, NY*

Background: Hormone receptor (HR) positive/ human epidermal growth factor receptor 2-negative (Her2-) breast cancer is generally considered 'immunologically cold' in comparison to TNBC or Her2+ breast cancer. Keynote-028 results showed a modest ORR of 12% to anti-PD1 antibody, pembrolizumab (PEM) in previously treated HR+/ HER2-/programmed death ligand 1-positive (PD-L1-positive) advanced breast cancer patients (pts). With limited options available, there is significant unmet need to expand clinical benefit from ICI. Odetiglucan, a novel beta glucan, acts as a pathogen-associated molecular pattern (PAMP) that drives a cascade of immune activating events. It repolarizes the immunosuppressive microenvironment, activates the maturation of antigen presenting cells and significantly enhances efficacy of ICI therapy in preclinical tumor models. In a Ph2 trial (IMPRIME 1) of odetiglucan + PEM in 44 pts with heavily pretreated metastatic TNBC, an ORR=15.9%, DCR=54.5%, mDOR=12.7mo, mPFS=2.86 mo, 12 mo OS rate=57.6%, and mOS=16.4 mo were observed. Clinical benefit was particularly evident in a subset of pts, mTNBC "converters" (12/44 pts) who were originally diagnosed with ER/PR+ disease and progressed through endocrine therapies +/- CDK4/6 inhibitors. In these 12 pts, an ORR=50%, DCR=83%, mDOR=11.2, mPFS=5.6 mo, 12-mo OS rate=64.8%, and mOS=17.4 mo were observed. **Methods:** Odetiglucan + PEM is now being explored in pts with hormone-resistant metastatic breast cancer (MBC). This is a phase 2, Simon's 2-Stage study of MBC pts who have progressed through prior hormonal therapy with >1 CDK4/6 inhibitor. Pts will receive odetiglucan 4 mg/kg/wk + PEM 200 mg Q3wk. Stage 1 will enroll 23 pts. If >4 pts have an objective response after 12 wks of treatment, the study will proceed to Stage 2 enrolling an additional 24 pts (N=47). Rejection of the null hypothesis requires >10 objective responses. Main eligibility criteria include: MBC having failed prior hormonal therapy with >1 CDK4/6 inhibitor, <2 chemotherapies, serum ABA ≥20 µg/mL, and no prior ICI exposure. Primary endpoint is ORR (RECIST v1.1); secondary endpoints are PFS, OS, DCR, DoR, and safety. Exploratory objectives assess impact of the treatment combination on immune activating events in peripheral blood and tumor biopsies, and correlate tumor microenvironmental changes with clinical benefit Select subpopulations may be explored. Point estimates with 95% confidence intervals (CIs) of ORR and DCR will be computed. Medians, first, and third quartiles with 95% CI will be estimated using Kaplan-Meier method for other secondary endpoints. Safety parameters will be summarized. The trial is sponsored by HiberCell, Inc. in collaboration with Merck & Co. ~25 US sites will participate. Clinical trial information: NCT05159778. Research Sponsor: HiberCell, Inc.

TPS1116 **Poster Session**

DOLAF: An international multicenter phase II trial of durvalumab (MEDI4736) plus olaparib plus fulvestrant in patients with metastatic or locally advanced ER-positive, HER2-negative breast cancer selected using criteria that predict sensitivity to olaparib. *First Author: Severine Guiu Lahaye, Institut de Cancerologie de Montpellier, Montpellier, France*

Background: PARP inhibitors have documented clinical activity in patients with HER2 negative breast cancer (BC) and a germline pathogenic variant (PV) in *BRCA1* or *BRCA2*. Defects in other genes involved in homologous recombination DNA repair (HRR) or mismatch repair pathway (microsatellite instability MSI) have been associated with preclinical cellular sensitivity to PARP inhibitors. Several preclinical and clinical studies have suggested synergy between immune checkpoint blockade and PARP inhibitors. Indeed, tumors with deficiency in HRR have higher mutagenic potential and produce a larger number of neoantigens. Around 60% of BC with a germline PV in *BRCA1/2* are ER+/HER2- tumors, and the ER-pathway remains a key target of their therapy. The combination of PARP inhibitors with endocrine therapy has shown to be superior to monotherapy. **Methods:** DOLAF is an open-label, international, multicentric, phase II trial assessing the combination of olaparib, fulvestrant, and durvalumab in ER+/HER2- metastatic or locally advanced BC with somatic or germline PV in *BRCA1, BRCA2* or other genes implicated in the HRR pathway *(ATM, BARD1, BRIP1, CDK12, CHEK1, CHEK2, FANCA, FAND2, FANCL, MRE11A, NBN, PALB2, PPP2R2A, RAD51B, RAD51C, RAD51D and RAD54L)* or in MSI status or other actionable genes (*AKT1, ESR1, FGFR1, FGFR2, FGFR3, and PIK3CA)* all based on central tumor NGS. Further an amendment in May 2021, patients with only alterations in these other actionable genes can no longer be included. Patients must have received 1 prior line of endocrine therapy for their metastatic BC, including CDK4/6 inhibitor and maximum of 1 line of chemotherapy in the metastatic setting. Patients receive olaparib (twice daily at 300 mg), fulvestrant (2 intramuscular injections of 250 mg every 28 days) and durvalumab (1500 mg intravenous every 4 weeks). The primary objective is to evaluate the progression-free survival rate at 24 weeks. Secondary endpoints include safety, overall survival, objective response rate, in the overall population and in the germline *BRCA* mutated population. With an optimum two-stage Simon design, $\alpha = 2.5\%$, $\beta = 5\%$, p0 (probability of inefficiency maximum) = 50%, p1 (probability of minimum efficiency) = 65%, it is necessary to include 158 patients. The strategy could be considered sufficiently effective if there are at least 87 patients without progression at 24 weeks. Given the lack of safety data from this association, a safety run-in phase including 6 patients has been completed without DLT. As of December 31, 2021, 266 patients have been screened of whom 102 have been treated. The first interim analysis occured in November 2021 after the inclusion of 64 evaluable patients. IDMC suggested that the trial continue as planned. Clinical trial information: NCT04053322. Research Sponsor: Astrazeneca.

TPS1117 **Poster Session**

postMONARCH: A phase 3 study of abemaciclib plus fulvestrant versus placebo plus fulvestrant in patients with HR+, HER2-, metastatic breast cancer following progression on a CDK4 & 6 inhibitor and endocrine therapy. *First Author: Kevin Kalinsky, Emory University at Winship Cancer Institute, Atlanta, GA*

Background: The use of cyclin dependent kinase 4 and 6 (CDK4 & 6) inhibitors plus endocrine therapy (ET) has transformed the management of hormone receptor-positive (HR+), human epidermal growth factor receptor 2-negative (HER2-) advanced breast cancer (ABC). However, most patients will experience disease progression. Identification of treatment options following progression is an unmet medical need. Additionally, as CDK4 & 6 inhibitors are now being deployed in the adjuvant setting, determination of optimal therapy following metastatic relapse is an important question. In patients with disease progression following a CDK4 & 6 inhibitor-based regimen, continuing CDK4 & 6 inhibition with abemaciclib while switching the ET backbone may provide benefit and delay the need for cytotoxic chemotherapy. Abemaciclib is an oral, selective, and potent CDK4 & 6 inhibitor administered continuously and approved as monotherapy or with ET for treatment of HR+, HER2- ABC. Abemaciclib has also been approved with ET for the adjuvant treatment of HR+, HER2-, node-positive, early breast cancer at high risk of recurrence and a Ki-67 score ≥20%. Fulvestrant is a selective ER degrader (SERD) approved for treatment of HR+, HER2- ABC. The postMONARCH study investigates whether abemaciclib plus fulvestrant will improve outcomes in patients with HR+, HER2- ABC after disease relapse or progression after adjuvant or first-line treatment with a CDK4 & 6 inhibitor plus ET. **Methods:** postMONARCH is a Phase 3, global, multicenter, randomized, double-blind, placebo-controlled study in patients with HR+, HER2- ABC and with disease progression on treatment with a prior CDK4 & 6 inhibitor plus an aromatase inhibitor as initial therapy for ABC or recurrence on/after treatment with a CDK4 & 6 inhibitor plus ET in the adjuvant setting. Eligible patients are randomized 1:1 to receive abemaciclib 150 mg twice daily or placebo, plus fulvestrant. Stratification factors include geography, presence of visceral metastasis, and duration of prior CDK4 & 6 inhibitor-based regimen. The study is powered at 80% with a cumulative Type I error of 0.025 to detect the superiority of abemaciclib plus fulvestrant versus placebo plus fulvestrant in terms of investigator-assessed progression free survival. Key secondary endpoints include overall survival, PFS by blinded independent central review, objective response rate, safety, patient-reported outcomes, and pharmacokinetics. This study opened in Jan 2022, plans for approximately 122 centers in 18 countries, and anticipates enrolling ~350 patients. Clinical trial information: NCT05169567. Research Sponsor: Eli Lilly and Company.

TPS1118 **Poster Session**

KEYNOTE-B49: A phase 3, randomized, double-blind, placebo-controlled study of pembrolizumab plus chemotherapy in patients with HR+/HER2- locally recurrent inoperable or metastatic breast cancer. *First Author: Hope S. Rugo, Department of Medicine, University of California San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: HR+/HER2– advanced breast cancer that progresses on endocrine therapy is treated with chemotherapy (chemo). The phase 1b KEYNOTE-028 trial showed durable activity with pembrolizumab (pembro) monotherapy in previously treated HR+/HER2–, PD-L1–positive (combined positive score [CPS] ≥1) advanced breast cancer. KEYNOTE-B49 (NCT04895358) is a phase 3, randomized, double-blind study of pembro + chemo vs placebo (pbo) + chemo in centrally assessed PD-L1–positive, HR+/HER2– locally recurrent inoperable or metastatic breast cancer (mBC) after progression on prior endocrine therapy. **Methods:** ~800 patients (pts) with HR+/HER2– locally recurrent inoperable or mBC who are candidates for chemo (no prior chemo for metastatic disease) with PD-L1 CPS ≥1 and documented progression on prior endocrine therapy will be enrolled. Prior endocrine therapy comprises ≥2 lines (≥1 in combination with a CDK4/6 inhibitor) in the metastatic setting or 1 line with CDK4/6 inhibitor treatment for mBC in pts who had a relapse within 24 mo of primary surgery. Pts without prior CDK4/6 inhibitor treatment may enroll if they had progressed within 6 mo of starting endocrine therapy for metastatic disease and had previously relapsed within 24 mo of primary tumor surgery while on adjuvant endocrine therapy. Pts are randomized 1:1 to receive pembro 200 mg IV or pbo Q3W, each in combination with investigator's choice of chemo: paclitaxel 90 mg/m^2 IV on days 1, 8, and 15 Q4W; nab-paclitaxel 100 mg/m^2 IV on days 1, 8, and 15 Q4W; liposomal doxorubicin 50 mg/m^2 IV on day 1 Q4W; or capecitabine 1000 mg/m^2 PO BID on days 1–14 Q3W. Randomization is stratified by tumor PD-L1 (CPS 1–9 vs ≥10), presence of visceral metastases (yes vs no), and chemo on-study (taxanes vs liposomal doxorubicin vs capecitabine). Treatment is continued until disease progression, unacceptable toxicity, withdrawal, or, for pembro/pbo, completion of 35 cycles (~2 years); chemo can be continued per investigator discretion. Tumor PD-L1 status is determined centrally using the PD-L1 IHC 22C3 pharmDx assay (Agilent Technologies; Carpinteria, CA, USA). Radiologic assessments are performed Q9W for 54 wk and then Q12W thereafter. AEs occurring from randomization until 30 d after treatment discontinuation (90 d for serious AEs) are graded per NCI-CTCAE v 5.0. Primary endpoints are PFS per RECIST v1.1 by BICR and OS in pts with PD-L1 CPS ≥10 and ≥1 tumors, separately. Enrollment is ongoing at 204 international sites. Clinical trial information: NCT04895358. Research Sponsor: Merck & Co., Inc., Kenilworth, NJ, USA.

TPS1119 **Poster Session**

Neoadjuvant survivin-targeted immunotherapy maveropepimut-S (MVP-S) to increase Th1 immune response in Ki67-high hormone receptor-positive (HR+) early-stage breast cancer (ESBC). *First Author: Sasha E. Stanton, Providence Cancer Center, Portland, OR*

Background: HR+ ESBC is associated with suboptimal pathologic complete response rate (pCR, ~10%) following neoadjuvant cytotoxic chemotherapy. Neoadjuvant anti-endocrine therapy with aromatase inhibitors (AI) may serve as an effective alternative. Efficacy can be gauged using the surrogate Ki67 cell proliferation histologic marker. Patients with poor Ki67 response (defined as Ki67 > 10%) following neoadjuvant AI exhibit poor prognosis and therapeutic resistance to both anti-endocrine therapy and chemotherapy. In a genomic analysis among Ki67-high HR+ tumors, we identified 8-fold upregulation of BIRC5 (survivin), a gene that regulates apoptosis and the cell cycle and that is associated with poor clinical outcome. Maveropepimut-S (MVP-S, previously named DPX-Survivac) leverages the non-aqueous, lipid-based DPX delivery platform to educate a specific and persistent T cell-based immune response to 5 HLA-restricted peptides from Survivin, a cancer-associated protein commonly upregulated in several cancers. Treatment with MVP-S and intermittent, low-dose cyclophosphamide (CPA) has shown tumor infiltration of survivin-specific T cells. Previous clinical trials have shown that MVP-S is well-tolerated, immunogenic, and could lead to clinical response in several cancer indications. Further exploration of the regimen in breast cancer could extend the application of this immunotherapy for this unmet medical need. **Methods:** NCT04895761 is phase I trial evaluating the safety and immunologic effects of neoadjuvant MVP-S plus letrozole (arm A, n = 6), with/without tumor-directed MR-guided radiotherapy (arm B, n = 6), or intermittent low-dose cyclophosphamide or CPA (arm C, n = 6). Postmenopausal patients with T1c+ HR+HER2- breast cancer with Ki67 > 10% will receive two doses of MVP-S and 7 weeks of neoadjuvant letrozole prior to surgery (all arms), whereas arm B will be treated additionally with concurrent 10Gy x 2 tumor boost radiation to facilitate immunogenic cell death, and arm C (n = 6) will be treated additionally with intermittent low-dose CPA (50mg BID) to facilitate regulatory T cell depletion. The primary objective is safety. Biomarker objectives are to evaluate for each treatment arm: 1) systemic type I survivin-specific immune response, as measured by IFN-γ ELISPOT; 2) changes in immune environment by GeoMx digital spatial genomic profiling; 3) and changes in tumor infiltrating lymphocytes (TILs) and Ki67. These data will be used to identify the most immunogenic MVP-S combination therapy for study in phase II trial powered to assess clinical outcome (pCR). Clinical trial information: NCT04895761. Research Sponsor: IMV INC.

TPS1120 **Poster Session**

ARV-471, an estrogen receptor (ER) PROTAC degrader, combined with palbociclib in advanced ER+/human epidermal growth factor receptor 2–negative (HER2-) breast cancer: Phase 1b cohort (part C) of a phase 1/2 study. *First Author: Erika P. Hamilton, Sarah Cannon Research Institute/ Tennessee Oncology, Nashville, TN*

Background: ARV-471 is a novel, potent, orally bioavailable PROteolysis TArgeting Chimera (PROTAC) protein degrader that selectively targets the ER. In xenograft models, ARV-471 demonstrated substantially greater ER degradation and antitumor activity compared with the selective ER degrader fulvestrant. In the phase 1 dose escalation portion (Part A) of the first-in-human phase 1/2 study, ARV-471 monotherapy was well tolerated and showed antitumor activity in patients with ER+/HER2- locally advanced or metastatic breast cancer who had previously received endocrine therapy and a cyclin-dependent kinase (CDK)4/6 inhibitor; the clinical benefit rate (rate of confirmed complete or partial response or stable disease ≥24 weeks) was 40% (95% CI: 26%–56%) in 47 evaluable patients. The phase 2 VERITAC expansion cohort (Part B) is further evaluating ARV-471 monotherapy in this patient population. Palbociclib, a CDK4/6 inhibitor, plus fulvestrant is a standard treatment option for patients with ER+/HER2- breast cancer who have had disease progression on endocrine therapy. ARV-471 plus palbociclib resulted in substantially greater tumor growth inhibition in xenograft models compared with palbociclib plus fulvestrant, supporting further investigation of the ARV-471 plus palbociclib combination in patients with ER+ breast cancer. Here we describe Part C of the phase 1/2 study, which evaluates the safety and clinical activity of ARV-471 plus palbociclib in patients with breast cancer who previously received endocrine therapy. **Methods:** Eligible patients (aged ≥18 years) have histologically or cytologically confirmed ER+/HER2- advanced breast cancer and have received ≥1 prior endocrine therapy and ≤2 prior chemotherapy regimens for advanced disease; prior CDK4/6 inhibitor therapy is permitted. Patients with known symptomatic brain metastases requiring steroids are excluded. ARV-471 and palbociclib will be administered orally once daily in 28-day cycles; ARV-471 will be given continuously and palbociclib for 21 days followed by 7 days off treatment. Primary objectives are to evaluate the safety and tolerability of ARV-471 plus palbociclib and select the recommended phase 2 dose and schedule of the combination (based on the incidence of dose-limiting toxicities during the first cycle and the frequency and severity of adverse events and laboratory abnormalities). Secondary objectives are to assess preliminary antitumor activity of ARV-471 plus palbociclib (based on overall response rate per Response Evaluation Criteria in Solid Tumors v1.1, clinical benefit rate, progression-free survival, and duration of response) and pharmacokinetic parameters. Clinical trial information: NCT04072952. Research Sponsor: Arvinas, Inc.

TPS1121 **Poster Session**

Phase 3 ENABLAR-2 study to evaluate enobosarm and abemaciclib combination compared to estrogen-blocking agent for the second-line treatment of AR+, ER+, HER2- metastatic breast cancer in patients who previously received palbociclib and estrogen-blocking agent combination therapy. *First Author: Elgene Lim, Olivia Newton John Cancer & Wellness Centre, Heidelberg, Australia*

Background: Targeting the androgen receptor (AR) may be the next important endocrine therapy for advanced breast cancer. The AR has been demonstrated to be a tumor suppressor when activated. Enobosarm is an oral selective AR targeting agonist that activates the AR in breast cancer. Preclinical studies in CDK4/6 inhibitor resistant PDX models demonstrated combinatorial synergistic activity of enobosarm plus CDK 4/6 inhibitors. An open-label, Phase 2 study, was conducted in 136 women with heavily pretreated ER+ HER2- metastatic breast cancer that were randomized to oral daily enobosarm at a dose of 9 or 18 mg. The efficacy evaluable (EE) group were patients that were AR positive (> 10% AR nuclear staining). In the EE population with measurable disease at baseline, 10 patients had received prior endocrine therapy + a CDK 4/6 inhibitor. Subsequent treatment with enobosarm resulted in a clinical benefit rate of 50% and the best overall response rate (ORR) was 30% (2CRs and 1 PR). Of the 10 patients, 7 had AR nuclear staining ≥40%. None of the patients with AR nuclear staining < 40% responded to enobosarm. Although a small subset of the study, it appears that enobosarm has activity in patients who had ≥40% AR staining and who had progressed on standard endocrine therapy with a CDK 4/6 inhibitor. Overall, treatment with enobosarm was well tolerated with significant positive effects on quality-of-life measurements. **Methods:** The ENABLAR-2 trial is an ongoing Phase 3, randomized, open-label, efficacy and safety study in patients with AR+ ER+ HER2- MBC with AR nuclear staining of ≥40%, who have progressed after one line of systemic therapy comprising estrogen blocking agent and palbociclib. The planned sample size is 186 patients randomized 1:1 to enobosarm + abemaciclib OR fulvestrant if the first line of therapy for MBC was a non-steroidal AI plus palbociclib, until disease progression, toxicity, or loss of clinical benefit. If first line therapy for metastatic breast cancer was fulvestrant plus palbociclib, then the patient will be randomized 1:1 to either enobosarm + abemaciclib OR an AI. Randomization will be stratified by AR% nuclear staining, ≥60% versus < 60%, as well as by estrogen blocking agent such that each cohort will have the same number of subjects previously receiving fulvestrant + palbociclib in first line therapy. The key objectives are to determine the safety and efficacy of enobosarm and abemaciclib combination versus an alternative estrogen blocking agent with the primary endpoint of PFS. Secondary endpoints include ORR, duration of response, overall survival, change from baseline in Short Physical Performance Battery (SPPB), change in EORTC Quality of Life Questionnaire (EORTC-QLQ) and change in body composition as measured by DEXA. Clinical trial information: NCT05065411. Research Sponsor: Veru Inc.

TPS1122 **Poster Session**

Phase Ib/II study of BCL-2 inhibitor lisaftoclax (APG-2575) safety and tolerability when administered alone or combined with a cyclin-dependent kinase 4/6 (CDK4/6) inhibitor in patients with estrogen receptor-positive (ER^+) breast cancer or advanced solid tumors. *First Author: Kevin Kalinsky, Department of Hematology and Medical Oncology, Glenn Family Breast Center and Breast Medical Oncology, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Various cancers evade apoptosis by overexpressing BCL-2 proteins. Investigational agent lisaftoclax (APG-2575) is a novel, potent, selective BCL-2 inhibitor, while palbociclib inhibits cyclin-dependent kinases (CDK) 4 and 6. In preclinical studies, palbociclib decreased proliferation of ER^+ breast cancer cell lines by arresting them in the G1 cycle phase. Preclinical data demonstrate favorable, complementary effects of palbociclib when combined with a BCL-2 inhibitor and support this combination in patients with ER^+/ human epidermal growth factor receptor 2-negative ($HER2^-$) metastatic breast cancer. **Methods:** This global multicenter open-label dose escalation and dose expansion study is assessing the safety of lisaftoclax monotherapy in patients with histologically or cytologically confirmed advanced solid tumors that have progressed on standard therapy or when combined with CDK4/6 inhibitor palbociclib in physiologically postmenopausal women with ER^+/ $HER2^-$ metastatic breast cancer that has progressed or relapsed after treatment with a CDK4/6 inhibitor. This trial consists of 2 parts: a phase Ib dose escalation phase using a standard 3+3 design to determine the maximum tolerated dose (MTD) of lisaftoclax as a single agent in patients with solid tumors, as well as both the MTD and recommended phase 2 (RP2D) dose of lisaftoclax when combined with palbociclib in women with ER^+/ $HER2^-$ metastatic breast cancer. Phase II of this study is a signal-seeking expansion of lisaftoclax at RP2D when combined with palbociclib in women with ER^+/ $HER2^-$ metastatic breast cancer. This phase is being conducted using Simon's Minimax two-stage design. The primary objective for phase II is to determine clinical benefit response, and secondary efficacy endpoints include overall response rate, duration of response, time to response, and progression-free survival. Lisaftoclax is being administered orally once daily in a 28-day cycle at the assigned dose. Clinical trial information: NCT04946864. Research Sponsor: Ascentage Pharma Group Corp. Ltd (Hong Kong).

TPS1123 **Poster Session**

TWT-203: Phase 1b/2 dose-confirming study of CFI-402257 as a single agent in advanced solid tumors and in combination with fulvestrant in patients with ER+/HER2- advanced breast cancer after disease progression on prior CDK4/6 and endocrine therapy. *First Author: Robert Wesolowski, The Ohio State University Comprehensive Cancer Center, Division of Medical Oncology, Columbus, OH*

Background: TTK (Threonine Tyrosine Kinase also known as Monopolar spindle 1 [Mps1]), is a dual-specificity serine-threonine kinase critical for anaphase promoting complex/cyclosome inhibition at the spindle assembly checkpoint, and is required for chromosome alignment and error correction. Inhibition of TTK causes cells to prematurely exit mitosis with unattached chromosomes, resulting in aneuploidy and cell death. Higher TTK tumor levels correlate with worse prognosis and may contribute to the survival and proliferation of aneuploid cells. CFI-402257, a potent and selective inhibitor of TTK inhibits the growth of a variety of human cancer-derived cell lines with IC50 of 8-40 nM. A first-in-human phase 1 study of CFI-402257 administered orally as a single agent, demonstrated a tolerable safety profile and evidence of clinical activity in patients with advanced solid tumors. The MTD was 168 mg daily, and the study expanded to 3 cohorts: solid tumors, HER2-negative breast cancer, and hormone receptor positive (HR+/HER2-) breast cancer in combination with fulvestrant. The dose limiting toxicity was manageable and reversible dose-dependent neutropenia. Investigator-confirmed partial responses (cPR) were observed in 5 patients (10.6%) with 25 (53.2%) exhibiting disease control. In the HR+/HER2- breast cancer population previously treated with cyclin dependent kinase 4/6 inhibitors (CDK4/6i) and aromatase inhibitors, there were 4 cPR's with a median duration of response of 256 days, with responses emerging after 2 cycles of therapy. Responses were observed with CFI-402257 as a single agent and in combination with fulvestrant. Based on these data, study TWT-203 will focus on advanced solid tumors and advanced HR+/HER2- breast cancers in combination with an approved endocrine therapy. **Methods**: Safety and clinical activity of CFI-402257 monotherapy will be evaluated in patients with advanced solid tumors (Part A) or in combination with fulvestrant in patients with HR+/HER2- advanced breast cancer (Part B). Part A will confirm the RP2D using a 3+3 design with a starting dose of 126 mg daily. Part B evaluates CFI-402257 in combination with fulvestrant in patients with HR+/HER2- advanced breast cancer following progression on prior CDK4/6i and endocrine therapy. Initially 6 patients will be treated with CFI-402257 and fulvestrant, and safety, tolerability, and PK evaluated, with further expansion to confirm the RP2D and characterize CFI-402257 activity. Efficacy endpoints include overall response rate and disease control rate. Safety endpoints include incidence of treatment emergent adverse events. Exploratory objectives include characterization of protein and molecular alterations relevant to the cell cycle and CFI-402257 response. Research Sponsor: Treadwell Therapeutics.

TPS1124 **Poster Session**

First-in-human global multi-center study of RLY-2608, a pan-mutant and isoform-selective PI3Kα inhibitor, as a single agent in patients with advanced solid tumors and in combination with fulvestrant in patients with advanced breast cancer. *First Author: Cesar Augusto Perez, Sarah Cannon Research Institute at Florida Cancer Specialists, Orlando, FL*

Background: Targeting constitutively active mutant kinases with selective small molecule inhibitors is a key therapeutic pillar of precision oncology. *Phosphatidylinositol-4,5bisphosphate-3 kinase, catalytic subunit alpha* (*PIK3CA*) mutations leading to oncogenic activation of PI3Kα represent the largest opportunity for this approach in solid tumors. However, there is no selective inhibitor that targets mutant PI3Kα in the clinic. Toxicity related to non-selective inhibition of WT PI3Kα (hyperglycemia) and other PI3K isoforms limits the tolerability, dosing and efficacy of the orthosteric inhibitor, alpelisib, the only approved solid tumor PI3K inhibitor. RLY-2608, a novel oral allosteric PI3Kα inhibitor, is uniquely designed to overcome these limitations via mutant- and isoform-selective PI3Kα inhibition for greater target coverage, improved tolerability and antitumor activity. We initiated a first-in-human (FIH), study to evaluate the clinical activity of RLY-2608 as a single agent in advanced solid tumor patients (pts) with *PI3KCA* mutations and in combination with fulvestrant in pts with *PIK3CA*mutant, HR+, HER2- metastatic breast cancer (MBC). **Methods:** This is a global, multi-center, dose escalation/expansion study (NCT05216432) of RLY2608 as a single agent in adults who have advanced solid tumors and are refractory, intolerant, or declined standard therapy and RLY-2608 in combination with fulvestrant in previously treated pts with HR+/HER2- MBC. Eligibility criteria include presence of *PI3KCA* mutation (blood or tumor) per local assessment, ECOG performance status 0-1, measurable or evaluable disease per RECIST 1.1 and no prior PI3K inhibitor (except combination group 2). RLY-2608 is administered on a continuous schedule with 4-week cycles. Adverse events (AEs) per CTCAE v5, PK, biomarkers (mutant ctDNAs and insulin pathway markers) and anti-tumor activity are assessed serially. Dose escalation employs a Bayesian Optimal Interval design to identify MTD and RP2D. Following dose escalation, pts will be treated with RLY-2608 at the MTD/RP2D in a monotherapy dose expansion with 5 groups (N = 75, 15 each): 1. Clear cell ovarian carcinoma 2. Head and neck squamous cell carcinoma 3. Cervical cancer 4. Other solid tumors 5. *PI3KCA* double mutations. In addition, two expansion cohorts will enroll patients with HR+/HER2- MBC treated with RLY-2608 and fulvestrant combination (N = 30, 15 each): 1. No prior PI3K therapy 2. Intolerant to PI3K inhibitors. The primary endpoints are MTD/RP2D and AE profile for single agent and combination; key secondary endpoints are *PI3KCA* genotype in blood and tumor, PK, biomarkers, and overall response rate. US enrollment began December 2021 and ex-USA startup is underway. Clinical trial information: NCT05216432. Research Sponsor: Relay Therapeutics.

TPS1125 **Poster Session**

Phase I trial of an alpha-lactalbumin vaccine in patients with moderate- to high-risk operable triple-negative breast cancer (TNBC). *First Author: George Thomas Budd, Department of Hematology/Oncology, Cleveland Clinic, Cleveland, OH*

Background: Triple-negative breast cancer (TNBC) is the subtype of breast cancer with the worst prognosis and is the subtype most often associated with germline mutations of BRCA1 and certain other genes. Alpha-lactalbumin (aLA) is a milk protein that is expressed in lactating breasts but not at other times or in other normal tissues. Expression of aLA is found in approximately 70% of TNBC (Cancers PMID: 27322324) so is an attractive immunologic target for TNBC based on the "retired protein hypothesis" (Semin Immunol PMID: 31926646). Pre-clinical studies have shown that vaccination with aLA provides treatment of established and, more potently, protection from development of autochthonous tumors in transgenic murine models of breast cancer and against 4T1 transplantable breast cancer in BALB/c mice (Nat Med PMID: 20512124). We are conducting a Phase I trial in patients with early stage TNBC to demonstrate the safety of this approach and to document the ability to produce a meaningful immunologic response to aLA. **Methods:** Patients with ER-negative, PR-negative, HER2-negative breast cancer of pathologic stage I-III or who had residual disease after standard pre-operative systemic therapy are being entered into a Phase I trial of alpha-lactalbumin with a GMP-grade zymosan adjuvant in Montanide ISA 51 VG vehicle. Participants must be within 3 years of initiation of treatment and have no evidence of recurrence. Patients receive a total of 3 vaccinations administered once every 2 weeks with doses escalated using a 3+3 trial design. Toxic events of Common Terminology Criteria for Adverse Events (CTCAE) grade 2 or greater are considered dose-limiting. Dose levels being tested are alpha-lactalbumin/zymosan 0.01 mg/0.01 mg, 0.1 mg/0.1 mg, and 1 mg/1 mg. Patients are being monitored for toxicity until 84 days after the first vaccination or resolution of toxicity, whichever is later. Blood is being drawn prior to therapy and 14, 28, and 56 days after the first vaccination to assess cellular response using enzyme-linked immunosorbent spot (ELISpot) assays of interferon-gamma and interleukin-17 production in response to aLA. Humoral response to aLA vaccination is being assessed by enzyme-linked immunosorbent assay (ELISA). After identification of the Maximum Tolerated Dose we will expand the dose levels associated with effective tumor immunity and enroll a cohort of patients without cancer planning to undergo prophylactic bilateral mastectomy. Funding Source: Department of Defense (W81XWH-17-1-0592 and W81XWH-17-1-0593). Clinical trial information: NCT04674306. Research Sponsor: Department of Defense.

TPS1126 **Poster Session**

Phase 1 pilot study with dose expansion of chemotherapy in combination with CD40 agonist and Flt3 ligand in metastatic triple-negative breast cancer. *First Author: Sangeetha M. Reddy, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Only a subset of patients with metastatic triple-negative breast cancer demonstrate response to currently approved PD-1 immune checkpoint blockade, and few have durable responses. Antigen presentation defects may be a reason for this low response because deficiency of antigen-presenting DC1 dendritic cells is associated with poor anti-tumor immunity. CD40 agonists are a class of agents that activate antigen presenting cells including dendritic cells and B cells and also repolarize macrophages. Flt3 ligand is a growth factor that increases dendritic cells. In line with this, we recently demonstrated in pre-clinical models that the combination of liposomal-doxorubicin chemotherapy, a CD40 agonist, and a Flt3 ligand improves outcomes of breast cancer compared to alternate combinations. **Methods:** This is a single arm phase I pilot study of liposomal-doxorubicin, CDX-1140 (CD40 agonist), and CDX-301 (Flt3 ligand) combination therapy in patients with metastatic or unresectable locally advanced metastatic triple-negative breast cancer. Patients will be randomized to 3 lead-in arms (triplet therapy, doublet immunotherapy only, liposomal-doxorubicin only) prior to receiving full triplet therapy with fresh tissue biopsies before and after the lead-in treatment. CDX-301 will be discontinued after 2 cycles; liposomal-doxorubicin and CDX-1140 will be continued until disease progression or clinically limiting toxicities. Primary endpoint is determination of a recommended phase 2 dose based on treatment-related adverse events including dose-limiting toxicities. Secondary endpoints include anti-tumor immune response after triplet therapy, after immunotherapy alone, and after liposomal-doxorubicin alone; median progression-free survival, overall response rate, duration of response, and clinical benefit rate. Key eligibility criteria are unresectable stage III or stage IV triple-negative breast cancer (ER ≤10%, PR ≤10%, HER2/neu negative), 1st to 3rd line metastatic treatment setting (1st line patients need to be PD-L1 negative by 22C3 assay), measurable disease by RECIST 1.1 criteria, consent for pre-treatment and on-treatment biopsies of amenable soft tissue tumor lesions, no prior treatment with an anti-CD40 antibody or a Flt3 ligand, no anthracycline treatment in the metastatic setting, no prior progression while on anthracycline-based therapy or within 6 months of completing neoadjuvant chemotherapy, and no history of non-infectious pneumonitis or current pneumonitis. This trial will enroll up to 45 patients across multiple sites. Clinical trial information: NCT05029999. Research Sponsor: Celldex Therapeutics, Other Foundation.

TPS1127 **Poster Session**

Phase 1b/2 study of ladiratuzumab vedotin (LV) in combination with pembrolizumab for first-line treatment of triple-negative breast cancer (SGNLVA-002, trial in progress). *First Author: Jane Lowe Meisel, Winship Cancer Institute, Atlanta, GA*

Background: Patients with metastatic triple-negative breast cancer (mTNBC) have a poor prognosis. Treatment combinations of anti-programmed death ligand 1 (anti–PD-L1) agents with chemotherapy have shown promise in mTNBC. LV is an investigational antibody–drug conjugate directed to LIV-1, a protein highly expressed on breast cancer cells, via a humanized IgG1 monoclonal antibody conjugated to monomethyl auristatin E (MMAE) by a protease-cleavable linker. LIV-1–mediated delivery of MMAE disrupts microtubules and induces cell cycle arrest and apoptosis. LV has also been shown to drive immunogenic cell death (ICD) to elicit an immune response. LV + pembrolizumab may result in synergistic activity through LV-induced ICD, creating a microenvironment favorable for enhanced anti–PD-L1 activity. Preliminary results show LV delivered once every 3 weeks (Q3W) + pembrolizumab was tolerable with encouraging antitumor activity in patients with mTNBC (Han 2019). Additionally, interim results of weekly LV monotherapy at doses up to 1.5 mg/kg were clinically active and generally well tolerated (Tsai 2021). Based on pharmacokinetic and pharmacodynamic modeling and simulation analysis, an intermittent LV + pembrolizumab dosing regimen is being evaluated to further enhance efficacy and improve the tolerability profile. Due to an unmet medical need for patients with mTNBC who are PD-L1 low or negative, Part D will focus on this patient population. **Methods:** SGNLVA-002 (NCT03310957) is an ongoing global single-arm, open-label phase 1b/2 study of LV + pembrolizumab as 1L therapy for patients with unresectable locally advanced/mTNBC. Part D is currently enrolling ~40 patients. Eligible patients must have advanced disease with no prior cytotoxic/anti–PD-L1 treatment, PD-L1 combined positive score < 10, measurable disease per RECIST v1.1 and an ECOG score ≤1. Patients with Grade ≥2 pre-existing neuropathy or active central nervous system metastases are not permitted. Patients will receive LV at 1.5 mg/kg on Days 1 and 8 plus pembrolizumab 200 mg on Day 1 Q3W. The primary objectives are to evaluate the safety/tolerability and objective response rate of LV + pembrolizumab. Secondary objectives include duration of response, disease control rate, progression-free survival, and overall survival. Safety and efficacy endpoints will be summarized with descriptive statistics. Global enrollment is ongoing in the US, EU, and Asia. Clinical trial information: NCT03310957. Research Sponsor: Seagen Inc.

TPS1128 **Poster Session**

A phase I/II trial evaluating the safety and efficacy of eribulin in combination with copanlisib in patients with metastatic triple-negative breast cancer (TNBC). *First Author: Nusayba Ali Bagegni, Washington University in St. Louis School of Medicine, St. Louis, MO*

Background: Metastatic (met) TNBC remains a clinical challenge with limited treatment options and inevitable chemoresistance. Aberrant PI3K pathway signaling is frequently observed in TNBC. Increasing evidence shows PI3K pathway activation maintains the stemness and chemoresistance of BC stem cells (CSCs), and PI3K inhibition sensitizes CSCs to chemotherapy (chemo). Eribulin (E), a non-taxane microtubule dynamics inhibitor, showed survival benefit in met HER2 negative BC. Preclinically, E impacts tumor vascular remodeling, inhibits epithelial-to-mesenchymal transition and metastasis – key mechanisms implicated in PI3K inhibition resistance. Copanlisib (C), a potent pan-class I PI3K inhibitor (*i*), improved anti-tumor effect in E-sensitive and resistant TNBC patient-derived xenograft models, irrespective of PIK3CA/PTEN mutation (mut) status, when combined with E. This phase I/II study is aimed to determine the safety and efficacy of E+C in pts with met TNBC. **Methods:** This trial includes a phase I portion with the primary objective to determine the dose limiting toxicity (DLT) and recommended phase 2 dose (RP2D) of E+C, followed by a phase II randomized portion of E+C (at RP2D) versus (*vs*) E with the primary objective of progression-free survival (PFS). Key secondary objectives include objective response rate (ORR) and clinical benefit rate (CBR) [phase I]; and ORR and CBR, by arm and by PIK3CA/PTEN mut status and assessment of treatment induced target engagement [phase II]. Key exploratory objectives include analysis of genomic, proteomic and metabolomic changes as potential response biomarkers in tumor tissue and blood. Key eligibility criteria include pts with: met TNBC who progressed on ≤5 chemo lines, including anthracycline/taxane (unless contraindicated), ECOG 0-1, adequate organ function and known archival tumor PIK3CA/PTEN mut status. Key exclusions: prior E or PI3K/mTOR/AKT*i*, grade ≥2 neuropathy, tumor AKT mut, congenital QT prolongation, and uncontrolled diabetes or hypertension. Phase I portion will follow a 3+3 design for E+C dose escalation to enroll 18 max pts, starting at E 1.1 mg/m^2 IV and C 45 mg IV on days (D) 1/8 of 21-D cycle (C) (to E 1.4 mg/m^2 and C 60 mg max). RP2D will be defined as the highest dose level at which at most 1 of 6 pts experience DLT during C1. 88 pts will be randomized (1:1) in the phase II portion to E+C *vs* E (1.4 mg/m^2 D 1/8), stratified by PTEN/PIK3CA mut status. Response assessment by Response Evaluation Criteria in solid tumors (RECIST) v1.1 will occur every 9 weeks (+/-7 D). Tumor biopsy is required at baseline and C2D1-2, and optional at progression. A sample size of 88 achieves 80% power to detect PFS difference of median PFS 6.95 *vs* 4 months (corresponding to a hazard ratio of 0.5755) between the 2 arms, based on 1-sided two-sample log rank test at 0.1 α level. The phase I study is actively enrolling pts. Clinical trial information: NCT04345913. Research Sponsor: U.S. National Institutes of Health.

TPS1129 **Poster Session**

Evaluation of a three-part equity intervention for women of color with breast cancer. *First Author: Jamil Rivers, The Chrysalis Initiative, Philadelphia, PA*

Background: Women of color (WOC) with breast cancer miss and fail key points in care due to racial disparities in cancer services. Conscious and unconscious bias means that these women are not treated in a timely way or as rigorously. They are offered fewer options, and the patient navigation and education needed for them to self-advocate is ignored. Black women in particular have the highest breast cancer death rates. Care delivery differs even independent of such variables as literacy, income, and education. Separately and incrementally, findings to date have shown the potential oof patient navigation, equity assessment, and mobile support to reverse these disparities. In pilot investigations — partnering with academic cancer centers — The Chrysalis Initiative (a nonprofit patient advocacy and research organization) has validated the potential of combining these approaches in a three-part intervention. Based on preliminary work, it is hypothesized patients will: experience significantly greater adherence to the recommended continuum of care, without disruption or barriers; more often seek second opinions and additional supportive resources, and engage in clinical trials; demonstrate less co-morbidities, through more preventive measures and healthful lifestyle; suffer fewer interactions perceived to be influenced by racism; undergo less financial distress, with guidance on managing and planning costs; feel more confident and more optimistic in their outlook; and achieve better clinical results and lower costs. **Methods:** To determine and document the full impact, both quantitatively and qualitatively, of the experimental three-part intervention, the trial is: delivering navigation/coaching services to the study population, using counselors who are predominantly WOC who have experienced the challenges of breast cancer care. Surveys and interviews pre- and post-intervention will add to impact measures; providing the experimental group with the BC Navi App on both iOS and Android devices. Developed in partnership with InTouch, the app supports engagement and tracking. It provides a dashboard for care evaluation to supplement EMR data; conducting an equity assessment of breast cancer services of partnering clinical programs through use of focus groups with staff, patients, and community; procedural checks; and data collection from center EHR systems. The review audits 40 domains of care based on NCCI, NCI, ASCO, ACR, and other standards. The assessment team works closely and collaboratively with each cancer center's clinical and administrative staff to reveal disparities and find consensus on ways to close gaps. This trial in progress is randomizing 200 subjects to the coaching/mobile app intervention arm and 100 to benefits of the equity assessment only, with comparison to nonWOC with breast cancer. The trial aims to disseminate the three-part intervention in easily reproducible form. Research Sponsor: Pfizer (in partnership with MD Anderson - Cooper), Conquer Cancer Foundation of the American Society of Clinical Oncology.

TPS1130 **Poster Session**

Phase I/II first-in-human CAR T–targeting MUC1 transmembrane cleavage product (MUC1*) in patients with metastatic breast cancer. *First Author: Cynthia Carol Bamdad, Minerva Biotechnologies, Waltham, MA*

Background: Metastatic breast cancer (MBC) remains incurable and novel immunotherapy for durable response remains an unmet need. Chimeric antigen receptor (CAR) T-cell therapy, an innovative form of immunotherapy wherein autologous T-cells are genetically modified to target tumor specific cell-surface markers, has been developed for treatment of solid tumors. huMNC2-CAR44 recognizes the growth factor receptor form of MUC1, which is the transmembrane cleavage product called MUC1*. MUC1* is a Class I growth factor receptor that is activated by ligand-induced dimerization of its truncated extra cellular domain, which activates the MAP kinase signaling pathway as well as survival pathways. Onco-embryonic growth factor $NME7_{AB}$ binds to an ectopic site on MUC1* that is only unmasked after MUC1 is cleaved and the tandem repeat domain is shed from the cell surface. The targeting head of the CAR, huMNC2, competes with $NME7_{AB}$ for binding to this ectopic site. huMNC2 does not bind to full-length MUC1, hence highly tumor-selective. 70% of solid tumor cancers express a huMNC2 reactive MUC1* and huMNC2-scFv bound robustly to 93% of the breast cancers with minimal staining of normal tissues. huMNC2-CAR44 T cells completely obliterated a variety of MUC1* positive solid tumors in NSG mice in vivo. IND enabling animal studies demonstrated that huMNC2-CAR44 T potently inhibited MUC1* positive tumors xenografted into female NSG mice, whether the tumor cells were MUC1 negative cells stably transduced with MUC1* or breast cancer cells such as T47D that naturally express MUC1*. In one study, huMNC2-CAR44 T treated mice survived tumor-free for over 12 weeks, whereas control group had to be sacrificed at 3 weeks due to disease progression. **Methods:** This is a first-in human, phase I/II trial evaluating the safety and efficacy of huMNC2-CAR44 T in patients with MBC. Key inclusion criteria include age ≥18 years, ECOGPS 0-1, available FFPE tumor sample, tumor IHC ≥30% MUC1* and preserved organ function. Dose escalation is standard 3+3 design with dosing levels ranging from 3.3x10^5 to 1.0x10^7 CAR+ cells/kg, and fludarabine/cyclophosphamide lymphodepletion pre-treatment. Phase I accepts patients with MBC that has progressed through at least 3 previous lines of therapy. The primary objective of Phase I is to determine safety and determine a recommended Phase II dose (RPIID), with the exploratory objectives of assessing CAR T cell expansion, persistence, tumor penetration and potential tumor escape. Six (6) patients have been enrolled and five (5) patients have been treated to date. Phase II will be comprised of 3 cohorts of 15 patients in each arm of luminal, HER2+ and triple negative breast cancers for a total of 45 patients in Phase II. Clinical trial information: NCT04020575. Research Sponsor: Minerva Biotechnologies.

Changes in cancer mortality by race and ethnicity following the Affordable Care Act implementation in California. *First Author: Elena Martinez, University of California San Diego Wertheim School of Public Health, La Jolla, CA*

Background: Implementation of the Affordable Care Act (ACA) has resulted in improvements in cancer outcomes but the extent to which these apply to specific racial and ethnic populations is unknown. We examined changes in health insurance distributions pre- and post-ACA and assessed cancer-specific mortality rates by race and ethnicity. **Methods:** The population included 167,181 newly diagnosed breast (n = 117,738), colorectal (n = 38,334), and cervix cancer (n = 11,109) patients younger than 65 years and 141,026 patients 65 years or older in the California Cancer Registry. Hazard rate ratios (HRRs) and 95% confidence intervals (CIs) were calculated using multivariable Cox regression to estimate associations with risk of 5-year cancer-specific death for each cancer site pre- (2007-2010) and post-ACA (2014-2017), and by race and ethnicity (American Indian/Alaska Natives, AIAN; Asian Americans; Hispanics; Native Hawaiian/Pacific Islanders, NHPI; non-Hispanic Blacks, NHB; and non-Hispanic whites, NHW). Difference-in-difference analysis was conducted to compare changes over time between younger (< 65 years) and older (65 years and older) patients. **Results:** Cancer-specific mortality for patients age < 65 was significantly lower post- vs. pre-ACA for colorectal cancer among Hispanic (HRR = 0.83; 95% CI: 0.74-0.93), NHB (HRR = 0.69; 95% CI: 0.58-0.81), and NHW (HRR = 0.90 95% CI: 0.84-0.97) but not Asian American (HRR = 0.95; 95% CI: 0.82-1.10) patients. The HRR for younger NHB colorectal cancer patients was significantly lower than that for patients 65 years of and older (HRR = 1.09; 95% CI, 0.95-1.25, p-interaction < 0.0001). A significantly lower risk of dying from cervix cancer was observed in the post- vs. pre-ACA period among younger NHB women (HRR = 0.68; 95% CI: 0.47-0.99), but this was not significantly different than that for older women (HRR = 0.41; 95% CI, 0.16-1.01, p-interaction = 0.30). No significant differences in breast cancer-specific mortality were observed for any racial or ethnic group. **Conclusions:** Findings show decreases in cancer-specific mortality for colorectal and cervix cancers for some racial and ethnic groups following ACA implementation in California. These results shed light on ongoing discussions as additional states consider Medicaid expansion. Future studies should assess shifts between health insurance plans resulting from the economic impact of the 2019 novel coronavirus (COVID-19) pandemic. Research Sponsor: U.S. National Institutes of Health.

1501 **Oral Abstract Session**

Association between state Medicaid policies and accrual of Black participants to cancer clinical trials. *First Author: Samuel U Takvorian, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: Black individuals remain underrepresented in U.S. cancer clinical trials, partly due to financial barriers to participation. While coverage of the routine costs of trial participation has long been mandatory for Medicare and the commercially insured, only 16 states have enacted similar mandates for Medicaid enrollees. Given the disproportionate representation of Black individuals in state Medicaid programs, we hypothesized that such mandates may have led to improved accrual of Black participants to cancer clinical trials. **Methods:** We conducted a retrospective, quasi-experimental study using de-identified data from the ECOG-ACRIN Cancer Research Group to evaluate changes in the accrual of Black participants to cancer clinical trials associated with state-mandated Medicaid coverage of routine trial costs. The study population included non-elderly adults enrolled in therapeutic clinical trials for breast, colorectal, lung, or prostate cancer from 2000-2019. We employed a difference-in-differences approach with event-study specification to compare outcomes in states that mandated Medicaid coverage of routine trial costs relative to states that did not, before and after mandates were enacted. Outcomes included the proportion of trial participants who had Medicaid insurance (vs. non-Medicaid) and the proportion who were Black (vs. non-Black). Models adjusted for age, sex, cancer type, cancer stage, study phase, and study site (community vs. academic). **Results:** Among 24,321 trial participants (mean age 52.0 [SD 8.2] years, 82.8% female), 7.2% had Medicaid coverage and 10.5% were Black. Compared to states without Medicaid coverage mandates, states with mandates had a statistically significant increase in the proportion of Black trial participants in the first year following the mandate (+6.4 percentage points [95%CI 1.8% to 11.0%]) but not in subsequent years. There was no association between state mandates and the proportion of trial participants enrolled in Medicaid (effects ranged from -0.7 percentage points [95%CI -4.6% to 3.3%] in the first year after mandates to -3.9% [95%CI -8.6% to 0.8%] in the third year). **Conclusions:** State-mandated Medicaid coverage of the routine costs of trial participation was associated with a short-term increase in the proportion of Black trial participants. These findings suggest that Medicaid policies have the potential to improve representation of racial minority groups in cancer clinical trials, and support recent federal legislation mandating state Medicaid programs to cover trial participation costs as of January 2022. Our study was limited by use of data from only one large cancer research group, focus on only four common cancers, and limited power to analyze the policy impact for other racial and ethnic minority groups. Additional work is needed to replicate these findings in larger cohorts of trial participants. 1502 **Oral Abstract Session**

Association between the Affordable Care Act Medicaid expansion and survival in young adults newly diagnosed with cancer. *First Author: Xu Ji, Emory University and Children's Healthcare of Atlanta, Atlanta, GA*

Background: Medicaid expansion through the Affordable Care Act (ACA), implemented by 26 states in January 2014 and 13 more states in later years, has been shown to improve insurance coverage and early diagnosis of cancer in young adults (YAs). Little is known about whether these improvements translate to a survival benefit in this population. We evaluated the association between the ACA Medicaid expansion and 2-year overall survival among YAs newly diagnosed with cancer. **Methods:** Using the National Cancer Database, we identified 345,414 YAs aged 18-39 years diagnosed with cancer between 2010 and 2017. YAs diagnosed pre-expansion were followed through September 30, 2013 or three months before Medicaid expansion implementation for late-expansion states, and YAs diagnosed post-expansion were followed through December 31, 2019. We applied the difference-in-difference (DD) method to estimate changes in 2-year overall survival before and after Medicaid expansion, in expansion- versus non-expansion states, controlling for key sociodemographic factors. DD analyses were performed for YAs overall, and stratified by cancer type, stage at diagnosis, race/ethnicity, comorbidity, and facility type. **Results:** Among all YAs, 2-year overall survival increased more in expansion states (90.39% pre-expansion to 91.87% post-expansion) than in non-expansion states (88.98% pre-expansion to 90.05% post-expansion), resulting in a net increase of 0.53 percentage points (ppt; 95% confidence interval [CI] = 0.11 to 0.95 ppt). The increase in 2-year overall survival in expansion states versus non-expansion states was greatest among subgroups of patients with female breast cancer (DD = 1.20 ppt; 95% CI = 0.28 to 2.13 ppt) and patients with stage IV disease at diagnosis (DD = 2.51 ppt; 95% CI = 0.28 to 4.74 ppt). Additionally, greater improvement in 2-year overall survival associated with the expansion was seen among racial/ethnic minority YAs (including Hispanic, non-Hispanic Black, and non-Hispanic others; DD = 0.98 ppt; 95% CI = 0.10 to 1.86 ppt) than their non-Hispanic White peers (DD = 0.41 ppt; 95% CI = -0.06 to 0.89 ppt), among patients treated in community cancer programs (DD = 1.10 ppt; 95% CI = 0.32 to 1.88 ppt) than academic comprehensive cancer programs (DD = 0.12 ppt; 95% CI = -0.52 to 0.77 ppt), and among patients with two or more comorbidities (DD = 6.37 ppt; 95% CI = 0.68 to 12.06 ppt) than patients with no comorbidity (DD = 0.48 ppt; 95% CI = 0.04 to 0.91 ppt). **Conclusions:** We provide the first evidence on the association between ACA Medicaid expansion and improved overall survival among YAs newly diagnosed with cancer. Survival benefits are notable among racial/ethnic minority patients and patients with high healthcare needs, and by patients' treatment facility type. Research Sponsor: U.S. National Institutes of Health.

Impact of oncology clinical pharmacist intervention on clinical trial enrollment in The U.S. Oncology Network's MYLUNG Consortium. *First Author: Elizabeth Koselke, McKesson / US Oncology Network, The Woodlands, TX*

Background: The Molecularly Informed Lung Cancer Treatment in a Community Cancer Network: A Pragmatic Consortium (MYLUNG) clinical trial platform aims to advance the use of precision medicine in non-small cell lung cancer patients through a series of prospective and iterative clinic trials. "Protocol 2" is evaluating the patient and tissue journey of newly diagnosed lung cancer patients presenting for care. Timely patient accrual to oncology clinical trials is a known practice challenge. The US Oncology Network recently implemented a clinical pharmacist (ClinReview) to provide remote clinical services to support Protocol 2 enrollment. **Methods:** An oncology-trained clinical pharmacist remotely reviewed chemotherapy regimen orders and a weekly custom recruitment report within six community network practices (n = 149 physicians). The ClinReview pharmacist identified, screened, and assisted with recruitment of eligible patients for enrollment in the MYLUNG study. Relevant and concise patient data were provided to the on-site research team to facilitate ease of enrollment. Enrollments and intervention data were tracked to monitor the impact of the pharmacist intervention. The primary outcome of monthly enrollment was evaluated using a paired t-test. **Results:** Over a 6-month period, the ClinReview pharmacist screened 367 potentially eligible patients, 325 patients were recommended for enrollment, and 103 patients (32%) were consented and enrolled. Enrollment due to this ClinReview intervention increased monthly and ranged from 5 in first month to 33 enrollments in month 6. Average monthly enrollment was significantly greater after ClinReview intervention (3.4 patients/month vs. 6.8 patients/month; p = 0.008). Of the 154 patients recommended for enrollment that were not enrolled, 104 (68%) exceeded their eligibility window allowed by the trial, 15 (10%) were deceased or enrolled into hospice care, 10 (6%) declined trial participation, and 25 (16%) transferred care or were treated at outside facilities. **Conclusions:** We demonstrate that incorporation of an oncology clinical pharmacist in clinical research teams significantly enhanced clinical trial enrollment. The remote pharmacist easily adapted into clinic workflows in community practices. Validation across a broader spectrum of differentially resourced oncology practices will be conducted as the MYLUNG clinical trials platform is executed. Research Sponsor: Amgen, AstraZeneca, Eli Lilly, Genentech, Mirati.

Average monthly patient enrollment by practice, before and with ClinReview intervention.

	Average enrollment before ClinReview intervention	Average monthly enrollment with ClinReview	Change after intervention (%)
Practice 1	2.2	6.0	177%
Practice 2	3.4	6.8	101%
Practice 3	0.7	1.7	150%
Practice 4	3.4	10.0	194%
Practice 5	5.8	7.5	30%
Practice 6	4.8	8.5	78%
Total	3.4	6.8*	101%

Operational metrics for the ELAINE II study combining a traditional approach with a just-in-time model. *First Author: Sibel Blau, Rainier Hematology Oncology/Northwest Medical Specialties, Seattle, WA*

Background: Trial recruitment that requires specific actionable mutations based on next-generation sequencing (NGS) is challenging. Barriers can include competing studies, physician study awareness, site proximity, mutation incidence, among other concerns. **Methods:** This study (NCT04432454) opened clinical sites using two methods during the COVID-19 pandemic. The "Traditional" approach included site selection, IRB and contract approval, and trial activation prior to a patient being identified for enrollment. The second approach used the Tempus "TIME" Trials network that would only open a site after identifying a patient with a mutation of interest and eligible for the trial. **Results:** The first patient enrolled was on 10/12/20 and the last patient was on 6/24/21. A total of 16 sites (6 Traditional and 10 TIME) participated. All Traditional sites, and none of the TIME sites, were affiliated with major academic institutions. Duration for full CTA execution for Traditional sites averaged 200.5 days (range 142 to 257) and for TIME sites averaged 7.6 days (range 2 to 14). IRB approval time average for Traditional sites was 27.5 days (range 12 to 71) and TIME sites was 3.0 days (range 1 to 12 days). Days from site selection to activation letter for Traditional sites was on average 250.0 days (range 187 to 281) and for TIME sites was 131.6 days (range 22 to 248). Time from study activation to first consent was 33.3 days (range 18 to 58) for Traditional sites and 8.8 days (range 1 to 35) for TIME sites. The first patient on-study was at a TIME site 115 days prior to a Traditional site and the first 7 patients enrolled were at TIME sites. Traditional sites consented 23 and enrolled 16 patients while the TIME sites consented 16 and enrolled 13. The trial enrolled all 29 patients in 8 months with the anticipated enrollment duration being 12 to 18 months. **Conclusions:** Although the Traditional and TIME programs had different operational models, they both contributed a significant number of patients and reduced the projected enrollment timeline. TIME sites enrolled the initial patients. These results demonstrate that the "Just-in-Time model," in conjunction with a Traditional model, can reduce projected overall time to enrollment in biomarker-driven studies. Research Sponsor: Sermonix Pharmaceuticals.

Number of patients enrolled at clinical sites by month.

	TIME	Traditional	Total
October 2020	2	0	2
November 2020	3	0	5
December 2020	0	0	5
January 2021	2	0	7
February 2021	1	2	10
March 2021	1	4	15
April 2021	0	4	19
May 2021	0	3	22
June 2021	4	3	29

1505 **Oral Abstract Session**

Impact of broadening trial eligibility criteria on the inclusion of patients with brain metastases in cancer clinical trials. *First Author: Joseph M. Unger, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: On October 2, 2017, the American Society of Clinical Oncology, Friends of Cancer Research, and the U.S. Food and Drug Administration (ASCO/FoCR/FDA) issued a joint research statement recommending that certain eligibility criteria in cancer clinical trials, including those related to brain metastases, be broadened to make trials more inclusive. We examined whether patterns of exclusions regarding patients with brain metastases changed over time in relation to these recommendations. **Methods:** We used data from ClinicalTrials.gov to evaluate patterns of trial eligibility criteria in phase I-III U.S.-based interventional clinical trials for patients with advanced breast, colorectal, or lung cancers from January 2013 through October 2021. Trial inclusion and exclusion criteria were abstracted; to enhance validity, reviewers were blinded to the year of trial activation. For each trial, we determined whether patients with brain metastases were not excluded, conditionally excluded (i.e., excluded in some circumstances), or wholly excluded. Trial registrations between October 2, 2017-December 31, 2018 were excluded to allow 1 year for newly conceived trials to adopt the recommendations, plus 3 months to account for the lag time between loading trial records and trial activation dates; thus, the independent exposure variable was January 1, 2019. An interrupted time series analysis with multinomial logistic regression was used to assess whether the ASCO/FoCR/FDA recommendations were associated with changes in brain metastases eligibility criteria. **Results:** We evaluated N = 1998 trials. Patients with brain metastases were not excluded in 307 trials (15.4%); conditionally excluded in 1459 trials (74.8%); and wholly excluded in 196 trials (9.8%). In the post-recommendation period, we found a 92% increase in the odds of trials with brain metastases not excluded compared to conditionally excluded (OR = 1.92, 95% CI, 1.08-3.45, p = .03). The estimated proportion of trials in which patients with brain metastases were not excluded increased from 9.2% had the recommendations not been made to 15.6% (p = .04). Conversely, the proportion of trials in which patients with brain metastases were conditionally excluded (76.9%) was lower than expected (85.3%, p = .02). We found no difference in the proportion of trials in which patients with brain metastases were wholly excluded (7.5% vs. 5.4%, p = .28). **Conclusions:** The ASCO/FoCR/FDA recommendations were associated with a shift in patterns of brain metastases exclusion criteria from conditionally excluded to not excluded. To our knowledge, this is the first evidence that cancer clinical trials have become more inclusive of a broader set of patients in response to the ASCO/FoCR/FDA recommendations. More inclusive eligibility improves trial access and representativeness, increasing trial validity and the pace at which trials enroll. Research Sponsor: Public Health Sciences Division of the Fred Hutchinson Cancer Research Center.

1506 **Oral Abstract Session**

Remote patient-reported symptoms and passive activity monitoring to improve patient-clinician communication regarding symptoms and functional status: A randomized controlled trial (PROStep). *First Author: Christopher Manz, Dana Farber Cancer Institute, Boston, MA*

Background: Oncologists suboptimally assess patient symptoms and functional status, possibly leading to poor symptom management or over-treatment. Remote patient-reported symptoms and passive activity monitoring may provide objective measures of symptoms and functional status to improve patient-clinician communication and symptom understanding. We assessed the impact of a clinician-centered dashboard of longitudinal patient-reported symptoms and step counts on patient-clinician communication regarding symptoms and functional status. **Methods:** This randomized trial enrolled 108 patients with incurable GI or lung cancers treated with chemotherapy at a large academic health center. Patients were randomized to either of Arms A) control, B) weekly patient-reported symptoms via text message + step tracking from a wearable activity monitor, with summary dashboards given to clinicians at each visit, or C) arm B plus text message-based prompts to patients encouraging discussion of symptoms and functional status prior to each visit. We used Kruskal Wallis tests to compare co-primary outcomes (patient-reported perceptions of clinician symptom and functional status understanding at 6 months after enrollment) between control (A) and intervention (B+C) arms on a 5-point scale (1 = Not at all; 2 = Slightly; 3 = Moderately; 4 = Considerably; 5 = Completely). **Results:** 33, 37, and 38 patients were enrolled in arms A, B, and C, respectively. Patients were 54.6% male, mean age was 58.9 years, 77% had GI cancer, and 23% had lung cancer. At six months, there was no difference between control and intervention arms in patient perception of clinician understanding of symptoms (Arm A: 4.5, Arm B/C: 4.5, p = 0.85) or functional status (Arm A: 4.5, Arm B/C: 4.3, p = 0.59). Patients reported that their oncology team seldom discussed PROstep data during appointments (mean 2.3 on 5-point scale where 2 = seldom). Hospitalization rates were 42% and 45% for Arms A and B/C (p = 0.8), respectively, and new palliative care referrals were 9% and 10% (p = 0.8), respectively. Mean adherence to weekly patient reports and Fitbit data (at least 4 of 7 days in a week) was 64% and 53%, respectively. Net promoter score was 8.3 on a 10-point scale. **Conclusions:** Clinician and patient-directed dashboards based on patient-generated health data did not lead to higher patient-perceived clinician understanding of symptoms and functional status, although this was limited by moderate adherence to remote symptom and step count collection and low frequency of clinician discussion of PROStep data with patients, highlighting challenges to clinical application of these data sources. Further efforts are needed to improve patient-clinician communication about symptoms and functional status. Clinical trial information: NCT04616768. Research Sponsor: Penn Institute of Translational Medicine and Therapeutics.

1507 **Oral Abstract Session**

Evaluating mass implementation of digital health solutions to improve quality and reduce disparities in a large multisite community oncology practice. *First Author: Amila Patel, Navigating Cancer, Seattle, WA*

Background: There is a priority to accelerate the delivery of digital health solutions (DHS) to provide patients with enhanced means for accessing care, but lack of understanding of their utility in certain populations. There are concerns that equitable adoption translate into disparities. We sought to implement a portfolio of DHS across a large practice and characterize engagement across populations to enhance clinical informatics solutions that support care delivery. **Methods:** This is a retrospective evaluation of cancer patients who engaged with a portfolio of DHS between March 1, 2019 and January 15, 2022. We included four tools with opt-in and opt-out functionality: (1) a care management (CM) platform utilized by clinical staff to manage patient activities, (2) an electronic patient-reported outcomes (ePRO) remote monitoring program for tracking symptoms and oral adherence, (3) a patient portal (PP) for securely accessing patient health records, and (4) digital education (DE) for patients regarding disease and treatments. The engaged population was defined as the number of enrolled patients with at least one (1) record of triage activity, (2) completed ePRO assessment, (3) PP login, and (4) DE read activity, for each tool, respectively. The start of the index period was adjusted based on the first go-live date of each tool. We evaluated factors (age, gender, race/ethnicity, preferred-language, marital status, and distance from clinic) associated with patient engagement using Chi-Square test and multivariate logistic regression. **Results:** This analysis included a total of 267,375 unique patients. Of the enrolled population per tool, 172,840 (73.6%), 9,938 (67.7 %), 49,771 (79.2%), and 12,044 (56.9%) patients were engaged in CM, ePRO, PP and DE, respectively. The majority (>50%) of engaged patients were female, White and non-Hispanic/Latino, English-language, and aged 61-80 yrs. After adjusting for covariates, we observed that White and non-Hispanic/Latino [(CM: OR 1.15, ePRO OR 1.46, PP: OR 1.48, and DE: OR 1.36) and English-language (CM: OR 1.2, ePRO OR 1.67, PP: OR 1.8 and DE: OR 1.89) patients were significantly (p-value <0.001) more engaged compared to their counterparts. Male patients were less likely to be engaged in CM (OR: 0.79) and ePRO (OR: 0.65) but more engaged in PP (OR: 1.1) compared to females. No significant difference was observed in engagement between non-rural (<20 mile) vs. rural (≥ 20 miles) and in all age groups 21-40, 41-60, 61-80 and >80 years as compared to reference age of 0-20 years for any digital tools except CM. **Conclusions:** DHS can be used to support the cancer patient journey and we demonstrated high utilization in an array of sociodemographic variables in our population. However, tools designed and implemented with different populations in mind to reduce staff burden and lessen the digital divide should be further explored. Research Sponsor: None.

1508 **Oral Abstract Session**

ePRO-based digital symptom monitoring in a community oncology practice to reduce emergency room and inpatient utilization. *First Author: Michael A. Kolodziej, ADVI, Washington, DC*

Background: We have previously reported on the successful implementation of an electronic patient-reported outcomes (ePRO)-based symptom monitoring tool in a community oncology practice. Basch et al reported that use of such a tool in the academic trial setting reduced ER visits and hospitalizations. We have examined the impact of the tool on ER and inpatient utilization in this real world patient population. **Methods:** Highlands Oncology Group (HOG) is a 21 physician oncology group located in Northwest Arkansas. Beginning in June 2020, HOG offered patients receiving parenteral cancer therapy enrollment onto Expain, an EMR-integrated ePRO system which enables remote symptom monitoring during therapy. EMR data were linked with the Arkansas State Health Alliance for Records Exchange (SHARE), the state's Health Information Exchange (HIE), to obtain ER visits/hospitalization data. All patients at HOG treated between September 30, 2020 and November 30, 2021 were included in this analysis. Clinical and demographic characteristics were compared in patients who enrolled on Expain versus those who did not, and corresponding p-values were calculated using Mann-Whitney and Chi-square tests. Crude rates for ER visits / hospitalizations were calculated as the total number of events per total person-time. **Results:** There were 855 patients enrolled on the ePRO system. Concurrently, in the same practice, 1773 patients were treated but not enrolled. Reasons for non-enrollment included patient's choice to not participate and patient not yet offered enrollment due to rolling enrollment. The non-ePRO cohort was slightly older (66.7 vs 63.3 yrs, $p < .001$), more commonly male (47.3% vs 39.3%, $p < .001$) and less likely to be White (85.3% vs 89.4%, $p = 0.003$). The cohorts were comparable with respect to cancer site distribution and included a diverse and representative distribution of common malignancies receiving systemic therapy in a community practice. The proportion of patients with metastatic disease was comparable (ePRO 52.9% vs non-ePRO 51.6%, $p = 0.55$). Health resource utilization rates were lower for patients in the ePRO cohort: ER visits: 1.72 vs 2.34 per 100 patient-months, rate ratio and 95% CI = 0.74 (0.60, 0.92), p-value = 0.005; hospitalizations: 4.76 vs 5.41 per 100 patient-months, rate ratio and 95% CI = 0.87 (0.77, 0.99), p-value = 0.04. **Conclusions:** Our findings confirm the substantial benefits of using an ePRO tool in reducing health care resource utilization, and extend the initial findings of previous publications in the academic, clinical trial setting to the real world setting. This observational data is subject to confounding factors and we are evaluating the robustness using various methods to address non-comparability of the cohorts. We are further examining the benefits in specific patient subsets and attempting to correlate these benefits with improved survival. Research Sponsor: None.

Disparities in NCI and nonprofit organization funding and effect on cancers with high incidence rates among Black patients and mortality rates. *First Author: Suneel Deepak Kamath, Cleveland Clinic, Taussig Cancer Institute, Cleveland, OH*

Background: National Cancer Institute (NCI) and nonprofit organization (NPO) funding is critical for research and advocacy, but may not be equitable across cancers or racial and ethnic groups. **Methods:** This study evaluated funding from the NCI and NPOs supporting lung, breast, colorectal, pancreatic, hepatobiliary, prostate, ovarian, cervical and endometrial cancers, leukemia, lymphoma and melanoma from 2015-2018. The primary objectives were to assess for disparities in NCI and NPO funding across different cancers compared to their incidence and mortality and their incidence rates across age, racial and ethnic groups. We also investigated if underfunding correlates with fewer clinical trials. Correlations between NCI and NPO funding for each cancer and its incidence, mortality and number of clinical trials were analyzed using scatter plots and Pearson correlation coefficients (PCCs). **Results:** Diseases with the largest combined NCI and NPO funding were breast cancer ($3.75 billion) and leukemia ($1.99 billion). Those with the least funding were endometrial ($94 million), cervical ($292 million), and hepatobiliary cancers ($348 million). Disease-specific funding correlated well with incidence, but correlated poorly with mortality (PCCs: 0.74, $p = 0.006$ and 0.30, $p = 0.346$, respectively). Breast cancer, leukemia and lymphoma were consistently well-funded, while colorectal, lung, hepatobiliary and uterine cancers were consistently underfunded. These data are summarized in the Table. NCI and NPO funding increased proportionately as incidence increased for White patients (PCC: 0.73, $p = 0.007$), Hispanic patients (PCC: 0.66, $p = 0.02$), Asian/Pacific Islanders (PCC: 0.77, $p = 0.003$) and Native Americans and Alaskans (PCC: 0.72, $p = 0.008$) while cancers with higher incidence in the Black population were underfunded (PCC: 0.52, $p = 0.08$). The amount of combined NCI and NPO funding for a particular cancer correlated strongly with the number of clinical trials for that disease (PCC: 0.91, $p < 0.0001$). **Conclusions:** Many cancers with high incidence and mortality are underfunded, including those with higher incidence among Black patients. Underfunding strongly correlates with fewer clinical trials, which could impede future advances in underfunded cancers. Research Sponsor: None.

Impact of a shared-care model between community and academic centers for facilitating access to allogeneic and autologous stem cell transplantation. *First Author: Joshua Fein, Hartford Healthcare, Hartford, CT*

Background: Despite curative or disease-controlling roles in AML/MDS and MM, access to allogeneic (allo) and autologous (auto) hematopoietic stem cell transplantation (SCT) remains far from universal. Socioeconomic status (SES) and geographic distance from SCT centers have been shown to be barriers to SCT access. In 2016, Hartford HealthCare (HHC) and the Memorial Sloan Kettering Cancer Center (MSK) pioneered a Shared-Care Model (SCM) to streamline access to allo and auto SCT at MSK, featuring a dedicated nurse SCT coordinator, shared hematology tumor boards, MSK-led didactics for HHC providers, and an electronic health record sharing pipeline. We sought to determine if this has improved access to SCT for HHC patients. **Methods:** A retrospective chart review was conducted of HHC patients aged 18-70 with new diagnoses of AML, MDS, and MM between 2016 and 2020. Socioeconomic status (SES) was estimated by 9-digit zip-code using the Area Deprivation Index (ADI), shown to be a surrogate for healthcare access. Referral or not to a SCT center, referral to MSK through the SCM, and reasons for non-referral were abstracted from the medical record. For patients referred for SCT at MSK, we also captured the number of peri-SCT days in New York City (NYC) and number of subsequent MSK and HHC clinic visits/hospitalizations within 1-year post-SCT. **Results:** A total of 126 patients was included, with 81 (64%) treated for AML/MDS and 45 (36%) for MM. The median age was 60 years (interquartile range [IQR]: 53-66). The majority were white (n = 101, 80%) followed by 10% (n = 13) Black/African American; 10% (n = 12) were of Hispanic ethnicity. The median ADI percentile was 38 (IQR: 20-51; higher percentiles reflect decreased SES). The median ADI for MSK SCT referrals from New York, New Jersey, and Connecticut 2016-2020 for the same indications was 19 (IQR: 10-30, $p < 0.001$). A total of 90 patients (71%) were referred to SCT centers. Leading reasons for no referral were favorable-risk disease (n = 10), goals of care (n = 9), and death prior to referral (n = 5); 3 patients were not referred due to comorbidities/performance status. No differences were found between patients referred to MSK vs. other centers. Thirty-four HHC patients were referred to MSK (21 AML/MDS, 13 MM), vs. 3 between 2010 and 2015. Twelve patients underwent allo SCT, with median 97 days in NYC (range: 68-247); 8 underwent auto SCT, with median 21 days in NYC (range: 15-48). **Conclusions:** Our findings show the feasibility of a shared-care model between a non-SCT-providing large regional hospital system and a major academic transplantation center. Close collaboration between institutions may minimize time patients spend away from home. The SES of HHC referrals was lower than the general MSK population, suggesting that a shared-care model may facilitate access to SCT for patients with previous barriers for this potentially curative therapy. Research Sponsor: None.

Time to biopsy of screening mammography-detected abnormalities: Evaluating the impact of same-day services implemented during the COVID-19 pandemic. *First Author: Kimberly Klinger, Massachusetts General Hospital, Boston, MA*

Background: Screening mammography programs often require patients undergo multiple visits (screening exam, diagnostic exam, and biopsy) before tissue diagnoisis of screen-detected abnormalities. During the COVID-19 pandemic, same-day breast imaging services were leveraged to decrease the number of visits following abnormal screening exams. Specifically, in May 2020, we implemented an immediate-read screening mammography program to synergize with our pre-existing same-day breast biopsy program, such that every effort was made to perform diagnostic imaging during the same visit after an abnormal screening mammogram. This study aims to evaluate the impact of these same-day breast imaging services on time and number of patient visits to undergo breast biopsy after an abnormal screening mammogram. **Methods:** Consecutive screening mammograms performed during normal business hours pre- (6/1/16 to 5/30/17) and post-implementation (6/1/20 to 5/30/21) of same-day services were identified. Patient demographics, imaging and biopsy results, and visit dates were extracted from the medical record. Multivariable logistic, linear, and ordinal regression models estimated with generalized estimating equations were fit to assess the association of period (pre- versus post-implementation), patient age, and race and ethnicity (White versus races other than White) with having a same-day biopsy (biopsy on the same day as the abnormal screening exam), number of days to biopsy, and number of visits. Adjusted odds ratios (aOR) and beta estimates (aBeta) of each covariate and corresponding 95% confidence intervals (CI) were estimated. **Results:** A total of 409/25,922 (1.6%) of patients (median age 61, IQR 50-70) pre-implementation and 221/20,452 (1.1%) patients (median age 62, IQR 49-71) post-implementation had screen-detected abnormalities leading to diagnostic breast imaging and biopsy. Median number of days from screening to biopsy decreased from 16 days pre-implementation to 5 days post-implementation ($p < 0.001$). Pre-implementation, 86.8% of patients required 3 visits between screening and biopsy, while post-implementation only 23.1% required 3 visits ($p < 0.001$). Compared to pre-implementation, the post-implementation period was associated with increased odds of undergoing same-day biopsy (aOR 20.7, 95% CI 8.3-51.7), $p < 0.001$), fewer days from abnormal screening mammogram to biopsy (aBeta -13.3, 95% CI -15.7 to -10.9, $p < 0.001$), and fewer visits (aOR 0.05, 95% CI 0.02-0.09), $p < 0.001$), controlling for age and race and ethnicity. **Conclusions:** Same-day breast imaging services decreased time and patient visits between abnormal screening mammogram and breast biopsy. Same-day services implemented out of necessity during the COVID-19 pandemic should be continued after the pandemic has subsided to improve timeliness of care. 1512 **Poster Discussion Session**

Patient- and provider-level factors associated with telehealth utilization across a multisite, multiregional cancer practice. *First Author: Joshua Pritchett, Mayo Clinic, Rochester, MN*

Background: In response to the COVID-19 pandemic, many cancer practices adopted telehealth, including telephone and video appointments. Following a period of initial expansion that began in March 2020, sustained telehealth integration has emerged across the Mayo Clinic Cancer Practice (MCCP) in 2021. The primary objective of this study was to identify factors associated with utilization of telehealth appointments. **Methods:** A cross-sectional, multi-site, retrospective analysis was conducted across MCCP – a multisite, multiregional cancer practice with tertiary referral campuses in Minnesota, Florida, and Arizona, as well as rural, community-based hospitals and clinics throughout the Upper Midwest. Multivariable models were used to examine the association of patient- and provider-level variables with telehealth utilization. **Results:** Outpatient appointments conducted in July – August 2019 (n = 32,932) were compared with those from 2020 (n = 33,662) and 2021 (n = 35,486). The rate of telehealth appointment utilization increased from <0.01% in 2019 to 11.0% in 2020 and 14.0% in 2021. The strongest provider-level predictor of telehealth utilization was female physician provider type (OR 1.06, 95% CI 1.01 to 1.11; P = 0.0297), a trend consistently observed across career stages, practice locations and settings in 2020 and 2021. Additionally, while the rate of telehealth utilization was not significantly different at referral and community-based campuses in 2020, providers at referral campuses were significantly more likely to utilize telehealth than community-based campuses in 2021 (OR 1.1, 95% CI 1.01 to 1.12; P = 0.0289). Regarding patient-level factors, rural residence (defined by Rural-Urban Commuting Area codes), which accounted for 44.2% of the patient population, was significantly associated with lower telehealth utilization as compared to patients with urban residences, particularly for video appointments (OR 1.04, 95% CI 1.02 to 1.07; P < 0.0001). Notably, the disparity in telehealth utilization between rural and urban populations was found to be less pronounced in 2021 as compared to 2020. **Conclusions:** Multivariable analysis across a multi-site, multi-regional cancer practice identified several factors associated with increased telehealth utilization. These included female physician provider type, referral-based campuses, and patients residing in urban settings. A detailed understanding of the factors that influence telehealth utilization – a method of care delivery which represents a "new normal" across many cancer practices – will be essential to enable continued equitable access to high-quality, high-impact, patient-centered cancer care. Association between telehealth and adherence with patient-reported outcomes (PRO)-based remote symptom monitoring among adolescent/young adults (AYA), middle age, and older adults with cancer. *First Author: Ishwaria Mohan Subbiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PRO-based remote symptom monitoring favorably impacts quality of life, healthcare utilization, and overall survival in patients (pts) with cancer. However remote PRO completion rates outside of a clinical trial remained widely varied. With the wide adoption of telehealth in cancer care during the pandemic, telehealth's impact on health behaviors such adherence w remote PROs is not fully characterized. To that end, we investigated PRO completion patterns in routine cancer care, pre- and during the pandemic. **Methods:** We queried a prospectively maintained institutional database of all PROs remotely delivered to pts at our institution from 1/1/18 to 12/31/21. Pts were divided into 2 time cohorts ("pre-pandemic" 1/1/18 to 3/31/20, "during pandemic" 4/1/20 to 12/31/21) and 3 age cohorts (AYA 15-39y, midage 40-64y, older adults 65y+). We calculated descriptive statistics and compared (t-test, ANOVA) between time and age cohorts and independent variables. **Results:** Overall 93,875 unique patients over 4 years received 1+ remote PROs as a part of their routine cancer care. PRO response rate increased from 35% prepandemic (12011 of 34742 pts responding) to 67% during pandemic (p <0.00001). To understand patient-level response patterns, we selected one representative global health PRO tool used widely across clinics in our institution and analyzed completion in a representative month over 4 years, 2 before (Oct '18, '19) and 2 mid-pandemic (Oct '20, '21). Overall 2738 pts (median age 60y, range 17-94y; 290 AYA 15-39y, 1444 midage 40-64y, 1004 older adults 65y+) were sent 3249 PROs during these 4m, 1378 PROs to 1075 pts in 2 pre-pandemic months & 1871 to 1663 pts in 2 mid-pandemic months. Overall, PRO response rate increased from 52% pre-pandemic to 81% during, non-responders dropping from 48% to 19%, and response rate without any reminder from the team increasing from 13% pre-pandemic to 79% during. Across all 3 age cohorts, overall PRO response rates increased (AYA up 21%, midage up 27%, seniors up 35%, p 0.012), PRO non-response rate decreased (AYA by 21%, midage by 27%, seniors by 35%, p 0.01), and PRO response rate without reminders from clinic team increased significantly (AYA, by 71%, midage by 78%, senior by 61%, p <0.00001). When further analyzing by visit type during pandemic, the improvements in overall PRO response rates are driven almost exclusively by telehealth where in-person PRO completion decreased by 19% (pre-pandemic 52%, during 33%) while pts who had an upcoming virtual visit had 94% PRO response rate (p < 0.00001). **Conclusions:** Substantially higher adherence with PRO-based remote symptom monitoring was seen during the pandemic with virtual visits accounting substantially for this broad adherence and the highest increases seen in older adults, highlighting the implications of telehealth on cancer care. Electronic research consents for complex early-phase I-II clinical trials integrated with telemedicine visits compared with in-person encounters. *First Author: Michael T. Buckley, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Based on our previous research with patient satisfaction for electronic consenting (95% of 940 respondents would recommend it another patient), we hypothesized that telemedicine (telemed) would be received as well as or better than in-person clinical research (CR) consent encounters for complex early-phase clinical trial (Phase I-II) and clinical genetic consent discussions by patients. Oncologist experiences to date have shown that telemed works well for uncomplicated clinical scenarios, but its performance alongside increased care complexity is less clear from the patient perspective. **Methods:** We conducted a one-time survey of adult patients having a telemed consent visit between 8/31/21 and 2/13/22 and an in-person clinic visit. Nine CR specific questions covered visit preference and empowerment across 6 high value consent agency domains. **Results:** 513 patients completed the survey and consented across 96 Clinical trials (CT), including genetic, therapeutic, diagnostic, and quality of life. Consent discussions were performed by 75 clinicians and 41 non-clinicians, with the majority (64%) for clinical genetic and Phase I-II CTs. Most patients (52%) preferred telemed over in-person clinic visits (19%) when all visit related factors (time, cost, convenience, quality of care, healthcare team interaction) were considered (P<.05) (Table). Comparing their last in-person visit with telemed, patients reported feeling either less stressed/overwhelmed (16%) for their consent discussion or about the same (39%) using telemed, and 6% were more stressed (P<.05). Patients expressed equal comfort taking agency-supported action across 6 domains regardless of consent setting. **Conclusions:** Electronic consenting via telemed is the preferred method for consent in complex early-phase clinical trials when all visit factors are considered and performs as well across 6 key agency domains when compared with in-person visits. Telemed does not contribute additional stress to consent appointments for most patients and performs well across complex clinical genetic and Phase I-II clinical trial discussions. Our findings suggest telemed and electronic consent should be offered as an option for patients throughout their treatment continuum. Beyond MSK, our data support a broader call for organizations to offer telemed platforms for CT discussions to increase overall patient satisfaction and potentially increase participation. Research Sponsor: None.

1515 **Poster Discussion Session**

Preliminary analysis of an expanded access study of the fixed-dose combination of pertuzumab (P) and trastuzumab (H) for subcutaneous injection (PH FDC SC) for at-home administration (admin) in patients (pts) with HER2-positive (HER2+) breast cancer (BC) during the COVID-19 pandemic. *First Author: Chau T. Dang, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Standard of care for HER2+ early/first-line metastatic BC (EBC/MBC) is P + H and concurrent chemotherapy (CT); PH FDC SC offers faster, more convenient admin vs intravenous (IV) P + H. COVID-19 has caused unprecedented strain on healthcare systems and disruption to cancer care; treatment (Tx) at home may: enable pts to continue cancer Tx; reduce exposure to COVID-19; free up hospital resources. This study's main objectives: to enable continuity of care during COVID-19; to assess safety of PH FDC SC given at home. **Methods:** This is an ongoing single-arm, hybrid, decentralized clinical trial (NCT04395508). Pts with HER2+ EBC/MBC who completed concurrent CT with P + H IV and are receiving/about to receive maintenance P + H IV, PH FDC SC, or H SC are switched to PH FDC SC given at home by a home health nursing provider (HHNP) until disease progression, unacceptable toxicity, pt withdrawal, or physician recommendation (pts with EBC will complete ≤18 cycles). The study endpoint is safety. A subset of pts took part in HARRIET, a substudy of at-home cardiac surveillance with artificial intelligence-guided cardiac ultrasound and optional 6L ECG acquired by an HHNP. **Results:** Data for 114 pts (1 male) were available at cutoff (Jan 19, 2022): 18 (16%) completed Tx; 20 (18%) discontinued; 76 (67%) remain on study; 79 (69%) had a COVID-19 vaccine while on study. Median age was 49 years; pts were balanced between EBC (n = 55, 48%) and MBC (n = 59, 52%); received a median of 6 (EBC) and 8 (MBC) cycles; and were from metropolitan (n = 109), urban (n = 4), and rural (n = 1) areas. 11 pts tested COVID-19-positive during the Tx phase: 8 continued Tx after appropriate COVID-19 Tx and/or quarantine. Safety is summarized in the table. No new adverse events (AEs) emerged due to home admin. AEs of special interest were grade (gr) 1–2: admin-related reactions (n = 76, 67%), hypersensitivity (n = 5, 4%), cardiac dysfunction (n = 4, 4%), except 1 case of gr ≥3 diarrhea. AEs leading to study Tx discontinuation or interruption/dose reduction occurred in 3 (3%) and 15 (13%) pts. A subset of 7 pts completed at-home cardiac surveillance testing; quantitative assessment of left ventricular ejection fraction was feasible in 3 (43%); 5 (71%) preferred at-home surveillance to clinic. **Conclusions:** In this preliminary analysis, safety of PH FDC SC at home was consistent with the established P + H safety profile, indicating that PH FDC SC at home is a viable option for continuing BC care during and beyond COVID-19. Clinical trial information: NCT04395508. Research Sponsor: Genentech, Inc.

AEs	Pts, n / %
Most common, any grade	
Injection site reaction	67 / 59
Diarrhea	17 / 15
Fatigue	10 / 9
Nausea	8 / 7
Injection site pain	6 / 5
Gr ≥3	4 / 4
Serious*	5 / 4
Fatal	0

Outcomes following off-site remote chemotherapy administration. *First Author: Abram Arnold, VA Nebraska Western Iowa Health Care System, Omaha, NE*

Background: The Veteran Affairs Nebraska Western Iowa Health Care System (VA-NWIHCS) utilizes teleoncology and remote chemotherapy services to expand care to veterans in rural Nebraska who have difficulty accessing the primary campus in Omaha. Remote sites in Lincoln (60 miles) and Grand Island (GI) (150 miles) facilitate remote chemotherapy administration with oversight from oncologists in Omaha. This study compares clinical outcomes in patients receiving care at these remote sites to those in Omaha. **Methods:** Data were retrospectively reviewed for 151 patients receiving first-line chemotherapy at VA sites in Omaha, Lincoln or GI between 1/1/2018-12/31/2020. Data collected included age, gender, performance status, comorbidities, overall survival (start of treatment to death/last contact), malignancy type and stage, number of delayed or missed treatment cycles, chemotherapy-related toxicities, and emergency room (ER) visits or hospitalizations. SAS version 9.4 was used for analysis. **Results:** The study population included 108 patients who received their chemotherapy infusions in Omaha, while 43 received their infusions at the remote sites. The demographics of the patients at both Omaha and remote sites (Lincoln/GI) was predominantly male, 96% vs 91% respectively; median age was 69 years in each group; 82% vs 93% (p = 0.24) had an ECOG PS of 0-1. The two groups were comparable in terms of common comorbidities: chronic obstructive pulmonary disease (36% vs 37% p = 0.90); chronic kidney disease (38% vs 28% p = 0.24); coronary artery disease (41% vs 19% p = 0.01). Groups had a similar proportion of patients with stage IV disease (39% vs 33%; p = 0.54), treatment with curative intent (60% vs 51%; p = 0.32), and most prevalent cancers: head/neck (14% vs 12% p = 0.80), lung (25% in each p = 0.99), and gastrointestinal (10% vs 14% p = 0.57). There was no difference in median OS between the on-site treatment and remote treatment groups [96.8 (n = 84) vs 92.4 (n = 32) months (p = 0.92) for patients with solid tumors; 67.7 (n = 24) vs 94.3 (n = 11) months (p = 0.73) for hematologic malignancies]. Chemotherapy-related toxicities were noted in 61% vs 53% of patients (p = 0.39) in Omaha vs remote sites, including febrile neutropenia (6% vs 2% p = 0.99), neutropenia (6% vs 5% p = 0.67), other cytopenia (11% vs 14% p = 0.59), dehydration (9% vs 2% p = 0.18), nausea (5% vs 7% p = 0.69), and neuropathy (3% vs 7% p = 0.35). At least one hospitalization occurred in 33% vs 21% (p = 0.13) of patients and at least one ER visit in 42% vs 26% (p = 0.07). A delay in at least one treatment cycle occurred in 29% vs 21% (p = 0.32) of cases and at least one cycle of treatment was missed in 15% vs 19% (p = 0.59). **Conclusions:** The evaluated outcomes in oncology patients treated in Omaha versus remote sites via telemedicine under the same providers were similar. Effective oncology care, including parenteral chemotherapy administration, can be provided via telemedicine and this model can help mitigate issues with access to care. Research Sponsor: None.

1517 **Poster Discussion Session**

Remote symptom monitoring after hospital discharge. *First Author: Robert Michael Daly, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Strategies to improve transitions from the hospital to home for patients with cancer are considered an important component of quality, patient-centered care in oncology. CMS evaluates cancer hospital performance based on the 30-day unplanned hospital readmission rate, and this measure has been endorsed by the National Quality Forum. Nationally, the 30-day readmission rate for oncology patients ranges from 19%-27%. These readmissions come at high psychosocial, physical, and financial costs for patients and caregivers. A remote monitoring intervention that includes frequent contacts with the patient is likely to be effective in improving this transition. **Methods:** We evaluated the feasibility, acceptability, and perceived value of a mobile health intervention to monitor and manage symptoms of adult medical and surgical oncology patients discharged from an NCI-designated cancer center to home. Patients were monitored for 10 days, which is the median time to readmission for an oncology patient. The technology supporting the program included: 1) a patient portal enabling daily electronic patient-reported outcomes assessments; 2) a pulse oximeter to provide data on blood oxygen level and heart rate; 3) alerts for concerning symptoms; 4) an application to allow staff to review and trend symptom data; 5) a secure platform to support communications and televisits between staff and patients; 6) an advanced feedback report to provide just-in-time patient symptom education. Feasibility and acceptability were evaluated through engagement (goal: > 50% response rate) and symptom alerts and perceived value was measured through a patient engagement survey that included a net promoter score (how likely the patient is to recommend the program to similar patients; goal > 0.7). **Results:** Between September 27, 2020 to December 31, 2021, the program enrolled 1,091 medical oncology (median age: 63 years, 55% female) and 4,222 surgical oncology patients (median age: 63 years,55% female). Of those enrolled, 65% of medical and 74% of surgical oncology patients participated in home remote monitoring by self-reporting symptom data. This resulted in 2,869 completed symptom assessment from medical and 16,009 completed assessments from surgical patients. Sixty-three percent of medical oncology assessments resulted in a yellow (moderate) or red (severe) symptom alert compared with 26% for surgical oncology patients. Pain was the predominant symptom generating red alerts for medical oncology patients (17%). Fifty-two percent of patients completed the engagement survey, and the net promoter score was 0.82. **Conclusions:** A remote monitoring program after discharge was feasible, acceptable, and perceived to be of value by oncology patients discharged from a cancer center. Surgical and medical patients have similar response rates but differ in symptom burden. Future work will evaluate the value of a remote symptom monitoring platform in decreasing readmissions. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

1518 **Poster Discussion Session**

A pragmatic cluster-randomized trial of a standing physician order entry intervention for colony stimulating factor use among patients at intermediate risk for febrile neutropenia (SWOG S1415CD). *First Author: Dawn L. Hershman, Columbia University College of Physicians and Surgeons, New York, NY*

Background: Primary prophylactic colony stimulating factors (PP-CSF) are prescribed to patients undergoing chemotherapy to reduce the risk of febrile neutropenia (FN) but their benefit for regimens with intermediate FN risk is uncertain. Within a pragmatic, randomized trial of a standing order entry (SOE) intervention for prescribing PP-CSF, we designed a substudy to evaluate the effectiveness of PP-CSF for patients receiving therapy with intermediate FN risk. **Methods:** TrACER was a cluster randomized trial where NCI community Oncology Research Program practices were randomized to usual care (UC) or a guideline-based SOE intervention. In the primary study, sites were randomized 3:1 to a SOE of automated PP-CSF orders for NCCN-designated high FN risk chemotherapy regimens and alerts against PP-CSF orders for low FN risk regimens (intervention) versus usual care. A secondary randomization assigned intervention sites to a SOE intervention either to prescribe or not prescribe PP-CSF for patients receiving intermediate FN risk regimens. Clinicians were allowed to override the SOE. Patients age ≥18 with either breast, colorectal or non-small cell lung cancer were enrolled and followed for 12 mo. PP-CSF was defined as initiation within 24-72 hours after systemic chemotherapy. Sample size calculations were based on an FN risk reduction from 15% to 7.5%, and provided 80% power at a planned enrollment of 90 patients per site. Mixed effect logistic regression models were used to test differences between sites randomized to prescribe or not prescribe PP-CSF. **Results:** Between January 2016 and April 2020, 24 sites (2,287 patients) were randomized to the intervention. Among intervention sites, 12 were randomized to either SOE to prescribe or an alert to not prescribe PP-CSF for the 542 patients receiving intermediate FN risk regimens. Rates of PP-CSF use were higher among sites randomized to prescribe PP-CSF (37.1% vs 9.9%, OR = 5.90 (95% CI 1.72-20.20; p = 0.0048)). Overall, the rates of FN were low and identical between PP-CSF and no PP-CSF arms (3.7% vs 3.7%). Among patients who did not receive PP-CSF, rates of FN were also low and similar between arms (3.8% vs 4.1%). **Conclusions**: While implementation of a SOE intervention for PP-CSF significantly increased PP-CSF use among patients receiving intermediate risk regimens, FN rates did not differ between arms. Despite SOE, 63% of patients assigned to receive PP-CSF did not receive it. FN rates overall were lower than expected and did not differ between patients that did or did not receive PP-CSF. Although this guideline-informed SOE influenced prescribing, the results suggest that neither the SOE nor PP-CSF itself provide sufficient benefit to justify their use for persons receiving intermediate FN risk regimens. Clinical trial information: NCT02728596. Research Sponsor: U.S. National Institutes of Health, Other Government Agency.

Cluster-randomized trial to evaluate the implementation of reproductive health care in cancer care delivery in community oncology practices: Results from ECOG-ACRIN E1Q11. *First Author: Ashlesha Patel, Cook County Health, Chicago, IL*

Background: Reproductive health (RH) needs of women newly diagnosed with cancer have been poorly addressed. RH management must be aligned with cancer treatment to optimize cancer survivorship. The primary objective of the EROS trial is to evaluate the effectiveness of implementing RH programming to improve RH care among reproductive aged women with cancer. **Methods:** E1Q11 used a cluster randomized design with 17 NCI Community Oncology Research Program (NCORP) Sites randomized to intervention (n = 8) or usual care (n = 9). Intervention sites received study-specific training delivered via webinar and tools to support RH care implementation. Pre-menopausal women aged 15-55 years newly diagnosed with cancer and pre-initiation of treatment were eligible. The primary endpoint was defined as the delivery of RH goal-concordant management within the first 3 months since enrollment. Data were obtained through patient completed questionnaires and medical record abstraction forms at baseline and 3 months. The management rate was analyzed using generalized estimating equations (GEEs) method. **Results:** From 7/2016 - 4/2021, 434 women enrolled (156 intervention, 278 usual care) and 392 were analyzable. The median age was 41 years. Patients self-identified as White 67.5%; Black 21.1%; Hispanic 15.9%. Most patients had breast cancer (83.5%) and local/regional disease (69.5%). A higher proportion of patients at intervention sites (77.1%, 108/140, 90% CI: 0.71-0.83) received goal-concordant RH care compared to patients enrolled from usual care sites (61.5%; 155/252, 90% CI: 0.56, 0.67). A total of 263/392 (67.1%) patients received goal-concordant RH care within the first 3 months of enrollment. The GEE analysis demonstrated patients enrolled from intervention sites were approximately twice more likely to receive goal- concordant RH care than patients at usual care sites (odds ratio, OR = 2.11, 95% CI: 1.30, 3.44, p = 0.003). Younger age (< / = 35 years vs. > 35 years) and better ECOG performance status (PS 0 vs. PS 1-3) were statistically associated with the adoption of RH goal-concordant management (OR = 2.85, 95% CI: 1.59, 5.12, p = 0.0004 and OR = 1.94, 95% CI: 1.04, 3.63, p = 0.04, respectively). The intervention effect on the primary endpoint remained after age and PS were adjusted in the model (adjusted OR = 2.23, 95% CI: 1.30, 3.84, p = 0.004). **Conclusions:** The EROS trial demonstrated significant improvement of goal-concordant reproductive health management amongst racially diverse women newly diagnosed with cancer treated in community oncology practices. Sites randomized to intervention more frequently delivered reproductive care compared to usual care sites. Findings support wider implementation of this intervention to improve reproductive health care delivery, improving cancer care quality for pre-menopausal women diagnosed with cancer. Clinical trial information: NCT01806129. Research Sponsor: This study was conducted by the ECOG-ACRIN Cancer Research Group (Peter J. O'Dwyer, MD and Mitchell D. Schnall, MD, PhD, Group Co-Chairs) and supported by the National Cancer Institute of the National Institutes of Health.

1520 **Poster Discussion Session**

Improving supportive care for patients with thoracic cancer. *First Author: Lakedia Banks, VA, Palo Alto, CA*

Background: Improving lung cancer care among Veterans is a priority within the Veterans Affairs due to higher rates of lung cancer incidence, morbidity, and mortality among Veterans compared to non-veterans. Unaddressed symptom burden is common due to many factors including complex comorbidities, psychosocial challenges, smoking history and limited social support networks. Additionally, complications from social determinants of health can obstruct successful discussions of symptom-burden between Veterans and their clinical care teams which can limit compliance with recommended symptom management strategies. To overcome these barriers, we conducted a randomized controlled trial to test the effectiveness of a lay volunteer-led proactive symptom assessment and symptom intervention. The objective was to determine if the intervention improved clinician documentation from baseline to 6-months post-enrollment compared to usual care. Secondary outcomes included change in patient activation, health-related quality of life (HrQOL), and symptom-burden. **Methods:** Patients were randomized into the lay volunteer proactive symptom assessment intervention plus usual cancer care (intervention group) or usual cancer care alone (control group). We conducted electronic health record review to assess primary cancer-clinician symptom documentation of Veterans' symptoms identified as moderate-to-severe at baseline and 6-months using the Edmonton Symptom Assessment Scale. Patient surveys with validated assessments were used to assess patient activation, HrQOL and symptom burden at baseline (time of enrollment) and 6-months post-enrollment. We used regression models to evaluate differences in our primary and secondary outcomes. **Results:** 60 Veterans were consented and randomized into the study (29 control; 31 intervention). There were no differences in demographic or clinical factors across groups. The median age was 70 years (range 56-85), 95% were male, 70% identified their race as White, 53% were married and 48% had a 2-year or 4-year college degree. The majority had at least 3 comorbidities (54%), diagnosed with stage 3 or 4 (62%) and received systemic treatment with chemotherapy and/or radiation (77%). At 6-months post-enrollment as compared to baseline, the intervention group had greater improvements in symptom documentation (56% from 12.5% vs. 29% from 43%, p = 0.01), greater improvements in patient activation (p<0.001), HrQOL (<0.001), and lower symptom burden (p<0.001) than the control group. **Conclusions:** Integration of proactive symptom assessment by lay volunteers has a significant and meaningful effect on symptom documentation, patient activation, quality of life, and reducing symptom burden among Veterans with lung cancer. Clinical trial information: NCT03216109. Research Sponsor: Carevive, Inc, U.S. National Institutes of Health.

1521 **Poster Session**

The initial outcome of deploying a mortality prediction tool at community oncology practices. *First Author: Ping Ye, The U.S. Oncology Network, McKesson, The Woodlands, TX*

Background: Hospice improves the quality of life and care for cancer patients and reduces the likelihood of unwanted death in the hospital . Advance Care Planning (ACP) allows physicians to proactively initiate hospice and end-of-life discussions with identified patients, promoting timely hospice care enrollment. We developed a machine learning (ML) model to predict 90-day mortality risk for patients with metastatic cancer. The tool was designed to enable earlier ACP discussions leading to increased hospice enrollment. This study assesses the ML tool usage on ACP documentation in a community oncology setting. **Methods:** Twelve practices across the nation were included in the study, all participating in the Oncology Care Model. Five practices implemented the ML tool during 10/26/2020-9/30/2021, with patients scored every two weeks to provide insights on mortality risk. Patients identified as high-risk were evaluated for ACP utilization, obtained from timely EMR data and historical claims. Seven practices did not implement the ML tool and served as the control for the study. **Results:** A total of 1,663 patients were predicted to have a high risk of mortality at the 12 practices during the timeframe. The median age was 74 years. 53% of patients were males, and 47% were females. ACP documentation varied among the practices. The range was 19.4%-55.8% among ML tool participating practices and 7.4%-31.0% among non-participating practices. The weighted mean of ACP utilization was 34.4% for participating practices and 14.0% for non-participating practices. Compared with non-participating practices, the ACP rate increased significantly by 2.5-fold for participating practices (p-value = 0.03, two-sided T-test). **Conclusions:** This initial outcome study showed improved ACP documentation after deploying a mortality prediction tool in a community oncology setting. We are currently working on propensity score matching and regression analysis to reduce the effect of confounding factors such as practices, patient demographics, diagnosis, and treatment. Future studies will evaluate the impact of mortality tool use on other outcomes, including hospice enrollment, emergency department visits, and hospital admission. Implementing the mortality prediction tool is an ongoing effort with more practices planned to adopt. Research Sponsor: None.

Imaging and physician visits at cancer diagnosis: COVID-19 pandemic impact on cancer care. *First Author: Rui Fu, University of Toronto, Toronto, ON, Canada*

Background: Understanding how cancer system responded to the first wave of the COVID-19 pandemic has crucial implications to de-escalation measures in future waves. Here we examined the pandemic impact on the provision of diagnostic imaging (MRI, CT, and ultrasound) and physician visits (virtual and in-person) at cancer diagnosis in Ontario, Canada. **Methods:** For each week of June 26, 2016–September 26, 2020, we identified cancer diagnoses whose time around diagnosis (91 days +/- the date of diagnosis) fell into this week and restricted those diagnoses to be one per person-day and to patients aged 18+ at the beginning of that week. For these cancer patients, we used physician claims database to identify diagnostic imaging and visits received around cancer diagnosis. In separate segmented negative binomial regression procedures, we assessed the trends in weekly volume of these services per thousand cancer patients in pre-pandemic (June 26, 2016 to March 14, 2020), the change in mean volume at the start of the pandemic, and the additional change in weekly volume in the pandemic (March 15, 2020 to September 26, 2020). **Results:** Among 403,561 cancer patients in the cohort, 41,476 (10.3%) were diagnosed in the pandemic. As COVID-19 arrived, mean diagnostic imaging volume decreased by 12.3% (95% CI: 6.4%-17.9%) where ultrasound decreased the most by 31.8% (95% CI: 23.9%-37.0%) and MRI did not change (p-value = 0.27). Afterwards, the volume of all scans increased further by 1.6% per week (95% CI: 1.3%-2.0%), where ultrasound increased the fastest by 2.4% for each week (95% CI: 1.8%-2.9%). Mean in-person visits dropped by 47.4% when COVID-19 started (95% CI: 41.6%-52.6%) while virtual visits rose by 5515% (95% CI: 4927%-6173%). In the pandemic era, in-person visits increased each week by 2.6% (95% CI: 2.0%-3.2%), but no change was observed for virtual visits (p-value = 0.10). **Conclusions:** Provision of diagnostic imaging and virtual visits at cancer diagnosis has been increasing since the start of COVID-19 and already exceeded pre-pandemic utilization levels. These findings imply the feasibility of combining virtual consultations with diagnostic imaging to manage new cancer patients and highlight the need to monitor the quality of these services. The promising use of hospital at home in an oncology setting. *First Author: Melanie Wain Kier, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Hospitalization at Home (HaH) is an emerging clinical model that delivers the essential elements of acute hospital-level care in the home and has demonstrated efficacy largely for inpatient medical conditions. Few programs have implemented HaH for patients with active cancer diagnoses. There is little data evaluating the impact of HaH on cancer outcomes, patient experience or cost effectiveness. In 2019, the Mount Sinai Health System (MSHS) expanded its HaH program to include oncology patients. Here, we describe our institution's experience of HaH in oncology. **Methods:** We performed a retrospective chart review for solid tumor, myeloma and lymphoma patients at MSHS from August 2019 to November 2021 enrolled in HaH. Patient eligibility for HaH required meeting established institutional HaH admission criteria. Demographics, cancer diagnosis, social situation, indication for antecedent ED or inpatient stay, and HaH admission were extracted from the electronic medical record. Our primary endpoint was rate of successful HaH admission, with success defined as discharge from HaH for complete recovery from the acute condition or transition to hospice. We also evaluated patient social support and home resources. **Results:** We enrolled 19 patients with multiple myeloma (n = 7), lymphoma (n = 1), and solid tumor (n = 11). Sixty-three percent (n = 12) were male, 74% (n = 14) were age 65 or older, and 42% (n = 8) were white. Patients were enrolled in HaH either from an inpatient service (n = 15) or from the emergency room (n = 4). While on the inpatient service, 6 of the 15 patients had received chemotherapy. Post-chemotherapy monitoring was the primary reason for HaH admission. Successful HaH admissions occurred for 79% (n = 15) of patients. The mean duration of HaH admission was 4.5 days (range 1-10 days). Three patients opted to re-enroll in HaH planned care at a later point. There were no significant issues with provider home visits, access, medication delivery, lab draws, or social support. **Conclusions:** The MSHS Oncology HaH program successfully cared for 79% of our cohort demonstrating the functionality of expanding the program to patients with cancer. We continue to increase enrollment for oncology patients. Further studies to assess patient outcomes, cost savings, and re-hospitalization rates when compared to the standard in hospital only care for oncology patients will help determine the benefits and preferred population to utilize oncology HaH. Reducing inpatient mortality in patients with cancer through multidisciplinary review and targeted interventions. *First Author: Manan P Shah, Stanford Health Care, Stanford, CA*

Background: Excess inpatient mortality is a marker of poor quality in cancer care. We developed a multidisciplinary mortality review committee to review each inpatient death to determine key drivers of mortality and develop targeted interventions to reduce our inpatient mortality index. **Methods**: Through retrospective review, inpatient deaths were identified at Stanford Health Care for patients with an ICD10 cancer diagnosis regardless of inpatient service. Details of each hospitalization were reviewed by a quality consultant and subsequently reviewed by a physician quality team member to identify opportunities for improvement. Most cases were then discussed in a monthly multidisciplinary committee meeting. The committee analyzed key drivers of inpatient mortality, communicated suggestions to the patient's outpatient and inpatient attending physicians, and/or identified opportunities for systemic change. The resulting targeted interventions were tracked using the observed versus expected mortality ratio for inpatient deaths over time. **Results**: From May 2017 through August 2021 we reviewed 528 inpatient oncology deaths. Patients' median age was 65 years, and the median length of stay was 8 days. 73% of patients had metastatic cancer, and 28% received chemotherapy within 14 days of death. 25% of patients had a prior ED visit, and 35% had a prior hospitalization within 30 days of admission. Only 26% of patients had an advanced directive on record at time of death. Opportunities for improvement were identified for 60% of cases (Table). Interventions have aimed to increase advance care planning conversations and documentation, develop predictive models for cancer-related readmissions and mortality, expand outpatient services for urgent symptoms, and expedite transitions to hospice. **Conclusions**: Understanding key drivers for preventable inpatient mortality through a multidisciplinary review process identified targeted interventions that have successfully contributed to reduction of the inpatient cancer mortality index. Research Sponsor: None.

Opportunities for improvement identified by physicians through secondary review of inpatient deaths (n = 528).

Opportunities for improvement identified in mortality review	% of cases
Lack of outpatient advance care planning conversations and documentation	24
Delay in transition to hospice	13
Delayed or inadequate incorporation of palliative care service	9
Medical futility or aggressive treatment with unlikely clinical benefit	9
Goals of care discordance between providers and patient/family	5

A pragmatic cluster-randomized trial of a computerized clinical decision support system to improve colony stimulating factor prescribing for patients with cancer receiving myelosuppressive chemotherapy (SWOG S1415CD). *First Author: Scott David Ramsey, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Primary prophylactic colony stimulating factors (PP-CSF) are prescribed to patients undergoing chemotherapy to reduce the risk of febrile neutropenia (FN). Prior studies have shown that 55-95% of CSF prescribing is inconsistent with practice guidelines. We conducted a cluster randomized trial to determine if guideline-informed standing orders for PP-CSF improved prescribing and reduced the incidence of FN. **Methods:** Patients age ≥18 with breast, colorectal or non-small cell lung cancer initiating first cancer-directed therapy with NCCN-recommended regimens were eligible. The intervention consisted of automated PP-CSF orders for high FN risk chemotherapy regimens and an alert not to use PP-CSF for low FN risk regimens. Regimen FN risk was based on NCCN guidelines. Clinicians could override the orders. Primary and secondary outcomes were PP-CSF use among patients receiving high and low risk regimens FN incidence within 6 months of initial therapy. Sample size estimates assumed an FN risk of 25% for high-risk chemotherapy. 32 NCI Community Oncology Research Program (NCORP) practices randomized 3:1 to the order entry system (intervention) versus usual care (UC) provided 90% power to detect a 50% reduction in FN at a planned enrollment of 90 patients per site. Mixed effect logistic regression models were used to test differences among randomized sites. 13 practices with pre-existing PP-CSF order sets enrolled in a parallel cohort study. Patients and other stakeholder groups informed study design, conduct and reporting. **Results:** Between January 2016 and April 2020, 2,946 patients were randomized (2287 intervention, 659 UC); 718 were enrolled in the cohort. Mean age across arms was 58.1. 77% of patients were female; 61% diagnosed with breast cancer. Among patients receiving high-risk regimens, PP-CSF use did not differ between arms (89.2% intervention; 95.8% UC, adjusted p = 0.21) and was similar to the cohort patients (93.0%). The FN rate for high-risk patients was 5.7% in intervention clinics and 4.2% in UC clinics (adjusted p = 0.26); FN was 14.9% among high-risk patients who did not receive PP-CSF. Among patients receiving low-risk regimens, PP-CSF use did not differ between arms (intervention 6.3%, UC 5.5%, adjusted p = 0.74) and was slightly lower than the cohort (8.3%). FN rates did not differ between low risk groups (intervention 1.5%, UC 0.8%, adjusted p = 0.51). **Conclusions:** Guideline-informed standing orders did not increase PP-CSF use in high-risk patients, nor did it decrease use in low-risk patients. Adherence to guidelines in both risk groups exceeded historical reports. FN rates among patients not receiving PP-CSF were substantially below those reported in CSF guidelines. Automated standing orders for PP-CSF do not appear to be helpful or necessary. Clinical trial information: NCT02728596. Research Sponsor: PCORI, U.S. National Institutes of Health.

Breast cancer screening and diagnosis in a community health system during the COVID-19 pandemic. *First Author: Andrew Rudberg, University of Minnesota Medical School - Duluth Campus, Duluth, MN*

Background: Following the onset of the COVID-19 pandemic in March 2020, there was a drastic reduction in elective procedures, including screening mammograms. This was accompanied by a precipitous drop in the number of breast cancer diagnoses in 2020 compared with other years. The first aim of this study was to determine the extent of reduced mammogram screening during the first year of the COVID-19 pandemic. Secondary aims of this study were to determine the effect of reduced screening on breast cancer staging at initial diagnosis and to determine if there was a significant difference in screening patterns between rural and urban settings. **Methods:** This was a retrospective study. Mammogram data and cancer diagnosis data was collected from the time periods of March 2019 - Feb 2020 (Year 1) and March 2020 - Feb 2021 (Year 2). The patient data was selected from the Duluth/Essentia Cancer registry and through the Essentia Breast Imaging registry. Patient records were reviewed for cancer diagnosis and stage. Data on the number of mammograms performed was collected from Essentia sites across northern Minnesota that offer mammography services, including Duluth First Street, West Duluth, Virginia, and International Falls. **Results:** The demographics of patients diagnosed with breast cancer were similar between the two years. The total number of screening mammograms between March – May 2019 was 3,124. The total from March – May 2020 was 1,016, which is a reduction in the number of screenings of 2,108. Comparing June 2019 – Feb 2020, the total was 10,102, as compared to 10,459 in June 2020- Feb 2021, a total of 357 higher. This translates to a reduction of 1,751 screenings in Year 2 compared with Year 1. Between Year 1 and Year 2, we saw an increase in the proportion of stage III/IV breast cancers diagnosed, from 9.6% in Year 1 to 16.9% in Year 2, accompanied by a decrease in stage I/II cancers from 90.4% to 83.1% (p = 0.06). The total diagnoses between Year 1 and Year 2 also decreased from 211 to 185. We saw a significant decrease in the proportion and number of residents that were diagnosed via screening mammograms from urban settings during COVID, while rural patients had a significant increase in proportion and number. **Conclusions:** There was a remarkable reduction in the total number of screening mammograms and breast cancers diagnosed during the first year of the COVID-19 pandemic compared with the year prior. Patients were lost to screening, and potential diagnoses were not made. Those that did come in were more likely to present with an advanced stage cancer. Patients from rural settings were more likely than those from urban settings to be diagnosed via screening mammogram during COVID, but more investigation should be done to determine screening patterns among these populations.Providers should emphasize the importance of screening mammograms with patients and should be attentive to higher-staged cancers due to missed screenings. Research Sponsor: University of Minnesota Medical School.

Time on treatment is prolonged in patients utilizing an ePRO based digital symptom monitoring platform in the community setting. *First Author: Christina Parrinello, Expain, New York, NY*

Background: Earlier and more effective management of cancer-related symptoms and treatment-related toxicities might improve the survival of patients receiving systemic anti-cancer therapy. One potential mechanism for improved outcomes could be prolonging time on therapy. We have previously reported on the successful real-world implementation of an electronic patient-reported outcomes (ePRO) tool in a community oncology practice. We now report on the impact of the tool on time on therapy for common anti-cancer treatments. **Methods:** We evaluated time on treatment across three community oncology practices that have implemented Expain, an EMR-integrated ePRO system which enables remote symptom monitoring during therapy. We compared drug-specific cohorts of patients that had been enrolled on the ePRO tool with a concurrent cohort of patients not enrolled on the ePRO platform. We examined time on treatment using a Kaplan Meier (KM) approach. Analysis was confined to patients with no prior administration of the parenteral therapeutic agent or a 90-day treatment-free washout period; and to patients with at least three months of potential follow-up. Analysis was only conducted for drugs with at least 80 patients in the Expain arm. **Results:** In each drug-specific cohort, the distribution of age, sex, and primary cancer diagnosis was similar in patients enrolled vs not enrolled on the ePRO (Mann-Whitney and Chi-square p > 0.05 except for the rituximab cohort which had more males in the ePRO cohort [67 vs 52%]). The impact of the ePRO-based symptom monitoring system on time on therapy was statistically significant for 5 agents. **Conclusions:** We confirm in the community setting the observation that digital symptom monitoring can increase time on therapy. We believe this is due to more effective management of treatment related toxicities, as well as more effective management of malignancy related or comorbid medical emergencies which might interrupt or lead to the discontinuation of therapy. We are evaluating the robustness of these results after using various methods to address any potential non-comparability of the cohorts. We are also examining the impact of prolonging time on treatment on survival. Research Sponsor: None.

Drug	ePRO (n)	Non-ePRO (n)	log-rank p value	% on therapy at 3 months (ePRO vs Non-ePRO)
bevacizumab	80	257	0.06	70.1 vs 57.4
carboplatin	254	616	0.02	49.1 vs 37.8
oxaliplatin	121	305	0.02	66.7 vs 52.1
pembrolizumab	117	357	< 0.01	79.5 vs 65.2
rituximab	112	472	< 0.01	65.9 vs 45.6

FDA analysis of expanded access use in pediatric patients from 2015 to 2020. *First Author: Elizabeth Duke, US Food and Drug Administration, Silver Spring, MD*

Background: Expanded Access is a regulatory mechanism that enables patients with a life-threatening condition or serious disease to receive treatment with an investigational drug outside of a clinical trial when no comparable or satisfactory alternative options are available. FDA has decades of experience with expanded access, but little has been reported about its use in pediatric cancer patients. **Methods**: FDA's central electronic database was queried for single-patient investigational new drug (spIND) applications submitted to the Office of Oncologic Diseases between January 2015 through December 2020. Data collection included IND receipt date, IND type/status, drug name, and patient demographics. Duplicate or exempt INDs, those cancelled by the physician-sponsor before initiating therapy, and those requested for indications that occur almost exclusively in adults (e.g. lung cancer) or were missing patient age were excluded. **Results**: Of 2,901 unique spINDs granted, 534 (18%) were for patients less than 18 years of age. The pediatric population was 57% male, median age 6.0 years (range 0.1 to 17); race/ethnicity were reported in <1%. Patients were treated in 132 zip codes across 39 states; one-quarter of submissions were from 5 large academic hospitals. Central nervous system tumors were the most common indication (Table 1). A total of 98 unique drugs were requested, with 1 to 73 spINDs for each drug; approximately 50% were for tyrosine kinase inhibitors, 25% for other small molecules, and the remainder for immunotherapies and other drug types. Median time for FDA to grant was 1 day. Follow-up information was provided for 75% (annual report or withdrawal letter); 1/3 were withdrawn within 1 year. Over the last 2 years, utilization of the program increased by 120%. **Conclusions**: While approximately 1% of all cancers per year are diagnosed in children under 17 years of age, 18% of spINDs over the last five years were for pediatric patients. Although utilization of this program for children is robust, efforts are needed to assess its impact on patient outcomes and ensure its availability to patients, families, and institutions more widely. These data highlight interest within the pediatric oncology community in accessing innovative therapies, which supports early investigation of promising new drugs in children. Research Sponsor: None.

Tumor types for pediatric spINDs (n = 534).

Class	N (%)	Tumor Type (N)
Nervous System	229 (43)	High-Grade Glioma/Diffuse Intrinsic Pontine Glioma (59); Low-Grade Glioma (67); Embryonal/Other brain tumor (68); Plexiform neurofibroma (35)
Hematologic	102 (19)	Acute Lymphoblastic Leukemia (25); Acute Myeloid Leukemia (36); Lymphoma (9); Other (32)
Sarcoma	90 (17)	Osteosarcoma (58); Ewing (6); Rhabdomyosarcoma (7); Other (19)

Evaluation of outcomes in patients (pts) with stage 4 non-small cell lung cancer (NSCLC 4) harboring actionable oncogenic drivers (AOD) when treated prior to report of mutation without tyrosine kinase inhibitors (TKI): An Integra Connect Database (ICD) retrospective observational study. *First Author: Robert E. Smith, Integra Connect, West Palm Beach, FL*

Background: In a prior analysis, we identified 525 pts with newly diagnosed NSCLC 4 harboring AOD in the ICD. Of these, 141 were treated prior to the reporting of AOD with chemotherapy (C), immune checkpoint inhibitor (ICI), or both. This report details the clinical outcomes of these 141 compared to the 384 treated after AOD reported. **Methods:** Real world data (RWD) were obtained from a curated ICD for pts with NSCLC 4 diagnosed 1/1/2018-12/31/2020 with cutoff of data 3/31/2021. Pts with EGFR, ALK, ROS1, BRAF, MET, RET, HER2, and NTRK were included if their treatment record were captured. Also included were demographics, ECOG score, date of first report of AOD and dates of initiations of first and any second line of therapy and date of apparent death (AD). Outcome measures were time to next treatment or apparent death (TTNT) and apparent survival (AS) (ICD model does not allow date of death per HIPAA de-identified Expert Determination). Descriptive statistics were used with Kaplan-Meier (K-M) estimates and Hazard Ratios (HR) by Cox regression. 3 cohorts were defined: Group (Gr) A with 384 pts treated after AOD reported and used as the comparator; the 141 pts treated before AOD with C, ICI or both were divided into Gr B (n = 51) who subsequently switched to TKI within 35 days and Gr C (n = 90) who did not switch. **Results:** As shown in data table, AS was significantly worse in Gr B and Gr C, TTNT was significantly worse in Gr C and with worsening trend in Gr B. Two potential confounders were identified: higher ECOG scores might indicate more urgency to assign treatment, but pts with ECOG ≥ 2 were similar in all 3 groups; also, difference in proportion of EGFRm by Group (Gr A 62%, Gr B 57%, and Gr C 29%), but separating cohorts by EGFR mutation status did not alter results. **Conclusions:** While subject to the limitations of a retrospective observational RWD study, this study strongly suggests outcomes are significantly compromised in pts harboring AOD but who are treated initially with C, ICI or both, even in pts quickly switched to TKI. Since a prospective clinical trial is not ethically feasible, these findings may stimulate review of current guidelines, fuel optimization of universal testing in NSCLC 4, and encourage utilization of liquid or ultra-fast NGS with their rapid turnaround times in order to improve survival in this setting. Research Sponsor: Thermo Fisher.

Cohort	n	ECOG ≥ 2	Median TTNT (range) in days	TTNT HR (p-value)	Median AS (range) in days	AS HR (p-value)	HR (p-value) adjusted for EGFR %

Oncologists' perspectives on individualizing dose selection for patients with metastatic cancer. *First Author: Rachel Jimenez, Massachusetts General Hospital, Boston, MA*

Background: The goal of treatment for patients with metastatic cancer (MC) is to prolong and maintain quality of life. Patients and oncologists have questioned the current paradigm of initial dose selection for systemic therapy and want additional information about the potential trade-offs between efficacy and toxicity. However, empirical data on oncologists' dose selection strategies and beliefs is lacking. **Methods:** ASCO conducted an international survey of medical oncologists who treat patients with metastatic breast or gastrointestinal cancers. Survey questions addressed experience with and attitudes towards reducing the standard dose of the first cycle of systemic therapy to minimize potential toxicity. The survey was open November 14 to December 13, 2021. **Results:** Among 3,099 eligible ASCO members, 367 completed the survey (response rate 12%), including 117 general oncologists (GO), 142 breast specialists (BRS), and 108 GI specialists (GIS). 77% of respondents practice in the US, 94% had experience leading a clinical trial, and 50% had been caregivers or patients themselves. Most respondents (52%) reported reducing the first dose of systemic agents at least 10% of the time in patients with MC to minimize toxicities. GIS were more likely to report reducing the first dose at least 10% of the time (72% vs. 50% of GO and 51% of BRS, $p < .005$). Of those who dose reduce, 89% reported discussing potential tradeoffs between efficacy and toxicity with patients. Among 10 common breast cancer drugs, capecitabine (76%) was the most likely to be dose reduced at initiation while tamoxifen (4%) was the least likely. Among 10 common GI cancer drugs, regorafenib (78%), capecitabine (71%) and sorafenib (66%) were most commonly dose reduced at initiation, while bevacizumab (7%) and panitumumab (8%) were the least likely. Overall, 65% of respondents agreed it is acceptable to lower starting doses to reduce side effects even at the potential expense of efficacy, with younger clinicians more likely to agree vs. older clinicians (72% age < 50 vs. 55% age > 50, $p < .005$). While the majority (53%) believe that oncologists should start with the recommended dose and lower it in response to side effects, GIS were more likely to disagree with this approach compared to BRS or GO (57% vs. 37% and 36% respectively, $p < .005$). In contrast, 45% of respondents believe that oncologists should start at a lower dose and consider increasing the dose for future cycles if the drug is well tolerated. There was strong support (89%) for future trials that seek to determine the minimal effective dose as opposed to the maximum tolerated dose. **Conclusions:** Oncologists frequently dose reduce to avoid toxicity in patients with MC but practices and attitudes regarding dose reduction vary considerably. Further research is needed to establish optimal dosing during drug development and to support oncologists and patients in selecting the starting dose in clinical practice. Research Sponsor: American Society of Clinical Oncology.

Will COVID-19 directives to reduce regularly scheduled physical examinations affect recurrence detection in patients with early breast cancer? *First Author: Ana-Alicia Beltran-Bless, Division of Medical Oncology, Department of Medicine, University of Ottawa, Ottawa, ON, Canada*

Background: The COVID-19 pandemic has significantly reduced routinely scheduled in person assessment and examination of early breast cancer patients (EBC). To assess if this is likely to impact the detection of recurrent disease, we reviewed recurrence patterns of EBC patients enrolled in a survivorship program that adheres to ASCO guidelines. **Methods:** Charts of EBC patients transferred through a single center Wellness Beyond Cancer Program (WBCP) and who subsequently had a breast cancer recurrence between February 1, 2013 and January 1, 2019 were reviewed. Patient, tumor and treatment characteristics were evaluated. **Results:** Of 206 patients eligible for the current study, 41 patients had ipsilateral breast recurrences (19.9%), 135 had distant recurrences (65.5%) and 30 had contralateral new breast cancers (14.6%). Ipsilateral breast recurrences were detected by the patient in 53.7% (22/41) and by routine imaging in 41.5% (17/21). The majority of distant recurrences (125/135, 92.6%) were detected via patient-reported symptoms. Contralateral breast primaries were detected by patients 16.7% (5/30) or by routine imaging (83.3%, 25/30). Only 2/206 (1.14%) recurrences/new primaries were detected by healthcare providers at routinely scheduled follow-up visits. There was a statistical difference in recurrence detection between image detected vs. self-detected in the following factors: grade 3 (26.5% vs 51%, $p < 0.007$), triple negative breast cancer (3.9% vs. 15.1%, $p = 0.03$), HER2 disease (18.4% vs. 9.8%, $p = 0.04$). **Conclusions:** Despite following ASCO follow-up guidelines for routinely scheduled follow-up appointments with physical examination, healthcare providers rarely detect recurrence disease. While reduced in person visits may affect other aspects of follow-up (e.g., toxicity management), it appears unlikely, provided patients attend regular screening tests, that reduced in-person follow-up is associated with worse breast cancer-related outcomes during the COVID-19 pandemic. Ancillary treatment referrals and visits after breast cancer surgery in a sociodemographically diverse population. *First Author: Vernice Hui Yan Chan, The University of Hong Kong, Pokfulam, Hong Kong, Hong Kong*

Background: Ancillary therapies by rehabilitative, palliative, and survivorship specialists mitigate breast cancer surgery's physical and emotional effects. Existing data suggest that patients from disadvantaged backgrounds may be less likely to receive such care. We investigated provider referrals and patient visits at a high-volume urban cancer center to identify associated sociodemographic factors and characterize which populations may not be maximally benefiting from ancillary services. **Methods:** Data was culled from electronic health records of surgically-treated breast cancer patients at Yale-New Haven Health System between 2010-2017. Postoperative provider referrals to Physical/Occupational Therapy, Palliative Medicine, and Survivorship Program were evaluated for associations with demographic and disease variables in univariable and multivariable logistic regression analyses. Patient utilization of referrals, defined as attending at least one consultation, were analysed similarly. **Results:** Among 5,496 patients identified, 2,288 (41.6%) were referred for ancillary treatments and 1,572 (28.6%) attended at least one consultation. Provider referrals were highest among patients of Hispanic and Black ancestry (57.5% and 54.9%, respectively), no health insurance (57.6%), lowest percentage high school degree for zip code (50.5%), and lowest median income for zip code (50.7%). These associations remained significant in multivariable analysis [all p<0.050]. In contrast, referral utilization was greatest among patients with private insurance (70.7%), highest percentage high school degree (72.8%), and highest median household income (72.2%), in addition to Hispanic ethnicity (73.5%). In multivariable analysis, highest median household income (OR 1.45, p = 0.019) and Hispanic ethnicity (OR 1.50, p = 0.048) remained associated. **Conclusions:** In a large urban health system serving a diverse population, traditional markers of poor healthcare access were positively associated with provider referral for ancillary services after breast cancer surgery. However, referral did not translate to utilization, suggesting that access remains a critical barrier to therapies that target post-operative morbidity and elevate quality of life. Research Sponsor: None.

Multivariable analysis of demographic factors associated with referrals and visits to ancillary services after breast cancer surgery.

CONTINUUM: A pilot care transition intervention for hospitalized patients with advanced cancer. *First Author: Daniel E Lage, Harvard Medical School, Boston, MA*

Background: Patients with advanced cancer are frequently hospitalized and experience burdensome transitions of care after discharge. Interventions to address patients' symptoms, support medication management, and ensure continuity of care after discharge are lacking. We sought to demonstrate the feasibility and acceptability of CONTINUUM (CONTINUity of care Under Management by video visits) for this population. **Methods:** We conducted a single-arm pilot trial (n = 54) of CONTINUUM at Massachusetts General Hospital (MGH). The intervention consisted of a video visit with an oncology nurse practitioner (NP) within 3 business days of hospital discharge to address symptoms, medication management, hospitalization-related issues, and care coordination. Prior to discharge, we enrolled English-speaking adults with advanced breast, gastrointestinal, genitourinary, or thoracic cancers experiencing an unplanned hospitalization who were receiving ongoing oncology care at MGH and being discharged home without hospice services. We defined the intervention as feasible if ≥70% of approached and eligible patients enrolled and if ≥70% of enrolled patients completed the intervention within 3 business days of discharge. At 2 weeks after discharge, patients rated the ease of use of the video technology and stated whether they would recommend the intervention. NPs completed post-intervention surveys to assess fidelity to the intervention protocol. **Results:** From 01/07/21 to 05/28/21, we enrolled 54 patients (77.3% of patients approached). Of the enrolled patients (median age = 65.0 years; 59.3% and 22.2% had advanced gastrointestinal or thoracic cancers, respectively), 83.3% of enrolled patients received the intervention within 3 business days of discharge. Patient rating of the ease of use of video technology was a mean of 7.8 out of 10, with 71.4% stating they "agreed" or "strongly agreed" that they would recommend the intervention. NP post-intervention surveys revealed that visits focused on symptom management (85.7%), followed by addressing post-hospital care issues (69.0%). At 30 day follow up, 38.8% were readmitted within 30 days of discharge, and 12.2% died within 30 days of discharge. **Conclusions:** We found that CONTINUUM, which consists of an NP-delivered video visit soon after hospital discharge addressing patients' symptoms, medications, and care coordination, represents a feasible and acceptable approach to provide post-discharge care for hospitalized patients with advanced cancer. Future studies will test the efficacy of the intervention for reducing hospital readmissions. Clinical trial information: NCT04640714. Oncology hospital at home in rural communities: The Huntsman at Home rural experience. *First Author: Kathi Mooney, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Oncology hospital at home programs have shown promise in decreasing unplanned health care utilization while improving quality of life. While most hospital at home programs serve local urban areas, we extended our oncology hospital at home program, Huntsman at Home, to provide equitable distribution of program services for cancer patients living in rural communities at a distance from our cancer center. **Methods:** Utilizing a community engagement approach we redesigned our urban Huntsman at Home program for 3 rural communities in Southeastern Utah, a 2 to 5 hour one-way drive from Huntsman Cancer Institute. We systematically collected patient data and program modifications required for rural community delivery during the program's first 6 months. Care was delivered by on-ground and telehealth nurse practitioner visits and on-ground registered nurse and physical therapy visits. Cardiovascular remote monitoring was utilized during acute care episodes. **Results:** A total of 47 cancer patients (31 men; 16 women; mean age 69 years) were admitted to the rural program during the first 6 months. Seven patients had 9 acute illness episodes of care. The average length of acute episode care was 6.1 days for treatment of infection, respiratory distress/ hypoxia, cardiac instability (hypotension, tachycardia), and dehydration/electrolyte imbalance and uncontrolled vomiting. Forty patients received subacute management aimed to prevent acute episodes and escalation to the emergency department (ED) or hospitalization. Subacute patients were in the program an average of 15.8 days. There were 4 appropriate escalations (2 hospitalizations, 1 ED visit returned to home and 1 ED visit with hospitalization) for symptoms related to disease progression requiring imaging and hospital-based procedures and one for diagnosis of a post-surgical PE. We found geographic and social determinates of health impacted rural patients' cancer burden, most notably transportation barriers (44.7%). Secondarily, we found food insecurity impacted nutritional status in 14.9% of patients. A significant number of patients experienced financial toxicity (29.8%) related to lost wages, co-pays and/or out of pocket expenses for care. Lack of health literacy impacted 48.9% of patients effectively navigating their health care and self-management at home. Robust communication and coordination between the hospital at home clinical team, local primary care providers, the rural hospital, community resources and the patients' cancer center oncology team were keys to improving care pathways. **Conclusions:** Rural oncology hospital at home is feasible and addresses geographic disparities in equitable access to acute and subacute cancer care in local communities. It requires adaptation to rural needs and culture, coordinated escalation procedures and a focus on addressing geographic and social determinates of health that impact cancer burden. The impact of an oncology-specific shared savings agreement. *First Author: Edward Thompson, CVS Health, Lincoln, RI*

Background: In response to rising healthcare costs, several innovative payment strategies have emerged to improve the value and efficiency of healthcare spending. One of these strategies is a shift from volume-based to value-based care (VBC), resulting in the introduction of alternative payment models, innovative provider contracting and new value frameworks. The purpose of this study is to evaluate the impact of a VBC arrangement on total cost of care for chemotherapy patients, specifically cancer-related drug costs, daily hospital inpatient admissions and emergency room visits. **Methods:** This is a cohort study of chemotherapy patients, in a single state, enrolled in a large national insurer from January 18, 2021, to September 30, 2021. Oncology patients were divided into two groups; the study group consisted of chemotherapy patients receiving care in a VBC arrangement; the control group consisted of chemotherapy patients receiving care at oncology practices not engaged with the insurer in a VBC agreement. The following levers were employed to improve value: digital symptom tracking, biosimilar or lower-cost drug options and NCCN regimen concordance. We defined cancer-related drug costs as the sum of allowed costs paid for medical and pharmacy claims during the study period. Additionally, we averaged the cost per hospital inpatient day and emergency room visit and compared these by group. **Results:** This study included 1,574 patients, 733 patients in the study group and 841 in the control group. A reduction of 5.1% (a difference of $441) in cancer-related drug costs per member per treatment month (PMPTM) was observed among patients in the study group. Patients in the study group reported 27.8% fewer inpatient days resulting in a savings of $194 PMPTM. Similarly, patients in the study group reported 70.0% fewer emergency room visits resulting in a savings of $59 PMPTM. **Conclusions:** In this study, chemotherapy patients participating in a shared savings VBC spent less on cancer-related drug costs, hospital inpatient days and emergency room visits through three value levers. Further studies are needed to assess if these results are similar all types of healthcare coverage and to what degree additional value levers further reduce costs. Additionally, the long-term health outcomes of these patients should be assessed. Research Sponsor: None.

Impact of cancer diagnosis, stage, and systemic therapies on immunogenicity after COVID-19 vaccination in patients with cancer: A systematic review and meta-analysis. *First Author: Guilherme Nader Marta, Academic Trials Promoting Team, Institut Jules Bordet and l'Université Libre de Bruxelles (U.L.B), Brussels, Belgium*

Background: Patients (pts) with cancer are at increased risk of severe COVID-19. Both underlying malignancy and anti-cancer treatments influence the immune system, potentially impacting the level of vaccine protection achieved. **Methods:** A systematic literature search of PubMed, Embase, CENTRAL and conference proceedings (ASCO annual meetings and ESMO congress) up to 28/09/21, was conducted to identify studies reporting anti-SARS-CoV-2 spike protein immunoglobulin G seroconversion rates (SR) at any time point after complete COVID-19 immunization (mRNA- or adenoviral-based vaccines) in cancer pts. Complete immunization was defined as 1 dose of JNJ-78436735 vaccine or 2 doses of BNT162b2, mRNA-1273 or ChAdOx1 nCoV-19 vaccines. Subgroup analyses were performed to examine the impact of cancer diagnosis, disease stage, and anti-cancer therapies on the SR. Overall effects were pooled using random-effects models and reported as pooled SR with 95% confidence intervals (CI). **Results:** Of 1,548 identified records, 64 studies were included in this analysis reporting data from 10,511 subjects. The Table shows the SR in the overall population and specific subgroups. In pts with solid malignancies (SM), disease stage and primary site did not significantly impact the SR. In pts with hematologic malignancies (HM), SR were significantly lower in pts with chronic lymphocytic leukemia (CLL) and non-Hodgkin lymphoma (NHL) compared to acute lymphoblastic leukemia (ALL), Hodgkin lymphoma (HL), and multiple myeloma (MM). Concerning the impact of cancer therapies on SR, pts with SM undergoing chemotherapy had numerically lower SR (N = 1,234, SR 87%, CI 81-92) compared to those treated with immune checkpoint inhibitors (N = 574, SR 94%, CI 88-97) or endocrine therapy (N = 326, SR 94%, CI 86-97) with or without another targeted therapy. Pts with HM treated with anti-CD20 therapy (within the last 12 months: N = 360, SR 7%, CI 2-20; or more than 12m: N = 175, SR 59%, CI 35-80), immune-modulating agents (BTK or BCL2 inhibitors) (N = 462, SR 47%, CI 32-64%) or other immunotherapies (anti-CD19/CART or anti-CD38) (N = 293, SR 37%, CI 23-53) had lower SR compared to pts treated with autologous (N = 353, SR 77%, CI 67-85) or allogenic stem cell transplantation (N = 509, SR 77%, CI 68-84). **Conclusions:** SR varies between cancer types and anticancer therapies with some cancer pts having low protection against COVID-19 even after complete vaccination. Research Sponsor: None.

Characteristics associated with functional resilience versus functional decline among adult patients with advanced non–small cell lung cancer. *First Author: Joy Tang, Ohio State University, Columbus, OH*

Background: As more treatment options become available for advanced non-small cell lung cancer (NSCLC), oncologists still have difficulty predicting functional resiliency versus functional disability throughout treatment. Functional resiliency refers to the ability to recover baseline functional status in the face of an intervening health care event. This study aims to identify characteristics associated with resilience among adults with advanced NSCLC. **Methods:** In a prospective cohort of participants with newly diagnosed stage IV NSCLC, resilience was evaluated based on three functional disability items in the EQ-5D-5L (modified: mEQ-5D-5L) through 12 months of follow-up compared to baseline scores. This included patients treated with chemotherapy, immunotherapy, targeted agents and no treatment. Participants were classified into four groups: functional decline, maintenance, resilient, or variable. Resilience was determined based on improvement in disability scores, with a 1-point increase in functional status score representing a 0.5 standard deviation change on the mEQ-5D-5L. Patient characteristics included demographics, comorbidities, ECOG performance status, presence of brain or bone metastases, mood (GAD-7, PHQ-9), and lung cancer-specific symptoms (QLQ-LC13). Treatment toxicity and toxicity grades were also recorded. Differences between groups were determined through Fisher's exact test or ANOVA. **Results:** Among 207 participants, 87 (42.0%) maintained functional status, 78 (37.7%) experienced functional decline, 22 (10.6%) were classified as resilient and 20 (9.7%) were variable. Characteristics associated with higher resilience ($p < 0.1$) included being employed ($p = 0.02$) and living in a metro setting ($p = 0.10$). Characteristics not associated with resilience included age, education level, smoking status, presence of brain metastases, ECOG performance status, or psychological symptoms. Approximately half the participants (n = 105, 50.7%) who received treatment experienced toxicities. One third (33.8%) experienced ≥ grade 3 toxicities. There was no significant association between toxicity grade and resilience grouping. **Conclusions:** Characteristics associated with functional resilience included employment status and living setting. At least half of adults with advanced NSCLC experience treatment-related toxicities. It is important to determine characteristics of resilience to better understand which patients will tolerate cancer treatments. Research Sponsor: None.

Impact of provider education on hepatitis B screening practices prior to patients receiving cancer treatment. *First Author: Michael Adashek, St. Joseph Mercy Hospital IHA Hematology Oncology, Ypsilanti, MI*

Background: Hepatitis B virus (HBV) reactivation is a known side effect of CD20 targeted therapies with complications ranging from transient hepatitis to fulminant hepatic failure and death. In 2020 the American Society of Clinical Oncology (ASCO) expanded its provisional clinical opinion (PCO) to recommend HBV screening for all patients prior to receiving non-hormonal systemic anti-cancer therapies and if positive, offer viral prophylaxis or treatment. We assessed in a single-institution prospective study if a provider-led educational session on the 2020 ASCO PCO was effective in increasing HBV screening among patients receiving systemic non-hormonal anti-cancer therapies. **Methods:** An educational session for 30 minutes on the benefits outlined in the ASCO 2020 PCO discussing hepatitis B screening was held at a community-based hematology/oncology practice in Michigan. HBV screening panel was added to pre-chemotherapy lab order sets. Provider compliance with HBV screening recommendations was assessed monthly. Patients with positive HBV serology were identified and referred to Hepatology for monitoring and anti-viral treatment/prophylaxis as indicated. Data from 1,984 patient encounters for cancer treatment utilizing either chemotherapy or rituximab among 12 providers from March of 2020 to December 2021. Multivariate and logistic regression analysis was performed. **Results:** The educational intervention on the best practices of screening for Hepatitis B was effective in raising screening. Prior to intervention, 79.3% of all patients receiving rituximab (N = 140) and 15.7% of all patients receiving chemotherapy (N = 1277) had documentation for Hepatitis B before cancer treatment. Post-intervention hepatitis B testing increased both among patients receiving rituximab to 95.8% (N = 48) and chemotherapy to 29.9% (N = 519). In summary, prior to intervention, just 22.0% of 1,417 patient encounters had documentation for Hepatitis B screening before undergoing a treatment regimen. Post-intervention this level was raised to 35.45% (= 37.41,). In this study, 3 cases (0.5%) of acute and 12 cases (2.0%) of chronic HBV were identified from the 603 tested patients. A mixed effects logistic regression model controlling for treatment type and provider found patient encounters occurring post-intervention were 2.30 times more likely to be screened (OR = 2.30, 95% CI = [1.81, 2.93], $p < 0.001$). **Conclusions:** Our single educational session discussing the 2020 ASCO PCO and testing techniques for HBV was effective at increasing the odds of screening 2.3 times among patients receiving non-hormonal systemic anticancer therapies adjusting for therapy and provider. This may serve as a model for other implementations of PCOs. Further research will assess long-term oncologic outcomes of those identified with HBV and effects of anti-viral interventions. Research Sponsor: None.

Long COVID-19 in patients with cancer: Report from the National COVID Cohort Collaborative (N3C). *First Author: Noha Sharafeldin, Department of Hematology & Oncology, School of Medicine, University of Alabama at Birmingham, Birmingham, AL*

Background: Post-acute sequelae of SARS-CoV-2 or long COVID, is characterized by persistence of symptoms and/or emergence of new symptoms post COVID-19 infection. As evidence accumulates and national initiatives arise to address this increasingly prevalent syndrome, characterization of specific patient groups is still lacking including patients with cancer. Using a nationally representative sample of over 4.3M COVID-19 patients from the National COVID Cohort Collaborative (N3C), we aim to describe characteristics of patients with cancer and long COVID. **Methods:** We employed two approaches to identify long COVID patients within N3C: i) patients presenting to a long COVID clinic at four N3C sites and ii) patients diagnosed using the recently introduced ICD-10 code: U09.9 Post COVID-19 condition, unspecified. We included patients with at least one positive COVID-19 diagnosis between 1/1/2020 and 2/3/2022. Patients had to survive at least 90 days from the date of their COVID-19 diagnosis. Analyses were performed in the N3C Data Enclave on the Palantir platform. **Results:** A total of 1700 adult patients with long COVID were identified from the N3C cohort; 634 (37.3%) were cancer patients and 1066 were non-cancer controls. The most common represented cancers were skin (21.9%), breast (17.7%), prostate (8.3%), lymphoma (8.0%) and leukemia (5.7%). Median age of long-COVID cancer patients was 64 years (Interquartile Range: 54-72), 48.6% were 65 years or older, 60.4% females, 76.8% non-Hispanic White, 12.3% were Black, and 3% Hispanic. A total of 41.1% were current or former smokers, 27.7% had an adjusted Charlson Comorbidity Index score of 0, 18.6% score of 1 and 11.2% score of 2. A total of 57.2% were hospitalized for their initial COVID-19 infection, the average length of stay in the hospital was 9.6 days (SD: 16.7 days), 9.1% required invasive ventilation, and 13% had acute kidney injury during hospitalization. The most common diagnosis among the non-cancer long COVID patients was asthma (26%), diabetes (17%), chronic kidney disease (12%), heart failure (9.4%), and chronic obstructive pulmonary disease (7.8%). Among long COVID patients, compared to non-cancer controls, cancer patients were more likely to be older (OR = 2.4, 95%CI: 1.1-5.4, $p = 0.03$), have comorbidities (OR = 4.3, 95%CI: 2.9-6.2, $p < 0.0001$), and to be hospitalized for COVID-19 (OR = 1.3, 95%CI: 1.0-1.7, $p = 0.05$), adjusting for sex, race/ethnicity, body mass index and smoking history. **Conclusions:** In a nationally representative sample of long COVID patients, there was a relative overrepresentation of patients with cancer. Compared to non-cancer controls, cancer patients were older, more likely to have more comorbidities and to be hospitalized for COVID-19 warranting further investigation to identify risk factors for long COVID in patients with cancer. Enabling community-led integrated women health care models for women cancers screening and early detection through EMPOWER (Enabling and Motivating Partnerships Owned by Women who Engage and Reclaim their lives) project. *First Author: Dorothy Nyongo, County first ladies association, Nairobi, Kenya*

Background: With the growing burden of Women cancers in East Africa, integrating cancer screening and prevention to optimize horizontal care delivery models is a paramount approach to strengthening women-centered and cost-effective primary healthcare. EMPOWER is a unique partnership with the government of Kenya, County referral hospitals, County First Ladies Association, International Cancer Institute, Patient organizations and Roche Kenya to demonstrate integrated cancer prevention and treatment within primary healthcare shared across the Kenyan Health system. **Methods:** EMPOWER clinics were launched with over 300 community health workers (including women living with disabilities) and HCPs were identified and trained to provide facility and community-based screening and early detection for breast cancer, cervical cancer, hypertension and diabetes through an integrated health systems strengthening approach. Mentorship was provided to HCPs through routinely held joint screenings and clinics, weekly Tumor Boards, Teleclinics, Telemedicine and Digital Pathology platforms. In addition, training support was provided through virtual preceptorships, skills-training workshops, hub-and-spoke oncological services provision and robust patient navigation. **Results:** 14 EMPOWER clinics have been launched across Kenya to increase community awareness of breast, cervical, and NCDs, strengthen capacity to deliver integrated Women cancer management services in County health clinics. In Kenya out of 25,502 people screened, 13,192 were screened for breast cancer with 97 abnormal findings identified; 10,349 screened for cervical cancer with 200 abnormal cervical screenings identified and 1,664 screened for prostate cancer with 32 abnormal findings. In addition, an integrated approach in Non Communicable Disease (NCD) care, diabetes and hypertension screening; 4,298 screened for diabetes and 6,116 screened for hypertension. All those diagnosed with cancers were linked to existing cancer care delivery systems and continuous support offered through the strengthened health care systems. Prostate cancer was added as more men turned up for screening events. **Conclusions:** This model is replicable and scalable across LMIC and recently the model inspired health providers' from Tanzania and Nigeria to adopt the same for women's cancers. EMPOWER has demonstrated a scalable care model in Kenya contributing to investments in pathology training and clinical treatment to improve challenges in referrals and updating guidelines to enable multi-disease tissue testing and handling and treatment with Standard of Care. Does the 4R oncology model improve clinicians' effectiveness in patient-facing planning of complex cancer care? *First Author: Julia R. Trosman, Center for Business Models in Healthcare, Chicago, IL*

Background: The 4R Oncology model was proposed within the NCI ASCO Teams Project as an approach to facilitate patient-facing care planning, team-based delivery and patient self-management. 4R (Right Info/Care/Patient/Time) enables care teams and patients to manage complex care with a novel 4R Care Sequence plan. We previously reported that 4R significantly improved patient self-management, namely patients' ability to organize and manage their care (Trosman JCO OP 2021). Here we report the impact of 4R on effectiveness of clinicians to plan and deliver complex multidisciplinary care. **Methods:** We surveyed clinicians (physicians and nurses) from 8 cancer centers (4 academic, 4 community) participating in a 4R adoption program. The survey was conducted Mar 2019 to Sep 2019 prior to 4R launch (Baseline cohort), and Nov 2021 to Jan 2022 post-4R launch (4R cohort). Baseline cohort included clinicians conducting care planning with patients. 4R cohort included clinicians who used 4R in care planning with new patients. The survey focused on clinicians' self-reported effectiveness in planning and management of guideline-based care. Descriptive statistics and Fisher's 2-sided test were used in analyses. **Results**: Baseline cohort's response rate was 79% (66/83); 4R cohort's response rate was 86% (62/72). 4R implementation was associated with significant improvement in all 5 metrics of effective care planning between the baseline and 4R cohorts (Table). Within the 4R cohort, 87% (54/62) clinicians found 4R Care Sequences useful or very useful for care planning and management. The majority, 79% (49/62), spent 10 minutes or less on average developing and administering 4R Care Sequence to a new patient, and 58% (36/62) reported decreased overall volume of post-visit inquiries about care plan from patients who received 4R. When asked about 4R delivery format, 65% (40/62) preferred paper, 23% (14/62) electronic delivery and 12% (8/62) had no preference. **Conclusions:** The 4R Oncology model is a promising approach to improving clinicians' effectiveness in patient-facing care planning and reducing the workload associated with patient inquiries. An ongoing 4R research and implementation program continues efforts to identify optimal implementation methods and integrate 4R into clinical practice across the U.S. Research Sponsor: The Coleman Foundation.

Demographic and laboratory determinants of humoral immune responses and impact of different anti-SARS-CoV-2 vaccine platforms in patients with cancer: A systematic review and meta-analysis. *First Author: Diogo Martins-Branco, Academic Trials Promoting Team, Institut Jules Bordet and l'Université Libre de Bruxelles (U.L.B), Brussels, Belgium*

Background: Patients (pts) with cancer have increased mortality from COVID-19 and their vaccination is crucial to prevent severe infection. We aimed to identify demographic and laboratory determinants of humoral immune responses to COVID-19 vaccination in pts with cancer and investigate differences in responses based on the vaccine platform. **Methods:** We searched for records in PubMed, Embase, and CENTRAL up to 28/09/21, as well as conference proceedings from ASCO and ESMO 2021. We included studies of pts ≥16 yr with a cancer diagnosis, who were vaccinated against SARS-CoV-2. Studies were excluded if ≥10% of the participants had other causes of immunosuppression or baseline anti-SARS-CoV-2 spike protein antibodies (Ab)/previous COVID-19 (PROSPERO ID: CRD42021282338). For this subgroup analysis of studies that reported a proportion of pts with cancer and positive Ab titers at any timepoint following complete vaccination, a random-effects model was used to estimate the humoral response rate (HRR) with 95% confidence intervals (CI). **Results:** We included 64 records, reporting data from 10,511 cancer pts. The HRR in the overall population and by subgroup are shown in Table. Elder patients with hematologic cancers (59%, CI 47-70%, N = 667) and patients with lymphopenia (50%, CI 25-75%, N = 111) or hypogammaglobulinemia (36%, CI 19-57%, N=226) were the subgroups with lower HRR. Male (77%, CI 69-84%, N = 2,659) and Asian (84%, CI 54-96%, N = 37) pts showed a trend to lower HRR when compared with females and other races, respectively. Pts vaccinated with mRNA vaccine platforms (79%, CI 74-83%, N = 9,404) had numerically higher HRR than those receiving the adenovirus vaccines (28%, CI 19-40%, N = 74). **Conclusions:** This study highlights demographic and laboratory determinants of weaker immune responses to SARS-CoV-2 vaccination, permitting better identification of more vulnerable pts. Despite the small number of pts included receiving adenovirus vaccines, these data also suggest prioritizing mRNA platform vaccination in pts with cancer. Research Sponsor: None.

Proportion of pts with anti-SARS-CoV-2 spike protein Ab.

Determinant	Subgroups (N of studies; pts)	Overall % (95% CI)	Solid cancers % (95% CI)	Hematologic cancers % (95% CI)
Overall	(64; 10,511)	78 (73-82)	95 (89-95)	64 (58-69)
Age	Younger (13; 1,240) vs Elder (13; 1,127)	79 (67-88) vs 71 (57-82)	93 (85-97) vs 93 (85-97)	71 (58-80) vs 59 (47-70)
Sex	Female (26; 2,840) vs Male (25; 2,659)	81 (73-87) vs 77 (69-84)	89 (84-93) vs 89 (84-93)	66 (55-75) vs 61 (51-69)
Race	White (4; 1,675) vs Black (4; 83) vs Asian (3; 37)	91 (81-96) vs 91 (75-97) vs 84 (54-96)

Analysis of the likelihood of depression versus distress screening to identify need for intervention. *First Author: Valerie Pracilio Csik, Sidney Kimmel Cancer Center, Philadelphia, PA*

Background: Psychosocial assessments are increasingly used to evaluate a patient-centered approach to quality cancer care delivery. Value-based oncology programs endorse screening metrics at every encounter. To comply with expectations of these programs, our cancer center utilizes two standardized tools: Patient Health Questionnaire (PHQ) to screen for depression at every encounter; National Comprehensive Cancer Network Distress Thermometer (NCCNDT) to screen for acute distress at clinically meaningful intervals. In 2021, oncology patients completed, on average, 5 annual appointments at Sidney Kimmel Cancer Center (SKCC), with a median appointment frequency of once every 19 days. Given the high encounter-per-patient ratio, we aimed to assess utility of frequent screening leading to supportive intervention. **Methods:** A retrospective analysis was conducted of medical oncology patients seeking care at SKCC with a completed depression and/or distress screening, as recorded in the patient's electronic health record, between 1/1/2021 and 12/31/2021. This analysis intended to evaluate the percentage of patients whose scores indicate need for intervention. Patients who received more than one screening were attributed the highest score recorded during the measurement period. **Results:** A total 13,342 patients were screened at least once for either depression (n = 7,433), distress (n = 1,325), or both (n = 4,584). 3% of all patients screened ever met the intervention threshold (IT) for depression; 33% met the IT for distress. Of the patients who received both types of screenings, 31% met the IT for distress without meeting the threshold for depression. Those 1,418 patients would not have been referred for intervention through depression screening alone. **Conclusions:** This analysis highlights routine depression screening among a cancer population with a high encounter-per-patient ratio may not be sensitive in identifying need for supportive intervention. It also suggests that distress screening is more likely to lead to a supportive intervention than depression screening alone. This analysis combined with the anecdotal assessment by social workers supports the value of distress at clinically meaningful intervals over depression screening at each encounter. Research Sponsor: None.

Depression versus distress screening results.

		Depression	
		Below IT (<10)	*Meets IT (≥10)*
Distress	*Meets IT (≥4)*	1418 (31%)	145 (3%)
	Below IT (<4)	2964 (65%)	57 (1%)

Impact of proactive symptom monitoring on quality of life (QoL) and treatment toxicity in patients with cancer receiving chemotherapy: A meta-analysis of randomized clinical trials. *First Author: Faris Tamimi, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Early recognition and management of symptoms can improve outcomes in cancer patients receiving treatment. A number of randomized trials have investigated the effects of adding proactive symptom monitoring to usual care (UC). These include web-based, application-based, or telephone-based assessments. Results have been variable, and the impact of proactive symptom monitoring on QoL, treatment toxicity and utilization of unscheduled acute care remains unclear. **Methods:** A systematic search of MEDLINE identified prospective, randomized trials that studied the effect of proactive monitoring and intervention versus UC in cancer patients receiving chemotherapy. The difference between proactive symptom monitoring and UC on the mean and SD for QoL using validated scales was collected for each study and pooled in a meta-analysis. Analysis was performed using the standardized mean difference (SMD) using random-effects modeling. The effect size was reported as the Hedges' adjusted g. We also calculated the odds ratios (OR) for the occurrence of several common symptoms of any grade in the individual trials and pooled them in a meta-analysis. Statistical significance was defined as $P < 0.05$. Quantitative significance was defined as a difference in QoL score exceeding the minimal clinically important difference (MCID) based on previous studies for each QoL framework. **Results:** Of the 17 trials which met eligibility criteria, FACT-G and EORTC QLQ C30 were the most consistently utilized QoL tools. The mean difference in score between intervention and control at the last evaluation visits was 2.82 (95% CI -0.57 to 6.21; P = 0.10) in FACT-G and 2.33 (95% CI -0.29 to 4.96; P = 0.08) in EORTC QLQ C30, neither of which met quantitative or statistical significance. There was a statistically significant reduction in fatigue (OR 0.67, 95% CI 0.46 to 0.97; P = 0.04), but no difference in constipation (OR 0.63, 95% CI 0.34 to 1.17; P = 0.15), nausea (OR 1.03, 95% CI 0.72 to 1.47; P = 0.89), pain (OR 0.83, 95% CI 0.62 to 1.10; P = 0.19), or diarrhea (OR 1.41, 95% CI 0.40 to 5.01; P = 0.60). SMD for symptom severity was calculated for fatigue, diarrhea, and nausea. Severity of fatigue was statistically lower with proactive symptom monitoring (SMD -0.45, 95% CI -0.69 to -0.22; $I^2 = 0\%$, $P < 0.001$), however, magnitude of effect was modest. **Conclusions:** Proactive symptom monitoring in cancer patients receiving treatment is not associated with significant or meaningful QoL improvement. Similarly, there is limited impact on individual toxicity. Research Sponsor: None.

Cancer health disparities in the state of Georgia: African American oncology care. *First Author: Nabin Raj Karki, Augusta University, Medical College of Georgia, Augusta, GA*

Background: Approximately 58,970 new cancer diagnoses are projected for 2022 in Georgia (GA), contributing to 18,750 deaths. African Americans (AA) make up about one-third of Georgia's population compared to 14% of the national population. Cancer survival rates are lower for AA than non-AA for almost all cancer types. Biological factors do not account for all these differences. We explore the impact of racial disparities on cancer care in Georgia. **Methods:** We used 2020 behavioral risk factor surveillance system (BRFSS) data to capture patient-reported data on various demographic and health coverage variables. Oncology patients in the stage of Georgia were selected for our analysis. We evaluated the effect of racial disparities on clinical services received. **Results:** In the state of GA, 9,090 participants responded to the 2020-BRFSS, of which 400 partcipants had a history of cancer diagnosis other than skin cancer. Males and females comprised 37% and 63%, respectively. AA represented 15.8% of the respondents. The majority of the oncology respondents reported having health care coverage (96%) and having insurance coverage for all cancer treatments (96.8%) despite having 81.9% of the participants unemployed. Compared to non-AA, AA participants reported lower rates of health insurance payment for cancer treatment (84% v 99.3%, P = 0.0022) and lower levels of annual incomes (percentage of annual income <50,000$/year was 72.3% vs 51.5%, P = 0.0151). AA participants were four times less likely to have full coverage for cancer-related treatment than non-AA (odds ratio=4.31). There was no statistically significant difference in secondary education rates, health care coverage, the inability to see a physician due to cost, receipt of summary of treatment or written instructions, denial of insurance coverage due to cancer, and clinical trial participation. Participants with at least secondary education were more likely to have full insurance coverage for all cancer treatment expenses (P = 0.0206). **Conclusions:** Among cancer patients in Georgia, income rates were lower in AA than in non-AA. They were also less likely to have full coverage for cancer-related treatment. Analysis suggests secondary education increases the likelihood of having full insurance coverage. Education and income disparity may have a bearing on the accessibility and quality of cancer care. Addressing these inequities on a societal level will be key in ensuring high-quality oncology care for all. Research Sponsor: None.

Differences in socioeconomic and health coverage for AA and non-AA respondents to the 2020 BRFSS survey: State of Georgia.

	Factor	African American (%)	Non-African American (%)	P-value
Health care coverage	Yes	95.2	96.1	0.7012
	No	4.8	3.2	
Participated in cancer clinical trial	Yes	0	6.1	0.2411
	No	100	93.9	
Health insurance paid for all cancer treatment	Yes	84	99.3	0.0022
	No	16	0.7	
Annual income	Less than 25k	40.4	23.3	0.0151
	25 – 50 k	31.9	28.5	
	More than 50 k	27.7	48.1

Machine learning (ML)–enabled, circulating tumor cell–based classification of patients for non-prerequisite adjuvant therapy. *First Author: Gowhar Shafi, Indx Technology, Mumbai, India*

Background: Oncology implicates highest precision using next generation diagnostics and progressive therapies assisted by predictive tools. If validated clinically, machine learning (ML) can provide better insights in precision oncology. Furthermore, it longitudinally may stratify the progression of cancer disease burden in a real time. We have developed, Circulating Tumor Cells (CTCs) driven ML model as a predictor for the treatment decision strategy for both surgery and adjuvant therapy in head and neck squamous cell carcinoma (HNSCC) patients. **Methods:** In this study, a total of 380 HNSCC patients who underwent either surgery alone or surgery plus adjuvant therapy were accounted for. CTCs in patients were stratified based on clinicopathological parameters and using OncoDiscover platform having anti EpCAM antibody system regulated by the Drug Controller of India. Following this, we explored the predictive performance of the ML model on the usefulness of adjuvant therapy in HNSCC patients after the surgery. The available data was randomly divided into two subsets. First, 75%, of the original data was applied for Training the ML, and rest 25% of the data was used as a Test set. Survival curves were generated by Kaplan–Meier method and calculated through the Log rank test. **Results:** XGBoost machine learning classifier was superior to Random Forest and SVM-based analyses in predicting the usefulness of adjuvant therapy post-surgery using CTC alone or in combination with other clinical parameters in HNSCC patients. Machine learning algorithms were compared for predicting the accuracy of patients stratification. The results for each model were: XGBoost model (Accuracy = 0.84, ROC value = 0.73, Kappa = 0.43); Random Forest model (Accuracy = 0.81 ROC value = 0.70, Kappa = 0.41); SVM model (Accuracy = 0.76, ROC value = 0. 69, Kappa = 0.40). The ROC value of the XGBoost model was highest (0.73) while the ROC value for the SVM model was lower (0.69). We observed that when CTCs were combined with clinicopathological parameters, the accuracy, kappa values and AUC-ROC drastically improved in predicting the usefulness of adjuvant therapy post-surgery. A similar trend was observed when CTCs were combined with clinicopathological parameters in predicting the line of chemotherapy, post-surgery. **Conclusions:** ML-enabled, CTCs driven predictions can be highly accurate and ascertain the patient treatments. CTCs can be a positive predictor for selecting patient's treatment regimen in both surgery as well in type of treatment (e.g. surgery alone or surgery + adjuvant therapy). It can also implicate to classify the patients and determine who necessitates an additional adjuvant therapy. Further investigations in this direction are necessary to predict the treatment options based on ML that may improve the overall survival of cancer patients. Research Sponsor: iNDX.Ai.

Applicability of a web app for lung cancer risk calculation and personalized recommendations for screening in Mexico. *First Author: Jose Felipe Muñoz Lozano, Centro Universitario Contra el Cancer, Monterrey, NL, Mexico*

Background: Lung cancer screening continues to be an area of great opportunity in public health, especially in developing countries. In Mexico, about 10,000 new cases of lung cancer are detected annually, of which less than 5% are diagnosed in early stages. There are no national programs for timely detection of lung cancer in our country, so it is essential to seek accessible measures to prioritize resources for high-risk people. **Methods:** We developed a web app that consisted of a short survey to stratify patients according to their risk of lung cancer (https://cuccuanl.com/tamiz_pulmon/). The questions were based on Nelson's criteria to categorize high-risk subjects who are deemed candidates for screening. The program contained automated logic programmed using JavaScript to guide people to the low or high-risk page if they met standard risk criteria in those age 50 and older. The high-risk page alerted people of their risk, displaying general information about lung cancer as well as contact information to make an appointment at our cancer center. An appointment could be also scheduled within the app if the person so wished. The web app was launched and distributed through social media. **Results:** After a period of 2 months, 939 people completed the survey. The median age of the responders was 40 years, and 61% were men. Of the total, 185 participants were 50 years of age or older. 268 people (29% of the total) were sent to the high-risk page, including persons under 50 years of age with symptoms highly suggestive of lung cancer. According to their smoking status, 80% of the subjects reported active smoking, while 9% reported heavy smoking, considered as more than 20 pack-years. Among all the people evaluated, 44 high-risk subjects scheduled a specialized medical appointment within the web app. **Conclusions:** This pilot study showed a high response of Mexican population seeking lung cancer risk evaluation, especially among the persons who smoke regularly. The use of web apps can result in mass diffusion which will help reach people with less medical access, a common scenario in many developing countries. Further analysis should be made to measure the real impact on lung cancer diagnosis and oncological outcomes. Our study shows how effective social media is as a means of diffusion on health topics. Research Sponsor: None.

Patients with high-risk features (n = 268)	**Percent**	**Absolute #**
Suggestive symptoms (all ages)	81%	218
Suggestive symptoms (≥50 years)	15%	41
≥20 pack years + ≥50 years	13%	35
Presence of EPOC	1%	2
Radon Exposure	0%	0
Laboral exposure to contaminated air	9%	25
≥100 wood smoke years	0%	0

Tobacco smoking status		**Absolute #**	**Percent**
<50 years old n = 754	Have never smoked	148	20%
	<20 pack-years	555	74%
	≥20 pack-years	51	7%
≥50 years old n = 185	Have never smoked	40	22%
	<20 pack-years	110	59%
	≥20 pack-years	35	19%

*None of the surveyed with ≥20 pack years had abandoned smoking for ≥20 years.

Development of an electronic health record registry to facilitate collection of Commission on Cancer (CoC) metrics for patients undergoing surgery for breast cancer. *First Author: Heather G. Lyu, MD Anderson Cancer Center, Houston, TX*

Background: Accurate and efficient data collection is a challenge for quality improvement initiatives and clinical research. We describe the development of a custom electronic health record (EHR) based registry to automatically extract structured Commission on Cancer (CoC) axillary surgery specific metrics from a custom synoptic note template included in the operative reports for breast cancer patients undergoing surgery. **Methods:** The "Smart" functionality of our enterprise-based EHR system was leveraged to create a custom Smart phrase to capture axillary surgery specific variables. A multidisciplinary team developed structured data elements correlating to each axillary surgery-specific variable. These data elements were then included in a note template for the operative report. Each variable could be aggregated and converted into a single flat database through the EHR's reporting workbench and serve as a live, prospective registry for all users within the EHR. **Results:** The final axillary surgery-specific note template in a synoptic format allowed for efficient and easy entry and automatic collection of breast cancer specific metrics. From initial adoption in February 2021 through December 2021, there were 1,254 patients who underwent breast surgery with axillary surgery. The operative notes allowed for automatic capture of metrics from 60.5% (n = 759) of patients. Data capture improved from 37.6% in the initial adoption period of six months to 86.2% in the last five months. Capture rate in December 2021 was 98%. **Conclusions:** We were able to demonstrate successful implementation of provider driven structured data entry into EHR systems that permits automatic data capture. The end result is a custom synoptic note template and a real-time, prospective registry of breast cancer-specific CoC metrics that are robust enough to use for quality improvement initiatives and clinical research. Research Sponsor: None.

Using machine learning on real-world data to predict metastatic status. *First Author: Foad H. Green, Syapse, San Francisco, CA*

Background: Real world data (RWD) is increasingly used to inform research, patient care, and population health in oncology; however, using RWD at scale requires accurate methods to identify clinically-relevant attributes. Metastatic status is a highly relevant clinical attribute in cancer patients but it is not routinely captured in structured formats and its determination conventionally requires review and interpretation by certified tumor registrars (CTRs). Clinical diagnoses, treatments, imaging procedures and other clinical variables documented in electronic health records (EHRs) can be used to differentiate metastatic from non-metastatic patients. This study describes an effective machine learning approach in utilizing prevalent and standardized data elements from EHRs across multiple health systems. **Methods:** 28,043 lung cancer and breast cancer patients from two large health systems within the Syapse Learning Health Network with data sources from CTR abstraction and EHRs were analyzed. Patients were labeled for reference metastatic status by CTRs and split into training (n = 22,434) and testing (n = 5,609) cohorts, with proportionate distribution of cancer type and metastatic status between cohorts. A regularized gradient boosting algorithm, XGBoost, was trained using over 750 variables from the patient records collected at the time of or after the initial cancer diagnosis. **Results:** Integration of ICD-10-CM codes with antineoplastic treatment history and radiologic imaging procedure orders achieved metastatic status prediction with increases to precision and recall in lung cancer (21% and 32% respectively) and breast cancer (39% and 9% respectively), when compared to the use of only ICD-10-CM diagnosis codes for secondary malignant neoplasms (Table). The addition of treatment and procedure data from different cancer types improved the model classification within individual cancer types. **Conclusions:** One of the biggest challenges in using RWD for precision oncology is identification of clinically-relevant phenotypes at scale. Here we demonstrate a scalable evidence-based method utilizing structured data for imputing metastatic status with high predictive power from two separate health systems. With further validation, this approach may be generalized to other cancer types, applied to temporal slices of data to identify changes in metastatic status, as well as provide a high-confidence designation of metastatic status for other use cases such as staging. Research Sponsor: None.

Model performance metrics.

	Precision	Recall
Lung and bronchus (ICD-10-CM only)	0.67	0.50
Lung and bronchus (Predictive model)	0.88	0.82
Breast (ICD-10-CM only)	0.56	0.82
Breast (Predictive model)	0.95	0.91

Performance of an artificial intelligence-based annotation algorithm for reporting cancer genomic profiling tests. *First Author: Hidenori Kage, Department of Next-Generation Precision Medicine Development Laboratory, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan*

Background: Cancer genomic profiling (CGP) tests have been approved in Japan since June 2019, with the requisite that all test results be discussed by molecular tumor boards (MTBs). More than 20,000 patients in over 200 designated hospitals have taken CGP tests by December 2021. As CGP tests have entered clinical practice, streamlining decision making by MTBs and standardizing interpretation of test results and treatment recommendations have become urgent issues. Here, we evaluated the utility of Chrovis, an annotation algorithm for reporting CGP tests to support MTBs make their recommendations. **Methods:** We retrospectively reviewed the reporting process of all approved CGP tests done at The University of Tokyo Hospital between December 2019 and November 2021. Chrovis provided annotation for each genetic variant by incorporating biologic, clinical, and therapeutic information by referencing several public knowledge databases and using natural language processing, and generated reports using the automated program. The MTB reviewed and made any necessary changes before finalizing the report. Changes in disclosure of germline findings were made according to the recommendations of a national guideline with consideration of past and family history. **Results:** Of the 243 tests, 91 changes in 81 Chrovis reports (33% of all reports) were made by the MTB. The most common type of change was germline disclosure with 26 changes (29%), followed by clinical trial information in Japan (18 changes, 20%) and recommendation of the patient-proposed national basket trial with multiple targeted agents (17 changes, 19%). Changes in germline disclosure increased from June 2021, when an update to a national guideline was released, while the proportion of changes in the latter two types remained unchanged. Gene alterations that led to the highest number of changes was *TP53*, with 13 changes. Changes in therapeutic recommendations were frequently observed in the RAS/MAPK pathway (*BRAF*, *KRAS*, *NF1*, *NRAS*) with 12 changes. More changes were required with a tumor-only tissue CGP panel (57 of 149) compared with a matched tumor/normal tissue CGP panel (24 of 94, p = 0.04), mostly due to germline disclosure (24 vs. 2 changes). **Conclusions:** We observed that automated algorithm-based reporting was sufficient in 67% of reports. Recommendation for germline disclosure still requires manual supervision, particularly with tumor-only tissue CGP panels if algorithms do not incorporate medical history. The process of recommending clinical trials needs improvement, e.g., standardizing database formats for inclusion and exclusion criteria. Research Sponsor: Xcoo, Inc.

Can an artificial intelligence-based platform reduce physician burden and increase access to clinical trials? *First Author: Limor Gortzak Uzan, Trialjectory, Closter, NJ*

Background: Clinical trials for cancer patients are an important treatment option and a resource for drug development. Although patients are more actively searching for treatment options through various approaches, the national average of cancer patients accrued to clinical trials remains static at only 2-4%. The most widely recognized resource is clinicaltrials.gov, which does not offer direct trial matching, is geared toward healthcare professionals and uses complex medical terms that are challenging for many patients. For clinicians, the absence of real-time access and insight into all relevant oncology trials, forms a burden on their already-limited time. Alleviating this burden could reduce barriers to clinical trial accrual. **Methods:** Using AI and an unsupervised natural language process approach, the Trialjectory platform monitors, analyzes and matches patients to clinical trials. Matching is achieved by patient response to a dynamic set of questions curated based on the eligibility criteria of available trials. The online questionnaire (www.trialjectory.com) collects detailed clinical data that include disease characteristics (histological, molecular and mutational status), treatment history, general health and comorbidities. All collected data points are incorporated into the matching process, yielding a high-quality actionable matched-trial list. A skilled support team is available to answer questions and concerns via email, text or phone calls. The platform enables patients to share the matched trial list with their oncologist for discussion. **Results:** from July 2019 - December 2021, 49,906 cancer patients completed Trialjectory's questionnaire. Patient accrual grew rapidly since the second half of 2019 with 1462, 2201, 9364,12685, and 24194 new questionnaire completions in each consecutive 6-month period from the 2nd half of 2019 through December 2021. 49,199 (98.6%) of registered patients were found eligible for available trials. Of the matched patients, 4428 patients (9%) applied to a clinical trial. Our matching engine identifies each specific trial match to each patient profile with a sensitivity of 90% and a specificity of 95%. When aggregated to a patient level, the chance that a patient will be matched for at least one trial from those that he is eligible to is 99.9%. Metrics are validated by automatically matching multiple artificially-created patient profiles and manually verifying the quality of the match. **Conclusions:** TrialJectory is an effective AI-based tool that offers cancer patients and their oncologists direct, precise and quick access to relevant clinical trials. Our data show a high adoption and growing registration rates and well-above average clinical trial application rate. By democratizing the access to clinical trials, increased opportunities are noted that might lead to increased trial participation. Research Sponsor: Trialjectory.

Machine learning models for accurate pretreatment prediction of chemotherapy associated LV dysfunction in patients with breast cancer and lymphoma receiving chemotherapy (WF-98213 PREVENT and CCCWFU9912 DETECT IV). *First Author: Suditi Shyamsunder, Virginia Commonwealth University, Richmond, VA*

Background: Cancer survivors receiving potentially cardiotoxic chemotherapy are at increased risk for developing left ventricular (LV) dysfunction. We implemented machine learning (ML) models to predict future LV dysfunction in patients with breast cancer or lymphoma scheduled to receive potentially cardiotoxic chemotherapy. **Methods:** We utilized prospectively collected data from NIH studies R01HL118740 (supported by the Wake Forest NCORP Research Base (UG1CA189824)) and R01CA167821. Data included measurements of LV function and demographic factors before, during, and 24 months after initiating potentially cardiotoxic chemotherapy. The two datasets were used both separately and collectively in the development of multiple ML models including penalized linear regression, support vector machine, and random forest (RF). A data preprocessing step properly handled missing information, data imbalance, and encoding. Hyperparameter tuning was performed using cross validation of training data. The final models were assessed with a 20% hold-out test dataset. Cardiotoxicity was defined as a pre- to 24-month post cancer treatment decline in LV ejection fraction (LVEF) of > 10% or to an absolute value of < 50%. **Results:** 276 patients were included in ML models (7% men, 93% women; age 52±13 years). The RF model based on the combined dataset had the best performance with a prediction accuracy, sensitivity, and specificity of 0.94, 0.81, and 0.98, respectively. The most important variables assessed pre-treatment as measured by the Gini impurity factor were in descending order, LVEF, global LV circumferential strain, LV end-systolic volume, body mass index, LV stroke volume, LV end-diastolic volume, and LV mass. **Conclusions:** Prior to cancer treatment, supervised ML methods such as RF models predicted declines in LVEF of > 10% and/or to absolute values below 50% would occur 24 months after initiating chemotherapy for breast cancer or lymphoma. With further improvement and validation using larger datasets, these models may play an important role in cardio-oncology care during and following cancer treatment. Feasibility of an explainable AI-based therapeutic recommendation-tool utilizing tumor gene expression profiles in advanced and refractory solid tumors. *First Author: Ouissam Al Jarroudi, Department of translational medicine, Centre Léon Bérard, Lyon, France*

Background: Precision oncology aims to guide patient (pts) treatment decisions by matching biological features with available drugs. Extensive genomic analysis allows to identify an actionable alteration in 40-60% of patients. In a recent study of 50 pts with advanced refractory diseases included in PROFILER (NCT01774409), whole exome and fusion transcripts had a limited value over a 90-tumor gene panel (TGP) to increase molecular-based treatment recommendations (MBTR). Herein, we evaluated the feasibility, in the same cohort of pts, of the AI-transcriptional-based therapeutic recommendation-tool OncoKEM to guide treatment recommendations. **Methods:** 77 fresh frozen (FF) and/or FFPE samples including paired specimens for 53 pts with available RNA-Seq gene expression profiles were included. For each pts, a tumor transcriptional profile (TTP) was generated by identifying differentially expressed genes between the pts tumor and a cohort of matched healthy tissue. A large database of drug transcriptional signatures (DTS) was queried in order to identify a "reversal relationship" between the TTP and a DTS. A total of 205 drugs were ranked, including a subset of 61 FDA and/or EMA approved targeted therapies (aTT). **Results:** Most common diagnoses were breast cancers (21% of which 63% were TNBC), followed by ovarian cancers (OC, 18%) and soft-tissue sarcomas (STS, 13%). The median number of previous treatment lines was 4 (range: 1 - 10). Among the 77 tumor samples analyzed, 54 (70%) specimens led to the generation of an OncoKEM report, with no differences between FF and FFPE samples (p = 0.85). The overlap between the top 10 proposed drugs between paired FF and FFPE samples was 56% on average. All patients had at least 2 propositions (range: 2-9) of aTT among the top 10 ranked drugs in the Onco KEM reports. Most frequently proposed drugs among the top 10 were palbociclib, talazoparib, infigratinib in TNBC; bosutinib, sapanisertib, SAR125844 in OC; ipilimumab, cabozantinib, sapanisertib in STS. Among the 30 pts (79%) without any MBTR based on TGP/WES/fusion transcript analysis, all had at least 2 proposed aTT in the Onco KEM report (median: 4, range: 2-9). Top ranked drugs were MET (18%), VEGFR (12%), Abl (12%), FGFR (11%), PI3K/AKT/mTOR (11%), PARP (10%) and CDK4/6 inhibitors (7%). **Conclusions:** AI-transcriptional-based therapeutic recommendation-tool OncoKEM is feasible and has the potential to expand personalized cancer treatment in pts with advanced & refractory diseases without tractable genomic alterations. The clinical relevance assessment is planned in an upcoming clinical trial. Research Sponsor: OmiCure.

Machine learning application to find patients with lower-risk myelodysplastic syndrome from real-world data. *First Author: Colden Johanson, Syapse, San Francisco, CA*

Background: It is a challenge to identify patients with myelodysplastic syndrome (MDS) using structured data from electronic health records (EHRs). Current claims-based algorithms incorporating diagnosis codes, clinical labs, and procedures have not been validated against an expert reference standard. A machine learning-based approach was investigated to identify erythropoietin-stimulating agent (ESA)-treated, lower-risk (LR)-MDS patients from structured EHR data. **Methods:** A sample of 1,549 patients from the Syapse Learning Health Network (SLHN) was identified as potential ESA-treated LR-MDS patients by a team of clinicians and epidemiologists based on diagnosis and medication data from multiple health systems' EHRs and cancer registries. Of these, 404 (25%) were confirmed as ESA-treated LR-MDS patients through a review of patient records by certified cancer registrars (CTRs). The sample was divided into training and validation sets at a ratio of 80/20, stratified by the outcome. Age, sex, diagnosis codes corresponding to MDS and chronic kidney disease, medication (ESA, luspatercept, lenalidomide), clinical lab tests (hemoglobin, absolute neutrophils, platelet, blast percentage), and evidence of bone marrow biopsy were included as the predictive variables for the models. Gradient boosting machines with a nested cross-validation scheme were adopted to build the optimal model on the training set. Model acceptance was evaluated based on precision and recall on the validation set. The optimal model was then applied to the remaining unscreened SLHN patient population. **Results:** The optimal model identified an additional cohort of 157 patients based on the predicted likelihood. Among these, 69 (44%) were CTR-confirmed ESA-treated LR-MDS patients, all of whom were previously missed by the initial expert-determined selection criteria, as shown in the table. **Conclusions:** The application of machine learning methods increased the rate of ESA-treated MDS patient identification even after the expertly-determined population was depleted. This suggests the application of machine learning models using EHR data may improve the efficiency of MDS patient identification and screening efforts for research, quality improvement, and clinical care. Research Sponsor: Bristol Meyers Squibb.

Natural language processing-optimized case selection for real-world evidence studies. *First Author: Jacob Koskimaki, CancerLinQ, Alexandria, VA*

Background: Much information describing a patient's cancer treatment remains in unstructured text in electronic health records and is not recorded in discrete data fields. Accurate data completeness is essential for quality care improvement and research studies on de-identified patient records. Accessing this high-value content often requires manual and extensive curation review. **Methods:** AstraZeneca, CancerLinQ, ConcertAI, and Tempus have developed a natural language processing (NLP)-assisted process to improve clinical cohort selection for targeted curation efforts. Hybrid, machine-learning model development included text classification, named entity recognition, relation extraction and false positive removal. A subset of nearly 60,000 lung cancer cases were included from the CancerLinQ database, comprised of multiple source EHR systems. NLP models extracted EGFR status, stage, histology, radiation therapy, surgical resection and oral medications. Based on the results, cases were selected for additional manual curation, where curators confirmed findings of the NLP-processed data. **Results:** NLP methods improved cohort identification. Successfully returned cases using the NLP method ranged from 75.2% to 96.5% over more general case selection criteria based on limited structured data. For all cohorts combined, 84.2% of the cases sent out for NLP curation were returned with curated content (Table). Each cohort contained a range of NLP-derived elements for curators to further review. In comparison, more general case selection criteria yielded a total of 3,878 cases returned out of 41,186 lung cancer cases sent for curation, for a success rate of only 9.6%. **Conclusions:** NLP-driven case selection of six distinct, complex lung cohorts resulted in an order of magnitude improvement in eligibility over candidate selection using structured EHR data alone. This study demonstrates NLP-assisted approaches can significantly improve efficiency in curating unstructured health data. Research Sponsor: AstraZeneca.

NLP-assisted cohort selection for the six pre-specified lung cancer cohorts.

Cohort	Cohort Description	Number of cases available from NLP-assisted identification methods	Number of cases sent to Tempus and ConcertAI for curation	Number of cases returned to CancerLinQ with curated content	Percent of successfully curated cases
1A	NSCLC, stage I, II, III, EGFR+, complete resection	408	408	341	83.6%
1B	NSCLC, non-squamous, stage I, II, III, EGFR wild type/unknown, complete resection	4313	1500	1285	85.7%
2A	NSCLC, stage III, unresectable, curative radiation to the chest total dose >= 50 Gy, did receive Imfinzi	852	620	466	75.2%
2B	NSCLC, stage III, unresectable, curative radiation to the chest total dose >= 50 Gy, did not receive Imfinzi	3050	750	724	96.5%
3	SCLC, received Imfinzi or Tecentriq	559	500	402	80.4%
4	NSCLC, received Tagrisso as first line treatment	971	812	647	79.7%
Total:		10153	4590	3865

Natural language processing of Veterans' electronic health records to confirm diagnoses of monoclonal gammopathy of undetermined significance. *First Author: Mei Wang, Division of Public Health Sciences, Department of Surgery, Washington University School of Medicine, Saint Louis, MO*

Background: The Veterans Health Administration (VHA) provides extensive electronic health records (EHRs) on Veterans nationwide. Our prior studies utilized VHA data to study the risk of progression from monoclonal gammopathy of undetermined significance (MGUS) to multiple myeloma. These studies relied on International Classification of Disease (ICD) codes and manual abstraction on clinical notes to both identify and verify MGUS patients. Diagnosis confirmation is necessary because many providers place a diagnosis on the clinical notes to order lab tests, which is often left in the EHR despite a negative test result. However, manual abstraction is labor intensive and time consuming. With the advancement in natural language processing (NLP), we developed a model to make MGUS confirmation more efficient. **Methods:** We randomly selected 700 patients within patients diagnosed with MGUS from 1999-2021 in the VHA identified via ICD codes. A random sample of 500 patients were selected and split into the training (80%) and the testing (20%) sets. The remainder (n = 200) served as the validation set. There were 32,708 unstructured hematology/oncology Text Integration Utility reports and 9,237 lab reports (including 2,322 discrete results and 6,915 unstructured comments). All reports were manually reviewed to confirm MGUS diagnoses and served as the reference standard. We compiled three lists of keywords suggestive of MGUS diagnosis, subtypes of immunoglobulins, and negation modifiers. We trained a symbolic NLP model to identify diagnoses using combinations of the lists along with M-protein levels from lab reports. The optimized combination that gave the highest recall and precision from the training set was used and evaluated on the testing and validation sets. **Results:** Among patients with ICD codes for MGUS, manual abstraction confirmed 84% MGUS diagnoses in the testing set and 80% in the validation set. Our NLP model in the training set confirmed 75% and achieved recall, precision, accuracy, and F1 score of 88.1, 98.7, 89.0, and 93.1%, respectively; in the validation set, our rule confirmed 76% patients and the recall, precision, accuracy, and F1 score were 89.4, 94.7, 87.5, and 92.0%, respectively. On average data abstraction took five minutes per patient (excluding data loading time), whereas NLP model completed 13 patients per minute. **Conclusions:** The developed NLP model to confirm MGUS diagnosis improves accuracy in diagnosis, compared to ICD codes alone. While the performance is similar to that of manual abstraction, our NLP model is an efficient and viable method in MGUS diagnosis confirmation. Research Sponsor: U.S. National Institutes of Health.

	Recall (%)	Precision (%)	Accuracy (%)	F1 score (%)
Dataset (patients/clinical reports/lab reports)				
Training (400/19,309/5,112)	86.52	94.85	85.50	90.49
Testing (100/4,907/1,437)	88.10	98.67	89.00	93.08
Validation (200/8,492/2,688)	89.38	94.70	87.50	91.96

Impact of trial site selection on minority patient recruitment in prostate cancer trials. *First Author: Charles Lagor, ConcertAI, Cambridge, MA*

Background: Historically, minority patients have been underrepresented in clinical cancer trials. Despite recognition of this problem, trials in the early 2000's showed a decrease from 10.5% to 6.2% in African American trial participation when compared to trials from the early 1990's. The drop in trial participation is also reflected in prostate cancer trials, although Black men have a 1.76 higher prostate cancer incidence rate than White men. Using prostate cancer as an example, we investigated the impact of trial site selection on potential minority patient recruitment; thus, overcoming a major system-level barrier to trial access. **Methods:** We created a prostate cancer cohort by filtering our real-world data sources (CancerLinQ, Electronic Medical Office Logistics) for adult male patients with ICD10 CM code C61* or ICD9 CM code 185 on 1/1/2015 or later (cohort #1). As a pre-requisite for computing site level prostate cancer patient counts, we used claims data to attribute missing site information. Finally, to identify the most promising sites for minority trial recruitment, we ranked sites by the proportion of Black patients and the overall cohort patient count. We repeated the above steps for a subset of cohort #1, which was based on the criteria for trial NCT00887198 investigating the prostate cancer drug abiraterone (cohort #2). **Results:** The prostate cancer cohort (#1) had 151,261 patients, of which 99,152 (65.6%) were attributed to sites. The percentage of Black patients being treated at the top ten sites ranged from 33.0% to 66.4%, with a median of 45.2% (see table). All ten sites had participated in an interventional cancer trial, and eight had participated in prostate cancer trials. Half of them were community, and half were academic sites. The abiraterone cohort (#2) had 1,267 patients, of which 1,174 (92.7%) were attributed to sites. Among the top ten sites the Black patient percentages ranged from 23.8% to 85.7%, with a median of 39.3%. **Conclusions:** In an analysis of 17 recent FDA drug registration trials for prostate cancer, Black trial participation ranged from only 1.4% to 6.2%, with a median of 3.0%. In contrast, Black patients being treated at the top sites in our data ranged from 33.0% to 66.4%, with a median of 45.2% (cohort #1). The percentages for the abiraterone cohort (#2) were similar, suggesting that even after applying trial criteria the Black patient percentages remain in the double-digits at top sites. Our results demonstrate that informed trial site selection could have a substantial positive impact on minority patient recruitment. Research Sponsor: None.

A novel support vector machine to predict sentinel lymph node status in elderly patients with breast cancer. *First Author: Abbas Hassan, University of Texas MD Anderson, Houston, TX*

Background: Routine sentinel lymph node biopsy in older breast cancer patients with favorable tumor biology is not recommended. However, cases must be evaluated on an individual basis to avoid under or over-treatment. Many nomograms have been developed to calculate the risk of nodal positivity, but machine learning (ML) is a novel tool that may improve the accuracy of nodal prediction. In this study, we developed a support vector machine (SVM) model to delineate factors indicative of sentinel lymph node positivity and refine individualized nodal risk assessment for this heterogeneous patient population. **Methods:** We conducted a single-institution comprehensive retrospective review of patients 70 years or older diagnosed with unilateral stage I–III primary breast cancer from January 2005 to January 2016. Patient data was partitioned into training and testing sets. A SVM model was developed to predict lymph node status using patients' demographics, tumor stage, genetic profile, and imaging data. Primary outcome was model performance determined by area under the curve (AUC). Secondary outcomes were accuracy, sensitivity and specificity. Permutation feature importance (PFI) analysis and accumulated local effect (ALE) plots were used to evaluate significant predictors identified by the SVM. **Results:** We identified 1706 consecutive patients who met the study criteria with a mean age of 76±4.5 years. The plurality of patients were Caucasian (82%), had ER+ (86%), PR+ (70%), HER2- (87%) stage I (72%) breast cancer. Sixteen percent of patients (n = 271) had a positive sentinel lymph node biopsy. The SVM model demonstrated good discriminatory performance for predicting sentinel lymph node positivity with mean AUC of 0.70 (95%CI, 0.62-0.77), mean accuracy of 84% (95%CI, 80-88%), mean sensitivity of 61% (95%CI, 57-66%), and mean specificity of 62% (95%CI, 52-73%). PFI and ALE identified higher disease stage, younger age, family history of breast cancer, margin status, estrogen and progesterone receptor positivity as independently associated with high risk of sentinel lymph node positivity. **Conclusions:** The proposed ML model accurately identified sentinel lymph node status in older patients with breast cancer. This model holds promise for counselling patients as to the potential risk for node positive disease which may impact surgical and adjuvant therapy recommendations. Research Sponsor: None.

Incidence and impact of proportional hazards violations in phase 3 cancer clinical trials. *First Author: Timothy Lin, Department of Radiation Oncology and Molecular Radiation Sciences, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Hazard ratio (HR)-based analyses used in oncology trials rely on the assumption of proportional hazards, i.e. a HR that is constant over time. Proportional hazards violations (PHVs) may lead to misinterpretation of trial results. Restricted mean survival time (RMST) is valid with non-proportional hazards and has received recent attention specifically for immunotherapy (IO) trials but has not been routinely adopted in oncology trial design as a whole. We aimed to comprehensively characterize the incidence and factors associated with PHVs among phase 3 oncology trials and assess RMST as an alternate measure of treatment effect in survival analysis. **Methods**: We used Clinicaltrials.gov to identify all superiority-design, 2-arm phase 3 cancer trials with time-dependent endpoints with published results through February 2020. We manually reconstructed patient-level data from published Kaplan-Meier (KM) curves, assessed PHVs with the Schoenfeld residual test ($p < .05$) and analyzed the RMST. To assess reconstruction accuracy, reported and reconstructed HRs were compared. Univariable logistic regression was used to assess the likelihood of PHVs by trial characteristic, with statistically significant factors ($p < .05$) included in a multivariable analysis. Concordance of RMST-based and HR-based analysis was established when both tests agreed as to the statistical significance of the comparison. **Results:** Of 342 KM comparisons eligible for reconstruction, 318 comparisons across 315 trials, enrolling 347,538 patients from 1989-2017, were accurately reconstructed and analyzed. PHVs were identified in 76/318 (23.9%) trials. There was no difference in likelihood of PHVs among IO vs non-IO trials (LR 2.31, 95% CI 0.30 17.85, P = .37), nor by disease site, year of trial initiation, or sample size. Few trials with PHVs (16/76) pre-specified a plan to account for non-proportional hazards in statistical design. Trials with an overall survival (OS) primary endpoint (PEP) were less likely to have PHVs than trials with a non-OS PEP (LR: 0.50, 95% CI 0.28 - 0.90, P = .02). Trials whose PEP was non-significant were more likely to have PHVs (LR 1.73, 95% CI 1.01 - 2.97, P = .047). No factor remained significantly associated with PHV in multivariable analysis. Overall, 291/318 (91.5%) KM comparisons were concordant. Among trials with PHVs, 5/76 were significant by RMST but not HR, and 5/76 were significant by HR but not RMST. Of these, 1 led to FDA drug approval, and 2 others are cited in NCCN guidelines. **Conclusions:** PHVs are common across all phase 3 cancer clinical trials. Attempts to account for PHVs in trial design are lacking despite the potential for trial misinterpretation in the event of non-proportional hazards. RMST-based analysis is broadly concordant with HR-based analysis and may aid in interpretation of trials with PHVs. Hence, we recommend that prospective trials include *a priori* a statistical plan to account for PHVs. Improving first-in-human and window-of-opportunity informed consent forms through participant feedback. *First Author: Anna Avinger, Emory Healthcare-Winship Cancer Institute, Atlanta, GA*

Background: Although patient advocates have created templates for standard consent forms, assessing patient preferences for First in Human (FIH) and Window of Opportunity (WO) trials consents is important given their unique risks. FIH trials are the first time a drug is tested in humans. In WO trials, treatment naïve patients receive a therapeutic agent in the window of time between diagnosis and standard of care (SOC) surgery. Our goal was to determine patient-preferred presentation of important information in FIH and WO consent forms. **Methods**: The study consisted of two phases: (1) analysis of consents for FIH and WO oncology trials open at a cancer center between 2019 and 2022; (2) interview patients who had reviewed consents for FIH or WO trials during the consent process. FIH consents were analyzed for the location(s) of information stating that the study drug has not been tested in humans (FIH info). The WO consents were analyzed for the location(s) of information stating the risk that trial may delay SOC surgery (WO info). Participants were asked about their preferred placement of the information in their own trial's consent form and whether the consent was clear. Interviews were audio-recorded and double coded. Consent form analysis was compared to patients' preferences. **Results**: 25 consents [20 FIH; 5 WO] were analyzed. 19/20 FIH consent forms included FIH info, and 4/5 WO consent forms included WO info. 42 patients were approached [19 FIH; 23 WO]; 34 [17 FIH; 17 WO] participated. 12/17 (71%) WO participants thought that the trial explanation in the consent form was clear. Conversely, only 9/17 (53%) FIH participants found it clear. **Conclusions**: Patients preferred that the important FIH and WO information be placed early in the consent, though exactly where varied. 82% of FIH participants wanted FIH information in the purpose, while only 19% of WO participants clearly preferred that WO information be in the purpose, and 41% preferred WO information to remain in the risks section. Using consent templates that reflect patient preferences accurately is essential for ethical informed consent; however, a one-size fits all approach may not accurately capture patient preferences, so multiple templates may be necessary. Research Sponsor: U.S. National Institutes of Health, U.S. National Institutes of Health, The Winship and Davidson Impact Fellowship and Winship Cancer Institute of Emory University.

Location of FIH and WO info in consent forms compared to patient preference.

Title	Purpose / Introduction	Title & Purpose	Purpose & Risks	Title, Purpose, & Risks	Title & Risks	Risks	
Location of FIH Info in consent forms (n = 20)	0	0	0	20% (5)	10% (2)	5% (1)	20% (4)
Patient preference for location of FIH info (n = 17)	0	18% (3)	6% (1)	29% (5)	29% (5)	6% (1)	6% (1)

Clinical development of new drugs for adults and children with cancer in 2010-2020: Longitudinal study of investigational drugs. *First Author: Andrea Arfe, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Many investigational drugs start clinical testing to evaluate potential therapeutic benefits for oncology patients, but few eventually receive FDA approval. Moreover, only a small number is evaluated in pediatric populations, potentially contributing to the paucity of new approved drugs for young patients with cancer. Limited information is available on the development pipeline of investigational drugs, including the range of drug types entering clinical trials, trial phases at which development stalls, or rate of regulatory approval. To inform current clinical development efforts, we characterized the development and outcomes for a comprehensive sample of New Molecular Entities (NMEs) that started clinical testing worldwide in 2010-2015. **Methods:** We performed a longitudinal study using AdisInsight, a commercial database of global pharmaceutical research and development. This is a comprehensive database of drug development activity, which collects and curates data from trial registries, conference proceedings, journal publications, and press releases. Using these data, we identified all NMEs starting their first clinical trial for an oncology indication in 2010-2015. We followed each NME from the start of its first phase I trial to the end of 2020, and identified all associated trials, final development status, and FDA deliberations. We classified trials as pediatric-eligible if patients aged < 18 years were eligible for participation. We used the Drugs@FDA website to identify all FDA actions, including marketing approvals and requests for pediatric trials under pediatric programs (i.e. BPCA requests or PREA requirements). **Results:** A total of 572 NMEs started initial phase I clinical trials in 2010-2015. Among these, the most studied classes were small molecules (N, %: 316, 55%), antibodies (148, 26%), and antibody-drug conjugates (44, 8%). Overall, the NMEs were studied in 6,141 clinical trials by the end of 2020, with a median of 3 trials per NME. The highest pre-approval development phase reached by an NME was phase I for 325 (57%), phase II for 153 (27%), and phase III for 94 (16%). Only 39 NMEs (7%) were approved by the FDA by the end of 2020. Among approved NMEs, the median time (range) from start of first phase I trial to date of first approval was 6 (3-10) years. Among all NMEs, only 67 (12%) were tested in pediatric-eligible trials by the end of 2020, and 5 (< 1%) were approved for use in selected pediatric populations. Three of these had been subject to BPCA requests, and all had PREA requirements waived. **Conclusions:** More efficient clinical development strategies are needed to accelerate the production of new cancer therapies, especially for children. Analyses such as this one should be conducted regularly to help identify areas in need of innovation and to assess the potential impact of regulatory initiatives (e.g. the RACE act, effective since August 2020). Research Sponsor: None.

TBCRC 057: An online survey about anxiety and willingness to participate in breast cancer clinical trials during the COVID-19 pandemic. *First Author: Karen L. Smith, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins School of Medicine, Baltimore, MD*

Background: Enrollment in clinical trials has declined during the COVID-19 pandemic. Simultaneously, breast cancer patients have reported heightened anxiety. We assessed whether breast cancer patients' anxiety about the pandemic affects their willingness to participate in trials. **Methods:** English or Spanish-speaking US residents with breast cancer were eligible to complete the online REDCap survey 8/6/21 – 9/30/21. Respondents rated their anxiety about the pandemic on an 11-point scale from 0 (no anxiety) to 10 (worst anxiety possible). Anxiety scores were categorized as no/mild (0-3), moderate (4-6) or severe (7-10). Knowledge about trials was assessed with 11 true/false items and attitudes toward trials with the Attitudes Toward Cancer Trials Scales - Cancer Treatment Subscale (ATCTS-CTS). Respondents rated their willingness to participate in a breast cancer clinical trial before and during the pandemic on 5-point scales from 0 (not at all willing) to 4 (definitely willing). Trial participants were considered "definitely willing." Change in willingness to participate in trials during the pandemic compared to prior was defined as a binary outcome, "less willing" vs "no less willing." Means were compared via t-test and mean difference was tested via paired t-test. Multivariable logistic regression was used to model the association of anxiety and other factors with being less willing to participate in trials during compared to prior to the pandemic. **Results:** Among 385 respondents, median age was 52 (range 25-85), 271 (70%) were non-Hispanic White and 202 (53%) had metastatic disease. 154 (40%) received care at academic centers and 37 (10%) were current trial participants. Most rated their anxiety as moderate (43%) or severe (38%). Mean willingness to participate in a trial was lower during compared to prior to the pandemic (2.97 vs 3.10; $p < 0.0001$). Fifty (13%) respondents were less willing to participate in a trial during the pandemic compared to prior. After controlling for covariates, those with severe anxiety had 5.07 times odds of being less willing to participate during the pandemic compared to prior than those with no/mild anxiety ($p = 0.01$). For every 1-point increase in ATCTS-CTS score (indicating better attitude toward trials) there was a 3% decrease in the odds of being less willing to participate during the pandemic ($p = 0.006$). For every 1-point increase in the clinical trials knowledge score (indicating more knowledge) there was a 15% decrease in the odds of being less willing to participate during the pandemic ($p = 0.02$). **Conclusions:** Pandemic-related anxiety is common in breast cancer patients and is associated with being less willing to participate in trials during the pandemic compared to prior. Education about trials, including safety modifications implemented during the pandemic, may mitigate anxiety and improve willingness to participate. Research Sponsor: Metastatic Breast Cancer Network.

Participation in cancer research in BNSSG, England: A Health Equity Audit 2021. *First Author: Kathryn Hamilton, South West England Public Health Training, Bristol, United Kingdom*

Background: Cancer is a cause of health inequalities, and nationally, patients from deprived communities have lower participation rates in cancer research. Equitable access to research benefits patients, healthcare organisations and improves applicability of research. **Methods:** We undertook a health equity audit of participation in cancer research (trials and non-trials based) in Bristol, North Somerset and South Gloucestershire (BNSSG), England from 1.4.2019-30.3.2020 using data from the Acute Trust patient datasets. Comparison cohorts were extracted from a regional primary care dataset (the system wide dataset). Firstly, an incident cancer cohort: diagnosed from 1.11.2019-1.10.2020. Secondly a "living with cancer" cohort: cancer flag in the 5 years prior to 1.7.2021. Deprivation is measured by IMD of home postcode small area (LSOA). **Results:** Results are presented for the audit in the table below, with 95% confidence intervals where appropriate. Compared to people newly diagnosed with cancer, adults aged 70 or older were 56% less likely to take part in research (OR 0.44, 95% CI 0.39-0.51), and adults aged 80 or older were 77% less likely to take part in research (OR 0.23, 95% CI 0.18-0.29). Compared to people newly diagnosed with cancer, people from the most deprived 20% of the population were 27% less likely to take part in research (OR 0.73, 95% CI 0.88-0.92). The most deprived research participants were more likely to be younger, have one or more comorbidities and a recent emergency admission. Patients from outside BNSSG (18%) appear similar in profile to those from within BNSSG, including for deprivation. Better data are needed for other factors relevant to equity, including ethnicity and Inclusion Health. **Conclusions:** This health equity audit confirms and quantifies inequities in access to cancer research in our region. Under-representation of deprived and older patients appeared multifactorial in this audit, but further work to understand facilitators and barriers to recruitment is needed. These results are a call to action. Research Sponsor: None.

Patient Group	Patients	Mean Age (95% CI)	Younger Patients (<18 years) N (%)	Teenagers and young adults (16-24 years) N (%)	Older patients (>70 years) N (%)	Older patients (>80 years) N (%)	Gender (% female)	Patients from Out of Area N (%)	Most deprived 20% population
BNSSG cancer research				participants	1,052	62y (61.0-63.0)*	36 (3.4%)*	12 (1.1%)	365 (34.7%)*

A retrospective cohort analysis of return-to-work outcomes for cancer survivors using a digital coaching intervention. *First Author: Yuri Aung, Imperial College, London, United Kingdom*

Background: Return-to-work (RTW) is a key unmet need for working age cancer survivors, with up to 40% failing to RTW 1 to 2 years post-diagnosis. This study sought to evaluate RTW outcomes of a multidisciplinary digital coaching intervention provided as routine employee support. **Methods:** A retrospective cohort analysis was conducted from October 2018 to February 2020 where cancer patients with more than 3 months absent from work were provided by their insurance carriers with a multidisciplinary intervention comprising digital resources and telephone calls with a health coach. A logit regression model was used to calculate a propensity score using covariates of age, gender, insurance benefit type, cancer diagnosis date and time from diagnosis. Participants were then matched on a 1:1 basis using the nearest-neighbour method without replacement to create a matched control group out of 1,856 participants who did not receive the intervention. Primary outcomes, derived from insurance-claims data as standard business practice, included rate and time to RTW, along with death and other reasons for claim closure. **Results:** 220 participants enrolled in the intervention, of which 125 met the criteria for analysis (median age 53, IQR 45-58, 91% female). These participants were matched with 125 controls (median age 53, IQR 47-59, 94% female). Median follow-up from cancer diagnosis was 79 weeks (IQR 60-106). Of the matched controls, 22 returned to work (17.6%) compared with 38 (30.4%) in the intervention group (P = .02). 19 matched controls died prior to claim closure (15.2%) compared with 13 in the intervention group (10.4%; P = .26). Finally, Kaplan-Meier method estimated median time for the first 15% of participants to RTW was 87.1 weeks for controls (CI 60.0-109.1 weeks) compared with 70.6 weeks for the intervention group (CI 52.6-79.6 weeks; P = .08). **Conclusions:** This study evaluated the impact of a digitally delivered coaching program in a real-world setting for cancer patients, demonstrating a 12.8% increase in RTW rate over 18 months compared to matched controls. These findings corroborate and add to the literature on cancer as a chronic and manageable disease in the workplace. Research Sponsor: CancerAid.

Applicability of a web app for breast cancer risk calculation and personalized recommendations for screening in Mexico. *First Author: Jose Felipe Muñoz Lozano, Centro Universitario Contra el Cancer, Monterrey, NL, Mexico*

Background: A minority of women with breast cancer in Mexico are being diagnosed through a screening program, which translates into late diagnosis and a worse prognosis. It is imperative to develop easy access and low-cost interventions to increase the screening rate. **Methods:** We developed a web app tailored to guide patients to seek medical consultation if they were at high risk for breast cancer or standard screening recommendations based on the predicted risk for age (https://cuccuanl.com/calcula-tu-riesgo-de-cancer-de-mama/). The web app consisted of an 8-question survey designed using object-based programming with HTML5, the additional logic was programmed on JavaScript. The program logic automatically guided patients to medical consultation if they were at high risk for breast cancer, or standard screening recommendations based on their predicted risk for age. On each confirmation page, the contact information of the hospital appeared, also, consultation at the clinic could be scheduled within the web app. The web app was distributed via social media on International Breast Cancer Awareness Day. **Results:** A total of 1,012 persons answered the survey after a follow-up period of two weeks. The median age of respondents was 34 years. Among participants, 10.8% were considered at very high risk for breast cancer due to symptoms, 22% were classified as high risk based on family history or more than 5 years of contraceptive use, and 19% were considered as average-risk population for whom age-based screening tests were recommended. The remaining 48% of participants were considered at low risk for breast cancer development and were directed to educational information about breast cancer awareness. Among all persons that answered our survey, 21 requested a specialized medical appointment within the web app. **Conclusions:** This pilot study showed a high response of Mexican population seeking breast cancer risk evaluation, 11% of women that responded to our survey had symptoms highly suggestive of breast cancer. The use of web apps can result in mass diffusion which will help reach people with less medical access, a common scenario in many developing countries. Further analysis should be made to measure the real impact on breast cancer diagnosis and oncological outcomes. This study shows how effective social media is as a means of diffusion on health topics. Research Sponsor: None.

Risk Category	% of Respondents (n = 1,012)
Low Risk (< 40 Years, No Risk Factors)	48%
Screening Recommendation (≥ 40 Years, No Other Risk Factors)	19%
High Risk (Oral Contraceptive Use for > 5 Years or Family History)	22%
Very–High Risk (Symptom Suggestive of Breast Cancer)	11%

Assessing health electronically for adolescent and young adult oncology patients (AHEAD Study). *First Author: Tyler Garrett Ketterl, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Screening and counseling for health risk behaviors (RB) are recommended but infrequently performed, particularly in individuals undergoing cancer therapy. Unmet needs among adolescents and young adults (AYAs) with cancer translate to poor physical and psychosocial outcomes. The authors aimed to 1) modify an existing RB electronic health assessment (eHA) and intervention tool and 2) determine the feasibility and acceptability of the RB eHA and intervention tool among AYAs with cancer and their oncology providers. **Methods:** The internally developed HRB eHA and intervention tool Check Yourself was adapted by a multidisciplinary healthcare professional panel for an AYA oncology population and informed by literature review and AYA stakeholder feedback. "Check Yourself Oncology" assesses risk and health domains including home, education, sexual health, safety, alcohol/drugs, mental health and medication adherence. Optional feedback is provided for sexual health, safety, alcohol/drugs and mental health domains. Eligible AYAs were 13 to 29 years old, diagnosed with cancer, receiving cancer directed therapy, follow-up scheduled with a Seattle Children's Hospital oncology physician or nurse practitioner, and fluent in English. 72 hours prior to their next oncology clinic visit, participants were text messaged or emailed a personalized link to the Check Yourself Oncology tool to be completed prior to their next visit. Upon completion, a detailed report was sent to the primary clinical oncology team prior to the patient's visit. Feasibility was defined as 1) ≥70% completion of the RB eHA and 2) a Feasibility of Intervention Measure (FIM) mean score >4. Acceptability was defined as an Acceptability of Intervention Measure (AIM) mean score >4 and qualitatively. The FIM and AIM were sent by REDCap survey following the clinical visit; verbal feedback from AYAs and clinicians was analyzed with qualitative content analysis. **Results:** Of 30 eligible, approached AYAs, 25 (83%) enrolled in the study and 23 (76%) completed the Check Yourself Oncology tool and follow-up assessments. The AYAs had a mean age of 17 years (SD = 2.9 years) and 50% identified as female. Four AYAs declined participation due to lack of interest, 1 due to declined parental consent, 1 passively declined after enrollment, and 1 declined further participation following the confidentiality terms. The mean FIM and AIM scores were 4.1 (SD=0.6) and 4.0 (SD =0.7) respectively. Seventeen AYAs (74%) felt that the feedback provided was relevant and useful. 74% of visits providers reported that they incorporated the results in the care of the patient and 87% reported the results positively impacted care. **Conclusions:** Risk behavior screening with motivational feedback though the modified eHA tool Check Yourself Oncology is feasible and acceptable in AYAs undergoing cancer directed therapy. Clinical trial information: NCT04484194. Research Sponsor: Seattle Children's Research Institute.

Evaluating an AI-based nutrition expert platform delivered via SMS-text to support patients with cancer. *First Author: Marissa Lubin Buchan, Savor Health LLC, New York, NY*

Background: Interventions incorporating nutritional strategies can prevent and manage nutrition-related symptoms, however, due to a shortage of oncology dietitians (RD CSO) combined with healthcare access disparities, many patients do not receive the support they need, resulting in poor outcomes and quality of life (QoL). High rates of cell phone utilization among all demographics offers a unique opportunity to provide interventions using mobile technology. **Methods:** Launched to select groups in 2019, Ina (trademarked by Savor Health LLC) is a virtual nutrition assistant powered by an artificial intelligence (AI)-enabled expert platform, to facilitate self-management of cancer treatment side effects. The platform combines evidence, expertise, and unique patient data to deliver the personalized guidance patients would receive from an RD CSO, "on-demand" via text. This study applied the RE-AIM framework to evaluate the intervention from five dimensions. **Results:** Reach: The program reached 1,706 users as of 2021. Based on self-report among 1209 users, 78% are patients, 18% are caregivers, and 5% are healthcare professionals with 66% female and 34% male. Ina supports all cancer types, and top diagnoses among users are genitourinary (28%), lung (20%), gynecologic (16%), gastrointestinal (15%), and breast (11%). Disease burden is high, with 62% of users reporting they are experiencing nutrition-addressable symptoms at any given time. Effectiveness: Based on weekly patient reported outcome (PRO) surveys, 87% of respondents report Ina helps them manage symptoms, and 80% report that using Ina has improved their QoL. The cumulative likelihood to recommend is 4.1 on a 5-point scale. Adoption: Users are from over 18 cancer organizations, proving the feasibility and accessibility of this intervention. Implementation: Ina is accessible 24/7 via text, and is offered to patients in a B2B2C model. Users typically receive responses to nutrition-related questions within seconds from the AI platform (or 1-3 minutes with live RD oversight). Each active user (one that engages at least once in a given month) asks an average of 2.8 questions per month. Maintenance: The median time users remain on the platform is 156 days (range 0-884) and 57% of evaluable users stayed on the platform 6 months or longer. The platform's database, which includes over 54,000 referenced interventions, grows daily via supervised machine learning supported by RD CSOs. When surveyed on future feature development, respondents are most interested in tele-nutrition (57%), mental health (65%), and stress management (62%). **Conclusions:** Initial data suggests this is a feasible and accessible tool to support cancer patients' unique nutrition and symptom-management needs. Clinical trials are needed to validate feasibility and assess impact on clinical and QoL outcomes. Product development to integrate language and cultural preferences is ongoing. Research Sponsor: None.

1570 **Poster Session**

Impact of the COVID-19 pandemic on oral oncolytic adherence. *First Author: Elias Pittos, CVS Health, Lincoln, RI*

Background: COVID-19 has substantially decreased cancer screening, management visits and surgeries. CVS Health recently developed a best-in-class mobile app and website that enables oncology patients to start and stay on therapy. This study examined the impact of COVID-19 on adherence to oral oncolytic agents in a large health plan with a significant digital health platform. **Methods**: This retrospective cohort study included adult patients with chronic myelogenous leukemia (CML), ovarian cancer or prostate cancer initiating oral oncolytics between 3/1/19 and 3/1/2021. Patients were divided into two groups: pre-COVID oral oncolytic initiators before 3/1/20 and COVID initiators after 3/1/20 and were followed for 1 year after therapy initiation. The primary outcome was optimal adherence to oral oncolytic agents as defined by a medication possession ratio (MPR) $\geq$ 0.8. Percent of digital engagement, defined as the number of times a patient interacted with the CVS digital platform, was examined as a secondary endpoint and was considered as a binary and categorical endpoint (none, low (< 28), moderate (28-105) and high (> 105)). Descriptive statistics and logistic regression modeling were performed; p-values < 0.05 were significant. **Results:** In total, 15,494 patients were included in the study, with 8,067 (52.07%) in the pre-COVID initiator group. Patient demographics were similar across study groups, with the exception of pre-COVID initiators who were less likely to be male (75.32% vs. 77.34%; p < 0.01) and receive copay assistance (38.37% vs. 41.70%; p < 0.01). No difference in digital engagement pre and during COVID was noted (74.55% vs. 73.60%; p = 0.18). Pre-COVID initiators were less likely to be optimally adherent than COVID initiators (84.75% vs. 85.96%; p = 0.04). Therapy persistence was more common among COVID initiators, with greater number of fills (Median [quartile (Q) Q1-Q3]: 10 [4-12] vs. 9[4-12]; p < 0.01) and less changes to therapy (8.87% vs. 9.95%; p = 0.02). After regression, COVID initiation of oral oncolytics was not associated with optimal adherence (odds ratio (OR) = 1.06 [95% (confidence interval (CI) 0.96-1.16]). Adherence increased as digital engagement increased (low: OR 0.64 [95% CI 0.56-0.72]; moderate: OR 0.67 [95% CI 0.56-0.76]; high: OR 1.71 [95% CI 1.48-1.99]). Other factors associated with increased adherence were copay assistance, male gender and age between 65 and 84 (all p < 0.05). Factors associated with decreased adherence were therapy change, CML and age < 50 years (all p < 0.05). **Conclusions:** The onset of the COVID-19 pandemic did not significantly impact optimal adherence for new-to-therapy oral oncology patients. Patients with high digital engagement during the pandemic experienced significantly improved adherence than those not engaged. Additionally, persistence and number of fills were slightly improved in COVID initiators, suggesting that the current pandemic may have influenced adherence behaviors. Research Sponsor: None.

Mobile app in oncology: A pilot survey on Latina patients with gynecological cancers and their perception on utilizing a mobile app. *First Author: Paulina Ramirez, Texas Tech University Health Sciences Center, El Paso, TX*

Background: Mobile applications have changed the way that users access information and revolutionized healthcare by allowing patients to educate themselves regarding their diagnosis and treatment. Challenges in developing a mobile health application include patient satisfaction and usage over time. Barriers to usage include trust, personalization, and accessibility. Investigating the patient population's preferences on app content and ease of use is imperative. The use of mobile applications specifically for Latina Gynecologic Oncology patients undergoing treatment has yet to be investigated. **Methods:** Fifty-six patients were recruited from the Gynecologic Oncology clinic at an urban academic health sciences center located on the Texas-Mexico border. Cross-sectional analyses were performed. Subjects were asked a series of 10-point Likert scale questions including how comfortable they would feel using medical applications on their smartphones. Linear regression models were fit with this scale score as the outcome. **Results:** The age of the 56 patients ranged from 28 to 77 years with a mean of 53.9 years (SD: 11.1). Spanish was the preferred language of 53.8% of the patients (28/52). Forty-four subjects were available for the regression analyses. Subjects were asked, "Would you feel comfortable using medical applications on your smartphone," where 1 represented "not at all comfortable" and 10 represented "very comfortable". The mean comfort scale score was 7.39 (SD: 2.85). Thirty of the 44 subjects (68.2%) replied "Multiple times per day" to the question about how frequently they use mobile apps on their phone. After controlling for the patient's age in a regression model, patients who used mobile apps multiple times per day had an average comfort scale score that was 1.75 points higher than that of women who did not use mobile apps on their phone multiple times per day (p = 0.03). After adjusting for the frequency of mobile app use, there was a reduction of 0.11 points (p = 0.002) in the comfort scale score for every one year increase in the patient's age. **Conclusions:** Our unique pilot study found a positive association between the frequency of current app use and anticipated comfort in using smartphone medical applications. Overall, patients demonstrated a considerable amount of comfort with the prospect of using a mobile app. These findings support the idea of creating a mobile app designed to monitor Latina Gynecologic Oncology patients in efforts to lessen patients' postoperative burden, improve mortality and morbidity outcomes, and decrease health care system costs. Research Sponsor: None.

Parameter estimates from the linear regression analyses in 44 patients.

Model	Frequency of mobile app usage:	Age: 1 year increase	Education: College vs. Less education	Adjusted R-squared
1	2.35 (p = 0.01)	-	-	0.13
2	1.68 (p = 0.046)	-0.10 (p = 0.003)	0.33 (p = 0.66)	0.28
3 (Final)	1.75 (p = 0.03)	-0.11 (p = 0.002)	-	0.30

Association between remotely-monitored activity, patient-reported outcomes, and physical function in patients with advanced pancreatic cancer. *First Author: Gillian Gresham, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Patients with pancreatic ductal adenocarcinoma (PDAC) experience significant functional decline over the course of their treatment, which can negatively impact their quality of life (QOL) and clinical outcomes. There are currently no standardized methods to monitor physical function (PF) in PDAC patients outside the clinic setting. The use of wearable technology to obtain continuous and objective activity data combined with routine collection of patient-reported outcomes (PROs) provides an opportunity to monitor PF and intervene in a timely matter. **Methods:** We conducted a single-site, single-arm prospective study in advanced stage 3 and 4 PDAC patients between 2019 and 2/2022. Patients used a wrist-worn wearable activity monitor (Fitbit) continuously for 8 weeks and completed NIH PROMIS surveys (PF, pain, fatigue, sleep disturbance, and emotional distress) at baseline, week 4 and week 8. ECOG performance status (PS), hand grip strength, and timed 15-foot walk test were also assessed at each timepoint. Pearson correlation coefficients were calculated for activity data (step counts, distance, stairs, time spent sedentary and in light, moderate, or vigorous activity, sleep), PROs, and functional outcomes. Multivariable regression models, adjusted for age, sex, and cancer stage, were fit to evaluate associations between activity metrics, PROs, and functional outcomes. Multivariable cox proportional hazard models were fit to evaluate the impact of activity levels on survival. **Results:** A total of 40 patients consented onto study: 50% female, median age: 67 years (range 47-85), 92% ECOG 1. Baseline activity data are summarized in Table. Statistically significant correlations between step counts and PF T-scores (coeff: 0.6, p = 0.001) and lower pain scores (coeff: -0.53, p = 0.002) were observed. Increased stairs count and time spent in moderate and high physical activity were also positively correlated with increased PF (p<0.001). No statistically significant correlations were observed between hand grip strength, activity metrics or PROs. Fewer average step counts and worse PF scores were significantly associated with poor survival with hazard ratios (HR) of 1.44 per 1000 steps (95% CI 1.06, 1.97, p = 0.02) and 1.69 (95% CI 1.1-2.56, p = 0.017), respectively, after adjusting for age, sex, stage, and ECOG PS. **Conclusions:** Findings from this research suggest that the use of wearable technology for remote monitoring of daily activity is feasible and may be used to supplement functional assessment and predict outcomes in PDAC patients. Larger trials are needed to validate findings. Research Sponsor: Pancreatic Cancer Action Network.

Activity metric	Mean (SD)
Steps/Day	4627.7 (3144)
Distance/Day (miles)	2.0 (1.4)
Stair flights/Day	4.3 (6.9)
Sedentary times (Hours)	14.7 (3.76)
Active minutes	
Light	162.6 (79.6)
Moderate	9.9 (12.9)

Interface software can markedly reduce time and improve accuracy for clinical trial data transfer from EMR to EDC: The results of two measure of work time studies comparing commercially available clinical data transfer software to current practice manual data transfer. *First Author: Maureen Thompson, NEXT Oncology, San Antonio, TX*

Background: Clinical studies and new drug approvals are delayed by slow data transfer and transcription errors from site entered data. These delays have been compounded by a shortage of data entry personnel at sites such that data entry approaches 10-30 days post visit. Data transfer is largely performed by manual keyboard entry from electronic medical records (EMR) into electronic case report forms (ECRF). **Methods:** We conducted two separate measure-of-work time studies to compare a commercially available interface software product, ProXimity to the current manual data entry. The clinical trial data from two different EMRs (ARIA and IKM G2) to an EDC (Medidata Rave). The EDC mirrored an IRB approved clinical study. Time to transfer data and error rates were the primary and secondary endpoints, respectively. For study 1 Aria EMR data from 3 subjects and 1497 data fields including demographics, vital signs, ECOG PS, physical findings, adverse events, and lab results including CBC, CMP, urinalysis, coagulation, serology were selected for visits from Screening and C2D1. For Study 2 IKM G2 data from 6 subjects and 834 data fields included demographics, vitals, and lab results. The data entry personnel were aware of the timed nature of the study. **Results:** Study 1 ProXimity took 13.2 min to transfer the data compared to 73.4 min for manual entry, with error rates of 0.8% compared to 3.5%, respectively. In Study 2 Proximity took 6.5 min compared to 29 min for manual entry, with error rates of 1.4% each due to non- conformant data (text). **Conclusions:** Software data transfer interfaces can markedly shorten the time for data entry, reduce error rates and reduce operational costs. PRECISE CURATE.AI: A prospective feasibility trial to dynamically modulate personalized chemotherapy dose with artificial intelligence. *First Author: Agata Blasiak, National University of Singapore, Singapore, Singapore*

Background: Most treatment guidelines recommend chemotherapy at maximum tolerated doses, which does not always lead to optimal efficacy, but implicitly results in toxicity. To overcome this challenge, we developed CURATE.AI, a small data, AI-derived platform that harnesses only a patient's own prospectively/longitudinally acquired data to dynamically identify their own optimal and personalized doses. We subsequently harnessed CURATE.AI to dynamically modulate individualized chemotherapy doses for patients in a prospective clinical trial. **Methods:** We conducted an open-label, multicenter, single-arm, prospective feasibility trial in patients diagnosed with advanced solid tumors and treated with single-agent capecitabine, XELOX or XELIRI (+/- biologics) (NCT04522284). The standard-of-care (SOC) capecitabine dose was 1000 mg/m^2, unless adjusted by clinician to account for patient's comorbidities and organ dysfunction. Using an AI-discovered second-order correlation between patient-specific variation of capecitabine doses and corresponding tumor marker (CEA, CA19-9 or CA-125) readouts for each cycle, CURATE.AI generated individualized patient digital avatars and recommended bespoke dose for the subsequent cycle. The clinicians were permitted to accept CURATE.AI dose recommendations, or reject the recommendations and dose based on clinical judgement. **Results:** Since August 2020 we recruited ten patients: single-agent capecitabine (n = 1), XELOX (n = 6), and XELIRI (n = 3). As of 20 Jan 2022, one patient remains on the trial. The prescribed dose was on average reduced by 20 % (± 13.8 %) as compared to the projected SOC dose. The nine reported patients completed 3.9 cycles (± 2.2 cycles), with the longest participation lasting 8 cycles. CURATE.AI recommendations were considered in 27 out of 40 total dosing decisions and accepted for prescription in 26 of those decisions. The reasons for not considering CURATE.AI included insufficient time from patient recruitment to the first dose administration and complex medical circumstances at the time of the dosing decisions. **Conclusions:** CURATE.AI has been successfully incorporated into the clinical workflow of dynamic dose selection in the treatment of solid tumors under a clinical trial. Prospective validation of CURATE.AI led to a reduction of an average prescribed capecitabine dose, which alongside additional preliminary findings may eventually play an important role in improving patient response rates and durations compared to SOC. Results from the PRECISE CURATE.AI trial support the initiation of a randomized clinical trial and potential expansion towards other oncologic indications. Clinical trial information: NCT04522284. Research Sponsor: Institute for Digital Medicine (WisDM) Translational Research Programme (R-719-000-037-733) at the Yong Loo Lin School of Medicine, National University of Singapore, Other Government Agency.

Analyzing patient engagement with digital health tools to facilitate equity across a large statewide community oncology practice. *First Author: Debra A. Patt, Texas Oncology, Dallas, TX*

Background: Digital health solutions (DHS) allow for enhanced remote communication between patients and clinical staff and the COVID-19 pandemic has brought these tools to the forefront of care delivery. Once adopted, barriers to adequate utilization still exist. Given the important need to decrease digital divides, and the diversity of patients and care settings across our clinic's 220 sites of service, we sought to understand how utilization of oncology DHS may be limited among certain populations. **Methods:** We investigated utilization among cancer patients who enrolled and engaged with a portfolio of DHS between March 1, 2019 and January 15, 2022. This portfolio includes three tools: (1) an electronic patient-reported outcomes (ePRO) remote monitoring program for tracking symptoms and oral adherence, (2) a patient portal (PP) for securely accessing patient health records, and (3) digital education (DE) for patients regarding disease and treatments. ePRO completion rate, average number of PP logins, and DE read rate were used as measures of utilization for each tool, respectively, and compared among patients with different age (< 65 and ≥65 years), language preference [English (EL) or Spanish (SL)], and distance from clinic (non-rural: < 20 miles OR rural: ≥20 miles). Mann-Whitney U and Chi-Square tests were used to compare continuous and categorical variables, respectively. **Results:** This study included a total of 77,347 unique patients representing 651,004 digital encounters. 9,938 patients engaged in ePRO, 49,771 patients in PP, and 12,044 patients in DE. Engagement across all DHS was high in patients of age group < 65 (ePRO: 72.7%, PP: 79.67% and PE 54.7%) as compared to ≥65 years, but the ePRO completion rate is high in ≥65 age group (59.0% vs 55.6%), whereas no significant difference was observed in the PP login activity and DE read rate. EL patients were significantly (p-value < 0.01) more engaged (ePRO 68% vs. 54%, PP: 80% vs. 62%, DE: 57% vs. 37%) and had higher digital utilization (ePRO completion rate: 57.31% vs 53.23%, average PP logins: 7.48 vs 7.14 and DE read rate: 96.2% vs 90.8%) than SL patients across the DHS. Patients living in rural areas comprised roughly 25% of the population and participated across tools similarly as patients living in non-rural areas (ePRO 67% vs. 69%, PP: 79% vs. 79%, DE: 56.9% vs. 56.8%). Utilization of the portfolio was variable based on rural vs non-rural status (ePRO completion rate: 56.3% vs. 57.4%, average PP logins: 7.9 vs. 7.3, DE read rate: 96.02.7% vs 96.3%). **Conclusions:** Despite variable engagement based on age, language, and rural status across the portfolio, patients within these populations continue to utilize the DHS. How we understand and explore enhancements to DHS remain under investigation for tool optimization for patient-specific barriers to care. Research Sponsor: None.

Comparative effectiveness of different interventions for cancer-related fatigue delivered digitally by online platforms. *First Author: Paris A. Kosmidis, Care Across, London, United Kingdom*

Background: As cancer treatments improve, patients' quality of life becomes even more important. In parallel, supportive care delivery is increasingly challenging, also due to resource pressures and COVID19. The effectiveness of digital and remote patient support tools as a complementary approach to improve patients' quality of life is under evaluation. Fatigue is considered among the most prevalent and persistent side effects regardless of tumour type; also, despite ongoing research, there is no single approach established. We compare the effectiveness of different self-care interventions delivered by online platforms to cancer patients in several countries. **Methods:** Patients report side effects (including Fatigue) on the CareAcross online platforms and receive tailored support to help them improve their quality of life. The supportive material encompasses many topics, and patients may receive several combinations. For Fatigue, different topics (nutrition, hydration, rest etc) were analysed to evaluate effectiveness based on prospectively collected patient reported outcomes. **Results:** 1456 breast, lung, colorectal or prostate cancer patients from 8 countries (mainly UK, Germany, France, Spain, Italy) reported Fatigue at least once. This analysis focuses on persistent fatigue: 1215 patients reported Fatigue more than once, receiving up to 7 permutations of topics (F1-F7; F4-7 consist of F1-3 combinations). All permutations include the "Physical Activity" topic (see Table). Overall, the "Hydration" topic stands out as consistently linked with the most effective material (all except F3). Comparative analysis between similar combinations shows that those with "Anemia warnings" and "Rest" tend to be more effective (F7>F6). Ambiguously, the "Physical activity before & after treatment", "Relaxation exercises" and "Fatigue diary" topics contribute to effectiveness (F5>F1), but do not counterbalance absence of the previous 3 (F1>F3). Food-related topics have unclear impact, too: "Food types" is absent from the top combination (F2) where "Food timing" is used; however, that topic is linked with a slightly inferior combination (F7>F5). **Conclusions:** Fatigue is a complex, multifactorial challenge; digitally delivered interventions can lower its incidence. Hydration appears effective, but the nature of these interventions complicates their thorough evaluation. Randomised studies may enhance these findings and enable additional personalisation towards further quality of life improvements. Research Sponsor: None.

Material (beyond "Physical Activity")	F1 (N = 65)	F2 (N = 77)	F3 (N = 79)	F4 (N = 213)	F5 (N = 200)	F6 (N = 205)	F7 (N = 376)
Physical activity before & after treatment			Y		Y	Y	Y
Relaxation exercises		Y	Y	Y	Y	Y	Y
Fatigue diary		Y	Y	Y	Y	Y	Y
Food types	Y		Y	Y	Y	Y	Y
Food timing		Y		Y		Y	Y
Hydration	Y	Y		Y	Y	Y	Y
Rest	Y			Y	Y		Y
Anemia warning	Y			Y	Y		Y
Effectiveness=reduced Fatigue incidence	27.7%	41.6%	21.5%	29.1%	34.0%	29.8%	32.2%

Electronic capture of cancer-related distress in a community oncology program. *First Author: Amit Sanyal, SSM Health Cancer Care, Madison, WI*

Background: Cancer related distress can be seen in as many as one in two patients. Many organizations such as the Commission on Cancer require distress screening. National Comprehensive Cancer Network (NCCN) distress thermometer is a common tool used for screening. We studied feasibility of embedding the NCCN thermometer into oncology electronic health record (EHR) for routine patient care. We concurrently studied feasibility of using a mobile health tool for serial evaluation of cancer related distress. **Methods:** A flowsheet containing NCCN distress thermometer questions was created in Epic EHR (Epic Systems, Verona, WI). Oncology nurses used the flowsheet for routine patient assessment. Patients with distress level ≥ 4 answered additional questions. Ancillary care providers such as palliative care nurses or social workers addressed the identified needs by providing appropriate 'services'. A field to capture these interventions was created. We also adapted our previously reported web based mobile tool [1] for monitoring cancer distress. Patients rated their distress on a 1-10 scale and highlighted the distress domain (physical, emotional, practical, family). Distress level ≥ 4 generated a color-coded flag for provider review and intervention. Data from both electronic tools was periodically analyzed to inform patient care and quality improvement. **Results:** Between January and December 2021, Epic EHR based distress flowsheet collected 28,594 distinct responses in 911 patients. 57.4%, 14.9%, 14.1%, 9.4% and 2.3% of the responses were in the physical, emotional, practical, familial and spiritual domains respectively. 'Other' responses were 1.4%. Cumulative frequency of non-physical problems was 42.5%. 1819 'services' were provided with 357 emotional, 351 work, 351 housing, 350 transportation and 350 financial need-based interventions. Of 1231 patients who used the distress scale and provided additional comments, 315 (25.5%) had distress levels ≥ 4. The mobile tool captured 849 unique patient responses to the distress question between April 2020 and February 2022. Distress level ≥ 4 was flagged by 281 unique patients (33.09%). Average distress level was 2.7. Emotional domain problems generated the greatest distress level followed by family, physical and practical problems in decreasing order. **Conclusions:** We demonstrate feasibility of electronic capture of cancer related distress to facilitate holistic patient care in a community-based oncology program. EHR based and mobile tool distress evaluations generated concordant results. Distress caused by emotional, practical and familial domain problems was nearly as frequent and often more severe than distress caused by physical problems, underscoring the need for comprehensive cancer care. Association between remote monitoring and acute care visits in high-risk patients initiating intravenous antineoplastic therapy. *First Author: Robert Michael Daly, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Acute care visits (emergency department [ED] visits or inpatient admissions) for patients with cancer are growing disproportionately. Traditional oncology care models have not effectively identified and managed at-risk patients to prevent acute care. A next step is to harness advances in technology and mobile applications to enable patients to report symptoms any time, enabling "digital hovering" - intensive monitoring and management of high-risk patients. Our objective was to evaluate a digital platform that identifies and remotely monitors high-risk patients initiating intravenous antineoplastic therapy with the goal of preventing unnecessary acute care visits. **Methods:** This was a single-institution matched cohort quality improvement study conducted at an NCI-designated cancer center between January 1, 2019 and March 31, 2020. Eligible patients were those initiating intravenous antineoplastic therapy who were identified as high-risk for seeking acute care. Patients were identified as high-risk for an acute care visit by their oncologist with decision support from a web-based machine learning model. Enrolled patients' symptoms were monitored using a digital platform. The platform is integrated into the EMR and includes: 1) a secure patient portal enabling communication and daily delivery of electronic patient-reported outcomes symptom assessments; 2) clinical alerts for concerning symptoms; and 3) a symptom trending application. A dedicated team of registered nurses and nurse practitioners managed reported symptoms. These clinicians acted as an extension of the primary oncology team, assisting with patient management exclusively through the platform. The primary outcomes evaluated were incidence of ED visits and inpatient admissions within six months of intravenous antineoplastic initiation. **Results:** Eighty-one high-risk patients from the intervention arm were matched by stage and disease with contemporaneous high-risk control patients. Matched cohorts had similar baseline characteristics, including age, sex, race, and treatment. ED visits and hospitalizations within six months of treatment initiation were analyzed using cumulative incidence analyses with a competing risk of death. The cumulative incidence of an ED visit for the intervention cohort was 0.27 (95% CI: 0.17, 0.37) at six months compared to 0.47 (95% CI: 0.36, 0.58) in the control group (p = 0.01). The cumulative incidence of an inpatient admission was 0.23 (95% CI: 0.14, 0.33) in the intervention group versus 0.41 (95% CI: 0.30, 0.51) in the control group (p = 0.02). **Conclusions:** The narrow employment of technology solutions to complex care delivery challenges in oncology can improve outcomes and innovate care. This program was a first step in using a digital platform and a remote team to improve symptom care in the home for high-risk patients. Research Sponsor: U.S. National Institutes of Health.

Lack of price transparency for prostate-directed radiation therapy relative to radical prostatectomy. *First Author: Rahul Neal Prasad, Department of Radiation Oncology, The Ohio State University Wexner Medical Center, Columbus, OH*

Background: For patients with low to favorable-intermediate risk prostate cancer (PC), management with active surveillance, radical prostatectomy (RP), external beam radiation therapy (EBRT), and brachytherapy (BT) are all National Cancer Center Network-supported definitive monotherapy options. Because therapy is non-urgent and choosing therapy can be complex, patients routinely seek second opinions and cost can be an important consideration. Recent federal price transparency (PT) guidance requires hospitals to provide payer-negotiated prices for ≥300 common services in a "shoppable," user-friendly, online format. 70 services, including RP, are specified, while the remainder are left to institutional discretion. Despite equipoise between radiation therapy (RT, inclusive of EBRT and BT) and RP in definitive treatment for PC, inclusion of prices for RT is optional. National Cancer Institute (NCI)-designated cancer centers (NCI-CC) are high volume referral centers who have the option to volunteer prices for RT; the rate at which NCI-CC choose to report payer-negotiated price estimates for prostate-directed RT is unknown. We hypothesize that reporting rates for BT and EBRT are significantly lower than for RP. **Methods:** Through online query, we identified "shoppable" price tools for NCI-CC in December 2021. Using billing codes and keyword searches, we queried these price tools for cost estimates for RP, EBRT (delivered using intensity modulated radiation therapy), and BT. Descriptive statistics, include frequency counts and proportions, were performed. The rate of reporting of "shoppable," negotiated prices for each therapy was assessed. These rates were compared using the chi-squared test (significance level of $\alpha = 0.05$). **Results:** Of the 63 NCI-CC offering clinical care, 58 (92%) published "shoppable" tools. 6 (10%), 7 (11%), and 51 (81%) published "shoppable" prices for EBRT, BT, and RP, respectively, demonstrating a significantly higher rate of publication of prices for RP than for EBRT or BT ($P < 0.001$). All of the published prices for BT were for high dose rate BT. The 11 Medicare Prospective Payment System–exempt NCI-CC had the highest rates of reporting "shoppable" prices at 91%, with 64%, 27%, and 36% including prices for RP, EBRT, and BT, respectively. **Conclusions:** Under existing regulations, patients with PC can obtain payer-negotiated price estimates for EBRT and BT from just roughly 10% of NCI-CC, while price estimates for RP are offered by > 80% of these institutions. This represents a potential obstacle to informed decision making, undermines the stated goals of US PT health policy, and the impact on utilization rates (or patient choice of therapy) is unknown. Moving forward, mandating the inclusion of common RT services (EBRT and BT) in "shoppable" price tools is a straightforward intervention that may be highly beneficial in this common cancer population. Pharmaceutical industry payments to physicians for the promotion of cancer drugs. *First Author: Aaron Philip Mitchell, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Personal financial payments from the pharmaceutical industry to oncologists are common and increasing. A prevalent view is that the purpose of industry payments to physicians is to facilitate education on new drugs. However, little is known regarding the distribution and trends in industry payments related to cancer drugs. The goal of this study was to characterize current patterns in industry payments related to cancer drugs, and test whether these patterns are consistent with an educational purpose. **Methods:** We included on-patent cancer drugs without generic/biosimilar competitors, and used publicly-available federal data sources to measure Medicare spending (proxy for overall drug revenue), number of prescribers, and industry payments (Open Payments, which includes data regarding which the drug[s] was the subject of each payment) for each calendar year from 2014-2018. We analyzed General Payments to individual physicians, which encompasses payment types such as meals, travel, consulting, and speaking fees. We tested two hypotheses implied by the claim that industry payments serve educational purposes. First, payment amounts should not be associated with drug revenue. To test this hypothesis, we used generalized estimating equations (GEE) to model the association between mean per-physician industry payments and Medicare spending. Second, payments related to a given drug should decline over time as physicians become educated. To test this hypothesis, we determined the relative year-to-year change in industry payments for all cases wherein consecutive years were observed, and used GEE to estimate the year-to-year change with respect to duration of time since initial FDA approval. **Results:** The sample included 89 drugs and 361 drug-year observations. The total amount of industry payments for oncology drugs increased during the study period, from $53,333,854 in 2014 to $90,343,731 in 2018. There was no association between log-transformed mean, per-physician industry payments and per-physician Medicare spending (estimate -0.001, 95%CI: -0.005, 0.004). In aggregate, Industry payments for cancer drugs were greatest immediately after FDA approval and trended downward over time; the estimated industry payments in the subsequent year for a drug with mean payments of $1,000 per-physician in the index year was: $681* for drugs 0-4 years since approval, $825 for drugs 5-9 years, and $679* for drugs≥10 years (*p<0.05). **Conclusions:** The absence of association between industry payments and Medicare spending and the decline in industry payments for drug subsequent to approval are consistent with claims that these payments function to facilitate physician education. Research Sponsor: U.S. National Institutes of Health.

Exploring country priorities and contextual considerations for implementing national cancer control plans (NCCP) among participants of International Cancer Control Partnership (ICCP) ECHO. *First Author: Darya Aleksandrovna Kizub, UT MD Anderson Cancer Center, Houston, TX*

Background: Promoting NCCP implementation by low- and middle-income countries (LMICs) is key to addressing inequities in cancer outcomes and the global burden of cancer. We explored contextual factors that may influence implementation of NCCP priorities in LMICs. **Methods:** Seven countries participated in the 2021 International Cancer Control Partnership ECHO (R) geared toward creating a community of practice to inform NCCP implementation. Using qualitative methods, we conducted focus group discussions (FGDs) with country teams who were asked to identify NCCP priorities and provide contextual considerations around implementing these in the 12-months program. FGDs were audio-recorded, transcribed, double-coded, and underwent thematic analysis. **Results:** Thirty-three participants from 6 Sub-Saharan African countries and 1 country in Asia took part in 7 FGDs, including 14 physicians, 9 non-governmental organizations, 6 Ministry of Health/NCCP and 4 cancer registry representatives. All seven country teams (100%) prioritized cancer early detection, especially for cervical (71%) and breast (57%) cancer, including by educating primary care clinicians (57%) and general population (43%) about cancer signs and symptoms. Related contextual factors included late-stage diagnosis of cancer (43%) and low knowledge about cancer among primary care clinicians and the general population (29% each), respectively. Finding resources for implementation of NCCP priorities was important given lack of funding (57% each). Harmonizing programs and building partnerships for implementation (57%) was prioritized given perceived fragmentation of efforts and benefit of leveraging limited resources (29% each). Improving access to treatment (43%) was a priority given a lack of oncology specialists (29%) and unaffordable treatment (14%). Improving access to palliative care (43%), including by writing guidelines (29%), was prioritized due to late-stage diagnosis and insufficient access to palliative care (14% each). Improving cancer registry data was essential for NCCP program planning (43% each), while cancer research (43%) was key to answering specific questions related to cancer registry data (14%) and program impact (29%). Additional contextual considerations for making progress on these priorities dicussed by country teams included leveraging existing programs (100%) and learning from other countries and ICCP technical experts (57% each). **Conclusions:** There were similarities in country NCCP priorities and contextual factors affecting implementation. These results allow for future exploration of how LMIC country teams implement NCCPs and examine the value of communities of practice promoted by ICCP and facilitated by ECHO, towards improving cancer outcomes. Financial payments from the pharmaceutical industry to U.S. cancer centers, 2014-2019. *First Author: Aaron Philip Mitchell, Duke University, Durham, NC*

Background: Payments from the pharmaceutical industry to US health care providers were made public through Open Payments in 2013. Since then, industry payments to individual physicians have been studied extensively, but payments to hospitals remain uncharacterized. The goal of this study was to examine trends in industry payments to US cancer centers. **Methods:** We identified all US cancer centers that were National Comprehensive Cancer Network (NCCN) members or were National Cancer Institute (NCI) comprehensive cancer center as of 2019. Each institution was manually mapped to Open Payments, which contains industry payment data. Where applicable, subsidiary hospitals were included with the parent center. Among the NCCN centers, we used National Plan and Provider Enumeration System data to identify medical oncologists practicing there. Oncologists were linked to Open Payments by name and address. We analyzed "research payments" (RP), which include payments related to preclinical and clinical research, and "general payments" (GP), which include non-research-related payments in categories such as speaker fees, consulting fees, meals, grants, charitable contributions, and licensing fees. We ascertained public research support from NIH data, and included all research project grants. We used correlation analysis and linear regression models to assess the association between industry payments to a cancer center and to oncologists practicing at that center. All dollar values were inflation-adjusted to 2019 dollars using the Consumer Price Index for medical care from the US Bureau of Labor Statistics. **Results:** Overall industry RP to US cancer centers increased from $527 million in 2014 to $653 million in 2019, while GP increased from $346 million to $786 million. NCI research funding increased from $1,397 million in 2014 to $1,583 million in 2019 (13.3% increase) while overall industry payments (RP+GP) increased from $873 million to $1,439 million (64.8% increase). Industry payments were highest as a portion of total income (industry + NCI) at MD Anderson (64.2%) and lowest at St. Jude (0.1%). Among NCCN institutions, industry payments to cancer centers and the oncologists practicing at those centers were correlated (coefficient = 0.382). A $1,000 increase in GP to a cancer center from a given pharmaceutical company was associated with a $1.00 ($0.61 - $1.30) increase in GP from that company to oncologists at that cancer center. **Conclusions:** From 2014-2019, cancer center funding from industry sources grew quickly, driven by an increase in non-research payments, and now approaches the amount of public research funding cancer centers receive. Cancer center acceptance of industry payments is associated with increased industry payments to its employed physicians, which are known to sway prescribing practices. These trends raise concerns regarding the ability of these institutions to fulfill their public missions. Research Sponsor: U.S. National Institutes of Health.

Disparity in initiation of checkpoint inhibitors among metastatic melanoma and lung cancer. *First Author: Meng Li, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Checkpoint inhibitors are transforming cancer care. However, the high prices of these medicines raise concerns over their affordability and disparity in use. The objective of this study is to describe the disparity in initiating checkpoint inhibitors and examine patient- and area-level factors associated with delayed initiation. **Methods:** This study is a retrospective cohort study using Optum data. We identified commercially insured patients newly diagnosed with metastatic lung cancer and melanoma since the introduction of checkpoint inhibitors in these cancers (lung cancer cohort: diagnosed between January 2015 and December 2020; melanoma cohort: diagnosed between January 2011 and December 2020). Time from metastatic cancer diagnosis to initiating checkpoint inhibitors was analyzed using Cox proportional hazard models. Independent variables included county-level measures (percentage of black population, percentage of Hispanic population, percentage of other minority, percentage of population living below poverty line, rurality, number of medical oncologist per population, and having a National Cancer Institute designated cancer center) and patient-level characteristics (age, sex, Charlson comorbidity index, any dual eligibility, Medicare Advantage, and year of diagnosis). We clustered standard errors at the county level. **Results:** The percentage of metastatic lung cancer and metastatic melanoma patients on checkpoint inhibitors increased from 23% to 52% from 2015 to 2020 and from 22% to 58% from 2011 to 2020. Counties with greater percentage of black, Hispanics, and other minorities were high urban with greater density of medical oncologists and NCI-designated cancer centers. However, greater percentage of Hispanic population in a county was associated with significantly slower initiation of checkpoint inhibitors for both the lung cancer and the melanoma cohorts (hazard ratios [HR]: 0.937 and 0.946, respectively; p-values: < 0.001 and 0.014, respectively). Percentage of other minority population in a county was associated with slower initiation for metastatic lung cancer (HR: 0.983; p-value: < 0.001). No other county-level factors had a significant coefficient from the multivariate Cox models. In terms of patient-level characteristics, older age, female, more comorbidities, any dual eligibility, and Medicare Advantage were associated with significantly slower initiation for the lung cancer cohort and older age and female were associated with significantly slower initiation for the melanoma cohort. **Conclusions:** Commercially insured metastatic lung cancer and melanoma patients who lived in counties with greater percentage of Hispanic population had slower initiation of checkpoint inhibitors after their cancer diagnosis, despite the fact that those counties had greater density of medical oncologists and NCI-designated cancer centers. The impact of physician-hospital integration on spending and quality of oncology care. *First Author: Pragya Kakani, Harvard University, Cambridge, MA*

Background: There has been increasing hospital and health system ownership of physician practices in recent years, particularly in oncology. However, relatively little is known about how this impacts care delivery for patients with cancer, who use many hospital-based services that may be impacted by integration. We evaluated the impact of physician-hospital integration in oncology on spending and quality of care for Medicare beneficiaries with cancer. **Methods:** We used Medicare Fee-for-Service claims from 2005-2019 linked with a unique Health System and Provider Database, developed by National Bureau of Economic Research and Harvard University researchers, to track practice ownership relationships over time. We used a stacked event study to assess outcomes for patients three years before and after oncologists move from independent practices to hospital- or system- owned practices. We compared outcomes to a control group with oncologists who shifted from independent to hospital- or system-owned practices in later years. We focused on two cohorts of patients. The first cohort included cancer patients with presumed incident or recurrent cancer based on $\geq$2 visits to an oncologist and no visit in the past year. For these patients, we evaluated the impact of physician-hospital integration on the likelihood of receiving chemotherapy following the visit. The second cohort included 6-month episodes for patients receiving chemotherapy. For these patients we evaluated the impact of physician-hospital integration on spending, utilization, and quality. Quality measures included receipt of timely chemotherapy (within 60 days) following surgery, inpatient readmissions, non-use of tamoxifen + strong CYPD26 inhibitors, and end-of-life intensity of care measures. **Results:** There was no change in the likelihood of receiving chemotherapy with an initial oncology consultation following an oncologist's transition to hospital-based employment. Total spending during six-month chemotherapy episodes increased by $1391 (95%CI: $465, $2316). The primary contributors to this growth were increases in spending on inpatient care, chemotherapy administration, and office visits. Spending growth, where observed, was driven primarily by higher Medicare prices for care in hospital outpatient settings. We found no positive impact of physician-hospital integration on timeliness of chemotherapy initiation, readmissions, concurrent use of tamoxifen+strong CYPD26 inhibitors, or intensity of end-of-life care. **Conclusions:** Physician-hospital integration resulted in higher prices and thus higher spending, but had limited impact on utilization and no detectable impacts on measures of quality. These results suggest that claims of quality improvements and concerns regarding overuse associated with physician-hospital integration may be overstated. Our results also support continued movement towards site-neutral payments. Research Sponsor: U.S. National Institutes of Health.

Market determinants of commercial prices for intravenous chemotherapy infusions. *First Author: Michael Milligan, Harvard Medical School, Boston, MA*

Background: Recent price transparency legislation mandated that hospitals across the country report their individually negotiated prices with insurers. Using this data, we sought to characterize the prices paid for standard intravenous (IV) chemotherapy infusions, and determine the hospital, regional, and market factors associated with higher prices. **Methods:** We utilized a database of U.S. hospital-reported price transparency data to characterize prices for the most commonly billed chemotherapy drug administration Common Procedural Terminology (CPT) codes—*96413* (initial IV chemotherapy infusion) and *96415* (additional hour of IV chemotherapy). We obtained standard charges and commercial prices negotiated with private payers from hospitals that directly administer chemotherapy. To assess variation in prices, we calculated the ratio of the 90th percentile price to the 10th percentile price among private payers in each hospital and among hospitals in each Hospital Referral Region (HRR). We performed multivariable linear regressions to assess hospital, regional, and market factors associated with higher prices. **Results:** A total of 1,458 hospitals reported at least one price for CPT code *96413* or *96415*. Hospitals reported 1 chargemaster and a median of 18 (IQR: 8–35) commercial prices negotiated with different private payers. National median commercial prices for CPT codes *96413* and *96415* were $536.00 (IQR: $326.43-$784.63) and $175.06 (IQR: $98.28-$327.25), respectively. Within each hospital, the 90th percentile commercial price was 2.2 times higher, on average, than the 10th percentile price for CPT code *96413*, and 2.8 times higher for *96415*. Among different hospitals within each HRR, the median commercial price at the 90th percentile hospital was 1.5 times higher than at the 10th percentile for CPT code *96413*, and 2.3 times higher for *96415*. On multivariable analysis, higher prices for CPT code *96413* were observed at for-profit hospitals ($215.12 higher than government not-for-profit hospitals, 95% CI: $55.22-$429.61). Higher prices for CPT code *96415* were observed at hospitals with higher predicted practice costs ($35.79 for every 1% increase in the geographical practice cost index, 95% CI: $16.69-$54.87), and a lower disproportionate share percentage ($0.96 for every 1% decrease in DSH patient percentage, 95% CI: $0.08-$19.41). **Conclusions:** Commercial prices for commonly billed IV chemotherapy infusions demonstrate significant variability. Prices for identical infusions vary by a factor of 2 depending on which hospital or private payer a patient selects. While prices for CPT code *96415* are largely explained by the relative cost of care, prices for the more expensive *96413* appear to be driven by the profit-status of the hospital. Further study is required to characterize the implications of such high levels of price variability on access to care and overall healthcare costs. Research Sponsor: None.

Time to access to novel anticancer drugs in Europe, a case study in seven European countries. *First Author: Colinda Post, AmsterdamUMC, Amsterdam, Netherlands*

Background: After European Medicines Agency Marketing Authorization (EMA-MA) different national reimbursement processes may contribute to unequal access throughout the EU. The aim of this study is to investigate the access time to new anticancer medicines in seven high-income Northern European countries and factors influencing the reimbursement process. **Methods:** We performed a retrospective database study. New anticancer medicines were included with a positive CHMP advice between January 2016 and January 2020, leading to EMA-MA followed by an application for national reimbursement approval in Germany, UK, France, The Netherlands, Belgium, Norway and Switzerland. The relevant Health Technology Assessment (HTA) - and reimbursement websites for each country were used to identify reimbursement dates. Time to access was defined as the time between EMA-MA and date of inclusion in the relevant reimbursement list. In addition we investigated the differences in national approval process and study-, medication- and patient- related factors which might influence the time to reimbursement. **Results:** We found that for the thirty-six new anticancer medicines, national reimbursement came on average 289 days after EMA-MA, with a variety of -125 in Switzerland (i.e. non EU-member) to 1415 days. Of these EMA-MA new anticancer medicines 42% were reimbursed in all countries. The average number of cancer medicines reimbursed in the examined countries was 27 (75%) , with a range of 24 (67%) in Belgium to 36 (100%) in Germany. The shortest average time from EMA-MA to reimbursement were in Germany, 2.33 days, France and Switzerland following with 207 days and 279 days respectively. The median time to reimbursement was 227 days with a range of 3 days in Germany to 553 days in Belgium. In Germany, where there is no pricing and reimbursement approval required when launching a pharmaceutical, 100% of the cancer medicines are reimbursed within five days. After one year, In the UK 56% of the medicines are reimbursed, followed by 53% in the Netherlands, France and Switzerland. Belgium and Norway have a one year reimbursement rate of 14% and 11% respectively. Access to anticancer medicines is dependent on regulatory procedures, HTA and price regulations. Germany has a fast market access for anticancer medicines with a price regulation one year after launching the medicines. In the other countries, price regulation is part of the launching process. Other factors which might accelerate the time to reimbursement we are examining are high clinical benefit score (ESMO-MCBS), (non-)orphan status of the medicines and submission by big pharmaceuticals. **Conclusions:** This study shows that after EMA-MA, except for Germany, on average it takes a long time for anticancer medicines to be reimbursed in Northern European countries. There is a considerably variety both within and among countries. Research Sponsor: None.

Reliability of cancer registry primary payer information and implications for policy research. *First Author: Amy J. Davidoff, National Cancer Institute, Rockville, MD*

Background: Researchers commonly use "Primary Payer at Diagnosis" measured in cancer registry data to assess the impact of health policy, such as the Affordable Care Act, on insurance, and the impact of insurance on cancer care and outcomes. Measurement error may bias estimated effect size and significance. Little is known about patterns of Medicaid or Medicare misreporting in registry databases commonly used for policy analysis. **Methods:** We used the National Cancer Institute's Surveillance, Epidemiology and End Results registry data for adults aged 19-64 years at diagnosis with known cancer stage, linked to most recently available (2007-2011) CMS records on Medicaid and Medicare enrollment at diagnosis month. We recoded the registry Primary Payer variable into 6 categories: private/managed care, Medicare, Medicaid, other government, status unknown, uninsured. State-year policy data regarding Medicaid eligibility and managed care enrollment were also linked. We compared the registry data to Medicaid and/or Medicare enrollment data, and calculated underreporting rates by patient characteristics and state policy. **Results:** The linked sample (N = 896,031) was 68% non-Hispanic white, 49% male. Overall, the registry data reported 7.8% Medicare and 10.1% Medicaid, while enrollment was 5.5% Medicare, 10.4% Medicaid, and 3.4% dual Medicare-Medicaid. The registry data concordantly identified 61.4% and 57.7% of persons identified per enrollment data to be Medicaid-only and Medicare-only, respectively (Table). Most Medicaid-only enrollees without concordant registry information were reported to have private insurance or be uninsured. Medicaid underreporting (39% overall), was higher for males (43%) vs females (37%), in low (46%) vs high (38%) poverty areas, for Medicaid poverty expansion or waiver enrolled (50%) vs cash assistance related eligibility (33%), and in states with large managed care enrollment, all at p<.001. If Medicaid and Medicare enrollment data were used to edit the registry data, 8% of persons would switch insurance assignment. **Conclusions:** Primary Payer data reported by cancer registries are subject to measurement error and may result in biased estimates of insurance-related policy impacts. Enhancement with objective Medicaid and Medicare enrollment data will reduce measurement error and may result in unbiased estimates necessary to support policy assessment. Research Sponsor: None.

Distribution of CMS Medicaid & Medicare enrollment by registry primary payer (column %).

Registry Payer Data	Total (100%)	Medicaid only (10.4%)	Medicare only (5.5%)	Dual enrolled (3.4%)	Neither (80.7%)
Private	68.0	19.3	28.2	7.6	79.6
Medicare	7.8	3.7	57.7	80.2	1.9
Medicaid	10.1	61.4	1.4	6.5	4.3
Other government	3.3	1.2	6.1	1.0	3.5
Unknown insurance status	5.6	3.9	5.2	4.0	5.9
Uninsured	5.1	10.6	1.3	0.7	4.9

Effect of immunotherapy and time-of-day infusion chronomodulation on survival in advanced cancers. *First Author: Blessie Elizabeth Nelson, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Emerging clinical studies report correlation of time-of-day infusion (TOI) to immunotherapy outcomes and the intricate interplay of the human circadian rhythm and cancer and immunotherapy exposure. Preclinical and clinical studies have shown cancer chronotherapy to play important role in transcriptional rhythmicity of oncogenic process. We evaluated the association of TOI and immunotherapy outcomes in a large cohort to determine impact of TOI on overall survival (OS) and progression free survival (PFS). **Methods:** We reviewed charts of patients with solid tumors who received immunotherapy, specifically anti programmed cell death protein 1 (PD1) and anti-programmed death-ligand 1 (PD-L1) agents at MD Anderson Cancer Center. Infusion times were divided into two hours cohorts from 8am-8pm and one overnight cohort from 8pm-8am. Accelerated failure time models were used to model OS (log-normal distribution) and PFS (Weibull distribution) with relation to TOI after adjusting for factors such as age, gender, tumor type and prednisone > 10mg daily use within 1 month of immunotherapy initiation to minimize confounding factors. **Results:** Of 6151 patients with advanced tumors, 4441 patients received immunotherapy therapy after adjusting for minimum 140 patients in each tumor cohort from 10/15/2016 until 10/15/2021. Tumor types included advanced lung cancer (31.4%), melanoma (28.7%), renal (14.4%), breast (7.6%), colon (6.2%), liver cancer (3.9%) and head and neck (H&N) cancers (2.8%). Median age was 63 (15-99) with 58% males and 42% female. 1894 (43%) patients received investigational agents and 2547 (57%) received standard of care therapies. Mechanism of action of various agents: anti PD1, anti-PDL1, TGF-βRII and anti-PDL1, anti-PD-1 with OX40+ T Cell activation, PD-1 / PD-L1 bispecific antibody, PD-L1 dependent 4-1BB agonist and anti PD-1 and CTLA-4 activity. Among all patients, median OS was 26.4 months while median PFS was 4.8 months. Preponderance of immunotherapy TOI occurred between 12-2pm and 2-4pm in all patients. Patients receiving overnight TOI with lung, renal and breast cancer demonstrated significantly ($p < 0.05$) poorer OS compared to TOI (10am-4pm) whereas in melanoma, significantly lower OS was seen with overnight, 8-10am and 6-8pm compared to 10am-4pm TOIs. Among H&N cancer patients, early TOI (8-10am) was associated with significantly lower OS compared to afternoon TOI (12pm-4pm). PFS trends were less distinct than for OS but showed a slighted inverted tendency towards lower PFS following daytime TOI. **Conclusions:** In this large cohort of patients treated with immunotherapy, clinically significant association of TOI with overall survival is seen. These intriguing findings warrant prospective validation in a future randomized trial to harness the role of chronomodulation of cancer therapies for improving outcomes. Research Sponsor: None.

Novel use of clinical pathways to identify poor prognosis lung cancer patients: Implementation and outcomes. *First Author: David Michael Jackman, Dana-Farber Cancer Institute, Boston, MA*

Background: Cancer patients in the last year of life have different clinical needs and evolving goals of care. Using our oncology decision-support pathways to help clinicians consistently identify such patients in a systematic and prospective fashion, at a discrete moment in the care trajectory, may be an important step towards matching the care of these patients with their stated goals. **Methods:** Medical oncologists from each disease group at the Dana-Farber Cancer Institute (DFCI) were tasked with identifying clinical settings in each oncology care pathway associated with an expected median survival of < 12 months. This information was embedded into the underlying data model of the pathways platform, allowing us to determine how often clinicians navigated through each poor prognosis node. **Results:** From 3/1/20 – 6/30/21, there were 264 navigations in 205 unique lung cancer patients receiving standard of care (i.e., not on clinical trial) for a clinical condition associated with poor prognosis. Overall, the median overall survival from the time of a patient's first navigation through a poor prognosis node during the defined study period was 6.4 months. Table lists outcomes for each specific setting. Patients with squamous or small cell lung cancer being treated in or beyond the third-line setting had notably poor outcomes, with less than a third of these patients surviving 6 months from the time of navigation. **Conclusions:** A clinical pathways platform can be a key tool in designating clinical scenarios associated with poor prognosis and identifying patients who may be particularly at risk. Pathways analytics provide real-world evidence corroborating the expected poor prognosis based on published studies and can identify specific clinical subsets for whom specific resources are warranted. By embedding this into the pathways data model, we aim to alert physicians to conduct goals of care conversations, offer supportive care resources, and match patients to appropriate treatment options and clinical trials. Research Sponsor: None.

Setting	Navigations	Died/ censored	6-month survival, %	Median overall survival (OS) from date of pathway navigation, months (95% CI)
Metastatic NSCLC, non-squamous, targeted therapies inappropriate or exhausted, 3rd line or beyond	95	77/18	51%	6.6 (5.0-8.3)
Metastatic NSCLC, squamous, 2nd line	26	16/10	64%	9.0 (2.6-13.3)
Metastatic NSCLC, squamous, 3rd line and beyond	23	18/5	33%	3.5 (1.8-5.5)
SCLC, second line	62	47/15	47%	5.7 (3.9 – 7.5)
SCLC, 3rd line and beyond	58	49/9	32%	4.2 (3.2-5.2)

Patient efficacy in telehealth is moderated by distress among patients with cancer: A cross-sectional survey study. *First Author: Joseph William McCollom, Wright State University, Dayton, OH*

Background: The COVID-19 pandemic increased the use of telehealth to reduce exposure, which was critical for patients with cancer. The extent to which patients with cancer view telehealth visits as meeting their medical needs was investigated using a cross-sectional survey. **Methods:** Patients currently receiving cancer treatment at a single cancer institute who had had at least one telehealth visit were emailed an online survey. Response rate was 5% (94/1944). The survey measured patients': 1) Emotional Thermometer (i.e. distress, anger, depression, anxiety, and need for help on a 0-10 scale); 2) Telehealth usability questionnaire (TUQ; 21-items with various subscales, like interaction quality; α=0.98).); and 3) Perceived Efficacy in Patient-Physician Interactions (PEPPI-5) scale (five items, e.g., "How confident are you in your ability to make the most of your visits with your doctors?"). Respondents completed the PEPPI-5 for in-person visits and for telehealth visits. Descriptive statistics were calculated for all measures. A generalized linear model was estimated predicting PEPPI-5 for telehealth visits from emotional thermometer and TUQ scores. The interaction between emotional thermometer and TUQ scores was estimated to test the hypothesis that emotional distress moderated the relationship between TUQ and efficacy in patient-provider interactions during telehealth visits. **Results:** Across all five thermometers, 30.8% (28/91) reported a high score on at least one metric. The most frequently reported high score was for anxiety, 23.3% (21/90) and least frequently reported high score was for anger, 12.2% (11/90). The mean TUQ score was 5.5 (SD=1.5) and mean PEPPI-5 score for telehealth visits was 8.1 (SD=2.4). As shown in Table, emotional thermometer scores did moderate the relation between TUQ and patient self-efficacy during telehealth visits. For high emotional thermometer scores, self-efficacy decreased as TUQ scores decreased. **Conclusions:** For patients experiencing high emotional distress, low comfort and ability with telehealth usability resulted in low patient self-efficacy in communicating with providers and getting medical needs met. Telehealth is a convenient and effective modality; however, in times of emotional distress for patients who are not familiar with telehealth, in-person clinic visits may result in greater patient self-efficacy. Research Sponsor: None.

Summary results from generalized linear model estimating patient efficacy during telehealth visits.

Parameter	Estimate	Standard Error	t-Value	P-value
Intercept	0.04	1.41	0.03	.97
TUQ	1.39	0.25	5.58	<.0001
Emotional Thermometer (low)	6.03	1.80	3.35	.001
TUQ X Emotional Thermometer	-1.00	0.32	-3.15	.002

Responses to telehealth expansion for older adults with cancer during the COVID-19 pandemic. *First Author: Robin T. Higashi, University of Texas Southwestern Medical Center, Dallas, TX*

Background: Synchronous video visits ("telehealth") were rapidly adopted to facilitate provision of cancer care during the COVID-19 pandemic, with little time to comprehensively assess patient and provider needs. Attitudes toward telehealth use during active treatment (vs. survivorship care) were largely unknown, as were perceptions of, experiences with, and needed support for telehealth use among older adults with cancer. Older adults in particular may face increased vulnerability to inequities in access to care due to limited digital literacy. **Methods:** We conducted surveys and semi-structured interviews with providers, staff, and older patients (age ≥60) from a comprehensive cancer center. Data collection occurred between Dec 2020 - Nov 2021. **Results:** We completed a total of 106 provider/staff surveys, 128 patient surveys, 20 provider/staff interviews, and 15 patient interviews. A majority of surveyed providers/staff felt that telehealth should "definitely be offered" during treatment-phase encounters (55.9% treatment follow-up; 69.1% results communication; 70.2% discussing treatment side effects). Similarly, most patients indicated they would be willing to have video visits with a member of their care team for: discussing treatment side-effects (73.5%), results communication (69.6%), and treatment follow-up (65.7%). Patients reported experiencing challenges with joining video visits (29%) and understanding the telehealth process (28%). Similarly, less than a third (30.8%) of providers/staff agreed or strongly agreed that the institution did a good job of preparing patients for their first telehealth encounter. Patients felt the institution should do more to communicate the advantages of telehealth to older adults in handouts and videos, which included: engaging multiple family members in critical appointments (e.g., treatment decisions, end-of-life), seeing their doctor when they were too sick to travel, and reducing potential exposure to infectious disease at the clinic. Participants suggested several strategies to assist patients with limited digital literacy: offering video tutorials of the connection process, creating "fake appointments" to practice online connections, and hiring a digital navigator to assist with technical difficulties and setup of the online portal. Despite challenges, a majority of surveyed patients (65.7%) and providers/staff (76.9%) intend to continue using telehealth after the COVID-19 pandemic passes. **Conclusions:** Use of telehealth for cancer care was received positively by older patients and providers/staff. Taking targeted steps to enhance implementation could reduce barriers to care, including among older adults and other populations with limited digital literacy, thereby promoting greater equity of access to telehealth benefits beyond the pandemic. Research Sponsor: Simmons Comprehensive Cancer Center, Community-Engaged Research Pilot Award.

Evaluation of a pharmacist-led video consultation to identify drug interactions among patients initiating oral anticancer drugs. *First Author: Morgan R.L. Lichtenstein, Columbia University Medical Center, New York, NY*

Background: The past decade has seen a dramatic increase in the number of oral anti-cancer drug (OACD) approvals in the United States. Though polypharmacy and drug-drug interactions (DDIs) likely contribute to OACD toxicity, the prevalence of these features in patients on OACDs remains largely unknown. We aimed to evaluate a one-time 30-minute pharmacist-led video consultation among metastatic cancer patients initiating OACDs to identify medication list inaccuracies as well as the prevalence, characteristics, and severity of OACD-related potential DDIs. **Methods:** We conducted a single-arm, prospective telehealth intervention study among 29 patients initiating OACDs to evaluate a one-time 30-minute pharmacist-led video consultation. The video visits focused on identifying and discussing polypharmacy and potential DDIs, and pharmacists then communicated recommendations to each patient's oncologist. We estimated the prevalence, characteristics (QTc prolongation, absorption interactions, etc.), and severity of OACD-related potential DDIs. Lexicomp and Micromedex were used to assess potential DDIs and measure severity on a standardized scale (A – D, X). In addition, we assessed the prevalence of medication list inaccuracies, polypharmacy, and patient satisfaction. **Results:** Twenty-five patients completed the intervention (86% completion rate) of whom 40% were 75 years of age or older and 60% were men. The majority were white (68%) and non-Hispanic (76%). Sixteen patients (68%) had a solid tumor diagnosis. Nearly half (48%) were insured by Medicare. The median number of medications per patient was 9 with a range of 4 – 21, and 96% of patients had at least 5 prescriptions listed. The median number of medication list errors was 2 with a range of 0 – 16, with at least 1 error for 76% and more than 1 error for 52% of patients. Pharmacists identified potential OACD-related interactions in 9 cases (40%). These included change in drug absorption or metabolism (7), QTc prolongation (1), hypotension (1), and bleeding (1). Interactions were classified as either category C (8) or D (2), requiring close monitoring or a change in treatment, respectively. All patients expressed a high level of satisfaction with the video visit. **Conclusions:** Polypharmacy, medication list errors, and potential DDIs are prevalent among patients initiating OACDs despite use of an electronic medical record requiring medication reconciliation. Our study suggests that a one-time remote 30-minute pharmacist-led video consultation can effectively identify and address OACD-related potential DDIs, which may decrease medication complexity and improve adherence in this population. Variation in telemedicine usage in gynecologic cancer: Are we widening or narrowing disparities? *First Author: Leslie Andriani, Penn Medicine Abramson Cancer Center, Philadelphia, PA*

Background: Telemedicine rapidly increased with the COVID-19 pandemic and may be a way to reduce care disparities. Our aim was to evaluate sociodemographic (race, insurance), patient, health system, and cancer factors associated with use of telemedicine in gynecologic cancers. **Methods**: We conducted a retrospective cohort study of patients with documented endometrial or ovarian cancer using the nationwide de-identified electronic health record-derived Flatiron Health data. We used multi-level regression models to analyze the association of telemedicine usage during COVID-19 pandemic (2020-2021) with sociodemographic, patient, health system, and cancer factors overall. **Results**: Of 13,450 patients with endometrial or ovarian cancer, 14.4 % (95%CI 14.0-16.1) used telemedicine during COVID-19 for their cancer care within the Flatiron Health network. Insurance was not associated with likelihood of telemedicine in any model. Region was significantly associated with telemedicine usage across models with patients living in the Northeast more likely to use telemedicine. **Conclusions**: In this large cohort study, we found regional disparities across cancer types and oncology settings. Expanding access to telemedicine may improve racial and geographic disparities in gynecologic cancer. Research Sponsor: American College of Obstetrics and Gynecology, University of Pennsylvania Basser Center for BRCA.

Hematology/oncology outpatient perspectives on telehealth one year into the COVID-19 pandemic. *First Author: Anne Hudson Blaes, University of Minnesota, Minneapolis, MN*

Background: Telehealth use expanded during the COVID-19 pandemic, but few studies have explored patient perspectives on it after the initial months. Using mixed methods, we aimed to understand patient telehealth perspectives and to examine for whom telehealth is less optimal. **Methods:** A modified Telemedicine Satisfaction and Usefulness Questionnaire (TSUQ) for hematology/oncology outpatient care was sent to patients ≥18 years old within the M Health Fairview Masonic Cancer Clinic with ≥1 prior telehealth visit (phone and/or video). Two focus groups were also conducted. We summarized cohort characteristics and views on telehealth. We dichotomized selected TSUQ items (measured on a 1-5 scale) and evaluated them using logistic regression, adjusted for age (<65 years, ≥65 years), gender, race (White, other), income (<$50,000, $50,000-99,000, ≥$100,000, prefer not to say), education (no college degree, at least college degree), and having cancer (yes, no). Focus group data were analyzed qualitatively. **Results:** Of 7848 invitations, 588 surveys were completed (7.5% response rate). For respondents, 71% were female, 68.7% married/partnered, 90.6% identified as White, and 36.1% had a graduate/professional degree with an annual salary ≥$150,000 (21%). Most had cancer (73.3%) but were not currently receiving treatment (36.5%); 40% each had employer-based insurance or Medicare. Focus group members (n = 16) were chosen from a demographic mix of 121 volunteers. Most survey respondents found telehealth satisfactory [mean 3.8 ± standard deviation (SD) 0.9] and easy to use (mean 3.4 ± SD 0.9), 72.2% found it convenient, and 82.2% agreed that it saved time. Most (78.6%) would be happy with a combination of telehealth and in-person care going forward, but those with cancer were less likely to prefer future telehealth care (adjusted odds ratio [OR] 0.52, 95% confidence interval [CI] 0.34 - 0.81). Being male and having lower incomes were associated with greater telehealth satisfaction, (male vs. female, OR 1.68, 95% CI 1.00 - 2.83), income <$50,000 vs. ≥$100,000 (OR 2.47, 95% CI 1.16 - 5.28). Focus group members reported between 1 - 30 telehealth visits (overall care range 8 months - 30 years). Views on telehealth mirrored survey results. Time saved and reduced exposure risk were beneficial, especially for those in rural settings and for those seeing genetic counselors or palliative care. However, concerns were voiced about fewer in-person interactions, communication gaps, and provider style variability. **Conclusions:** Our findings show that oncology patients prefer care in person despite telehealth's benefits. Additional work is needed to ascertain the optimal, and possibly patient subgroup-specific, combination of in-person and telehealth in ambulatory hematology/oncology care to manage the needs of different populations. Utilization of telemedicine among patients newly diagnosed with cancer. *First Author: I-Wen Pan, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The use of telemedicine among cancer patients remains limited. Because of the COVID-19 pandemic, CMS expansion of telehealth with 1135 waiver was enacted in March 2020, broadening the opportunities to provide patient care using telemedicine. This study examined the impact of the CMS expansion on the use of telemedicine among cancer patients. **Methods:** We identified newly diagnosed patients with 5 common cancers (breast, prostate, lung, colorectal, and lymphoma) between 3/2019 and 12/2020 from Optum's de-identified Clinformatics Data Mart Database. Patients who had 6 months of full enrollment (3 months before and 3 months after the first [index] cancer diagnosis date), had cancer claims on 3 separate dates within 3 months of the index date for the specific cancer diagnosis, and no prior history of cancer were included. We defined telemedicine use as patients who had a telemedicine procedure code within 1 month of their index diagnosis and had the cancer diagnosis on the telemedicine claim. We conducted an interrupted time series analysis to examine the impact of CMS expansion on telemedicine use. A multivariable logistic regression model was used to identify factors associated with telemedicine use during the post-expansion period. **Results:** Of 96,632 patients included, the average crude rate of telemedicine use was 0.12% before and 14.2% after the expansion in March 2020 (see Table). There was a significant impact of expansion on telemedicine use (21% increase; p<0.001). The peak rate (adjusted) was 28% in April 2020, decreasing and plateauing in July/August 2020, with rates staying in the range of 10-12% between August and December 2020. During the post-expansion period, lymphoma, prostate, and lung cancer patients (adjusted rates: 14.6%, 15.7%, and 15.9%, respectively) were more likely to use telemedicine compared to patients who had breast (12.7%) or colorectal (12.3%) cancer. Patients who were older (adjusted rates: ≥65 years, 13.8%; 50-64, 14.2%; 20-49, 18.6%), Black (12.4% vs 14.4% for White, 15.5% for Hispanic and 16.6% for Asian), resided in East South Central census division (8.4% vs 23.5% in New England) and had Medicare (12.2% vs 20.3% for commercial insurance) were less likely to use telemedicine (all p<.001). **Conclusions:** After the CMS telehealth expansion, the use of telemedicine among newly diagnosed cancer patients increased significantly. Telemedicine use varied by patient age, geographic location, race/ethnicity, and payer. Further research is needed to understand the pattern of telemedicine use. Research Sponsor: U.S. National Institutes of Health.

Unadjusted rates of telemedicine use before/after March 2020 expansion by cancer site.

Cancer site	Before % (N)	After % (N)
Breast	0.15 (18688)	13.3 (13627)
Prostate	0.11 (15916)	15.1 (11609)
Lung	0.08 (9543)	15.0 (6962)
Colorectal	0.13 (6879)	12.3 (5077)
Lymphoma	0.13 (4704)	15.7 (3627)
Overall	**0.12 (55730)**	**14.2 (40902)**

Telemedicine adoption and utilization among financially distressed patients with cancer during the COVID-19 pandemic: Insights from a longitudinal nationwide survey. *First Author: Abbas Hassan, University of Texas MD Anderson, Houston, TX*

Background: Telemedicine use during the COVID-19 pandemic among financially distressed patients with cancer, with respect to the determinants of adoption and patterns of utilization, has yet to be delineated. We sought to systematically characterize telemedicine utilization in financially distressed patients with cancer during the COVID-19 pandemic. **Methods:** We conducted an analysis of survey data assessing the use of telemedicine in patients with cancer during the COVID-19 pandemic collected by Patient Advocate Foundation (PAF) from May 2020 to December 2020. Primary study outcome was telemedicine utilization rate. Secondary outcomes were independent predictors of telemedicine utilization patterns, volume, and utilization preferences. Multivariate and poisson regression analyses were used to identify predictive factors. **Results:** Of the 1,390 respondents, 627 completed two survey waves and were included in this study. Telemedicine adoption during the pandemic was reported by 67% of patients, with most (63%) preferring video visits. Younger age (odds ratio, 6.07; 95% CI, 1.47-25.1), and higher comorbidities (odds ratio, 1.79; 95% CI, 1.13-2.65) were independent predictors associated with telemedicine adoption. Younger age (19-35 yrs.) (incidence rate ratios [IRR], 1.78; 95%CI, 24-115%) and higher comorbidities (≥3) (IRR; 1.36; 95%CI, 20-55%) were independent predictors associated with higher utilization volume. As area deprivation index increased by 10 units, the number of visits decreased by 3% (IRR 1.03, 95%CI, 1.03-1.05). **Conclusions:** The rapid adoption of telemedicine may exacerbate existing inequities, particularly among vulnerable financially under-resourced patients with cancer. Policy-level interventions are needed for the equitable and efficient provision of this service. Research Sponsor: None.

The role of telemedicine in care of patients with cancer: A real-world experience from a Peruvian cancer institute during the COVID-19 pandemic. *First Author: Katia Roque Perez, Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru*

Background: For patients with cancer, the COVID-19 pandemic has increased morbidity and mortality due to their bigger susceptibility to infection and to the discontinuity of treatment. In this context, telemedicine has become an invaluable tool for cancer care. The purpose of this study is to describe the impact of telemedicine in the care of cancer patients from a Latin American public institution. **Methods:** Retrospective, descriptive and cross-sectional study of cancer patients who received medical care through telemedicine from the Department of Medical Oncology of the Instituto Nacional de Enfermedades Neoplasicas (INEN) during the COVID-19 pandemic, from March 2020 to February 2021. Data collection was performed in real time by medical oncologists. Impact was mesuared with a comparison between the amount of cancer care during the COVID 19 pandemic vs the previous year. A modified version of the University of Kansas Cancer Center telephone satisfaction survey was conducted. Variables included the process of requesting an appointment by telemedicine, satisfaction with telemedicine service and distribution of drugs. **Results:** 16 456 telemedicine visits were carried out in one year time, 96.1% were conducted by telephone and only 3.9% used a video communication platform. 73% of patients were female and 62% were in the age group from 31 to 60 years old. 43% corresponded to solid tumors where breast cancer was the most frequent diagnosis. Patients in active treatment represented 70% (n = 11587), with 64% of patients being treated with curative intent and 36% within the palliative setting. Regarding the result of telemedicine visits, 62% (n = 10,281) had a medical prescription (40% corresponded to hormonal therapy; and 19%, to intravenous or subcutaneous systemic treatment). Overall, 8% (n = 56) of cases required an in-person visit. In the annual comparative analysis (against in-person visits during the previous year), the gap was 23% (60%, 20%, 8% and 13% during the first, second, third and fourth quarters, respectively). According to the type of medical care, telemedicine accounted for the 27.6% of the total medical care employed during in the year. The maximum level of usage was in May 2020 with 52% and in February 2021 with 48%, coinciding with the first and second waves of COVID in Peru. The satisfaction survey was applied to 5765 randomly chosen patients from July to October 2020. The mean scores for the 3 variables studied were: 4.6 / 5 points for the process of requesting an appointment, 4.58 / 5 points for telemedicine service and 4.33 / 5 points for the distribution of medicines and orders. **Conclusions:** Telemedicine is key to guarantee the continuity of care for cancer patients with an adequate level of satisfaction. If the Telemedicine service had not been implemented, the number of medical consultations would have dropped to 40% in comparison to the previous year. Research Sponsor: None.

Improving care coordination for adolescents and young adults with cancer. *First Author: Emily Ruth Haines, Wake Forest School of Medicine, Winston-Salem, NC*

Background: In the US, many of the 90,000 adolescents and young adults (AYAs) (i.e., individuals ages 15-39) diagnosed with cancer each year do not receive services to address the range of needs they experience during cancer treatment. AYAs' unmet needs are associated with higher distress, poorer health-related quality of life, and higher physical symptom burden. However, AYAs often do not use services available to them through their cancer programs, even when they face no access issues (e.g., cost, insurance status, local service capacity). AYAs report barriers to service use including lack of awareness, challenges navigating large volumes of information and complex health systems, and hesitance to broach needs with providers without prompting. To facilitate a systematic and patient-centered approach to addressing AYAs' unmet needs, we leveraged user-centered design to develop the AYA Needs Assessment & Service Bridge (NA-SB). NA-SB includes a patient-reported outcome measure assessing AYAs' physical, psychosocial, and practical needs, and a collection of referral pathways for connecting AYAs to services based on the needs they report. In this feasibility pilot study, we are evaluating the implementation of NA-SB in the University of North Carolina Lineberger Comprehensive Cancer Center (UNC) AYA Cancer Program. **Methods:** Eligible participants include AYAs ages 18-39 currently undergoing cancer treatment at UNC (n = 25-50). The needs assessment portion of NA-SB is administered electronically through REDCap during routine clinical encounters with the AYA team. After an AYA completes the needs assessment, an AYA provider (i.e., social worker/nurse practitioner) reviews their responses and initiates referral pathways. Six weeks following their completion of the needs assessment, AYAs complete a survey assessing their perceptions of (1) the usability of the NA-SB needs assessment, (2) the feasibility, acceptability, and appropriateness of implementing NA-SB, and (3) the extent to which their needs have been met. We are also assessing participating providers' perceptions of NA-SB's implementation through periodic check-in calls. Results: We will report descriptive statistics on participant demographics, needs reported, and quantitative outcomes. We will analyze data from provider check-in calls inductively to further elaborate on implementation experiences and determinants. Conclusion: By harnessing patient-reported data to facilitate care coordination for AYAs, NA-SB has the potential to improve processes of care and subsequent outcomes for AYAs, an underserved and understudied population. This pilot study represents a critical first step towards translating NA-SB into routine cancer care for AYAs. Clinical trial information: NCT04586127. Research Sponsor: U.S. National Institutes of Health.

TPS1599 **Poster Session**

Evaluating the feasibility of using an electronic patient-reported outcome (ePRO) smartphone application (app) and biosensor by patients with cancer undergoing systemic treatments. *First Author: Karma L. Kreizenbeck, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Almost half of the nearly 370,000 patients with cancer who receive chemotherapy in the United States each year experience Emergency Department (ED) visits and unplanned hospital inpatient (IP) stays during treatment, largely due to poorly controlled symptoms. Recent studies have shown that utilizing PRO information in oncology practice can improve symptom management and patient outcomes. This study aims to examine the feasibility and usability of a PRO app paired with a biosensor to identify patients who are at high risk for ED and IP visits. **Methods:** This prospective, pragmatic, observational study will evaluate the feasibility and usability of a clinic-provided smartphone app and smartwatch biosensor for monitoring patients undergoing systemic cancer treatment. Eligible patients are 18–80 years old, ECOG PS 0–2, have a biopsy-proven solid tumor diagnosis of cancer (excluding non-melanoma skin cancer), and are scheduled to receive the first dose of intravenous (IV) or oral cancer therapy as an initial or new line of treatment. Patients should be able to provide informed consent, wear the biosensor daily, and complete the app ePRO survey and questionnaires in English. Study exclusion criteria include receiving radiation or hormone therapy only, residing in a skilled nursing facility, participating in another clinical trial, current pregnancy, and wearing pacemakers, implantable cardioverter defibrillators, cochlear implants, and/or neurostimulator devices. The app collects PROs (PRO-CTCAE), app usability and satisfaction (modified mHealth App Usability Questionnaire [mMAUQ]) and patient satisfaction with the biosensor (modified Quebec User Evaluation of Satisfaction with Assistive Technology [QUEST 2.0]). The study is divided into two phases: (1) vanguard (N = 30); (2) operational (N = 70). Patients will be asked to wear the biosensor and enter PROs into the app daily for a 2-week (vanguard) or 6-week period (operational). The vanguard sample size allows for the recruitment of ~10 patients at each of the three participating oncology community clinics as is standard for initial device and software testing and development. Study endpoints for feasibility include: (1) vanguard – patient recruitment and protocol adherence, completeness of data capture, app usability, user satisfaction of biosensor; (2) operational – validity of self-reported hospital visits, feasibility of using electronic case report forms. Data collected from the vanguard will inform modifications to the app for the operational phase. The operational phase sample size is sufficient to assess data capture completion and clinical trial recruitment procedures in diverse practice settings (e.g., low volume vs. high volume, rural vs. urban). Clinical trial information: ISRCTN25569053. Research Sponsor: Genentech, Inc.

TPS1600 **Poster Session**

Natural history study for children and adults with rare solid tumors. *First Author: Diana Grace Varghese, National Institutes of Health, Bethesda, MD*

Background: Rare cancers is defined as fewer than 15 cases per 100,000 people per year and account for 27% cancers diagnosed and lead to 25% of cancer-related deaths. Nearly 13% (1 in 8) of all cancers diagnosed in adults ages 20 and older are rare. All pediatric cancers are rare and approximately 12,600 children under the age of 20 years are diagnosed with cancer each year. Rarity of these diseases has caused a stagnation in understanding the tumor biology and developing newer therapies. Initiatives like Orphan Drug Act (1983) and Rare Disease Act (2002) has led to improvement in funding and research about these rare tumors. The Cancer Moonshot Research Initiative funded My Pediatric and Adult Rare Tumor (MyPART) network (cancer.gov/mypart) in the NCI Pediatric Oncology Branch and launched a longitudinal Natural History Study for Children and Adults with Rare Solid Tumors (NCT03739827). **Methods:** A prospective study to evaluate the natural history of rare pediatric and adult solid tumors comprehensively and longitudinally. Patients of any age with a rare solid tumor (<15 cases per 100,000 people per year) are eligible. Patients with germline mutation who are at risk of developing these tumors or relatives of participants are also eligible. Patients can participate from home or are are invited to NIH for annual evaluations. Participants complete individual medical history, family history, patient related-outcomes measurements (PROs) and provide samples (blood, saliva) for DNA analysis. Tumors are analyzed using a 500+ gene panel (TruSight500, Illumina Panel) and undergo a comprehensive genomic and epigenomic analysis. Participants invited to NIH undergo a clinical evaluation, genetic counseling, blood collection (standard clinical labs, germline DNA/RNA, immune phenotypes, cytokines, exosomes), and imaging studies, as indicated. The goals of this study are to 1) Estimate and define the clinical spectrum of rare cancers 2) Evaluate and follow biological relatives of patients with rare tumors or carriers of germline genetic variants that predispose to development of rare tumors 3) Develop a better understanding of these diseases in an effort to develop a) Novel therapeutic interventions, b) Preventive/screening guidelines, c) Endpoints for future clinical trials, and d) Relevant patient reported outcomes that can improve our understanding of patients psychosocial and functional needs. Subprotocols under this protocol for children and adults include adrenocortical cancer (NCT04447014), neuroendocrine neoplasms (NCT04488263) and Chordoma (NCT0391046) to gather tumor specific data. Study accrual is ongoing. Clinical trial information: NCT03739827. Research Sponsor: U.S. National Institutes of Health.

TPS1601 **Poster Session**

Addressing Latinx CANcer Care Equity (ALCANCE) randomized controlled trial: Precision medicine and community health workers. *First Author: Gladys M. Rodriguez, Division of Oncology, Stanford University School of Medicine, Stanford, CA*

Background: Cancer mortality has declined over the past decade due to clinical advances including precision medicine. Despite these clinical advancements, low-income and racial/ethnic minorities experience worse cancer morbidity and mortality. Specifically, these populations have lower rates of genomic testing and are significantly underrepresented in precision medicine research. Community-based, culturally tailored approaches are needed to address these ongoing disparities. The objective of this randomized controlled trial is to test whether a community health worker (CHW)-led intervention can improve patient understanding of precision medicine topics and delivery of evidence-based cancer care more than usual cancer care alone. **Methods:** We developed a county-wide cancer care initiative and a community advisory board (CAB) comprised of patient, caregiver, payer, clinician, and governmental stakeholders in Monterey County—comprised of 60% Latinx, non-English speaking, immigrant populations. As guided by the CAB, we developed a CHW-model to provide education on precision medicine and screen for complications of social determinants of health in 1:1 discussions with patients. In collaboration with a local community oncology clinic, we plan to randomize 110 patients with cancer who are receiving active treatment into usual care or usual care plus the CHW-led intervention. Inclusion criteria includes patients who are: 1) 18 years of age or older; 2) racial/ethnic minorities; 3) low-income; 4) uninsured or insured by Medicaid and/or local agricultural employers; and 5) speak English or Spanish. Exclusion criteria includes: 1) lack capacity to consent to study procedures; 2) plan to move from the area within a year. We will measure the effect of the intervention on patient knowledge of precision medicine using a survey adapted from Davies et al. Secondary outcomes include effect on health-related quality of life using the Functional Assessment of Cancer Therapy – General, patient activation using the Patient Activation Measure, satisfaction using the Satisfaction with Decision Scale, prognosis and treatment preferences using an adapted survey by Weeks et al., healthcare utilization, and receipt of evidence-based cancer care. We will administer surveys at baseline, 3-, 6- and 12-months post-enrollment. To date, 67 participants have been enrolled. This study will show if CHW-models increase knowledge of precision medicine in this population. Clinical trial information: NCT04843332. Research Sponsor: California Initiative to Advance Precision Medicine through grant #OPR18113, This work is also supported, in part, by the Lung Cancer Research Foundation.

TPS1602 **Poster Session**

Screening for high frequency malignant disease (SHIELD). *First Author: H.A. Nguyen, Guardant Health, Inc., Redwood City, CA*

Background: Implementation of asymptomatic cancer screening has yielded positive impacts on global cancer mortality rates. However, significant screening adherence gaps exist. A blood-based multi-cancer screening test with clinically significant performance in cancers where early detection and intervention can save lives, can address adherence gaps, especially by reducing access barriers inherent to current screening options. Effective evaluation of such a test in screen relevant populations requires studies designed to enroll individuals across multiple cancer types, taking into account prevalence rates for the cancers being evaluated, allowing for overlapping screen-eligible populations, and ensuring representation of individuals from diverse ethnicities and geographies. **Methods:** SHIELD (Screening for High Frequency Malignant Disease; NCT# 05117840) is a prospective, observational, multi-center basket study ongoing in the United States and Europe uniquely designed to recruit individuals across multiple cancer types. The study's primary objective is to evaluate the performance of a blood-based multi-cancer screening test (GuardantLUNAR-2, Guardant Health, USA) to detect cancer in screen-relevant individuals as compared to the reference standard cancer screening modality. The study will recruit eligible individuals into multiple separate cohorts with specified pathways for cancer screening. Within each cohort, eligible individuals consent to whole blood collection within 90-days of the standard of care screening method. Clinical diagnoses, including the diagnosis of cancer, are made per standard of care. Primary outcomes are sensitivity, specificity, negative predictive value, and positive predictive value of the test as compared to the standard of care screening modality. Secondary outcome is the number of screen-detected cancers, early- (stage I/II) and late-stage (stage III/IV), per 1000 screened individuals. Follow-up continues for 24 months with outcomes collected at one and two-years to investigate the possibility of incidental non-screen relevant cancer cases and interval screen-relevant cancer cases that had not reached clinical threshold for detection at initial screening. Additional cancer specific follow-up is designed per cohort. The first cohort to enroll screen-eligible individuals, cohort A, is focused on those who meet guideline criteria for lung cancer screening with low dose CT. Additional cancer-risk cohorts will begin enrolling as the study expands and are designated cohort B, C, etc. Cohort A: Eligibility criteria are aligned with lung cancer screening guidelines – age 50-80 years with > 20 pack-year smoking history who are current smokers or have quit < 15 years prior, without a cancer history, preinvasive lung lesions, or current treatment for pneumonia. Cohort A enrollment, targeting 9,000 subjects over 24 months at up to 120 global sites, began in January 2022. Clinical trial information: NCT05117840. Research Sponsor: Guardant Health.

TPS1603 **Poster Session**

Telehealth weight loss program for breast cancer survivors is feasible and acceptable: Preliminary results of pilot clinical trial. *First Author: Julia C. Tchou, University of Pennsylvania Health System, Philadelphia, PA*

Background: Current weight loss programs for breast cancer survivors utilize a hybrid of in-person visits or individualized telephone-based sessions modeled after the Diabetes Prevention Program. Telehealth may be an effective and efficient means of communicating with patients who otherwise cannot participate in in-person visits. To test this concept, we conducted a pilot single-arm study (NCT04855552) to examine the feasibility and acceptability of a weight loss group program via telehealth for breast cancer survivors. **Methods:** Patients > = 18 years with ECOG performance 0 or 1, a BMI of ^{3} 25 kg/m^{2}, and completion of adjuvant radio- and/or chemo-therapy > 6 months were eligible. Patients attended weekly zoom teleconference counseling grouped sessions either at noon or 5 pm led by a licensed clinical psychologist for 20 weeks followed by sessions in weeks 22 and 24. Patients were encouraged to use MyFitnessPal.com, an online tool, to monitor calorie intake and physical activity and digital scales to monitor weight to share with study staff to enhance accountability and provide opportunity for feedback. Feasibility was defined as a ratio of enrolled/eligible patients ≥50%. Acceptability was assessed from surveys pre- and post-treatment, and qualitatively from exit interviews. Secondary endpoints included changes in Quality of Life-Breast Cancer Patient (QOF-BC), Patient Health Questionnaire (PHQ-9), and percent weight loss from baseline to 24 weeks. **Results:** Clinical characteristics of patients are summarized in Table. The ratio of enrolled (n = 12)/eligible (n = 23) participants was 52% thus confirming study feasibility. One patient dropped out after 2 sessions. Qualitative results from exit interviews showed that 7/9 patients rated the telehealth format as "extremely acceptable". Surveys also indicated that the format and delivery of the program remained acceptable across most domains with no significant changes, except an increase in "approval" from 4.1 to 4.7 (p= 0.05). Patients' mood improved on the PHQ-9 from 4.2 to 1.2 (p = 0.03), and QOL-Physical Wellbeing improved from 56.9 to 66.3 (p = 0.004). Overall, 199 of 236 participant-sessions (84%) were attended. Percent weight loss was 6.5% +/- 2.5%. **Conclusion:** This proof-of-concept weight loss program was feasible and acceptable for our patients yielding improvements in QOL, mood, and a clinically significant weight loss over 6-months. This group-based video approach represents an intervention strategy that could be widely-disseminated and may provide stronger accountability/support than a one-on-one approach in some patients. Future work is aimed at refining strategies to increase patient enrollment/retention. Clinical trial information: NCT04855552. Research Sponsor: intramural institutional funds.

Participants (n = 12)	N or Average (SD)
Age	60 (14)
Race	
White	11
Black	1
Home distance from hospital (miles)	39 (42)
Pre-trial weight (lbs)	192 (40)
Post-trial weight (lbs)	170 (23)

2000 **Oral Abstract Session**

Phase II randomized study comparing proton craniospinal irradiation with photon involved-field radiotherapy for patients with solid tumor leptomeningeal metastasis. *First Author: Jonathan T. Yang, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Leptomeningeal metastasis (LM) is associated with limited survival and treatments. Photon involved-field radiotherapy (IFRT) is the standard of care radiotherapy (RT) but benefits are limited. We hypothesized that proton craniospinal irradiation (pCSI) encompassing the central nervous system (CNS) compartment would result in superior CNS disease control compared to IFRT. **Methods:** We conducted a randomized phase 2 study comparing pCSI vs. IFRT in patients with non-small cell lung cancer (NSCLC) or breast cancer LM. Eligibility criteria included radiographic and/or cytologic LM and Karnofsky performance status (KPS) ≥ 60. Patients were stratified by histology (breast vs. NSCLC) and systemic disease (active vs. stable) and were randomized in a 2:1 ratio of pCSI:IFRT. Patients with all other solid tumor histologies were enrolled to an exploratory pCSI arm. RT was 3Gy x 10 fractions for all patients. The primary endpoint is CNS progression-free survival (CNS PFS), defined as time from randomization to CNS progression (POD); secondary endpoints include overall survival (OS) and treatment-related adverse events (TAEs). A target of 81 patients to compare pCSI and IFRT was designed with a one-sided alpha of 0.025 and a power of 0.8 based on stratified log-rank test. Analysis is based on intent-to-treat. **Results:** From 4/2020-10/2021, 42 and 21 patients were randomized to pCSI and IFRT, respectively. Baseline factors were not different: median age was 56 vs. 61 years (p = 0.5); both cohorts included 57% NSCLC and 52% with active systemic disease. At median follow up of 7.1 months, 25 patients had CNS POD (pCSI = 9 [21%], IFRT = 16 [76%]) and 28 died (pCSI = 15 [36%], IFRT = 13 [62%]). At planned interim analysis, significant benefit in CNS PFS was observed with pCSI (median = 7.5 months, 95% CI: 6.6-NA) vs. IFRT (median = 2.0, 95% CI: 1.0-5.1, p < 0.001). As a result, the Data and Safety Monitoring Committee recommended early discontinuation of the trial. In addition, OS benefit with pCSI (median = 8.2 months, 95% CI: 7.4-NA) vs. IFRT (median = 4.9 months, 95% CI: 3.1-NA, p = 0.04) was observed. In a multivariable analysis including age, KPS and stratification factors, CNS PFS and OS benefit for pCSI remained significant. Grade 3 non-heme TAEs occurred in 3 patients with pCSI and 5 with IFRT. For the exploratory pCSI cohort, 35 patients enrolled, the median age was 61, 20 (57%) had active systemic disease and ovarian (7 [20%]) was the most common histology. At median follow up of 9.6 months, 7 (20%) had CNS POD and 20 (57%) died. Median CNS PFS was 5.4 months (95% CI: 4.8-9.1), OS was 6.6 months (95% CI: 5.4-12.1) and 4 patients had Grade 3 TAEs. **Conclusions:** In this trial, the first randomized study of RT for LM, we demonstrated improved CNS PFS of pCSI compared to IFRT, meeting the primary endpoint. pCSI also had a significant OS benefit. Grade 3 toxicities were comparable. Clinical trial information: NCT04343573. Research Sponsor: None.

2001 **Oral Abstract Session**

Randomized phase II/III trial of veliparib or placebo in combination with adjuvant temozolomide in newly diagnosed glioblastoma (GBM) patients with MGMT promoter hypermethylation (Alliance A071102). *First Author: Jann Nagina Sarkaria, Mayo Clinic, Rochester, MN*

Background: PolyADP-ribose polymerase (PARP) is an important modulator of DNA repair following temozolomide (TMZ) therapy. Pre-clinical testing demonstrated significant survival benefit for the combination of TMZ and PARP inhibitor veliparib in a subset of GBM pt-derived xenografts with MGMT promoter hypermethylation. **Methods:** After central pathology review and MGMT testing, patients (pts) with newly diagnosed, MGMT promoter hypermethylated GBM who had completed concurrent radiation and TMZ were randomized to adjuvant therapy with TMZ (Days 1-5 q28 days) combined with either placebo or veliparib (Days 1-7 q28 days). Veliparib/placebo+TMZ treatment was continued for up to 6 cycles. Pts accrued on the phase II and III portions of the trial were included in the primary endpoint analysis of overall survival (OS), with 90% power to detect a hazard ratio of 0.71 using a one-sided log-rank test with type I error rate of 0.05. The planned phase III sample size was 400 pts with data maturity after 302 deaths. **Results:** The phase II and III portions of the trial were open to accrual from 12/15/2014 to 2/6/2017 and 11/8/2017 to 10/15/2018, respectively; 447 pts were accrued to the trial and used in this intention to treat analysis. The two treatment groups were well balanced for prognostic factors, 421 pts initiated treatment, median follow-up was 57.8 months (mos), 380 pts had disease progression and 335 pts have died. There was no difference in OS (p = 0.15; HR 0.89 (0.71-1.11), median OS 28.1 vs. 24.8 mo. for TMZ+veliparib vs. TMZ+placebo, respectively) and no difference in secondary endpoint progression free survival (PFS, p = 0.31; HR 1.05 (0.86-1.30), median 13.2 vs. 12.1 mo, respectively). There was a notable trend for extended OS with TMZ+veliparib treatment at intermediate time-points between 24 and 42 mos (3-year OS 36.6% vs. 28.9% with TMZ+placebo, p = 0.09). In an unplanned exploratory analysis, treatment with TMZ at the time of first recurrence was associated with extended post-recurrence OS (p = 0.03) for pts treated on the experimental arm; median post-recurrence OS with TMZ salvage was 17.0 mo in the TMZ+veliparib arm and 12.6 mo in the TMZ+placebo arm, as compared to 9.6 mo in either arm if TMZ salvage was not used. These data are consistent with a possible effect of veliparib limiting the emergence of TMZ resistance in a subset of GBM pts. **Conclusions:** Veliparib combined with adjuvant TMZ therapy was not associated with significant extension in OS or PFS in newly diagnosed, MGMT hypermethylated GBM pts. However, a subset of pts treated with TMZ+veliparib may have an extended survival following re-treatment with TMZ at first recurrence. Clinical trial information: NCT02152982. Research Sponsor: U.S. National Institutes of Health, Alliance Industry Partners.

LBA2002 **Oral Abstract Session**

Primary analysis of a phase II trial of dabrafenib plus trametinib (dab + tram) in *BRAF* V600–mutant pediatric low-grade glioma (pLGG). *First Author: Eric Bouffet, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

2003 **Oral Abstract Session**

Prognostic validation and refinement of a classification system for extent of resection in glioblastoma: A report of the RANO *resect* group. *First Author: Philipp Karschnia, Department of Neurosurgery, Ludwig-Maximilians-University, Munich, Germany*

Background: Terminology to describe extent of resection in glioblastoma is inconsistent across clinical trials. A surgical classification system for glioblastoma was previously proposed based upon the absolute residual contrast-enhancing (CE) tumor (in cm^3) and the relative reduction of CE tumor (in percentage) on postoperative MRI. Class 0 was defined as 'supramaximal CE resection' (also including removal of non-CE tumor), class 1 as 'maximal CE resection', class 2 as 'submaximal CE resection', and class 3 as 'biopsy'. We aimed to (I) explore the prognostic utility of the proposed classification system and (II) define how much non-CE tumor needs to be removed to translate into a survival benefit. **Methods**: An international Response Assessment in Neuro-Oncology (RANO) group was formed, entitled RANO *resect*. The members of the RANO *resect* group retrospectively searched the databases from seven neuro-oncological centers in the USA and Europe for patients with newly diagnosed glioblastoma. Clinical characteristics, volumetric information from pre- and postoperative MRI, and outcome were collected. Kaplan-Meier survival analysis and log-rank test were applied to calculate survival, and Cox's proportional hazard regression model to adjust for multiple variables. Significance level was set at $p \leq 0.05$. **Results**: We encountered 1021 patients with newly diagnosed glioblastoma, including 1008 IDHwt patients. 744 IDHwt patients were treated with radiochemotherapy per EORTC 26981/22981 following surgery. Among such homogenously treated patients, higher extent of resection was favorably associated with outcome: patients with 'maximal CE resection' (class 1) had superior outcome compared to patients with 'submaximal CE resection' (class 2) or 'biopsy' (class 3) (median OS: 20 versus 16 versus 10 months; $p = 0.001$). Similar findings were made when assessing progression (median PFS: 9 versus 8 versus 5 months; $p = 0.001$). Extensive resection of non-CE tumor (≥60% of non-CE tumor removed and ≤5 cm^3 residual non-CE tumor) provided an additional survival benefit in patients with complete CE resection (class 1), thus defining class 0 ('supramaximal CE resection') (median OS: 29 versus 20 months; $p = 0.003$). Smaller pre-operative tumor volumes were associated with larger extent of resection. The favorable prognostic effect of CE resection was conserved in a multivariate analysis when stratifying for molecular and clinical markers including pre-operative tumor volume and MGMT promotor status ($p = 0.001$). **Conclusions**: The proposed classification system for extent of surgery in glioblastoma is highly prognostic and may serve for stratification and design of clinical trials. Removal of non-CE tumor beyond the CE tumor borders translates into additional survival benefit in glioblastomas, providing a rationale to explicitly denominate such a 'supramaximal CE resection.' Intramuscular (IM) INO-5401 + INO-9012 with electroporation (EP) in combination with cemiplimab (REGN2810) in newly diagnosed glioblastoma. *First Author: David A. Reardon, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: Novel T cell-enabling therapies plus checkpoint inhibition may improve OS in GBM. INO-5401 (synthetic DNA plasmid encoding hTERT, WT-1, PSMA) plus INO-9012 (synthetic DNA plasmid encoding IL-12), with cemiplimab (PD-1 inhibitor), was given to patients with newly diagnosed GBM with MRD to evaluate tolerability, efficacy, and immunogenicity. Median OS and immunogenicity at 18 months (OS18) are reported. **Methods**: This is a phase I/II, single arm, two cohort (A: unmethylated MGMT and B: methylated MGMT) study. Primary endpoint is safety; efficacy and immunogenicity are secondary. Nine mg INO-5401 plus 1 mg INO-9012 (4 doses Q3W, then Q9W) was given IM with EP in combination with cemiplimab (350 mg IV Q3W). Hypofractionated RT (40 Gy over 3 weeks) with TMZ was given to all patients, followed by maintenance (Cohort B only), which was a novel therapeutic approach. Immunogenicity was assessed by quantifying INO-5401-specific peripheral cellular immune responses via IFN-g ELISpot and flow cytometry. Intra-tumoral gene expression was analyzed by RNA-Seq of FFPE GBM tissue. Differences in gene expression were analyzed using the Wilcoxon rank sum test. **Results**: Fifty-two subjects were enrolled: 32 in Cohort A; 20 in Cohort B (35% women; median age 60 years [range 19-78 years]). The adverse event profile was consistent with known single-agent (INO-5401, INO-9012, EP or cemiplimab) events; most events were ≤Grade 2 and no related events were Grade ≥4. Median OS durations in Cohorts A and B were 17.9 months (95% CI 14.5-19.8) and 32.5 months (95% CI 18.4-not reached), respectively. Flow cytometry revealed activated, antigen specific CD4+CD69+PD1+ and CD8+CD69+PD1+ T cells, the latter with lytic potential as defined by presence of perforin and granzyme A. Both subsets exhibited HR < 1.0 and $p < 0.05$ when accounting for a 0.1% T cell frequency change, translating to a 23% and 28% reduced risk of death, respectively. Gene expression levels in pre-treatment tissues were similar between alive and deceased groups for INO-5401 antigens and immune cell markers; however, the alive group displayed significantly reduced expression of genes associated with anti-apoptosis, pro-proliferation, and immune response suppression. Post-treatment tumor tissue displayed altered gene expression for immune-related markers versus pre-treatment tissue, including markers of T cell infiltration, activation, and lytic potential. **Conclusions**: INO-5401 + INO-9012 has an acceptable risk/benefit profile and elicits robust immune responses that correlate with enhanced survival when administered with cemiplimab and RT/TMZ to newly diagnosed GBM patients. Pre-treatment gene expression signatures in MGMT-unmethylated patients were statistically associated with OS18. Overall, INO-5401 elicits antigen-specific T cells that can infiltrate GBM tumors. Clinical trial information: NCT03491683. Research Sponsor: Inovio.

2005 **Oral Abstract Session**

Reproducibility of outcomes in sequential trials using CMV-targeted dendritic cell vaccination for glioblastoma. *First Author: John H. Sampson, Duke University Medical Center, Durham, NC*

Background: Vaccination with dendritic cells (DCs) fares poorly in primary and recurrent glioblastoma (GBM). Moreover, GBM vaccine trials are often underpowered due to limited sample size. **Methods:** To address these limitations, we conducted three sequential clinical trials utilizing Cytomegalovirus (CMV)-specific DC vaccines in patients with newly diagnosed GBM eligible to receive standard of care resection and adjuvant radiation therapy and temozolomide chemotherapy. Autologous DCs were generated and electroporated with mRNA encoding for the CMV protein pp65. Serial vaccination was given throughout adjuvant temozolomide cycles, and ^{111}Indium radiolabeling was implemented to assess migration efficiency of DC vaccines. Patients were followed for median overall survival (mOS) and OS. **Results:** Our initial study was the phase II ATTAC study (NCT00639639; total n = 12) with 6 patients randomized to vaccine site preconditioning with tetanus-diphtheria (Td) toxoid. This led to an expanded cohort trial (ATTAC-GM; NCT00639639) of 11 patients receiving CMV DC vaccines containing granulocyte-macrophage colony-stimulating factor (GM-CSF). Follow-up data from ATTAC and ATTAC-GM revealed 5-year OS rates of 33.3% (mOS 38.3 months; CI_{95} 17.5-undefined) and 36.4% (mOS 37.7 months; CI_{95} 18.2-109.1), respectively. ATTAC additionally revealed a significant increase in DC migration to draining lymph nodes following Td preconditioning (*P = 0.049*). Increased DC migration was associated with OS (Cox proportional hazards model, HR = 0.820, *P = 0.023*). Td-mediated increased migration has been recapitulated in our larger confirmatory trial ELEVATE (NCT02366728) of 43 patients randomized to preconditioning (Wilcoxon rank sum, Td n = 24, unpulsed DC n = 19; 24h, *P = 0.031* and 48h, *P = 0.0195*). In ELEVATE, median follow-up of 42.2 months revealed significantly longer OS in patients randomized to Td (*P = 0.026*). The 3-year OS for Td-treated patients in ELEVATE was 34% (CI_{95} 19-63%) compared to 6% given unpulsed DCs (CI_{95} 1-42%). **Conclusions:** We report reproducibility of our findings across three sequential clinical trials using CMV pp65 DCs. Despite their small numbers, these successive trials demonstrate consistent survival outcomes, thus supporting the efficacy of CMV DC vaccine therapy in GBM. Clinical trial information: NCT00639639, NCT02366728. Research Sponsor: U.S. National Institutes of Health.

2006 **Oral Abstract Session**

Baseline tumor genomic and gut microbiota association with clinical outcomes in newly diagnosed glioblastoma (GBM) treated with atezolizumab in combination with temozolomide (TMZ) and radiation. *First Author: Shiao-Pei S. Weathers, The University of Texas MD Anderson Cancer Center, Department of Neuro-Oncology, Houston, TX*

Background: Checkpoint inhibitor (CPI) therapy has demonstrated overall limited efficacy in the treatment of GBM. Sixty newly diagnosed GBM patients unselected for MGMT status underwent treatment with concurrent atezolizumab with radiation therapy and TMZ followed by adjuvant atezolizumab and TMZ (NCT03174197). Clinical data has been reported previously. **Methods:** Genomic (WES with somatic mutation and SCNA determination N = total 42 samples, 33 baseline, 9 TP-2), transcriptomic (RNA seq N = total 72 samples, 54 baseline, 18 TP-2), and metagenomic sequencing of fecal samples (N = total 45 samples, 26 pre samples, 13 post RT samples, six 6m samples) analyses were conducted on pre-treatment samples. Findings were correlated with clinical outcome including OS and PFS. Twenty of the 60 patients underwent re-resection for suspected recurrent disease of which nine patients had WES and RNA seq performed successfully on paired pre and post treatment samples. **Results:** Somatic mutation, copy number and ploidy profiles were consistent with known aberrations in GBM. An unsupervised molecular network-based stratification of pre-treatment tumor mutations resulted in patients being grouped in 3 clusters with survival difference. Patients with GBM harboring an *EGFR* aberrancy were associated with a relatively worse mOS following treatment compared to patients with tumors enriched with *PTEN* alterations, while patients with *IDH1* mutations had the longest mOS. Gene set enrichment analysis of gene expression in tumors from patients (< mOS vs ≥mOS) identified genes associated with lymphocyte activation and immune response in patients with longer survival ($p < 0.01$) Unsupervised hierarchical clustering of bacterial taxa demonstrated two distinct clusters with significant difference by OS. Survival analysis and Analysis of Compositions of Microbiomes with Bias Correction (ANCOM-BC) revealed distinct taxa associated with OS (*Ruminococcus* spp.) and response to treatment (*Eubacterium* spp.), respectively. **Conclusions:** In this small CPI-treated GBM cohort, WES, SCNA and RNA seq identified pre-treatment tumor features that separated patients by survival. The fecal microbiome observations in our GBM cohort warrants further investigation. Clinical trial information: NCT03174197. Research Sponsor: Genentech.

2007 **Oral Abstract Session**

A targeted gene expression biomarker and association with meningioma outcomes and radiotherapy. *First Author: William Cheng Chen, UCSF Department of Radiation Oncology, San Francisco, CA*

Background: Improvements in risk stratification of meningioma are needed to guide post-operative management and application of adjuvant therapy. Although profiling of DNA methylation, copy number variants (CNVs), RNA sequencing, and exome sequencing have better elucidated meningioma biology, these approaches have not revealed clinically tractable biomarkers for radiotherapy responses. In this study, we develop and validate a targeted gene expression biomarker to predict meningioma outcomes and benefit from radiotherapy. **Methods:** Targeted gene expression profiling was performed on a development set of 173 meningiomas (median follow-up 8.1 years) and a validation set of 331 consecutive meningiomas (median follow-up 6.1 years) treated at independent institutions (70% WHO grade 1, 24% WHO grade 2, 6% WHO grade 3). All patients underwent surgery (n = 504) with or without postoperative radiotherapy (n = 73 with radiation). Regularized Cox regression within the development set resulted in a continuous gene expression risk score for local freedom from recurrence (LFFR). The model (34 genes and 7 housekeeping genes) and thresholds for low, intermediate, and high-risk scores were locked and applied to the validation set. **Results:** The gene expression risk score outperformed WHO grade (validation 5-year LFFR delta-AUC 0.15, 95% CI 0.076-0.229, p = 0.001) and DNA methylation grouping (delta-AUC 0.075, 95% CI 0.006-0.130, p = 0.01) for LFFR, disease-specific survival, and OS, achieving a negative predictive value for recurrence at 5-years of 93.2%. The biomarker reclassified 35.8% of WHO grade 1 tumors as intermediate or high risk (5-year LFFR/OS 62%/79%), and 18.3% of WHO grade 2-3 tumors as low risk (5-year LFFR/OS 78%/100%). The biomarker was independently prognostic after accounting for WHO grade, extent of resection, primary versus recurrent presentation, CNV status, DNA methylation group, and Ki67 labeling index, and was predictive for LFFR after postoperative radiotherapy, with a hazard ratio of 0.41 for intermediate to high risk propensity-matched meningiomas (95% CI 0.2-0.9, p = 0.0002) versus 0.79 for low risk meningiomas (95% CI 0.1-8.8, p = 0.5182). **Conclusions:** Targeted gene expression profiling of 504 meningiomas resulted in a biomarker which improved discrimination of meningioma local recurrence, disease-specific survival, and overall survival, and also predicted benefit from radiotherapy. Research Sponsor: UCSF.

2008 **Oral Abstract Session**

Genomic analysis and clinical correlations of non-small cell lung cancer (NSCLC) brain metastasis (BM). *First Author: Anna Skakodub, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Approximately 30% of patients with NSCLC present with BM, and up to 50% of patients ultimately develop BM. While modern NSCLC-directed agents yield excellent systemic response, most patients require focal treatment. Prior reports of BM genomics have been limited by low numbers, missing clinical data, and lack of matched specimens. Here, we report the largest cohort to date of molecularly profiled NSCLC BM samples with clinical correlates. **Methods:** Clinical data and outcomes for 244 patients with NSCLC and resected BM were identified, and BM samples were assessed with one of four versions (341, 410, 468, 505) of MSK-IMPACT, a custom FDA-approved next generation sequencing-based tumor sequencing assay. 51 (20.9%) patients had matched primary site tissue, and 44 (18%) patients had matched tissue from another metastatic site or CSF. Genomic alterations were filtered for driver variants using OncoKB. **Results:** Median age was 66 years (range 31-91), and median follow-up was 2.3 years (IQR 1.3-4.3). Adenocarcinoma was the most common histology (183, 78%). Half presented with a single BM, and 121 (51%) patients were treatment naive. Most (197, 83%) received adjuvant stereotactic radiosurgery (SRS) to the resection site and 28% received SRS to additional BM. After resection, 130 (55.1%) had CNS progression, often regional (54, 42%). SRS to new BMs (32%) was the most common salvage treatment. Median overall survival from BM diagnosis was 2.5 years (95%CI 2.1-3.2). Median CNS-progression-free survival was 1.2 years (95%CI 0.9-1.4). The most frequently altered genes in BM samples were *TP53* (72%), *CDKN2A* (34%), *KRAS* (31%), *KEAP1* (26%), and *EGFR* (21%). *CDKN2A* was more frequently altered in BM samples when compared to NSCLC primary samples (34% vs 14%, p = 0.003, q = 0.034). With regard to overrepresented gene sets, cell cycle pathway alterations were enriched in BM (56% vs 31%, p = 0.002, q = 0.022). BM samples had a significantly higher fraction of genome altered relative to the primary samples ($p < 0.0001$, $q < 0.0001$). After grouping patients based on type of CNS progression, we found that *EGFR* alterations were enriched in patients with leptomeningeal failures when compared to both patients without progression (42% vs 18%, p = 0.03, q = 0.93) and to patients with either local or regional progression (42% vs 19%, p = 0.03, q = 0.9). **Conclusions:** In the largest-ever assembled cohort of genomically-profiled NSCLC BM, we found significant enrichment for *CDKN2A* and cell cycle pathway alterations in BM compared to extracranial disease, as well as a higher fraction of genome altered, in BMs compared to matched primary tumor controls. We also observed *EGFR* alteration enrichment in patients who develop LMD, suggesting specific biologic underpinnings driving patterns of CNS failure. Further investigation into the role of systemic therapy and time course will elucidate potential mechanisms for CNS failure in patients with NSCLC. Research Sponsor: None.

2009 **Poster Discussion Session**

Dabrafenib + trametinib (dab + tram) in relapsed/refractory (r/r) *BRAF* V600–mutant pediatric high-grade glioma (pHGG): Primary analysis of a phase II trial. *First Author: Darren R. Hargrave, Great Ormond Street Hospital for Children NHS Foundation Trust, Great Ormond Street, London, United Kingdom*

Background: HGGs comprise ≈10% of pediatric central nervous system tumors and are a leading cause of childhood cancer-related death. Overall response rates (ORRs) with current standards of care are low, particularly in the second line, and 2-y overall survival (OS) rates are ≤35%. *BRAF* V600 mutation is infrequent (≈5% of pHGGs) but associated with improved survival from time of initial diagnosis. In previous trials, dab monotherapy and dab + tram yielded encouraging outcomes in *BRAF* V600–mutant HGG in pediatric and adult patients (pts), respectively. We describe the results of a Phase II study (NCT02684058) of dab + tram in r/r *BRAF* V600–mutant pHGG. **Methods:** Pts aged 1 to <18 y with *BRAF* V600–mutant HGGs and Karnofsky/Lansky performance status ≥50% who had failed first-line therapy were enrolled in a single-arm cohort. Pts received dab twice daily (<12 y, 5.25 mg/kg/d; ≥12 y, 4.5 mg/kg/d) + tram once daily (<6 y, 0.032 mg/kg/d; ≥6 y, 0.025 mg/kg/d). The primary endpoint was ORR (independent review; HGG-RANO criteria); secondary endpoints included ORR (investigator review), duration of response (DOR), progression-free survival (PFS), OS, and safety. **Results:** A total of 41 pts with diverse WHO Grade III/IV gliomas were enrolled; median time since diagnosis was 17.4 mo (range, 2.7-174.3 mo), and most had prior surgery (97.6%), radiotherapy (90.2%), and/or systemic antineoplastic therapy (80.5%). At data cutoff (August 23, 2021; median follow-up, 25.1 mo), 21 pts (51.2%) remained on treatment; most discontinuations (16 of 20) were due to progressive disease. Median exposure was 72.7 wk (range, 1.3-172.1 wk). The primary endpoint was met, with an independently assessed ORR of 56.1% (95% CI, 39.7%-71.5%). Median DOR was 22.2 mo (95% CI, 7.6 mo-not estimable [NE]; 12-mo Kaplan-Meier [KM] DOR rate, 62.2%), and median PFS was 9.0 mo (95% CI, 5.3-24.0 mo; 12-mo KM PFS rate, 44.1%). There were 14 deaths (34.1%), with 12 due to HGG and 2 due to serious adverse events (AEs; encephalomyelitis and intracranial pressure increased [n = 1 each], not treatment related per investigators); median OS was 32.8 mo (95% CI, 19.2 mo-NE; 12-mo KM OS rate, 76.3%). The most common all-cause AEs were pyrexia (51.2%), headache (34.1%), dry skin (31.7%), vomiting (29.3%), and diarrhea (24.4%). Two pts (4.9%) had AEs leading to discontinuation (both rash), and 26 (63.4%) had AEs leading to dose modification. **Conclusions:** Treatment with dab + tram demonstrated an improvement in ORR, response durability, and survival compared with estimates based on historical observations with current treatment approaches in r/r *BRAF* V600–mutant pHGG. Safety was consistent with the established profile of dab + tram in other indications. Thus, dab + tram may represent a critical treatment advance for this pt population with high unmet need. Clinical trial information: NCT02684058. Research Sponsor: Novartis Pharmaceuticals Corporation.

2010 **Poster Discussion Session**

Long-term control and safety of larotrectinib in a cohort of adult and pediatric patients with tropomyosin receptor kinase (TRK) fusion primary central nervous system (CNS) tumors. *First Author: Sébastien Perreault, Department of Neurosciences, CHU Hopital Sainte-Justine, Montréal, QC, Canada*

Background: Neurotrophic tyrosine receptor kinase (*NTRK*) gene fusions are known oncogenic drivers in a variety of tumor types. Larotrectinib is a highly selective, CNS-active TRK inhibitor that demonstrated an objective response rate (ORR) of 30% and a 24-week disease control rate (DCR) of 73% across 33 evaluable adult and pediatric patients with TRK fusion primary CNS tumors, as of July 2020 (Doz et al, *Neuro Oncol* 2021). We report updated data on an expanded dataset of patients. **Methods:** Patients with TRK fusion primary CNS tumors in two clinical trials (NCT02637687, NCT02576431) were included. Larotrectinib was administered at 100 mg twice daily (BID) in adults and 100 mg/m^2 (max 100 mg) BID in pediatric patients. Response was investigator-assessed. **Results:** As of July 2021, 38 adult and pediatric patients with TRK fusion primary CNS tumors were identified: high-grade glioma (HGG; n =23), low-grade glioma (LGG; n =9), and other (n =6; includes glioneuronal, neuroepithelial, diffuse leptomeningeal, neuroblastoma, recurrent small round blue cell, and not otherwise specified). Median age at enrollment was 10.8 years (range 1.3–79.0; 28 [74%] patients < 18 years old). The gene fusions involved *NTRK2* (n = 28), *NTRK1* (n = 6), and *NTRK3* (n = 4). Sixteen (42%) patients received one prior line of systemic therapy and 16 (42%) received ≥2 prior lines. The ORR for 37 evaluable patients was 30% (95% confidence interval [CI] 16–47): three complete responses, eight partial responses, 21 stable disease (16 patients ≥24 weeks), and five progressive disease. The 24-week DCR was 73% (95% CI 56–86) for all patients, 68% (95% CI 45–86) for patients with HGG, and 89% (95% CI 52–100) for patients with LGG. Twenty-five of 31 patients (81%) with measurable disease at baseline had tumor shrinkage. Median time to response was 1.9 months. Median duration of response (DoR) was not reached; median follow-up was 25.6 months. The 12-month DoR rate was 64%. Median progression-free survival (PFS) was 16.5 months (95% CI 6.7–not estimable); median follow-up was 27.4 months. Median overall survival (OS) was not reached; median follow-up was 26.7 months. The 24-month OS rate was 65%. Treatment duration ranged from 0.1+ to 38.7+ months. Twenty-two patients (58%) progressed on treatment and three continued treatment post-progression for ≥4 weeks. Treatment-related adverse events (TRAEs) were reported in 21 patients (55%); the majority of these patients (18/21 [86%]) reported Grade 1 or 2 TRAEs. No Grade 3 or higher treatment-related neurological adverse events were reported. There were no treatment discontinuations due to TRAEs. **Conclusions:** Larotrectinib achieved a high DCR, rapid and durable responses, and a manageable safety profile in patients with TRK fusion primary CNS tumors. These results support testing for *NTRK* gene fusions in patients with CNS tumors. Clinical trial information: NCT02637687, NCT02576431. Research Sponsor: Bayer HealthCare and Loxo Oncology.

2011 **Poster Discussion Session**

CA-4948 for the treatment of melanoma brain metastasis. *First Author: Bently Patrick Doonan, The Medical University of South Carolina, North Charleston, SC*

Background: Melanoma is a growing clinical health concern where the incidence has doubled over the last 30 years. A major driver of melanoma associated deaths is the development of brain metastases (MBM). It is estimated that 40-60% of patients with metastatic melanoma will develop MBM. Current treatment strategies have a great local control rate, but do not prevent recurrent disease, with a distant intracranial failure rate of 50% at 1 year. Novel treatments and an improved understanding of the MBM tumor microenvironment are needed. Toll-like receptor signaling is activated in cutaneous melanoma, triggering innate inflammatory activation downstream through the adapter proteins MyD88 and interleukin (IL)-1 receptor-associated kinase (IRAK-1 and -4). Increased expression of IRAK-4 stimulates transcription of multiple cellular kinases and transcription factors, and production of inflammatory chemokines and cytokines. This places IRAK-4 as a central driver of both intrinsic tumorigenicity and immune evasion in melanoma. In this study we examine IRAK-4 activation in MBM, as well as preclinical responsiveness to CA-4948, an oral first-in-class small molecule inhibitor of IRAK-4 that has demonstrated clinical activity and has an acceptable safety in cancer patients. **Methods:** Using multiparameter IHC and proteomics analysis IRAK-1, IRAK-4, and NF-κB pathway activation were examined in patient MBM tissues and compared to normal controls. Plasma, cerebrospinal fluid, and brain tissue were assessed via UPLC-MS/MS for CA-4948 drug concentration following single oral high dose in a murine model. Using an aggressive preclinical model of MBM, B16F10, downstream biomarker response to treatment including phospho-NF-κB, phospho-ERK1/2, and phospho-P38 was measured in control and CA-4948 treated animals using multi-parameter IHC. Survival response was also tested using the B16F10 model. **Results:** Our data confirm elevated IRAK-1, IRAK-4, and NF-κB signaling in patient MBM. We also demonstrate that CA-4948 is capable of achieving therapeutically relevant concentrations in the brain parenchyma, and shows single agent activity in an aggressive preclinical model of MBM. We further confirm decreased ERK1/2, MAPK and NF-κB activation in response to CA-4948 treatment. **Conclusions:** We present here for the first time that IRAK-4 is a strong candidate for targeted therapy in MBM. We further validate CNS penetrance of the oral IRAK-4 inhibitor CA-4948, where single agent markedly reduces the proliferative capacity of aggressive preclinical MBM, resulting in improved survival. These data warrant further investigation of CA-4948 for the treatment of melanoma brain metastases, with far reaching potential as an adjunct to standard of care. Research Sponsor: Curis, Inc., J. David Vandivier Memorial Melanoma Research Fund.

2012 **Poster Discussion Session**

Feasibility and conduct of INSIGhT, a platform trial of patients with glioblastoma using Bayesian adaptive randomization. *First Author: Eudocia Quant Lee, Dana-Farber Cancer Institute, Boston, MA*

Background: Individualized Screening Trial of Innovative Glioblastoma Therapy (INSIGhT) trial is a phase II platform trial using response adaptive randomization and deep genomic profiling to more efficiently test experimental agents in MGMT unmethylated glioblastoma and potentially accelerate identification of novel therapies for phase III testing. We report on the feasibility and conduct of this approach. **Methods:** Tumor genotyping was performed prior to treatment assignment on eligible participants with newly diagnosed MGMT-unmethylated glioblastoma to identify biomarker signatures. Initial randomization was 1:1:1:1 between control (temozolomide) and 3 experimental arms (abemaciclib, CC-115, and neratinib). Subsequent randomization was adapted based on Bayesian estimation of biomarker-naïve and biomarker-specific probabilities of treatment impact on progression-free survival (PFS). Ineffective or toxic arms were discontinued by protocol amendment. The primary endpoint was overall survival (OS). **Results:** INSIGhT randomized 71 patients to the control arm, 73 patients to the abemaciclib arm, 12 patients to the CC-115 arm, and 81 patients to the neratinib arm between 2/9/2017 and 5/14/2021. Following the initial equal randomization period, early data were repeatedly analyzed during the study to capture early signals of treatment effects across the enrolled population or in specific biomarker subgroups. The results of these interim analyses influenced the randomization probability for future enrolled patients. In total, 77% of the participants were randomized before assessing their biomarker profile and 23% were biomarker randomized. The CC-115 arm opened and closed three times during the safety lead-in. The randomization probability to the CC-115 arm decreased based on poor early PFS results and the arm eventually closed after 12 patients due to toxicity. The randomization probability to the abemacicilb arm increased based on promising early PFS results. After the completion of accrual into the abemaciclib arm, the trial switched to block randomization to finish enrolling into the remaining neratinib and control arms. A total of 28 interim analyses and 32 randomization tables were created throughout the course of the trial with 4 adjustments (3 due to CC-115 closures and 1 due to completion of the abemaciclib arm). Biomarker association trends for neratinib and abemaciclib were similar to those seen in preclinical modeling of the trial. **Conclusions:** Relative to a standard randomization design, the adaptive platform design facilitated more efficient and economical testing of experimental arms by sharing a control arm, decreasing the probability of enrollment to potentially ineffective arms, and increasing the probability of enrollment to potentially effective arms. Additional future arms are planned on INSIGhT. Clinical trial information: NCT02977780. Research Sponsor: Lilly, PUMA , Beacon, Dana-Farber institutional funds.

2013 **Poster Discussion Session**

Radiosurgery dose reduction for brain metastases on immunotherapy (RADREMI): Results of an a priori interim analysis of a multicenter phase I trial. *First Author: Shearwood McClelland, Indiana University School of Medicine, Indianapolis, IN*

Background: Symptomatic radiation necrosis rates in patients treated with immune checkpoint inhibitor (ICI) therapy and concomitant single-fraction stereotactic radiosurgery (SRS) are as high as 20% (PMID: 29327059). We present updated results from the Radiosurgery Dose Reduction for Brain Metastases on Immunotherapy (RADREMI) trial following completion of an a priori interim analysis, aimed to identify reduced-dose SRS that is safe and efficacious for this patient population. **Methods:** RADREMI (clinicaltrials.gov, NCT04047602) is a prospective multicenter single arm Phase I trial involving patients age > 18 receiving ICI with SRS for 1-10 brain metastases on MRI. Patients had biopsy-confirmed primary malignancy with disease-specific graded prognostic assessment estimated median survival of at least 6 months and no previous whole brain radiation therapy. Six-month symptomatic radiation necrosis (radiographic radiation necrosis + clinical symptoms requiring steroid administration and/or operative intervention) was the primary endpoint, based on an expected rate of 5% and a historical rate of 16%. Secondary endpoints included 6-month local control and radiographic radiation necrosis. Response Assessment in Neuro-Oncology criteria defined local control; findings were compared to historical 6-month local control of 87-91% with RTOG 90-05 SRS dosing. A pre-determined interim futility analysis (based on the null hypothesis of no fewer than 15 of the first 20 patients reaching the primary endpoint achieving 6-month local control for RADREMI dosing) was performed using the Fisher's exact test. **Results:** Between December 18, 2019 and September 10, 2021, 43 lesions were treated in 16 patients receiving ICI delivered within 30 days before SRS who were enrolled on trial and met the primary endpoint (median follow-up = 9.1 months). All patients received RADREMI SRS dosing (18 Gy for lesions 0-2 cm, 14 Gy for lesions 2.1-3 cm, and 12 Gy for lesions 3.1-4 cm). The most common ICI used was single-agent pembrolizumab (51% of lesions, 56% of patients), followed by single-agent nivolumab (28% of lesions, 13% of patients). The six-month rates of symptomatic and radiographic radiation necrosis were zero; the six-month local control rate was 98% per treated lesion (42/43), and 94% per treated patient (15/16), comparable to historical controls ($p > 0.05$) and sufficient to not reject the interim futility analysis null hypothesis. **Conclusions:** Interim analysis reveals that the safety and efficacy of RADREMI dosing for reducing SRS dose in brain metastasis patients receiving concomitant ICI persists with excellent local control and no morbidity in a multi-institutional collaborative trial. Further results following completion of trial enrollment will provide additional evidence regarding the safety and efficacy of RADREMI SRS dosing. Clinical trial information: NCT04047602. Research Sponsor: Indiana University Simon Comprehensive Cancer Center Clinical Trials Office Core Services Grant.

2014 **Poster Discussion Session**

Evaluation of tumor responses and overall survival in patients with recurrent glioblastoma (GBM) from a phase IIa trial of a CMV vaccine immunotherapeutic candidate (VBI-1901). *First Author: Patrick Y. Wen, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA*

Background: Cytomegalovirus (CMV) antigens have been reported in over 90% of GBMs. $CD4^+$ and $CD8^+$ T cells are most frequently directed against the gB and pp65 antigens, respectively, which are immunogenic targets in a CMV-based GBM immunotherapeutic. **Methods:** A total of 20 first-recurrent GBM patients were enrolled, with Karnofsky Performance Status of at least 70, across 2 arms of the Phase IIa extension phase to receive VBI-1901 (a gB/pp65 enveloped virus-like particle [eVLP]) adjuvanted with either GM-CSF (given intradermally) or $AS01_B$ (given intramuscularly) (NCT03382977). Patients were vaccinated with VBI-1901 every 4 weeks, with serologic immune-monitoring 2 weeks after each vaccination and surveillance brain MRI scans every 6 weeks. **Results:** 10 patients (6 women, 4 men) with a median age of 58 (33-67 yrs) were enrolled into the GM-CSF arm and 10 patients (3 women, 7 men) with a median age of 65 (40-67) enrolled into the $AS01_B$ arm. The 12-month OS rates for the GM-CSF and $AS01_B$ arms were 60% and 70%, respectively; the 18-month OS rate for the GM-CSF arm was 30%, and for the $AS01_B$ arm is expected to be 30%-40% (data has not yet matured). Two durable partial responses (locally determined by RANO) have been observed in the GM-CSF arm, with one patient progression-free and on protocol after 2 years with a tumor size reduction of 93% relative to start of treatment. Immunological analyses demonstrate that prolonged, monthly dosing with VBI-1901 does not lead to immunological tolerance. Dynamic boosting and loss in the peripheral blood of CMV-specific CD4 Tem cells after treatment with VBI-1901 formulated with GM-CSF may correlate with tumor responses. **Conclusions:** The U.S. FDA granted Fast Track Designation to VBI-1901 adjuvanted with GM-CSF in first-recurrent GBM patients, and an expansion of the ongoing trial with this formulation in this patient population, with the addition of randomization with a contemporaneous control arm, is anticipated to begin in H1 2022. Acknowledgement: GlaxoSmithKline Biologicals SA provided the $AS01_B$ adjuvant used in this study. Clinical trial information: NCT03382977. Research Sponsor: VBI Vaccines, Cambridge, MA, USA.

Risk of intracranial hemorrhage with direct oral anticoagulants versus low molecular weight heparin in glioblastoma: A retrospective cohort study. *First Author: Lauren Reed-Guy, Hospital of the University of Pennsylvania, Philadelphia, PA*

Background: Glioblastoma (GBM) is associated with a high rate of venous thromboembolism (VTE), but there is little data to guide anticoagulation in GBM patients, in whom the risks of VTE must be balanced against the risk of intracranial hemorrhage (ICH). **Methods:** We performed a single-institution retrospective cohort study of patients with GBM diagnosed with VTE from 2014-2021 who were treated with low molecular weight heparin (LMWH) or a direct oral anticoagulant (DOAC). The cumulative incidence of ICH was compared between the LMWH and DOAC groups. The primary outcome was clinically relevant ICH within the first 30 days of anticoagulation, defined as any ICH that was fatal, symptomatic, required surgical intervention, and/or led to cessation of anticoagulation. Key secondary outcomes included clinically relevant ICH within 6 months, fatal ICH within 30 days and 6 months, any bleeding within 30 days and 6 months, and recurrent VTE within 6 months. Fisher's exact test was used for comparison of primary and secondary endpoints between the two groups. Cumulative incidence curves were generated using the Kaplan-Meier method, and the cumulative incidence of clinically relevant ICH at both the 30-day timepoint and 6-month timepoint was compared between the DOAC and LMWH groups using the Gray test to account for death as a competing risk. **Results:** A total of 121 patients were identified in the primary cohort for 30-day outcome analyses (DOAC, n = 33; LMWH, n = 88). For 6-month outcome analyses, the cohort included only patients who were maintained on their initial anticoagulant (DOAC or LMWH) and did not switch anticoagulants during the 6 months following diagnosis of VTE (DOAC, n = 32; LMWH, n = 75). The cumulative incidence of clinically relevant ICH at 30 days was 0% (0/33) in the DOAC group and 9% (8/88) in the LMWH group ($p = 0.11$). The cumulative incidence of clinically relevant ICH at 6 months was 0% (0/32) in the DOAC group and 24% (18/75) in the LMWH group ($p = 0.001$), with 4 fatal ICHs in the LMWH group. Other outcomes are displayed in the Table. **Conclusions:** Our study suggests that DOACs are associated with a lower incidence of clinically relevant ICH in patients with GBM-associated VTE compared to LMWH. These data support the use of DOACs as a safe alternative to LMWH in patients with GBM. Research Sponsor: None.

Primary and secondary outcomes.

	LMWH (n = 88 at 30 days; 75 at 6 months)	DOAC (n = 33 at 30 days; 32 at 6 months)	p-value
Primary outcome – no. (%)			
Clinically relevant ICH within 30 days	8 (9)	0 (0)	0.11
Secondary outcomes – no. (%)			
Fatal ICH within 30 days	2 (2)	0 (0)	1.0
Any bleeding within 30 days	17 (19)	1 (3)	0.024
Clinically relevant ICH within 6 months	18 (24)	0 (0)	0.001
Fatal ICH within 6 months	4 (5)	0 (0)	0.32
Any bleeding within 6 months	31 (41)	3 (9)	0.001
Rate of recurrent VTE in 6 months	3 (4)	0 (0)	0.55

2016 **Poster Discussion Session**

Repeated opening of the blood-brain barrier with the skull-implantable SonoCloud-9 (SC9) device: Phase 1 trial of nab-paclitaxel and SC9 in recurrent glioblastoma. *First Author: Adam M. Sonabend, Northwestern Medicine Malnati Brain Tumor Institute of the Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, IL*

Background: The blood-brain barrier (BBB) is a major impediment to pharmacological treatment of gliomas, a diffuse tumor infiltrating the peri-tumoral normal brain. Low-intensity pulsed ultrasound directed at the brain with concomitant administration of intravenous microbubbles (LIPU/MB), temporarily opens the BBB. This technique was previously shown with a first generation of the device in combination with carboplatin chemotherapy (Idbaih et al. 2019). Here we investigate the pharmacokinetics and safety of this approach in the context of repeated delivery of albumin-bound paclitaxel (ABX) to the peri-tumoral brain. To perform LIPU/MB-based BBB opening prior to ABX infusions, we used a novel 6 x 6 cm device with 9 ultrasound emitters (SC9) that is implanted in a skull window after tumor resection. **Methods:** A Phase 1 dose-escalation trial using Bayesian adaptive design was initiated at our institution (NCT04528680). Patients with recurrent operable glioblastoma, a WHO PS $\leq$ 2 and normal bone marrow and organ function were eligible. After tumor resection and implantation of SC9, repeated cycles of BBB opening by LIPU/MB immediately followed by ABX, was performed every 3 weeks. Intraoperative LIPU/MB and low dose ABX was given prior to tumor resection for investigation of pharmacokinetics. **Results:** Seventeen patients have been enrolled and six dose levels of ABX were used (40-260 mg/m^2). Severe, reversible taxane-associated encephalopathy was observed in one patient at the max. planned dose level (260 mg/m^2). The patient continued treatment at a lower dose in subsequent cycles. One patient developed grade 2 cumulative peripheral neuropathy. Other mild to moderate and reversible toxicities for ABX including myelosuppression, fatigue, alopecia were observed as expected. Intraoperative sonication and pharmacokinetic studies showed that ABX tissue concentrations in non-enhancing peri-tumoral brain were increased several-fold after LIPU/MB. On electron microscopy, sonicated tissue showed ultra-structural alterations in brain capillary endothelial cells. Molecular studies showed transcriptional dysregulation of membrane transporters, pathways related to trans-cytosis, cell permeability as well as cell-cell and cell-matrix adhesion. Updated results will be presented. **Conclusions:** The LIPU/MB using skull-implantable ultrasound enhances the penetration of large chemotherapeutic drugs such as ABX in large regions of the brain, a procedure that can be performed repeatedly and safely. LIPU-based BBB opening leads to ultrastructural and transcriptional alterations in brain endothelial cells. A Phase 2 clinical trial is planned to investigate efficacy of this approach. Funding: NIH/NCI 1R01CA245969-01A1, Carthera (SC9 devices), Celgene/BMS, Malnati Brain Tumor Institute, Moceri Family Foundation. Clinical trial information: NCT04528680. A controlled comparison of cerebral volume loss after brain irradiation with proton versus photon radiotherapy. *First Author: Melissa Gardner, Massachusetts General Hospital, Boston, MA*

Background: Previous work has demonstrated cerebral volume loss after glioma treatment with concurrent photon radiotherapy (PHT) and chemotherapy. Proton radiotherapy (PRT) minimizes exposure of normal brain tissue compared with PHT. The objective of this study was to compare neurotoxic effects of PRT vs PHT in a retrospective case-matched control series of WHO grade 2 and 3 gliomas. **Methods:** PRT subjects were selected from ongoing longitudinal single-arm outcome studies being conducted at our institution (NCT01358058, NCT03286335). PHT subjects were identified via medical record search and were individually matched to PRT subjects using an eleven-tiered criterion (i.e., age, sex, tumor type, tumor location, laterality, IDH mutation status, 1p19q deletion status, concurrent chemotherapy, adjuvant chemotherapy, total Gy dose, and number of fractions). When individual matching was not possible on all 11 variables, efforts were made to identify the closest possible match. Only those subjects with at least two years of progression free survival and available T1 and T2/FLAIR MRI at baseline, one year, and two years following RT were included. The resulting sample included 17 PRT and 17 PHT patients with grade 2 and 3 gliomas (19 male; mean age = 40.10y; SD = 11.27). Non-parametric analyses were used to compare groups on demographic and tumor/treatment-related variables. Diffuse cerebral volume loss was estimated by manually measuring lateral ventricular volume in the *tumor-free hemisphere*. **Results:** Mann-Whitney tests of independence showed no significant differences between groups on any of the demographic variables or clinical characteristics. One-way ANOVA demonstrated that ventricular volume increase after two years was significantly greater in patients treated with PHT than with PRT, ($F(1, 32.00) = 5.90$, $p < .021$, $\eta^2 = .156$). Change in ventricular volume in the PHT group was 24.85% (SD = 14.45%) and in the PRT group was 12.03% (SD = 16.3%). **Conclusions:** The findings of this study suggest that 2 years post treatment for glioma, PRT is associated with less brain volume loss and ventricular expansion than PHT. The findings support the hypothesis that PRT can reduce neurotoxicity within the tumor-free hemisphere. This study is limited by the retrospective design and lack of randomization to treatment arms, though cohorts were well-matched following a rigorous set of criteria. The effects of PRT beyond 2 years after treatment remain unknown. Preservation of brain structure may be critically important for maintenance of brain function in this population of patients who have prolonged survival. Longitudinal cognitive assessment in brain tumor patients undergoing PHT vs PRT is needed and is currently being collected in NRG BN-005 (NCT03180502), which may provide important data regarding functional impact of the brain changes we have demonstrated. Real-world data to enable large-scale assessment of WHO CNS5 glioma classification. *First Author: Joshuah Kapilivsky, Tempus Labs, Inc., Chicago, IL*

Background: In 2021, the WHO revised its classification of central nervous system tumors (WHO CNS5) around IDH status and inclusion of key somatic alterations in addition to histopathological traits. While providing a more specific classification system for patients, the guidelines introduce new logistical challenges for pathologists, relying on multi-modal data for accurate classification. In this study, we use a combined clinical/molecular real world dataset to reclassify a cohort of adult diffuse gliomas and evaluate prognostic impact using real-world overall survival (rwOS). **Methods:** We retrospectively analyzed a de-identified dataset of 2,703 adult diffuse glioma samples profiled with the Tempus xT assay (DNA-seq of 595-648 genes at 500x coverage, whole-exome capture RNA-seq). Original diagnoses were identified from sample pathology reports. We assessed mutation status for genes relevant to WHO CNS5 classification (*IDH1/2*, *ATRX*, and *TERT*) and copy number alterations for genes *CDKN2A/B* and *EGFR*, as well as arms 1p, 19q and chromosomes 7 and 10. Samples were excluded if the original diagnosis or molecular findings indicated a diffuse midline or pediatric glioma. Necrosis and microvascular proliferation were inferred from gene expression profiles using machine learning. rwOS was defined as time from original diagnosis until death. To account for left truncation, samples were only considered at risk of death after study entry (*e.g.,* date of sequencing if sequenced as part of clinical care). **Results:** Using relevant clinicopathological traits and genomic alterations, we assigned WHO CNS5 labels to all samples—512 *astrocytoma,* IDH-*mutant*; 186 *oligodendroglioma,* IDH-*mutant, and 1p/19q co-deleted*; and 2,005 *glioblastoma,* IDH-*wildtype* (IDH-*wt*). We further stratified *astrocytoma,* IDH-*mutant* samples by grade, resulting in 308 classified as grade 4. Of the samples with an original diagnosis of astrocytoma, oligodendroglioma, or glioblastoma, 13.9% changed under the WHO CNS5 guidelines, including 166 glioblastomas re-classified as grade 4 *astrocytoma,* IDH-*mutant*, and 125 astrocytomas re-classified as *glioblastoma,* IDH-*wt*. WHO CNS5 reclassification resulted in more accurate prognostic stratification (rwOS) than the original diagnosis (likelihood ratio test; P < 8e-32). For example, the observed hazard ratio (HR) of an original astrocytoma diagnosis (versus glioblastoma) (Cox PH Model; HR = 0.42[CI:0.32,0.56]) was less extreme than the observed HR of an *astrocytoma,* IDH-*mutant* diagnosis (versus *glioblastoma,* IDH-*wt)* under WHO CNS5 (Cox PH Model; HR =0.08[CI:0.04,0.19] grades 2-3; HR = 0.18[CI:0.12,0.26] grade 4). **Conclusions:** This work highlights the utility of comprehensive molecular profiling in classifying patients with adult diffuse gliomas according to the newest WHO CNS5 guidelines, and confirms the improved prognostic stratification within a retrospective real-world dataset. 2019 **Poster Discussion Session**

Biological and prognostic relevance of epigenetic regulatory genes in high-grade gliomas (HGGs). *First Author: Sonikpreet Aulakh, West Virginia University, Morgantown, WV*

Background: Gliomagenesis is regulated by dynamic epigenetic modifications of DNA methylation, deregulation of histones and alteration of the human Switch/Sucrose Non-Fermentable (SWI/SNF) chromatin remodeling complexes. These epigenetic genes are responsible for treatment resistance by inducing stemness of glioma cells and immune cells with in the tumor microenvironement (TME). We evaluated the key chromatin remodeling (CR) genes and their interactions with other regulatory genes that are of prognostic importance. **Methods:** 1856 HGGs underwent molecular profiling at Caris Life Sciences (Phoenix, AZ). Analyses included next-generation sequencing of DNA (592 Genes, NextSeq or WES, NovaSeq) and RNA (WTS, NovaSeq). Cell infiltration in the TME was estimated by quanTIseq. X^2/Fisher's-exact/Mann-Whitney U tests were used for comparison, and significance was determined as p-value adjusted for multiple comparison by the Benjamini-Hochberg method ($q < 0.05$). Overall survival (OS) was calculated from the start of temozolomide (TMZ) to last contact using insurance claims data. **Results:** In a cohort of 1856 HGGs, 181 (9.8%) displayed >=1 mutation of 19 CR genes considered, including mutations (mt) of histone methyltransferases (HM) comprising *SETD2* (62, 3.4%), *KMT2D* (18, 1.0%), *KMT2C* (11, 0.6%); SWI/SNF complexes (SSNF) including *ARID1A* (32, 1.74%), *ARID2* (15, 0.82%), *SMARCA4* (14, 0.76%) and *ARID1B* (12, 0.66%); and others including (*DNMT3A*, 0.94%, *ASLXL1*: 13, 0.98%). When compared to CR-WT, CR-mt HGGs showed higher prevalence of Tumor Mutational Burden-High (TMB-H) (23% vs. 1.3%), MSI-H/dMMR (13% vs. 0.2%), gLOH (9.5% vs 4.3%), and mts in *IDH1/2* (29% vs. 14%), *TP53* (55% vs. 36%), *MSH6* (8.8% vs. 0.6%), and *PIK3CA* (18.8% vs. 8.3%) (all $q<0.05$). Investigation of CR-mt subgroups showed that SSNF mt had the highest *MGMT*-promoter methylation (68%) and *IDH1/2* mt (46%), while HM and others showed similar prevalence. In *IDH*-WT and MSS HGGs, the CR association with TMB-H, *MSH6*, *TP53* and *PIK3CA* persisted ($q<0.05$). When studying the immune profile, CR-mt HGGs showed significantly lower expression of immune-related genes including PD-L1 (Fold change: 0.76), PD-L2 (0.72), IDO1 (0.65), TIM3 (0.76) and CD86 (0.77) and colder TME as manifested by lower infiltrations of M2 (0.87) and higher Treg (1.27, all $q<0.05$); such effects were not observed in the subgroup of *IDH* WT/MSS tumors. Among TMZ-treated HGG tumors, CR mt was associated with improved OS (33 months vs 22m, HR: 0.713, 95% CI: 0.581-0.876, p = .001). In the *IDH* WT/MSS subgroup this effect was also observed (31.6m vs 19.2m, HR: 0.764, 95% CI: 0.59-0.99, p = 0.041). **Conclusions:** Nearly 10% of HGGs carry mts in CR genes. CR-mt HGGs possess significantly more favorable genetic alterations and colder TME compared to the CR-WT HGGs and showed better OS when treated with TMZ. Multivariate modeling and analysis of associations with specific targeted therapies is underway. Research Sponsor: None.

2020 **Poster Discussion Session**

Evaluation of the response assessment criteria in newly diagnosed and recurrent glioblastoma. *First Author: Gilbert Youssef, Dana-Farber Cancer Institute, Boston, MA*

Background: The Response Assessment in Neuro-Oncology (RANO) and modified RANO (mRANO) criteria are the two most widely used criteria to evaluate treatment response in glioblastoma (GBM) clinical trials. Unlike RANO, mRANO omits the evaluation of FLAIR sequence and requires a repeat scan to confirm responses. It also uses the post-radiation (RT) MRI as a baseline MRI in the newly diagnosed setting instead of the pre-RT MRI used in RANO. We sought to compare the 2 response assessment criteria and evaluate the differences between them in a large patient population. We also sought to compare them to immunotherapy RANO (iRANO) in patients who received immunotherapy. **Methods:** We conducted a retrospective review of consecutive patients with newly diagnosed (nGBM) and recurrent (rGBM) IDH wild-type GBM treated at Dana-Farber Cancer Institute from 2014 to 2020. Bidimensional measurements of enhancing disease and evaluation of FLAIR sequences were performed by two independent readers on patients' brain MRIs obtained before change of treatment, and discrepancies were evaluated by a third reader. Dates of disease progression (PD) were identified using RANO, mRANO, iRANO, and other response assessment criteria variations. Spearman's correlations between PFS and OS were calculated using an iterative multiple imputation method to account for any right-censoring. **Results:** 526 and 580 patients were included in the newly diagnosed and recurrent cohorts, respectively. Spearman's correlations were not significantly different between RANO and mRANO in the nGBM (0.69 [95% CI 0.62 to 0.75] vs. 0.67 [0.60, 0.73]) and rGBM (0.45 [0.37, 0.52] vs. 0.50 [0.42, 0.57]) cohorts. Evaluation of FLAIR sequences did not improve the correlation between PFS and OS in patients who received antiangiogenic therapy. Addition of confirmation scans was associated with stronger Spearman's correlations only when PD was identified within 12 weeks of completion of RT in the nGBM cohort, but did not affect the Spearman's correlations in the rGBM cohort. The use of the post-RT MRI as a baseline was associated with a higher Spearman's correlation in nGBM than the use of pre-RT MRI (0.67 [0.60, 0.73] vs. 0.53 [0.42, 0.62]). Among 98 patients with nGBM and 175 patients with rGBM who received immunotherapy, the Spearman's correlations (nGBM and rGBM) with iRANO (0.63 [0.44, 0.76] and 0.34 [0.17, 0.49]) were similar to RANO (0.73 [0.60, 0.82] and 0.42 [0.28, 0.54]) and mRANO (0.65 [0.48, 0.77] and 0.43 [0.28, 0.56]). **Conclusions:** RANO and mRANO demonstrated similar correlation between PFS and OS. The evaluation of FLAIR can be omitted, while confirmation scans appear to be only beneficial in the nGBM settings during the first 12 weeks of completion of RT. There was a nonsignificant trend in favor of the use of post-RT MRI as the baseline scan in the nGBM setting. The application of iRANO criteria did not add significant benefit in patients who received immunotherapy. Research Sponsor: None.

2021 **Poster Session**

CSF proteomics for differentiation of brain malignancies. *First Author: Nicholas Mikolasjewicz, University of Toronto, Toronto, ON, Canada*

Background: Accurate diagnosis and prognostication of intra-axial brain tumors hinges on invasive brain sampling, which carries risk of morbidity. Minimally invasive sampling of proximal fluids, also known as liquid biopsy, can mitigate this risk. Although the cerebrospinal fluid (CSF) is the ideal liquid biopsy source, the traditionally high volumes required for impactful analyses have deterred progress. The objective of this study was to identify diagnostic and prognostic CSF proteomic signatures in glioblastoma (GBM), brain metastases (BM), and central nervous system lymphoma (CNSL). **Methods**: CSF samples were retrospectively retrieved from the Penn State Neuroscience Biorepository and profiled using shotgun proteomics with ultra-low sample volumes. Proteomic signatures were identified using machine learning classifiers and survival analyses. **Results**: Using 30μL CSF volumes, we recovered 800 unique peptides across 73 samples [20 normal pressure hydrocephalus (NPH, non-tumor control), 22 GBM, 17 BM, and 14 CNSL]. Externally-validated proteomic-based classifiers identified malignancy with AUROC of 0.94 and distinguished individual tumor entities from others with AUROC ≥0.96. More clinically relevant triplex classifiers, comprised of just 3 peptides, distinguished individual tumor entities with AUROC ≥0.90. Novel biomarkers were identified among the top classifiers, including TFF3 and CACNA2D2, and characterized using single-cell RNA sequencing data. Survival analyses validated previously implicated prognostic signatures, including blood brain barrier disruption. **Conclusions**: Reliable classification of intra-axial malignancies using ultra-low CSF volumes is feasible, which has ramifications for longitudinal tumor surveillance. Novel biomarkers identified here necessitate future validation. Based on emerging evidence, upfront implantation of CSF reservoirs in brain tumor patients warrants consideration. Brain metastases in the setting of stable extracranial disease: A systematic review and meta-analysis. *First Author: Alyssa Y. Li, University of Toronto, Toronto, ON, Canada*

Background: Intracranial metastatic disease (IMD) is a life-altering complication for many patients with cancer. Improvements in systemic therapies have transformed the epidemiology of IMD, with some patients presenting with IMD in the context of stable extracranial disease (IMD-SECD). Among patients with metastases in other sites with similarly stable systemic disease, surgical resection and targeted therapy can result in long-term disease control and extended overall survival (OS), yet little is known about the clinical outcomes for patients with IMD-SECD. **Methods:** We searched MEDLINE, EMBASE, CENTRAL, and grey literature sources up to June 21, 2021 for studies reporting brain metastasis (BrM) with controlled extracranial disease (ECD) as well as IMD-SECD secondary to any primary cancer (criteria: presence of BrM and ≤2 extracranial metastatic sites, with no prior second-line chemotherapy and second-line brain-directed therapy). In studies comparing IMD-SECD and IMD patients, hazard ratios (HR) for OS and intracranial progression-free survival (iPFS) were pooled using random-effects meta-analysis, while medians for OS were estimated from single-arm IMD-SECD studies based on distribution-free summary survival curves. **Results:** Of 1067 records identified, 68 studies involving 5325 patients with IMD-SECD were included. Patients with IMD-SECD had prolonged OS (HR 1.93; 95% CI, 1.44-2.59; n = 10 studies; n = 877 patients) and iPFS (HR 1.59; 95% CI 1.31-1.92; n = 4 studies; n = 673 patients) compared with IMD patients. Subgroup analysis of patients with BrM and controlled versus uncontrolled ECD found prolonged OS with controlled ECD (HR 2.46; 95% CI, 1.36-4.44; n = 4 studies; n = 135 patients). Pooled median OS for all IMD-SECD patients was 20.85 months (mo) (95% CI, 16.35-25.98; n = 27 studies; n = 2159 patients). Stratification by primary cancer type showed median OS 20.18 mo (95% CI, 10.43-38.20; n = 2 studies; n = 109 patients) and 27.46 mo (95% CI, 18.27-49.66; n = 13 studies; n = 497 patients) for patients with IMD-SECD secondary to breast cancer and non-small cell lung cancer, respectively. **Conclusions:** Patients with IMD-SECD demonstrate prolonged OS and iPFS compared with patients with IMD, who may have more extensive systemic disease. Our results suggest that patients with IMD-SECD may represent a distinct subpopulation of patients with IMD with a uniquely favourable prognosis. It is possible that aggressive and timely treatment may significantly prolong survival for these patients. Future prospective trials should aim to investigate the efficacy of current treatment regimens in patients with IMD-SECD to further clarify optimal treatment pathways in this unique population of patients. Dynamic monitoring of cerebrospinal fluid circulating tumor DNA to identify unique genetic profiles of brain metastatic tumors and to better predict intracranial tumor response in patients with non–small cell lung cancer with brain metastases: A prospective cohort study. *First Author: Meichen Li, Department of Medical Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

Background: Cerebrospinal fluid (CSF) can be used as a type of liquid biopsy to detect brain tumors. We aimed to explore the genetic profiles of CSF-derived circulating tumor DNA (ctDNA) to predict intracranial tumor response and monitor mutational evolution during systemic treatment in non-small cell lung cancer (NSCLC) patients with brain metastases. **Methods:** We conducted aprospective study of 92 newly diagnosed NSCLC patients with brain metastases. Paired CSF and plasma samples were collected at baseline, 8 weeks after treatment initiation, and at disease progression. Primary extracranial tumor samples were available for 58 patients and all samples underwent targeted next generation sequencing of 425 cancer-related genes. **Results:** At baseline, the positive detection rates of ctDNA in CSF, plasma, and extracranial tumors were 63.7% (58/91), 91.1% (82/90), and 100% (58/58), respectively. A high level of heterogeneity was observed between paired CSF and plasma samples, while concordance in driver mutations was also observed. A higher number of unique copy number variations (CNVs) were detected in CSF ctDNA than in plasma. CtDNA-positivity in baseline CSF samples was associated with poor outcomes (HR = 2.565, P = 0.003). Moreover, patients with increased concentrations of ctDNA in CSF after 8 weeks of treatment had significantly shorter intracranial progression-free survivals (PFS) than patients with decreased concentrations of CSF ctDNA (6.13 months vs 13.27 months, HR = 3.92, P = 0.007). Increased concentrations of plasma ctDNA were associated with shorter extracranial PFS (6.13 months vs 11.57 months, HR = 2.626, P = 0.032). From clonal evolution analyses, the accumulation of subclonal mutations in CSF ctDNA was observed after 8 weeks of systemic treatment. The clonal mutations remained more than 80% in CSF after 8-weeks of treatment also predicted a shorter intracranial PFS (HR = 3.785, P = 0.039). **Conclusions:** CSF ctDNA revealed unique genetic profiles of brain metastases, and dynamic changes in CSF ctDNA could better predict intracranial tumor response and track clonal evolution during treatment in NSCLC patients with brain metastases. Research Sponsor: None.

Comparison of TAS0953/HM06 and selpercatinib in *RET* fusion-driven preclinical disease models of intracranial metastases. *First Author: Igor Odintsov, Brigham and Women's Hospital, Boston, MA*

Background: Patients with *RET* fusion-positive NSCLC have an estimated 25% incidence of CNS metastasis at diagnosis, and up to 40% during disease progression. Effective anti-RET therapy that penetrates the blood-brain barrier is essential to extending survival. TAS0953/HM06 is a structurally distinct RET-specific inhibitor that exhibits a distinct binding mode to RET and is effective against RET solvent front (G810) and gatekeeper (V804) mutations. TAS0953/HM06 also inhibits growth of xenograft tumors established from *RET* fusion-driven tumors of multiple histologies. TAS0953/HM06, therefore, represents a potentially effective strategy to overcome the emergence of acquired resistance to first generation RET-selective inhibitors. Here, we compared the brain penetration and efficacy of TAS0953/HM06 to selpercatinib (FDA-approved RET inhibitor) in models of intracranial *RET* fusion-positive cancers, specifically NSCLC and sarcoma. **Methods:** We compared the brain: plasma ratio of unbound TAS0953/HM06 and selpercatinib in mice to determine the unbound partition coefficient, Kp_{uu}, brain. We injected ECLC5 (NSCLC cell line, *TRIM33-RET*) and HMSC-RET (immortalized human mesenchymal stem cells in which *SPECCL1-RET* was introduced by CRISPR-Cas9 genomic engineering, sarcoma model) cells expressing luciferase into the cerebellum of mice. Tumor-bearing mice were treated with TAS0953/HM06 (50 mg/kg BID), selpercatinib (10 mg/kg BID) or vandetanib (multi-kinase RET inhibitor, 50 mg/kg QD), and assessed weekly for tumor growth via bioluminescence imaging. **Results:** Kp_{uu}, brain, of TAS0953/HM06 and selpercatinib were 1.3 and 0.20, respectively. Substances with brain $Kp_{uu} > 0.3$ in mice are regarded as brain-penetrable. TAS0953/HM06 was superior to selpercatinib at inhibiting growth of ECLC5 ($p < 0.0001$) and HMSC-RET ($p = 0.0005$) brain xenograft tumors, and increasing survival of tumor-bearing animals (ECLC5: TAS0953/HM06 139±0.5 days, selpercatinib 95+2.3 days, $p = 0.002$; HMSC-RET: TAS0953/HM06 41± 2.2 days, selpercatinib 20±3 days, $p = 0.0001$). Vandetanib, which is highly brain-penetrant, did not cause a significant decrease in growth of either brain tumor xenograft models. At the doses used, the 3 RET inhibitors induced similar regression in several peripheral subcutaneous xenograft tumor models. **Conclusions:** Our data in animal models suggest that TAS0953/HM06 penetrates the CNS more effectively than selpercatinib, and is superior at decreasing CNS disease and extending survival. TAS0953/HM06 represents a promising new therapeutic option for patients with RET fusions with acquired resistance mutations, including those with brain metastasis and those resistant to first-generation selective RET inhibitors. TAS0953/HM06 is currently undergoing a biomarker-driven phase 1/ 2 clinical trial for patients with solid tumors driven by *RET* alterations (NCT04683250). HER2 expression and extensive molecular characterization of resected brain metastases from colorectal cancer: The HEROES study. *First Author: Alessandra Prete, Medical Oncology 1, Veneto Institute of Oncology IOV–IRCCS, Padua, Italy*

Background: Brain metastases (BM) from primary colorectal cancer (prCRC) are rare (1-3%); few is known about CRC BM predictive factors, prognosticators and molecular pathways. High rate of *HER2* amplification (*HER2*+) in CRC with BM was previously described, being *HER2*+ overall rare in CRC (<5%); however, *HER2*+ impact on prognosis of CRC with BM is uncertain. Enrichment in high microsatellite instability (MSI-H) and *BRAF*V600E mutations (mut) was also documented in BM tissue compared to matched prCRC. We designed this study to describe molecular landscape and clinical characteristics of CRC with BM, with special focus on *HER2*. **Methods:** HEROES was a retrospective-prospective, observational study in which patients (pts) with resected BM from CRC and treated at our institution from 1 January 2010 until 31 December 2021 were enrolled to perform extensive molecular analysis of matched prCRC and BM tissue. Molecular characterization and TMB were obtained with Next Generation Sequencing (NGS, FoundationOne CDx). *RAS/BRAF* and MSI were respectively assessed with MassArray (Myriapod Colon Status kit) and immunohistochemistry (IHC) to validate NGS results. *HER2* status was assessed with IHC/in situ hybridization (ISH). Tumor-infiltrating lymphocytes (TILs) were counted on hematoxylin-eosin-stained tissue. TMB was defined high if ≥ 5.02 mut/mB; TILs if ≥ 1.6 (cutoff set with ROC curve using R software v 4.1.2). Primary objective was to describe molecular landscape of paired BM and prCRC, with special focus on HER2. Secondary objectives were to search for new prognosticators of PFS after BM resection (BM-PFS), intracranial-only PFS (BM-iPFS) after BM resection, and OS in pts with resected BM from CRC. **Results:** Out of 100 pts with BM from CRC, 22 underwent BM resection and were included in the analysis. 18 out of 22 pts were aged ≥ 70 (82%); 19 (86%) had left colon or rectal origin. 17 (70%) had concomitant lung metastases. *HER2*+ was found on 4 (18%) BM, 3 (14%) of which had also *HER2*+ in matched prCRC; 3 (14%) BM carried *BRAF*V600Emut; 2 (9%) BM had MSI-H. Acquired *HER2*+ and *BRAF*V600Emut on BM were reported in two different pts. *KRAS*mut were consistent between BM and prCRC. Factors positively influencing BM-iPFS were low TMB (HR 0.36; 95%CI 0.12-1.10; p = 0.0275) and absence of *HER2* (*HER2*neg) on BM (HR 0.20; 95%CI 0.03-1,52; p = 0.0013). *HER2*neg BM were also related to longer BM-PFS (HR 0.35; 95%CI 0.07-1.76; *p*=0.0402), as well as *KRAS*mut BM (HR 0.35; 95%CI 0.11-1.06; *p*=0.0096). Longer OS was found in pts with ECOG PS 0-1 (p<0.0001), with ≤ 1 metastatic site (HR 0.30; 95%CI 0.09-0.94; p = 0.0076) or with high TILs in prCRC (HR 0.32; 95%CI 0.10-1.03; p = 0.0368). **Conclusions:** Even with the limitation of small sample size, this study supports *HER2*+ enrichment in both prCRC and BM from CRC. *HER2*neg, low TMB or *KRAS*mut BM conferred better prognosis. ECOG PS 0-1, ≤ 1 metastatic site and TILs-enriched prCRC were related to better OS. Research Sponsor: None.

Prospective validation of a new imaging scorecard to assess leptomeningeal metastasis: A joint EORTC BTG and RANO effort. *First Author: Emilie Le Rhun, Lille University Hospital, Lille, France*

Background: Validation of the 2016 RANO MRI scorecard for leptomeningeal metastasis failed for multiple reasons. Accordingly, this joint EORTC Brain Tumor Group and RANO effort sought to prospectively validate a revised MRI scorecard for response assessment in leptomeningeal metastasis. **Methods:** Coded paired cerebrospinal MRI of 20 patients with leptomeningeal metastases from solid cancers at baseline and follow-up after treatment and instructions for assessment were provided via the EORTC imaging platform. The Kappa coefficient was used to evaluate the inter-observer pairwise agreement. **Results:** Thirty-five raters participated, including 9 neuroradiologists, 17 neurologists, 4 radiation oncologists, 3 neurosurgeons and 2 medical oncologists. Among single leptomeningeal metastases-related imaging findings at baseline, the best median concordance was noted for hydrocephalus (Kappa = 0.63), and the worst median concordance for spinal linear enhancing disease (Kappa = 0.46). The median concordance of raters for the overall response assessment was moderate (Kappa = 0.44). Notably, the interobserver agreement for the presence of parenchymal brain metastases at baseline was fair (Kappa = 0.29) and virtually absent for their response to treatment. 394 of 700 ratings (20 patients x 35 raters, 56%) were fully completed. In 308 of 394 fully completed ratings (78%), the overall response assessment perfectly matched the summary interpretation of the single ratings as proposed in the scorecard instructions. **Conclusions:** This study confirms the principle utility of the new scorecard, but also indicates the need for training of MRI assessment with a dedicated reviewer panel in clinical trials. Electronic case report forms with "blocking options" may be required to enforce completeness and quality of scoring. Research Sponsor: EORTC Brain Tumor Group.

Changing recognition of breast cancer–related leptomeningeal disease and response to therapy: A retrospective single institution review. *First Author: Gerald Carter Wallace, Moffitt Cancer Center, Tampa, FL*

Background: Breast cancer related leptomeningeal disease (BC-LMD) is a dire diagnosis for 5-8% of breast cancer patients with overall survival (OS) measured in weeks without treatment. As new treatments prolong survival with breast cancer, the risk of developing BC-LMD may be increasing. We hypothesized that the rate of BC-LMD diagnosis increased significantly with time. We also predicted that OS with BC-LMD had changed with time and in relationship to molecular subtype and treatment following BC-LMD diagnosis. **Methods:** With approval of the local Scientific Research Committee and IRB, we conducted a retrospective analysis of medical records for patients treated or diagnosed with breast cancer at MCC from 2011-2020. Patient demographics, tumor characteristics, treatments, and outcomes were collected. Kaplan Meier survival curves were used to determine median overall survival (OS), progression of disease, and differences by molecular subtype. Univariate and multivariate analyses were used to determine characteristics of primary tumors and treatments which affected OS. **Results:** Of the 133 cases identified, significantly more were diagnosed between 2016-2020 than 2011-2015 ($p < 0.01$). Significant increases were seen in HER2+ and TNBC patients ($p < 0.05$) but not for ER/PR positive (HR+) disease ($p = 0.058$). HER2+ LMD associated with longest overall survival (OS; 7mths) followed by HR+ disease (3mths) and TNBC with the shortest OS (2mths). Systemic metastases preceded BC-LMD diagnosis in 72% of cases and CNS metastases in 85% of cases. HER2+ disease also conferred increased survival after CNS metastases were diagnosed until progression to LMD (8mth vs 2mth for HR+ and 1mth for TNBC LMD; $p < 0.05$). Positive impact on survival by HER2 targeted therapies may account for improved OS in this population. Other factors which increased OS generally were: WBRT, continuation of systemic therapy, delivery of intrathecal chemotherapy, and participation in clinical trials. Having TNBC and decision to defer treatment were associated with reduced OS. **Conclusions:** This study highlights the importance of identifying patients with BC-LMD early and with the intention to treat. Prospective clinical trials and population-based studies are needed to advance treatment of BC-LMD. Research Sponsor: None.

2028 **Poster Session**

Multi-institutional randomized phase 3 trial comparing cancer stem cell-targeted versus physician-choice treatments in patients with recurrent high-grade gliomas (NCT03632135). *First Author: Tulika Ranjan, Department of Neuro-Oncology, Cancer Center Southern Florida, & Tampa General Hospital, Tampa, FL*

Background: Clinical outcomes in patients with recurrent high-grade glioma (HGG) remain poor. Cancer stem cells (CSCs) have been implicated in metastasis, treatment resistance and recurrence of HHGs. We have shown in several clinical studies that anti-CSC-directed therapy selected by ChemoID assay provides benefits in many cancer types; however, this is the first report of a randomized clinical trial evaluating whether CSC-targeted cytotoxic agents selected by ChemoID assay-guided therapy improves survival in patients with recurrent HGG. **Methods:** In this parallel-group, randomized, phase-3 clinical trial, patients at 13 clinical sites in the USA with grade-III/IV recurrent glioma (2016 WHO guidelines) were randomized 1:1 to either ChemoID assay-guided therapy or physician-choice therapy, and then treated and followed until unacceptable toxic effects, hospice, or death. The primary endpoint was overall survival (OS). **Results:** Combined median follow-up was 9 months. Median OS (mOS) was 12.5 months (95% CI, 10.2-14.7) in the ChemoID assay-guided group vs 9 months (95% CI, 4.2-13.8) in the physician-choice group (log-rank $P = .010$). Risk of death was significantly lower in the ChemoID assay group (HR = 0.44; 95% CI, 0.24-0.81; $P = .008$). Median progression free survival (PFS) was 10.1 vs 3.5 months (95% CI, 4.8-15.4 vs 1.9-5.1) (HR, 0.25; 95% CI, 0.14-0.44; $P < .001$). **Conclusions:** Primary endpoint was met in this randomized clinical trial. The mOS was 3.5 months longer in the ChemoID assay-guided group vs the physician-choice group. Clinical trial information: NCT03632135. Research Sponsor: Cordgenics, LLC.

Mebendazole in recurrent glioblastoma: Results of a phase 2 randomized study. *First Author: Nandini Menon, Tata Memorial Centre, Mumbai, India*

Background: Recurrent glioblastoma (GBM) has dismal outcomes and limited treatment options. Mebendazole (MBZ) is an anti-helminthic drug with in-vivo and in-vitro activity against glioma cell lines and has been demonstrated to be well tolerated in combination with lomustine (CCNU) and temozolomide (TMZ). In this phase 2 study, we sought to determine whether the addition of MBZ to CCNU or TMZ would improve overall survival (OS) in recurrent GBM. **Methods:** Adult patients with ECOG PS 0-3, with recurrent glioblastoma who were not eligible for re-radiation, were randomized 1:1 between CCNU-MBZ (n = 44) and TMZ-MBZ (n = 44). The primary endpoint was OS at 9 months, selected to reflect the BELOB trial. A 9-month OS of 55% or more in any arm was hypothesized to warrant further evaluation and a value below 35% was too low to warrant further investigation. **Results:** At 17.4 months, 68 events for OS analysis had occurred. The 9-month overall survival was 36.6% (95%CI 22.3-51) and 45% (95%CI 29.6-59.2) in the TMZ-MBZ and CCNU-MBZ arms respectively. ECOG PS was the only independent prognostic factor impacting OS (HR-0.478 95%CI 0.268-0.851; P = 0.012). Twenty-three patients (28.6%) enrolled had an ECOG PS 2-3 with inferior outcomes (median OS-5.67, HR-2.092 95%CI 1.175-3.731). Analysis restricted to ECOG PS 0-1 (n = 65) patients revealed a 9-month OS of 39.6% (95% CI 22.4-56.3) and 57.9% (95% CI 38.7-73) in TMZ-MBZ and CCNU-MBZ arms respectively. Grade 3-5 adverse events were seen in 8 (18.6%; n = 43) and 4 (9.5%; n = 42) patients in the TMZ-MBZ and CCNU-MBZ arms respectively. **Conclusions:** The addition of MBZ to TMZ or CCNU failed to achieve the pre-set benchmark of 55% 9-month OS. This was probably due to 28.6% of patients with poor PS of 2-3. In patients with ECOG PS 0-1, CCNU-MBZ had a 9 month OS of 57.9% and needs to be evaluated further. Clinical trial information: CTRI/2018/01/011542. Research Sponsor: Brain Tumor Foundation (BTF) of India, the Indian Cooperative Oncology Network (ICON) and the India Cancer Research Consortium (ICRC) under ICMR (Indian Council of Medical Research).

2030 **Poster Session**

Phase 2 trial of bavituximab with chemoradiation and adjuvant temozolomide in newly diagnosed glioblastoma. *First Author: Ina Ly, Massachusetts General Hospital, Boston, MA*

Background: Glioblastoma (GBM) and tumor endothelial cells express phosphatidylserine (PS), a highly immunosuppressive membrane phospholipid. PS receptors engage with immune cells, leading to expansion of myeloid-derived suppressor cells (MDSCs) which promote an immunosuppressive and pro-angiogenic tumor microenvironment. Bavituximab (BAV) – a chimeric monoclonal antibody – binds to β2-glycoprotein 1 (β2-GP1) to form a complex of β2-GP1 with PS, resulting in immune activation against tumor cells and anti-angiogenic effects. Pre-clinical data in GBM models suggest synergistic effects of PS blockade, radiation (RT), and temozolomide (TMZ). Here, we present results from a phase II trial (NCT03139916) of BAV, RT and TMZ in GBM patients. **Methods:** 33 adults with newly diagnosed IDH-wild-type GBM were enrolled and received 6 weeks of RT+TMZ, followed by 6 cycles of TMZ. BAV (3 mg/kg) was given weekly, starting at week 1 of RT+TMZ, for 18 weeks with the option to continue if tolerated. The primary endpoint was the proportion of patients alive at 12 months (OS-12). The null hypothesis would be rejected if OS-12 was ≥ 72%. As an exploratory endpoint, the immune profile in tumor tissue and peripheral blood mononuclear cells (PBMCs) was assessed using nanoString and multispectral immunofluorescence, with the goal to assess on-target effects of BAV in longer vs. shorter surviving patients (split based on median survival). Relative cerebral blood flow (rCBF) from dynamic susceptibility contrast MRI was also obtained. **Results:** 24 patients were alive at 12 months and OS-12 was 73% (95% CI 59-90%) so the study met its primary endpoint. Median OS was 15.4 months. As best response, 79% of patients had stable disease, 12% had a partial response and 9% had progressive disease. Eight grade 3 or 4 adverse events were seen (no grade 5 AEs). Ten pre-treatment and 7 post-treatment tissue samples were available. Analysis of RNA from pre-treatment tumor specimens showed a significantly positive shift in myeloid-related gene expression in patients with longer survival, with enrichment of 116 and 120 transcripts as well as downregulation of 2 and 1 gene for PFS and OS, respectively. There was no differential expression in PBMCs. Including all tissue samples, there was a marked reduction of MDSCs after BAV compared to time of diagnosis (p = 0.011). Decreased rCBF post-RT/pre-cycle 1 TMZ was associated with improved OS (HR 4.63, p = 0.029). **Conclusions:** OS-12 was 73%, meeting the primary endpoint and suggesting potential activity of BAV in newly diagnosed GBM. BAV leads to on-target depletion of intratumoral immunosuppressive MDSCs and anti-angiogenic effects. As expected, based on the mechanism of action of BAV, there was no difference in PBMC gene expression profile in patients with long and short survival. Combining BAV with immune checkpoint inhibitors in the future may augment tumor immune response. Clinical trial information: NCT03139916. Research Sponsor: NCCN.

2031 **Poster Session**

Clinical application of a functional 3D ex vivo test to predict therapeutic response in patients with HGG: A progression-free survival analysis. *First Author: Lindsay J Lipinski, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: High grade gliomas (HGG) including glioblastoma (GBM) are among the most aggressive brain cancers, with patients exhibiting highly variable treatment responses in both newly diagnosed (ND) and recurrent disease. Temozolomide (TMZ) + radiation therapy is the guideline directed standard of care (SOC) in the ND setting; it has remained relatively unchanged for > 15 years, despite variable patient responses. Current available biomarkers do not inform personalized therapy. Functional drug response testing using patient specific tumor cells may have the potential to inform effective therapy selection, thus advancing functional precision oncology. Progression free survival (PFS) is a meaningful surrogate to overall survival (OS) in GBM and therefore, represents a measure of clinical benefit. **Methods:** The 3D-PREDICT clinical study (NCT03561207) allows enrollment of HGG patients with ECOG ≤ 3, perhaps representing a more accurate real-world population compared to most clinical studies in the same patient cohort. Tumor tissue was prospectively collected during SOC biopsy/resection and analyzed in an *ex vivo* cell culture test using a panel of agents prescribed as HGG therapeutics. **Results:** Data pertain to 56 3D-PREDICT patients who had > 6 months of follow up as of December 31, 2021 or experienced progression/death < 6 months post tissue collection. There were 42 3D-PREDICT patients who had *IDH* wild type ND GBM and received SOC. PFS analysis of these patients showed 3D *ex vivo* testing was able to prospectively predict TMZ clinical responders vs. non-responders (Kaplan-Meier, p = 0.039; HR 0.516, 95% CI 0.234,1.137). Test predicted TMZ responders had a relative PFS advantage of 3.7 months. Of the 42 patients, 38 had known *MGMT* methylation status with 23 patients (60%) being unmethylated. Test predicted responders (9) included unmethylated patients; test predicted non-responders (33) included methylated patients. The data suggest *ex vivo* testing of patient specific tumor tissue may identify ND HGG patients *a priori* who respond to TMZ, irrespective of *MGMT* methylation status. Beyond TMZ response prediction, the test assesses tissue response to 11 additional known HGG therapies and therefore may provide a tool to inform potential alternative treatments to TMZ for ND patients. Also evaluated were 14 3D-PREDICT recurrent HGG patients who received test directed salvage therapy; mean PFS after tissue collection from re-resection was 9.0 months (range 2.3 – 24.7 mo) for 9 patients at first recurrence, and 5.7 months (range 1.8 – 11.4 mo) for 5 patients with 2 to 6 recurrences. These examples demonstrate initial test utilization informing salvage therapy selection, correlated with PFS improvements in recurrent HGG. **Conclusions:** This functional 3D *ex vivo* cell culture platform provided survival benefit in analyzed ND and recurrent cohorts. Clinical trial information: NCT03561207. Research Sponsor: None.

2032 **Poster Session**

Investigating the impact of NGS data availability on clinical decision-making in brain cancer. *First Author: Adam Eckburg, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Next-generation sequencing (NGS) of cancer specimens is a valuable diagnostic tool that can provide detailed information regarding specific somatic genetic alterations within a tumor with potential for targeted treatment. Despite the increasing availability of NGS, preliminary data by John et al. from ASCO 2021 suggested that clinical decision making is not frequently impacted by NGS results in the setting of glioblastoma. Herein, we report how NGS data impacts other primary tumor types, including astrocytoma, oligodendroglioma, and various rare subtypes. **Methods:** A retrospective chart review was performed to assess the proportion of brain cancer patients receiving targeted treatment instead of standard therapeutics after NGS sequencing. Pertinent medical information was ascertained from Epic and the Electronic Data Warehouse. Targeted treatments were defined as those recommended by the Tempus report for NGS-identified potentially actionable mutations. Patients were stratified into one of three categories: astrocytoma, oligodendroglioma, or other rare subtypes (including meningioma, ependymoma, ganglioma, pleomorphic xanthoastrocytoma, atypical teratoid rhabdoid tumors, glioneuronal tumors, and CNS lymphomas). **Results:** Of 44 Astrocytoma patients with potentially actionable mutations, four (9.1%) were treated with targeted therapy in the form of Enasidenib, ONC201, Nivolumab, and Depatuxizumab, while 40 received NGS agnostic treatment. In 37 Oligodendroglioma patients, three (8.1%) were treated with either targeted Vorasidenib or Ivosidenib, while 34 were started on NGS agnostic therapies. Lastly, four (10.0%) of 40 patients with other rare primary tumor types received either Ibrutinib, Dabrafenib+Trametinib, Vigabatrin, or Vemurafenib as targeted therapy. Avastin and/or standard Temozolomide chemotherapy were the most common NGS agnostic therapies employed by clinicians across all three subclasses. **Conclusions:** Although a substantial number of potentially actionable mutations were detected by NGS, the presence of this data paired with Tempus targeted recommendations rarely impacted clinician decision-making, ranging from 8.1-10.0% of the time. Despite the availability of resources to prescribe targeted treatment, providers consistently chose NGS agnostic therapies instead. Utilization of targeted treatment may become more frequent over time, as more novel agents come to market and their efficacy is further elucidated. Research Sponsor: None.

2033 **Poster Session**

A phase I clinical trial on intracranial administration of autologous myeloid dendritic cells (myDC) in combination with ipilimumab and nivolumab in patients with recurrent glioblastoma (rGB). *First Author: Julia Katharina Schwarze, Department of Medical Oncology, Vrije Universiteit Brussel (VUB)/ Universitair Ziekenhuis Brussel (UZ Brussel), Brussels, Belgium*

Background: Intracerebral administration of ipilimumab (IPI) and nivolumab (NIVO) following resection of rGB was demonstrated to be safe and resulted in encouraging survival (Duerinck, Schwarze et al. JITC 2021; Neyns et al. ESMO 2021). CD1c(BDCA-1)$^+$ and CD141(BDCA-3)$^+$ myDC play a pivotal role in initiating an adaptive anti-tumor immune response by re-licensing cytotoxic T lymphocytes within the tumor microenvironment. **Methods:** Eligible patients (pts)(diagnosed with rGB following radiation and temozolomide treatment; not in need of steroids) underwent a leukapheresis followed by immunomagnetic bead isolation and cryopreservation of CD1c (BDCA-1)$^+$ / CD141(BDCA-3)$^+$ myDC. At the time of surgery, an escalating number of myDC (1, 10, and 20x10^6 myDC) were injected into the brain tissue lining the resection cavity following maximal safe resection of the rGB (ICer) or injected intratumorally (ITum) following stereotactic biopsy (STx). IPI (5 mg) plus NIVO (10 mg) were co-injected with myDC. NIVO was administered intracavitary (ICav, 10mg) using an Ommaya port and intravenously (IV, 10mg) Q2w (max 12x). **Results:** Fourteen pts (9 male; median 48y [range 20-78]) were recruited (resection n = 11; STx n = 2) and underwent a successful leukapheresis and isolation of myDC; peroperative administration of myDC was preceded by resection in 10 pts (1 pt did not undergo surgery due to clinical deterioration/cerebral edema), and by STx in 2 pts. Respectively 6 (incl both pts who underwent a STx), 3, and 4 pts were treated at the 3 dose levels. All pts received ITum/ICer/IV-administrations of IPI and NIVO as planned. Median number of postoperative ICav/IV NIVO-administrations was 7 (range 2-11). Most frequent adverse events (AE) were headache (n = 11), fatigue (n = 9), transient dysphasia (n = 6), and nausea (n = 5). Bacterial colonization of the Ommaya occurred in 3 pts necessitating removal. Immune-related AE were infrequent and mild. No G5 AE occurred. No dose-limiting toxicities were seen with increasing numbers of myDC. After a median follow-up of 54w, 3 pts remain progression-free (after 42+, 51+, 54+ weeks of FU), 6 (46%) pts have died; median PFS is 13w (95% CI 0-26), median OS has not been reached; 6-months PFS- and OS-rate are respectively 30% and 84%, 12-months PFS- and OS-rate are respectively 23% and 51%. OS compares favorably to an historical cohort of Belgian rGB patients (n = 469; Log-Rank p = 0.018). Gene expression profiling of resected tissue, analysis of cellular counts, cytokines, NIVO/IPI-concentrations in on-treatment cerebrospinal fluid samples is ongoing. **Conclusions:** Intracranial administration of autologous myDC plus IPI and NIVO in combination with IV NIVO was found to be feasible, sufficiently safe and associated with encouraging survival justifying further investigation in pts with resectable rGB. Clinical trial information: NCT03233152. Research Sponsor: Kom op tegen Kanker.

EO2401, a novel microbiome-derived therapeutic vaccine for patients with recurrent glioblastoma: ROSALIE study. *First Author: Wolfgang Wick, Universitätsklinikum Heidelberg and German Cancer Research Center, Heidelberg, Germany*

Background: EO2401 (EO) was designed to activate existing commensal memory T-cells cross-reacting with tumor associated antigens (TAAs). EO includes microbial-derived, synthetically produced peptides corresponding to HLA-A2 restricted epitopes with molecular mimicry to three TAAs upregulated in glioblastoma (GB), IL13Rα*2*, BIRC5 and FOXM1, with the CD4 helper peptide UCP2 and the adjuvant Montanide. Pre-clinically EO generates strong immune responses and cross-reactive CD8 cells recognizing the TAAs. **Methods:** This ongoing Ph 1/2 trial (NCT04116658) investigates EO (SC q2 wks X 4 then q4 wks), EO with nivolumab (3 mg/kg q2 wks; EN), and EN with bevacizumab (10 mg/kg q2 wks; ENB) among four Cohorts (Cs) of pts with GB at first progression after radiotherapy/temozolomide. After the Ph 1 of EO followed by EN (C1), C2 investigated EN without (C2a) or with (C2b) surgery while C3 investigated ENB (population as C2a). **Results:** Among 40 treated pts (C1 n = 3, C2a n = 23, C2b n = 3, C3 n = 11), median age was 60, 53% male, 40% had KPS 90-100% and 35% had O6-methylguanine DNA-methyltransferase promotor hypermethylated tumors. All evaluable pts demonstrated strong CD8 T-cell ELISPOT responses against the 3 vaccine peptides, with tetramer staining of specific CD8 detected in 24/25 investigated pts after in vitro stimulation and in 19/20 pts directly ex vivo. Cross-reactivity against targeted TAAs was confirmed in 20/21 pts. Majority of response were detected by week 4 after 1st dose and as early as 2 weeks for some pts. EO, EN, and ENB were well tolerated (max exposure EN 68 wks, ENB 30 wks) with EO associated toxicity limited to local administration site reactions (48%; grade 1-2). The frequency and severity of nivolumab- or bevacizumab-associated AEs was consistent with historical monocompound experience. With a median follow-up of 9.3 months (range, 2.8-15.6), median progression-free survival (PFS), survival at 6 months (OS-6) and at 12 months for EN (C1+C2a+C2b) were 1.8 months (3 ongoing at 5.9, 7.1, and 14.7 months), 85%, and 50.1% (19/29 alive), respectively. With a median follow-up of 3.7 months (range, 2.2-7.2), pts on ENB (C3) have median PFS and OS-6 of 5.5 months (7 ongoing), and 80% (10/11 alive), respectively. ORR for EN and ENB were 10% and 36%, respectively (5 of 7 ongoing). In C2a, 12/23 pts stopped treatment due to neurological symptoms and PD on first MRI (median 5 wks, range 2-8). In C3 (ENB), only 1/11 pts stopped early due to PD. **Conclusions:** EO2401 generated strong systemic immune responses and was well tolerated in combination with nivolumab +/- bevacizumab. The addition of bevacizumab to EN improved PFS while survival across treatment cohorts is pending ongoing follow-up. To prolong EN exposure that is likely required for therapeutic activity in recurrent GB, the trial has been expanded with additional pts to evaluate low-dose bevacizumab (5 mg/kg q2 wks up to x 6) for early progressive neurological symptoms. Clinical trial information: NCT04116658. Research Sponsor: Enterome.

2035 **Poster Session**

Multicenter phase 2 trial of the PARP inhibitor (PARPi) olaparib in recurrent IDH1 and IDH2-mutant contrast-enhancing glioma. *First Author: Kristina Fanucci, Yale Cancer Center, New Haven, CT*

Background: Isocitrate dehydrogenase (*IDH*) *1* and *IDH2* mutations (*IDH1/2*mt) are the most common mutations in gliomas, occurring in over 70% of low grade and 20% of higher grade gliomas. *IDH1/2*mts are associated with improved prognosis, although tumors typically recur and progress to a higher grade despite first lines of treatment. Recent preclinical studies have suggested *IDH*mt and accumulation of 2-HG confer a "BRCAness" phenotype, a vulnerability that can be targeted through PARPi. To test this hypothesis, we conducted a multicenter study of olaparib monotherapy in patients (pts) with *IDH1/2*mt gliomas that had progressed despite standard therapy. **Methods:** Eligible pts had contrast enhancing and biopsy confirmed *IDH1/2*mt glioma that progressed despite standard therapy. Pts with prior treatment with PARPi or *IDH*mt inhibitors were excluded. The primary endpoint was overall response rate (ORR). Secondary objectives were progression free survival (PFS), overall survival (OS) and duration of response (DR). Olaparib 300 mg orally twice daily was given. A standard Simon 2 stage design was used. Stage 1 included 15 pts. If 2/15 pts responded stage 2 would expand by 30 pts. Responses were assessed with RANO criteria and reviewed centrally. **Results:** 15 evaluable pts were enrolled. Most recent histology as per 2021 WHO classification was 12 astrocytoma (4 grade 2, 3 grade 3, 5 grade 4) and 3 oligodendroglioma (2 grade 2, 1 grade 3). A total of 13 pts' tumors had *IDH1* R132H mutations; 2 pts had *IDH2*mt (R172G, R172K). All pts had >1 and 10 pts had >2 prior lines of systemic therapy (median 2, range 1-4). Most toxicities were grade 1 or 2. Nausea (67%) and fatigue (47%) were most frequent. Grade 3 lymphopenia, thrombocytopenia, and hypertension were seen in 1 patient each. Best response was stable disease (SD) in 9 pts and 6 pts had disease progression (PD). The median PFS was 3.6 months, 6-month PFS rate 26.7%, median OS 13.2 months. For pts with SD, median PFS was 5.5 months; 4 pts had SD for > 6 months. 2/6 pts with PD had confirmed WHO grade 4 by histology; 4 had *CDKN2A* deletion. *CDKN2A* deletion was unknown for 2 pts. **Conclusions:** Olaparib was well tolerated in this pt population. The study did not meet the pre-specified response-based threshold for moving to step 2, but prolonged SD was observed in pts with grades 2 and 3 histologies, suggesting olaparib monotherapy could be of clinical benefit in select pts. Grade 4 tumors per the 2021 WHO classification defined by histology or *CDKN2A* mutation derived minimal to no benefit from this drug highlighting the usefulness of this new classification for future patient stratification and trial design and suggesting investigation of this treatment earlier in the disease course might be of interest. Further studies are needed to identify other molecular or clinical predictive markers of benefit from PARPi as well as novel drug combinations for improved efficacy in this population. Clinical trial information: NCT03212274. Research Sponsor: CTEP (1UM1CA186689), the Catherine Ivy Foundation and the Rising Tide Foundation.

2036 **Poster Session**

A phase II, multicenter, single-arm trial of eribulin in patients with bevacizumab-resistant recurrent glioblastoma. *First Author: Masamichi Takahashi, Department of Neurosurgery and Neuro-Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: Glioblastoma (GBM) is one of the worst prognostic cancers and there is no effective treatment after failure of bevacizumab. Eribulin is a microtubule inhibitor used for the treatment of patients with metastatic breast cancer and liposarcoma. We previously reported that eribulin strongly inhibits the RNA-dependent RNA polymerase (RdRP) activity of TERT protein in cancer cells, and has a strong anti-tumor effect against GBM cells with TERT promoter mutation. In this study we aim to investigate the efficacy and safety of eribulin in patients with bevacizumab-resistant recurrent GBM. **Methods:** This is an open-label, multicenter, single-arm phase II trial. Eligible patients aged 20-75 years with bevacizumab-resistant recurrent GBM were enrolled from 2018-2020. Patients received eribulin 1.4 mg/m^2 on days 1 and 8 of 21-day cycle until disease progression or intolerable toxicity was observed. The primary endpoint was one-year overall survival rate (1yOS%). The 35 patients are needed to achieve an 80% power at a one-sided alpha of 10%, under threshold 1yOS% of 10% and expected 1yOS% of 25%. **Results:** Thirty-seven patients aged 26-73 (median: 54) years were treated. Twenty-six of 37 (70.3%) patients were diagnosed as IDH-wildtype GBM, 4 (10.8%) were with IDH-mutant GBM and 7 (18.9%) were GBM, NOS. Thirty-four (91.9%) patients had a Karnofsky performance status of 70 or 80 at the registration. Thirty-one (83.8%) patients received additional treatments, including 28 (75.7%) bevacizumab, 11 (29.7%) re-irradiation and 3 (8.1%) resection after failure of eribulin. Among 37 subjects, 32 surgical specimens were analyzed for TERT promoter mutation and 15 for RdRP activity. 1yOS% was 29.7% [80% CI: 20.5 to 39.5 ($p < 0.0001$), 95% CI: 16.1 to 44.6]. Median OS was 9.0 months [95% CI: 6.2 to 11.0] and median progression-free survival was 1.5 months [95% CI: 1.4 to 1.7]. Neither TERT nor RdRP statuses was associated with prolonged OS. Among all the target lesions evaluated, two lesions decreased more than 50% in size and the patients survived more than one year, however no obvious PR was confirmed at the final evaluation. The disease control rate was 25.7% [95% CI: 12.5 to 43.3]. Common ≥ grade 2 AEs were neutropenia (70.3%), leukopenia (56.8%), lymphopenia (27.0%), elevation of γ-GTP (13.5%), elevation of ALT (10.8%), elevation of AST (8.1%), alopecia (8.1%). Treatment-related grade 3 or 4 AEs occurred in 59.5% of subjects. There were no AEs leading to death. **Conclusions:** Eribulin was safely applied for the patients with recurrent GBM. This phase II study met its primary endpoint of 1yOS%, although no obvious response was observed. Further investigation to reveal the biomarkers related to longer survival is underway. Clinical trial information: UMIN000030359. Research Sponsor: Japan Agency for Medical Research and Development (AMED).

2037 **Poster Session**

Final data from the phase 2a single-arm trial of SurVaxM for newly diagnosed glioblastoma. *First Author: Michael J Ciesielski, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Newly diagnosed glioblastoma (nGBM) routinely treated with surgery, radiation, and temozolomide (TMZ), still result in early progression and near-universal lethality within 5 years. Tumor associated "survivin" is expressed in >95% of nGBM and targetable by SurVaxM immunotherapy. Results from the recently completed multi-center phase 2a trial of SurVaxM in nGBM are presented. **Methods:** nGBM patients (pts) were enrolled at 5 trial sites. Eligibility criteria included: age ≥ 18, Karnofsky performance status ≥70, IHC confirmation of survivin expression, expression of HLA-A*02, A*03, A*11 or A*24 MHC-I alleles and residual contrast enhancement of ≤1 cm^3 by MRI within 72h post-resection. Pts received standard TMZ chemoradiation followed by initiation of 4 priming doses of SurVaxM (500 mcg in emulsion with Montanide ISA 51, every 2 weeks) with 100 mcg sargramostim. Maintenance doses of SurVaxM-Montanide plus sargramostim were thereafter administered every 12 weeks. Adjuvant TMZ was administered for at least 6 cycles, after at least the first dose of SurVaxM and beginning no sooner than 28 days after completion of chemoradiation. Pts were monitored by MRI every 8 weeks, and progression was assessed using modified RANO criteria. The primary endpoint was 70% progression free survival (PFS) at 6 mos. Primary analyses of median PFS (mPFS) and median overall survival (OS) were measured from first immunization. Safety, tolerability, and immune responsiveness were also determined. **Results:** 63 pts with nGBM were enrolled, comprised of 38 males and 25 females with a median age of 60 years. The cohort was consistent with the 4 commonly observed primary molecular GBM subtypes (classical, mesenchymal, neural and proneural). SurVaxM was well tolerated, with no serious adverse events. A strong positive correlation, accounting for censoring, was observed between PFS and OS of all pts (r = 0.79; 95% CI (0.66,0.87)). SurVaxM was immunogenic and produced survivin-specific CD8+ T-cells and antibody (IgG) titers in both methylated and unmethylated MGMT pts and both groups showed clinical benefit. **Conclusions:** SurVaxM appeared to be safe and well-tolerated in pts with nGBM. SurVaxM was effective at stimulating survivin-specific immune responses and the primary endpoint was met. SurVaxM represents a promising therapy for nGBM, including for those pts with unmethylated MGMT genes. For pts treated with SurVaxM, PFS may be an acceptable surrogate for OS. Clinical trial information: NCT02455557. Research Sponsor: MimiVax, Other Foundation.

Multiparametric analysis in GBM plasma extracellular vesicles (Evs) and surface marker expression profile. *First Author: Abudumijiti (Zack) Aibaidula, Department of Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic Graduate School of Biomedical Sciences, Mayo Clinic, Rochester, MN*

Background: Glioblastoma (GBM) is the most common malignant brain tumor with poor clinical prognosis. Management of GBM is hampered by the lack of an accurate test that can be used for differential diagnosis of tumor progression from inflammatory pseudoprogression. Plasma extracellular vesicles (EVs) has been shown to be a promising source for biomarker identification. In this project, we aimed to identify GBM plasma EV markers that could serve as the basis of a liquid biopsy. **Methods:** Sample preparation, assay controls and instrument calibration were performed following MIFlowCyt-EV guideline. Plasma samples were subjected to 2-step centrifugations to remove cell debris and platelets. 10ul of plasma sample was diluted with 90ul filtered PBS, then stained for EV surface markers including CD9, CD31, CD45, CD41a and CD11b, as well as actin phalloidin. Stained plasma samples were purified using IZON qEV1/70nm column, then EV fractions were analyzed using full spectrum Cytek Aurora flow cytometer. Clustering analysis was performed on EV events (CD9 +/ actin phalloidin -) using t-SNE and FlowSOM extensions from FlowJo plugins. **Results:** Compared to normal donors, GBM plasma EVs were bigger in size (higher SSC value) and expressed higher levels of CD9, CD31, CD45 and CD11b while ND plasma EVs had higher CD41a expression. t-SNE and FlowSOM analysis demonstrated that GBM plasma EVs had a unique surface marker expression profile compared to ND EVs. It also showed 10 EV sub-populations that differed in size as well as various surface marker expression levels. Four of these subpopulations were enriched in GBM EVs, while three of these were enriched in ND EVs. **Conclusions:** This multiparametric analysis revealed that GBM plasma EVs had a unique surface marker expression profile compared to ND plasma EVs. Further separation and molecular profiling analysis based on each sub population could reveal EV biomarkers that are unique to each sample population. Convection-delivered adenoviral gene therapy reprograms the immunosuppressive glioblastoma microenvironment. *First Author: Jacob S Young, Department of Neurosurgery & Division of Neuro-Oncology, University of San Francisco, San Francisco, CA*

Background: Immune checkpoint inhibition has not improved outcomes for glioblastoma patients, and single- cell approaches reveal the glioblastoma microenvironment is largely comprised of immunosuppressive cells. We hypothesized intratumor convection enhanced delivery (CED) of adenoviral gene therapy could recruit and activate anti-tumor immune cells in the glioblastoma microenvironment. **Methods:** Syngeneic GL261 (3x105 cells/mouse) or SB28 glioblastoma (3 x 10^4) cells were implanted into the frontal lobe of immunocompetent C57BL/6J mice (18 mice/arm). Intracranial bioluminescence (BLI) and body weight (BW) measurements were used to assess glioblastoma growth and treatment toxicity, respectively. After tumor engraftment, glioblastomas were treated with conformal ionizing radiation mimicking stereotactic radiosurgery (SRS) in human patients as a positive control for tumor inhibition (18Gy/1Fx). Attenuated adeno-associated virus 9 (AAV9) vectors encoding *Gfp* as a negative control, or encoding experimental cytokines driving recruitment and activation of anti-tumor immune cells in other intracranial tumors (*Ccl4*, *Il1b*, or *Apoa1*) were delivered using CED (2x1011 vg/mouse). Glioblastomas were collected for histologic, single-cell, and molecular analyses 5 days after treatment (6 mice/arm) and at endpoints after monitoring for survival (12 mice/arm). CED targeting was validated using AAV9-GFP and confocal microscopy. Treatment responses were assessed using H&E, IHC, multiplexed cytokine assays, and single cell mass cytometry (CyTOF) to define immune cell types in the glioblastoma microenvironment. **Results:** Histologic analyses revealed AAV9-CCL4, AAV9-IL1B, or SRS induced glioblastoma macrophage infiltration, and AAV9-IL1B, AAV9-APOA1, or SRS induced glioblastoma T cell infiltration. AAV9-APOA1 (18.5 days versus 15 days, $p < 0.001$) or AAV9-IL1B (16.5 days versus 15 days, $p = 0.001$) CED treatments prolonged median survival from SB28 allografts. Glioblastoma cytokine analysis revealed inhibition of pro-tumor cytokines (IL6, LIF) after experimental CED treatments. Systemic cytokines were minimally changed by CED treatments. CyTOF showed decreased immunosuppressive macrophage infiltration and increased CD8+ T cell or microglia infiltration of the glioblastoma microenvironment after experimental CED treatments. There was no evidence of systemic or central toxicity in any treatment condition. **Conclusions:** Convection-enhanced delivered of adenoviral gene therapy reprograms the glioblastoma immune microenvironment and improves survival in an immunologically "cold" syngeneic glioblastoma model. Research Sponsor: Neurosurgery Research and Education Foundation.

2040 **Poster Session**

Harnessing genetically engineered hematopoietic progenitor cells to redirect the tumor immune microenvironment against glioblastoma (TEM-GBM Study). *First Author: Marica Eoli, Neuro-Oncology Unit-Istituto Neurologico Carlo Besta-Milano, Milan, Italy*

Background: Immunotherapies represent powerful tools that are transforming the treatment of many cancers. However, immune dysfunction in cancer is multifactorial requiring multiple points of action, especially in immunologically-cold tumors. **Methods:** We have developed a genetically modified, autologous hematopoietic stem cell-based platform designed to deliver Interferon-alpha (IFNa) specifically into the tumor microenvironment through Tie-2 expressing monocytes (Temferon), in order to activate the immune system in an agnostic way against the tumor and re-establish immunosurveillance. **Results:** As of Jan 2022, 3 escalating doses of Temferon (from 0.5 to $2.0x10^6$/kg) were tested across 15 patients assigned to 5 cohorts affected by newly diagnosed, unmethylated MGMT glioblastoma (GBM). The follow-up range from surgery is 5 – 27 mo (3 – 24 mo after Temferon). In all patients, we observed rapid engraftment of gene modified progenitors and fast recovery from sub-myeloablative conditioning (median engraftment across all the cohorts: Neu D+13, PLT D+14). Temferon-derived differentiated cells, as determined by the presence of vector genomes in the DNA, were found at increasing proportions in blood and bone marrow, reaching up to 30% at 1 mo for the highest dose cohorts tested and persisting up to 18 mo, albeit at lower levels. Despite the significant proportion of engineered cells, only very low median concentrations of IFNα were detected in the plasma (D+30, 5.9; D+90, 8.8pg/mL) and in the CSF (D+30, 1.5; D+90, 2.4pg/mL), indicating tight regulation of vector expression. SAEs were mostly attributed to conditioning chemotherapy (e.g. infections) or disease progression (e.g. seizures). 1 SUSAR (persistent GGT elevation) has occurred. Median OS is 14 mo from surgery (10 mo post Temferon). A patient from cohort 3, had at D+120 disease progression with two distant enhancing lesions, and increased tumor necrosis. One year following Temferon, with no 2nd line therapy added, there was approximately 40% reduction in enhancing tumor volume compared to D+180. Four pts from the low dose cohorts underwent 2nd surgery. Vector genomes were detectable in tumor biopsies. Single cell RNA seq performed on CD45+ cells purified from the GBM TME highlighted the presence of an Interferon gene signature in all patients, resulting in macrophage repolarization in some of them. **Conclusions:** Our interim results show that Temferon is well tolerated, with no dose limiting toxicities identified to date. The results provide initial evidence of Temferon's potential to modulate the TME of GBM patients. Clinical trial information: NCT03866109. Research Sponsor: Genenta Science.

2041 **Poster Session**

Population-based retrospective analysis of response assessment criteria in patients with glioblastoma. *First Author: Parandoush Abbasian, Medical Physics, Physics and Astronomy, University of Manitoba, Winnipeg, MB, Canada*

Background: Patients with glioblastoma are often treated with radiation and chemotherapy following surgery. Disease recurrence often occurs early in the disease course and during initial therapy, yet assessment of treatment response with MRI is highly variable in some situations. We sought to describe the clinical and imaging assessment and outcomes of an unselected cohort of patients with glioblastoma following the publication of the Response Assessment in Neuro-Oncology criteria. **Methods:** Patients diagnosed with glioblastoma in Manitoba, Canada, from 2012-2018 were identified from the Manitoba Cancer Registry. Chart review was performed to identify treatments given and decisions made by the treating team, and imaging analysis was performed to assess based on RANO and mRANO criteria. Determination of progression versus pseudoprogression according to these criteria was performed using clinical decision-making and review of follow-up imaging for confirmation. At time of the response assessment visit, patients were assessed by a primary oncologist (Radiation or Medical) and were also discussed at multidisciplinary Case Conference (comprised of Medical and Radiation Oncology, Neurosurgery, Neuropathology, and Neuroradiology). Treatment decisions were made with patient and primary oncologist, guided by input from the Case Conference. Tumour measurements were performed both in 2D using Product of Perpendicular Diameter analysis (PPD) and 3D volumetric measurements with/without necrotic region. Overall Survival (OS) and Progression Free Survival (PFS) were estimated to evaluate the effectiveness of response assessments and Kaplan-Meier method was used to compare the time to progression resulted from RANO, mRANO, and clinical impression. **Results:** A total of 285 patients were identified with a pathological diagnosis of glioblastoma. Of those, 199 (35% male, 65% female) were treated with concurrent temozolomide and radiation (75% 60Gy and 25% < 60Gy), and more than 90% went on to receive adjuvant temozolomide. Median Overall Survival of the 199 was 13.2 months. Of those treated with concurrent therapy, 122 (61%) had MRI studies with equivocal results within the first 6 months, with confirmatory MRI showing true progression in 73 (59.8%), pseudoprogression in 45 (36.9%), and 4 patients with undetermined outcome. Formal RANO and mRANO comparison is ongoing. **Conclusions:** Response assessment for patients with glioblastoma remains a frequent challenge despite the use of MRI and established response criteria, with more than half of patients having equivocal imaging changes and a high frequency of pseudoprogression. Research Sponsor: CancerCare Manitoba Foundation.

2042 **Poster Session**

A phase 2 study of trametinib for patients with pediatric glioma or plexiform neurofibroma with refractory tumor and activation of the MAPK/ERK pathway. *First Author: Sébastien Perreault, Department of Neurosciences, CHU Hopital Sainte-Justine, Montréal, QC, Canada*

Background: Pediatric low-grade gliomas (PLGG) are the most frequent brain tumors in children and the majority of PLGG have activation of the MAPK/ERK pathway. Plexiform neurofibromas (PN) are found in up to 50% of patients with neurofibromatosis type 1 (NF1). Trametinib has been used widely to treat PLGG and PN, but no clinical trial has reported its efficacy. **Methods:** This multicenter phase II trial includes patients aged ≥ 1 month to ≤ 25 years with progressing/refractory PLGG groups or PN. The primary objective was to evaluate the overall response rate after daily oral trametinib administration for eighteen 28-day cycles. **Results:** As of January 31st, 2022, 60 patients with PLGG and 45 patients with PN have been enrolled. Median age is 9.5 years (range 1.8-25.4) for PLGG and 11 years (range 0.7-19.8) for PN. Median follow-up is 18 months (range 0.1-38.1). Fifty-three patients with PLGG were evaluable. The overall response includes: 1 complete response (CR) (1.9%), 7 partial response PR (13.2%), 17 minor response MR (32.1%), 23 stable disease (SD) (43.4%) and 5 progressive disease (PD) (9.4%). Twenty-eight patients with a total of 32 PN were available for volumetric analysis. Volumetric assessment demonstrated an overall response rate of 60.7% compared to 24.1% when using RECIST 1.1 and 62.5% of PN showed a decrease of more than 20% in volume. Median volume change was a decrease of 30% (range -93.5 to 14.3). A total of 59 (69.4%) patients discontinued treatment as planned after 18 cycles and 9 (10.6%) patients had to stop trametinib due to adverse events. **Conclusions:** Response rates observed in our study suggest that trametinib is a potentially effective targeted therapy for patients with recurrent/refractory PLGG and PN. Treatment was overall well tolerated. This trial will continue to gather data on duration of response and long-term outcome for PLGG and PN treated with trametinib. Clinical trial information: NCT03363217. Research Sponsor: CIHR, Fondation des Gouverneurs de l'Espoir. Fondation des toiles.

2043 **Poster Session**

A single-institution, retrospective examination of new contrast enhancement, progression, and pseudoprogression in *IDH* mutant glioma. *First Author: Ethan A. Wetzel, UCLA, Los Angeles, CA*

Background: *IDH* mutant glioma patients are followed by MRI, where new contrast enhancement (CEnew) is a hallmark of tumor progression. Interpretation of CEnew is confounded by pseudoprogression (PsP), the appearance of CEnew that spontaneously resolves on subsequent scans. PsP has been characterized in *IDH* wildtype patients, but is poorly understood in the *IDH* mutant category. This study represents an examination of the characteristics and impacts on patient survival of CEnew in *IDH* mutant gliomas. **Methods:** Of the 724 confirmed *IDH* mutant glioma patients treated at UCLA between 1998 and 2022, 587 were included (median follow-up = 5.23 years). Patients were excluded based on these criteria: <4 MRI scans, unknown *IDH* status, and unknown WHO 2016 diagnosis. CEnew was first identified by direct review of images and confirmed by the radiology report. Any new enhancement appearing on the first post surgical MRI was not considered CEnew. CEnew was interpreted as progression after surgical resection indicating tumor or the re-initiation of chemotherapy or radiation and was considered PsP after the resolution of enhancement without new treatment initiation. Some PsP patients could have received bevacizumab. Kaplan-Meier survival analyses were used to examine overall survival differences between groups. **Results:** 327 of 587 patients developed CEnew. The incidence of CEnew was higher in Grade 4 Astrocytoma (G4 Astro) versus all other pathologies and lowest in LO ($p < 0.05$). The Enhancement Free Survival (EFS) was shortest for G4 Astro patients ($p = .002$); LO patients had the longest median EFS of 2602 days ($p = 0.002$). The development of CEnew and presence of preoperative enhancement were both found to be negative survival prognosticators in all pathologies ($p < 0.05$). From our analysis, 92 patients developed PsP and 177 developed progression. The median duration of a PsP spot was 244 days. PsP spots appeared earlier than progression spots (median 538 vs 1113 days, $p = .001$). The incidence of PsP was highest in the G4 Astro group and lowest in LO patients. Survival analysis of patients with progression versus those with PsP and progression shows PsP is associated with longer OS in the entire cohort and the LO, AO, AA, and G4 Astro groups ($p < 0.05$). 100% of PsP patients received radiation therapy (RT). The median time from the end of RT to PsP was 209 days. **Conclusions:** While CEnew in *IDH* mutant gliomas is associated with reduced OS, poorer outcome is driven by progressors. PsP represents 28% of CEnew instances, typically occurs within 1 year of RT and have superior outcome to progressors and equivalent to of patients that do not display CEnew. Research Sponsor: None.

	All	CEnew (%)	PsP (%)	Progression (%)	No CEnew (%)

Phase I study of drug-resistant immunotherapy (DRI) with gene-modified autologous $\gamma\delta$ T cells in patients with newly diagnosed glioblastoma multiforme (GBM) receiving maintenance temozolomide (TMZ). *First Author: Louis B. Nabors, University of Alabama, Birmingham, AL*

Background: $\gamma\delta$ T cells, MHC unrestricted immune cells, target NKG2D ligands differentially expressed on tumor cells. DeltEx drug resistant immunotherapy (DRI), a novel ex vivo expanded, activated $\gamma\delta$ T cell expresses MGMT, conveying TMZ resistance. NCT04165941, a phase 1 trial assessing the safety of single and multiple infusions of autologous DeltEx DRI cells presents updated safety and efficacy data. **Methods:** Adult newly diagnosed GBM patients with adequate organ function and KPS≥70% are enrolled. Cells engineered from apheresis after tumor resection were infused through a Rickham catheter placed during surgery. Cohort (C) 1, 2 and 3 receive 1, 3 and 6 doses of cells respectively on day (D) 1 of each 28-day maintenance cycle. Patients receive 1 x 10^7 $\gamma\delta$ T cells intratumorally on D1 with 150 mg/m^2 of TMZ intravenously with the Stupp regimen. Primary endpoint is safety; secondary endpoints include progression free and overall survival. Immunologic and genomic correlative analyses are being conducted. Dose limiting toxicities (DLTs) are defined as treatment related ≥ grade 3 cardiopulmonary or hepatic toxicity, grade 4 toxicity exceeding 72 hours or neurologic deterioration that exceeds 2 weeks. **Results:** 12 patients (58% male; median age 66.5 (range: 21-76); 66.7% IDH-WT, 66.7% MGMT unmethylated) were enrolled with 6 dosed (3 in C1, 3 in C2). No patients had DLTs, cytokine release syndrome (CRS), or neurotoxicity. The most common adverse events (AEs) were Grade 1/2 events including fever, leukopenia, nausea, and vomiting attributable to TMZ or radiotherapy. One subject had Grade 3 treatment related AEs of UTI, dehydration, and thrombocytopenia. Three evaluable C1 patients have PFS of 8.3, 11.9, 7.4 months and OS of 15.6, 17.7 and 9.6 months respectively. In C2, three patients have been dosed, with one patient with stable disease at 8.2 months after receiving all three doses and no DLTs. Patient recruitment continues with anticipated completion in 2022. **Conclusions:** Data demonstrates that single, repeat doses of DRI T cells have manageable toxicity with encouraging trend in PFS. Research Sponsor: In8Bio, Inc.

2045 **Poster Session**

Digital monitoring and assessments in patients with glioblastoma. *First Author: Yasaman Damestani, Karyopharm Therapeutics Inc., Newton, MA*

Background: Glioblastoma (GBM) is an aggressive primary tumor with poor prognosis and survival. Patients (pts) experience debilitating symptoms that have a negative effect on quality of life (QoL). A multidisciplinary approach is necessary to facilitate the reduction of morbidity, preserve QoL, and maximize benefits of treatment. Selinexor (SEL) is a first-in class, oral, selective inhibitor of nuclear export that blocks exportin 1 approved for use in multiple myeloma and diffuse large B-cell lymphoma and has shown activity in GBM. Digital measurements in the KING study through wearable sensors and other devices capture actionable daily data at home for improved care, symptom management, and QoL, are reported here. **Methods:** XPORT-GBM-029 (NCT04421378) is an ongoing phase 1 dose finding study followed by an open-label randomized phase 2, 5-arm trial to evaluate SEL in combination with standard therapies for newly diagnosed and recurrent GBM (n = 350): radiation+-SEL /radiation and temozolomide; radiation and temozolomide±SEL; lomustine±-SEL; bevacizumab±SEL; tumor treating field±SEL. The study is conducted at 18 sites in the US and Canada. GBM progression is assessed by standard clinical and imaging as well as QoL measurements by novel digital tools. Four parameters to determine the impact on QoL (cognitive function, lateralization, fatigue, sleep) are measured remotely by smartwatch and smartphone to continuously measure activity and sleep, and to complete a cognitive battery at baseline and before each MRI. **Results:** To date, pts wearing the smartwatch had higher compliance during the day for activity and gait measures compared to night for sleep measures. Younger pts had better compliance. Over the course of SEL treatment, changes were observed in balance (characterized by double support % and walking asymmetry) and activity level (characterized by step count and walking distance). Of the pts who participated in the cognitive battery (CANTAB) tests, 2 pts had a minor change in cognition measures including psychomotor and processing speed, episodic and spatial working memory, and executive function after 2 SEL treatment cycles. Overall, the CANTAB measures are stable, which align with the mRANO (MRI) results. The correlation between the CANTAB cognition measures and MRI data will be evaluated once more clinical data become available. Ongoing analyses will apply machine learning and statistical tools to determine potential correlations between digital and clinical data, such as physical examinations, AEs, Karnofsky scores, mRANO, NANO, KPS, and PRO QoL questionnaires. **Conclusions:** This is the first demonstration of digital measurement feasibility in a longitudinal study of pts with GBM. Digital measurements for pts with GBM could provide information on the impact of SEL-based treatment and functional outcomes in clinical trials and increase communication between clinicians and pts, thereby improving QoL and care management. Clinical trial information: NCT04421378. Research Sponsor: Karyopharm Therapeutics.

2046 **Poster Session**

Impact of *EGFR*$^{A289T/V}$ mutation on relapse pattern in glioblastoma. *First Author: Fontanilles Maxime, Cancer Centre Henri Becquerel, Rouen, France*

Background: The prediction of the relapse pattern is an important issue in glioblastoma for personalized approach. Molecular factors, such as *MGMT* promoter methylation, influence relapse in- or out-field of the initial radiotherapy volume. Recently, a recurrent mutation located at position 289 of the extracellular domain of the *epidermal growth factor receptor* (*EGFR*^{A289mut}) has been associated with a more infiltrative phenotype in glioblastoma. The primary objective of the present study was to explore the impact of *EGFR*^{A289mut} on the pattern of relapse after a chemo-radiotherapy based treatment of patients suffering from glioblastoma. **Methods:** An ancillary study from a monocentric prospective cohort of patients suffering from glioblastoma was conducted. All patients received radiotherapy and concomitant temozolomide. The population was divided into two groups according to *EGFR*^{A289} status (mutated versus wild-type). Primary endpoint was the overlap score (varying from 0 to 1) between initial irradiated tumor volume (Vinit) and relapse volume (Vr). Vinit was the initial 95% isodose of the radiotherapy and Vr was delineated using the enhanced MRI T1-weighted part of the relapse tumor. Secondary endpoints explored the impact of other *EGFR* extracellular mutations, *EGFR* amplification and *EGFRvIII* on the relapse pattern, as well as the impact of *EGFR*^{A289mut} on survival. *EGFR* alterations were identified using next-generation sequencing or droplet-digital PCR based methods on formalin-fixed paraffin-embedded samples collected at initial diagnosis. **Results:** One hundred patients were included: 11% of the population had *EGFR*^{A289mut} glioblastoma (n = 11/100). *EGFR*^{A289mut} glioblastomas had a relapse pattern more marginal compared to *EGFR*^{A289wt} glioblastomas: a mean overlap score Vinit/Vr of 0.78 was observed in the EGFR^{A289mut} group versus 0.94 in the *EGFR*^{A289wt} group (p = 0.021). The proportion of *EGFR*^{A289mut} glioblastomas in the outfield relapse (overlap score < 0.8) has a trend to be higher than in the infield relapse (overlap score > 0.8): 25% (n = 2/8) versus 9.8% (n = 9/92) for the EGFR^{A289wt} population, p = 0.21. Neither *EGFR* amplification nor *EGFRvIII* did influence overlap score Vinit/Vr. In our population, *EGFR*^{A289mut} did not influence survival. **Conclusions:** *EGFR*^{A289mut} influences the relapse pattern in a population of patients suffering from glioblastoma. The role of *EGFR*^{A289mut} as a decision-making biomarker for personalized radiotherapy should now be investigated in dedicated clinical trial. Clinical trial information: NCT02617745. Research Sponsor: Ligue Contre le Cancer Normandie.

2047 **Poster Session**

Paxalisib in patients with newly diagnosed glioblastoma with unmethylated MGMT promoter status: Final phase 2 study results. *First Author: Patrick Y. Wen, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA*

Background: Paxalisib, a potent oral selective brain-penetrant small molecule PI3K/mTOR inhibitor, has shown activity in nonclinical brain cancer models and promising phase 1 data in progressive / recurrent high-grade gliomas (NCT01547546). This multicenter phase 2 progressive design trial (NCT03522298) aimed to establish the maximum tolerated dose (MTD) for once-daily (QD) dosing, and to evaluate safety, tolerability, pharmacokinetics (PK), and clinical activity of paxalisib in patients with newly diagnosed glioblastoma and unmethylated MGMT promotor status. **Methods:** Eligible patients were males or females, aged ≥18 years, who had undergone surgical resection and chemoradiotherapy (Stupp Regimen), and were considered to be progression free before starting adjuvant paxalisib. Stage 1 used a standard 3+3 dose-escalation design to determine the MTD in this population. Stage 2 was a two-arm, open-label, expansion cohort with patients randomized 1:1 to receive paxalisib at the MTD under fed or fasted conditions. In both stages, treatment comprised daily paxalisib administered in 28-day cycles, continuously until disease progression or unacceptable toxicity. Efficacy analyses are based on investigator review and from date of diagnosis. **Results:** Patients (n = 30; 70.0% males, 83.3% white, mean age 58.5 years) had a mean time since diagnosis of 3.75 months. The majority (n = 29) received between 1 and 6 treatment cycles and one received 29 cycles. In Stage 1 (n = 9), an MTD of 60mg was established on the dose-limiting toxicities of hyperglycemia (n = 1) and stomatitis (n = 1) at 75mg. Paxalisib at 60mg was well-tolerated and adverse events were consistent with other PI3K inhibitor medicines. At the MTD (60mg), the PK profile was linear and dose-proportional with no differences in T_{max} and elimination half-life under fed and fasted conditions. For the overall ITT population, the median progression free survival was 8.4 months (RANO) and 8.6 months (mRANO) and the median overall survival was 15.7 months. In a mITT (n = 22 patients treated with 60mg daily and ≥1 post-baseline assessment), the median PFS was 9.6 months (mRANO). **Conclusions:** The primary study endpoints were met; PK and safety were consistent with prior clinical experience. The MTD showed encouraging clinical activity, prolonging PFS and improving OS. Further efficacy confirmation of paxalisib 60 mg QD in newly diagnosed glioblastoma in a pivotal trial is ongoing (GBM AGILE, NCT03970447). Clinical trial information: NCT03522298. Research Sponsor: Kazia Therapeutics Ltd.

Revolumab: A phase II trial of nivolumab in recurrent IDH-mutant high-grade gliomas. *First Author: Caroline Dehais, AP-HP, Sorbonne Université, Hôpital Pitié-Salpêtrière, Service de Neurologie 2 - Mazarin, Paris, France*

Background: Novel effective treatments are urgently needed for IDH-mutant high-grade gliomas (HGGs) recurring after radiotherapy and chemotherapy. While single-agent immune checkpoint blockade (ICB) showed limited efficacy in IDH-wildtype glioblastoma, results in IDH-mutated HGGs are not yet available. In this multicenter, single-arm, phase II trial (REVOLUMAB, NCT03925246), we assessed the efficacy of the anti-PD1 Nivolumab in recurrent IDH-mutant HGGs. **Methods:** Main eligibility criteria: adult patients with IDH-mutant HGG recurring after radiotherapy and ≥ one line of alkylating chemotherapy, KPS > 50%, less than 10mg/day prednisone equivalent. The primary endpoint was the 24-weeks progression-free survival (PFS) rate according to the RANO criteria by investigator assessment. Patients received intravenous Nivolumab 240 mg every 2 weeks for 8 cycles, followed by 480 mg every 4 weeks for a maximum duration of one year. 39 patients were planned to be enrolled based on a one-stage A'Hern's design (p0 = 30%, p1 = 50%, type I error rate = 5%, power = 80%). **Results:** Between July 2019 and June 2020, 39 patients with recurrent IDH-mutant HGG (n = 21 WHO grade 3, 13 grade 4, and 5 grade 2 tumors with MRI evidence of anaplastic transformation; n = 10 1p/19q- codeleted, 17 non-codeleted tumors) were enrolled. The median follow-up duration was 17.6 months (11.6-24). The median time since diagnosis was 4.05 years (0.39-16.72), the median time since radiotherapy was 4.47 years (0.55-12.66), the median number of previous chemotherapy lines was 2 (1-4). Eight patients completed Nivolumab treatment as planned, thirty patients stopped treatment due to tumor progression and one patient due to adverse event (AE) unrelated to study drug. At 24 weeks, 11/39 patients were alive without disease progression (28.2% CI95% [15%; 44.9%]). According to RANO, one patient (2.6%) achieved complete response (CR), 3 patients (7.7%) partial response (PR), 13 patients (33.3%) stable disease, and 22 (56.4%) had progression as their best response. Median PFS and OS were 1.84 (CI95% [1.81 ; 5.89]) and 14.7 months (CI95% [9.18; NR]), respectively. There was no difference in PFS between 1p/19q-codeleted and non-codeleted tumors. No patient definitively stopped Nivolumab due to side effects; the safety profile was consistent with prior studies of Nivolumab in gliomas and other cancers. **Conclusions:** To our knowledge, this is the first reported trial of ICB in IDH-mutant gliomas. Nivolumab failed to achieve its primary endpoint. However, Nivolumab was well tolerated and long-lasting responses were observed in a subset of this population, which support further evaluation in combination with other agents such as anti-VEGF or IDH inhibitors. This trial was funded by French Ministry of Health.The sponsor was Assistance Publique – Hôpitaux de Paris. Study drug was supplied by Bristol Myers Squibb (CA209-818). Clinical trial information: NCT03925246. Research Sponsor: PHRC-K 2016.

Prognostic value of hPG_{80} (circulating progastrin) in IDH-wild type glioblastoma treated with radio-chemotherapy. *First Author: Ludovic Doucet, Institut de Cancerologie de l'Ouest, Medical Oncology, Saint-Herblain, France*

Background: hPG_{80} (circulating progastrin) is a protein secreted by many cancer types, playing a role in tumorigenesis by regulating cancer stem cells, angiogenesis, proliferation/differentiation and decreasing apoptosis. hPG_{80} is detectable in plasma of cancer patients and previous studies have shown its prognostic role in various cancers. Given the lack of circulating biomarker in glioblastoma, we evaluated the prognostic value of plasma hPG_{80} in patients with *IDH* wild type glioblastoma **Methods:** This multicentric retrospective study included *IDHwt* glioblastoma patients treated with standard radio-chemotherapy. The ELISA DxPG80.lab kit (Biodena Care, Lausanne, Switzerland) was used to measure hPG80 levels after surgery with a detection threshold of 1 pM in all plasma EDTA samples according to the manufacturer's instruction. The prognostic impact of hPG_{80} was evaluated on patient's progression-free survival (PFS) and overall survival (OS). **Results:** We included 70 patients (38 males /32 women) with a median age of 64 years (Range 19 - 84). Karnofsky index was > 70% in 52 (91%) of 57 evaluable patients. Tumor biopsy (B), partial resection (PR), complete resection (CR) were performed in 22, 25 and 23 patients respectively. MGMT promotor was methylated in 22 (40%) of the 55 evaluable patients. After surgery, hPG_{80} was detected in 48 (69%) patients (hPG80+) with a median concentration of 9.52 pM (IQR 5.21 - 21.20). Complete surgery was associated with undetectable levels of hPG80 (52% (CR) vs 28% (PR) vs 14% (B), p = 0.006) and lower concentration if hPG80+ (CR: 5.8 pM [IQR 1.92 - 11.38] vs PR: 12.84 pM [IQR 8.09 - 37.09]; p = 0.04 vs B: 9.86 pM [IQR 4.66 - 21.63]; p = 0.16). With a median follow-up of 39 months (22.4-NR), 86% of patients had progressed and 70% had died. In univariate analysis, hPG_{80} positivity was associated with PFS (5.6m vs 8.5m, p = 0.053) and OS (14.5 vs 22m, p = 0.04) in hPG_{80}+ vs hPG_{80}- patients respectively. hPG_{80}+ patients with complete surgery had worse median OS than hPG_{80}- patients (14.5 vs 22.0 m; p = 0.051 respectively. Cox proportional hazards model did not fit for covariate analysis. **Conclusions:** Our findings show that hPG_{80} could serve as a new circulating prognostic biomarker in IDHwt glioblastoma patients treated with radio-chemotherapy. Further explorations are ongoing in larger cohorts including longitudinal evaluation during the course of the disease. Research Sponsor: None.

Radiotherapy and olaptesed pegol (NOX-A12) in partially resected or biopsy-only MGMT-unmethylated glioblastoma: Interim data from the German multicenter phase 1/2 GLORIA trial. *First Author: Frank Anton Giordano, Department of Radiation Oncology, University Hospital Bonn, Bonn, Germany*

Background: Pre-clinical studies consistently demonstrate that inhibition of the CXCL12/CXCR4/CXCR7 axis abrogates recruitment of pro-vasculogenic bone marrow-derived cells after radiotherapy (RT) of glioblastoma (GBM) and promotes T cell exclusion from the tumor microenvironment (TME). The German multicenter phase 1/2 trial GLORIA (NCT04121455) assesses safety of RT plus escalating dose levels (DL) of the CXCL12-neutralizing RNA-Spiegelmer Olaptesed pegol (OLA; NOX-A12) in patients with chemotherapy-resistant GBM. **Methods:** Until now, GLORIA enrolled 10 patients newly diagnosed with incompletely resected (n = 8) or biopsied (n = 2) GBM with ECOG≤2, age ≥18 and without MGMT promoter hypermethylation. All patients receive standard RT (60 Gy in 30 fractions or 40.05 Gy in 15 fractions) and continuous (24/7) i.v. infusions of either 200 mg (DL1; n = 3), 400 mg (DL2; n = 3) or 600 mg (DL3; n = 4) per week of OLA for 26 weeks. The primary endpoint (EP) is safety as per incidence of treatment-related adverse events (AE). Secondary EPs include radiographic response as per mRANO criteria, dynamic susceptibility contrast perfusion (DSC) and the fraction of highly-perfused tumor (FTB^{high}) as well as the apparent diffusion coefficient (ADC). Target lesions (TL) and non-target lesions (NTL, i.e. in-field satellite lesions) are analyzed separately. Tumor tissue is assessed by high-plex immunofluorescence imaging (co-detection by indexing; CODEX). Matched reference cohorts serve as controls for MRI (n = 14) and CODEX (n = 8) data. **Results:** Combination of RT and OLA was well-tolerated and safe. Of all G ≥ 2 AEs (n = 77), 3 (4%) were deemed to be solely OLA-related, including 1 grade 3 AE at DL3. There were no dose limiting toxicities and no treatment-related deaths. In total, eight of the nine patients (89%) with TLs at baseline showed a TL response during OLA therapy, with four (40%) reaching partial remission (PR) as per radiologic mRANO criteria (n = 2 at DL1 and n = 2 at DL3). All three patients treated at DL1 and all four of DL3 reached PR of one or more NTLs. In three cases (n = 2 at DL1; n = 1 at DL3), at least one NTL completely disappeared. Under OLA, radiographic responses of NTL were best at the highest DL (DL1 +49.5/DL2 +488.3/DL3 -59%), as was the increase in diffusion (mean ADC increase +46.4/+28.2/+56.7%) and the decrease in FTB^{high} (mean -33.5/-32.8/-47.7%). Matched pre-/post-surgery CODEX of a confirmed pseudoprogression revealed intralesional clusters of proliferating cytotoxic T cells. Analysis of tissue from a non-responding patient showed T-cell encapsulation by M2-polarized macrophages in an immune-cell enriched TME. Additional follow-up is ongoing. **Conclusions:** Interim data from the ongoing GLORIA trial demonstrates safety of RT plus OLA and suggests promising clinical efficacy of a new class of drugs targeting CXCL12 in GBM. Clinical trial information: NCT04121455. Research Sponsor: Noxxon Pharma AG.

2051 **Poster Session**

Comparison of survival outcomes of patients with newly diagnosed glioblastoma treated with standard chemoradiation in and outside of clinical trials. *First Author: Rifaquat Rahman, Dana-Farber/Brigham and Women's Cancer Center, Boston, MA*

Background: Randomized clinical trials use stringent eligibility criteria to select patients which can raise concerns about generalizability of study results. Recent interest in external controls and new trial designs has increasingly focused on the possible use of real-world data sources. We examined potential differences of survival outcomes in clinical trial and real-world datasets in newly diagnosed glioblastoma. **Methods:** Patient-level data from 4 independent datasets were analyzed. Non-trial data were derived from an institutional dataset of 453 patients with newly diagnosed glioblastoma treated outside of a clinical trial with standard radiation therapy with concurrent and adjuvant temozolomide at a large academic center. Trial patients included patients on the control arm of several multi-institutional trials (NCT00689221, n = 273; NCT00813943, n = 89; NCT00943826; n = 459) and patients treated on trial at our institution (n = 210). Non-trial patients were compared with each of the 4 clinical trial datasets in pairwise comparisons with Cox regression with adjustments for age, sex, extent of resection, KPS and MGMT status. **Results:** Patient-level data from 1,484 patients were analyzed. Non-trial patients were older compared to patients in the multi-institutional trials (mean 58.6 vs. 56.1 years (NCT00943826), 53.9 years (NCT00813943), 55.7 years (NCT00689221); p < = 0.001). The non-trial cohort had fewer women (43.5% vs. 35.9%, p = 0.02), greater proportion of lower KPS patients (47% KPS <90 vs. 31% KPS <90, p < 0.001) and greater proportion of MGMT methylated patients (49% vs. 33%, p < 0.001) compared to NCT00943826 patients. There were no other significant differences between patient characteristics of non-trial patients and the 4 trial datasets. Trial participation was not associated with improved survival in multivariable analysis after adjustments for clinical covariates (non-trial patients vs. each trial dataset; Table, P > 0.05). **Conclusions:** Glioblastoma patients treated on multi-institutional clinical trials that were included in our analysis did not have statistically significant differences in survival compared to patients treated outside of a clinical trial at a large academic center after adjustment for relevant variables. Our findings support the possible use of real-world data in the development of external control arms for future trials in newly diagnosed glioblastoma. Research Sponsor: Joint Center for Radiation Therapy Foundation Grant.

Clinical characteristics and outcome of a large cohort of patients with primary central nervous system (CNS) tumors and tropomyosin receptor kinase (TRK) fusion. *First Author: Audrey-Anne Lamoureux, CHU Sainte-Justine, Montréal, QC, Canada*

Background: TRK fusions are detected in less than 3% of central nervous system (CNS) tumors. Given their rarity, there are limited data on the clinical course of affected patients. **Methods:** We contacted 166 oncology centers worldwide to retrieve data on patients with TRK fusion-driven CNS tumors. Data extracted included demographics, histopathology, *TRK* gene fusion, treatment modalities and outcomes. **Results:** Ninety-two patients with TRK fusion-driven primary CNS tumors were identified including 76 pediatric patients (82.6%), 15 adults (16.3%) and 1 not specified (1.1%). Median age at diagnosis was 4.4 years (range 0.0–78.3) and 58.7 % were male. *NTRK2* gene fusions were found in 45 patients (48.9%), *NTRK1* and *NTRK3* aberrations were detected in 27 (29.3%) and 20 (21.7%), respectively. Tumor types included 56 high-grade gliomas (HGG; 60.9%), 20 low-grade gliomas (LGG; 21.7%), 4 embryonal tumors (4.3%) and 12 others (13.0%). Median follow-up was 40.5 months (range 3–226). During the course of their disease, 75 (81.5%) patients underwent surgery with a treatment intent, 67 (72.8%) patients received chemotherapy, 50 (54.3%) patients received radiation therapy, while 47 (51.1%) patients received NTRK inhibitors (6 as first line treatment). There were significant differences in the median progression-free (PFS) and overall survival (OS) between pediatric patients compared to adults. The pediatric median PFS was 32 months (95% CI: 15.5–48.5) compared to 8 months for the adult (95% CI: 4.5–11.5, p = 0.015). The pediatric median OS was 182 months (95% CI: 25.1–338.9) compared to 24 months (95% CI: 18.3–29.7 p < 0.001) for adult patients. There was no difference in the PFS of LGG compared to HGG. However, the OS was significantly worse for the HGG when compared to LGG (p = 0.039). The median OS for LGG was not reached and the median OS for HGG was 70 months (95% CI 7.5–132.5). Nineteen patients with HGG (38.0 % 19/50 evaluable patients) died compared to only one patient with LGG (5.6% 1/18 evaluable patients, p = 0.014). **Conclusions:** We report the largest cohort of patients with TRK fusion-driven primary CNS tumors. These results will help us to better understand clinical evolution and compare outcomes with ongoing clinical trials. Research Sponsor: None.

2053 **Poster Session**

Predictions of overall survival (OS) and progression-free survival (PFS) for specific therapeutic interventions in newly diagnosed glioblastoma multiforme (GBM) using Cellworks Singula: myCare-024-04. *First Author: Manmeet Singh Ahluwalia, Baptist Health South Florida, Coral Gables, FL*

Background: Comprehensive molecular profiling reveals significant differences in treatment response among GBM patients. A mechanistic multi-omics biology model allows biosimulation of molecular effects of cell signaling, drugs and radiation on patient-specific *in silico* diseased cells. The Cellworks Singula Therapy Response Index (TRI) identifies the magnitude of disease control and survival for specific anti-tumor strategies. TRI ranks the anticipated outcome of each therapy with a continuous TRI Score, 0 to 100, for each patient's unique genomic network. **Methods:** TRI's ability to predict OS and PFS was prospectively evaluated in a retrospective cohort of 270 IDH wildtype GBM patients from The Cancer Genome Atlas (TCGA) with known clinical outcomes treated with physician prescribed therapies (PPT). The median age was 57.5 years for 162 males and 108 females. There were 73 MGMT methylated with median OS deceased of 17.1 months and living of 9.5 months and median PFS of 6.5 months. There were 197 MGMT unmethylated with median OS deceased of 14.0 months and living of 13.6 months and median PFS of 6.0 months. Stratified random sampling was used to split the data into independent training (N = 153) and validation (N = 117) subjects. Multivariate Cox Proportional Hazard and Proportional Odds models were used to model OS and PFS as a function of the pre-defined Singula TRI and clinical thresholds. Cox Proportional Hazards (PH) regression and likelihood ratio (LR) tests were used on the independent validation subjects to assess the hypothesis that Singula is predictive of OS and PFS above and beyond standard clinical factors. **Results:** In the validation set, Singula TRI was significantly predictive of OS and PFS in univariate analyses and remained significantly predictive in multivariate analyses which included age, sex, MGMT methylation status and drug class. Singula TRI facilitates selection of optimal personalized therapies by providing patient-specific estimates of OS and PFS for 18 NCCN guideline GBM therapies. **Conclusions:** Cellworks Singula was strongly predictive of OS and PFS and provided predictive value beyond physician prescribed therapy, patient age, sex and MGMT methylation status. This information may be used to estimate increases in OS and PFS when comparing Singula TRI recommended therapies versus standard care. These positive results suggest the utility of biosimulation-informed therapy selection to improve survival of GBM and merits validation in prospective clinical studies. Research Sponsor: None.

Deep learning-based brain tumor segmentation on limited sequences of magnetic resonance imaging. *First Author: Jacky Huang, Stanford University-School of Medicine, Stanford, CA*

Background: Deep learning algorithms trained to segment brain tumors from magnetic resonance imaging (MRI) perform well in ideal conditions supplied by curated datasets. An example is the MICCAI BraTS 2018 dataset, which provides a set of four MRI sequences (T1, T1 post-gadolinium contrast-enhanced, T2, FLAIR) on 285 samples, along with ground truth segmentations annotated by experts. In real-world settings, however, it is not uncommon for patients to undergo MRI with a limited number of image sequence acquisitions. We examined the effect of restricting the imaging sequence set when training a deep learning model for brain tumor segmentation. Our goal was to identify a limited subset that still achieved acceptably high performance. **Methods:** In our experiments, we used the convolutional neural network-based U-Net architecture. Instead of the standard BraTS task, we focused on sub-segmenting specific areas of brain tumors: the active, enhancing tumor (AT) and the tumor core (TC; AT plus the cystic/necrotic core). We trained the architecture on 285 samples of the BraTS 2018 dataset using one or both of two sequences: T1 contrast-enhanced (T1CE) and FLAIR. Using each training model, we predicted segmentation masks given a volumetric MR image of a brain tumor on 66 samples in the held-out validation dataset. We submitted the predicted segmentations to the Center for Biomedical Image Computing and Analytics (CBICA) imaging portal for evaluation, which reports prediction accuracy by returning dice scores on each prediction. **Results:** As shown in the Table, the U-Net model using T1CE alone yielded high performances, with median dice scores of 0.84461 and 0.88267, when segmenting AT and TC, respectively. On the other hand, using FLAIR alone generated lower performances on the same tasks of segmenting the AT (0.25996) and the TC regions (0.51153). Combining T1CE and FLAIR provided no additional performance improvement compared with T1CE used as a standalone sequence. **Conclusions:** We achieved high performances in two brain tumor sub-segmentation tasks using a limited number of MRI sequences in training a deep-learning algorithm. T1CE alone produced high performances on both TC and AT segmentations. Given the ubiquity of the T1CE sequence, the ability to achieve high performance tumor segmentations in the face of limited image sequence availability is critical when applying our algorithm in real-world clinical or research settings. Research Sponsor: U.S. National Institutes of Health.

Median dice scores achieved on each segmentation task.

Segmentation type	Imaging Sequence Subset	Median Dice Score
AT	T1CE	0.84461
AT	FLAIR	0.25996
AT	T1CE + FLAIR	0.84208
TC	T1CE	0.88267
TC	FLAIR	0.51153
TC	T1CE + FLAIR	0.83766

2055 **Poster Session**

Prognostic significance of therapy-induced myelosuppression in newly diagnosed glioblastoma. *First Author: Michael Weller, Department of Neurology, University Hospital and University of Zurich, Zurich, Switzerland*

Background: Myelosuppression is the major toxicity encountered during temozolomide chemoradiotherapy for newly diagnosed glioblastoma. **Methods:** We assessed the association of myelosuppression (neutropenia, thrombocytopenia, anemia, lymphopenia) during temozolomide chemoradiotherapy alone or in combination with experimental agents with progression-free survival (PFS) or overall survival (OS) in 2073 patients with newly diagnosed glioblastoma enrolled into five clinical trials: CENTRIC, CORE, EORTC 26082, AVAglio, and EORTC 26981. A landmark analysis approached was used. For each primary association analysis, a significance level of 1.7% was used. **Results:** Lower neutrophil counts at baseline were associated with better PFS (p = 0.011) and OS (p < 0.001), independently of steroid intake. Females experienced uniformly more myelotoxicity than males. Lymphopenia during concomitant chemoradiotherapy was associated with OS (p = 0.009): low-grade (1-2) lymphopenia might be associated with superior OS (HR 0.78, 98.3% CI 0.58-1.06) whereas high-grade (3-4) lymphopenia might be associated with inferior OS (HR 1.08, 98.3% CI 0.75-1.54). There were no associations of altered hematological parameters during concomitant chemoradiotherapy with PFS. During maintenance chemoradiotherapy, no significant association was found between any parameter of myelosuppression and PFS or OS, although exploratory analysis at 5% significance level indicated that either mild-to-moderate (HR 0.76, 95% CI 0.62-0.93) or high-grade lymphopenia (HR 0.65, 95% CI 0.46-0.92) were associated with superior OS (p = 0.013), but not PFS. **Conclusions:** The association of higher neutrophil counts at baseline with inferior PFS and OS requires further prospective evaluation. The link of therapy-induced lymphopenia to better outcome may guide the design for immunotherapy trials in newly diagnosed glioblastoma. Research Sponsor: EORTC Brain Tumor Group.

Capicua (CIC) mutations in gliomas in association with MAPK activation for exposing a potential therapeutic target. *First Author: Sourat Darabi, Hoag Family Cancer Institute, Newport Beach, CA*

Background: Capicua (CIC) Gene is a tumor suppressor, transcriptional repressor, and a member of the high mobility (HMG)-box protein family. *CIC* is a negative regulator of MAPK and RTK pathways; inactivating *CIC* mutations (mut) occur in approximately 40% of oligodendrogliomas (OLIG) and less frequently in other gliomas putatively activating downstream signaling. With a goal to identify potential novel treatment options for various gliomas, we explored key signaling pathways associated with *CIC* mut. **Methods:** Consecutive glioma tumors were analyzed using Next-Gen DNA sequencing (NextSeq, 592 genes or NovaSeq, whole-exome), RNA sequencing (NovaSeq, WTS) and IHC (Caris Life Sciences, Phoenix, AZ). Immune cell fraction was calculated by QuantiSeq; MAPK activation score (MPAS) was evaluated using RNAseq data. A comparison was made using Chi^2 or Fisher's-exact test with correction for multiple-comparison (q) using Benjamini-Hochberg. **Results**: A total of 196 (3.7%) tumors with *CIC* mut were seen in 5266 gliomas tumors analyzed, with the highest prevalence seen in OLIG (143 of 285, 50.2%). There was no difference between grade 3 (73 of 142, 51.4%) and grade 2 OLIG (70 of 143, 49%). *CIC* mut were infrequent in astrocytomas (16 of 829, 1.9%; grade 3, 12/510 or 2.4%; grade 2, 4/261 or 1.5%; grade 1, 0/58). *CIC* mut were present in glioblastomas (24/2753 or 0.6%), gliosarcomas (1/128 or 0.8%), and other mixed subtypes (12/185 or 6.5%). *CIC* mut were associated with higher prevalence of *IDH1/2* mut (92% in *CIC*-mut vs. 17% in wild type), *MGMT* promoter methylation (97% vs. 47%), *FUBP1* mut (32% vs. 1%) but lower *PTEN* mut (1% vs. 25%) and *TP53* mut (12% vs. 39%) (all $q < 0.05$). Significant mutual exclusivity for *CIC* mut and MAPK pathway drivers observed: *EGFR* amplification (1.5% vs. 27%), *EGFR* mut (0.5% vs. 12.6%), *NF1 mut (4% vs. 18%) (all q < 0.05). BRAF* mut rate was similar in *CIC*-mut or wild-type (1% vs. 3%, p = ns). Although associated with a higher tumor mutation burden (cutoff > = 10 mut/MB, 13% vs. 3%), a lower prevalence of PDL1 expression (1% vs. 16%) and lower M1 macrophage infiltration were seen (all $q < 0.05$). Similar effects were seen when stratifying by oligodendroglial and astrocytic histology. *CIC* mut were associated with increased MPAS score in OLIG (p = 0.01), particularly when compared to tumors lacking additional MAPK drivers (p = 0.001). This effect was not seen in astrocytic tumors, although *EGFR* alterations (including CNA, *EGFRvIII, EGFR* fusion and mut) were independently associated with increased MPAS scores ($p < 0.001$). **Conclusions**: *CIC* mut were frequent in oligodendrogliomas but occurred rarely in other glioma tumors and are associated with favorable prognostic markers. RNA expression analysis suggests *CIC* mut is associated with MAPK activation in OLIG, as are *EGFR* alterations in astrocytomas. Targeted inhibition of this pathway in selected gliomas may be a promising therapeutic avenue and should be explored further. Research Sponsor: None.

Phase IB trial of pegylated arginine deiminase (ADI-PEG 20) plus radiotherapy and temozolomide in patients with newly diagnosed glioblastoma. *First Author: John S. Bomalaski, Polaris Pharmaceuticals Inc., San Diego, CA*

Background: ADI-PEG 20 exploits the different metabolic ability for synthesizing arginine (Arg) between normal and neoplastic cells to reduce tumor cell growth. Preclinical and clinical studies have shown that cancers which are either Arg auxotrophic, with silencing of argininosuccinate synthetase (*ASS1*), or Arg non-auxotrophic, respond to ADI-PEG 20 monotherapy or ADI-PEG 20 combined with various chemotherapies, respectively. ADI-PEG 20 has shown efficacy as monotherapy in ASS1 negative mouse glioblastoma (GBM) models and the combination of ADI-PEG 20 with temozolomide (TMZ) and with radiation (RT) in both ASS1 negative and ASS1 positive mouse GBM models. Based on these rationales, ADI-PEG 20 was added to standard RT + TMZ in patients with newly diagnosed GBM. This is the first clinical trial combining ADI-PEG 20 with RT. **Methods:** This phase IB, open-label, single-arm, standard 3+3 dose escalation with a recommended phase 2 dose (RP2D) expansion study (NCT04587830) was initiated in June 2020. Weekly ADI-PEG 20 is added to concurrent RT + TMZ and to 6 cycles of adjuvant TMZ (Stupp protocol). ADI-PEG 20 could be continued for up to 2 years. RANO criteria are used to determine response by evaluating MRI at 1, 3 and 6 months after RT, and every 3 months thereafter. Major eligibility criteria are age 20-75 years with newly diagnosed, histologically confirmed GBM with Karnofsky performance status ≥ 60. Endpoints include safety, pharmacodynamics, immunogenicity, progression free survival (PFS) and overall survival (OS). **Results:** Cohorts 1 (18 mg/m^2) and 2 (36 mg/m^2) were completed without dose limiting toxicity (DLT). Enrollment to cohort 3 (RP2D phase, 36 mg/m^2) is ongoing with 23/26 patients. The major adverse events (AEs) were fatigue (52%), constipation (39%) and neutrophil decrease (39%). Dermatologic or allergic reactions occurred in 12/23 (52%), and all were grade 1-2 except for anaphylactic shock in 1 and vasculitis/rash in 1. 22/23 are alive, with median PFS = 9.5 months. The first 6 study patients are all alive for at least 11 months, with the longest at 1.5 years. 10 are off treatment due to progressive disease in 6, severe AE in 2, consent withdrawal in 1, and medical decision in 1. Mean peripheral blood Arg levels were suppressed (< 10uM) for 4-6 weeks in most subjects, with a reciprocal elevation of citrulline levels. Anti-ADI-PEG 20 antibodies tended to increase as peripheral Arg levels increased. **Conclusions:** The addition of ADI-PEG 20 to RT + TMX was safe, and no DLT was observed. The RP2D of ADI-PEG 20 was determined to be 36mg/m^2. AEs were those typically seen with RT + TMZ, with perhaps an increase in rash reported with the addition of ADI-PEG 20. Anaphylaxis and vasculitis were seen (1 subject with each), and have been observed previously with ADI-PEG 20. The preliminary OS data are encouraging. A registration phase 2/3 trial of this triplet is being considered. Clinical trial information: NCT04587830. Research Sponsor: Polaris Pharmaceuticals, Inc.

2058 **Poster Session**

Preliminary results of a phase II study of retifanlimab (PD-1 inhibitor) plus or minus epacadostat (IDO1 inhibitor) in combination with bevacizumab and hypofractionated radiotherapy for recurrent glioblastoma: NCT03532295. *First Author: Jian Li Campian, Mayo Clinic in Rochester, Rochester, MN*

Background: Immunotherapies targeting the programmed cell death-1 (PD-1) pathway in recurrent glioblastoma (rGBM) have failed. We hypothesize that combining therapies targeting multiple immunosuppressive pathways with cytotoxic and antiangiogenic therapies will improve survival. Here, we evaluate the safety and efficacy of an anti-PD-1 monoclonal antibody (retifanlimab), hypofractionated radiotherapy (HFRT), and bevacizumab, with or without an oral IDO1 inhibitor (epacadostat), in patients with rGBM in a nonrandomized, noncomparative sequential two-arm Phase II study. **Methods:** This is an open-label Phase II study of 2 sequential cohorts (Table). Cohort A first examines retifanlimab + bevacizumab + HFRT in patients with *IDH1/2-WT* rGBM. After a toxicity monitoring period, Cohort B, which adds epacadostat, starts enrolling. Key inclusion criteria includes dexamethasone ≤ 4 mg/day at registration and candidacy for reirradiation. Previous bevacizumab use for radiation necrosis is permitted. The primary endpoint is OS probability at 9 months (OS-9). Secondary endpoints include PFS, OS, and toxicity. Exploratory endpoints include immunological phenotyping of blood and tissue. An increase of OS-9 from 38% (bevacizumab alone) to 60% is considered clinically relevant. **Results:** From 6/2020 to 12/2021, we have completed accrual for cohort A and the interim analysis results are presented here: 25 patients with rGBM enrolled, with 23 evaluable. Median age is 64.3 years (42.1-81.8), 30.4% female, 30.4% *MGMT* promotor methylated, median KPS 90 (range 70-100), baseline dexamethasone 0 mg (range 0-4) with 52.2% of patients on dexamethasone during the first 3 cycles, median baseline ALC 1,000 cells/μl (range 300-3,700). Patients received a median of 6 cycles to date (range 2-20). Median follow-up is 11.97 months per the reverse Kaplan-Meier method. Interim analysis shows a median PFS of 9.9 months (95%CI: 5.5 to not reached (NR)) and median OS of 12.2 months (95%CI 7.3-NR). Notably, Cohort A met the primary endpoint with an OS-9 of 71.4% (95%CI: 46.7% -86.1%). No dose limiting toxicities have been yet observed. Two treatment-related grade 3 toxicities have occurred (myositis, hypertension). Cohort B enrollment is ongoing, and correlative studies pending. **Conclusions:** Interim analysis suggests retifanlimab combined with HFRT and bevacizumab in patients with rGBM is well-tolerated and had encouraging OS and PFS at the time of data cutoff. Cohort B, which adds epacadostat, is currently enrolling. Clinical trial information: NCT03532295. Research Sponsor: Incyte.

Indirect assessment of tumor-infiltrating lymphocyte activity in serum for predicting outcome in patients with glioblastoma treated with immunotherapy in the recurrent setting. *First Author: Christina Jensen, Biomarkers & Research, Nordic Bioscience, Herlev, Denmark*

Background: Glioblastoma (GBM) is an aggressive brain tumor and despite efforts in developing new effective therapies, patient survival remains low. There is increasing interest in using immune checkpoint inhibitors (ICIs) for GBM, however the immunosuppressive (cold tumor) characteristics of GBM limit the efficacy of ICIs. Consequently, there is a need to identify patients with active tumor-infiltrating lymphocytes (hot tumor). Several studies have shown that brain extracellular matrix such as type IV collagen has a dynamic composition with protease-induced alterations. In this study, we evaluated the clinical utility of a non-invasive biomarker of granzyme B degraded type IV collagen (C4G) reflecting tumor-infiltrating lymphocyte activity and of matrix metalloproteinase (MMP) degraded type IV collagen (C4M) in GBM patients treated with nivolumab (anti-PD-1) and bevacizumab (anti-VEGF) in the recurrent setting. **Methods:** C4G and C4M were measured in serum from 22 controls and 39 GBM patients previously treated with surgery, radiotherapy and chemotherapy in the primary setting. After GBM recurrence, 18 patients underwent salvage resection (arm A) however 21 patients had no possibility for resection (arm B). All patients were treated with nivolumab and bevacizumab (NCT03890952 phase II study). Baseline GBM samples were taken before the second-line treatment. The association between C4G levels and outcome was evaluated by Cox regression analysis for overall survival (OS) and odds ratio (OR) calculations for complete response (CR) rate after dichotomizing patients into low vs high levels of C4G (median cutpoint). **Results:** C4G (p = 0.004), but not C4M (p = 0.166), was significantly elevated in serum from GBM patients compared to controls. Moreover, patients with high C4G levels had a significantly increased likelihood of experiencing CR (OR=6.68, p<0.0001). Furthermore, patients with high C4G experienced improved OS compared to low C4G (HR=0.39), and this remained significant after adjusting for other significant risk factors (treatment arm and MGMT methylation) by multivariate analysis (HR=0.44) (table). **Conclusions:** A non-invasive biomarker reflecting tumor-infiltrating lymphocyte activity (C4G) has the potential to identify GBM patients responding to nivolumab and bevacizumab in the recurrent setting. In the future, this may provide a non-invasive biomarker tool for stratifying patients with GBM for ICI trials. Clinical trial information: NCT03890952. Research Sponsor: Danish Cancer Society.

2060 **Poster Session**

Safety and efficacy of glasdegib in combination with temozolomide and radiotherapy in patients with newly diagnosed glioblastoma: Phase Ib/II GEINO 1602 trial. *First Author: María Ángeles Vaz, Medical Oncology Department, Hospital Universitario Ramón y Cajal, Madrid, Spain*

Background: Hedgehog signaling through Smoothened (SMO) protein in gliomas promotes cell cycle progression and leads to glioma stem cells (GSCs) maintenance, which constitutes one of the key hallmarks for glioblastoma (GB) resistance against anticancer therapies. Glasdegib, a SMO inhibitor, may disrupt GSCs and lead to enhanced efficacy of the Stupp scheme. **Methods:** Newly diagnosed GB pts received glasdegib with standard radiotherapy (RT)/ temozolomide (TMZ) followed by maintenance with glasdegib monotherapy. The primary objective was to determine the recommended phase 2 dose (RP2D) in a 3+3 dose escalation (DE) strategy in phase Ib and overall survival (OS) in phase II. Secondary objectives included progression-free (PFS) according to RANO criteria, safety, changes in performance status, and exploratory biomarker analysis. **Results:** Between 2018 and 2020, 79 GB pts were enrolled and 78 received at least one dose of glasdegib. In DE, 4 pts received Glasdegib at 100 mg/QD and 6 pts received 75 mg/QD. DLTs were reported in 3/4 pts in 100 mg dose level, and 1/6 pts in 75 mg dose level, declaring 75 mg/QD of glasdegib as RP2D. For phase II, 68 additional pts were treated at 75 mg/QD dose. The median age was 55 years (range: 28-78), 54% were male, 45% were MGMT unmethylated, and 1 pts had an IDH1/2 mutation. Glasdegib treatment lasted a median of 6 m (range: 0.5-21.9). Overall, 72 (97.3%) pts completed concomitant therapy, 65 (87.8%) started adjuvant therapy, 28 (37.8%) completed adjuvant therapy, and 23 (31.1%) continued glasdegib monotherapy. Treatment combination was discontinued due to treatment-related adverse events (TRAEs) in 9 (12.2%) pts. For those pts that received RT/TMZ combined with glasdegib at 75 mg/QD dose, 7 (9.5%) presented grade (G) ≥3 hematological TRAEs during concomitant treatment and 2 (3.1%) during the adjuvant treatment. There were no G≥3 TRAEs of any type during the maintenance phase. Neutrophil count decrease G≥3 was reported in 6 (8.1%) pts and platelet count decrease G≥3 in 7 (9.5%) pts. Cutaneous events G≥3 were reported in 3 (4.1%) pts. ECOG, Minimental and Barthel indexes, were maintained when comparing baseline with end of treatment (p = 0.181, 0.25 and 0.346 respectively). Stabilization was the most common response, reported in 60 (81.1%) pts. After a median follow up of 7.8 m (range 0.7-25.9), median PFS was 6.9 m (95% CI: 6.1-8.5). The 6-m PFS rate was 62.1% (95% CI: 50.9-75.8) and the 18 m OS rate was 63.3% (95% CI: 47.5-84.4). **Conclusions:** The addition of glasdegib to standard RT and TMZ was safe. Glasdegib monotherapy showed no G ≥3 TRAEs. Most patients had disease stabilization, with a promising preliminary PFS and OS for newly diagnosed GBM. Final survival results are awaited. Clinical trial information: NCT03466450. Research Sponsor: GEINO though industry partner Pfizer.

2061 **Poster Session**

Phase 1 trial of ruxolitinib, temozolomide, and radiation in high-grade gliomas. *First Author: Manmeet Singh Ahluwalia, Rose Ella Burkhardt Brain Tumor and Neuro-Oncology Center, Neurological Institute, Taussig Cancer Institute and Cleveland Clinic, Cleveland, OH*

Background: Ruxolitinib is a novel, selective inhibitor of JAK1 (Janus kinase 1) and JAK2 and JAK3. JAK signaling involves recruitment of signal transducers and activators of transcription (STATs) to cytokine receptors, activation, and subsequent localization of STATs to the nucleus leading to modulation of gene expression. Dysregulation of the JAK/STAT pathway has been associated with several types of cancer and increased proliferation and survival of malignant cells. Preclinical evidence supports inhibition of JAJK STAT pathway arrogated glioma growth. **Methods:** Ruxolitinib is a novel, selective inhibitor of JAK1 (Janus kinase 1) and JAK2 and JAK3. JAK signaling involves recruitment of signal transducers and activators of transcription (STATs) to cytokine receptors, activation, and subsequent localization of STATs to the nucleus leading to modulation of gene expression. Dysregulation of the JAK/STAT pathway has been associated with several types of cancer and increased proliferation and survival of malignant cells. Preclinical evidence supports inhibition of JAJK STAT pathway arrogated glioma growth. **Results:** 60 patients were treated on the study and there were no dose limiting toxicity seen on the protocol. Survival data was calculated for GBM. The OS for arm 1 was 18.17 (10.15, NA) and was not reached for arm 2. The 1 year OS was 0.62 for arm 1 and 0.93 for arm 2. Patients that received ruxolitinib + radiation x 60 Gy + daily temozolomide at 75 mg/m2 for 6 weeks over 6 weeks (Arm 2) had significantly better PFS and OS than those that received ruxolitinib + radiation x 60 Gy alone. **Conclusions:** Dose of 20 mg twice daily of ruxolitinib is safe with radiation and temozolomide. Preliminary survival data appears promising compared to the historical benchmarks and randomized phase 2 trial is planned. Clinical trial information: NCT03514069. Research Sponsor: Incyte.

Predicting CNS penetration of precision medicine therapies in oncology: A comparison of the CNS TAP tool and the BOILED-Egg computational model. *First Author: Gianni Walker, University of Michigan College of Pharmacy, Ann Arbor, MI*

Background: The number of available targeted therapies has vastly expanded in recent years; however, only a selection of such therapies achieve adequate central nervous system (CNS) penetration. The CNS Targeted Agent Prediction (CNS TAP) Tool was developed to aid in the selection of precision medicine therapies based on preclinical data, clinical data, patient-specific genomic data, and importantly, optimal blood brain barrier penetration. Using a standardized murine pharmacokinetic (PK) model, we sought to determine the concordance of CNS penetration prediction by the CNS TAP Tool compared to the SwissADME BOILED-Egg computational model. **Methods:** Eleven drugs were chosen based on the most commonly altered and targeted pathways by our CNS tumor board. Mice were injected individually with the compounds of interest and sacrificed at four different time points to quantify drug concentration via LC-MS in brain tissue and blood samples for PK analyses (1,2,4,7 hours). The percent brain penetration ($AUC_{brain/plasma}$) was compared to published human phase I PK data and pathway IC-50 to determine if agents were adequately CNS penetrant. These results were compared against the CNS TAP Tool and BOILED-Egg prediction of CNS penetrance. **Results:** All 11 drugs chosen (Table) demonstrated adequate CNS penetration, suggesting likely CNS efficacy. The CNS TAP Tool correctly predicted 10/11 agents (91% concordance), the lone exception being panobinostat. In contrast, the BOILED-Egg model only successfully predicted 3/11 agents (27%). When restricting the analysis to drugs with >50% CNS penetration (ponatinib, panobinostat, and ONC-201), the BOILED-Egg model successfully predicted CNS penetration of all agents. **Conclusions:** The clinician-curated CNS TAP Tool more accurately predicted CNS penetration of precision medicine therapies than the BOILED-Egg computational model, which performed best for drugs that achieve extremely high CNS penetration. The resulting PK and CNS penetration data for all agents was utilized to update and refine the CNS TAP tool for future patient use. Research Sponsor: Hematology Oncology Pharmacy Association (HOPA) Research Fund Award.

3D-volumetric assessment of response to ivosidenib in IDH-mutant gliomas. *First Author: Sushant Puri, Johns Hopkins Hospital, Baltimore, MD*

Background: Isocitrate Dehydrogenase (IDH) mutant gliomas represent a distinct class of primary brain tumors. Mutant IDH is a driver mutation implicated in gliomagenesis and a potential therapeutic target. Ivosidenib, an inhibitor of mutant IDH1, is currently being evaluated to treat gliomas. In the present study we assess our single-institutional experience with the off-label use of ivosidenib to reduce tumor growth rate in patients with IDH mutant gliomas. **Methods:** We have longitudinally analyzed the imaging of patients with histology-proven radio- and chemotherapy-naïve IDH-mutant WHO Grade 2 and 3 astrocytomas (AS) and oligodendrogliomas (OG) treated with off-label ivosidenib between 2019 and 2022. First, each patients' FLAIR images were anonymized, bias-corrected, co-registered and semi-automatically segmented for volumetric analysis using 3D Slicer 4.11. MR acquisition dates were hidden, and the order of scans was randomized to prevent expectation bias. Volumetric trends and PFS were analyzed. Progressive disease was defined as a ≥40% increase in volume from baseline as per modified RANO criteria. **Results:** Eleven patients were included in the analysis (median age 46 years [range 26-62], 2F, 8AS/3OG, 7 Grade 2). Mean±SD follow-up time on ivosidenib was 16.1±15.5 months. Tumor volume reduction was noted in 82% of patients at least at one time point. Average volume change at best response was -11.4±12.8%. Mean time to best response was 12.1±9.3 months. PFS-6 and PFS-12 were 91% (n = 11), and 88% (n = 8), respectively. Mean PFS was 24.4 months (CI95% 18.8-29.9). Median PFS was not reached. Patients older than 45 years had significantly higher volume reduction compared to younger patients (18.9±6.3% vs. -2.4±13.2%;-p = 0.047, 2-tailed T-test). Ivosidenib was discontinued in in 2 patients for 2D radiographic changes, and in one for increased seizure frequency. **Conclusions:** The use of ivosidenib in treatment-naïve gliomas was associated with a high response rate; however, on average it required longer than a year to achieve best response. In this cohort, older patients had higher volume reduction. The drug was well tolerable. Further analysis of an expanded cohort is underway. Research Sponsor: None.

The epileptic landscape of IDH mutant gliomas. *First Author: Michael Drumm, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Tumor-associated epilepsy (TAE) is a frequent complication of diffusely infiltrative gliomas. TAE not only impairs quality-of-life, but it can even be life-threatening. Furthermore, glioma cells have been shown to proliferate and migrate faster when exposed to firing neurons. We previously showed that isocitrate dehydrogenase 1 mutant (IDHmut) gliomas were more likely to cause preoperative seizures than IDH wildtype (IDHwt) gliomas, and that the chemical product of IDHmut, D2HG, increased synchronized network bursts in cultured neurons (PMID: 28404805). But the mechanism whereby this occurs, whether IDHmut inhibitors can block this, and whether seizure risk also varies by IDHmut status postoperatively, are unknown. **Methods:** Methods are embedded in Results. **Results:** We discovered that exogenous 3 mM D2HG had a 150% greater effect on the firing rate of cultured mouse cortical neurons when nonneoplastic glia cells were present versus when they were absent (P=0.002). Although a recently published study suggested that D2HG causes seizures through mTOR activation (PMID: 34994387), we found that D2HG reduced neuronal mTOR activity in neuronal-glial cocultures by 54% (P=0.0004). Patch clamp analyses showed that, while D2HG does not directly activate glutamate receptors, it does act as a glutamate transport substrate, thus potentially interfering with the ability of glial cells to take up glutamate released into the synaptic cleft. Coculture with patient-derived IDHmut glioma cells increased the firing rate of human cortical neuron/astrocyte spheroids by up to 272%, and an IDHmut inhibitor currently being tested in clinical trials, AG881, reduced the excitatory effect of IDHmut glioma cells on spheroids by 79% (P=0.0008). Using a novel *in vivo* model of TAE, wherein EEG recordings were taken of immunocompetent mice engrafted with an isogenic pair of Sleeping Beauty transposase-engineered mouse glioma lines (NRAS/ATRX/TP53mut ± IDHmut), we found that IDHmut gliomas produced 7.6-fold more epileptiform spikes than IDHwt gliomas (P=0.004). RNA-Seq analysis of the peritumoral mouse brain tissue showed that this increase in spikes was associated with significantly increased expression of key genes known to be upregulated in epilepsy, including *SLC12A5*, *THSB1*, *VEGFA, FOSL2*, and *SYNPO*. Treatment with 5 mg/kg AG881 by daily oral gavage reduced those spikes in IDHmut-engrafted mice by 51% within three days (P=0.027), whereas vehicle control had no effect (P=0.33). Among 247 patients with grade 2–4 adult-type diffuse gliomas, multivariable time-to-event analysis showed that postoperative seizure risk increased with preoperative seizures, subtotal resection, and IDHmut astrocytoma. **Conclusions:** Together, these data show that (i) the D2HG product of IDHmut gliomas increases neuronal excitation in a glial-dependent manner; (ii) IDHmut also affects postoperative seizure risk; (iii) IDHmut inhibitors may improve TAE control. Research Sponsor: U.S. National Institutes of Health, Lou and Jean Malnati Brain Tumor Institute at Northwestern Medicine.

Characterizing malignant transformation in patients with *IDH*-mutant glioma. *First Author: Vicki Liu, University of California-Los Angeles, Los Angles, CA*

Background: Gliomas, which constitute the majority of primary brain cancers in adults, are assigned to a particular grade based on histological and molecular criteria set forth by the World Health Organization (WHO). A subset of initially low grade glioma patients transition to a higher grade at recurrence through a process known as malignant transformation (MT). Despite its significant implications on clinical prognosis, MT remains a poorly understood phenomenon in regards to its incidence rates, effects on survival, and potential prognostic factors. Our study aims to elucidate MT in patients that possess a mutation in the *isocitrate dehydrogenase* (*IDH*) gene, one of the most common genetic alterations in gliomas. **Methods:** All known *IDH* mutant glioma patients, seen at UCLA between 1986 and 2022, who received at least 1 repeat resection for presumed recurrent disease were included. Based on surgical pathology reports, patients were categorized into MT and non-transforming progression groups, and further stratified by diagnosis in compliance with the 2016 WHO Classification of Tumors of the Central Nervous System. Relevant clinical information, including patient demographics, survival data, tumor microscopic descriptions, and magnetic resonance imaging, was accessed via electronic medical records. Kaplan Meier analyses were conducted to evaluate the predictive power of various clinical, pathological, and radiological markers. **Results:** Of 724 total *IDH* mutant patients screened, 253 received a second surgery and were thus incorporated in this study. Among the 196 patients with lower grade pathologies capable of MT, 129 (65.8%) progressed to a higher grade at recurrence while 71 (36.2%) did not. By diagnosis, the incidence rates of MT for initial grade 2 astrocytomas, grade 3 astrocytomas, and grade 2 oligodendrogliomas were determined to be 74.7%, 48.9%, and 66.1%, respectively. MT was associated with worse overall survival and post-recurrence survival compared to non-transformation in astrocytomas, a trend not seen in oligodendrogliomas. Across all relevant diagnoses, a subset of 36 MT patients did not receive treatment in the interval between initial and recurrent surgery, demonstrating the existence of spontaneously occurring MT. Furthermore, consolidating data from pathology and MRI reports revealed that a greater extent of abnormal molecular characteristics at initial diagnosis and earlier post-operative contrast enhancement may predict MT. **Conclusions:** These results highlight the distinct nature of gliomas that undergo MT, particularly in tumors of astrocytic differentiation. Considering its adverse impact on clinical outcome, understanding and anticipating this phenomenon is instrumental for the determination of optimal treatment among glioma patients. Research Sponsor: None.

Risk factors for cranial irradiation-related late neurocognitive toxicity: A prospective cohort study. *First Author: Debarati Bhanja, Penn State College of Medicine, Hershey, PA*

Background: Neurocognitive dysfunction is a common complication of cranial irradiation, occurring in up to 50% of irradiated brain tumor patients. Symptoms often severely compromise quality of life long before patients succumb to their tumor; however, risk factors are poorly understood, and consequently, prognostication and prevention have not been possible. The objective of this study was to evaluate the prognostic value of vascular risk factors for the development of irradiation-related brain injury. **Methods:** This single-institution prospective cohort study included patients with malignant primary brain tumors who received cranial irradiation as part of their initial tumor-directed therapy. Three putative vascular risk factors – homocysteine, total cholesterol, apoprotein E genotype (ApOE) – were measured and dichotomized (above vs. below the laboratory normal). Univariate analyses compared each risk factor with four measures of neurocognitive dysfunction: mini-mental status exam (MMSE), MRI white matter changes at 6 months (MRI), physician (Phys) assessment, and patient (Pat) assessment. Decision analysis was used to construct a prediction algorithm. **Results:** 80 patients were included in this analysis. Elevated homocysteine was the most powerful and consistent predictor of neurocognitive toxicity, followed by elevated triglycerides and the ApOE genotype (Table). Logistic regression revealed a highly significant ($p<0.01$) association between homocysteine level and each of the four outcome variables. Decision tree analysis using homocysteine level (high vs. low) and ApoE genotype (yes vs. no) provided the most efficient predictive algorithm. **Conclusions:** Two putative vascular risk factors (homocysteine level > 14 and ApOE genotype) provide moderate ability to predict post-radiation neurocognitive dysfunction using a variety of simple but clinically meaningful definitions of dysfunction. This predictive algorithm should be validated in prospective trials. If these findings are corroborated, studies examining additional risk factors as well as studies looking at risk factor mitigation will be appropriate. Research Sponsor: None.

Association of vascular risk factors with four measures of neurocognitive dysfunction (Risk Ratio [95% CI]).

Risk Factor	MMSE	MRI	Phys Assessment	Pat Assessment
Homocysteine	2.72 [1.71-4] P = 0.0002	2.20 [1.32-3.68] P = 0.0068	2.13 [1.89-5.18] P<0.0001	2.04 [1.38-3.00] P = 0.0029
Triglycerides	1.86 [1.22-2.83] P = 0.0076	2.13 [1.35-3.35] P = 0.0021	1.93 [1.23-3.06] P = 0.0082	1.39 [0.97-2.00] P = 0.1
ApOE	1.96 [1.27-3.00] P = 0.0029	1.38 [0.86-2.21] P = 0.2	1.86 [1.17-3.00] P = 0.011	1.43 [1.00-2.05] P = 0.064

Treatment patterns of patients with glioblastoma multiforme in the real-world setting in a developing country. *First Author: Juan José Sánchez Hernández, Hospital de Oncologia Centro Medico Nacional Siglo XXI, Mexico City, Mexico*

Background: Glioblastoma multiforme (GBM) is the most common and aggressive malignant primary brain tumor. Surgery followed of temozolomide administered concurrently with radiation therapy (RT) and followed by adjuvant temozolomide for six cycles significantly improved survival compared with radiation therapy alone in a randomized controlled trial published by Stupp and colleagues. Real world evidence in patients with GBM is scarce in Latin America. **Methods:** A retrospective study was conducted at the Hospital de Oncología, Centro Médico Nacional Siglo XXI, a referral center in Mexico City. We included histologically confirmed patients with GBM treated in a period from January 2015 to January 2019. Descriptive statistics and Kaplan-Meier method with log-rank were used for analysis. Cox regression was used for multivariate analysis. **Results:** A total of 184 patients were included, 96 were men (52,2%) and 88 were women (47.8%); median age was 56 years (range 18 - 87). ECOG performance status scale 0-1, and ≥ 2 represented 34.2% and 65.8% of the cohort, respectively. Maximal surgical resection was performed in 172 patients (93%). After surgery or biopsy, 12 patients (6.5%) did not receive any subsequent oncology treatment. Treatment with concomitant RT with TMZ was offered to 156 patients (84.4%) and RT alone to 16 patients (8.7%). The most common RT modality was conventional fractionation (60 Gy in 30 fractions) in 75% of cases. After concurrent therapy, 135 (86.5%) received adjuvant TMZ, of which 53.4% received ≤ 5 cycles and 46.6% received ≥ 6 cycles. The median overall survival of the entire cohort was 20.1 months (95% CI 13.3 - 26.9 months). Survival in patients with adjuvant TMZ was superior versus patients who did not receive complete multimodal treatment (26.3 months vs 10.5 months, $p < 0.001$). In the multivariate analysis, adjuvant chemotherapy was the only independent factor with statistical significance HR 0.18 (95% CI, 0.08 to 0.41 [$p < 0.001$]). **Conclusions:** In this retrospective study our data confirm that receiving adjuvant TMZ treatment is beneficial in prolonging overall survival compared to those who do not receive adjuvant therapy in patients with GBM. Research Sponsor: None.

The interim result of a phase I/II study of nivolumab with or without ipilimumab in combination with multi-fraction stereotactic radiosurgery for recurrent, high-grade, radiation-relapsed meningioma. *First Author: Jiayi Huang, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: There is a lack of effective therapy for recurrent high-grade meningiomas who relapsed after prior radiation therapy (RT). ETCTN 10186 is a phase I/II study to evaluate the feasibility and preliminary clinical efficacy of combining reirradiation using fractionated radiosurgery with nivolumab plus or minus ipilimumab for recurrent high-grade meningiomas. The preliminary results from the phase I portion are reported here. **Methods:** Recurrent grade II-III meningioma patients were treated with radiosurgery plus nivolumab with or without ipilimumab. Key eligibility criteria include age ≥ 18 years; ECOG score ≤ 2; tumor diameter 1-5 cm; prior radiation dose ≤ 70 Gy; normal organ function; no active autoimmunity. During the phase I portion, eligible patients were treated according to treatment-escalation schema following the modified 3+3 design (Table 1). The maximum tolerated combination (MTC) will be the regimen at which ≤ 1/6 patients experience dose-limiting toxicity (DLT) within 8 weeks of the start of study therapy. During the phase II portion, a total of 24 evaluable patients will be enrolled at the MTC using Simon's MiniMax two-stage design. The primary endpoint of the phase I portion is to determine the MTC. Objective radiological responses (ORRs) are defined as per the Macdonald criteria. One cycle of immunotherapy is defined as 4 weeks of nivolumab with or without concurrent ipilimumab. **Results:** From 7/2019 to 3/2021, 13 patients were enrolled in the phase I, including 6 with regimen A and 7 with regimen B (Table). The median prior RT dose was 56 Gy (18-70) at a median interval of 2.8 years (1.3-13.3). There was no DLT in either cohort, so regimen B was deemed the MTC. The median cycles of immunotherapy completed were not significantly different between cohort A and B (11 vs. 6, p = 0.41, respectively). Three cohort A patients and 2 cohort B patients completed all planned doses of immunotherapy. Most patients stopped due to progression, and only one cohort B patient stopped due to treatment-related toxicity (grade 3 hypophysitis and encephalitis after 6 cycles of immunotherapy). After a median follow-up of 11.1 months, there have been 5 progressions and 4 deaths. The 6 month-PFS and 12 month-PFS rates are 62% and 54%, respectively. Two ORRs have been reported by institutional assessment, and central radiology review is ongoing and will be reported. **Conclusions:** Reirradiation using fractionated radiosurgery with nivolumab plus or minus ipilimumab are well tolerated for radiation-relapsed high-grade meningiomas. Phase II study of regimen B is currently enrolling. Clinical trial information: NCT03604978. Research Sponsor: U. S. National Institutes of Health.

Treatment regimens.

	Dose		
Treatment Level	**Nivolumab**	**Ipilimumab**	**Radiosurgery**
Regimen A (n = 6)	480 mg IV Q4W x 13 doses	–	8 Gy x 3 QOD
Regimen B (n = 7)	3 mg/kg IV Q2W x 12 doses; then 480 mg IV Q4W x 7 doses	1 mg/kg IV Q6W x 4 doses	8 Gy x 3 QOD

Spatiotemporal multiomic landscape of human medulloblastoma at single cell resolution. *First Author: Hailong Liu, Beijing Tiantan Hospital Capital Medical University, Beijing, China*

Background: Medulloblastoma is the most common malignant childhood tumor type with distinct molecular subgroups. While advances in the comprehensive treatment have been made, the mortality in the high-risk group is still very high, driven by an incomplete understanding of cellular diversity. **Methods:** We use single-nucleus RNA expression, chromatin accessibility and spatial transcriptomic profiling to generate an integrative multi-omic map in 40 human medulloblastomas spanning all molecular subgroups and human postnatal cerebella, which is supplemented by the bulk whole genome and RNA sequences across 300 cases. **Results:** This approach provides spatially resolved insights into the medulloblastoma and cerebellum transcriptome and epigenome with identification of distinct cell-type in the tumor microenvironment. Medulloblastoma exhibited three tumor subpopulations including the quiescent, the differentiated, and a stem-like (proliferating) population unique to cancer, which localized to an immunosuppressive-vascular niche. We identified and validated mechanisms of stem-like to differentiated process among the malignant cells that drive tumor progression. Integration of single-cell and spatial data mapped ligand-receptor networks to specific cell types, revealing stem-like malignant cells as a hub for intercellular communication. Multiple features of potential immunosuppression and angiogenesis were observed, including Treg cells and endothelial cells co-localization in compartmentalized tumor stroma. **Conclusions:** Our study provides an integrative molecular landscape of human medulloblastoma and represents a reference to advance mechanistic and therapeutic studies of pediatric neuro-oncological disease. Research Sponsor: National Science Foundation of China.

2070 **Poster Session**

Impact of systemic therapy regimen on survival of PCNSL. *First Author: James Janopaul-Naylor, Department of Radiation Oncology at Winship Cancer Institute at Emory University, Atlanta, GA*

Background: Primary CNS Lymphoma (PCNSL) is a rare and often fatal disease. Treatment includes multi-agent systemic therapy with a backbone of high-dose methotrexate (HD-MTX). Despite multiple drug and radiotherapy combinations for induction and consolidation treatment there remains no clear standard of care. The purpose of this analysis is to evaluate how varying treatment approaches impacted clinical outcomes at our institution. **Methods:** Data retrospectively collected for 95 consecutive patients with PCNSL pathologically confirmed from 2002 to 2021. Primary endpoint was OS with secondary endpoints of PFS and LC. Progression based on RANO criteria. Kaplan-Meier analyses, Log-rank test and Cox proportional hazard models used for time to event endpoints. MVA by backward selection applying an alpha of 0.2 for associations with 1st line chemo agents, number of cycles of HD-MTX (>6 or 0-5), size of enhancing tumor at presentation, CSF cytology, type of surgery (biopsy, STR, or GTR), and use of WBRT. **Results:** Most patients had KPS >70 (64.2%), were HIV negative (89.5%), and had no history of solid organ transplant (95.8%). Diagnosis was made by biopsy (73.7%) or resection (GTR 13.7%, STR 12.6%). 54.3% had <14 cc contrast-enhancing tumor volume (median 12.6 cc, range 0.5 - 67.8 cc) and 48.6% had single enhancing lesion. Of the 62 patients treated first line with at least 1 cycle of HD-MTX, 61.3% were treated with HD-MTX + Rituximab (R) and 33.9% with HD-MTX + R + temozolomide (TMZ). With or after induction HD-MTX, 1-3 patients received one or a combination of cytarabine, thiotepa, procarbazine, vincristine, carmustine, or ASCT. Of the 60 patients with evaluable CSF, 30.0% had positive cytology. IT chemotherapy (ITc) was administered to 12 patients (5 with + cytology, 4 with - cytology, 3 with unknown cytology). WBRT for consolidation after chemotherapy used for 3 patients and as monotherapy for 9 patients. 2-year OS and PFS rate was 50.1% (95% CI 38.6%-60.5%) and 38.5% (95% CI 27.9%-49.0%). On MVA, > 6 cycles of MTX was associated with superior OS, PFS, and LC. For patients receiving any chemotherapy, addition of R was associated with inferior OS while ITc was associated with improved OS, PFS, and LC (Table). There was no OS association on MVA with TMZ, GTR, consolidation WBRT, or size or number of initial lesions (p>0.05). **Conclusions:** Completion of induction HD-MTX and use of ITc was associated with better outcomes in this population. Incorporation of R into 1st line therapy was associated with worse OS. Survival remained poor throughout the study period, underscoring importance of further innovation. Research Sponsor: U.S. National Institutes of Health.

Phase II single-arm, multi-center, physician-initiated clinical trial of convection-enhanced delivery of nimustine hydrochloride (ACNU) against diffuse intrinsic pontine gliomas. *First Author: Ryuta Saito, Department of Neurosurgery, Nagoya University Graduate School of Medicine, Nagoya, Japan*

Background: Diffuse intrinsic pontine glioma (DIPG) is one of the deadliest central nervous system tumors of childhood, with a 1 year survival of 40%. Intracerebral convection-enhanced delivery (CED) is an approach for administering chemotherapy to patients with brain tumors. We present the results of a multi-institute physician-initiated phase II clinical trial of CED of nimustine hydrochloride (ACNU) against DIPGs. **Methods:** We did a phase 2, single-arm, multi-center, prospective, physician-initiated clinical trial. Eligible patients were aged 3–21 years and had initially diagnosed DIPG. A Karnofsky performance score of at least 50 at study entry; and had completed standard external beam radiation therapy at least 4 weeks but no more than 5 weeks before enrollment. Accrual of 20 patients were planned. The 1 year survival rate from study entry was set as the primary endpoint, and prespecified threshold of the lower limit level of the 95% confidence interval was set as 30%. CED of 7 mL ACNU at the concentration of 0.75 mg/mL was given intratumorally through the 1-2 cannulas implemented surgically. Use of oral or intravenous temozolomide chemotherapy was allowed simultaneously with CED of ACNU. The analysis of the primary endpoint was done in the per-protocol population (patients who received the full dose of treatment), and all patients who was recruited in this trial were included in the safety analysis. This study is registered with Japan Registry of Clinical Trials (jRCT2021190003). **Results:** From April, 2018 to March, 2020, 21 children were enrolled in the trial, of whom 20 were evaluable for the primary endpoint. ACNU was not given for one patient because of the adverse event of intracerebral hemorrhage due to catheter insertion surgery. Other than this patient, all 20 patients got 1-2 catheters inserted and received CED of ACNU. For these patients, CED of 7 mL ACNU at the concentration of 0.75 mg/mL was given intratumorally through the 1-2 cannulas implemented surgically. Temozolomide chemotherapy was administered simultaneously in 15 patients. As a result, progression-free survival was 8.0 months and overall survival was 15 months. 1 year survival from recruitment was 55% and was 65% from initiation of standard radiation therapy. **Conclusions:** As the lower limit level of the 95% confidence interval of the 1 year survival rate from recruitment to the study, which was the primary end-point of the study, exceeded prespecified threshold of 30%, CED of ACNU in the brainstem of children with diffuse intrinsic pontine glioma who have previously received radiation therapy seems to be an effective therapeutic strategy. This therapeutic strategy warrants further development for children with DIPG. Clinical trial information: jRCT2021190003. Research Sponsor: Japan Agency for Medical Research and Development (AMED).

2072 **Poster Session**

Prostate-specific membrane antigen expression in meningioma. *First Author: Heinrich Elinzano, Rhode Island Hospital, Providence, RI*

Background: Meningioma is the most common CNS tumor, yet there is no effective therapy for relapsed/refractory meningioma after surgery and radiation therapy. Although most meningiomas follow a relatively benign course, some have a more aggressive course with rapid tumor growth, brain invasion, higher recurrence rates or extracranial metastasis. Prostate-specific membrane antigen (PSMA) is a transmembrane peptidase upregulated on endothelial cells of malignant solid tumors including glioblastoma and metastatic brain tumors, but not in normal vasculature. PSMA has been investigated as a therapeutic target and as a molecular imaging marker to monitor response to treatment and evaluate disease activity in PSMA-avid tumors. PSMA expression however has not been studied in meningioma. **Methods:** Archival tumor specimens (96 tumor samples: 58 WHO grade 1, 35 WHO grade 2, 3 WHO grade 3) from 69 patients were stained for H&E, PSMA and CD31 and slides were scanned (Leica Aperio AT2 whole slide image scanner). 37 of these samples were recurrent tumors and 13 had prior radiation therapy (intensity-modulated, Gamma knife, craniospinal). 21 of the 69 patients had paired samples of initial and recurrent tumors. QuPath was utilized as open access solution to machine learning generating raw data for PSMA, CD31, PSMA/CD31 ratio and PSMA/vasculature ratio. Paired t-test, unpaired t-test and ROC curves were used for statistical analysis. **Results:** PSMA expression was seen in all of the study samples. PSMA expression ($p = 0.0147$) was lower in grade 1 compared to grade 2 and 3 tumors, but not different among histologic subtypes. PSMA/vasculature ratio ($p = 0.0015$) was lower in grade 1 compared to grade 2 and 3 tumors. PSMA expression ($p = 0.002$) and PSMA/vasculature ratio ($p = 0.0015$) were higher in recurrent compared to non-recurrent tumors. PSMA expression ($p = 0.0442$) was higher in recurrent compared to initial tumors among paired samples. When comparing initial tumors of paired samples to non-recurrent tumors, ROC curves demonstrated CD31 expression (AUC:0.7278; $p = 0.0008$), PSMA/CD31 ratio (AUC:0.7843; $p = < 0.0001$) and PSMA/vasculature ratio (AUC:0.6256; $p = 0.0328$) to be predictors of tumor recurrence. Tumors with prior radiation therapy had higher PSMA/vascular ratio ($p = 0.0439$) compared to those without. **Conclusions:** PSMA is expressed in tumor vasculature of meningioma of any grade, increases at recurrence and persists with prior radiation therapy. Since it is present in meningioma of different grades and throughout the course of the disease, it could potentially be utilized as consistent diagnostic biomarker, relevant factor for risk of recurrence stratification and novel therapeutic target for these tumors. Phase II multicentric Italian trial on repositioning of the antipsychotic drug chlorpromazine and its combination with temozolomide in patients with MGMT unmethylated glioblastoma: The RACTAC trial. *First Author: Giuseppe Lombardi, Department of Oncology, Oncology 1, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy*

Background: The poor prognosis of patients affected by glioblastoma (GBM) prompts the search for new and more effective therapies, particularly for GBMs with unmethylated MGMT. In this regard, drug repurposing, can represent a safe and inexpensive way to bring novel pharmacological approaches from bench to bedside. Chlorpromazine, a medication in use since six decades for the therapy of psychiatric disorders, shows in vitro features that make it eligible for repositioning in GBM therapy. In our experimentation on six GBM cell lines, chlorpromazine inhibited cell viability in an apoptosis-independent way, induced polyploidy, reduced cloning efficiency as well as neurosphere formation and downregulated the expression of stemness genes. Notably, we found that chlorpromazine synergized with temozolomide, in reducing cell viability and strongly cooperated in reducing cloning efficiency and inducing cell death in vitro for all the GBM cell lines assayed. **Methods:** With these assumptions, we started a multicentric single arm Phase II clinical trial on newly diagnosed GBM patients with unmethylated MGMT by adding chlorpromazine to temozolomide in the adjuvant phase of the standard first-line therapeutic protocol. The experimental procedure involves the combination of CPZ with standard treatment with TMZ in the adjuvant phase of the Stupp protocol after radiochemotherapy combination. CPZ is administered orally at a dose of 50 mg/day – GG 1-28 – of every cycle of the adjuvant treatment with TMZ. At present, 38 patients out of 41 patients planned have been enrolled. Clinical trial information: NCT04224441. Research Sponsor: None.

TPS2074 **Poster Session**

A phase Ia/Ib study of intrathecal deferoxamine in patients with leptomeningeal metastases. *First Author: Jessica Wilcox, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Leptomeningeal metastases (LM) represent an aggressive form of advanced cancer with few durable therapeutic options. One of the principal barriers in treating LM is the paucity of knowledge on cancer cell survival and proliferation within the nutrient-sparse cerebrospinal fluid (CSF). Single-cell RNA sequencing of patient-derived CSF has identified that cancer cells in the spinal fluid employ the single iron-binding transporter and receptor system, lipocalin-2/SLC22A17, to gather sparse iron to sustain their metabolic needs. This phenotype is recapitulated in preclinical mouse models of LM. Depletion of CSF iron via intracisternal administration of deferoxamine, a parenteral iron chelator, dramatically reduced LM growth and significantly prolonged survival in preclinical models. Exploiting LM iron dependency using intrathecal deferoxamine (IT-DFO) represents a novel therapeutic approach for patients with LM. **Methods:** This is a prospective, open-label, single center phase Ia dose escalation study of IT-DFO in patients with LM from any solid tumor malignancy to determine the maximum tolerated dose (MTD) and recommended phase II dose (RP2D), followed by a phase Ib dose expansion of IT-DFO at the RP2D in patients with LM from non-small-cell lung cancer (NSCLC). Eligibility criteria include newly diagnosed or recurrent LM identified by magnetic resonance imaging (MRI), positive CSF cytology, and/or elevated CSF circulating tumor cells (CTCs), age $\geq$ 18 years, Karnofsky Performance Status $\geq$ 60, and life expectancy $\geq$ 8 weeks. All patients will receive IT-DFO in 28-day cycles at a frequency of twice weekly (cycle 1), once weekly (cycle 2), and once every two weeks (cycle 3+). Patients will be monitored for LM progression by neurological examination, neuraxial MRI, and CSF cytology as per modified Response Assessment in Neuro-Oncology LM criteria. Phase Ia will involve a modified accelerated titration over 9 dosing cohorts (IT-DFO dose range 10mg to 495mg) with monitoring for dose-limiting toxicities until the MTD is reached. Phase Ib will further explore the safety of IT-DFO at the RP2D in 20 patients with NSCLC LM. Secondary objectives include the determination of pharmacokinetic and pharmacodynamic properties of IT-DFO and its metabolite, ferrioxamine, in the CSF and serum (phase Ia/Ib), and efficacy outcomes (phase Ib) including LM-objective response rate, LM-clinical benefit rate, LM-duration of response, LM-progression-free survival, and overall survival. Exploratory analyses will prospectively correlate CSF CTC enumeration with treatment response and characterize the impact of IT-DFO on cancer cell metabolism, resistance pathways, and the CSF immune microenvironment. Clinical trial information: NCT05184816. Research Sponsor: MSK Center for Experimental Therapeutics, Other Foundation.

TPS2075 **Poster Session**

A study of neo-adjuvant and adjuvant ofra-vec (VB-111) for treatment of surgically accessible recurrent GBM. *First Author: Patrick Y. Wen, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA*

Background: Ofranergene obadenovec (ofra-vec, VB-111) is an anti-cancer gene based immune activator and targeted vascular disruptor. The dual mechanism of action triggers a broad antiangiogenic effect and induces of a tumor directed immune response. A previous study demonstrated a survival benefit for patients with recurrent glioblastoma (rGBM) treated with ofra-vec monotherapy, that was continued after progression in combination with bevacizumab. Glioblastoma is an immunologically "cold" microenvironment which fosters immunosuppression and antagonizes anti-tumor immune responses. The role of T-cell infiltration in combating cancer has been increasingly recognized and associated with improved participant outcomes. Based on these observations, this study will assess the hypothesis that neoadjuvant use of ofra-vec will lead to a statistically significant increase in tumor infiltrating T lymphocyte (TIL) density within the tumor and enhanced systemic tumor-specific T cell responses. **Methods:** Study NCT04406272 is a multicenter, randomized, blinded, placebo-controlled, phase 2 surgical trial to evaluate early immunologic pharmacodynamic parameters for the viral cancer therapy ofra-vec in rGBM. 45 participants with rGBM indicated for resection will randomized to one of three treatment arms: Neoadjuvant Arm: intravenous ofra-vec prior to resection, and ofra-vec every 6 weeks after resection. Adjuvant Arm: placebo prior to resection, and ofra-vec every 6 weeks afterwards. The control arm will receive placebo prior to resection followed by standard of care. Upon evidence of contrast-enhancing progression, bevacizumab may be initiated as needed for supportive care; however, ofra-vec will continue until progression is supported at two consecutive time points. Tumor samples will be obtained and archived at the time of surgery, and blood samples will be obtained as pharmacodynamic markers throughout the study to allow DNA sequencing of T cells. The primary endpoint is to evaluate the influence of neoadjuvant ofra-vec on TIL density. Other endpoints include safety and tolerability, peripheral T cell response, 6mPFS and OS. Study is open for enrolment. Clinical trial information: NCT04406272. Research Sponsor: VBL therapeutics.

TPS2076 **Poster Session**

A phase 0/surgical window-of-opportunity study in progress, evaluating evolocumab in patients with high-grade glioma or glioblastoma. *First Author: Kirit Singh, Duke Brain Tumor Immunotherapy Program, Duke University Medical Center, Durham, NC*

Background: High-grade gliomas (HGGs) are immunologically 'cold' tumors. This phenomenon is partly due to reduced expression of major histocompatibility class (MHC) I on the surface of tumor cells, which prevents CD8+ cytotoxic T lymphocyte activity (CTLs). Blockade of proprotein convertase subtilisin/kexin type 9 (PCSK9) increases MHC class I expression, enhances CTL tumoral infiltration, and potentiates checkpoint inhibition *in vivo*. Evolocumab is an FDA-approved fully human IgG2 monoclonal antibody PCSK9 inhibitor which is clinically indicated for hyperlipidemia. This study seeks to determine whether evolocumab can cross the blood-brain barrier (BBB) and enhance MHC I expression on resected tumor cells, serving as a potential future adjunct for immunotherapy. **Methods:** This study will enroll ten patients over 18 years who have newly diagnosed or recurrent HGG. These patients will also need to be undergoing resection of their tumor as part of their planned treatment pathway. Following informed consent, patients will receive evolocumab (420mg, subcutaneously) 7-14 days before surgical debulking of the tumor. We will collect tissue which is not required for histological tumor analysis and compare it with a contemporaneous matched control cohort. This will consist of resected tumor specimens from patients not treated with evolocumab. Quantification of the drug will be performed using mass spectroscopy, flow cytometry, and single-cell sequencing. The primary objective of this study is to evaluate whether evolocumab can cross the BBB and be measured in resected tumor specimens taken from patients with HGG. Secondary objectives include an analysis of lipid metabolism and MHC-I expression on the tumor via flow cytometry and CITEseq. Wilcoxon rank-sum test or a two-sample t-test, will compare groups for these endpoints. Exploratory analyses will determine if evolocumab leads to changes in tumorigenic pathways and the immune profile of tumor infiltrating lymphocytes (TILs). Bioinformatic analyses will be performed using protein set enrichment, gene ontology (GO) annotations, and search tools from the retrieval of interactive genes/proteins (STRING). Progress: The study was activated on 10/04/2021 (NCT04937413) and at the time of submission has enrolled 5 participants (4 to control arm, 1 to intervention arm). Clinical trial information: NCT04937413. Research Sponsor: Duke's Brain Tumor Immunotherapy Program.

TPS2077 **Poster Session**

DSP-0390, an oral emopamil binding protein (EBP) inhibitor, in patients with recurrent high-grade glioma: A first-in-human, phase 1 study. *First Author: David A. Reardon, Center for Neuro-Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: The brain's cells are fully dependent on their own de novo biosynthesis of cholesterol as the blood-brain barrier prevents its uptake from the circulation. In normal glial cells, proper regulation of cholesterol synthesis depends on its cell density and is turned off when the cell density exceeds a certain level. On the other hand, gliomas maintain high levels of cholesterol synthesis to support abnormal growth under any condition. Upregulation of cholesterol synthesis genes is associated with decreased survival in patients with glioblastoma (GBM). Therefore, gliomas are potentially sensitive to cholesterol synthesis inhibition. DSP-0390, an investigational small molecule, is an inhibitor of EBP, an enzyme in one of the last and crucial steps of cholesterol biosynthesis. By inhibiting de novo cholesterol synthesis, cytotoxicity can be induced more selectively against hyperproliferative GBM cells. DSP-0390 has shown significant antitumor activity in orthotopic xenograft models of human GBM (data on file). **Methods:** DSP-0390 will be evaluated in a phase 1 study in patients with recurrent, high-grade glioma (NCT05023551). Key eligibility criteria: age ≥18 years; Karnofsky Performance Status score ≥70%; and adequate renal, hepatic, and hematologic function. Patients must not have multifocal disease, leptomeningeal metastasis or extracranial metastasis, abnormal electrocardiograms, or significant cardiovascular disease. In Dose Escalation, 21–30 patients with World Health Organization (WHO) grade III or IV malignant glioma who progressed after ≥1 prior therapy will be enrolled. Dose level enrollment will be guided by a Bayesian Logistic Regression Model until identification of the maximum tolerated dose or recommended dose for expansion. Dose Expansion for clinical activity will enroll approximately 20–40 patients with WHO grade IV GBM who progressed after primary therapy and have measurable disease. Patients will receive oral DSP-0390 once daily. Study endpoints include safety (treatment-emergent adverse events [AEs], serious AEs, and dose-limiting toxicities), efficacy (6-month progression-free survival [PFS], objective response, PFS, duration of response, and 12-month overall survival), pharmacokinetics (PK), and pharmacodynamic biomarkers. This study is currently recruiting in the United States and Japan. Clinical trial information: NCT05023551. Research Sponsor: Sumitomo Dainippon Pharma Oncology, Inc.

TPS2078 **Poster Session**

GBM AGILE: A global, phase 2/3 adaptive platform trial to evaluate multiple regimens in newly diagnosed and recurrent glioblastoma. *First Author: Timothy Francis Cloughesy, University of California, Los Angeles, CA*

Background: GBM AGILE (Glioblastoma Adaptive, Global, Innovative Learning Environment) is a biomarker based, multi-arm, international, seamless Phase 2/3 Response Adaptive Randomization platform trial designed to rapidly identify experimental therapies that improve overall survival and confirm efficacious experimental therapies and associated biomarker signatures to support new drug approvals and registration. GBM AGILE is a collaboration between academic investigators, patient organizations and industry to support new drug applications for newly diagnosed and recurrent GBM. With its adaptable structure, GBM AGILE has continued trial activation, inclusion of new investigational therapies, and enrollment globally through the challenges of a global pandemic. **Methods:** The primary objective of GBM AGILE is to identify therapies that effectively improve the overall survival in patients with ND or recurrent GBM. Bayesian response adaptive randomization is used within subtypes of the disease to assign participants to investigational arms based on their performance. Operating under a Master Protocol, GBM AGILE allows multiple drugs from different pharmaceutical/biotech companies to be evaluated simultaneously and/or over time against a common control. New experimental therapies are added as new information about promising new drugs is identified while other therapies are removed as they complete their evaluation. The master protocol/ trial infrastructure includes efficiencies through an adaptive trial design, shared control arm and operational processes such as risk-based monitoring and enhanced remote activities. GBM AGILE has screened over 1000 patients and enrollment rates are 3 to 4 times greater than traditional GBM trials, with active sites averaging 0.75 to 1 patients/sites/month. While enrollment had an initial dip during the early stages of the pandemic (April-May, 2020), with flexible processes including remote based monitoring, minimizing in person visits, and remote provision of IMP, the enrollment rebounded by June, 2020. Through the use of improved and efficient processes allowed within a master protocol/adaptive platform trial infrastructure, GBM AGILE has been seamlessly operating a global trial during a global pandemic. Clinical trial information: NCT03970447. Research Sponsor: Bayer, Kazia Therapeutics Limited, Kintara Therapeutics, Inc., Asian Fund for Cancer Research, National Brain Tumor Society, National Foundation for Cancer Research.

TPS2079 **Poster Session**

A randomized phase II study of anlotinib combined with STUPP versus STUPP alone in patients with newly diagnosed glioblastoma (GBM). *First Author: Yuanyuan Chen, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: Postoperative with radiotherapy, and concomitant and up to 6 cycles of maintenance temozolomide (TMZ) chemotherapy (STUPP regimen) is now the standard treatment for newly diagnosed GBM, while the effectiveness is limited. Anlotinib is a novel, multi-kinase inhibitor against both tumor angiogenesis and tumor cell proliferation with encouraging findings in preclinical GBM models. Our previous single-arm study (NCT04119674) showed that the addition of anlotinb to STUPP exhibited promising progression-free survival (PFS) in patients with GBM. Therefore, a phase II trial was designed to assessed the efficacy and safety of anlotinib with the STUPP regimen. **Methods:** This is a multicenter, randomized, controlled, phase II superiority trial. Approximately 150 patients will be randomly assigned 1:1 to receive TMZ-based radiochemotherapy with anlotinib or TMZ-based radiochemotherapy with placebo. All patients will receive radiotherapy (fractionated focal irradiation in daily fractions of 1.8–2.0 Gy given 5 days per week for 6 weeks, for a total of 54–60 Gy) concurrently with TMZ (75 mg/m2 QD) and anlotinib (10 mg QD, d1–14/3wks) or placebo. Anlotinib or placebo is administrated during the 28-day treatment break. Adjuvant therapy start four weeks after radiotherapy completion, including six cycles of TMZ (150–200mg/m2, d1–5/4wks) and eight cycles of anlotinib (10 mg QD, d1–14/3wks) or placebo. Patients who complete adjuvant therapy are administrated anlotinib or placebo continuously until the disease progressed or unacceptable toxic effects developed. Eligibility criteria include histologically confirmed newly diagnosed GBM and a World Health Organization (WHO) performance status ≤ 2. Additional inclusion criteria include patients between 18 and 75 years old with adequate wound healing of craniotomy or biopsy; adequate hematologic, hepatic, and renal function; acceptable blood coagulation levels; and the stable or decreasing usage of glucocorticoid doses within 5 days before randomization. Exclusion criteria include potentially fatal intracranial hemorrhage on magnetic resonance imaging (MRI); tumors located only in the brainstem; prior chemotherapy or radiotherapy administered for GBM; and IDH1/2 mutation. The primary objective of this study is to compare PFS accessed by Independent Review Committee in patients receiving anlotinib in addition to standard treatment with patients receiving standard treatment only. Secondary endpoints include overall survival (OS), PFS accessed by investigators, overall response rate (ORR), severity and frequency of AEs (CTCAE V5.0), and quality of life (QOL). The disease control rate (DCR) and duration of response (DOR) will also be explored. Clinical trial information: NCT04959500. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd. Research Sponsor: None.

TPS2080 **Poster Session**

A phase I/IIa, open-label, multicenter, non-randomized clinical trial to assess the safety and efficacy of CYNK-001 in combination with recombinant human interleukin 2 in adults with recurrent resection eligible IDH1 wild-type glioblastoma (GBM). *First Author: Daniela Annenelie Bota, University of California Irvine, Irvine, CA*

Background: CYNK-001 is a CD56+CD3- enriched, off-the-shelf, allogeneic natural killer (NK) cell product expanded from placental CD34 cells. CYNK-001 exhibits *in vitro* cytotoxicity against patient-derived GBM cell lines and secretes cytolytic cytokines during co-culture with cancer cells. CYNK-001 administered via the intracranial (IC) route exhibited *in vivo* antitumor activity in a U-87MG orthotopic mouse model. **Methods:** A Phase I/IIa clinical trial is enrolling IDH1 wild-type GBM patients at first or second recurrence with contrast-enhancing measurable disease (per RANO criteria) who are candidate for surgical resection. Screening MRI scans for inclusion are performed within 14 days prior to Day -5 lymphodepletion with Cyclophosphamide 900mg/m^2 and fludarabine 30mg/m^2 plus mesna. Using a standard 3+3 dose escalation schema, patients will receive the first cycle of CYNK-001 intravenously (IV) at an initial dose of 2.4 x10^9 cells on Days 1, 8 and 15 after lymphodepletion. Cell supportive IL-2 at 6M IU administered SQ on Days 1, 3, 5, 8, 10, 12, and 15 within 3 hours prior to CYNK-001 IV infusion where applicable. Cycle 2 begins with surgical resection on Day 22 in which CYNK-001 is administered directly into the tumor cavity wall at an initial dose of 100 x10^6 NK cells and an Ommaya catheter placement. Subsequent CYNK-001 IC administrations via the Ommaya are on days 29 and 36 with 6M IU IL-2 SQ. DLT is evaluated for all dosing cohorts from day 1 to 7 days post last dose of cycle 2. Once a maximum tolerated dose is identified, a safety lead-in cohort with an additional 3 cycles of CYNK-001 IC will be administered prior to initiating the Phase IIa portion of the study. Endpoints: The primary endpoint is dose-limiting toxicity for the Phase I analysis and 6-month progression free survival post tumor resection for the Phase IIa component. Post-resected tumor tissue will be characterized for effector immune cell function and immune suppression with assessments directed at CYNK-001 tumor distribution using methodology developed at Celularity Inc. Approximately 66 patients are planned for this Phase I/IIa study. Approximately 66 patients are planned for this Phase I/IIa study. Clinical trial information: NCT05218408. Research Sponsor: Celularity Inc.

TPS2081 **Poster Session**

Bortezomib sensitization of recurrent glioblastoma with unmethylated *MGMT* promoter to temozolomide, a phase II study (NCT03643549). *First Author: Dorota Goplen, Department of Oncology, Haukeland University Hospital, Bergen, Norway*

Background: Patients with glioblastoma with functional O6 methylguanine DNA methyltransferase (*MGMT*) DNA repair enzyme gain limited benefit from temozolomide (TMZ). Bortezomib depletes the MGMT enzyme, restoring the tumor s susceptibility to TMZ, if the chemotherapy is administered in the precise schedule. Additionally, bortezomib inhibits the tumor growth by blocking autophagy flux. Thus, pre-treatment with bortezomib prior to temozolomide leads to DNA repair enzyme depletion and blockade of autophagy-induced survival signals. **Methods:** The academic, industry independent, multicenter, open label, single arm, non-randomized phase II trial is designed to investigate the survival benefits for patients treated with bortezomib 48hrs prior to TMZ. Efficacy of this therapy will be compared to historical cohorts receiving standard management. The study will include 53 patients with recurrent or progressive, MGMT unmethylated glioblastoma. The additional 10 patients were treated in the phase IB. All patients will receive a combination of bortezomib 1.3mg/m2 administered IV on days 1, 4, 7, during each 4-week chemotherapy cycle with PO TMZ at 200mg/m2 5 days/week q4w starting on day 3. Dose reduction of TMZ is allowed if reduced bone marrow tolerance is present. Major eligibility criteria include histologically confirmed glioblastoma with unmethylated MGMT promoter, MRI evidence of recurrence within 14 days prior to enrolment, age ≥ 18 years with life expectancy > 8 weeks, KPS ≥ 70, radiologically (MRI) confirmed tumor relapse/progression ≥ 12 weeks since completed radiotherapy, tumor not available for radiosurgery, adequate bone marrow, renal and liver function, no contraindications for bortezomib and/or TMZ. Endpoints: Estimation of the median progression free survival (PFS) and overall survival (OS) of patients with recurrent or progressed glioblastoma as well as progression free rate at 6 months. Secondary objectives: Therapy response assessed by contrast enhanced MRI (RANO criteria) and neurological examination (NANO criteria) as well as identification of novel biomarkers that correlate with treatment response. Twenty-four of the planned 53 patients are enrolled. Five of them receive treatment. The prespecified activity goal for the first stage of the study was met. Discussion: Patients with glioblastoma harboring active MGMT enzyme have median survival of 12.7 months, compared to 21.7 months for patients with the *MGMT* gene promoter silenced by methylation. This dismal prognosis for the approx. 55% of GBM patients underscores the unmet need for novel combination therapies that sensitize the tumors to chemotherapy. Results from this trial will serve as preliminary evidence of the role of bortezomib administered in a precise manner to abolish the temozolomide resistance of GBM with unmethylated MGMT promotor. The study is currently active and recruiting. Clinical trial information: NCT03643549. Research Sponsor: National Program for Clinical Therapy Research in the Specialist Health Service, Norway.

TPS2082 **Poster Session**

Window-of-opportunity study of ONC201 in pediatric patients with diffuse intrinsic pontine glioma (DIPG) and thalamic glioma. *First Author: Yazmin Odia, Miami Cancer Institute, Baptist Health South Florida, Miami, FL*

Background: H3 K27M-mutant diffuse midline glioma is a universally fatal malignancy primarily affecting children and young adults; while radiotherapy (RT) provides transient benefit, no effective systemic therapy is currently available. ONC201, a first-in-class imipridone, is an oral, blood-brain barrier penetrating, selective small molecule antagonist of dopamine receptor D2/3 and agonist of the mitochondrial protease ClpP. Previously, ONC201 monotherapy demonstrated durable objective responses in adults with recurrent H3 K27M-mutant glioma. This phase 1 trial was designed to evaluate ONC201±RT in pediatric patients with H3 K27M-mutant midline glioma DIPG. **Methods:** This multicenter, open-label, dose escalation and expansion phase 1 study of ONC201 is comprised of eight arms that will evaluate the recommended phase 2 dose (RP2D) of ONC201, biomarkers, and pharmacokinetics (PK) of ONC201±RT in various treatment settings. Arm G previously defined the RP2D for ONC201 administered twice weekly on consecutive days in patients with H3 K27M-mutant glioma who had completed radiotherapy. Arm H, for which enrollment is ongoing, will estimate the influence of tumor location and blood-brain barrier integrity on PK and intratumoral ONC201 exposure in biopsy-eligible pediatric tumors (DIPG or contrast-enhancing thalamic glioma). Patients eligible for Arm H will be aged 2-≤19 years, ≥2 weeks from last RT administration, and have a Karnofsky/Lansky performance score ≥50; prior confirmation of H3 K27M mutation is not required. In Arm H, single-agent ONC201 administration will occur on two consecutive days each week during each 21-day cycle at the RP2D defined in Arm G. Evidence of disease progression is not required; as such, ONC201 may be administered in the maintenance setting or for recurrent disease. Arm H has a planned enrollment of 27 patients. Each patient will undergo biopsy at a single prespecified biopsy window, which will be assigned at enrollment (Table); plasma for PK analysis will be collected from all patients at all time points shown in the Table, with additional collection pre-dose and 0.5 h post first dose. Clinical trial information: NCT03416530. Research Sponsor: Chimerix, Inc, U.S. National Institutes of Health, Making Headway Foundation, Fly A Kite Foundation.

Arm H: tumor biopsy collection schedule.

Cohort	Cycle 1, Day 1:1-3 h post first dose	Cycle 1, Day 1:22-26 h post first dose[a]	Cycle 1, Day 2:1-3 h post second dose	Cycle 1, Day 2:6-10 h post second dose	Cycle 1, Day 2:22-26 h post second dose
Thalamic	n = 3	n = 3	n = 3	n = 3	n = 3
DIPG	n = 3	0[b]	n = 3	n = 3	n = 3

TPS2083 **Poster Session**

Design and initiation of an adaptive, randomized, controlled study of berubicin, a topoisomerase 2 poison that crosses the blood brain barrier (BBB), for the treatment of recurrent glioblastoma multiforme (GBM) after first-line therapy. *First Author: Sandra Silberman, Cortice Biosciences, New York, NY*

Background: Berubicin (also known as WP744) is a patented doxorubicin (Dox) analog with evidence that it crosses the BBB and has significant central nervous system (CNS) uptake. Induction of apoptosis and DNA damage by Berubicin was compared with Dox and showed much greater potency of Berubicin in all tested cancer cells, also significantly and consistently showing higher cytotoxicity than Dox. In models of intracranial orthotopic gliomas, Berubicin prolonged survival when compared to temozolomide, currently a standard of care in GBM. Evaluation of these models also showed that Berubicin had greater infiltration into the tumor compared to normal tissue, providing additional justification for its observed improved efficacy. Based on this data, a Phase 1 dose escalation study was conducted in patients with recurrent primary brain tumors. Berubicin was well tolerated, with myelosuppression (neutropenia and thrombocytopenia) as dose-limiting toxicities. Of 25 patients evaluable for efficacy, there was 1 complete response (14+ years), 1 partial response durable for 12 weeks, and 9 patients with stable disease over 6 weeks for a clinical benefit rate of 44%. **Methods:** CNS Pharmaceuticals, Inc. ("CNSP") has licensed Berubicin and initiated a randomized, controlled clinical trial of Berubicin vs. Lomustine in adults with recurrent GBM after first line therapy. The primary endpoint of this study, being conducted in the United States and Europe, is overall survival (OS), with a projected 243 patients enrolled in a 2:1 randomization design (Berubicin:Lomustine). This study has pharmacokinetic (PK) evaluations of all patients enrolled, with at least 15 patients undergoing complete PK assessments throughout the initial dosing period (3 days of IV administration of Berubicin over 2 hours, repeated every 3 weeks). Patients will be stratified on the basis of MGMT methylation, there will be documentation of IDH WT status, and no prior administration of bevacizumab will be allowed. An interim analysis will evaluate the comparative effectiveness of these treatments, an adaptive design intended to demonstrate that Berubicin's efficacy is at least equal to that of Lomustine such that continuation of the study is in patients' best interests (futility analysis). The overall survival endpoint and sample size have been calculated to be able to show a statistical difference between the two therapies as second line treatment for GBM. Additional studies in malignant diseases of the CNS (e.g., pediatric brain tumors, primary CNS lymphoma, metastatic tumors) are also being explored based on the potential for anthracycline activity in these indications. For the present study posted on clinicaltrials.gov as, additional details and contact information is available. Clinical trial information: NCT04762069. Research Sponsor: CNS Pharmaceuticals, Inc.

TPS2084 **Poster Session**

The PROTECT Study: A phase II, open-label trial of prophylactic skin toxicity therapy with clindamycin and triamcinolone in patients with glioblastoma treated with tumor-treating fields. *First Author: Mario E. Lacouture, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Glioblastoma Multiforme (GBM), is the most common and aggressive brain tumor. Tumor Treatment Fields (TTFields) is a noninvasive, regional antimitotic treatment modality approved for the treatment of recurrent and newly diagnosed GBM by the US Food and Drug Administration. TTFields delivers low intensity (1-3 V/cm), intermediate frequency (100-300 kHz), alternating electric fields to the tumor through noninvasive transducer arrays placed on the skin, around the region of the body containing the tumor. During mitosis, TTFields disrupt the formation of the mitotic spindle during metaphase resulting in apoptosis. Dermatologic adverse events (AEs) to TTFields include dermatitis and infections and were reported in 54% of patients in a phase III trial. Topical triamcinolone and clindamycin have demonstrated anecdotal benefit because of their anti-inflammatory and antimicrobial activity. Pre-clinical studies have shown no negative effect on impedance when applied onto skin under the arrays. The effect of topical triamcinolone and clindamycin for the prevention of skin AEs to TTFields has not been studied prospectively. **Methods:** We are conducting a phase II multicenter clinical trial in patients receiving standard-of-care TTFields therapy for GBM to determine the efficacy of a prophylactic intervention: topical clindamycin 1% solution and triamcinolone 0.1% lotion in preventing grade ≥2 epicutaneous device-related events. Eligible patients must be ≥18 years of age, newly diagnosed with GBM and initiating TTFields within 7 days of study enrollment. The primary objective is to determine the effect of topical clindamycin 1% and triamcinolone 0.1% on the prevention of grade ≥2 device-related skin AEs. Secondary objectives include investigating the effect of study agents on skin-related quality of life (using the PRO-CTCAE modules for rash, ulcer, and pruritus), evaluating the efficacy of study agents applied to the scalp at every array change by standardized photography evaluated by a blinded investigator, measuring the duration of skin toxicities and usage of the TTFields device, measuring the duration of treatment interruptions and time to first grade ≥ 2 skin events, determining the bacterial flora of scalp infections, and determining the effect of study agents on TTFields' impedance. Patients will be on study for 90 days. An end-of-study assessment will occur on day 90, and a post-treatment visit will occur on day 120. The first patient was enrolled on October 21, 2020 and hitherto, 8 patients have been consented. Participating sites include Memorial Sloan Kettering Cancer Center, Columbia University Medical Center, Tufts University Medical Center, Northwestern University, Washington University, University of Cincinnati, and John Theurer Cancer Center - Hackensack Meridian Health. Clinical trial information: NCT04469075. Research Sponsor: NOVOCURE LTD.

Nemvaleukin alfa monotherapy and in combination with pembrolizumab in patients (pts) with advanced solid tumors: ARTISTRY-1. *First Author: Ulka N. Vaishampayan, University of Michigan Cancer Center, Ann Arbor, MI*

Background: Nemvaleukin alfa (nemvaleukin, ALKS 4230) is a novel, engineered cytokine that selectively binds to the intermediate-affinity interleukin-2 (IL-2) receptor (IL-2R) to preferentially activate antitumor $CD8^+$ T cells and natural killer (NK) cells with minimal expansion of immunosuppressive regulatory T cells. It is sterically occluded from binding to the high-affinity IL-2R, leveraging antitumor effects of the IL-2 pathway but mitigating toxicity associated with preferential binding of IL-2 to the high-affinity IL-2R. **Methods:** ARTISTRY-1 (NCT02799095) is a 3-part, first-in-human, phase 1/2 study of IV nemvaleukin alone and in combination with pembrolizumab in pts with advanced solid tumors. Parts A (dose escalation to 10 μg/kg/day), B (monotherapy in pts with melanoma or renal cell carcinoma [RCC]), and C (combination) included nemvaleukin 3 or 6 μg/kg/day ´5 and pembrolizumab every 21 days. Investigator-assessed antitumor activity (confirmed responses as per RECIST v1.1) and safety are reported as of 29 October 2021. **Results:** In Part A (N = 46), nemvaleukin recommended phase 2 dose was 6 μg/kg/day IV; maximum tolerated dose not reached. One pt had dose-limiting toxicity (grade 4 acute kidney injury) at 10 μg/kg. Pts in Parts B and C were heavily pretreated (1–9 prior lines of therapy, including prior checkpoint inhibitor therapy). Durable antitumor activity was observed for nemvaleukin monotherapy, including in RCC (objective response rate [ORR], 18.2% [4/22]) and in melanoma (ORR, 8.7% [4/46]), with 2 partial responses (1 unconfirmed) in 30 pts with cutaneous melanoma (ORR, 6.7%) and 2 PRs (1 unconfirmed) in 6 pts with mucosal melanoma (ORR, 33.3%). Durable antitumor activity was also observed for combination therapy (ORR, 16.1% [22/137]; disease control rate [DCR], 59.9%), including in platinum-resistant ovarian cancer (PROC; ORR, 28.6% [4/14]; DCR, 71.4%), with 2 complete responses and 2 PRs (1 unconfirmed) in 14 pts. Forty-three pts remain on therapy. The most frequent grade 3/4 treatment-related adverse events in Parts B and C, respectively, were anemia (9%, 10%), neutropenia (34%, 9%), and decreased neutrophil count (12%, 9%). Safety was consistent with previous reports. In pharmacodynamic studies, nemvaleukin monotherapy induced robust expansion of CD8+ T and NK cells, with minimal effect on regulatory T cells. **Conclusions:** ARTISTRY-1 showed proof of principle for preferential expansion of $CD8^+$ T cells and NK cells by nemvaleukin. Nemvaleukin was generally well tolerated and demonstrated promising efficacy. Durable responses were observed with monotherapy and combination therapy in heavily pretreated pts across a range of tumors, warranting further investigation. The US FDA granted nemvaleukin Fast Track designation for treatment of mucosal melanoma and PROC, and Orphan Drug designation for mucosal melanoma. Clinical trial information: NCT02799095. Research Sponsor: Alkermes, Inc.

2501 **Oral Abstract Session**

First-in-human study of SRF388, a first-in-class IL-27 targeting antibody, as monotherapy and in combination with pembrolizumab in patients with advanced solid tumors. *First Author: Aung Naing, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The immunoregulatory cytokine IL-27 upregulates inhibitory immune checkpoint receptors (eg, PD-L1, TIGIT) and downregulates proinflammatory cytokines (eg, IFNγ, TNFα). SRF388 is a fully human IgG1 blocking antibody to IL-27 with potential to promote immune activation in the tumor microenvironment. A phase 1 study was conducted to establish the preliminary safety of SRF388 and to identify recommended phase 2 doses (RP2D) suitable for monotherapy and combination expansions (NCT04374877). **Methods:** The dose-escalation study (accelerated single patient followed by standard 3+3) enrolled patients (pts) with advanced treatment-refractory solid tumors. Upon RP2D selection, monotherapy and combination expansions opened for treatment-refractory clear cell renal cell cancer (ccRCC), hepatocellular cancer (HCC), and non-small cell lung cancer. SRF388 was administered IV every 4 weeks (wks) as monotherapy and every 3 wks with pembrolizumab. Tumor response was assessed by RECIST1.1. **Results:** The monotherapy dose-escalation enrolled 29 pts with doses ranging from 0.003 to 20 mg/kg. Median age was 64 years. Most pts were female (62%) with ECOG PS of 1 (72%). Approximately 80% had prior PD-(L)1 blockade, and 48% had ≥4 prior therapies. Treatment-related adverse events (TRAEs) occurred in 21%, and all were low grade. Fatigue was the only TRAE reported in ≥10% (n = 3). No dose-limiting toxicities (DLTs) or Grade ≥3 TRAEs were observed. Median time on study was 9 wks (range 0–59). One patient with highly treatment-refractory NSCLC experienced a confirmed partial response (PR) at 8 wks that was durable for 20 wks. Nine pts (31%) experienced disease stabilization at 8 wks, with 6 of 9 exhibiting durable disease control at 6 months. Of the 7 pts with ccRCC in the dose-escalation portion of the trial, 3 (43%) experienced durable disease control for ≥20 wks (range: 20-32). With doses up to 20 mg/kg, SRF388 PK remain linear with an estimated $T_{1/2}$ of 10-12 days. PK characteristics and safety profile support dosing every 3 or 4 wks. Based on safety, tolerability, PK, peripheral pSTAT1 inhibition, and preliminary efficacy, 10 mg/kg was selected as the RP2D. Both the pembrolizumab safety cohort (n = 10) and Stage 1 of the ccRCC monotherapy expansion (n = 17) have fully enrolled. Of the 10 evaluable pts with ccRCC, 1 confirmed monotherapy PR has been reported, enabling Stage 2 initiation. Changes in several serum cytokines and chemokines were observed after SRF388 administration, including expected increase in circulating IL-27 levels. **Conclusions:** Results of IL-27 pathway blockade with a first-in-class therapeutic demonstrates that SRF388 has good tolerability with encouraging preliminary antitumor activity as a monotherapy. Updated data, including safety and clinical outcomes as well as correlative biomarker analyses, will be presented. Clinical trial information: NCT04374877. Research Sponsor: Surface Oncology, Cambridge, MA, USA;.

2502 **Oral Abstract Session**

Interim safety and efficacy results from AURELIO-03: A phase 1 dose escalation study of the IL-2/IL-15 receptor βγ superagonist SOT101 as a single agent and in combination with pembrolizumab in patients with advanced solid tumors. *First Author: Elena Garralda, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: SOT101 (previously SO-C101) is a fusion protein of IL-15 and the IL-15 receptor α sushi+ domain. Synergistic effects of SOT101 and an anti-programmed cell death protein 1 antibody have been validated in various tumor mouse models inducing a protective memory response. **Methods:** In this phase 1 study, safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary efficacy of increasing doses of SOT101 administered subcutaneously were investigated in patients (pts) with advanced solid tumors as monotherapy (Part A) and in combination with pembrolizumab every 3-week cycle (Part B). Dose escalation followed a standard 3+3 design. Data cut-off was 26 January 2022. **Results:** Overall, 51 pts were treated: 30 in Part A monotherapy at 0.25 to 15 μg/kg SOT101 and 21 in Part B combination therapy (Tx) at 1.5 to 12 μg/kg SOT101. The median (range) number of previous lines of Tx was 3 (1-9) in Part A and 2 (1-6) in Part B. In Part A, 19 (63.3%) pts had previous check-point inhibitor (CPI) Tx, of whom 9 (30 %) were refractory, 5 (16.7%) relapsed. In Part B, 11 pts (52.4%) had previous CPI Tx, and the outcome was 9 (42.9%) pts relapsed, 1 (4.8%) refractory. The most common treatment-emergent adverse events (TEAEs) were transient, and included pyrexia, chills, lymphopenia, anemia, transaminase elevation and vomiting. Most TEAEs were ≤ Grade 2. No treatment-related death was reported. For both monotherapy and combination Tx, the recommended phase 2 dose of SOT101 was determined to be 12 μg/kg. In Part A, in 13 pts at 6 to 12 μg/kg SOT101, the observed clinical benefit rate was 38%. A partial response (PR) was confirmed in 1 pt with skin squamous cell carcinoma, CPI refractory, PR duration 46 days (d), on treatment 154 d. Four pts (all CPI pretreated) had stable disease (SD), range 33-183 d. Final median duration on treatment was 84 d, range 43-183 d. The median duration of clinical benefit was 190 d. In Part B, the observed clinical benefit rate across all SOT101 doses was 63%. A complete response (CR) was confirmed in 1 pt with mesothelioma, CPI naïve, starting at the first tumor assessment, and the pt is ongoing in cycle 5. Three pts, 2 CPI pretreated, had a PR, range 51-232 d, 2 ongoing with PR, and 1 Tx discontinuation while still on PR. Five pts, 3 CPI pretreated, had SD, range 92-340 d, 2 ongoing with SD. The 3 CPI pretreated pts had SD range 41-340 d, 1 pt ongoing. The preliminary median duration on combination Tx was 113 d, range 7-429 d. The preliminary median duration of clinical benefit was 131 d. **Conclusions:** SOT101 as monotherapy and in combination with pembrolizumab showed a favorable safety profile. Highly promising efficacy signals with one ongoing CR and several long-lasting PRs were reported in CPI-naïve and CPI pretreated pts, including CPI-resistant tumors. Clinical trial information: NCT04234113. Research Sponsor: Sotio Biotech AG.

2503 **Oral Abstract Session**

Dose escalation of a phase 1b/2 study of modakafusp alfa, an immune-targeting attenuated cytokine, in patients (pts) with metastatic solid tumors. *First Author: Melissa Lynne Johnson, Sarah Cannon Research Institute, Nashville, TN*

Background: Modakafusp alfa (TAK-573) is a first-in-class immune-targeting attenuated cytokine designed to deliver attenuated interferon alpha-2b (IFNα2b) moieties to CD38-expressing cells. It consists of two attenuated IFNα2b molecules genetically fused to the Fc portion of a humanized, anti-CD38, IgG4 monoclonal antibody. Specificity for CD38 and reduced IFN receptor binding affinity of the attenuated IFNα2b molecules significantly reduces the potential for off-target binding and toxicity. Modakafusp alfa has demonstrated immune cell activation and antitumor activities in preclinical mouse models, including tumor models that do not express CD38, and has shown strong clinical responses and immune activation in pts with refractory/relapsed multiple myeloma. The dose-escalation phase of this phase 1b/2 study (NCT04157517) investigated safety, pharmacokinetics, immunogenicity, pharmacodynamics (PD), and preliminary efficacy of modakafusp alfa in metastatic solid tumors. **Methods:** Adult pts with advanced/metastatic solid tumors received modakafusp alfa IV on day 1 of a 21-day cycle (Q3W). Dose escalation started at 0.1 mg/kg and proceeded based on cycle 1 safety data via a Bayesian model with overdose control principles. **Results:** Twenty-one pts were dosed in the escalation phase at 0.1 (n = 3), 0.2 (n = 3), 0.4 (n = 3), 0.75 (n = 3), 1.0 (n = 3), and 1.5 mg/kg (n = 6) Q3W; median age 63 y (range 42–80); male 57.1%; GI malignancies 71.4%; median prior lines of therapy 3 (range 2–7). Two pts had dose-limiting toxicities in cycle 1 at 1.5 mg/kg; 1 pt with baseline bone infiltration had grade 4 thrombocytopenia and 1 pt had grade 3 confusion. As of Nov 2021, across all doses, pts received a median of 2 treatment cycles (range 1–11). Modakafusp alfa treatment-related adverse events (TRAEs) reported in 81% of pts included infusion-related reactions (52.4%), chills (47.6%), and nausea (33.3%). Grade ≥3 TRAEs reported in 42.9% of pts included neutropenia (14.3%) and hypertension (9.5%). There was a greater than dose proportional exposure increase in the dose range 0.1–1.5 mg/kg, with no exposure accumulation after Q3W dosing. Incidence rate of post-treatment anti-drug antibody (ADA) was 100%. PD data suggested saturation of peak IFN pathway modulation at ≥0.2 mg/kg in the peripheral blood with duration of modulation increasing with dose. Among the 14 response-evaluable pts, 7 had best response of stable disease, including 1 with cutaneous melanoma who had 21% target lesion reduction. **Conclusions:** Modakafusp alfa had a manageable safety profile in the dose range 0.1–1.5 mg/kg in pts with solid tumors. Proof of mechanism was validated. The recommended phase 2 dose was determined as 1.0 mg/kg Q3W based on assessment of holistic data and will be tested in combination with a checkpoint inhibitor in selected tumor types. Characterization of ADA and its impact is ongoing. Clinical trial information: NCT04157517. Research Sponsor: This study was funded by Takeda Pharmaceutical Company Limited.

2504 **Oral Abstract Session**

Phase 1 trial of TIM-3 inhibitor cobolimab monotherapy and in combination with PD-1 inhibitors nivolumab or dostarlimab (AMBER). *First Author: Gerald Steven Falchook, Sarah Cannon Research Institute at HealthONE, Denver, CO*

Background: TIM-3 expressed on tumor-infiltrating T cells is associated with T-cell suppression. AMBER (NCT02817633) is evaluating cobolimab (TSR-022/GSK4069889) monotherapy and with PD-1 inhibitors in advanced solid tumors. **Methods:** Multi-center, open-label study conducted with the following escalation arm (Parts 1A–C primary analysis reported here): (1A) cobolimab (IV Q2W) monotherapy at 7 doses (6 weight-based [0.03–10 mg/kg] and 1 flat [1200 mg] dose); (1B) cobolimab (1 mg/kg) + nivolumab (3 mg/kg IV Q2W); and (1C) cobolimab (100, 300, or 900 mg) + dostarlimab (500 mg IV Q3W). Primary endpoints were safety, tolerability, and recommended phase 2 dose (RP2D, monotherapy and combination). **Results:** 104 patients (pts) were included: 1A (n=46), 1B (n=7), or 1C (n=55); 4 pts from 1A crossed over to 1C (included in 1A and 1C safety and efficacy analyses). Most common cancers were non-small cell lung cancer (NSCLC) and melanoma (1A), NSCLC (1B), and NSCLC, skin, and peritoneal mesothelioma (1C). In 1A, 30.4% had ≥5 lines (L) of prior therapy; 42.9% had 3L in 1B; 33.3% had 2L in 1C. Treatment-related treatment-emergent adverse events (TR-TEAE) occurred in 67.4% (1A), 85.7% (1B), and 67.3% (1C); most commonly in 1A (n≥4) fatigue (13.0%) and nausea (8.7%); 1B (n≥3) diarrhea (57.1%) and nausea and vomiting (42.9% each); and 1C (n≥8) fatigue (20.0%) and rash (14.5%). Grade (Gr)≥3 TR-TEAEs occurred in 4.3% (1A), 28.6% (1B), and 14.5% (1C). There were no Gr5 TR-TEAEs or TR-TEAEs leading to dose delay. Serious TR-TEAEs occurred in 2.2% (1A), 0% (1B), and 12.7% (1C). TR-TEAEs led to discontinuation in 2.2% (1A), 28.6% (1B), and 9.0% (1C). Dose limiting toxicities (DLTs) occurred in 3.0% (1/33) in 1A (Gr3 lipase increased [10 mg/kg]); 40.0% (2/5) in 1B (Gr3 diarrhea and ALT and AST elevation); and 0% in 1C. Cobolimab serum exposure increased in a dose proportional manner at the therapeutic dose range. Preliminary mean terminal phase $t_{1/2}$ ranged from 2.5–5.8 days for 0.03–0.3 mg/kg and 6.9–10.2 days for 1–10 mg/kg doses (1A), 6.9 days for 1B, and 9.5–12.3 days for 1C. **Conclusions:** Cobolimab + dostarlimab was well tolerated and showed preliminary anti-tumor activity, warranting further investigation of the RP2D + docetaxel in a randomized, phase 2 study. Funding: GSK (213348). Clinical trial information: NCT02817633. Research Sponsor: GlaxoSmithKline.

Efficacy by cobolimab dose.

n (%)	1A* (cobolimab): 1 mg/kg N=9	1A*: 10 mg/kg N=13	1A*: 1200 mg N=7	1B (cobolimab + nivolumab): 1 mg/kg N=7	1C (cobolimab + dostarlimab): 100 mg N=13	1C: 300 mg N=20	1C: 900 mg N=22
ORR	0	0	0	3 (42.9)	1 (7.7)	5 (25.0)	3 (13.6)
DCR	1 (11.1)	4 (30.8)	1 (14.3)	3 (42.9)	2 (15.4)	14 (70.0)	9 (40.9)

4 pts in 1A crossed over to 1C (included in 1A and 1C analyses). *ORR and disease control rate (DCR) were 0% in 0.03, 0.1, 0.3 (n=3 each) and 3 mg/kg (n=8) groups.

2505 **Oral Abstract Session**

Phase 1 first-in-human study of anti–ILT3 mAb MK-0482 as monotherapy and in combination with pembrolizumab in advanced solid tumors: Dose escalation results. *First Author: Martin Gutierrez, Hackensack University Medical Center, Hackensack, NJ*

Background: Immunoglobulin-like transcript 3 (ILT3) is an inhibitory receptor associated with immune tolerance and T-cell suppression within the tumor microenvironment. MK-0482, a novel humanized IgG4 mAb targeting ILT3, is undergoing phase 1 evaluation ± pembrolizumab (pembro) in advanced solid tumors (NCT03918278; MK-0482-001). Dose escalation data are presented. **Methods:** Eligible patients with advanced solid tumors were enrolled into sequentially escalating dose cohorts of MK-0482 monotherapy (0.2-2250 mg) or MK-0482 (7.5-2250 mg) + pembro 200 mg; both were administered IV Q3W for up to 35 cycles or until progressive disease (PD), unacceptable toxicity, death, or withdrawal. Patients receiving MK-0482 monotherapy could cross over to MK-0482 + pembro after PD. Primary objectives were safety, tolerability, and determination of the recommended phase 2 dose (RP2D). Secondary and exploratory objectives included assessing pharmacokinetics (PK), blood receptor occupancy (RO), anti–drug antibodies (ADA), and objective response rate (ORR) per RECIST v1.1 by investigator assessment. **Results:** Seventy-five patients were enrolled (n = 29, MK-0482 monotherapy; n = 46, MK-0482 + pembro); 8 patients crossed over to receive the combination. Median age was 63 years (range, 34-86); 73% had ECOG PS 1, 72% received ≥2 lines of prior anticancer therapy, and 32% received prior PD-1/PD-L1 inhibitors. Treatment-related AEs (TRAEs; any-grade/grade 3 or 4) were reported in 34%/7% of patients with MK-0482 monotherapy, 67%/4% with MK-0482 + pembro, and 50%/13% in those who crossed over. The most common TRAEs (≥10% of all patients) were pyrexia (10%) with MK-0482 monotherapy; fatigue (24%) and arthralgia, diarrhea, hyperthyroidism, hypothyroidism, and pruritus (11% each) with MK-0482 + pembro; and arthralgia (25%), hyperthyroidism and hypothyroidism (13% each) for patients who crossed over. Dose-limiting toxicities occurred in 2 patients who received MK-0482 + pembro: 1 grade 5 myositis (MK-0482 750 mg; the only TRAE leading to death) and 1 grade 2 myositis (MK-0482 2250 mg). Preliminary PK and blood RO data suggested that target-mediated drug disposition of MK-0482 was likely saturated in blood mononuclear cells at doses ≥75 mg. ADA to MK-0482 was observed in ~20% of patients, but no clear impact on MK-0482 PK was observed. A confirmed ORR of 15% (8 PR) was observed in patients who received MK-0482 + pembro, including patients who crossed over; no confirmed responses were observed in patients who received MK-0482 monotherapy. MK-0482 750 mg + pembro was selected as the RP2D based on the totality of data. **Conclusions:** MK-0482 ± pembro was generally well tolerated, and combination therapy provided modest antitumor activity in patients with heavily pretreated advanced solid tumors. The RP2D of MK-0482 + pembro is under further evaluation in tumor-specific cohorts. Clinical trial information: NCT03918278. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

2506 **Oral Abstract Session**

A phase 1b, multicenter, dose-escalation study of subasumstat (TAK-981) in combination with pembrolizumab in patients (pts) with advanced solid tumors. *First Author: Sanjay Goel, Rutgers Robert Wood Johnson Medical School, Bronx, NY*

Background: SUMOylation is a post-translational modification with a role in limiting type 1 interferon (IFN-1)-dependent immune responses. Subasumstat is a small-molecule inhibitor of SUMOylation with the potential to increase antitumor immunity and overcome tumor resistance to checkpoint inhibitors (CPI) by inducing IFN-1 signaling. Preclinical data suggest that subasumstat enhances antigen cross-presentation, promoting T cell dependent antitumor responses; subasumstat plus an anti-PD-1 CPI has shown synergistic tumor growth inhibition and activation of CD8+ T cells and natural killer cells in syngeneic mouse models. We report data from the dose escalation part of a phase 1b study of subasumstat with pembrolizumab in pts with relapsed/refractory, CPI-exposed, non-squamous non-small-cell lung cancer (NSCLC) or microsatellite-stable colorectal cancer (MSS-CRC). **Methods:** Pts received escalating doses (40, 60, 90, and 120 mg) of subasumstat IV in 3 dosing schedules: days 1 and 8 (QW), days 1, 4, 8, and 11 (BIW), or days 1, 8, and 15 (90 mg only) of 21-day cycles, plus pembrolizumab 200 mg IV on day 1 of each cycle for 2 years or until disease progression or unacceptable toxicity. Dose escalation was guided by Bayesian optimal interval design. Phase 1b primary objectives were safety, tolerability, and the recommended phase 2 dose of subasumstat with pembrolizumab. **Results:** As of October 13, 2021, 43 (35 MSS-CRC; 8 NSCLC) pts had received ≥1 dose of subasumstat (22 BIW [40–120 mg]; 15 QW [90–120 mg]; 6 on days 1, 8, 15 [90 mg]). Median number of treatment cycles was 3; 28 (65%) pts had discontinued treatment, 21 (49%) due to progressive disease. Median age was 58 years (range 34–77); 56% of pts were male. One pt had a dose-limiting toxicity of grade 3 angioedema at 120 mg BIW. The maximum tolerated dose was not identified. Treatment-emergent adverse events (TEAEs) occurred in 38 (88%) pts; subasumstat-related TEAEs occurred in 34 (79%) pts, and included chills in 20 (47%), pyrexia in 16 (37%), fatigue in 9 (21%), anemia in 6 (14%), and stomatitis in 5 pts (12%; 3 [50%] in the 120 mg BIW cohort). Grade ≥3 TEAEs occurred in 24 (56%) pts; subasumstat-related grade ≥3 TEAEs reported in 10 (23%) pts included anemia, pyrexia, and increased aspartate aminotransferase (2 [5%] pts each). Pharmacokinetic activity of subasumstat was linear and decreased in a tri-phasic manner. Subasumstat exerted pharmacodynamic activity including target engagement, SUMOylation inhibition and increased IFN-1 signaling. Partial responses were observed at ≥40 mg dose levels in pts with NSCLC and MSS-CRC. **Conclusions:** Subasumstat plus pembrolizumab showed a favorable safety profile and promising anti-tumor activity in pre-treated NSCLC and MSS-CRC pts. Updated data will be presented at the meeting. Subasumstat plus pembrolizumab is currently in phase 2 clinical development (NCT04381650). Clinical trial information: NCT04381650. Research Sponsor: Takeda Development Center Americas, Inc. (TDCA).

2507 **Oral Abstract Session**

Single-cell profiling of human heart and blood in immune checkpoint inhibitor-associated myocarditis. *First Author: Steven Michael Blum, Massachusetts General Hospital and Dana-Farber Cancer Institute, Boston, MA*

Background: Myocarditis due to immune checkpoint inhibitors (ICIs) is uncommon; however, myocarditis due to ICIs leads to severe morbidity and even death in 20-40% of cases. The molecular underpinnings of ICI-associated myocarditis are poorly understood, and there is an unmet clinical need to identify therapeutic targets and biomarkers that can aid in disease management. **Methods:** Heart tissue was obtained through endomyocardial biopsy or autopsy of patients receiving ICIs and was profiled with paired single-cell RNA sequencing (scRNA-seq) and T cell receptor sequencing (TCR) using the 10x Genomics Chromium system. A control dataset was constructed using scRNAseq data of heart tissue from patients receiving ICIs but without myocarditis and a published dataset from healthy patients not receiving ICIs. Peripheral blood mononuclear cells (PBMCs) were collected at the time of myocarditis diagnosis in a larger cohort of patients and analyzed with ICI-treated controls. The CITE-Seq protocol was used to measure paired scRNA-seq, TCR, and surface proteomics in PBMCs, using serial timepoints where available. **Results:** Heart tissue from 13 patients with myocarditis, including three fatal cases, and seven controls yielded 77,712 single cells. Blood profiling from 27 patients with ICI myocarditis and ICI-treated controls across 54 samples yielded over 230,000 cells. ICI myocarditis tissue demonstrated an increased T cell infiltrate (OR 8.94, FDR = 0.0021). Expression of multiple inflammatory pathways, most notably interferon responses, was up-regulated across multiple immune and non-immune cell types in the setting of myocarditis, providing important pathophysiological insights. T cell clones were also found to be shared between blood and heart, enabling the identification of putative pathogenic T cell subsets. **Conclusions:** Increased intramyocardial T cells and the activation of interferon response gene networks were seen in the setting of ICI myocarditis. These preliminary findings highlight potential pathological pathways in ICI myocarditis that could serve as biomarkers or therapeutic targets. Research Sponsor: U.S. National Institutes of Health.

2508 **Oral Abstract Session**

Major adverse cardiac events (MACE) with immune checkpoint inhibitor (ICI)-based therapies for cancer: A pooled analysis of investigational clinical trials sponsored by the National Cancer Institute Cancer Therapy Evaluation Program (NCI-CTEP) in the United States and Canada. *First Author: Abdul Rafeh Naqash, Medical Oncology/ TSET Phase 1 Program, Stephenson Cancer Center, University of Oklahoma, Oklahoma City, OK*

Background: MACE due to ICIs are infrequent immune-related adverse events (irAEs) that comprise a spectrum of cardiac toxicities with variable manifestations. ICI-related MACE can lead to significant morbidity and mortality, hence the need to better define presentations of MACE and their association with non-cardiac irAEs in ICI-treated patients. **Methods:** We conducted a retrospective pooled analysis of MACE captured in the serious adverse events reporting database of the NCI-CTEP for NCI-sponsored investigational clinical trials between 6/2015-12/2019. Patients (pts) were eligible if they had been treated with anti-programmed cell death protein-1/programmed death-ligand 1 (anti-PD-[L]1) alone or in combination with additional anti-cancer therapies. **Results**: A total of 6,925 pts received anti-PD-(L)1-based therapies; 48% (n = 3354) were treated with single-agent anti-PD-(L)1 therapy. Of 6925 pts, 0.6% (n = 40) qualified as ICI-related MACE. Myocarditis accounted for 45% (n = 18/40) of total ICI-MACE. Approximately 77.5% (n = 31/40) of MACE were ≥ grade 3. Multi-system organ involvement with other non-cardiac irAEs was seen in 65% (n = 26/40). Most pts with myocarditis (83%, n = 15/18) had one or more non-cardiac irAEs associated; non-cardiac irAEs were observed in 50% (n = 11/22) of non-myocarditis MACE. Incidence of MACE was higher with anti-PD-(L)1 + targeted therapies vs. anti-PD-(L)1 + anti-CTLA-4 (2.1% vs. 0.09%,*p = 0.08*). Most of these were non-myocarditis MACE. There was a significantly higher incidence of myocarditis with anti-PD-(L)1-based combinations vs. single-agent anti-PD-(L)1 therapies (0.39%, n = 13/3341 vs. 0.14%, n = 5/3566, *p = 0.04*. Most pts with myocarditis had been treated with anti-PD-1-based combinations (72%, n = 13/18); the most common combination being anti-PD1+ anti-CTLA-4 (92%, n = 12/13). Pts with myocarditis presented after a median of 2 ICI doses and after a median of 35 days from the initial ICI administration. In pts with myocarditis, a concurrent or preceding history of myositis was present in 53% (n = 8/15). Deaths related to myocarditis were identified in 22.5% (n = 4/18). All four patients who died had concurrent myositis, with three having concurrent transaminitis. **Conclusions**: Our results represent the first report of a comprehensive pooled analysis of ICI-MACE obtained from NCI CTEP-sponsored investigational clinical trials. Based on our results, increasing patient and prescriber awareness in understanding patterns of ICI-MACE and associated non-cardiac irAEs should be emphasized. Furthermore, better characterization of the risk and patterns of non-myocarditis MACE with the use of anti-PD(L)-1 ICIs concurrently with non-ICI-based anti-cancer therapies is needed. Research Sponsor: U.S. National Institutes of Health.

2509 **Clinical Science Symposium**

Efficacy of anti-PD1/PD-L1 immunotherapy in non–small cell lung cancer is dependent upon Immunoscore IC CD8 and PD-L1 status. *First Author: Jerome Galon, HalioDx, Marseille, France*

Background: Anti-PD1 and PD-L1 antibodies (mAb) are immune checkpoint inhibitors (ICIs) to treat patients with metastatic non–small cell lung cancer (NSCLC). Unfortunately, only a handful of patients respond to ICIs. **Methods:** A cohort of patients with metastatic NSCLC (n=133) treated with anti-PD1 or anti-PD-L1 mAb in two independent care centers was evaluated. An independent cohort of 132 patients from another hospital was used as a validation. Immunoscore IC, an in vitro diagnostic test (CE-IVD), was used on a routine single FFPE slide, and duplex immunohistochemistry CD8 and PD-L1 staining was quantified using digital pathology. Quantitative and spatial parameters related to cell location, number, proximity, and clustering were analyzed. An Immunoscore IC–based model discriminated patients into 2 categories or 3 categories. **Results:** Anti–PD-L1 clone (HDX3) had similar characteristics as other anti–PD-L1 clones (22C3, SP263) with a mean overall agreement above 95%. Intra- and inter-laboratory concordances for classifying patients at 1% cut-off according to digital anti–PD-L1 (HDX3) were 100% and 94%, respectively. Routine laboratory evaluation of PD-L1 expression showed an agreement with digital anti–PD-L1 quantification of 92% and 97% at 1% and 50% cut-offs, respectively. Using univariate Cox model after FDR correction, 5 pathological dichotomized variables were significantly associated with PFS (all $p < 0.0001$). These variables included: CD8 free of PD-L1, CD8 clusters, CD8 cells in proximity of PD-L1 cells, CD8 number, PD-L1 cells in proximity of CD8 cells. Similar results were found using univariate Cox analysis on continuous variables (all $p < 0.003$) in two independent cohorts of patients. Using multivariate Cox model Immunoscore IC classification improved the discriminating power of prognostic model, which included clinical variables and pathologist PD-L1 assessment. In two categories, the Immunoscore IC risk score was significantly associated with both patients' PFS ($p < 0.0001$) and OS ($p < 0.0001$) in the training cohort and in the validation cohort (PFS: $p = 0.0047$, OS: $p < 0.0001$). Further increased hazard ratios were found when stratifying patients into 3 categories of Immunoscore IC. At 6 months, PFS rates were 10% versus 60% in the training cohort and 20% versus 62% in the validation cohort for high-risk and low-risk Immunoscore IC score, respectively. All patients (100%) with high-risk Immunoscore IC score relapsed in less than 18 months, in contrast to 34% and 33% of low-risk Immunoscore IC patients who did not relapse for more than 36 months in the training and validation cohorts, respectively. **Conclusions:** These data underline that Immunoscore IC is a potent tool to predict the efficacy of ICIs in patients with NSCLC. Immunoscore IC characterized patients who are resistant to ICIs. Research Sponsor: Veracyte, Other Foundation, Other Government Agency.

External validation of the VIGex gene-expression signature (GES) as a novel predictive biomarker for immune checkpoint treatment (ICT). *First Author: Alberto Hernando-Calvo, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: VIGex is a 12- gene GES classifier initially developed on the Nanostring platform and validated for RNA-seq. VIGex classifies samples into Hot, intermediate-Cold (I-Cold) and Cold subgroups. The Hot subgroup as defined by VIGex has been associated with better (PFS) in patients (pts) treated on phase 1 ICT trials at Vall D'Hebron Hospital (VH) (ESMO2020). We investigated the performance of VIGex in pts treated with Pembrolizumab (P) in the INSPIRE clinical trial (NCT02644369) at Princess Margaret Cancer Centre (PM) and compared VIGex with other predictive ICT biomarkers. **Methods:** Pts with advanced solid tumors were treated with P 200 mg IV Q3wks. RNA-seq from baseline biopsies was performed using the Illumina NextSeq550 platform. Tumor RNA-seq data were transferred from PM to VH and classified by the VIGex algorithm blinded to clinical data. Bespoke circulating tumor DNA (ctDNA) was assayed at baseline (B) and start of cycle 3 (C3) using a pt-specific amplicon-based NGS assay (Signatera). Tumor mutational burden (TMB) was defined as the number of non-synonymous mutations per megabase and PD-L1 was assessed by immunohistochemistry (22C3). Hot subgroup (HOT) was compared to I-Cold + Cold (COLD). We defined 4 groups based on the combination of VIGex subgroups and the change in ctDNA at cycle 3 from baseline (ΔctDNA). Survival times were calculated with the Kaplan–Meier method and Cox proportional-hazard models were constructed. **Results:** Out of 76 pts, median age was 55y (range 21-81y), M:F 31:45, all ECOG 0-1, 16 High-grade serous ovarian, 12 triple negative breast, 12 head and neck, 10 melanoma and 26 other. Median no. of P cycles was 3 (range 1–35); follow up was 14m (range 1-67); Median PFS 10.9m and median overall survival (OS) 14m. Overall response rate (RECIST 1.1) was 24% in HOT and 10% in COLD ($p = 0.22$ two-sided Fisher's exact test). The HOT subgroup was significantly associated with higher OS and PFS when included in a multivariate model adjusted by tumor histology, TMB and PD-L1 (HR 0.43; 95%CI 0.23-0.81; $p = 0.009$) and (HR: 0.48; 95%CI 0.25-0.95; $p = 0.036$) respectively. A total of 57 pts had both VIGex and ΔctDNA data. The addition of ΔctDNA further improved the predictive performance of VIGex for OS (Table). **Conclusions:** VIGex maintained its predictive power for ICT outcomes when applied to an independent external dataset using RNA-seq. The predictive information provided by VIGex was independent of PD-L1 and TMB. Our data indicates that the addition of ΔctDNA to baseline VIGex may refine prediction for ICT outcomes. Research Sponsor: Drug only from MERCK and study is supported in part by Princess Margaret Cancer Foundation.

Subgroup	Median OS (months) [95CI%]	HR (95%CI)	P value
COLD + ↑ ΔctDNA	4.8 [3.02-NA]	Reference	NA
HOT + ↓ ΔctDNA	46 [27.5-NA]	0.16 (0.06 - 0.43)	**< 0.001**
COLD + ↓ ΔctDNA	22 [17.6-NA]	0.36 (0.12 – 1.04)	0.059
HOT + ↑ ΔctDNA	13 [6.6-NA]	0.34 (0.14 - 0.81)	**0.015**

Identifying gut microbial signatures associated with B cells and tertiary lymphoid structures (TLS) in the tumor microenvironment (TME) in response to immune checkpoint blockade (ICB). *First Author: Elise F Nassif, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: While ICB has significantly improved clinical outcomes across several cancer types, only 15-20% of patients develop a durable response. Thus, novel and targetable biomarkers are needed. There is increased appreciation of the role of the gut microbiome, and TLS and B-cells in the TME in response to ICB. Here, we investigate the association between these two determinants of response in patient specimens from three randomized phase 2 neoadjuvant ICB trials of nivolumab +/- ipilimumab (melanoma (MEL; NCT02519322; n=23), non-small-cell lung cancer (NSCLC; NCT03158129; n=31), sarcoma (SARC; NCT02301039; n=17). **Methods:** Patients were categorized as responders (R) or non-responders (NR) based on major pathologic response, as defined in each histotype (MEL and NSCLC viable tumor ≤10%; SARC hyalinization>30%). Baseline fecal samples were profiled via 16S rRNA gene sequencing from all three cohorts to assess the composition of patient gut microbiomes. Transcriptional profiles of biopsies collected pre-ICB for MEL and SARC, and post-ICB for MEL, SARC, and NSCLC were used to assess TLS (CXCL13, CCL18, CCL19, CCL21) and B-cell (PAX5, CD79B, CR2, MS4A1) signatures in the TME, by calculated mean values of normalized gene expressions. Comparison between samples were carried out using the Wilcoxon signed-rank test. **Results:** There were 21 R overall (NSCLC n=9; MEL n=9; SARC n=3). Despite significant differences in alpha and beta diversity across cohorts, relative abundance of *Ruminococcus* was significantly higher in R (p=0.003; NSCLC p<0.001; MEL p=0.049; SARC p=0.7). B-cell signature was significantly higher post-ICB in R (R vs NR, post, TLS p=0.13; B-cell p=0.003), with consistent trends in each cohort. Longitudinal evaluation of transcriptional profiles showed that expression of TLS and B-cell signatures increased with treatment in R (pre vs post, MEL and SARC; TLS p=0.0098; B-cell p<0.001) but not NR (pre vs post; TLS p= 0.87; B-cell p= 0.15), with consistent trends in sarcoma and melanoma subgroups. Combined correlative analysis with matched specimen showed that patients with higher pre-ICB relative abundance of *Ruminococcus* (above median) had significant increase in B-cell signatures (pre vs post, MEL and SARC; TLS p=0.052; B-cell p=0.002) which was not seen in patients with low abundance (below median) of *Ruminococcus* (pre vs post, MEL and SARC; TLS p=0.56; B-cell p=0.69). **Conclusions:** Unifying signatures in the gut microbiome are associated with response to ICB and increased B-cell infiltration and TLS formation in the TME. We expect these findings to energize mechanistic studies and new microbiome-based interventional approaches to improve clinical outcomes with ICB. Clinical trial information: NCT02519322, NCT03158129, NCT02301039. Research Sponsor: None.

2512 **Poster Discussion Session**

Phase I/IIa study of PM8001, a bifunctional fusion protein targeting PD-L1 and TGF-β, in patients with advanced tumors. *First Author: Ye Guo, Oncology, Shanghai East Hospital, Tongji University, School of Medicine, Shanghai, China*

Background: PM8001 is a bifunctional protein composed of the extracellular domain of the TGF-β RII receptor (a TGF-β "trap") fused to a humanized anti-PD-L1 IgG1 single-domain antibody. This is the first dose escalation and expansion phase I/IIa study to evaluate the safety and preliminary anti-tumor activity of PM8001 in advanced tumors. **Methods:** This study is comprised of a standard 3+3 dose escalation (Part A: 1, 3, 10, 20, 30, and 45 mg/kg Q2W) followed by dose expansion (Part B). Primary endpoints include safety for Part A, and ORR per RECIST 1.1 for Part B. Secondary endpoints include pharmacokinetics (PK), immunogenicity, DCR, PFS, and OS. **Results:** As of 16 December, 2021, a total of 108 subjects had received at least 1 dose of PM8001 with 25 subjects in Part A (0.3 mg/kg [n = 1], 1 mg/kg [n = 3], 3 mg/kg [n = 3], 10 mg/kg [n = 4], 20 mg/kg [n = 7], 30 mg/kg [n = 3], and 45 mg/kg [n = 4]) and 83 subjects in Part B (10 mg/kg Q2W [n = 1], 20 mg/kg Q2W [n = 63], 20 mg/kg Q3W [n = 11]), and 30 mg/kg Q3W [n = 8]). In Part A, only 1 DLT occurred in the 20 mg/kg dose group. MTD was not reached. Finally, 20 mg/kg Q2W was recommended as the RP2D for Part B. Of the 108 subjects, the median duration of PM8001 exposure was 6.9 weeks (range, 1.4-71.9). Any-grade TRAEs occurred in 84 subjects (77.9%), with 18 subjects (16.7%) reported with ≥ Grade 3. The most commonly reported ≥ Grade 3 TRAEs were anemia and rash (3 subjects each). Any-grade irAEs occurred in 66 subjects (61.1%), with 13 subjects (12.0%) reported with ≥ Grade 3. The most commonly reported ≥ Grade 3 irAEs were anemia (3 subjects). PK analysis showed a nearly linear dose-exposure relationship with PM8001 dosing from 1 to 45 mg/kg. Pharmacodynamic analysis demonstrated close to 100% PD-L1 target occupancy on PBMCs from the 20 to 45 mg/kg groups after multiple doses. An adequate inhibition to below the limit of quantitation of TGF-β1 was observed in the 1 mg/kg and higher dose groups. Of the 108 enrolled subjects, 67 subjects completed at least one efficacy evaluation. The ORR per RECIST 1.1 by investigator was 10.4% (7/67; 95% CI, 4.3%-20.4%), with 7 subjects achieving PR; the DCR was 53.7% (36/67; 95% CI, 41.1%-66.0%). Four additional PRs were observed after the data cut-off date. Of the total 11 PRs, 4 PRs occurred in patients who previously progressed after anti-PD-1 treatment. Most responses (10/11) occurred within 6 infusions, which indicates a rapid response towards PM8001 treatment. To date, 8 responders are still on treatment. **Conclusions:** PM8001 showed an acceptable safety profile and promising anti-tumor activity in advanced solid tumors, especially in patients previously treated with checkpoint inhibitors, which supports further studies to explore the safety and efficacy of PM8001 as a monotherapy and in combination with other anti-tumor agents. Global Phase II monotherapy and combination studies are currently ongoing. Clinical trial information: ChiCTR2000033828. Research Sponsor: Biotheus Inc.

2513 **Poster Discussion Session**

A phase 1 trial of the bifunctional EGFR/TGFβ fusion protein BCA101 alone and in combination with pembrolizumab in patients with advanced solid tumors. *First Author: Philippe L. Bedard, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: BCA101 is a first-in-class bifunctional fusion protein consisting of an anti-EGFR monoclonal antibody (mAb) and TGFβ receptor 2 extracellular domain (TGFβRII-ECD). Herein, we report the safety, pharmacokinetic (PK), pharmacodynamic (PD), and preliminary efficacy data of BCA101 as monotherapy and in combination with pembrolizumab among patients (pts) with advanced solid tumors refractory to standard therapies. **Methods:** Pts received BCA101 as a single agent (SA) or in combination with pembrolizumab at escalating doses in a parallel 3+3 design starting at 64 mg intravenously (IV) weekly (qw); and at 240 mg IV qw with pembrolizumab 200 mg IV q3w. Primary endpoint: safety and tolerability (CTCAE v5.0); dose limiting toxicity (DLT) period: 21 days. Secondary endpoints: overall response rate (ORR), PK/PD profile, progression-free survival (PFS), and changes in plasma and intra-tumoral TGFβ signaling assessed by SMAD2 phosphorylation. **Results:** As of 08-Feb-2022, 60 pts have received BCA101 (part A). Forty-five pts (colorectal, n=14; pancreatic, n=7; head and neck squamous cell carcinoma [HNSCC], n=6) received SA BCA101 at doses up to 1500 mg IV weekly. Fifteen subjects (SCC of the anal canal [SCAC], n=8; HNSCC, n=7) received BCA101 doses ranging from 240 to 1500 mg IV qw in combination with pembrolizumab. Maximum tolerated dose has not been reached. Common adverse events (AEs) attributed to BCA101 include rash (70%), fatigue (23%), pruritis and epistaxis (17% each); all grade (G)2 or less. One DLT was observed at the 1250 mg SA dose (G3 anemia, hematuria). No drug-related G4 AEs or deaths were observed. At data cutoff, best response in the SA arm was stable disease (SD) in 15/39 (39%) evaluable pts. In combination, partial response (PR) was observed in 3/11 (27%) evaluable pts (2 in SCAC, 1 in HNSCC) and a disease control rate (DCR) of 9/11 (82%). Two of 3 responders have been on study >4 months; including 1 confirmed PR in a HNSCC pt refractory to anti-PD-1 therapy and cetuximab. Saturation of the EGFR target was observed at BCA101 doses ≥750 mg. Dose proportional increase in Cmax and AUC were observed with doses of BCA101 750-1500 mg. Prolonged neutralization of plasma TGFβ1 was achieved at all doses ≥500 mg. Among paired tumor biopsies (n=23), pSMAD2 reduction up to 62% was observed at doses ≥500 mg. **Conclusions:** BCA101 is well tolerated and clinically active as a SA and in combination with PD-1 blockade with a predictable PK/PD profile. A recommended dose of 1500 mg both as SA and in combination has advanced to the part B expansion phase for pts with HNSCC, SCAC, and cutaneous SCC. Clinical trial information: NCT04429542. Research Sponsor: Bicara Therapeutics.

2514 **Poster Discussion Session**

Efficacy and safety of NT-I7, long-acting interleukin-7, plus pembrolizumab in patients with advanced solid tumors: Results from the phase 2a study. *First Author: Aung Naing, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Checkpoint inhibitors (CPIs) are usually ineffective in patients (pts) with immune-cold microsatellite stable colorectal cancer (MSS-CRC) or pancreatic cancer (PDAC) and in those who progressed on previously treated with antibodies against PD1 or PD-L1. Here, we report the combination of NT-I7 plus pembrolizumab (pembro) on CPI-naïve MSS-CRC and PDAC cohorts, and patients (pts) with CPI-treated triple-negative breast cancer (TNBC), non-small cell lung cancer (NSCLC), and small cell lung cancer (SCLC) cohorts of this ongoing phase 2a trial. **Methods:** Pts with CPI-naïve relapsed/refractory (R/R) MSS-CRC and PDAC, and CPI-treated R/R TNBC, NSCLC, and SCLC, were enrolled. NT-I7 (efineptakin alfa) 1200 μg/kg intramuscularly every 6 weeks and 200 mg pembro intravenously every 3 weeks were administered until disease progression/unacceptable toxicity. The primary endpoint of the Phase 2a is the objective response rate (ORR), assessed by RECIST v1.1 and iRECIST. The secondary endpoints are duration of response (DoR), disease control rate, progression-free survival, and overall survival. **Results:** As of 14 Jan 2022, 92 pts with metastatic or locally advanced cancer who had received a median of 3 prior treatments were enrolled in the study; 32 in PDAC, 28 in MSS-CRC, 22 in NSCLC, 6 in TNBC, and 4 in SCLC. The median age was 62 years [29-81], ECOG PS 0 in 23 (25%), 1 in 68 (74%) and 2 in 1 (1%). Among 71 evaluable pts, the median follow up (months) was 7.7, 5.3, 5.0, 3.7, and 2.4 in TNBC, MSS-CRC, NSCLC, PDAC and SCLC, respectively. The ORR was 50% (1/2) in SCLC, 12% (3/25) in MSS CRC, 8% (2/26) in PDAC 6% (1/16) in NSCLC and 0% (0/2) in TNBC per iRECIST; and 50% (1/2) in SCLC, 4% (1/25) in MSS CRC, and 4% (1/26) in PDAC per RECIST 1.1. All 7 responders are ongoing. The two PDAC pts had DoR over 1.35 months (mos) and 6.64 mos with the best tumor reduction 100% and 72% respectively. The one SCLC pt had DoR over 1.5 mos with the tumor reduction 67%. The one NSCLC pt had DoR over 2.73 mos with the tumor reduction 60%, and the three MSS-CRC pts had DoR 6.34, 2.96, and 0.03 mos with the tumor reduction 60%, 56%, and 43% respectively. A sustained and significant (approximate 3X from baseline) increase of peripheral lymphocytes in all arms was observed as shown in our previous report. Among 92 treated pts, NT-I7-related adverse events (AEs) occurred in 67 (72.8%) pts, including 52 (56.5%) Grade (G)1-2, 13 (14.1%) G3, and 2 (2.2%) G4. There were no NT-I7 related G5 AEs. Additional updated efficacy, safety and biomarker data will be presented. **Conclusions:** The combination of NT-I7 and pembro demonstrated antitumor activity and manageable toxicity profile in heavily pretreated pts with CPI-naïve MSS-CRC and PDAC and CPI-treated TNBC, NSCLC, and SCLC, suggesting that the addition of NT-I7 to CPI can overcome the primary resistance to CPI in the former group and acquired resistance in the latter. Clinical trial information: NCT04332653. Research Sponsor: Neoimmunetech, Inc.

2515 **Poster Discussion Session**

First clinical and immunogenicity results including all subjects enrolled in a phase I study of Nous-209, an off-the-shelf immunotherapy, with pembrolizumab, for the treatment of tumors with a deficiency in mismatch repair/microsatellite instability (dMMR/MSI). *First Author: Marwan Fakih, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Defective DNA mismatch repair (dMMR) leads to high levels of microsatellite-instability (MSI-H) and insertions or deletions in coding regions, triggering the generation of tumor-specific frameshift peptides (FSPs). We selected 209 shared FSPs among subjects with dMMR/MSI-H cancers, to generate an off-the-shelf vaccine for the treatment of dMMR/MSI-H tumors. Those FSPs were cloned into four proprietary Great Apes Adenoviral (GAd) and four Modified Vaccinia Ankara (MVA) vectors to create a polyvalent viral vectored vaccine named Nous-209 *[Leoni, G. et al. Cancer Res, 2020. 80(18): p. 3972-3982.]*. **Methods:** This phase 1 first in human (FIH) study (NCT04041310) evaluates safety and tolerability of two dose levels of the Nous-209 in combination with pembrolizumab, assesses immunogenicity and detects preliminary evidence of anti-tumor activity. Nous-209 is administered intramuscularly, concomitantly with pembrolizumab: one prime (GAd-209-FSP) at the 2nd pembrolizumab infusion and three boosters (MVA-209-FSP) at subsequent infusions each 3 weeks apart. The study is composed of two sequential cohorts i.e. dose escalation and dose expansion. **Results:** All evaluable subjects with 1st- or 2nd-line metastatic dMMR/MSI-H colorectal (CRC), gastric or gastroesophageal junction (GEJ) cancers enrolled in this phase I (n = 20) were evaluated as of February 03, 2022. Three subjects enrolled in dose level (DL) 1 (2 CRC and 1 GEJ cancer) showed durable confirmed partial responses (PRs). In DL 2 (12 CRC and 5 gastric cancers), 7 subjects had PRs, 6 had stable disease (SD) and 4 had progressive disease (PD) as best response. Most progressors progressed at the 1st CT and none of the responders have progressed. The median follow-up for subjects in DL1 is 24.7 months (22.3-26.7), and 7.6 months (0.9-19.4) in DL 2. The median progression free survival (PFS) and median duration of response (DoR) have not been reached. No dose limiting toxicities (DLTs) were observed. Vaccine immunogenicity was demonstrated in periphery by *ex-vivo* interferon-gamma ELISpot in 67% of subjects in DL 1, and 82% of subjects with evaluable samples in DL 2. The intratumoral TCR repertoire on pre/post tumor biopsies was analyzed in 3 evaluable subjects with PR and in 1 with PD: expansion and diversification of T cells post treatment with Nous-209 was noted only for the former. Vaccine-reactive TCR clones infiltrating the tumor biopsy post treatment were found in the only subject evaluated to date, with a long-term response. **Conclusions:** The combination of the Nous-209 and pembrolizumab is safe and well tolerated, and shows signs of clinical efficacy. Nous-209 elicits a neoantigen-specific T cell response expanding within the tumor, possibly contributing to the clinical outcome. Clinical trial information: NCT04041310. Research Sponsor: Nouscom Srl.

2516 **Poster Discussion Session**

Phase I trial of adjuvant autogene cevumeran, an individualized mRNA neoantigen vaccine, for pancreatic ductal adenocarcinoma. *First Author: Vinod P. Balachandran, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Pancreas ductal adenocarcinoma (PDAC) is a lethal cancer that claims ~90% of patients in <24 months of diagnosis. PDAC is also refractory to immunotherapy as most tumors exhibit an immune excluded/desert phenotype. However, although characterized by low mutation rates, most PDACs harbor mutations that can generate immunogenic neoantigens. Here, we report the results of a phase-I trial of autogene cevumeran, a systemic RNA-lipoplex individualized neoantigen-specific immunotherapy (iNeST) vaccine, to stimulate immunity against neoantigens in resected PDAC patients. **Methods:** We conducted an investigator-initiated, single-center, phase-I trial of adjuvant autogene cevumeran containing up to 20 neoantigens in each individualized vaccine, identified from resected PDACs using real-time next generation sequencing and bioinformatic neoantigen discovery. Following surgery, patients received atezolizumab (1 dose; week 6), autogene cevumeran (8 weekly doses starting week 9; doses 9,10 – weeks 17, 46), and modified (m) FOLFIRINOX (12 cycles; starting week 21). Primary endpoint: safety. Other endpoints: feasibility (actual vs. target treatment time), vaccine response (responder = positivity by two independent blood assays: IFNg ELISpot and T cell clonal expansion), and recurrence-free survival (RFS). Target accrual: n=20. **Results:** n=19 patients underwent surgery and received atezolizumab at 6.3 weeks (median; 95% CI 6.0–6.57) after surgery with no ≥ grade 3 (Gr3) adverse events. n=16/19 patients (84%) received autogene cevumeran at 9.4 weeks (median; 95% CI 9–10) after surgery. n=1/19 (5%) had insufficient neoantigens for vaccine manufacture. n=1/16 (6%) developed a vaccine-related Gr3 fever and hypertension. n=15/16 vaccinated patients (94%) received mFOLFIRINOX (median 12 cycles; 95% CI 7–12). Autogene cevumeran expanded polyclonal (median 7.5 clones, 95% CI 2–28), IFNg-producing neoantigen-specific $CD8^+$ T cells in 50% (n=8/16) of patients from undetectable levels to large fractions (median 2.9%, Table) of all blood T cells. At an early median follow-up of 15 months, vaccine responders (n=8) had a longer RFS vs. non-responders (n=8) (median not reached vs. 13.7 months, HR 0.08, 95% CI 0.01-0.5, $P = 0.007$). **Conclusions:** Autogene cevumeran is safe, feasibly manufactured in a clinically relevant timeframe, and immunogenic in PDAC. Vaccine induced neoantigen-specific immunity preliminarily correlates with improved PDAC outcome. Further clinical trials in PDAC are warranted. (This imCORE Network project was funded by Genentech Inc and BioNTech; additional funding from Stand Up To Cancer, Lustgarten Foundation). Clinical trial information: NCT04161755. Research Sponsor: Genentech Inc, BioNTech, Other Foundation.

2517 **Poster Discussion Session**

Recommended phase 2 dose (RP2D) of HB-200 arenavirus-based cancer immunotherapies in patients with HPV16+ cancers. *First Author: Siqing Fu, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Treatment options are limited for patients with recurrent or metastatic human papillomavirus 16 positive (HPV16+) cancers. Generation and maintenance of HPV16+ cancers requires stable expression of HPV16-specific E7 and E6 oncoproteins, which are also a source of tumor-specific immunogenic neoantigens. HB-201 and HB-202 are replicating live-attenuated vectors based on lymphocytic choriomeningitis virus and Pichinde virus, respectively, which express the same non-oncogenic HPV16 E7E6 fusion protein and infect antigen presenting cells to induce tumor-specific T cell responses. The Phase 1 part of this study of HB-200 therapy (HB-201 single-vector therapy and HB-202/HB-201 two-vector alternating therapy) was conducted to determine RP2D for further exploration alone or in combination with pembrolizumab. **Methods**: The Phase 1 part used a 3+3 dose escalation design with up to 3 dose levels (DLs) of HB-201 and 4 DLs of HB-202/HB-201 explored. Patients with HPV16+ head and neck squamous cell carcinoma (HNSCC) or with other HPV16+ cancers were evaluated. Safety, tolerability, immunogenicity, and preliminary antitumor activity by Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 or immune RECIST were assessed to determine RP2D. **Results**: As of January 2022, 65 patients with a median of 3 prior anticancer treatments have been enrolled in the Phase 1 part of the study. All had HPV16+ confirmed genotype; the most common primary site was oropharynx, followed by anal and cervix. Adverse events were generally mild or moderate. For HB-201, 3 DLs, 2 dosing schedules and 2 administration routes were assessed across 40 patients. At DL3 of HB-201 administered intravenously (IV), dose-limiting toxicity (DLT) occurred in 1/6 patients in the HNSCC group (Grade 4 encephalopathy, fully recovered) and 1/2 patients in the non-HNSCC group (Grade 3 rash, fully recovered). Preliminary safety, efficacy, and immunogenicity data support IV injection of DL3 (5×10^7 units) every 3 weeks (Q3W) as the RP2D for HB-201 single-vector therapy. For HB-202/HB-201, 4 DLs and 2 administration routes were assessed across 25 patients. At DL4 of HB-202/HB-201 IV, 1/5 subjects in the HNSCC group reported a DLT (Grade 4 hepatitis, recovering at time of discontinuation). RP2D for HB-202/HB-201 will be determined in the very near future. Tumor control, including partial response, have been observed in subjects treated with either HB-201 or HB-202/HB-201 as monotherapy. **Conclusions**: HB-201 and HB-202/HB-201 were generally well tolerated and showed preliminary antitumor activity in heavily pre-treated patients with HPV16+ solid tumors. DL3 was selected as RP2D for HB-201 monotherapy. In the Phase 2 part of the study a combination of HB-201 at 5×10^6 units IV Q3W with pembrolizumab is being tested in HPV16+ HNSCC patients. Clinical trial information: NCT04180215. Research Sponsor: Hookipa Biotech Gmbh.

2518 **Poster Discussion Session**

Phase II evaluation of the combination of PDS0101, M9241, and bintrafusp alfa in patients with HPV 16+ malignancies. *First Author: Julius Strauss, Laboratory of Tumor Immunology and Biology, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: More than 630,000 cases of HPV related cancer occur worldwide annually. About 15-20% of cases respond to PD-(L)1 inhibitors and about 30% respond to dual PD-L1/TGF-β blockade including 10% of checkpoint refractory pts, but for the majority of pts with checkpoint refractory disease there is no effective standard therapy. Preclinical studies show that the combination of PDS0101, a therapeutic vaccine targeting HPV 16 E6/E7, M9241, a tumor-targeting IL-12 immunocytokine, and bintrafusp alfa (BA), a bifunctional fusion protein targeting TGF-β and PD-L1, resulted in maximum T cell infiltration and tumor reduction compared to any 1 or 2 of these agents alone. Prior clinical data suggests that the combination is preferentially active in HPV 16+ disease. **Methods:** 30 pts with advanced HPV 16+ cancer were treated with PDS0101, M9241 and BA (NCT04287868). Pts received BA at 1200 mg IV q2wks, M9241 at 16.8 mcg/kg SC q4wks or 8 mcg/kg SC q2wks, and PDS0101 as two 0.5 ml SC injections q4wks. Dose reductions or skipped doses for toxicities of BA and M9241 were allowed. 5 pts had surgical resection of tumor for disease control and were censored for PD but not survival. **Results:** 30 pts (9 cervical, 2 vaginal/vulvar, 6 anal, 13 oropharyngeal) were treated. 13/30 had grade 3 treatment related AEs including grade 3 anemia in 9 pts associated with grade 3 hematuria in 3 pts and grade 3 GI bleeding in 3 pts. 2 pts had grade 3 AST/ALT elevation. Grade 3 flu like symptoms and grade 3 hemophagocytic lymphohistiocytosis were each seen in 1 pt. One pt had grade 3 lymphopenia/leukopenia plus grade 4 neutropenia and one pt had grade 4 AST/ALT elevation. There were no grade 5 treatment related AEs. 7/8 (88%) pts with checkpoint naïve disease had objective responses (OR) including 1 delayed response after initial PD with 4/7 (57%) responses ongoing (median 17 months follow up). 10/22 (45%) with checkpoint refractory disease have had disease reduction including 6/22 (27%) with OR and 4/6 (67%) responses ongoing (median 12 months follow up). 6/8 (75%) pts with checkpoint naïve disease and 17/22 (77%) pts with checkpoint refractory disease are alive after a median of 17 and 12 months follow up respectively. For checkpoint refractory pts, M9241 dosing appears to affect response rates. 5/8 (63%) pts receiving M9241 at 16.8 mcg/kg had an OR compared to 1/14 (7%) who received M9241 at 8 mcg/kg with an OR. However, despite differences in response rates with higher vs lower M9241 dose, survival outcomes were similar irrespective of M9241 dose (p = 0.99 by Kaplan Meier analysis). **Conclusions:** The combination of PDS0101, M9241 and BA appears to have a manageable safety profile along with early evidence of clinical activity for pts with checkpoint naïve and refractory advanced HPV 16+ cancer. Moreover, growing data suggest that all 3 drugs in the combination contribute to the encouraging outcomes being observed. Clinical trial information: NCT04287868. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

2519 **Poster Discussion Session**

Identifying mechanisms of acquired immune escape from sequential, paired biopsies. *First Author: F. Stephen Hodi, Dana-Farber Cancer Institute, Boston, MA*

Background: Resistance to immune checkpoint blockade (ICB) can manifest as disease progression either at the initiation of treatment (primary resistance) or after some initial response (acquired resistance). To better understand the mechanisms underlying acquired resistance, the imCORE Network is conducting a study (NCT03333655) to examine changes in tumor biology from pre-treatment to disease progression across cancer types. **Methods:** Eligible patients included those experiencing clinical benefit on ICB (defined as objective response or stable disease longer than 6 months) and had evaluable tissue samples from both pre-treatment and within 30 days of progression. Samples were subjected to whole exome sequencing (WES), RNA sequencing (RNA-Seq), and immunohistochemistry (IHC). Whole blood samples or adjacent normal tissue were used as a reference for tumor variant calling. **Results:** As of December 3rd, 2021, 24 enrolled patients have complete sample pairs. Of those, melanoma, bladder, and lung were most common (n = 7, 6 and 5 pairs, respectively), but our cohort also included patients with breast cancer, squamous head & neck, and renal cell carcinoma. IHC data unexpectedly showed a modest, but consistent increase in tumor infiltrating CD8+ T cells at progression. In addition, IHC evidence of a decrease in MHC-I proteins (HLA-A and B2M) suggest that in 5 out of 24 cases, key proteins needed for antigen presentation are lost. Global differential gene expression analysis showed that immune gene expression was significantly increased at progression, including numerous chemokines and significant enrichment in gene sets responsible for antigen presentation machinery. Protein-altering mutations at progression appeared in B2M in one patient, and CXCL9 in another. However, in most cases it is unclear what genetic alterations are responsible. We do not observe evidence of consistent IFNγ and Jak/stat signaling loss or antigen presentation loss. **Conclusions:** While ICB resistance is thought to be associated with a lack of immune response within the TME, we found that acquired resistance is usually associated with either maintenance or an increase in immune infiltration. Multiple alterations that are unique to individual patients also continue to emerge. Our data shows ICB resistance is multifactorial and associated with dynamic changes to markers amid immune activation and inhibition. Clinical trial information: NCT03333655. Research Sponsor: Roche/Genentech.

2520 **Poster Discussion Session**

Effect of intratumoral INT230-6 on tumor necrosis and promotion of a systemic immune response: Results from a multicenter phase 1/2 study of solid tumors with and without pembrolizumab (PEM) [Intensity IT-01; Merck KEYNOTE-A10]. *First Author: Jacob Stephen Thomas, Division of Oncology, USC Keck School of Medicine, Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: INT230-6 is a new product with a unique dual anti-cancer mechanism. The drug is comprised of cisplatin (CIS) and vinblastine (VIN) co-formulated with an amphiphilic molecule that enables drug dispersion throughout a tumor and passive diffusion into cancer cells following intratumoral (IT) delivery. A neoadjuvant study in breast cancer confirms that a single injection can kill 95% of an injected tumor and recruit TILs. **Methods:** INT230-6 treatments are Q2W for up to 5 treatments followed by maintenance dosing every 9 weeks. Dose is set by the tumor's longest diameter or volume. One arm received INT230-6 plus PEM 200mg IV Q3W. Biopsies from injected tumor are taken pretreatment and Day 28 for immunohistochemistry (IHC) analysis. **Results:** Sixty-two subjects received INT230-6 alone (median age 61, with 4 prior treatments), and 21 INT230-6 + PEM (median age 70, with 3 prior treatments). To these subjects over 575 image guided INT230-6 IT injections were given (320 to visceral tumors such as lung, liver, pancreas). Doses ranged from 0.14 to 175mL (87.5 mg of CIS, 17.5 mg VIN - higher than typical IV doses). Pharmacokinetic data shows > 95% of the INT230-6 active agents remain in the tumor. The most common (> 25%) adverse events (AEs) related to INT230-6 were localized pain (58%), nausea (40%), and fatigue (29%). The most common AEs attributed to the PEM combination were nausea (62%), localized pain (57%), vomiting (57%), decreased appetite (43%), fatigue (43%) and constipation (29%). The incidence of grade 3 AEs for the INT230-6 arm was 11% and for the PEM combination was 14%. There were no related grade 4 or 5 AEs in the INT230-6 arm; and one grade 4 neutrophil count decrease was seen on the PEM combination. There were no dose limiting adverse events. No patient discontinued therapy due to toxicities related to either drug or injection procedure. The monotherapy arm enrolled patients from 17 tumor types; while the PEM combo recruited primarily pancreatic, CRC, triple negative breast, or bile duct cancer. IHC results confirm a marked reduction in proliferating tumor cells with influx of CD4 and CD8 T-cells. Seven of the INT230-6 monotherapy patients had non injected tumor shrinkage in 9 visceral/deep lesions. Estimated median overall survival (mOS) was over 1 year for both arms. **Conclusions:** In this clinical trial, deep and superficial tumor injections into patients with widely metastatic disease was feasible and well tolerated. Biopsies confirm the dual anti-cancer mechanism, and study patients live longer than would be expected for these refractory populations. INT230-6's rapid tumor killing and immune activation properties may offer an alternative to control refractory patients (even those that are chemotherapy refractory) and the product is moving into randomized controlled registration trials. Clinical trial information: NCT03058289. Research Sponsor: Intensity Therapeutics, Inc.

First-in-human dose escalation and expansion study of MT-6402, a novel engineered toxin body (ETB) targeting PD-L1, in patients with PD-L1 expressing relapsed/refractory advanced solid tumors: Interim data. *First Author: Eugene R Ahn, Cancer Treatment Centers of America Chicago, Zion, IL*

Background: MT-6402 is a unique and potent PD-L1-targeted engineered toxin body (ETB) capable of directly killing PD-L1 expressing tumor and immune cells by internalization of a fused Shiga-like toxin A subunit (SLTA) resulting in permanent SLTA-mediated ribosomal inactivation. The targeting of PD-L1 expressing tumor cells may directly drive tumor regression whereas targeting of PD-L1 expressing immune cells may release immunosuppression and drive immune recognition of the tumor. MT-6402 also delivers an HLA-A*02 restricted cytomegalovirus (CMV) class I antigen into PD-L1 expressing cells (antigen seeding) that can be recognized by existing CMV-specific cytotoxic T cells. **Methods:** A first-in-human dose escalation and expansion study in patients with PD-L1-expressing advanced solid tumors was initiated in 2021. As of 1 Jan 2022, 6 patients received at least one dose of MT-6402, 4 of whom were eligible for Dose Limiting Toxicity (DLT) assessment in Cohort 1. **Results:** A significant reduction in CD14+ monocytes starting in cycle 2 was observed in patients on therapy after each MT-6402 administration, indicating an HLA-independent PD effect consistent with preclinical observations. 5 of 6 patients had a marked decrease in Monocytic Myeloid Derived Suppressor Cells (MDSC). The reduction in MDSC and monocytes in the periphery overlapped with increased CCL2 levels, a chemokine that directs movement of myeloid cells. One patient with osseous metastases from non-small cell lung cancer (NSCLC) who is HLA-A*02 and CMV+ showed complete CMV-specific T-cell extravasation at day 8 and serum cytokine signatures consistent with antigen dependent responses and T cell mobilization. This patient had reduced tracer uptake of metastatic bone lesions with 3/4 lesions resolving completely. A second HLA A*02 CMV+ patient followed a similar trend towards loss of peripheral CMV-specific T cells with a concurrent increase in total CD8 T cells. The CD8 T cells from these 2 patients had elevated T-bet expression from baseline, indicating antigen specific TCR stimulation and expansion. The activated immune response was also accompanied by increased IP-10 and IL-2 cytokine signatures in the serum. Consistent with these findings, one of these two patients had transient (1-12 h) grade 2 infusion related reaction and the other had transient (1-12 h) grade 2 cytokine release syndrome, both on Day 15. These results describe a novel approach to checkpoint modulation by MT-6402, that adds antigen seeding to PD-L1 directing mechanisms. MT-6402 was well tolerated and no DLT was observed in Cohort 1 (16 μg /kg, QW in 4-week cycles). **Conclusions:** Dose escalation is ongoing. The results hold promise for development of MT-6402 for solid tumors, including in the R/R setting. Data for additional patients will be presented at the meeting. Clinical trial information: NCT04795713. Research Sponsor: Molecular Templates, Inc.

The association of pre-existing autoimmune disease and immune-related adverse events secondary to immune checkpoint inhibition therapy in a UK multicenter cohort. *First Author: Anna Claire Olsson-Brown, Clatterbridge Cancer Centre, Liverpool, United Kingdom*

Background: Pre-existing autoimmune disease (AID) potentially increases the propensity for the development of immune related adverse events (irAE) in response to oncological immune checkpoint inhibitors (ICIs) is biologically plausible and clinically observed. However, due to consistent clinical trial exclusion of those with pre-existing AID, the impact on the frequency and severity of irAEs is uncertain. Here we analyse this relationship in a large, real-world, UK multi-centre cohort. **Methods:** A retrospective analysis of 2049 patients treated with ICIs over a two year period was undertaken across 12 National Health Service centres by the UK National Oncology Trainees Collaborative for Healthcare Research (NOTCH). Patients received ICIs as standard of care for malignant melanoma, non-small cell lung cancer and renal cell carcinoma. The presence of pre-existing AIDs was assessed and classified as either autoantibody driven or autoinflammatory then correlated with clinically significant irAEs (i.e. ≥grade 2 or all-grade endocrinopathies). Statistical analyses included T-test, Mann-Whitney and Chi-squared. For overall survival (OS) Kaplan-Meier and log-rank tests were utilised. **Results:** Pre-existing AID were present in 13% (n = 257) of the overall cohort. Pre-existing endocrinopathies (30%; n = 76) were most common followed by rheumatological AIDs (18%; n = 46). In the pre-existing AID cohort there was a female predominance (48% vs 39%; p = 0.006) but no difference in smoking history (p = 0.074) or ethnicity (p = 0.12). There was no difference in ICI treatment between those with and without pre-existing AID (p = 0.2800). IrAEs occurred in 45% (n = 117) patients with pre-existing AID vs 33% (n = 583) without (p£0.001). The median time to onset of irAEs was similar. IrAEs with an increased incidence in the pre-existing AID cohort were colitis (p = < 0.001), arthralgia (p = 0.008) and dermatological irAEs (p = 0.014). There was no difference in the incidence of irAEs in patients with autoantibody driven vs autoinflammatory pre-existing AID (44.0 % vs 44.8%, p = 0.905). In the overall cohort, those with pre-existing AIDs had a median OS of 20.4 months (95% CI: 19.4-21.7) vs 14.1 months (95% CI: 12.8-16.3) in those without pre-existing AID (p = 0.004). **Conclusions:** This large multi-centre ICI-treated cohort demonstrates that pre-existing AID is a predisposing factor for the development of irAEs, however the incidence is lower than previously quoted. The pathological basis of pre-existing AID did not differentially affect irAE manifestation. Patients with pre-existing AID had improved OS compared to those without which has not been observed in previously reported studies. ICI treatment should be considered in those with pre-existing AID but further studies are needed to determine how best to optimise outcomes whilst mitigating the impact of irAEs. Research Sponsor: None.

2523 **Poster Discussion Session**

Preexisting autoantibodies as predictor of immune-related adverse events for advanced solid tumors treated with immune checkpoint inhibitors. *First Author: Arthur Daban, APHP, Paris, France*

Background: Immune checkpoint inhibitors (ICIs), used alone or as a combination are standard of care in many cancers. Generally well tolerated, they can generate immune-related adverse events (irAEs). No biomarkers are available to identify patients who are more likely to develop irAEs. The aim of this study was to assess the association between preexisting autoantibodies, occurrence of irAEs and survival outcomes. **Methods:** We performed a prospective study including 221 patients receiving ICIs for advanced solid tumors between May 2015 and July 2021. Autoantibodies testing (anti-neutrophil cytoplasmic, anti-nuclear, thyroid peroxidase and thyroglobulin) was performed before ICIs initiation. The associations among preexisting autoantibodies, the occurrence, the severity, the delay of irAEs and the survival outcomes, including progression-free survival (PFS) and overall survival (OS) were analyzed. Statistical analyses were performed with T-test, Cox regression models, univariate and multivariate analyses and Kaplan-Meier's method. **Results:** Of the 221 patients, 151 (68%) were men, the median age was 66,5 (range 21-90) years and 103 (81%) had an ECOG-PS of 0 or 1. Seventy-three percent (n=162) received an anti-PD-(L)1 in monotherapy, 27% (n=59) an anti-PD-(L)1 in combination, for a renal cell carcinoma in 45% (n=99) and a lung carcinoma in 41% (n=90). In total, 129 (58%) patients had preexisting antibodies. IrAEs were significantly more frequent in patients with preexisting autoantibodies: 64 patients (50%) in the positive group vs. 20 patients (22%) in the negative group, OR = 3.5 (95%CI=1.8 - 6.8), p=0.00002. Median time interval between ICI initiation and irAE was shorter in the positive group vs. the negative group, 13 weeks (IQR=43weeks) vs. 28.5 weeks (IQR=12weeks) respectively (p=0.01). Twelve patients (9.4%) experienced multi toxicities in the positive group vs. two (2%) in the negative group, OR=4.5 (95%CI0.98-36), p=0.04. ICIs exposure was identical in preexisting and non-preexisting autoantibodies groups. After a median follow-up of 25 months (95%CI=19-31), median PFS and OS were significantly longer among patients experiencing irAE: 12.6 months (95%CI=11-22.7) vs 5 months (95%CI=4.2-7.0), p= 0.0003 and 30 months (95%CI= 22.7-NR) vs 21 months (95%CI=15-34.6), p= 0.016. In multivariate analyses irAEs remain statistically associated with survival outcomes. Preexisting autoantibodies were not associated with survival outcomes. **Conclusions:** The presence of preexisting autoantibodies is significantly associated with the occurrence of irAE in patients treated with ICIs. Earlier and multiple irAEs were observed in the presence of preexisting autoantibodies. Thus, these biomarkers could help to identify patients at risk of irAEs and would prompt us to closely monitor them. Research Sponsor: None.

2524 **Poster Session**

Safety and efficacy results from the expansion phase of the first-in-human study evaluating TGFβ inhibitor SAR439459 alone and combined with cemiplimab in adults with advanced solid tumors. *First Author: Debbie Robbrecht, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: SAR439459 (SAR459) is a human anti-TGFβ monoclonal antibody that neutralizes all isoforms of TGFβ. In preclinical models, combining SAR459 with an anti-PD-1 showed improved anti-tumor activity compared to SAR459 single agent. In the dose escalation, acceptable tolerability was observed, the MTD was not reached and the preliminary RP2D was 22.5mg/kg Q3W when combined with cemiplimab (CEMI; S. Williamson et al. J Clin Oncol 39, 2021[suppl 15; #2510]). Reduction of plasma TGFβ was ≥90% at doses ≥0.25mg/kg Q2W, with a trend of a decrease in intra-tumoral TGFβ (D. Robbrecht et al. JITC 2021;9 [suppl 2; #250]). Here we report safety and efficacy results of the dose expansion. **Methods:** The expansion phase of this open-label, phase 1/1b study aimed to determine the optimal dose of SAR459 (7.5 mg/kg or 22.5 mg/kg Q3W) in patients (pts) with advanced melanoma (MEL) resistant to anti-PD(L)1 therapy (Part 2A); and the ORR (confirmed responses) in all treated pts with SAR459 22.5 mg/kg + CEMI 350 mg Q3W in pts with MEL, Non-small Cell Lung Cancer (NSCLC), or Hepatocellular Carcinoma (HCC), resistant to anti-PD(L)1; as well as in pts with mesenchymal Colorectal Cancer (CRC) or Urothelial Cancer (UC), anti-PD(L)1 naïve (Part 2B). **Results:** From October 2019 to September 2021, 109 pts with ECOG PS 0-1 enrolled in Part 2A (14) and Part 2B (95). Overall, the median age was 63 years and 83% of pts received up to 3 prior treatment lines for advanced disease (range 1-8). Based on preliminary data, the ORR in Part 2B was 8% (Table). No significant association between clinical response and plasma TGFb level at baseline or modulation upon treatment was observed. The correlation between tumor TGFb level and clinical benefit is inconclusive due to limited number of tumor biopsies. No response was observed in Part 2A. Overall, 100% of pts had at least one treatment emergent adverse event (AE), 67% were G≥3, 34% related G≥3, 17% G5, and 4% related G5. The limited number of patients treated with SAR459 alone at the RP2D did not allow to demonstrate added toxicity due to the combination. Overall, 51 pts (47%) reported hemorrhagic AE of any grade, 8 pts (7%) had G≥3 and 5 pts (5%) had fatal outcome. The rate of bleeding and severe hemorrhagic AE was higher in HCC pts compared to the other cohorts: 11/14 (79%) pts had a hemorrhagic AE, of which 3 (21%) G≥3 and fatal. An exploratory analysis showed a trend for higher frequency of any grade SAR459-related and fatal hemorrhagic AE in patients with higher exposure. **Conclusions:** The NCT03192345 study was discontinued due to a lack of efficacy, and a high bleeding risk particularly in pts with HCC. Clinical trial information: NCT03192345. Research Sponsor: Sanofi.

2525 **Poster Session**

The impact of COVID-19 infection on immune-related adverse events in patients with cancer receiving immune checkpoint inhibitors. *First Author: Mengni Guo, AdventHealth Orlando, Orlando, FL*

Background: Immune checkpoint inhibitors (ICIs) can cause a variety of inflammatory autoimmune tissue damage, referred to as immune-related adverse events (irAEs). COVID-19 is associated with increased amounts of proinflammatory cytokines, which may synergistically affect the outcome of irAEs. Data are limited regarding the impact of COVID-19 on irAEs in ICI-treated cancer patients. **Methods:** We retrospectively analyzed adult patients with malignant solid tumors treated with ICIs at AdventHealth Orlando between August 2020 and August 2021. All COVID-19 infections were confirmed by PCR. Patients who had the most recent ICI treatment over one month before or after the positive COVID-19 test were excluded from the study. For COVID-19 positive group, only the irAEs that developed after COVID-19 infection were considered as events. **Results:** A total of 579 patients were included in our study, with 46 (7.9%) in COVID-19 positive group, and 533 (92.1%) in COVID-19 negative group. The baseline characteristics of patients in the two groups were similar in terms of age, ethnicity, ECOG, cancer histology, and type of ICI. With a median follow-up of 10 months (1-73 months), no differences in the time from ICI initiation to irAE onset, corticosteroid use, or additional immunosuppressant use were seen. A trend in higher incidence of all-grade diarrhea/colitis (8.7% vs. 3.0%, p=0.07) and grade 3 and 4 hepatitis (4.3% vs. 0.8%, p=0.08) was noted in the COVID-19 positive group, however the difference was not statistically significant. No significant difference in the incidence of pneumonitis (2.2% vs. 1.1%, p=0.44), nephritis (2.2% vs. 0.8%, p=0.34) or dermatitis (6.5% vs. 6.4%, p=1.00) were noted between COVID-19 positive and negative groups. We noticed a higher incidence of all-grade irAEs in the COVID-19 positive group (30.4% vs. 19.9%, p=0.18), but the difference was not statistically significant. The incidence of grade 3 and 4 irAEs was significantly higher in the COVID-19 positive group (10.9% vs. 3.2%, p=0.02). Nine COVID-19 related death occurred while no irAE-related death was noted in the entire cohort. **Conclusions:** Our study suggested that COVID-19 may pose a risk of severe irAEs in cancer patients receiving ICIs. Close monitoring and possible delaying ICI administration could be considered when cancer patients were infected with COVID-19. Research Sponsor: None.

Clinical features of the irAE between COVID-19 positive and COVID-19 negative groups.

Variable	COVID-19 positive N=46	COVID-19 negative N=533	P-value
All grades irAE, n (%)	14 (30.4)	106 (19.9)	0.18
Grade 3-4 irAE, n (%)	5 (10.9)	17 (3.2)	0.02
Corticosteroid use for irAE, n (%)	8 (57.1)	60 (56.6)	0.78
Use of additional immunosuppressant for irAE	0 (0.0)	4 (3.8)	1.00
Time to irAE, median (range)			
Treatment cycle	6 (2-72)	6 (1-56)	0.54
Days	255.5 (48-1662)	153.5 (7-1415)	0.25
Death related to irAE, n (%)	0 (0.0)	0 (0.0)	1.00

2526 **Poster Session**

A multicenter, randomized, double-blind, phase III trial comparing denosumab biosimilar QL1206 and denosumab in patients with bone metastases from solid tumors. *First Author: Huiping Li, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/ Beijing), Department of Breast Oncology, Peking University Cancer Hospital and Institute, Beijing, China*

Background: This phase III study compared clinical efficacy, safety of the first biosimilar QL1206 with denosumab in solid tumor patients with bone metastases. **Methods:** Patients aged 18-80 years, with bone metastatic solid tumors and ECOG performance status of 0-2 were randomly assigned 1:1 to receive subcutaneous QL1206 or denosumab (120 mg Q4W, both) based on stratification factors (tumor types, previous skeletal-related event [SRE], and current systemic anti-tumor therapy). The primary efficacy endpoint was the percentage changes from baseline to week 13 in urinary N-telopeptide/creatinine ratio (uNTX/uCr); Clinical equivalence would be confirmed if the two-sided 90% confidence intervals (CI) of the least-squares mean (LSM) difference of natural log-transformed ratio of week 13 uNTX/uCr to baseline calculated by analysis of covariance were within the margins of ±0.135. The secondary endpoints included the percentage changes from baseline to week 25 and 53 in uNTX/uCr, the percentage changes from baseline to week 13, 25 and 53 in serum bone-specific alkaline phosphatase (s-BALP) and the time to on-study SRE. Adverse events (AE), immunogenicity (IG) and pharmacokinetics (PK) were also assessed. Population PK was analyzed using nonlinear mixed effects model. **Results:** 717 patients were randomized to the QL1206 (n = 357) and denosumab (n = 360) groups, respectively. The median percentage changes at week 13 in uNTX/uCr were -75.2% for QL1206 and -75.8% for denosumab. LSM of natural log-transformed ratio of week 13 uNTX/uCr to baseline were -1.429 (standard error 0.130) and -1.441 (0.130) in the two groups. The LSM difference between the two groups was 0.012 (90% CI -0.078 to 0.103; P = 0.8208), within the equivalence margins. Analyses for subgroups of sex, age, and randomization strata showed almost no significant differences. The secondary endpoints were also similar between the two groups (median percentage changes in s-BALP from baseline to week 13: -38.0% vs -37.1%; hazard ratio of time to SRE: 1.264 [95% CI 0.670 to 2.383]; both P > 0.05). In the safety set, treatment-emergent AE occurred in 332 of 356 patients (93.3%) in the QL1206 group and 348 of 361 (96.4%) in the denosumab group. The proportions of positive anti-drug antibody (14/345 [4.1%] vs 16/352 [4.5%]), neutralizing antibody (three [0.9%], each), and PK characteristics were similar between the two groups. **Conclusions:** The results suggest that QL1206, the first biosimilar denosumab, is similar to denosumab with respect to clinical efficacy, acceptable safety, IG, and PK characteristics. The totality of evidence supports clinical equivalence of QL1206 and denosumab. Clinical trial information: NCT04550949. Research Sponsor: Qilu Pharmaceutical Co., Ltd.

2527 **Poster Session**

Safety, tolerability, and preliminary efficacy of nadunolimab, a first-in-class monoclonal antibody against IL1RAP, in combination with pembrolizumab in subjects with solid tumors. *First Author: Shekeab Jauhari, Sarah Cannon Research Institute, Florida Cancer Specialists and Research Institute, Lake Mary, FL*

Background: Interleukin-1 Receptor Accessory Protein (IL1RAP) is expressed on cancer and stromal cells of many solid tumors. IL1RAP interacts with IL-1R1, modulating downstream factors (e.g. IL-6, IL-8) and CRP level. Nadunolimab (CAN04), a fully humanized ADCC-enhanced IgG1 antibody, targets IL1RAP and blocks IL-1α and IL-1β. IL-1 promotes an immune suppressive microenvironment, e.g. by recruitment of MDSC which may induce checkpoint inhibitor resistance. Here, initial data are reported from the phase Ib clinical trial CIRIFOUR, evaluating nadunolimab combined with pembrolizumab in solid tumor patients (pts) progressed on prior anti-PD-(L)1 therapy. **Methods:** Primary objective was evaluating safety and tolerability of nadunolimab combined with pembrolizumab in pts with metastatic NSCLC (n = 5), head and neck squamous cancer (n = 9) or malignant melanoma (n = 1), progressed on prior anti-PD-(L)1 therapy of ≥12 weeks (wks). Dosing started with a priming dose of 0.5 mg/kg nadunolimab on Day -7, followed by 5 mg/kg nadunolimab weekly combined with standard pembrolizumab dosing. A safety lead-in phase 3+3 design was employed. Secondary objectives included preliminary efficacy and responses based on RECIST/iRECIST. Serum biomarkers and tumor biopsies were also analyzed. **Results:** Fifteen pts received at least one dose of 5 mg/kg nadunolimab with pembrolizumab: median age 63 years (50-79), 27% female, 100% Stage IV, 93% and 7% received prior pembrolizumab or nivolumab respectively, 7% ECOG 0, 93% ECOG 1. The pts had received a mean of 2.3 (range 1-6) previous lines of treatment. SAE were reported in 47% with one considered treatment-related (febrile neutropenia). Two treatment-related grade 3 AE were reported: one febrile neutropenia (DLT), one pneumonitis. No pts discontinued treatment due to treatment-related AE. One patient (7%) had unconfirmed PR as best response, 8 (53%) showed SD, and 6 (40%) iUPD. At time of analysis, 5 pts (33%) received ongoing treatment. Of these, two pts had received therapy for over 31 wks, another two for over 49 wks. Decreased IL-6 was observed after four wks and persisted during treatment. Reduced neutrophil-lymphocyte ratio (NLR) was observed throughout the study, appeared after first treatment, and was driven by a moderate reduction in circulating neutrophils. Decreased IL-6 and NLR were most pronounced in pts with longest disease control duration. IL1RAP expression on cancer and stromal cells was confirmed in tumor biopsies. **Conclusions:** The nadunolimab and pembrolizumab combination was considered safe and tolerable with preliminary evidence of prolonged disease control. The favorable safety provides basis for evaluation of further therapy with this combination. Next, nadunolimab and pembrolizumab will be assessed with carboplatin/pemetrexed in non-squamous NSCLC. Clinical trial information: NCT04452214. Research Sponsor: Cantargia AB.

2528 **Poster Session**

Customized autoantibodies (autoAbs) profiling to predict and monitor immune-related adverse events (irAEs) in patients receiving immune checkpoint inhibitors (ICI). *First Author: Sofia Genta, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Using a customized microarray, we previously reported that patients (pts) who develop irAEs grade (G)≥2 and those who do not, have different median fluorescent intensity (MFI) levels of specific autoAbs at baseline (pre-ICI). Leveraging a larger dataset, we evaluated whether overall baseline autoAbs elevation and early increases in autoAbs after ICI can predict irAEs as well as if steroid treatment can reduce autoAbs. **Methods:** Plasma was obtained from pts receiving ICI in two clinical trials (MET4-IO, NCT03686202 and INSPIRE, NCT02644369) and from healthy controls (hc). Collection time points in MET4-IO and INSPIRE studies included: baseline, 3-4 weeks (w), 6-8 w, 24 w and at the end of treatment and baseline and 6 w respectively. Arrays with 162 autoAg customized for frequent irAEs were incubated with plasma and probed with Abs to detect IgG and IgM reactivity. AutoAbs with MFI >500 per individual were compared between hc and pts with and without irAEs G≥2 by the Student-t test. **Results:** Samples from 114 pts and 14 hc were analyzed (pts characteristics are summarized in the Table). G≥2 irAEs included: hypothyroidism (13), pneumonitis (10), colitis (7), hepatitis (4), skin toxicity (7), infusion reaction (2), pancreatitis (2), meningitis (1), hypophysitis (1), corneal ulcer (1), high creatinine (1), myocarditis (1), myositis (1), diabetes (1), mucositis (1), myasthenia (1) and adrenal failure (1). Hc had less autoAbs with MFI >500 as compared to pts at baseline (median 32 vs 62 $p<0.001$). IgG with MFI >500 were higher at baseline in pts who developed G≥2 irAEs vs those without G≥2 irAEs (median 39 vs 33, $p=0.03$). In 23 pts with plasma collected at the time of irAEs, we observed a significant increase of autoAbs with MFI>500 from baseline (median 84 vs 77 $p= 0.009$). Paired samples at the time of irAEs and after steroids were available for 9/23 pts, showing lower autoAbs after steroid treatment (54 vs 79 $p=0.006$). No differences in autoAbs with MFI>500 pre and post ICI were seen in pts without G≥2 irAEs (baseline vs first post ICI collection median 58 vs 60, $p=0.13$). **Conclusions:** We observed a higher number of IgG with MFI >500 at baseline and a greater increase after ICI administration in individuals with irAEs compared to those without irAEs. Steroid treatment resulted in a decrease in autoAbs. A prospective study is ongoing to validate the potential role of autoAbs for risk stratification and monitoring of irAEs. Research Sponsor: Dr. Spreafico's research founding.

Initial findings from a first-in-human, multicenter, open-label study of ATOR-1017, a 4-1BB antibody, in patients with advanced solid malignancies. *First Author: Gustav J. Ullenhag, Department of Radiology, Oncology and Radiation Science, Section of Oncology, Uppsala University, Uppsala, Sweden*

Background: ATOR-1017 is a human agonist Fcγ-receptor cross-linking dependent IgG4 antibody targeting the co-stimulatory receptor 4-1BB (CD137). ATOR-1017 activates T cells and natural killer cells in the tumor environment, leading to immune-mediated tumor cell killing. **Methods:** In this first-in-human, dose escalation, multicenter, phase 1 study (NCT04144842), adult patients with solid tumors refractory to standard therapy were enrolled in single patient cohorts for doses up to 40 mg, and thereafter in cohorts of 3-6 patients, to receive ATOR-1017 in a 21-day cycle. Intra-patient dose escalation of ATOR-1017 is allowed depending on the occurrence of Dose-Limiting Toxicities (DLTs) during cycle 1. ATOR-1017 is administered intravenously as monotherapy every three weeks until unacceptable toxicity, progressive disease, or withdrawal of consent. The primary objectives of the study are to determine the maximum tolerated dose, assess adverse events (AEs), evaluate DLTs, and to determine the recommended phase 2 dose. Secondary objectives include pharmacokinetics (PK), immunogenicity, and clinical efficacy, assessed with CT scans using Immune Response Evaluation Criteria in Solid Tumors (iRECIST). Exploratory objectives include assessment of pharmacodynamic (PD) biomarkers. **Results:** 22 patients (18 females), median age 55 years (34-76) with solid tumors, previously treated with median of 4 (0-6) lines of chemotherapy and/or 2 (0-3) lines of immunotherapy, were included and received at least one cycle ATOR-1017. Nine dose levels have been evaluated; 0.38 mg, 1.5 mg, 5 mg, 15 mg; 40 mg, 100 mg, 200 mg, 360 mg, and 600 mg and dose escalation is ongoing. Treatment-related (TRAEs) were reported in 12 out of 22 patients (54.5%); most common (≥10%) were fatigue (13.6%) and neutropenia (13.6%). Five patients experienced a grade 3-4 TRAE; neutropenia (n = 2), febrile neutropenia (n = 1), chest pain (n = 1), increased liver enzymes (n = 1) and leukopenia/thrombocytopenia (n = 1). No patients discontinued due to TRAEs, no DLTs were observed, and the maximum tolerated dose has not been reached. The median time for patients in the study was 12 weeks (range 4-67). As per data cut-off, January 18, 2022, four patients remained on treatment and 18 patients had discontinued treatment. The reasons for discontinuation include confirmed disease progression (n = 10), clinical deterioration (n = 4), withdrawal of consent (n = 1), death due to disease progression (n = 3). Preliminary PK data showed dose-proportional kinetics. Dose-dependent increase in PD biomarkers demonstrated target-mediated biological activity and proof-of-mechanism. The best response was stable disease observed in a total of 10 patients (45%). **Conclusions:** ATOR-1017 is safe and well-tolerated at doses up to 600 mg and has shown biologic activity. No DLTs have been reported so far and dose escalation continues. Clinical trial information: NCT04144842. Research Sponsor: Alligator Bioscience.

2530 **Poster Session**

Novel platform for identifying multiple cancer-specific antigens. *First Author: Danielle Mor, Augusta University, Augusta, GA*

Background: Virtually all cancer treatments that kill cancer cells also adversely affect normal cells and often have debilitating side effects. A key challenge has been to identify antigens that are suitable for antibody-based targeted therapeutics. We have developed a novel platform to detect and identify multiple cell surface antigens that are unique to human cancers. **Methods:** Breast Cancer cells (Hs578T) or Melanoma cells (Hs895.T) were injected into rabbits to generate polyclonal xeno-antibodies. The resulting serum against each cancer was then incubated with normal cells of the same tissue type derived from the same patients; Breast Epithelium (matched-pair Hs578Bst) or Skin Fibroblasts (matched-pair Hs895.Sk) in order to absorb antibodies that cross-react with antigens on normal tissue (U.S. Patent Application No. 16/243,161). Flow cytometry was used for measuring the binding capacity of the unfiltered serum and filtered serum (lacking cross-reacting antibodies) on both the cancer cells and normal cells. Cytotoxicity assays were performed using a secondary ADC (anti-rabbit IgG specific antibody conjugated to MMAF), to determine the cytotoxicity of the unfiltered antibodies and filtered antibodies on normal and cancer cells. **Results:** Flow cytometry revealed, for antibodies against breast cancer, there was 90.3% and 88.6% binding to breast cancer cells and normal breast epithelial cells, respectively, pre-filtration; and 78.9% and 23% binding, respectively, post-filtration. For antibodies against melanoma, there was 89.2% and 86.6% binding to melanoma cells and normal skin fibroblasts, respectively, pre-filtration; and 55.1% and 0% binding, respectively, post-filtration. The Table summarizes the cytotoxicity of unfiltered and filtered antibodies on cancer cells and normal cells. Remarkably, there was preferential killing of all the cancer cells tested by both unfiltered and filtered antibodies, while there was no cytotoxicity in the normal cells using filtered antibodies. Cytotoxicity was also observed when antibodies generated against one type of cancer were incubated with other cancer types. **Conclusions:** This data suggests that our xeno-antibody based method can detect cancer-specific sites, not found on normal cells, and diverse cancer types may share a common antigenic signature. These findings are significant for identifying unique antigens on cancer cells and designing targeted therapies against cancer. Research Sponsor: Cancer Antibodies Inc.

Phase I clinical trial of NEO-201, an anti-tumor-associated CEACAM-5/6 monoclonal antibody in solid tumors. *First Author: Christopher Cole, Women's Malignancies Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: NEO201 is a humanized IgG1 monoclonal antibody generated against tumor-associated antigens from colorectal cancer which binds specifically to tumor-associated CEACAM-5 and CEACAM-6 variants without binding CECAM 5/6 on normal epithelial tissues. NEO-201 reactivity is positive in the majority of adenocarcinomas including colon (85%), pancreas (86%), lung (79%), and breast (53%). Preclinical data showed that NEO-201 exerts anti-tumor activity through antibody dependent cellular cytotoxicity and complement dependent cytotoxicity. Here we present outcomes from a phase I trial of NEO-201 in advanced solid tumors (NCT03476681). **Methods:** This was a classic 3+3 dose escalation trial, with cohort expansion at the RP2D. NEO-201 was administered intravenously every two weeks in a 28-day cycle. The primary objective was to assess the MTD/RP2D of NEO-201 in patients with advanced solid tumors. The secondary objective was to assess the preliminary antitumor activity and exploratory objectives assessed pharmacokinetics and the effect of NEO-201 administration on immunologic parameters and possible relationships with response. Of 17 patients enrolled, 11 had colorectal, 4 had pancreatic and 2 had breast cancer. 4 patients received NEO-201 at dose level (DL) 1 (1 mg/kg), 6 patients at DL 1.5 (1.5 mg/kg) and 7 patients at dose DL 2 (2 mg/kg). **Results:** At the time of data cutoff, all patients had discontinued therapy. 11 of 14 evaluable patients discontinued due to disease progression and 3 patients discontinued due to DLT (grade 4 febrile neutropenia and prolonged neutropenia, each in 1/6 patients at DL2, and grade 3 febrile neutropenia in 1/6 patients at DL 1.5). Most common grade 3/4 toxicities were neutropenia (94%), white blood cell decrease (59%), lymphocyte decrease (29%), and febrile neutropenia (24%). Protocol was modified to allow administration of G-CSF and based on safety and PK data the RP2D was established as 1.5mg/Kg. Median number of doses received was 4.7. 13 subjects were able to undergo disease assessment after two cycles. The best response observed was stable disease (SD) in 5/9 evaluable patients with colorectal cancer. Minor CA-19-9 reductions were observed in two pancreatic cancer patients at DL 1.5. Correlative endpoints revealed that all patients enrolled in the trial expressed NEO-201 target antigen on their tumor tissue. Analysis of soluble factors in serum revealed that a high level of soluble MICA at baseline was correlated with a downregulation of NK cell activation markers and progressive disease. Unexpectedly, flow cytometry showed that NEO-201 also binds to circulating T regulatory cells and depleted these cells especially in patients with SD. **Conclusions:** NEO-201 was safe and well tolerated at the MTD of 1.5 mg/kg. Depletion of T regulatory cells suggests that the combination of NEO-201 with immune checkpoint inhibitor should be tested in future clinical trials. Clinical trial information: NCT03476681. Research Sponsor: U.S. National Institutes of Health.

In-vivo reprogramming macrophages and dendritic cells with Allocetra-OTS: Successful mono- and combination-antitumor therapy. *First Author: Dror Mevorach, Hadassah Medical Center, Jerusalem, Israel*

Background: Chimeric antigen receptor (CAR) T cells can activate an immune response to a cancer-specific antigen but is less effective in solid tumors. Immune check point inhibitors (ICI) revolutionized the treatment of solid tumors, however, in many tumors only partial response is achieved. Here we questioned the role of synergistic effect of Allocetra-OTS (cellular therapy for in-vivo reprogramming macrophages and dendritic cells, Enlivex Therap.) on solid tumor progression. **Methods:** To follow tumor growth *in vivo*, HeLa-CD19 cells were stably transduced with pLenti-PGK-V5-Luc-Neo. For CAR preparation, fresh mononuclear cells (MNC) were transfected with CD19-CAR plasmids. For the intraperitoneal solid tumor model, SCID-Bg mice were injected intraperitoneally (IP) with human HeLa-CD19 or HeLa-CD19-luciferase cells, 10×10^6 allocetra-OTS or vehicle, and 10×10^6 CD19-CAR T cells or mock T cells. In an immune-competent model, Balb/c mice were treated IP with AB12 (mesothelioma) with pLenti-PGK-V5-Luc-Neo and treated with anti-CTLA4 with or without Allocetra-OTS. Mice were monitored daily for clinical signs and peritoneal fluid accumulation and weekly for tumor growth. Kaplan-Meier log rank test was done for survival. Peritoneal cells were evaluated using single cell analysis and flow cytometry. Tumors were examined for bacterial presence by immunohistochemistry staining with antilipoteichoic acid (LTA) and antilipopolysaccharide (LPS). For allocetra-OTS preparation, enriched mononuclear fractions were collected by leukapheresis from healthy eligible human donors and induced to undergo early apoptosis. **Results:** SCID mice survived 30±5 days (range 27–37) and were sacrificed or died from solid tumor in the peritoneal cavity after accumulation of bloody peritoneal fluid and clinical deterioration. Results were verified using IVIS of intraperitoneal HeLaCD19-Luc cells. CAR T cell therapy significantly ameliorated survival to 55±11 days ($p < 0.05$ vs MOCK) but Alloctra-OTS further ameliorated survival to 75±10 ($p < 0.001$) with 20-40% complete remission. In AB12 model, anti CTLA4 therapy significantly ameliorated survival from 26±5 to 38 ±9 days ($p < 0.05$). However, Allocetra-OTS monotherapy ameliorated survival to 45 ±12 days ($p < 0.02$) and combinational therapy to 75±9 days ($p < 0.0001$) with complete remission in 60-75% of mice. Single cell analysis revealed that restoration of large peritoneal macrophages (LPM), were associated with antitumor activity. **Conclusions:** During intraperitoneal tumor progression, allocetra-OTS as monotherapy or combinational therapy with CAR or anti-CTLA4 significantly reduced tumor size and enable complete remission in up to 75% treated mice. Based on excellent safety profile in > 30 patients treated for sepsis and Covid19, human phase I/II of allocetra-OTS plus ICI, for peritoneal metastases, is planned for 2022. Research Sponsor: Enlivex Ltd.

2533 **Poster Session**

A phase 1, first-in-human (FIH) study of the anti-HER2 CAR macrophage CT-0508 in subjects with HER2 overexpressing solid tumors. *First Author: Kim Anna Reiss, University of Pennsylvania Abramson Cancer Center, Philadelphia, PA*

Background: Most solid tumors are resistant to immunotherapy. In pre-clinical studies, CAR-M infiltrate tumors, phagocytose tumor cells, activate the tumor micro environment (TME), recruit T cells, and present tumor antigens to T cells leading to robust anti-tumor immunity. CT-0508 is a first in class CAR-M, comprised of autologous monocyte derived macrophages expressing an anti-HER2 CAR. Here we present preliminary clinical results from the CT-0508 Phase 1 FIH study. **Methods:** This multi-center, open-label study is evaluating CT-0508's safety, tolerability, and manufacturing feasibility in 18 participants (pts) with advanced solid tumors overexpressing HER2 who have progressed on prior therapies. Monocytes are isolated from mobilized apheresis products, differentiated into macrophages and engineered with an anti-HER2 CAR. Group 1 pts (n = 9) receive a fractionated dose (D1, D3, D5) and Group 2 pts (n = 9) receive the full dose on D1. CT-0508 is administered without preparative chemotherapy (bridging is permitted). Serial blood samples, 1 pre and 2 post-treatment biopsies are collected to investigate safety, pharmacokinetics and mechanism of action. **Results:** Seven pts (4F/3M), median age 64 (49-73), have been treated [breast (2), esophageal (2), cholangiocarcinoma, ovarian and parotid gland cancers]. A median of 3 (2-10) prior lines of therapy have been administered, most pts (85.7%) received prior anti HER2 therapy. CT-0508 was successfully manufactured with high viability, purity and CAR expression, and was well tolerated with no dose limiting toxicities or AEs leading to discontinuation or dose modification. Two related SAEs were reported in the same pt (Grade 1 CRS, hospitalized for monitoring and Grade 2 infusion reaction, resolved within 1h). Three other pts had Grade 1-2 CRS; resolved within 4d with no use of tocilizumab needed. There were no major organ toxicities and no on-target off-tumor toxicities. Post-infusion cytokines were transiently elevated in most pts and were self-limiting. Among the 4 pts who reached week 8, the best overall response was stable disease (n = 3) and 1 pt progressed, with a median follow up of 8w. CT-0508 rapidly egressed from peripheral blood. CT-0508 CAR mRNA was detected in all tumor biopsies of the first 2 pts. CT-0508 activated the TME, with increased myeloid cell activation, T cell infiltration, activation and proliferation. TCR sequencing demonstrated peripherally expanding T cells enriched for tumor infiltrating lymphocyte clones, suggesting expansion of tumor reactive T cells. Correlative data from additional pts will be presented. **Conclusions:** In 7 pts, CT-0508 was safe and feasible to manufacture. Early correlative data demonstrate trafficking, TME modulation, and potential induction of anti-tumor T cell immunity. The study is actively enrolling. Clinical trial information: NCT04660929. Research Sponsor: Carisma Therapeutics.

Antitumor activity of T cells expressing a novel anti-folate receptor alpha (FOLR1) costimulatory antigen receptor (CoStAR) in a human xenograft murine solid tumor model and implications for in-human studies. *First Author: Owen R. Moon, Instil Bio, Inc., Dallas, TX*

Background: ITIL-306 is an autologous tumor-infiltrating lymphocyte (TIL) therapy that integrates T-cell receptor (TCR)-specific antigen recognition (Signal 1) with robust costimulation via the novel CoStAR transgene upon engagement with FOLR1 (Signal 2; Sukumaran, et al. *JITC.* 2021;9:198). Here, we assessed IL-2 independent effector function by anti-FOLR1 CoStAR T cells in vitro and evaluated activity in a novel, more representative murine solid tumor model. **Methods:** For in vitro studies, healthy donor T cells were manufactured to express anti-FOLR1 CoStAR or left nontransduced (NTD). Product cells were stimulated with a single (Day [D]0; ±IL-2) or serial (D0, 7, 14, 21; no IL-2) addition of target cells expressing membrane-anchored OKT3 (Signal 1) and FOLR1 (Signal 2). T-cell activation and proliferation were measured. For in vivo studies, the carcinoembryonic antigen (CEA)-positive (Signal 1) H508 cell line was engineered to express FOLR1 (Signal 2) and injected into 6 mice/group (D–21). NTD or healthy donor T cells expressing HLA-A*02-restricted anti-CEA TCR only, anti-FOLR1 CoStAR only, or dual TCR+CoStAR were given intravenously (D0), and compared with PBS control. Tumor growth, survival, and T-cell expansion were assessed in 2 donors to D96. **Results:** After single and serial stimulation, only anti-FOLR1 CoStAR T cells showed sustained proliferation without exogenous IL-2. PD-1 positivity was low (< 10%) on anti-FOLR1 T cells up to D24. In vivo, T-cell persistence on D14 was increased in dual TCR+CoStAR vs anti-CEA TCR only mice (P< .001) and all other groups (P< .01-.001). Tumor growth up to D58 was significantly lower in dual TCR+CoStAR (< .5 cm^3) vs all other groups (each > 2 cm^3; P< .0001). Survival was significantly longer in dual TCR+CoStAR (P< .01) vs all other groups; only dual TCR+CoStAR mice were alive at D58, with 5/6 alive at D96. The second donor showed similar tumor control irrespective of exogenous IL-2 in responder mice, with > 50% alive at D96, and robust T-cell expansion in dual TCR+CoStAR mice. **Conclusions:** When combined with TCR-specific binding, CoStAR significantly enhanced T-cell proliferation, persistence, and antitumor activity in vivo vs TCR alone, resulting in tumor control and prolonged survival. Effects were not observed with CoStAR alone, underscoring that signaling through CoStAR alone does not induce T-cell effector function. The sustained proliferation of anti-FOLR1 CoStAR T cells without exogenous IL-2 support in vitro and in vivo supports a clinical TIL regimen free of high-dose IL-2. These results suggest that CoStAR may improve the clinical performance and benefit/risk profile of TILs, whereby fewer toxicities are expected with the removal of post-TIL IL-2 support. This will be explored in an upcoming first-in-human clinical study with ITIL-306. Research Sponsor: Instil Bio, Inc.

Efficacy and safety of autologous expanded tumor infiltrating lymphocytes (TILs) in multiple solid tumors. *First Author: Rodabe Navroze Amaria, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: TIL therapy has been used extensively in metastatic melanoma patients for many years, now with ongoing efforts to commercialize treatment. The efficacy of TIL outside of melanoma is largely unknown thus we designed and implemented a trial using TIL manufactured at a single academic center for treatment refractory metastatic colorectal (CRC), pancreas (PDAC) and ovarian (OVA) cancers. **Methods:** Patients with CRC, PDAC and OVA refractory to standard therapies with ECOG PS 0-1 and normal organ function were eligible for TIL harvest. Ex vivo TIL expansion and manufacturing was conducted at the MD Anderson TIL lab under conditions that included IL2 and 41BB stimulation (using urelumab). All patients received a lymphodepletion regimen consisting of cyclophosphamide 60mg/kg days -7 and -6 and fludarabine 25mg/m2 days -5 through day -1, followed by infusion of pooled *ex-vivo* expanded TIL. Patients received up to 6 doses of high dose IL-2 (600,000 IU/kg) after TIL infusion. The primary endpoint was evaluation of the objective response rate (ORR) using RECIST 1.1 criteria with secondary endpoints including disease control rate, duration of response, PFS, OS and safety. **Results:** A total of 17 patients underwent TIL harvest and 16 were treated on protocol; including 8 CRC, 5 PDAC and 3 OVA. Median age was 57.5 (range 33-70) and 50% were females. Median number of lines of prior therapy was 2 (range 1-8). Median number of TIL infused was 76 X 10^9 (range 20.3 x 10^9-150 x 10^9). Median doses of cyclophosphamide and fludarabine administered were 2 (range, 2-2) and 3 (range, 1-5), respectively. Median doses of IL-2 administered was 6 (range, 1-6). There were no responders. Best response included prolonged SD in a patient with PDAC lasting until 18 months. Grade 3 or higher toxicities attributable to therapy was seen in 14 subjects (87.5%; 95% CI: 61.7 – 98.4) with the majority of toxicities representing expected pancytopenia from lymphodepletion. Infusion product analysis showed the presence of effector memory cells with high expression of CD39 irrespective of tumor type. Early on-treatment biopsy of PDAC patient with prolonged SD showed presence of proliferating (KI67+) CD4+ and CD8+ TIL. **Conclusions:** Generation of TIL at a single academic center for CRC, PDAC and OVA is feasible and treatment is associated with no new safety signals. For these tumor types, further research is required to identify host factors associated with resistance to TIL therapy and optimize manufacturing processes to create more effective TIL cell therapy. Clinical trial information: NCT03610490. Research Sponsor: Iovance.

Examination of mutation signature and mutation spectrum as predictors of response to immune checkpoint blockade therapy. *First Author: Danae Bowen, UC Riverside School of Medicine, Riverside, CA*

Background: In recent years, there has been promising progress in the use of immune checkpoint blockade (ICB) as a treatment for various cancer types such as lung, kidney, bladder, skin, colon, and breast cancer. In order for this modality to have increased success, more precise selection tools are needed to predict which patients will benefit from treatment. Tumor Mutational burden (TMB) has been implicated as a biomarker for ICB response due to the increased tumor immunogenicity present in high TMB samples. However, we hypothesize that the quality of mutations may also have an impact in determining immune response, rather than just the quantity of mutations alone. **Methods:** A retrospective analysis of 2041 patients across multiple solid tumor types was conducted using an open-access, open-source cancer genomics database (Gao, Sci Signal, 2013), with the goal of assessing the influence of mutational signature on patient response to ICB (including CTLA-4, PD-1, and PDL-1). Patient demographics, treatment variables/outcomes, and tumor variables, including mutation spectrum, and mutation count, were evaluated. A paired two sample test for means was used to analyze data with $p < 0.05$ considered statistically significant. Response outcomes were determined per RECIST v 1.1. **Results:** Our data demonstrate that mutational spectrum profiles show distinct patterns when considering response to ICB, independent of TMB. Patients with breast invasive ductal carcinoma who responded to ICB had less C > A mutations ($p = 0.020$) and more C > T mutations ($p = 0.017$) compared to non-responders. Lung adenocarcinoma responders had less C > T mutations ($p = 0.003$) and more C > A mutations ($p = 0.0003$) compared to non-responders. Furthermore, both head and neck squamous cell carcinoma and glioblastoma multiforme responders had more T > A mutations ($p = 0.047$ and $p = 0.011$, respectively) than non-responders. However, in other cancer types studied (urothelial, colon, renal, lung squamous, and melanoma), there were no obvious trends to distinguish responders from non-responders. Preferentially mutated gene targets were also considered for all 10 cancer types (including CARD11, SMARCA4, GLI1, PIK3R1, PTPRT, among others), many of which were also tied to the unique mutational signatures observed and which may be separately identified as novel ICB therapy targets. **Conclusions:** We found that specific mutation type may impact response to ICB in at least 4 cancer types, including breast, lung adenocarcinoma, head and neck squamous cell carcinoma and glioblastoma multiforme. Of note, this trend was not found in other cancer types which are typically found to have higher TMB. Moving away from solely considering the magnitude of mutations in tumor samples and towards identifying specific mutational signatures may aid in providing necessary specificity for selecting patients for ICB cancer therapy. Multicenter phase Ib trial in the U.S. of salvage CT041 CLDN18.2-specific chimeric antigen receptor T-cell therapy for patients with advanced gastric and pancreatic adenocarcinoma. *First Author: Gregory P. Botta, UCSD Moores Cancer Center, La Jolla, CA*

Background: Claudin 18.2 (CLDN18.2) is a highly selective cell lineage marker with limited expression in normal gastric tissues and significantly higher expression in primary gastric, pancreatic tumors and their metastases. Anti-CLDN18.2-targeted CAR T cells, termed CT041, were developed to evaluate tumor response and patient-reported outcomes in the gastric and pancreatic cancer. Preliminary results of the trial (NCT03874897) showed an objective response rate (ORR) of about 60% in gastric cancer from a non-Western population. Here we report the results of CT041 for metastatic gastric cancer after ≥ 2 prior lines of systemic therapy or pancreatic cancer ≥ 1 prior line from six centers in the United States. **Methods:** This single-arm, open-label, phase Ib study (NCT04404595) investigated autologous CT041 CAR T cells in patients with CLDN18.2 positive advanced gastric (including diffuse, signet-ring) or pancreatic adenocarcinoma. All patients completed a conditioning regimen consisting of fludarabine, cyclophosphamide, and nab-paclitaxel prior to CT041 CAR T cells. The primary objective was to assess the safety, efficacy and cytokinetic profile of CT041. Adverse Events (AEs) were graded according to CTCAE 5.0, and tumor response was assessed per RECIST 1.1. **Results:** As of February 15, 2022, 11 patients (5 gastric and 6 pancreatic) with a median of 2 prior lines of therapy (range 1- 4) were treated with CT041 at a dose between 2.5 and 4 x 10^8 cells. There were no dose limiting toxicities, treatment-related deaths, severe cytokine release syndrome (CRS), immune effector cell-associated neurologic syndrome (ICANS), or severe gastrointestinal (GI) related AEs. All CRS were grade 1 or 2. Only one patient received tocilizumab. No grade 4 AEs were observed except for hematologic toxicities related to conditioning. The first eight patients were evaluable for response by the date of data cut-off: 1 patient achieved a complete response after two CT041 doses (gastric), 2 had partial response (gastric), 2 had stable disease with tumor shrinkage (pancreatic) and 3 (pancreatic) had progression of disease after an initial biochemical response. ORR was 37.5% (3/8) in all patients including 100% (3/3) in the gastric subgroup (all ≥ 3 prior lines). The last three patients had not reached the time for response assessment. CAR T cell expansion correlated with ctDNA reduction. The median duration of response and the progression-free survival had not been reached. **Conclusions:** These preliminary results indicate that CT041 therapy was safe and had therapeutic efficacy in patients with advanced GI cancers. In heavily pre-treated gastric cancer, CT041 may have significantly improved anti-tumor activity compared to historical treatment regimens. Clinical trial information: NCT04404595. Research Sponsor: CARsgen.

The addition of fludarabine to cyclophosphamide for lymphodepleting chemotherapy enhances the persistence of infused NY-ESO-1 TCR anticancer therapy TBI-1301. *First Author: Marcus O. Butler, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Adoptive transfer of T cell receptor (TCR) gene-engineered T cells can induce durable anti-cancer responses. TBI-1301 is a novel gene therapy produced by engineering autologous lymphocytes to express an NY-ESO-1-specific TCR using a retrovirus vector that encodes siRNA to silence endogenous TCR. In this study, we examined a repeat infusion of TBI-1301 and the addition of fludarabine to cyclophosphamide for pre-infusion lymphodepletion. **Methods:** Eligibility included informed consent, HLA-A*02:01 or A*02:06 haplotype, and NY-ESO-1 expression by IHC. Eligible patients underwent harvest of PBMC which were processed at the treating site to generate engineered TBI-1301 cells. The study design infused 5x10^9 cells on day 0 and day 14 to patients following lymphodepletion with cyclophosphamide (CY; 750 mg/m^2 on day -7 and -6) plus fludarabine (FLU; 30 mg/m^2 on day -7 and -6). Repeat infusions were performed in two cohorts: Cohort B - patients who had previously received NY-ESO-1 TCR-transduced cells and Cohort C - NY-ESO-1 TCR treatment naïve patients. Endpoints included safety, efficacy, and biological correlates for persistence of NY-ESO-1-specific T cells post infusion. **Results:** Ten patients were enrolled in cohorts B and C. Nine patients in total are evaluable for response and toxicity, and no DLTs have been observed. In cohort B, 5 patients (5 synovial sarcoma) were treated, and 5 have received the target dose. In cohort C, 5 patients (3 synovial sarcoma, 2 melanoma) were treated, and 4 have received the target dose. One patient received a single infusion due to bacteremia on week 2. One of 5 patients in cohort B was previously treated with TBI-1301 cells in cohort C. In each cohort, 4 patients experienced grade 1-2 cytokine release syndrome. Best overall response by RECIST v1.1 was 3 stable disease, and 2 progressive disease in cohort B; and 2 stable disease and 2 progressive disease in cohort C. When compared to the earlier cohort, biomarker analysis demonstrated substantially longer persistence of transferred TBI-1301 cells in infused patients who received fludarabine (up to 372+ and 460+ days), and the cells displayed a less differentiated phenotype. **Conclusions:** Repeat infusions of TBI-1301 following lymphodepletion appears to be safe and to possess anti-tumor activity. Addition of FLU to the lymphodepletion regimen may contribute to longer persistence of gene-engineered T cells. Clinical trial information: NCT02869217. Predictors of severe CRS in longitudinal CAR T-cell clinical trial data. *First Author: Caleb Strait, Acorn AI at Medidata, A Dassaults Systems company, New York, NY*

Background: Cytokine release syndrome (CRS) is a life-threatening toxicity of chimeric antigen receptor (CAR) T-cell therapy and there is a limited understanding of its risk factors. Known markers of severe CRS lack specificity or require central lab facilities, making them unsuitable for safety surveillance during trials. Using data from anti-CD19 CAR-T trials from the Medidata Enterprise Data Store (MEDS) we analyzed laboratory tests with repeated measurements to identify differences in trends that persist across a variety of study designs, sponsors and indications. Our aim was to capture the dynamic response to lymphodepletion (LD) and CAR-T infusion events in the time course values of laboratory markers and compare these in the severe CRS (grade 3 and higher) and non severe CRS groups. **Methods:** Subjects in the anti-CD19 CAR-T trials obtained from MEDS had relapsed or refractory disease in one of the following: B Acute Lymphoblastic Leukemia (B-ALL), Mantle Cell Lymphoma (MCL), Non-Hodgkin Lymphoma (NHL) and Diffuse Large B-cell Lymphoma (DLBCL). Laboratory markers with repeated measurements across all studies were included in the analysis. Response to LD, CAR-T infusion and the onset of hematologic recovery was modeled with piecewise linear splines with knots at the boundaries of the pre LD (-18d to LD), the LD - infusion and post infusion (1d to 6d and 6d to 18d) intervals using linear mixed effects regression. **Results:** The dataset consisted of 542 patients: 24.1% B-ALL, 44.4% NHL, 16.8% MCL, 14.6% DLBCL; mean age 54.8 (SE = 0.021) years, 67.7% males. 27.3% had CRS 3+ with a median time-to-event of 4.5 days. Average rates of change (units per day) for the severe CRS subjects in the pre LD, LD-infusion and post infusion intervals relative to the rest are shown (table). None of the markers had a significant relative rate of change prior to LD. The average change in Albumin, Platelets and Hematocrit was consistently lower in severe CRS patients. **Conclusions:** Longitudinal laboratory marker data may be used to derive predictors of severe CRS in patients undergoing anti-CD19 CAR-T therapy. While some of the laboratory markers discussed above corroborate earlier findings, modeling the pre and post infusion kinetics can yield novel markers with improved precision in severe CRS prediction and better patient safety. Research Sponsor: None.

PARAM	Pre LD (-18d - LD)	LD-Infusion (LD - 1d)	Post infusion (1d - 6d)	Post infusion (6d - 18d)
Albumin (g/L)	-14.15	-13.61 (p < 0.001)	-16.83 (p < 0.001)	-14.78 (p < 0.001)
Basophils/Leukocytes (%)	-1.28	-1.26	-1.36 (p = 0.04)	-1.29
Hematocrit (%)	-18.24	-18.97 (p = 0.01)	-18.79 (p = 0.02)	-19.28 (p = 0.005)
Hemoglobin (g/L)	-72.40	-73.71 (p = 0.02)	-73.09	-75.95 (p = 0.006)
Platelets (10 ^ 9/L)	-86.09	-83.15 (p = 0.02)	-94.86 (p < 0.001)	-88.07 (p = 0.002)

STRIvE-01: Phase I study of EGFR806 CAR T-cell immunotherapy for recurrent/refractory solid tumors in children and young adults. *First Author: Catherine Michelle Albert, Seattle Children's Research Institute, Seattle, WA*

Background: The epidermal growth factor receptor (EGFR) is a cell surface tyrosine kinase receptor associated with cell proliferation and differentiation. EGFR expression and activating mutations are associated with aggressive neoplastic disease, chemotherapy resistance, and increased metastatic potential. Published data and EGFR immunohistochemistry (IHC) performed on tissue microarrays indicate that 15-40% of pediatric solid tumors (ST) express EGFR. The unique EGFR monoclonal antibody (mAb) 806 selectively binds to an epitope that is conformationally hidden when EGFR is tethered but revealed when tethering is perturbed as occurs with EGFR overexpression, truncation, or through extra-cellular domain missense mutations. **Methods:** Children and young adults (CYA) with EGFR-expressing recurrent/refractory (R/R) ST were enrolled on a Phase 1 trial to examine the safety and feasibility of administering autologous chimeric antigen receptor (CAR) T cells derived from autologous T cells genetically modified to express a second generation EGFR806-specific scFV-IgG4hinge-CD28tm/cyto-4-1-BB-zeta and EGFRt tracking/suicide contract. All subjects received lymphodepleting chemotherapy with fludarabine and cyclophosphamide prior to the administration of cryopreserved CAR T cells a the prescribed dose level. The biologically effective dose (BED) or maximum tolerated dose was determined based upon observed toxicity through day 28 from initial CAR-T infusion and using a 3+3 statistical design. **Results:** Eleven subjects (n=10 evaluable, age range 9-25, median 18) were enrolled and received either dose level (DL) 1 (0.5×10^6 CAR-T/kg, n=4) or DL2 (1×10^6 CAR-T cells/kg, n=7). CAR T were manufactured successfully in all subjects. Most common toxicities were fatigue, tumor-related pain and cytokine release syndrome (n=2, maximum CTCAE grade 1). Dose limiting toxicity of CTCAE grade 4 transaminase level and hyperbilirubinemia occurred at DL2 (n=1). Maximum circulating CAR-T expansion was 29.66 cells/uL (range 0.05-29.66 cells/uL) with median persistence of 28 days (range 0-90). Two subjects on DL1 and one subject on DL2 demonstrated mixed response on day 28 and tolerated additional CAR T infusion without dose limiting toxicity. **Conclusions:** EGFR806 directed CAR-T cells have an acceptable toxicity profile in CYA with R/RST and demonstrate anti-tumor activity in some patients. Additional analyses are ongoing to identify biomarkers of response and toxicity. Clinical trial information: NCT03618381. Research Sponsor: Seattle Children's Therapeutics.

Development of B-cell maturation antigen (BCMA)-specific $CD8^+$ cytotoxic T lymphocytes using induced pluripotent stem cell technology for multiple myeloma. *First Author: Jooeun Bae, Dana Farber Cancer Institute, Boston, MA*

Background: A strategy for reversal of T cell exhaustion is reprograming of antigen-specific CTL to early lineage memory T cells with selective anti-tumor activities. To accomplish this goal, we epigenetically reprogrammed BCMA-specific $CD8^+$ CTL to a pluripotent state through key defined transcription factors, established "induced Pluripotent Stem Cells (iPSC)" exhibiting transcriptional and epigenetic features, re-differentiated them back into antigen-specific CTL and evaluated their properties and functional activities against multiple myeloma (MM). **Methods:** Functionally activeIFN-g producing HLA-A2 heteroclitic $BCMA_{72\text{-}80}$ (YLMFLLRKI)-specific $CD8^+$ CTL were applied for iPSC via transduction of four reprogramming factors (OCT3/4, SOX2, KLF4, c-MYC). Upon characterization of the BCMA-specific iPSC with high pluripotency potential, embryoid body was formed from the iPSC and further polarized into mesoderm layer development as evidenced by upregulation of transcriptional regulators (ABCA4, BMP10, CDH5, FOXF1, HAND1, PLVAP, SNAI2, TBX3). Next, BCMA-specific embryoid body-derived hematopoietic progenitor cells (HPC; $CD34^+$ $CD43^+$/$CD14^-$ $CD235a^-$) were sorted and induced to undergo T cell differentiation in the presence of Fc-DLL4 signaling and rectonectin. **Results:** Our RNAseq analyses demonstrated unique transcriptional profiles of HPC from different iPSC clones committing to $CD8^+$ T cells or other cell lineages (monocytes/granulocytes, B lymphocytes/NK cells). Principal component analyses demonstrated a high similarity and low variability of transcription profiles within the replicates of HPC committed to the same cell lineage. In addition, distinct genome-wide shifts and differential gene expression profiles were detected in HPC committed to each specific cell differentiation pathway. Specifically, the HPC commit to $CD8^+$ T cells utilized a diverse repertoire of modulators promoting development of T cell maturation, specific immune response regulation, memory T cells, cytotoxicity and interferon induction, which were significantly higher than shown in HPC that differentiate to other cell lineages. In parallel, specific repression genes were identified in the HPC commit to $CD8^+$ T cells, which develop TGF-β receptor, rearrangement of Ig heavy chain genes and inhibitory receptors. The T cells differentiated were mainly $CD45RO^+$ memory CTL and fully rejuvenated without immune checkpoints expression and regulatory T cells and with high anti-MM activities. **Conclusions:** These findings identify genetic and epigenetic mechanisms and regulatory elements, which play key roles during lineage specific commitment of HPC developed in iPSC into $CD8^+$ CTL and help to further design a next generation of regenerative medicine that provide the appropriate signals for T cell lineage commitment from progenitor cells. Research Sponsor: Donation.

CD19/CD20 bispecific chimeric antigen receptor (CAR) in naïve/memory T cells for the treatment of relapsed or refractory non-Hodgkin lymphoma. *First Author: Sarah Marie Larson, University of California, Los Angeles, Los Angeles, CA*

Background: Although chimeric antigen receptor (CAR)-T cells produce impressive outcomes in B-cell malignancies, a substantial fraction of patients with relapsed/refractory B-cell leukemia and lymphoma treated with anti-CD19 CAR-T cell therapy (CART19) either do not respond to treatment or relapse, with poor CAR-T cell persistence or CD19 antigen escape being two key factors that limit durability of response. In order to address these factors, we initiated a clinical trial with naïve/memory T ($T_{N/MEM}$) cells engineered to express bispecific anti-CD19/CD20 CARs (CART19/20) (NCT04007029). **Methods:** This trial is a Phase 1, first-in-human, dose-escalation trial enrolling patients with relapsed or refractory follicular lymphoma (FL), diffuse large B-cell lymphoma (DLBCL), mantle-cell lymphoma (MCL) and chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL). Following lymphodepletion chemotherapy with fludarabine and cyclophosphamide, patients received CART19/20 cell doses ranging from 50×10^6 to 200×10^6 CAR-positive cells. The primary endpoint was to evaluate the safety of CART19/20 as measured by adverse events and dose limiting toxicities. Secondary endpoints were efficacy as assessed by disease response, progression-free survival (PFS), overall survival (OS), and CAR transgene persistence. **Results:** As of February 7, 2022, dose-escalation has been completed with 9 patients enrolled and 8 patients infused (3 FL, 4 DLBCL including 2 transformed follicular and 1 primary mediastinal B cell, and 1 MCL). with CART19/20 cells on this study. The median age at the time of CART19/20 infusion was 59 and median prior lines of therapy was 3.5. All patients had stage IV disease and 7 of 9 patients required bridging therapy. Grade-1 cytokine release syndrome (CRS) occurred in 6 of 8 patients, and no patient experienced immune effector cell-associated neurotoxicity syndrome (*ICANS*). Among all patients, only one dose of tocilizumab was administered to one subject, and no steroids were given. With a median follow-up of 12 months from time of CART19/20 infusion (range: 4+ to 24+ months), 7 of 8 of patients remain in a complete remission. Median PFS and OS were not reached, and all patients with a complete remission demonstrate ongoing B-cell aplasia. **Conclusions:** This study demonstrates that CART19/20 cells are safe and effective in patients with relapsed/refractory NHL and potentially obviates the challenges of the commonest causes of relapse after CAR-T cell therapy by means of modifying $T_{N/MEM}$ cells and dual-antigen targeting, respectively. Given the strong safety and response observed, dose escalation was completed with the second dosing level (DL2) of 200×10^6 CAR-positive cells, and DL1 of 50×10^6 CAR-positive cells was chosen as the therapeutic dose for future trial expansion. Clinical trial information: NCT04007029. Research Sponsor: Parker Institute for Cancer Immunotherapy, The Kaplan Family Foundation, UCLA.

Changes in circulating tumor DNA (ctDNA) and outcomes in solid tumors treated with immune checkpoint inhibitors (ICIs). *First Author: Laith Al-Showbaki, Princess Margaret Cancer Care Centre, Toronto, ON, Canada*

Background: Quantification of ctDNA levels can be a reliable prognostic tool in several malignancies. More recently, detection of genomic alterations in ctDNA have been validated as a predictive biomarker to guide treatment planning. Dynamic changes in ctDNA levels over time and in response to treatment may also provide prognostic information. However, less is known about the value of changes to ctDNA levels in response to immune checkpoint inhibitors (ICIs). **Methods:** We searched MEDLINE (host:PubMed) and reviewed trials exploring outcomes of patients with advanced solid tumors receiving ICIs in which outcomes were reported based on changes to ctDNA levels. ctDNA clearance was defined as reported in individual trials. Typically, this was defined as either >50% reduction or a reduction to undetectable levels. We extracted progression free survival (PFS) and/or overall survival (OS) values, related 95% Confidence intervals (CI) and/or p-values. Data were then included in a meta-analysis utilizing the generic inverse variance and random effects model. Variation in effect size was examined using random effects meta-regression analysis. **Results:** A total of 17 trials were included in the meta-analysis; ctDNA levels were detectable in all participants in all studies prior to initiation of ICIs. Method of detection included next generation sequencing and/or droplet digital polymerase chain reaction assays . Overall, low to undetectable ctDNA levels, measured 6-16 weeks after starting treatment was associated with significantly better PFS, (HR 0.20 95% CI, 0.14-0.28; p<0.001). Similarly, OS was superior in patients with substantially reduced or undetectable ctDNA levels after receiving ICIs, (HR 0.18, 95% CI, 0.12-0.26; p<0.001. The results were consistent across all disease sites, lines of treatment, level of change (undetectable vs. >50% reduction) and whether treatment exposure comprised single or multiple ICIs (see Table). **Conclusions:** In unselected advanced solid tumors, a substantial fall in ctDNA levels in response to ICIs is associated with substantial improvements in both PFS and OS. ctDNA change is an early response biomarker which may allow for de-escalation of cross-sectional imaging in patients receiving ICIs, or support treatment de-escalation strategies. Further research is needed to quantify variations in sensitivity between the available NGS assays, as well as differences discovery range between assay platforms. Research Sponsor: None.

Baseline peripheral T-cell composition in relation to radiographic phenotypes of immune-related pneumonitis. *First Author: Brian S. Henick, Columbia University Medical Center, New York, NY*

Background: Pneumonitis is one of the most morbid complications from immune checkpoint inhibitor (ICI) treatment, but pathogenic mechanisms are unclear and no biomarkers permit pre-treatment risk assessment. We sought to characterize peripheral T cell subsets of pneumonitis patients on the single cell level. **Methods:** Blood was collected before and during ICI treatment in 24 patients. Cells were processed for single cell RNA sequencing (scRNAseq) employing CITEseq methodology using multiplexed cell surface markers labelled with a cocktail of oligonucleotide-tagged Total-Seq anti-human antibodies against CD4, CD8, CD45RA and CD27 followed by Chromium 10X sequencing. Principal Component Analysis was performed with iCellR, K-nearest-neighbor-based Network graph drawing Layout, and PhenoGraph clustering to assign cell types. CT scans were performed per standard of care and were reviewed by an experienced thoracic radiologist. **Results:** Seven of 24 patients developed pneumonitis; 9 did not experience an immune-related adverse event, and the remainder experienced arthritis (4), thyroiditis (3), or neurotoxicity (1). Pneumonitis patients had expanded proportions of TH2 $TCF7^+$ T cells at baseline as compared to the other patients. Radiographically, two patients' pneumonitis manifested as Chronic Hypersensitivity Pneumonitis (CHP), and four had Organized Pneumonia (OP). At baseline, CHP patients had significantly lower levels of $CD8^+$ TCM cells (CXCR3+), double-positive T cells, gamma-delta T cells, and higher levels of naïve-like $CD4^+$ TN $TCF7^+LEF1^+$ and $CD4^+$ TH1/2 $CXCR3^+GATA3^+$ cells compared to OP. Gene expression levels also distinguished between these radiographic phenotypes. **Conclusions:** The peripheral T cell composition of patients who developed pneumonitis was distinct from those who did not in our cohort and unique by radiographic manifestation, suggesting potential pathogenic mechanisms and a prelude to circulating predictive markers of ICI toxicity. Research Sponsor: U.S. National Institutes of Health.

2546 **Poster Session**

Early circulating tumor DNA (ctDNA) kinetics using a tumor-naïve assay as a predictive biomarker in early-phase immunotherapy (IO) clinical trials. *First Author: Enrique Sanz Garcia, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: ctDNA kinetics with tumor-informed assays can predict treatment outcome in patients (pts) treated with anti-PD1 IO (*Bratman et al*, Nature Cancer 2020). We evaluated whether early ctDNA kinetics with a tumor-naïve assay were associated with clinical outcomes in advanced solid tumor patients treated on early phase IO trials. **Methods:** Advanced solid tumor pts treated with investigational IO agents at the Princess Margaret Phase I program were enrolled. Baseline (B) and pre-cycle 2 (C2) (3-4 weeks after first dose) plasma samples were prospectively collected via an institutional liquid biopsy program (LIBERATE, NCT03702309). ctDNA was assessed using the tumor-naïve 425-gene Geneseeq Prime panel in a clinical laboratory. Mutations in each gene detected in ctDNA were measured as Variant Allele Fraction (VAF). Mean VAF from all mutations was calculated. Radiological response was measured per RECIST criteria and correlated using ROC curves. Hyperprogression (HPD) was defined using VHIO criteria (*Matos et al*, CCR 2020). Survival outcomes were estimated using the Kaplan Meier method. **Results:** From 12/2017 to 3/2020, 162 plasma samples from 81 pts with 25 different tumor types were collected. Pts were treated within 25 different IO phase I/II trials, 72% of which involved a PD-1/PD-L1 inhibitor. Median age was 58y (range 21 – 79), 54% female, 76% ECOG1. Sarcoma and colorectal (11%, each) followed by breast (8%) and melanoma (7%) were the most frequent tumors. Median follow up was 10.3 months (m) (1.8-46.9). CR 4% (n = 3), PR 6% (n = 5), HPD 11% (n = 9). Clinical benefit (CB) rate (CR+PR+SD > 6 months) was 20% (n = 16). ctDNA was detected in 122/162 samples (75.3%) (60 at B, 62 at C2). The most frequent mutations were *TP53* (32%), *PI3KCA* (12%), *PKHD1* (11%), and *KRAS* (9%). Mean VAF at B below median was not associated with OS (HR = 0.68 95%CI 0.4-1.16; p = 0.16) or PFS (HR = 0.93 95%CI 0.56-1.54; p = 0.77). Mean VAF change (difference between mean VAF at B and at C2) was associated with response (AUC = 0.99) and CB (AUC = 0.86). A decrease in mean VAF from B to C2 was seen in 24 pts (37.5%) and was associated with longer PFS (median PFS 2.7 vs 1.8 m; HR: 0.43, 95%CI 0.24-0.77; p < 0.01) and OS (median OS 10.8 vs 9.1 m; HR: 0.54; 95%CI 0.3-0.96; p = 0.03) compared to an increase in mean VAF. These differences were more marked if there was > 50% decrease in mean VAF from B to C2 (n = 11, 17%) compared to decrease < 50% or increase: median PFS 3.6 vs 1.8 m (HR: 0.29, 95%CI 0.13-0.62; p < 0.01) and median OS not reached vs 9.6 m (HR: 0.23, 95%CI 0.09-0.6; p < 0.01). No differences in mean VAF change were seen between HPD and PD pts. **Conclusions:** In a pan-cancer solid tumor early phase trial IO cohort, a decrease in ctDNA within 4 weeks of treatment was associated with increased CB, OS and PFS. HPD pts did not show greater increases in ctDNA. Tumor-naïve ctDNA assays may be useful to identify early treatment benefit in phase I/II trials with IO. Pharmacogenomic prediction of immune-related adverse events from immune checkpoint inhibitors among Asian patients. *First Author: Yiqing Huang, Department of Haematology Oncology, National University Cancer Institute Singapore, Singapore, Singapore*

Background: Immune checkpoint inhibitors (ICIs) have ushered in a unique entity known as immune-related adverse events (IrAEs) that can be debilitating and challenging for physicians. Given that genomic variation underlies both disease susceptibility and drug response, there is reasonable cause to believe that genomic markers are predictive of IrAEs. We perform a pioneering pharmacogenomic study to uncover genomic biomarkers associated with IrAEs from ICIs. **Methods:** Since March 2018, we recruited cancer patients treated with ICIs from the National University Cancer Institute Singapore and Tan Tock Seng Hospital. IrAEs were clinical characterized and graded according to the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE) version 5. DNA was extracted and genotyped by Infinium Global Screening Array (700K markers). Statistical analyses were performed using SVS/HelixTree. Genetic association was performed by logistic regression. Bonferroni corrected $P < 7.1E-08$ was considered statistically significant. **Results:** We conducted a pilot pharmacogenomic genome-wide association study (GWAS) on 307 patients of Asian Ancestry. Median age was 62. Majority were male (68.1%), Chinese (75.9%), ECOG PS 0-1 (91.6%), stage IV cancer at diagnosis (64.6%). Non-small cell lung cancer (36.2%), renal cell carcinoma (12.4%) and hepatocellular carcinoma (7.2%) were the three most common cancers. Top four ICIs used were pembrolizumab, nivolumab, atezolizumab and durvalumab, respectively (44.6%, 26.1%, 10.1% and 10.1% respectively). Nine percent of patients received dual ICIs concurrently. Median duration of treatment was 152 days and median follow up was 212 days. IrAEs were seen in 50.5% of patients. Skin (21.8%), endocrine (6.8%) and hepatotoxicity (5.9%) were the most common IrAEs. Eight percent of patients had CTCAEv5 grade ≥3 toxicity, of which hepatotoxicity (2.6%), skin (1.6%) and pulmonary toxicities (1.3%) were the most common. A preliminary pharmacogenomic investigation revealed one potential novel genetic locus associated with IrAEs: *LOC105373202* rs5915369; Unadjusted P= 6.6E-08, OR (95%CI) = 27.8 (3.7-206.5), minor allele = A, 10.7% in cases vs 0.4% in controls. We also identified an additional 3 independent SNPs (rs167609, rs2341687, *DMD*rs5928214) with nominal significance ($7.1E-0-8 \leq P < 5.0E-7$). **Conclusions:** This pilot pharmacogenomics GWAS uncovered 4 potential novel genetic loci predictive of IrAEs from ICIs amongst Asian patients. Further pharmacogenomic discovery/replication and functional validation studies are currently onongoing to identify specific genomic biomarkers that predispose individual patients to IrAEs. Circulating *KRAS* variant-specific shedding and association with survival in patients with metastatic pancreatic ductal adenocarcinoma (mPDAC) receiving chemoimmunotherapy. *First Author: Jacob E. Till, University of Pennsylvania Abramson Cancer Center, Philadelphia, PA*

Background: Circulating tumor DNA (ctDNA) is increasingly used as a prognostic marker with high ctDNA shedding associated with poor survival. Gene-, but not variant-specific, differences in ctDNA shedding have been reported. Tumor burden, mitotic rate, and cell death rate have been proposed as contributors to ctDNA shedding. Here we investigate associations of ctDNA shedding for the two most common mPDAC *KRAS* variants, G12D and G12V, with tumor burden, mitotic score, and overall survival (OS). **Methods:** Pretreatment (baseline) ctDNA was analyzed by droplet digital PCR for 86 (including 44 G12D, 30 G12V) patients with mPDAC receiving front-line chemoimmunotherapy in a randomized open-label Phase II study (NCT03214250). Baseline tumor burden in total, within the pancreas, and distally, was assessed by sum of RECIST target lesion diameters. Tumor tissue variant allele fraction (tVAF) and mitotic score (geometric mean expression of 65 mitosis-associated genes) were calculated from DNA and RNA sequencing. **Results:** ctKRAS shedding (dichotomized at median mutant copies/mL) was associated with OS for G12D bearing tumors (p = 0.03) but not G12V (p = 0.17, log-rank test). To identify variant-specific features of shedding, we examined the Spearman correlation for total tumor burden and ctKRAS shedding; G12D but not G12V shedding was correlated with tumor burden (p = 0.01 and p = 0.22 respectively). However, the higher tVAF in G12V compared to G12D tumors (p = 0.048, Mann-Whitney test) could result from differences in purity, ploidy, and *KRAS* copy number. Thus, we used tVAF as a scalar to calculate an adjusted tumor burden which was significantly correlated with both G12D and G12V ctDNA shedding (p = 0.004 and 0.02, respectively). When a patient's distal vs. pancreatic lesions were analyzed separately, pancreatic tumor burden was not correlated with G12D or G12V shedding (p = 0.10 and 0.33, respectively) but distal burden was correlated with both (p = 0.001 and 0.02, respectively). While there was no difference by *KRAS* variant for the correlation between adjusted tumor burden and shedding, these results do suggest that, in patients with mPDAC, distal rather than primary tumor burden may drive ctDNA shedding. Finally, tumor mitotic rate was combined with adjusted total tumor burden in a linear regression model; both were significant for predicting G12D shedding (p = 0.007 and p < 0.0001, respectively) but not for G12V (p = 0.045 and p = 0.16, respectively). **Conclusions:** These data suggest that ctDNA shedding and survival associations may be *KRAS* variant-specific in mPDAC. Tumor mitotic score and location of tumors may explain some variant-specific differences in shedding. As clinical ctDNA tests become more widely used, further investigation of variant-specific shedding in *KRAS* and other genes may be key for proper interpretation of ctDNA tests. Circulating cytokines as predictors of response to immune checkpoint inhibitors (ICIs) in patients (pts) with melanoma (Mel) and non–small cell lung cancer (NSCLC). *First Author: Giulia Pasello, Medical Oncology 2, Istituto Oncologico Veneto IOV-IRCCS, Department of Surgery, Oncology and Gastroenterology, University of Padova, Padua, Italy*

Background: ICIs lead to durable response and a significant survival improvement in a limited number of advanced stage Mel and NSCLC pts. The identification of predictive circulating biomarkers could be a promising tool to optimize pts' selection and outcome for ICIs treatment. **Methods:** This is a prospective real-world study enrolling advanced stage Mel and NSCLC pts referred to four Italian Centers and treated with ICIs. The primary endpoint is to verify the presence of an association between circulating cytokines (IL-1b, IL-2, IL-4, IL-5, IL-6, IL-8, IL-10, TNFα, GM-CSF) and disease control rate (DCR), progression free survival (PFS) and overall survival (OS). Pts undergo a blood collection, before every cycle for 6 cycles (T1-T6) and at tumor assessment till disease progression (PD) or for 2 years. Biomarker levels were assessed by Luminex xMAP based technology using R&D High Sensitivity kits. Each marker was categorized according to high and low levels by maximizing its discriminative ability, and the association with the outcome was tested in univariate and multiple analyses. **Results:** We report preliminary results on the T1-T2 blood samples from the first 78 enrolled pts (32 females/46 males; 43 Mel/35 NSCLC; median age 69 years). Serum IL-6, IL-8 and IL-10 were significantly higher at T1 and T2 in pts with PD (Kruskal-Wallis test). The median relative increase (RI) of IL-8 was 32% and 2% in pts with PD and disease control (DC), respectively (p = 0.0001). At multiple logistic analysis, IL-6 and IL-8 at T2 and the RI of IL-8 were independent factors predicting the probability of DC, with an overall accuracy of 83.8%. High levels of IL-6 and IL-8 at T2 were significantly associated with a low probability of DC (OR = 0.13, 95%CI: 0.03-0.52 and OR = 0.09, 95%CI: 0.02-0.37, respectively), and the RI showed a significantly lower probability of DC (OR = 0.14, 95%CI: 0.02-0.58). With a median follow-up of 10.6 months (m), mPFS and mOS were 5.8 m, 95%CI: 2.3-7.4 and 8.3 m, 95%CI: 4.0-13.8 for NSCLC; 6.9 m, 95%CI: 2.8-15.9 and 12.6 m, 95%CI: 4.7-NE for Mel pts, respectively. In the multiple Cox model, elevated IL-6 and IL-8 at T1 (HR = 3.03, 95%CI: 1.55-6.37, HR = 2.86, 95%CI: 1.46-5.63), elevated IL-10 at T2 (HR = 2.86, 95%CI: 1.39-5.94), and a RI of IL-8 (HR = 4.22, 95%CI: 1.85-11.21) remained significantly associated with a worse PFS. Higher levels of IL-6 (HR = 3.85, 95%CI: 1.13-20.0) and IL-8 (HR = 4.29, 95%CI: 1.98-9.83) at T2 and a RI of IL-8 (HR = 3.06, 95%CI: 1.43-6.72) remained significantly associated with a worse OS. **Conclusions:** High serum levels of IL-8 and IL-6 at T2 of ICI, combined with an increase of IL-8 from baseline, are strong predictors of PD, PFS, OS, in pts with advanced Mel and NSCLC. The role of the other cytokines tested, their time fluctuations and associations with clinical prognostic factors, gender, and immuno-related adverse events will be presented at the meeting. Research Sponsor: RF-2018-12367604 MoH; 2018 5x1000 Istituto Oncologico Veneto.

Methylated circulating tumor DNA (cfMeDIP) as a predictive biomarker of clinical outcome in pan-cancer patients (pts) treated with pembrolizumab (P). *First Author: Enrique Sanz Garcia, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Bespoke mutation-based circulating tumor DNA (ctDNA) predicts response to P but relies on availability of tumor tissue and presence of mutations. Cell-free methylated immunoprecipitation and high-throughput sequencing (cfMeDIP-seq) may overcome these limitations and be applied to more pts. **Methods:** Pts with mixed solid tumors divided into 5 cohorts received P 200 mg Q3wks in the investigator-initiated INSPIRE trial (NCT02644369). cfMeDIP-seq was performed at baseline (B), pre cycle 3 (C3) and later cycles. Methylation probability was inferred from read depths in 300 bp bins. cfMeDIP score was the probability-weighted sum of 3270 pan-cancer differentially-methylated regions in the TCGA PanCanAtlas. ctDNA concentration was assayed using tissue-informed bespoke targeted NGS (Signatera). ΔctDNA and ΔcfMeDIP denote the change in ctDNA or cfMeDIP between B and C3, respectively. Association with OS or PFS was assessed using Cox proportional hazards model, adjusting for cohort (aHR). Multivariable analysis (MVA) also included tumor mutation burden and PD-L1 status. **Results:** 194 plasma samples from 87 pts were analysed with cfMeDIP-seq (84 at B, 55 at C3, 55 at later cycles). Demographics: male 33%; median age = 61 yrs (34–82); Cohorts: triple negative breast (26%), ovarian (25%), head & neck (21%), melanoma (12%), others (15%). Median follow-up = 10.6m (0.6–64.4); Median PFS = 1.9m; Median OS = 10.6m. cfMeDIP at B below median was associated with better OS (aHR = 0.51, 95%CI 0.29-0.91; p = 0.02) in MVA. ΔcfMeDIP was evaluable in 53 pts; any decrease in ΔcfMeDIP was predictive for OS (aHR = 0.36, 95%CI 0.18-0.72; p < 0.01) and PFS (aHR = 0.42, 95%CI 0.22-0.82; p = 0.01). Both ΔctDNA and ΔcfMeDIP were evaluable in 51 pts; decrease in ΔctDNA and ΔcfMeDIP predicted for longer OS (aHR = 0.45, 95%CI 0.23-0.86; p = 0.02 vs aHR = 0.39, 95%CI 0.19-0.80; p = 0.01); and PFS (aHR = 0.44, 95%CI 0.23-0.83; p = 0.01 vs aHR = 0.5, 95%CI 0.25-0.99; p = 0.04), respectively. When both ΔctDNA and ΔcfMeDIP are integrated in MVA, ΔcfMeDIP was predictive for OS (aHR = 0.48, 95%CI 0.23-1; p = 0.05). A decrease in ΔcfMeDIP and/or ΔctDNA was associated with longer OS (aHR = 0.2, 95%CI 0.09-0.45) and PFS (aHR = 0.27, 95%CI 0.13-0.58) compared to an increase in both assays (p < 0.01) (Table). **Conclusions:** We applied for the first time cfMeDIP-seq and mutation-based ctDNA analysis concurrently in pan-cancer pts treated with checkpoint blockade. ΔcfMeDIP correlated strongly with OS and PFS, representing a promising plasma-based predictive epigenetic biomarker in pts treated with P. ΔctDNA and ΔcfMeDIP can complement each other to predict outcomes, demonstrating that they may capture different biological changes. Clinical trial information: NCT02644369. Research Sponsor: BMO Chair in precision cancer genomics, Pharmaceutical/Biotech Company.

Group	OS-12m (%) (95%CI)
$\downarrow\Delta$ctDNA $\downarrow\Delta$cfMeDIP (n = 16)	87.5 (72.7-100)
$\downarrow\Delta$ctDNA $\uparrow\Delta$cfMeDIP (n = 10)	70 (46.6-100)
$\uparrow\Delta$ctDNA $\downarrow\Delta$cfMeDIP (n = 8)	62.5 (36.5-100)

The FLARE score, circulating neutrophils, and association with COVID-19 outcomes in patients with solid tumors. *First Author: Elia Seguí, Medical Oncology, Hospital Clínic de Barcelona, Spain, Barcelona, Spain*

Background: Inflammation and neutrophils play a central role in severe Covid-19 disease. In previous data, we showed that the FLARE score, combining both tumor and Covid-19-induced proinflammatory status (proinflam-status), predicts early mortality in cancer patients (pts) with Covid-19 infection. We aimed to assess the impact of this score in a larger cohort and characterize the immunophenotype (IF) of circulating neutrophils. **Methods:** Multicenter retrospective cohort (RC) of pts with cancer and Covid-19 infection across 14 international centers. Circulating inflammatory markers were collected at two timepoints: baseline (-15 to -45d before Covid-19 diagnosis) and Covid-19 diagnosis. Tumor-induced proinflam-status was defined by high dNLR (neutrophils/(leucocytes-neutrophils)>3) at baseline. Covid-19-induced proinflam-status was defined by +100% increase of dNLR between both timepoints. We built the FLARE score combining both Tumor and Infection-induced inflammation: T+/I+ (poor), if both proinflam-status; T+/I- (T-only), if inflammation only due to tumor; T-/I+ (I-only), if inflammation only due to Covid; T-/I- (favorable), if no proinflam-status. The IF of circulating neutrophils by flow cytometry was determined in a unicenter prospective cohort (PC) of pts with cancer during Covid-19 infection and in healthy volunteers (HV). Primary endpoint was 30-day mortality. **Results:** 524 pts were enrolled in the RC with a median follow-up of 84d (95%CI 78-90). Median age was 69 (range 35-98), 52% were male and 78% had baseline PS <1.Thoracic cancers were the most common (26%). 70% had active disease, 51% advanced stage and 57% were under systemic therapy. dNLR was high in 25% at baseline *vs* 55% at Covid-19 diagnosis. The median dNLR increase between both timepoints was +70% (IQR: 0-349%); 42% had +100% increase of dNLR. Pts distribution and mortality across FLARE groups is resumed in the Table. Overall mortality rate was 26%. In multivariate analysis, including gender, stage and PS, the FLARE poor group was independently associated with 30-day mortality [OR 5.27; 1.37-20.3]. 44 pts were enrolled in the PC. Median circulating neutrophils were higher in pts with cancer (n=10, 56.7% [IQR: 39-78.4%]) vs HV (n=6, 35.8% [IQR: 25.6-21%]), and particularly higher in pts with cancer and severe Covid-19 infection (n=7, 88.6% [IQR: 80.9-94%] (p=0.003). A more comprehensive characterization of the IF of circulating neutrophils, including Lox1/CD62/CD64, will be presented at ASCO. **Conclusions**: The FLARE score, combining tumor and Covid-19-induced proinflam-status, can identify the population at higher risk for mortality. A better characterization of circulating neutrophils may help improve the prediction of Covid-19 outcomes in pts with cancer. Research Sponsor: AMGEN.

	Distribution	30d mortality	
FLARE T+/I+	5% (n=19)	68%	p=0.001
FLARE T+/I-	20% (n=74)	39%	
FLARE T-/I+	37% (n=136)	33%	
FLARE T-/I-	38% (n=140)	3%

NK cell activity and methylated HOXA9 circulating tumor DNA as prognostic biomarkers in patients with non-small cell lung cancer treated with PD-1/PD-L1 inhibitors. *First Author: Sara Witting Christensen Wen, Department of Oncology, Vejle Hospital, University Hospital of Southern Denmark, Vejle, Denmark*

Background: PD-1/PD-L1 inhibitors have improved survival for patients with non-small cell lung cancer (NSCLC), but better prognostic biomarkers are needed. **Methods:** We prospectively collected plasma from 82 patients with NSCLC before initiating treatment with PD-1/PD-L1 inhibitors and before treatment cycles 2-4. We used the NK Vue assay to measure interferon gamma (IFNγ) as a surrogate for natural killer cell activity (NKA) with a cutoff of 250 pg/mL. Circulating tumor DNA (ctDNA) in the form of methylated HOXA9 was measured by droplet digital PCR. ctDNA status was classified as detectable or undetectable ctDNA. **Results:** Patients were classified into three groups according to IFNγ levels at the available time points. The NKA-low group had a persistently low level of IFNγ or dropped to and remained at a low level after baseline (<250 pg/mL, n=29), the NKA-mixed group experienced either an increase from low to normal levels or vice versa (n=34), while the NKA-high group maintained a normal level of IFNγ (≥250 pg/mL, n=13). The median PFS was 64 days (95% confidence interval (CI) 48-115 days), 228 days (95% CI 146-353 days), and 214 days (95% CI 101-693 days), respectively, for NKA-low, NKA-mixed, and NKA-high (p=0.003). The median OS was 170 days (95% CI 110-285 days), 487 days (95% CI 361-761 days), and 1,131 days (95% CI 235 days to not reached), respectively (p<0.001). Patients were divided according to detectable (ctDNA+, n=41) or undetectable (ctDNA-, n=32) ctDNA after one treatment cycle. Median PFS was 97 days (95% CI 58-192 days) and 228 days (95% CI 146-353 days), respectively, for ctDNA+ and ctDNA- (p=0.018). Median OS was 235 days (95% CI 170-525 days) and 544 days (95% CI 361-1158 days), respectively (p=0.007). A score combining NKA and ctDNA both measured after the first treatment cycle had a strong prognostic impact. Group 1 had a low level of IFNγ (<250 pg/mL) and detectable ctDNA (n=27), group 2 had either low levels of IFNγ and undetectable ctDNA or vice versa (n=29), and group 3 had normal levels of IFNγ (≥250 pg/mL) and undetectable ctDNA (n=15). Median PFS was 69 days (95% CI 48-213 days), 183 days (95% CI 102-235 days), and 307 days (95% CI 140-693 days), respectively, for group 1, 2, and 3 (p=0.022). Median OS was 221 days (95% CI 121-539 days), 419 days (95% CI 235-650 days), and 1,158 days (95% CI 250 days to not reached), respectively (p=0.002). Biomarker score 1 was a marker of poor prognosis for OS with a hazard ratio (HR) of 3.971 (95% CI 1.763-8.943, p=0.001) compared to biomarker score 3. It remained statistically significant with a HR of 5.560 (95% CI 2.359-13.101, n=71, p<0.001) when adjusting for PD-L1 status, histology, and performance status. **Conclusions:** A biomarker score combining the levels of NKA and ctDNA status after the first cycle of treatment may be used to stratify the prognosis in patients with NSCLC treated with PD-1/PD-L1 inhibitors. Network analysis to determine association between immuno-related toxicities and immune soluble profile in patients treated with anti–PD-1. *First Author: Andrea Botticelli, Department of Radiological, Oncological and Anatomo-Pathological Science, "Sapienza" University of Rome, Rome, Italy*

Background: Immune checkpoint inhibitors (ICIs) have peculiar, immune-related adverse events (irAEs), as a consequence of interfering with self-tolerance mechanisms. The incidence of irAEs varies by ICI class, administered dose and treatment schedule. The aim of the study was to define a baseline (T0) immune profile (IP) predictive of irAE development. **Methods:** A prospective, multicenter study evaluating the IP of 79 patients with advanced cancer, treated with anti-PD-1drugs as a first- or second-line setting was performed. The results were then correlated with irAEs onset. The IP was studied by means of multiplex assay, evaluating circulating concentration of 12 cytokines, 5 chemokines, 13 soluble immune checkpoints and 3 adhesion molecules. IDO levels were evaluated through a modified liquid chromatography–tandem mass spectrometry. Data were first pre-processed by performing logarithmic transformation and Shapiro-Wilk-test. A connectivity heatmap was obtained by calculating Spearman correlation coefficients. Two different networks of connectivity were constructed, based on the toxicity profile. **Results:** Toxicity was predominantly of low/moderate grade. High-grade irAEs were relatively rare, while cumulative toxicity was high (23%). A positive and statistically significant correlation between the cumulative toxicity and IP10 and IL8, sLAG3, sPDL-2 sHEVM, sCD137, sCD27 and sICAM1 was found. Moreover, patients who experienced irAEs had a markedly different connectivity pattern characterized by disruption of most of the paired connections between cytokines (all the connections of the cytokine IL8, most of the connections between the pro-inflammatory chemokines, or all the connections of CD137, CD27, and CD28), while sPDL-2 pair-wise connectivity values seemed to be intensified. Network connectivity analysis identified a total of 187 statistically significant interactions in patients without toxicity and a total of 126 interactions in patients with toxicity. Ninety-eight interactions were common to both networks, while 29 were specifically observed in patients with toxicity. **Conclusions:** A peculiar pattern of immune dysregulation in patients who develop irAEs was defined. This immune serological profile could lead to the design of a personalized therapeutic strategy in order to prevent, monitor and treat irAEs at an early stage. Research Sponsor: None.

Auto-reactive antibodies as predictive markers for immune checkpoint–induced pneumonitis. *First Author: Mehmet Altan, MD Anderson Cancer Center, Houston, TX*

Background: Certain immune-related adverse events (irAEs) that emerge with immune checkpoint blockade share clinical features of autoimmune conditions. Preexisting auto-reactive antibodies and their contribution to irAEs have not been well defined, and observations are limited. **Methods:** We longitudinally collected patient plasma samples from a clinical trial that combines immune checkpoint inhibitors, Ipilimumab, and Nivolumab (I+N) with subsequent radiation therapy (Lonestar, NCT03391869). Plasma samples were collected at baseline, after 12 weeks of I+N (induction), and at the time of Grade $\geq$ 2 pneumonitis (CTCAEv5.0). Auto reactive antibody profiles were analyzed using a fluorescence-based assay system that measures more than 130 antigens and is capable of assaying antibody reactivity for IgG and IgM fractions, including nuclear-cytosolic and tissue-specific antigens. Selected antibodies had a reportable result range, reference intervals, and reproducibility with quality controls. A paired t-test was used to compare the mean of longitudinally collected baseline and toxicity samples. An unpaired t-test was used to compare differences between groups. The False Discovery Rate was used to control the Type I error rate of multiple comparisons. **Results:** In the study cohort, G$\geq$2 pneumonitis was observed in 11 patients out of 194 (5.6%). Serum was collected at baseline for all 11 patients, and 9 of the 11 patients had a serum sample collected at the time of pneumonitis event. Longitudinal serum samples (baseline and post-induction) collected from 32 patients without any irAEs were used as control. At baseline AChR3 and calmodulin antibodies were elevated in patients who developed pneumonitis, compared with baseline samples from controls ($p \leq 0.05$). At the time of pneumonitis IgM antibodies against AChR3, CXCL10, NSE, BAFF, CA242, Cytokeratin 19 were noted to be elevated in serum for pneumonitis cases compared with post induction samples from control ($p \leq 0.005$). **Conclusions:** We identified auto reactive antibodies associated with a higher risk of immunotherapy associated pneumonitis in patients treated with ipilimumab and nivolumab. These included auto reactive antibodies against proteins associated with lung injury (AChR3), lung inflammation (BAFF, CXCL10) and against alveolar epithelium (Cytokeratin 19). Future studies are warranted to determine if auto-reactive antibodies can be used as pre-treatment risk markers or to diagnose pneumonitis and may offer insights into to mechanisms that predispose toward pneumonitis. Comprehensive transcriptomic analysis of immune checkpoint markers in a pancancer cohort: Implications for response and resistance. *First Author: Hirotaka Miyashita, Mount Sinai Beth Israel, New York, NY*

Background: Although immune checkpoint blockade (ICB) has revolutionized cancer treatment, not all patients with cancer benefit from ICB. One possible explanation for poor responders/resistance is the variable expression level of the target molecules (e.g., PD-1 and PD-L1) in the tumor microenvironment. There are recent or ongoing trials targeting variable pathways for immune evasion (e.g., LAG3 or IDO1). It is therefore of interest to know the expression levels related to variable immune checkpoints so that clinical trials can focus on the patients who can benefit from the cognate treatment. **Methods:** Overall, 514 patients with various solid tumors seen at the University of San Diego, Moores Center for Personalized Cancer Therapy were analyzed. The expression levels of checkpoint markers (ADORA2A, BTLA, CD276, CTLA4, IDO1, IDO2, LAG3, NOS2, PD-1, PD-L1, PD-L2, PVR, TIGIT, TIM3, VISTA, and VTCN) in the tumor samples were measured through RNA sequencing and normalized to internal housekeeping gene profiles, and ranked from 0 to 100 percentile based on a reference population. The expressions of each checkpoint marker were correlated with cancer types, microsatellite instability (MSI), tumor mutational burden (TMB), and programmed death-ligand 1 (PD-L1) status on immunohistochemistry. **Results:** In this cohort, 60% were female, median age of 60, and included 30 different tumor types, with colorectal cancer being the most common (27%). The rank values of all checkpoint markers were distributed broadly from 0 to 99 or 100. CD276 and NOS2 had the highest (68^{th} percentile) and lowest (13.5 percentile) median rank values, respectively. When rank values were categorized to "Low" (0-24), "Intermediate" (25-74), and "High" (75-100), 41.6% of patients showed high expression of CD276 while only 13% showed high expression of PD-L1. Each patient had a distinctive protfolio of the categorical expression levels of 16 checkpoint markers. Several checkpoint markers, especially NOS2, showed a significant correlation with cancer type. (median rank values in colorectal, stomach, pancreatic, and breast cancer were 79, 76, 5 and 0 respectively, $p < 0.001$) Five markers (IDO1, LAG3, PD-1, PD-L1, and TIGIT) showed significant correlation with MSI, while seven markers (CTLA4, IDO1, LAG3, PD-1, PD-L1, PD-L2, and TIGIT) were significantly associated with positive PD-L1 status. However, no significant association was seen based on TMB or tissue-specific grouping of patients. **Conclusions:** The expression of immune checkpoint markers varies from patient to patient, though transcript expression of several markers correlates with cancer type, MSI, and PD-L1 status. Clinical trials with patient selection based on the expression level of checkpoint markers matched to the corresponding ICB drug are warranted. Research Sponsor: None.

The immune micro-environment of inflammatory breast cancer is characterized by an influx of CD163+ tumor-associated macrophages. *First Author: Christophe Van Berckelaer, Multidisciplinary Breast Clinic, Unit Gynaecologic Oncology, Antwerp University Hospital (UZA), Edegem, Belgium*

Background: Inflammatory breast cancer (IBC) is a rare form of breast cancer characterized by rapid progression. A specific immune response seems to be an important driver for the aggressive biological behavior. We previously demonstrated that the spatial composition of the tumor immune micro-environment (TIME) is associated with survival in IBC. However, it remains an enigma how the TIME can contribute to the IBC phenotype. Since the number of tumor-infiltrating lymphocytes (TILs) between IBC and non-inflammatory breast cancer (nIBC) is similar and PD-L1 expression is higher, the functional state or composition of the immune infiltrate might determine the fulminant course of IBC. In this study, we assess the composition of the TIME in both IBC and a cohort of subtype-matched nIBC patients. **Methods:** We collected clinicopathological variables, evaluated PD-L1 positivity (SP142, Ventana) and scored TILs in a cohort of 161 IBC and 115 molecular subtype-matched nIBC patients. Affymetrix data (for CIBERSORT analysis) was available for 30 IBC and 20 nIBC patients. Immunostainings for CD8+ cytotoxic T cells, FOXP3+ Tregs, CD79a+ activated B cells and CD163+ TAMs (Hematoxylin-DAB) were done according to validated protocols. All slides were were evaluated in Visiopharm to quantify the number (density) and area (relative marker area, RMA) of DAB+ immune cells in both the invasive margin (IM) and the tumor stroma (TS). **Results:** Patients with IBC presented with higher stage disease ($P < 0.001$), but there were no other significant differences in clinicopathological parameters. In both cohorts, TAMs were the most abundant immune subset followed by B cells, CD8+ T cells and Tregs. For every subset the number of immune cells was higher in the IM than in the TS. Independent of molecular subtype or stage, IBC patients had more infiltration with TAMs in the TS. This was shown using both density (Median IBC: 424/mm2 vs nIBC: 290/mm2, OR: 0.82, 95% CI 0.76 – 1.00, $P = 0.008$) and RMA (Median IBC: 1.02% vs nIBC: 0.73%, OR: 0.87, 95% CI 0.77 – 1.00, $P = 0.04$). As previously described, PD-L1 positivity was significantly higher in the IBC cohort ($P = 0.005$), but no other significant differences in TIME composition between IBC and nIBC were found. Gene expression of CD163 correlated with the number of CD163+ TAMs ($R = 0.38$, $P = 0.005$) and CIBERSORT analysis confirmed a profile enriched for macrophages in IBC. Interestingly, the number of M1 macrophages was also higher in IBC ($P = 0.03$) and there was a strong correlation between the number of CD163+ TAMs in the TS and the M1 macrophage CIBERSORT subset ($R=0.48$, $P < 0.001$), possibly indicating that not only the number but also the functional state of TAMs is different in IBC. **Conclusions:** Using an extensive immune-phenotyping protocol we demonstrate, in a large cohort of IBC patients, that IBC is characterized by a specific tumor micro-environment in which TAMs play an important role. Characterization of tumor antigen expression and myeloid immune profiles to inform the development of immune stimulating antibody conjugates (ISACs).

First Author: Lisa K. Blum, Bolt Biotherapeutics, Redwood City, CA

Background: Immuno-oncology (IO) has historically focused on T cell-driven effects, but a growing class of myeloid therapies are under investigation. This class includes immune-stimulating antibody conjugates (ISACs), which comprise a tumor-targeting antibody conjugated to an immune-stimulating payload. ISACs may require both tumor-associated antigens and tumor-resident myeloid cells for activity. As new IO strategies such as TLR-activating ISACs are developed, understanding the myeloid landscape is relevant for cancer biology and drug development. **Methods:** Tumor microarrays with formalin-fixed paraffin embedded sections of breast (BC), colorectal (CRC), gastric (GC), head and neck squamous cell (HNSCC), and non-small cell lung (NSCLC) cancers were analyzed by immunohistochemistry for tumor antigens (HER2, CEA, PD-L1), myeloid cell markers (CD68/CD163/CD11c/BDCA2), and CD8+ T cells. **Results:** Tumor infiltrating myeloid cells and CD8+ T cells varied across indications (Table). Low densities of intra-tumoral CD8+ T cells (<100/mm^2) were observed in CRC, with higher CD8+ T cell counts observed in other cohorts. In contrast to T cells, substantial myeloid infiltrates were observed across tumor types. While MSI status was associated with higher CD8+ T cell infiltration in CRC, myeloid cells were abundant in both MSI and MSS samples. Monocyte-derived (mDC) and conventional DCs (cDC), which respond strongly to TLR activation, were present in all indications, with highest numbers observed in NSCLC. HER2+ BC samples had high infiltration of plasmacytoid DCs, a key TLR7-responsive population. PD-L1 expression on immune cells was associated with higher CD8+ T cell and myeloid cell numbers. In contrast to HER2 and PD-L1, CEA expression was independent of immune infiltration. **Conclusions:** Abundant myeloid infiltrates were observed across solid tumors, independent of T-cell infiltration. The presence of myeloid cells in multiple tumor types offers broadscale therapeutic targets for ISACs and other myeloid-directed therapies that can activate the innate immune system as a bridge to adaptive immunity. Assessment of a 4-chemokine signature in prediction of T-cell inflammation and response to immune checkpoint inhibition across tumor types.

First Author: Joan Miguel Romero, Research Institute of the McGill University Health Centre, Montréal, QC, Canada

Background: Immune checkpoint inhibitors (ICI) are highly effective in select cancers. Novel predictors of T cell-inflammation may identify a broader subset of tumors with ICI responsiveness. Our group has identified four chemokines (CCL4, CCL5, CXCL9, CXLC10) able to predict a T cell-inflamed phenotype in primary and metastatic pancreatic tumors. Here, we test whether this 4-chemokine signature can predict T cell-inflammation across additional tumor types and response to ICI. **Methods**: Using matched genomic and transcriptomic data from 6,455 patients spanning 25 tumor types from The Cancer Genome Atlas, we searched for associations between the 4-chemokine signature and metrics of antitumor immunity. Further, we tested the association of this signature with markers of DNA damage repair deficiency. We also investigated the ability of this signature to predict response to immunotherapy using real-world data from a pan-cancer cohort of 82 patients in the Personalized OncoGenomics Program who had received ICI. **Results**: The majority of tumor types displayed sub-populations with high expression of the 4-chemokines (4-chemokine^{hi}) and transcriptional hallmarks of the cancer-immunity cycle. Testicular germ cell tumors, cervical squamous cell carcinomas, and head and neck squamous cell carcinomas were the strongest expressors of the signature. Immunomodulatory genes, including *PD-L1*, *PD-1*, *TIM3*, *LAG3*, *TIGIT*, *CTLA-4*, and *FASLG*, were significantly overexpressed ($p<0.05$) in the 4-chemokine^{hi} cohorts. Genesets of processes involved in the cancer-immunity cycle, including MHC I expression and cytolytic activity, were upregulated in the 4-chemokine^{hi} cohorts ($p<0.05$). While a global relationship between tumor mutation burden (TMB) and 4-chemokine expression across tumor histological type was seen (rho=0.42, p=0.02), high TMB was associated with only a subset of 4-chemokine^{hi} tumors. Among patients treated with ICIs, those with 4-chemokine^{hi} tumors had a longer median time to progression (104 versus 71 days, p=0.013) and overall survival (391 versus 195 days, p=0.016). The 4-chemokine signature outperformed TMB for overall survival prediction. **Conclusions**: Subpopulations of T cell-inflamed patients exist across tumor types and may therefore respond favourably to ICI. The 4-chemokine signature has the potential to select a wider spectrum of patients that may benefit from ICIs. Research Sponsor: Terry Fox Research Institute, Other Foundation, Other Government Agency.

Multivariate cox proportional hazards model for TTP and OS.

	Metric	Group	N	HR	P value
TTP	TMB	<10	42	Reference

FORTITUDE: Results of a phase 1a study of the novel transgene-armed and tumor-selective vector NG-350A with and without pembrolizumab (pembro).

First Author: Lee S. Rosen, UCLA Division of Hematology-Oncology, Santa Monica, CA

Background: Stimulating CD40 may support anti-cancer immune responses; however, on-target toxicity limits systemic dosing. NG-350A is a tumor-selective and blood stable adenoviral T-SIGn vector expressing a potent fully human IgG agonistic anti-CD40 antibody (mAb). NG-350A was designed to selectively deliver anti-CD40 to multiple tumor sites via IV delivery, driving immunological tumor re-engineering while avoiding systemic toxicity. We report results from a first-in-human trial after completion of enrollment. **Methods:** FORTITUDE (NCT03852511) is a phase 1 study of NG-350A ± pembro in patients (pts) with metastatic/advanced epithelial tumors. NG-350A monotherapy (mTx) was dose-escalated in separate intratumoral (IT; increasing numbers of doses) or IV (one cycle; three increasing dose levels) cohorts. IV NG-350A + pembro (200 mg Q3W for ≤8 cycles) was then assessed. **Results:** As of Jan 2022, 28 heavily pre-treated pts had received NG-350A, either as IT mTx (n=9; two dose levels), IV mTx (n=16; IV dose levels 1, 3 & 4) or IV + pembro (n=3; IV dose level 2). The MTD of NG-350A ± pembro was not reached, with no DLTs at the highest IT and IV dose levels. The safety profile of NG-350A was consistent with acute reactions to viral particles and asymptomatic aPTT prolongations (Table). No systemic CD40 transgene protein was detected at any dose level and the only SAE to occur in >1 pt was pneumonia. No objective responses were observed; however, 3/6 patients treated with NG-350A mTx at IV dose level 4 achieved stable disease (dose not yet tested with pembro). Dose-dependent specific increases in serum IL-12, IFNγ and IL-17a were detected in pts treated with IV NG-350A mTx from ~Wk 2. Increases were sustained at ≥5x baseline levels 7 wks after dosing in the majority of evaluable pts treated at higher IV dose levels. These responses did not occur with IT dosing (or in prior studies with an unarmed vector); further follow-up is ongoing for NG-350A + pembro. IV NG-350A also led to the expansion of T cell clones in blood; most of these were newly detected. **Conclusions:** NG-350A ± pembro was well-tolerated, with no evidence of CD40-related toxicity. NG-350A IV mTx led to specific and sustained cytokine responses consistent with the MoA of the encoded anti-CD40 Ab. Peak cytokine elevations were typically higher than reported with systemic anti-CD40 Abs, suggesting NG-350A can drive local immunological tumor changes while avoiding systemic toxicity. A further trial (FORTIFY, NCT05165433) will continue dose-escalation of NG-350A + pembro to identify a dose level for efficacy assessments. Clinical trial information: NCT03852511. Research Sponsor: PsiOxus Therapeutics Ltd.

Dose escalation of davoceticept, a conditional CD28 costimulator and dual checkpoint inhibitor, in advanced malignancies (NEON-1).

First Author: Diwakar Davar, University of Pittsburgh Medical Center, Hillman Cancer Center, Pittsburgh, PA

Background: Strong preclinical rationale supports combining checkpoint inhibition (CPI) with T cell costimulatory agonists, particularly of CD28, a critical T cell costimulatory molecule recognized as a key target of checkpoint inhibition. Davoceticept (ALPN-202) is a variant CD80 vIgD-Fc fusion that mediates PD-L1-dependent CD28 costimulation and inhibits the PD-L1 and CTLA-4 checkpoints. It has demonstrated superiority to CPI-only therapies in multiple tumor models *in vitro* and *in vivo*, while demonstrating favorable preclinical safety. **Methods:** This is an open-label dose escalation and expansion study of davoceticept in adults with advanced solid tumors or lymphoma (NCT04186637). Patients with cancers refractory to standard therapies including CPIs, or cancers without available standard or curative therapy are eligible. Dose escalation studied two dose schedules, Q1W and Q3W. Objectives include safety and tolerability, PK, PD and preliminary anticancer activity. Disease assessments are evaluated by RECIST v1.1 for solid tumors. A prior presentation discussed the first 5 cohorts of the Q1W schedule; this presentation updates progress in dose escalation, including the Q3W schedule. **Results:** As of January 2022, 57 adults with various advanced solid tumors, most commonly colorectal and pancreatic, received davoceticept monotherapy, which was well tolerated through 10 mg/kg Q3W. It demonstrated dose-dependent PK and target saturation. Immune-related AEs (irAEs), occurred in 20/57 (35%), mostly of the skin, endocrine and gastrointestinal systems. All but 4 of the irAE were grade 1-2. Only one DLT (chronic active gastritis grade 3) was observed at 3 mg/kg Q3W. Among 48 evaluable patients, unconfirmed partial responses were observed in 2 (colorectal and renal cell). Stable disease, at first scan at 6 weeks, was observed in 23 (48%); 11 (23%) demonstrated volume reduction (target lesion ΔSLD < 0%); 2 had SD for > 6 months, and 1 had an ongoing SD at 8 months. At doses above 0.1 mg/kg, *ex vivo* analyses showed agonism of T cell CD28, and flow cytometry demonstrated increased circulating activated (ICOS+), proliferating (Ki-67+) and central memory T cells, and reduced regulatory T cells, consistent with CD28 engagement. **Conclusions:** Davoceticept was well tolerated at doses capable of engaging CD28 costimulation *in vivo*, with early signs of activity and peripheral immune activation in a largely treatment-refractory, non-immunogenic tumor population. These findings support an additive benefit of combining CD28 agonism with checkpoint inhibition and identify biologically active dose regimens of davoceticept for subsequent single agent development, and provide further rationale for combination study. Expansion cohorts, including cutaneous melanoma and PD-L1-positive cancers, are planned, and a combination study with pembrolizumab has initiated (NCT04920383). Clinical trial information: NCT04186637. Research Sponsor: Alpine Immune Sciences.

2561 **Poster Session**

LAG3 transcriptomic expression correlates with high levels of PD-1, PD-L1, PD-L2, and CTLA-4 checkpoints and with high tumor mutational burden across cancers. *First Author: Jacob J. Adashek, University of South Florida, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Lymphocyte Activation Gene 3 (LAG3) or CD223 is an immune checkpoint that can be found on various T cells: CD4+, CD8+, regulatory T cells (Tregs), natural killer T cells, natural killer cells, and plasmacytoid dendritic cells. The expression of LAG3 molecule acts to increase T-cell exhaustion, leading to decreased tumor killing as well as an increase in immune suppressive cytokine release. Many clinical trials of LAG3 inhibitors have had modest effects, but recent data suggests that the LAG3 antibody relatlimab together with nivolumab (anti-PD1) provided greater benefit than nivolumab alone in patients with melanoma. **Methods:** The RNA expression levels of 397 genes in various types of solid tumors from 514 patients seen at the UCSD Moores Cancer Center were analyzed at a CLIA-licensed laboratory, OmniSeq (https://www.omniseq.com/). Following removal of germline variants, synonymous variants, indels and SNVs with < 5% VAF, TMB is reported as mutations/megabase. Transcript abundance was normalized to internal housekeeping gene profiles and ranked (0-100 percentile) in a standardized manner to a reference population of 735 tumors spanning 35 histologies. Odds ratio for high LAG3 expression was calculated and Bonferroni corrected for multiple genes and cancer histologies with > 40 samples. **Results:** A total of 116 (22.6%) tumors had high LAG3 (≥75) across 32 different histologies. Cancers with the highest proportion of LAG3 were neuroendocrine (47%), uterine (43%), sarcoma (33%), breast (31%), ovarian (30%), pancreatic (24%), lung (20%), stomach (16%), and colorectal (15%). There was significant association for high LAG3 with high PD-L1 (adj P < 0.001), high PD-1 (adj P < 0.0014), high PD-L2 (adj P < 0.0014), high CTLA-4 (adj P < 0.0014), TMB ≥10 mt/mb (adj P = 0.0504). There was no significant association between histologies colorectal (adj P = 0.1834), breast (adj P = NS), ovarian (adj P = NS), pancreatic (adj P = NS), or gender (adj P = 0.272). **Conclusions:** High LAG3 was found in almost a quarter of tumor samples and significantly associated with other immune checkpoints with FDA-approved drugs. Ongoing studies combining LAG3 inhibitors and specific immune checkpoint inhibitors may yield more clinical benefit if individualized immunomic transcript interrogation is undertaken, rather than population-based approaches without employment of rationally combined agents matched to each patient's cancer. Research Sponsor: None.

LB101, a conditionally tetravalent PD-L1xCD47 bispecific monoclonal antibody (mAb), combines tumor microenvironment (TME) targeted delivery (PD-L1) and a single biological high potency effector (CD47). *First Author: Jonny Finlay, LockBody Therapeutics, a Centessa Company, Cheshire, United Kingdom*

Background: Anti-PD-L1 antibodies are well-established as potent immune effectors in solid tumors expressing PD-L1 and demonstrate binding to these tumor cells within the TME. By contrast, due to the ubiquitous expression of CD47 on normal cells and tissues, anti-CD47 therapeutic agents with an active antibody Fc can lead to serious dose-limiting toxicities and profound biodistribution problems. To overcome these issues, we have generated LB101, a next-generation conditionally activated PD-L1xCD47 bispecific mAb with two anti-CD47 domains blocked by two further anti-PD-L1 domains, linked by two proprietary IgG-derived hinges, which inhibit CD47 interactions in the periphery, but are degraded in the PD-L1+ TME, thereby activating CD47 blockade to induce antibody-dependent cellular phagocytosis (ADCP). **Methods:** An IgG1-based, conditionally activated bispecific molecule was examined in binding, phagocytosis, PD-L1 blocking and flow cytometry assays. Efficacy analyses were performed in an hPD-L1+ syngeneic model in hPD-L1+/hPD1+ C57BL/6 mice, and preliminary safety and exposure analyses were completed in monkey. **Results:** In its intact locked form, LB101 exhibited anti-PD-L1 assay potency similar to atezolizumab. CD47 binding was only observed for LB101 after unlocking by hinge linker cleavage, leading to strongly enhanced ADCP by human CD14+ cells. In monkey, plasma stability of the locked construct was established with a PK profile mimicking that of a typical PD-L1 mAb. In the MC38 mouse model, systemically administered LB101 monotherapy delivered at equimolar dose to atezolizumab, led to no anemia, weight-loss, or overt toxicity. Monotherapy LB101 exhibited greatly improved efficacy and durability of response (14/16 tumors eradicated) over isotype control IgG (0/16) and atezolizumab (1/16). The CD47 naked parent IgG1 mAb was not tolerated in mouse, with 100% lethality above 2mg/kg. In rechallenge experiments, all naïve mice established tumors rapidly while none of the mice from groups with prior LB101-induced regressions exhibited tumor growth. **Conclusions:** Single agent LB101 immunotherapy delivered systemically in a difficult to treat syngeneic mouse model resulted in PD-L1 directed, local tumor-specific CD47 effector engagement leading to significant tumor regressions as compared to atezolizumab without overt toxicity. Future developments will focus on developing LB101 as a single agent therapeutic and exploring the potential of LockBody technology in improving the therapeutic index of other anti-cancer biological effectors through conditional activation within the TME. Research Sponsor: Centessa Pharmaceuticals.

TransCon IL-2 β/γ, a novel long-acting prodrug with sustained release of an IL-2Rβ/γ-selective IL-2 analog, demonstrates improved pharmacokinetics and profound expansion of cytotoxic immune cells in non-human primates. *First Author: David Rosen, AscendisPharma, Redwood City, CA*

Background: Recombinant interleukin-2 (IL-2, aldesleukin) is an approved cancer immunotherapy but causes severe side effects including cytokine release syndrome (CRS) and vascular leak syndrome (VLS). This is believed to be due to activation of IL-2Rα^+ endothelial cells and inflammatory eosinophils as well as high C_{max} due to the short half-life requiring frequent high dose administrations. Also, potent activation of immunosuppressive IL-2Rα^+ regulatory T cells (Tregs) may limit IL-2's efficacy. TransCon IL-2 β/γ is a novel long-acting prodrug with sustained release of an IL-2Rβ/γ-selective IL-2 analog designed to optimally address these shortcomings. **Methods:** Naïve male and female cynomolgus monkeys received 2-3 doses of TransCon IL-2 β/γ intravenously Q2W. Blood samples were taken to assess plasma concentrations of IL-2 β/γ (active drug), serum cytokines, hematology and immunophenotyping. Histopathology was also performed. **Results:** Administration of TransCon IL-2 β/γ induced robust increases in absolute lymphocyte counts (ALC), with no/minor increases in eosinophil counts. The increase in ALC was primarily driven by potent activation and expansion of CD8$^+$ T cells, NK cells and $\gamma\delta$ T cells, relative to CD4$^+$ T cells and Tregs. At doses with maximum pharmacodynamic (PD) responses, TransCon IL-2 β/γ induced on average > 20-fold ALC increases, > 19-fold CD8$^+$ T cell increases, > 50-fold Effector Memory CD8$^+$ T cell increases, > 18-fold NK cell increases and > 400-fold $\gamma\delta$ T cell increases compared to pre-dose levels. These changes corresponded with a low C_{max} and a long effective half-life (> 30 hours) for IL-2 β/γ. A clear induction of soluble CD25 and chemokine MCP-1 was seen after dosing, while levels of IL-5, IL-6, IFN-γ and TNF-α remained low. Further, histopathology showed no signs of vascular damage, tissue necrosis, pulmonary edema or eosinophilia. **Conclusions:** In cynomolgus monkeys, TransCon IL-2 β/γ demonstrated remarkable PD responses in CD8$^+$ T cells, NK cells and $\gamma\delta$ T cells over Tregs and eosinophils. No signs of VLS or CRS were observed. These results are likely due to the selective IL-2Rβ/γ bias along with the slow and sustained release of IL-2 β/γ resulting in low C_{max} and long circulatory half-life enabled by the TransCon prodrug technology. The massive expansion of $\gamma\delta$ T cells, which are known to possess considerable anti-tumor activity, is to our knowledge a unique finding for TransCon IL-2 β/γ among IL-2 variants in clinical development. Altogether, the responses seen in monkeys are suggestive of a potentially substantial improvement in the therapeutic index beyond what has been achieved by aldesleukin or new IL-2 variants to date. TransCon IL-2 β/γ is currently being evaluated in a clinical Phase 1/2 trial as monotherapy and in combination with pembrolizumab (NCT05081609). Research Sponsor: Ascendis Pharma.

A novel polymeric peptide delivery platform and association with targeted co-delivery of antigens and STING agonists with antitumor immune response. *First Author: Max Mu Wang, Medical Scientist Training Program, Northwestern University, Chicago, IL*

Background: Use of tumor antigens for the development of patient-specific cancer vaccines has been a promising therapeutic strategy. However, challenges remain in delivering subunit vaccine components in a coordinated fashion to elicit antitumor immune responses. To overcome these, we developed rationally designed vaccines using a novel nanoplatform called the Protein-Like Polymer (PLP), in reference to its globular structure reminiscent of native proteins, with unique characteristics that allow for sustained/targeted delivery of tumor antigens in conjunction with STING agonists. **Methods:** PLPs containing a model melanoma antigen were synthesized via ring-opening metathesis polymerization (ROMP) and characterized. A library of compounds were generated with different sidechain linkage chemistries (amide, ester, or disulfide), degrees of polymerization, and inclusion/exclusion of Oligo(ethylene glycol) (OEG) side chains. *In vitro* uptake and functional assays using gp100-specific T Cells were conducted with fluorescently-labeled and non-labeled polymers respectively. *In vivo* experiments were done using a B16F10 murine melanoma tumor model over-expressing gp100. Ability of PLPs to co-deliver immunomodulatory compounds was tested by electrostatically coupling a small molecule STING agonist 2'3' cGAMP which formed stable nanostructures. The optimized construct was also tested in an OVA system to prove generalizability. **Results:** Conjugating peptide antigens using a cleavable disulfide linkage, which reduces intracellularly in antigen presenting cells (APCs), resulted in increased endosomal localization and efficacy. Incorporating a diluent amount of OEG side chains increased resistance to enzymatic degradation while improving bioactivity and uptake by APCs. *In vivo* studies using PLPs conjugated with gp100 resulted in significant increases in survival time and reduced tumor burden in B16 melanoma. Increasing the DP, and therefore the density of antigen side chains, improved vaccine efficacy and resistance to proteolysis. Mice treated with STING-PLP complexes showed significantly smaller tumors vs control at day 14 (0.038g vs 0.76g; p < 0.0001) and allowed for subcutaneous administration of 2'3' cGAMP, which otherwise diffuses rapidly away from the injection site. OVA-PLPs behaved similarly in their cognate system but showed no activity when tested on gp100-specific cells and vice versa demonstrating antigen-specificity. **Conclusions:** This work validates the potential of PLPs to overcome major limitations in cancer vaccine development. The modularity of the platform allows for complex nano-architectures including systems capable of delivering challenging compounds, ie small molecule STING agonists, subcutaneously through electrostatic coupling. This technology has the potential to revolutionize cancer vaccinology. Research Sponsor: U.S. National Institutes of Health.

Exploiting GLAAD molecules to drive an antitumor immune response in a colorectal cancer mouse model. *First Author: Yemi Adesokan, Gnubiotics Sciences SA, Epalinges, Switzerland*

Background: Only a minority of colorectal cancer (CRC) patients benefit from immune checkpoint inhibitors (ICI), with less than half of eligible patients responding to the treatment. Abnormal glycosylation of tumor cells is a signature of cancer development. Here, we described novel immunomodulatory molecules, named GLAAD (glycopeptides with adjuvant and tumor-associated antigen delivery). We hypothesized that GLAAD, by sharing similarities with aberrant glycans expressed in many cancers, may be a safe and effective treatment strategy to promote response and overcome resistance to ICI, thus addressing an urgent clinical need. Using a CRC mouse model, we tested whether two GLAAD candidates reduce tumor burden when orally administered alone or in combination with ICI. **Methods:** C57/BL6J mice were supplemented with 3% GNU-201 or 3% GNU-101 in the drinking water starting 14 days prior to tumor cell injection (d-14), while control mice received normal drinking water. On day 0, all mice were injected subcutaneously with MC38 CRC cells in each flank. On days 6, 9, 12, and 15, mice in each group received anti-PD1 antibody (aPD1) or an isotype control. Tumor size was measured every 3rd day. On day 18, the mice were sacrificed. **Results:** The aPD1 therapy alone showed a limited anti-tumor efficacy overall. Groups treated with GNU-201, GNU-101, GNU-201+aPD1 or GNU-101+aPD1 exhibited reduced growth, resulting in a significantly reduced tumor volume vs control on day 18. In contrast, GLAAD candidates alone significantly reduced tumor volume compared with control and led to a numerically larger decrease than aPD1 treatment alone, suggesting a higher efficacy. When analyzing tumor infiltrating myeloid cells on day 18, no differences were seen for neutrophils or dendritic cells but the proportion of macrophages was decreased in mice receiving GNU-201 or GNU-101. GNU-101 resulted in reduced serum levels of IL-10, a molecule participating in the suppression of antitumor immune responses. The tested GLAAD candidates stimulated robust anti-tumor T cell responses. GNU-201 and GNU-101 supplementation alone or in combination with aPD1 increased the proportion of T cells and among those CD8+ T cells, IFNγ producing CD4+ T cells, IFNγ+ and perforin+ CD8+ T cells. GNU-101 and GNU-201 elicited memory T cell responses after priming of the mice, measured as the *ex vivo* recall response (CD69 expression) of CD8+ T cells isolated from the tumor. **Conclusions:** GNU-201 and GNU-101 as standalone treatment induce a strong anti-tumor response that is as good as or even better than aPD1 alone. The therapeutic efficacy is associated with increased tumor infiltration and activation of T cells, in particular CD8+ T cells, highlighting the role of these GLAAD candidates as potent adjuvants in supporting specific tumor-associated antigen recognition by the immune system. Research Sponsor: Gnubiotics Sciences SA.

Phase 1b study of GS-3583, a novel FLT3 agonist Fc fusion protein, in patients with advanced solid tumors. *First Author: Anthony W. Tolcher, Next Oncology, San Antonio, TX*

Background: We have previously shown that systemic administration of GS-3583, a Fms-like tyrosine kinase 3 (FLT3) agonist Fc fusion protein leads to expansion of conventional dendritic cells (cDC), both subtype 1 (cDC1) and subtype 2 (cDC2), in the periphery of healthy volunteers (Rajakumaraswamy N, et al. *J Clin Oncol.* 2021;39[suppl_15]:2559.). This mechanism may increase cDC in the tumor microenvironment and promote T cell mediated antitumor activity in patients with solid tumors. **Methods:** This ongoing, Phase 1b, open label study is investigating the safety, tolerability, immunogenicity, pharmacokinetics, and pharmacodynamics of escalating multiple doses of GS-3583 monotherapy in adult patients with advanced solid tumors using a standard 3 + 3 design. GS-3583 was administered intravenously on Days 1 and 15 of Cycle 1 and on Day 1 of each subsequent 28-day cycle for up to 52 weeks or until progressive disease or unacceptable toxicity. Dose-limiting toxicity (DLT) was evaluated during the first 28 days of GS-3583 therapy at each dose level. **Results:** At the time of the Dec 3, 2021 data cut-off, 9 patients have enrolled in 3 dose escalation cohorts. Median (range) age was 71 (44-79); 4 (44%) patients were male. Tumor types were pancreatic (n=3), ovarian (n=4), and rectal (n=2). To date, no DLTs or discontinuation due to adverse events (AE) have been observed. Three patients had Grade ≥3 AEs which were also recorded as serious AEs, none of which were considered related to GS-3583. Dose dependent increase in GS-3583 exposure was observed in the evaluated dose range 2 to 12 mg with target-mediated drug disposition appearing to be saturated at doses above Dose Level 2. GS-3583 accumulation was observed at higher dose levels. GS-3583 treatment resulted in expansions of cDC1 and cDC2 at all 3 doses (Table); a dose-dependent trend in the magnitude and the durability of cDC expansion was observed. At the highest dose evaluated, GS-3583 produced ≥100-fold expansion of both cDC1 and cDC2 at multiple time points. Dose escalation on the study is still ongoing. **Conclusions:** GS-3583 was safe and well tolerated and induced dose-dependent expansion of cDCs in the periphery in patients with advanced solid tumors up to doses of 12 mg. These findings support further dose escalation and clinical development of GS-3583 in combination with agents that would stimulate the expanded cDCs to produce anti-tumor responses. Clinical trial information: NCT04747470. Research Sponsor: Gilead Sciences, Inc.

Dose Level (mg GS-3583)	1 (2 mg)	2 (6 mg)	3 (12 mg)
Median peak cDC1 fold expansion (range)	124 (188 – 15)	83 (0)	191 (283 – 99)
Observation of peak cDC1 expansion	C1D24	C2D15	C2D1
Median peak cDC2 fold expansion (range)	147 (154 – 34)	201 (0)	217 (273 – 162
Observation of peak cDC2 expansion	C1D15	C2D15	C2D1

A phase II study to evaluate the safety and efficacy of radiotherapy combined with irinotecan liposome followed by camrelizumab and apatinib for advanced solid tumors that failed standard treatments. *First Author: Jie Shen, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

Background: Liposomes deliver the drug to tumors based on enhanced permeability and retention (EPR) effects. Radiotherapy further prompts the distribution of liposomal drugs to tumor sites receiving radiotherapy by altering the tumor microenvironment. In addition, radiotherapy might enhance systemic antitumoral responses to immunotherapy. Herein, we aimed to explore safety and efficacy of radiotherapy in combination with irinotecan liposome, immunotherapy, and antiangiogenic therapy in advanced solid tumors patients (pts) that failed standard treatments. **Methods:** Anopen single-arm, multi-center, phase II study was conducted to enroll solid tumors pts who have failed standard treatments. Eligible pts would receive radiotherapy combined with irinotecan liposome followed by camrelizumab and apatinib. Radiotherapy of 24 Gy/3 fractions/3-10 days was given to the targeted lesions. Irinotecan liposome (80mg/m^2 i.v.) was administered once within 48 hours after radiotherapy and followed by camrelizumab (200mg i.v. q3w) and apatinib (250mg po qd) until disease progression or unacceptable toxicity. The primary endpoint was the objective response rate (ORR) of the irradiated lesions evaluated by the investigators as per RECIST V1.1. The secondary endpoints were disease control rate (DCR) and treatment-related adverse event (TRAE). **Results:** As of Dec 2021, 55 pts were enrolled includin 9 with biliary tract cancer, 8 with pancreatic cancer, 8 with sarcoma, 5 with lung cancer, 2 with liver cancer, 2 with cervical cancer, 2 with gastric cancer, and 22 with other cancer types. 26 (47.3%) pts failed at least 3 lines of therapy before enrollment. The median follow-up was 41 weeks and 42 pts can be evaluated. 15 partial response, 26 stable disease, and 1 progressive disease were achieved. The ORR and DCR of irradiated target lesions were 35.7% and 97.6%, respectively. The ORR and DCR of every cancer type are listed in table. TRAEs (all grades) occurred in 87.3% (48/55) pts. The most common grade 3-4 related TRAEs were lymphocyte count decreased (29.1%), white blood cell count decreased (10.9%), and anaemia (10.9%). **Conclusions:** The combination of radiotherapy, irinotecan liposome, camrelizumab, and apatinib demonstrated promising anti-tumor activity and well tolerance in various advanced solid tumors that failed standard treatments. Clinical trial information: NCT04569916. Research Sponsor: None.

Cancer types	Evaluable(N≥2)	ORR of theirradiated lesions	PR	SD
Biliary tract cancer	8	12.5%	1	7

Safety results of Q-1802, a Claudin18.2/PD-L1 bsABs, in patients with relapsed or refractory solid tumors in a phase 1 study. *First Author: Jifang Gong, Department of Gastrointestinal Oncology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/ Beijing), Peking University Cancer Hospital and Institute, Beijing, China*

Background: Q-1802 is a humanized bispecific antibody that targets both the tumor -specific antigen CLDN18.2 and the immune checkpoint PD-L1. **Methods:** This is a first-in-human, phase 1a/1b, multicenter, dose escalation and dose expansion study of Q-1802 administered intravenously to adult pts with resistant/ refractory advanced or metastatic solid tumors who had failed standard therapies. Monotherapy of Q-1802 was conducted in 20-30 enrolled subjects. In the dose escalation phase (phase 1a), an accelerated titration followed by a 3+3 design was used to assess the safety and tolerability of Q-1802 monotherapy (dose range 0.1 mg/kg to 20 mg/kg); and determine the maximum tolerated dose (MTD). Q-1802 was administered Q3w on a 21-day treatment cycle and dose limiting toxicity (DLT) observation period. Tumor assessments per RECIST v1.1 were performed once every 6 weeks (2 cycles). Q-1802 PK and PD analyses were performed. **Results:** As of Jan 20, 2022, a total of 9 patients (median age 57y; most patients received ≥3 prior regimens) were enrolled in phase 1a with DLT evaluation of the 20 mg/kg cohort currently in progress. The most common tumor types were GI cancers. There were no DLTs up to 10 mg/kg of Q-1802, inclusive. Phase 1a with DLT evaluation of the 20 mg/kg cohort currently in progress. The most common treatment related adverse events (TRAEs) were Gastrointestinal AE (66.7%, 6/9), including nausea 6/9 (66.7%), vomiting 5/9 (55.6%), abdominal pain 2/9 (22.2%) and diarrhea 2/9 (22.2%). The second common TRAEs were IRR (infusion related reaction) (33.3%, 3/9), including Fatigue 3/9 (33.3%), Fever 2/9 (22.2%), Chill 2/9 (22.2%), face pain 1/9 (11.1%). There was G1/2 except for one patient experienced a G3 skin rash, and one patient reported with a G3 Gastrointestinal AE. Two SAEs (G2 fever and G3 Gastrointestinal AE) were reported, both were considered as possibly related to study drug, but recovered shortly. No death reported due to study related treatment. Safety evaluation of the 20 mg/kg dose level is in progress. One Gastric cancer patient (moderate CLDN18.2 expression at baseline) with prior heavily treatment observed clinical benefit and response with Non-CR/Non-PD at first tumor assessment at dose of 10mg/kg and continues the therapy. Q-1802 drug exposure increased with increasing dose. The elimination of Q-1802 appears to follow first-order elimination kinetics. **Conclusions:** Q-1802 bsABs has presented safe and well-tolerated profile up to doses of 10 mg/kg. The dose escalation is still in progress. Clinical trial information: NCT04856150. Research Sponsor: QureBio Ltd.

2569 **Poster Session**

Breath biopsy early detection of lung cancer using an EVOC probe targeting tumor-specific extracellular β-glucuronidase. *First Author: Christiaan Frederick Labuschagne, Owlstone Medical, Cambridge, United Kingdom*

Background: Lung cancer is a leading cause of mortality with 5-year survival less than 20%, largely a result of many cases being diagnosed late. Early detection can increase cancer survival up to 13-fold underscoring the need for effective screening. Targeted Low dose computed tomography (LDCT) has been shown to be effective but its impact to date has been limited due to slow adoption and variable uptake in high-risk populations. Breath analysis represents a non-invasive screening approach either alone or alongside LDCT. Numerous studies have investigated potential endogenous breath biomarkers of lung cancer. Many have produced promising results but to date, no validated biomarkers with clear connections to cancer metabolism have been revealed. We have explored an alternative, probe-based approach based around Exogenous Volatile Organic Compound Probes (EVOC Probes). The probes target tumour associated extracellular b-glucuronidase, a glycosidase enzyme that normally resides within lysosomes. **Methods:** We use a hydrophilic non cell permeable substrate probe D5-ethyl-βD-glucuronide (D5-EtGlu) that upon hydrolysis by the target enzyme releases D5-ethanol, a unique volatile reporter molecule detectable on breath. This provides a readout of tumour associated enzyme activity using breath analysis. **Results:** Administering D5-EtGlu to mice resulted in tumour specific release of D5-ethanol, enabling discrimination between healthy and tumour bearing animals. Increased expression of b-glucuronidase in lung cancer tissue and the tumour microenvironment was confirmed with immunohistochemistry (IHC) in clinical samples. A phase 1a clinical trial administered D5-EtGlu to healthy individuals in a single ascending dose study to establish safety and background D5-ethanol levels in healthy individuals. This resulted in no adverse events and low/no D5-ethanol signal verifying the inaccessibility of D5-EtGlu to intracellular b-glucuronidase. The next stage, currently ongoing, is a proof of mechanism in humans. D5-EtGlu is administered intravenously to confirmed lung cancer patients followed by breath analysis. D5-ethanol breath levels will be compared to cancer free individuals receiving the same dose of D5-EtGlu. **Conclusions:** Non-invasive breath testing has great potential to contribute to diagnosis for lung cancer including a potential role in screening. Our current work is evaluating the use of an administered probe to stimulate tumour-specific enzyme activity and produce a marker detectable on breath. Continued success could result in a sensitive and highly specific method for lung cancer early detection. Research Sponsor: Owlstone Medical.

Artificial intelligence-powered pathology image analysis merged with spatial transcriptomics reveals distinct TIGIT expression in the immune-excluded tumor-infiltrating lymphocytes. *First Author: Gahee Park, Lunit Inc., Seoul, South Korea*

Background: TIGIT is a promising emerging immunotherapeutic target. However, the specific sources of TIGIT expression within the tumor microenvironment are largely unknown. Here, we present an AI-powered spatial tumor-infiltrating lymphocyte (TIL) analyzer, Lunit SCOPE IO, to integrate image analysis from whole slide images with single-cell molecular profiling. **Methods:** We used The Cancer Genome Atlas (TCGA) RNA expression data across 23 cancer types (n=6,930). Lunit SCOPE IO was developed, trained, and validated based on >17k H&E whole-slide images, to segment cancer area (CA) and cancer-associated stroma (CS) and to detect tumor cells and TILs. The intratumoral TIL, stromal TIL, and tumor cell purity (TCP) in the CA+CS area were calculated. The public spatial transcriptomics (ST) dataset for breast cancer was downloaded from the 10X Visium web page. Lunit SCOPE IO was applied to the associated H&E WSIs to match distinct TIGIT expression to single cells identified in the WSIs. **Results:** TIGIT was highly expressed in TGCT (3.45±0.11; median±SEM), LUAD (3.07±0.05), and HNSC (2.89±0.06), and was highly enriched in samples with microsatellite instability-high or tumor mutational burden-high (≥ 10/Mb) compared to those without them (fold change = 1.30, $p < 0.001$). At a macroscopic, bulk-level in the TCGA dataset, TIGIT expression was positively correlated with intra-tumoral TIL density (R=0.37, $p<0.001$) and stromal TIL density (R=0.42, $p<0.001$), but it was negatively correlated with TCP (R=-0.27, $p<0.001$). Lunit SCOPE IO analyzed the images from ST analysis and calculated intra-tumoral TIL, stromal TIL, and TCP of each region of interest, containing 2 (IQR 0-7) cells. Interestingly, at a microscopic, cell-level, TIGIT expression was still higher in areas of enriched stromal TIL ($P < 0.001$) and lower in tumor cell-dense areas, but it was not significantly correlated with enriched intra-tumoral TIL areas, meaning that TIGIT expression is likely derived from the excluded TILs in the CS area. **Conclusions:** Interactive analysis of spatial transcriptomics with AI-powered pathology image analysis revealed that TIGIT expression in the tumor microenvironment is exclusive to confined areas with stromal TIL enrichment, reflecting the exclusion of TIL from the tumor nest. Research Sponsor: None.

	Fold change of TIGIT expression	P value
TCGA: iTIL < mean versus iTIL ≥ mean	1.58	< 0.001
TCGA: sTIL < mean versus sTIL ≥ mean	1.55	< 0.001
TCGA: TCP < mean versus TCP ≥ mean	0.75	< 0.001
ST: iTIL < mean versus iTIL ≥ mean	0.47	< 0.001
ST: sTIL < mean versus sTIL ≥ mean	2.39	< 0.001
ST: TCP < mean versus TCP ≥ mean	0.28	< 0.001

Evaluation of pharmacodynamic and patient enrichment biomarkers for SAR444881, a first-in-class anti-ILT2 monoclonal antibody for cancer immunotherapy. *First Author: Ilana Mandel, Biond Biologics, Misgav, Israel*

Background: Leukocyte Ig-like receptor B1 [LILRB1; ILT2] is an inhibitory receptor expressed on various immune cells. ILT2 binds to classical and nonclassical MHC class I molecules, with highest affinity to HLA-G. ILT2-mediated inhibition leads to impairment of immune cell proliferation, differentiation, phagocytosis, cytotoxicity and cytokine secretion. Antagonism of ILT2 signaling may serve as a novel target for anti-cancer immunotherapy. SAR444881 (BND-22) is a novel humanized IgG4 monoclonal antagonist antibody which selectively binds to ILT2 and blocks its interaction with MHC I molecules. SAR444881 induces robust macrophage and lymphocyte-driven anti-tumor activity in *in vitro* and *in vivo* models. To overcome the limitation that LILRB proteins are not expressed in rodents, we conducted a series of *in vivo* studies using humanized mouse models, cancer patient biopsies and *ex vivo* co-culture systems to interrogate the pharmacodynamic (PD) response of ILT2 antagonism as well as inform the combinatorial and patient enrichment strategies for SAR444881. **Methods:** SAR444881-induced modulation of PD biomarkers was evaluated in humanized xenograft models. Ex vivo co-culture system has been established using patient tumor tissues and isolated PBMC or other immune cells. Biomarker expression on immune cells and secreted soluble proteins were monitored by flow cytometry and ELISA, respectively. Procured tumor samples of patients with various advanced solid tumors, including Head and neck squamous cell carcinoma (HNSCC), Gastric Cancer (GC), Non-Small Cell Lung Cancer (NSCLC) and Colorectal Cancer (CRC) were utilized to evaluate protein or gene expression levels of potential predictive biomarkers (ILT2, HLA = G, PD-L1) using immunohistochemistry (IHC) and whole transcriptomic analysis (RNAseq). **Results:** 1) PD biomarkers: in murine models, SAR444881 modulates intra-tumoral sub-populations of CD8+ T cells, NK cells and Macrophage polarization; 2) Combination strategy: functional study in an *ex vivo* system showed that addition of an anti-PD-1 antibody induced an increased production of pro-inflammatory cytokines, including IFNγ and TNFα, compared to SAR444881 or anti-PD-1 alone. Concomitantly, combining SAR444881 with cetuximab resulted in increased phagocytosis compared to isotype control. 3) Predictive biomarkers: protein and gene profiling results suggest enriched expression of ILT2 in majority of biopsies from several tumor types including NSCLC, HNSCC and CRC. **Conclusions:** These data inform the PD response biomarkers, combination, and patient enrichment strategies for the clinical development of SAR444881 to maximize its benefits for cancer patients. An ongoing phase 1/2 trial of SAR444881 mono- and combination therapy in patients with advanced solid tumors is testing these concepts in the clinic (NCT04717375). Research Sponsor: Sanofi, Biond Biologics.

2572 **Poster Session**

Safety and tolerability of T-SIGn vectors when administered using "flat" versus "low-high-high" (LHH) dosing regimens. *First Author: Thomas Lillie, PsiOxus Therapeutics Ltd, Abingdon, United Kingdom*

Background: Tumor-selective viruses, particularly those dosed systemically to deliver transgenes, are potentially powerful cancer therapies. However, acute cytokine reactions to viral particle (vp) infusion may affect vector tolerability [Small 2006], thereby limiting the maximum tolerated dose (MTD) and subsequent transgene delivery. T-SIGn vectors (e.g. NG-641 and NG-350A) are transgene-armed variants of the epithelial tumor-selective adenovirus enadenotucirev (EnAd). Acute serum cytokine increases post-dosing have been seen at the MTD of EnAd ("flat" dosing of 3×10^{12} vp on Days [D] 1, 3 and 5) [Machiels 2019]. Following supportive preclinical data [McElwaine-Johnn 2019], we explored if a LHH dosing regimen, in which a lower dose is given on D1 prior to two higher doses on D3 and 5, may improve vector safety/tolerability thereby allowing higher cumulative doses to be given. **Methods:** Data were pooled from three Phase 1 dose-escalation studies in advanced/metastatic epithelial cancer: SPICE (EnAd + pembrolizumab/nivolumab; NCT02636036), FORTITUDE (NG-350A ± pembrolizumab; NCT03852511) and STAR (NG-641; NCT04053283). Serum cytokines were measured using a 17-analyte Luminex assay. IL-6/MCP-1 data for D1, 3 and 5 (pre- and 6-10 hrs post-dose) were analyzed to examine acute cytokine changes. TNFα/IFNγ were examined due to their association with cytokine release syndrome (CRS). Samples analyzed from SPICE/FORTITUDE were taken before PD-1 inhibitor administration. **Results:** 84 patients (SPICE n=51; FORTITUDE n=18; STAR n=15) were included in these analyses; 79 had cytokine data. AEs and Gr≥3 AEs within 1 wk of first dose, and DLTs at any time, were less frequent with a LHH vs flat dosing regimen (Tbl). Importantly, a LHH dose of 1-6-6 (1×10^{12} vp on D1; 6×10^{12} vp on D3 and 5; greater than the previous flat MTD) was tolerated. Acute increases in TNFα/IFNγ were limited and no severe CRS was seen. Increases in IL-6/MCP-1 with 1×10^{11} or 1×10^{12} vp flat dosing were negligible, whereas acute increases in IL-6/MCP-1 were seen after the first dose of 3×10^{12} vp when given as a flat dose (negligible increases on D3/5). Notably, cytokine responses with 1-3-3 dosing (1×10^{12} vp on D1; 3×10^{12} vp on D3 and 5), including after the first 3×10^{12} vp dose on D3, were negligible. Cytokine responses after the first dose of 6×10^{12} vp in the 1-6-6 regimen were similar to those seen with the first dose of the flat 3×10^{12} vp regimen. **Conclusions:** LHH dosing appears to induce a desensitization mechanism allowing higher cumulative doses of T-SIGn vectors to be given without the associated acute reactions to viral infusions. This finding may have implications for optimizing safety-efficacy profiles of viral vectors in cancer. Clinical trial information: NCT02636036, NCT03852511 and NCT04053283. Micro-organospheres retain patient tumor microenvironment for precision immuno-oncology. *First Author: Shengli Ding, Xilis.Inc, Durham, NC*

Background: Current patient-derived organoid (PDO) models are largely devoid of immune components. We developed a precision microfluidic and membrane platform to generate patient-derived micro-organospheres (MOS) that retain tumor-resident immune and stromal components for personalized immuno-oncology (IO) assays. **Methods:** MOS were generated from lung, kidney, and colorectal cancer patients. The composition and function of patient tumor-resident immune cells in MOS were characterized by flow cytometry, single-cell RNA-seq, antibody staining, and TCR-seq. High-content and longitudinal imaging with AI analyses were used to quantify tumor cell death and immune cell dynamics inside MOS in response to IO therapies including checkpoint inhibitors, T cell bispecific antibodies, and adoptive tumor infiltrating lymphocyte (TIL) therapies, followed by single-cell analyses. **Results:** Tumor and stromal cells quickly form tissue niches inside MOS to sustain the viability and function of encapsulated immune cells. MOS derived from lung and kidney cancer patients respond to Nivolumab, indicated by the Annexin V apoptosis marker. ESK1* (TCB antibody targeting HLA-A2/WT1) induces killing in eight lung tumor patients derived MOS. We further developed a MOS T-cell potency assay as autologous TILs or PBMC efficiently infiltrate MOS from lung, kidney and CRC patients and induce tumor cell apoptosis. Adjunctive therapies combining TCB with TILs enhanced the potency of adoptive cell therapy against lung tumor. Based on the data, three ongoing and upcoming personalize IO clinical trials will further validate the ability of the MOS assay to predict patient response to TCB, checkpoint combinations, and adoptive cell therapy. **Conclusions:** MOS provide a rapid and scalable personalized platform for developing and testing IO therapies such as checkpoint inhibitors, bispecific antibodies, and T cell therapies on patient tumor models that still retain the original tumor microenvironments. Research Sponsor: None.

2574 **Poster Session**

Phase 1b study of the novel first-in-class G protein-coupled estrogen receptor (GPER) agonist, LNS8801, in combination with pembrolizumab in patients with immune checkpoint inhibitor (ICI)-relapsed and refractory solid malignancies and dose escalation update. *First Author: Carolyn Muller, University of New Mexico, Albuquerque, NM*

Background: LNS8801 is an oral, highly selective, small molecule agonist of the G protein-coupled estrogen receptor (GPER). LNS8801 normalizes c-Myc levels in cancer cells, inhibits proliferation, suppresses invasion, and enhances immune recognition. In preclinical models, LNS8801 has demonstrated increased activity with ICIs. In the first-in-human dose escalation study, LNS8801 was safe and tolerable alone and in combination with pembrolizumab in patients with metastatic solid tumors (NCT04130516). **Methods:** Patients who are relapsed and refractory (r/r) to PD-1/L1 ICIs and have measurable disease are enrolling in a Phase 1b cohort and receive LNS8801 (125 mg, QD, PO) and pembrolizumab (200 mg, Q3W, IV) (NCT04130516). The primary objective is safety and tolerability assessed according to NCI CTCAE v5.0. Secondary endpoints include pharmacokinetic, pharmacodynamics (eg., increase in serum prolactin over the initial 10 hours of dosing to assess GPER engagement), objective response rate and clinical benefit rate per RECIST v1.1. **Results**: Updates from the dose escalation portion of the study include long term benefit in a monotherapy patient with cutaneous melanoma on treatment for 2 years with RECIST stable, metabolically inactive disease by PET; a metastatic uveal melanoma patient on therapy for a year, and growing confidence in LNS8801's favorable safety profile and predictive systemic biomarkers. As of 2/1/22, 13 ICI r/r patients were treated with LNS8801 and pembrolizumab, including those who entered the study directly after confirmed progression on ICIs. Cancer types include lung (3), colorectal, vaginal, nasopharyngeal, neuroendocrine, uterine, and pancreatic cancer, mesothelioma (2), and cutaneous and uveal melanoma. 46% of patients had AEs possibly related to study drugs (31% grades 1-2 and 31% grade 3), with colitis (15%) and fatigue (23%) appearing in more than 10% of patients. Of the 10 evaluable patients, 7 had stable disease (SD), with 4 patients demonstrating tumor regression. At the data cut-off, duration of treatment ranged from 0.7–7.5 months with 4 patients treated between 4.8 and 7.5 months and 4 patients continuing on treatment. All evaluated patients with SD had a prolactin response indicative of systemic target engagement. **Conclusions**: The combination of LNS8801 and pembrolizumab is tolerable without unanticipated toxicities and demonstrates encouraging anti-tumor activity in patients that are r/r to ICIs, including patients who enrolled immediately after confirmed progression on pembrolizumab alone. These data, as well as continued follow-up on patients with long-term benefit from dose escalation, support further development of LNS8801 as a cancer therapeutic. Clinical trial information: NCT04130516. Research Sponsor: Linnaeus Therapeutics.

Phase I study of epacadostat in combination with sirolimus in advanced malignancy. *First Author: Chao Hui Huang, University of Kansas Medical Center, Westwood, KS*

Background: Epacadostat (E) is an inhibitor of Indoleamine 2,3 dioxygenase-1 (IDO1) which is a rate-limiting enzyme in the catabolism of tryptophan to kynurenine. The inhibition of IDO1 leads to increase tryptophan and reversal of immunosuppression by increasing the proliferation of T cells, suppression of regulatory T cells (Tregs) and activation of mTOR which suppresses autophagy. Sirolimus (S) can reverse the mTOR activation induced by E, suppress the expression of PD-L1 and function of Tregs. We initiated a phase I trial to test the safety and tolerability of SE combination in patients with advanced solid tumors, with plans for an expansion phase II study in patients with advanced recurrent lung cancer once maximum tolerated dose (MTD) was defined. **Methods:** The phase I trial portion of the study used a modified 3+3 design in which the dose transition rule was similar to standard 3+3 design with the modification based on sirolimus PK data. S had a lead-in of 3mg/day(d) at day -7 followed by 1mg/d with E added on day 1 of Cycle 1 starting at 300mg bid in a 28d cycle at dose level 1; then S is escalated to 6mg/d followed by 2mg/d maintenance with E at 300mg bid at level 2. An additional level 3 was added with S at 6mg/d followed by 2mg/day with E at 400 bid based on results of E at 400-600 mg bid in combination with a checkpoint inhibitor with improved control of peripheral kynurenine and intra-tumoral kynurenine reductions. Enrollment continued until Dose limiting toxicity (DLT) which was defined as grade 3 hematologic toxicities or grade 3 or 4 non-hematologic toxicities up to Cycle 2 day 1. MTD was defined as DLT not exceeding 33% of subjects. **Results:** The phase I study enrolled 15 patients, with 9 patients evaluable. The types of cancers were non-small cell lung ca (1), colorectal (5), esophagus (1), gallbladder (1) and sarcoma (1). DLT was not observed up to level 3. Adverse events attributed to SE were Grade 1 Diarrhea (2), stomach pain (1); elevated liver enzymes (ELE) (1), decreased white blood cell (1), anorexia (1), hypokalemia (1), dizziness (1), skin rash (1); Grade 2 ELE (1), Anemia (1), Vertigo (1), Constipation (1), Nausea (2); Grade 3: Diarrhea (1), serotonin syndrome (1), dyspnea (1). The best response observed was stable disease in 3 patients, 5 patients had disease progression and 1 patient was not assessable for response due treatment discontinuation related to side effect of serotonin syndrome. The Expansion Cohort (Part 2) did not proceed since the sponsor decided to discontinue further development of E. **Conclusions:** The combination of SE is feasible, tolerable with mostly grade 1 and 2 toxicities. There were few grades 3 toxicities. SE produced stable disease as best response in 33% of patients. Research using the combination of SE as an immunomodulatory therapy in patients with lung cancer resistant to checkpoint inhibitor is worth additional exploration. Clinical trial information: NCT03217669. Research Sponsor: Epacadostat.

Systemic TLR7/8 micelles trigger a novel and potent anti-tumor response by strong recruitment of neutrophils leading to massive tumor cell killing. *First Author: Simon Skjøde Jensen, MonTa Biosciences, Kgs Lyngby, Denmark*

Background: Clinical use of TLR7/8 agonists is currently restricted to topical application of Imiquimod for treatment of superficial basal cell carcinoma since systemic administration is prevented due to dose-limiting toxicity. Here, we present a novel micelle-based drug delivery technology containing a lipid-anchored TLR7/8 agonist for intravenous administration. The MBS8 formulation shows good efficacy in mouse cancer models, is well tolerated in rodents and non-human primates and is currently being tested in clinical studies (NCT04855435). **Methods:** MBS8 was tested in 12 syngeneic mouse cancer models as monotherapy or in combination anti-PD-1 and anti-PD-L1 antibodies. MBS8 was administered IV as slow bolus. Tumors and spleens were analysed using histology, immunohistochemistry, ELISPOT and flow cytometry. Phenotyping of tumor microenvironment was done using flow cytometry and Nanostring analyses. Safety and tolerability were tested in mice, rats and monkeys. Safety-related and PD biomarkers were identified in monkeys using a multiplex MSD technology and validated in whole human blood stimulated with MBS8 *ex-vivo*. **Results:** In several syngeneic mouse tumor models, MBS8 led to complete eradication of established tumors. The complete responders showed tumor rejection upon re-challenge. In these mice, a $CD8^+$-dependent tumor-specific immune memory response was evident. Tumors demonstrated a massive tissue necrosis (> 80%) within 24-48h after the first drug administration and showed massive neutrophil infiltration 6h after dosing. Antigen specific $CD8^+$ T-cells were detected in tumors 24 hours after treatment with increased $CD8^+$:T_{reg} cell ratio and enhanced antigen presentation in tdLN. MBS8 showed both additive and synergistic effect when combined with anti-PD-1 or anti-PD-L1 antibody treatment. Moreover, in tumors being resistant to anti-PD-1 treatment, co-administration of MBS8 reverted sensitivity to anti-PD-1 treatment in a synergistic manner. A panel of cytokines induced by MBS8 upon repeat dose administration in monkeys was identified in plasma as potential biomarkers. Ten of them were further evaluated in whole human blood treated with MBS8 *ex vivo*. Currently, these cytokines are being used in Phase I clinical studies. **Conclusions:** MBS8 showed significant anti-cancer activity in multiple *in vivo* solid tumor models when administered either as monotherapy or in combination with ICIs. MBS8 demonstrated a novel mode of action with neutrophils playing a central role as primary effector cells causing a rapid killing of tumors. Further, adaptive immune response was initiated including generation of tumor specific $CD8^+$ cells and establishment of the immune memory. MBS8 was well tolerated in rodents and cynomolgus monkeys at the dose levels above therapeutic effective doses identified in mice, thus providing a good therapeutic window. Research Sponsor: MonTa Biosciences.

Phase I dose escalation of LAVA-051, a novel bispecific gamma-delta T-cell engager (Gammabody), in relapsed/refractory hematological malignancies. *First Author: Annemiek Broijl, Department of Hematology, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: LAVA-051 is a 27kD humanized bispecific single domain antibody (VHH) that directly engages CD1d and the Vδ2-TCR chain of Vγ9Vδ2-T cells and additionally stabilizes the interaction between CD1d and type 1 NKT cells (Nature Cancer 2020;1:1054-1065) to mediate potent killing of CD1d-expressing tumor cells. By engaging innate-like T cell subsets with inherent antitumor activity, namely Vγ9Vδ2-T and type 1 NKT cells, LAVA-051 has the potential to combine high therapeutic efficacy with limited off-tumor toxicity. CD1d is expressed by tumor cells in the majority of patients with CLL (chronic lymphocytic leukemia) and MM (multiple myeloma), while expression in AML (acute myeloid leukemia) is most pronounced on (myelo)monocytic subtypes. Tolerability studies in non-human primates with cross-reactive surrogate bispecific γδ-T cell engagers showed a good safety profile without signs of CRS (cytokine release syndrome). **Methods:** This is an open label, accelerated titration design, phase 1/2a study in patients with relapsed/ refractory CLL, MM, and AML (NCT04887259). The phase 1 study starts with single-patient cohorts for the first 3 dose levels followed by a 3+3 design. The primary objectives of the study are to investigate the safety and tolerability of LAVA-051 and to determine its recommended Phase 2a dose (RP2D). Secondary objectives of the study include evaluation of PK, PD, immunogenicity, and preliminary antitumor activity. The (flat) starting dose was determined to be 0.45 μg. LAVA-051 is administered by IV infusion over 2 hours twice a week. **Results:** As of Feb 14, 2022, a dose level of 45 μg has been reached with no reports of CRS (ASTCT grading) or dose limiting toxicities (DLTs). Six patients in total have been treated with LAVA-051; 4 patients (2 MM, 2 CLL) were evaluable for DLTs during cycle 1 at dose levels 0.45 μg, 3 μg, 15 μg and 45 μg. Treatment emergent AEs (TEAEs) (CTCAEv5.0) were predominantly of grade 1 and 2 severity (e.g. fever, chills, and headache) . One patient (45 μg) reported a grade 2 infusion related reaction (IRR) that lasted less than 12 hours following the first administration only. Frequency and severity of TEAEs did not increase with escalating doses and all TEAEs were reversible. One patient with CLL developed symptoms consistent with a tumor flare reaction during cycle 1, and continues on cycle 5 of treatment with stable disease at 15 μg. PK data indicate increasing drug exposure in correlation with increasing doses of LAVA-051, and PD data indicate a dose-dependent increase in LAVA-051 receptor occupancy of the Vγ9Vδ2-T cell receptor. Importantly, no consistent or significant changes in measured cytokines have been observed. Updated results will be presented at the congress. **Conclusions:** LAVA-051 has been well tolerated early in dose escalation with on-mechanism pharmacodynamics consistent with Vγ9Vδ2-T cell engagement. Clinical trial information: NCT04887259. Research Sponsor: LAVA Therapeutics N.V.

2578 **Poster Session**

Assessing PD-L1 without a biopsy and through PD-L1 PET imaging with 18F-BMS-986229. *First Author: Michael A. Postow, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Programmed death ligand-1 (PD-L1) is usually determined by immunohistochemistry (IHC). Determining PD-L1 status by whole body, non-invasive PD-L1 PET imaging with 18F-BMS-986229 tracer infusion may be a way to circumvent limitations to PD-L1 IHC such as poor tissue availability; discrepant PD-L1 IHC results among different tumors within the same patient; and inability to measure PD-L1 longitudinally given challenges with repeated biopsies. **Methods:** Within the prospective ADAPT-IT trial (NCT03122522) testing an abbreviated course of nivolumab (nivo) + ipilimumab (ipi) in patients with unresectable stage III or IV melanoma, we investigated PD-L1 PET imaging in a 10-patient expansion cohort at baseline and after 6 weeks of treatment. Maximum standard uptake value (SUV max) and mean of all SUV max for lesions for PD-L1 PET were calculated on a whole patient level for each target/ non target lesion. Standard treatment response was determined by RECIST v1.1 at weeks 6 and 12. PD-L1 IHC was scored using the E1L3N antibody by tumor proportion score (TPS), Immune Cell Score (ICS), and a Combined Positive Score (CPS). Comparisons between PD-L1 PET parameters and response were determined by complete or partial response (CR/PR); stable disease (SD), and progressive disease (PD) at respective imaging timepoints. Absolute changes in PD-L1 SUV mean and max were calculated between scans. The correlation between PD-L1 PET and IHC was estimated using Spearman's coefficient correlation. **Results:** Five patients (50%) had a PR to treatment at week 6; one of these PR became a CR at week 12 and one PR was not assessable at week 12. All RECIST responders at week 6 (n = 5) had baseline PD-L1 SUV mean ≥3.00, and all progressors at week 6 (n = 3) had baseline PD-L1 SUV mean ≤2.60 (Table). A similar trend was observed when assessing response at week 12 and when considering baseline PD-L1 SUV max. Patients had changes in their PD-L1 SUV levels between baseline and week 6. Baseline PD-L1 SUV mean (inclusive of all lesions within a patient) correlated with PD-L1 IHC by TPS, ICS, and CPS (r = 0.64, 0.5, 0.47, respectively). No patients had side effects from 18F-BMS-986229 tracer infusion. **Conclusions:** The signal of PD-L1 positivity by PET imaging with 18F-BMS-986229 at baseline appears associated with early efficacy from nivo + ipi in this small cohort and may offer additional information than PD-L1 IHC. The ability to assess PD-L1 on a whole patient level at multiple timepoints on treatment may have future implications in how best to sequence and combine immunotherapies but further study in larger patient cohorts is needed. Clinical trial information: NCT03122522. Research Sponsor: Bristol Myers-Squibb.

The effects of AVM0703 mobilization of endogenous gamma delta/invariant TCR+ bispecific natural killer T-like cells against solid tumors and blood cancers. *First Author: Theresa Deisher, AVM Biotechnology, LLC, Seattle, WA*

Background: Glucocorticoids (GC) are a common component of blood cancer regimens, typically at doses 40 mg or lower due to concerns of pancreatitis and hepatotoxicity (Walasik-Szemplińska et al. Thyroid Research. 2019;12:13; Ataallah et al. Cureus. 2020;12[7]) and neuropsychiatric effects. AVM Biotechnology has developed a high concentration, high volume, preservative-free, patent pending formulation of dexamethasone (AVM0703), that allows administration of up to 21 mg/kg (1470 mg for 70 kg) over a one-hour IV infusion. Prophylactic use of circadian physiologic hydrocortisone reduces the risk of GC neuropsychiatric side-effects (Warris LT, et al. J. Clin. Oncol. 2016;34:2287; Meijer & de Kloet Endocrinology. 2017;158:448). Acute supra-pharmacologic doses (>6 mg/kg) AVM0703 mobilizes endogenous bispecific gamma delta invariant TCR+ bi-specific Natural Killer T-like cells (AVM-NKT) (PCT/US21/19773), via a non-GC receptor, that rapidly home to diseased organs in preclinical models and are directly related to tumor killing, including Non-Hodgkin's Lymphoma, Melanoma, and Multiple Myeloma. **Methods:** Cancer cell lines and (mouse host) were i) immune-resistant mouse A20 B lymphoma (Balb/c), ii) xenografted human T-ALL CCRF-CEM (NCRnu), iii) mouse B16F10 melanoma (B62DF1), and iv) mouse MOPC315 (Balb/c). Cancer cell lines were inoculated into the flank either as single cell suspensions or encased in Matrigel. When tumor volume reached between 100-500mm^3 well-established tumors, mice were orally gavaged with a human equivalent dose (HED) of 15-18 mg/kg AVM0703 as monotherapy, or as a preconditioning prior to adoptive cell transfer (ACT), or in combination with chemotherapy. Responses were determined by tumor volume measurements, tumor immunohistochemistry or flow cytometry detection of residual cancer cells. **Results:** Immunohistochemistry analysis of tumors from AVM0703 treated mice demonstrated pseudoprogression similar to checkpoint inhibitors: *i.e.* tumors were measurable however in some cases all cancer cells had been eradicated. Therefore, subsequent tumor monitoring at end point was done by flow cytometry to quantify the total number of live cancer cells more accurately than tumor measurements by calipers or immunohistochemistry, due to pseudoprogression and limitations of examining only a few sections from each tumor. **Conclusions:** AVM0703 led to: i) complete response (CR) in 27% of immune-resistant mouse A20 tumors as monotherapy and CR in 60% when combined with 2 doses of cyclophosphamide/fludarabine (CyFlu); ii) tumor eradication and long-term memory against xenografted human T-ALL; iii) enhancement of ACT equivalent to CyFlu preconditioning in mouse melanoma; and iv) preliminary 95% CR against mouse multiple myeloma. Research Sponsor: AVM Biotechnology, U.S. National Institutes of Health.

Radiotherapy-immunotherapy related pneumonitis prediction from pretreatment CT using a deep graph-based integrative model. *First Author: Linlin Yang, Shandong Cancer Hospital and Institute, Jinan, China*

Background: Early prediction of symptomatic pneumonitis (grade ≥ 2) could potentially assist the comprehensive management for non-small cell lung cancer (NSCLC) patients who received radiotherapy combined with immunotherapy. A more accurate integrative model for symptomatic pneumonia prediction using CT images is needed. **Methods:** This retrospective study contains 243 NSCLC patients (62 symptomatic pneumonitis) who underwent radiotherapy combined with immunotherapy between January 2015 and June 2021. Five-fold cross-validation was performed for training and testing. There were 195 cases in the training set (50 symptomatic pneumonitis) and 48 cases in the validation set (12 symptomatic pneumonitis) in each fold. The deep graph integrative model (DG) was composed of two pretrained 3D UNet encoders to extract deep features from tumor and lung volumes of pre-treatment CT images, respectively, and a graph attention layer (GAT) for integration and classification. The encoders were fine-tuned using manually segmented tumor and lung CT volumetric patches from the training set. Evaluation measures include area under ROC curve (auc), sensitivity (sen), and specificity (spe). **Results:** Our new DG achieved auc, sen, and spe of 0.823, 0.767, and 0.810, which outperformed conventional CT radiomics model (auc 0.743, sen 0.620, spe 0.752), 3D UNet based deep radiomics model (auc 0.761, sen 0.746, spe 0.737), and our model without GAT (auc 0.796, sen 0.762, spe 0.782). The improvement was statistically significant ($p < 0.001$). **Conclusions:** Our DG model improved symptomatic pneumonia prediction using CT images, which can be used as a tool to effectively improve the safety and personalized treatment of combined radiotherapy with immunotherapy for NSCLC patients. Research Sponsor: National Natural Science Foundation of China.

Outcomes of patients (pts) treated with novel immunotherapy (IT) agents in phase 1 clinical trials (Ph1-CT) at early lines for advanced disease. *First Author: Juan Jose Soto Castillo, Medical Oncology Department-Phase 1 Functional Unit, Catalan Institute of Oncology (ICO), L'Hospitalet De Llobregat, Barcelona, Spain*

Background: The overall survival (OS) benefit observed with immune checkpoint inhibitors led to their approval in many tumor types. Given the large number of IT compounds in early clinical development, many pts are offered IT within Ph1-CT even before having exhausted standard of care (SOC) therapies. We assessed outcomes of pts receiving novel IT treatments within Ph1-CT at the Phase 1 Unit of Catalan Institute of Oncology (ICO), Barcelona, Spain. **Methods:** We retrospectively reviewed a correlative series of pts with advanced/metastatic solid tumors treated with IT within Ph1-CT at ICO from January 2018 to June 2021. Primary endpoint was to assess clinical outcomes measured by median progression-free survival (mPFS) and median OS (mOS) according to number of prior lines (PL) for recurrent/metastatic disease, grade 3-4 toxicity (G3-4 Tox) and age. Data on prior IT (yes vs no) and availability of alternative SOC were evaluated. Overall response rate (ORR) was assessed according to RECIST 1.1. Clinical benefit rate (CBR) was defined as complete/partial response + stable disease for ≥6 months (m). PFS/OS were calculated by Kaplan-Meier method. Log-rank test was used for comparisons. Median PFS of alternative SOC according to historical data was recorded by tumor type and line of treatment. **Results:** A total of 104 pts received IT within Ph1-CT: IT monotherapy = 39 (37.5%), IT combinations = 65 (62.5%) (IT+IT = 59 [90.8%], IT+targeted therapy = 6 [9.2%]). Median age was 54 y (42-77), 62.5% were men and all had ECOG 0-1. Four most frequent cancers were urothelial (19.2%), colorectal (15.3%), head & neck (12.5%) and glioblastoma (11.5%). Number of PL: 0 = 20 (19.2%) pts, 1 = 37 (35.6%) pts, ≥2 = 47 (45.2%) pts. Nine (8.6%) pts had received prior IT. G3-4 Tox rate for the overall population was 19.2% and for pts who had received prior IT was 33%. ORR was 11.5%; CBR was 24%. Overall mPFS and mOS were 2.7m and 8.6m, respectively. Pts with less PL had greater mPFS and mOS ($p < 0.05$) (Table). Pts with available alternative SOC had lower mPFS but similar mOS compared to historical SOC (2.6m vs 4.8m, 11.4m vs 11.8m, respectively). G3-4 Tox (yes vs no) and age (< 70 vs ≥70) did not significantly impact on mOS or mPFS ($p = 0.18$ and $p = 0.83$, respectively). At end of Ph1-CT treatment, 47 (45.2%) pts worsened their ECOG status, 15 (14.4%) pts were enrolled in a subsequent trial and 22 (21.1%) pts received SOC. **Conclusions:** In our cohort of pts treated with novel IT within Ph1-CT, overall clinical outcomes were modest in terms of mPFS, mOS, and CBR. However, pts with less pre-treated tumors seem to achieve higher survival benefit from early treatment with IT within Ph1-CT, although this benefit remains unclear in pts with alternative SOC. Research Sponsor: None.

Pts	PFS(m)	OS(m)
≤1 PL vs ≥2 PL	3.8 vs 2.5, **p 0.003**	14.1 vs 8.7, **p 0.002**
≤2 PL vs > 2 PL	3.6 vs 1.3, **p 0.002**	11.5 vs 1.7, **p 0.004**
Pts in IT Ph1-CT (with vs without available SOC)	2.6 vs 2.1, **p 0.048**	11.4 vs 4, **p 0.0083**

2582 **Poster Session**

A phase 1 first-in-human dose finding/randomized phase 2 study of IMM60 and pembrolizumab (PEM) in advanced melanoma and non–small cell lung cancer (NSCLC; IMP-MEL). *First Author: Nicholas Coupe, Oxford University Hospital, Oxford, United Kingdom*

Background: Invariant natural killer T-cells (iNKTs) share features of innate cells (NK-like) and T-cells (can prime and boost an adaptive immune response). The importance of this relatively rare lymphocyte subset has generated increased interest due to its dual ability to have a direct cytotoxic effect on CD1d expressing tumors and also its ability to induce long-lasting antitumor CD8 T cell responses mediated by cross priming and licensing of dendritic cells. Various clinical approaches involving the use of allogenic iNKT cells (both untransduced and CARs) are in development and here we describe initial clinical studies with IMM60, a synthetically derived agonist of iNKT cells which is formulated in a liposome(PORT-2). In preclinical studies, IMM-60 treatment results in maturation of DCs and B cells and a potent stimulation of iNKT cell-derived IFN-g. In efficacy studies, IMM60 demonstrated monotherapy activity in PD-1 resistant models, (eg., B16-F10), up-regulation of PD-L1 expression on cancer cells as a consequence of its priming effect, and was able to overcome resistance to PD-1 antibody therapy. **Methods:** IMP-MEL is an open-label first-in-man phase 1/2 study, currently enrolling adult subjects with advanced NSCLC and melanoma. IMM60 containing liposomes were administered IV Q3W at 3 escalating dose levels for 6 doses alone or with PEM 200mg Q3W. The study seeks to assess the safety and efficacy of IMM-60 alone and in combination with PEM. **Results:** 5 subjects have been enrolled in the monotherapy cohort having a median of 3 prior therapies (min 2, max 5). Median age was 64.5 years. No treatment related adverse events have been reported nor any objective disease responses in the evaluable monotherapy subjects (n=3) to date. **Conclusions:** IMM-60 is well tolerated when administered IV as monotherapy at the doses tested. The liposomal formulation leads to a favorable preliminary safety profile. Full results of the phase 1 will be reported at the meeting with analysis of circulating cytokines and flow cytometric analysis. The trial plans to transition to phase 2 testing IMM60-alone vs PEM monotherapy vs the combination of IMM60 with PEM. Clinical trial information: 80472712. Research Sponsor: iOX Therapeutics, University of Oxford.

A phase 1 study of the novel immunotoxin MT-5111 in patients with HER2+ tumors: Interim results. *First Author: Brian Andrew Van Tine, Washington University in Saint Louis, St. Louis, MO*

Background: MT-5111 is a 55kD engineered toxin body (ETB) targeting HER2 in solid tumors that binds to an epitope distinct from trastuzumab and pertuzumab, offering potential combination strategies with other HER2-targeting agents. MT-5111 may demonstrate efficacy in patients (pts) resistant to other HER2-targeting agents, as its mechanism of action induces direct cell kill via enzymatic and permanent ribosome destruction. **Methods:** This is a phase 1 study in adults with advanced HER2+ solid tumors. The dose-escalation portion (Part A) enrolls pts into sequential dose cohorts, followed by Part B expansion cohorts for HER2+ breast cancer (BC), gastroesophageal adenocarcinoma (GEA), and any other HER2+ cancer (CA). MT-5111 is dosed weekly IV over 30 min in each 21-day treatment (tx) cycle until disease progression, unacceptable toxicity, death or withdrawn consent. **Results:** As of Jan 2022, 27 pts had enrolled in Part A cohorts (0.5 to 10 μg/kg/dose) with completed DLT assessments: 9 (33%) pts were male and 18 (67%) female, median age 67 and a median of 4 prior systemic and 2 prior HER2-targeting tx. Common tissue types were BC (9/30%), biliary CA (6/22%), GEA (4/15%). The following safety data reflect 33 treated pts to date including ongoing 13 μg/kg/dose Part A and 10 μg/kg/dose BC expansion cohorts. No Grade (G) 4/5 tx-emergent adverse events (AEs) or DLTs occurred. Tx-related AEs occurred in 17 (52%) pts, most commonly G1/2 fatigue (8/24%). 3 pts had G1 troponin elevations without clinical signs or symptoms of cardiac distress: 1 at 6.75 μg/kg/dose, 2 at 10 μg/kg/dose. 2 pts (3 and 4.5 μg/kg/dose) had reversible G2 and G1, respectively, infusion-related reactions (IRR)s. A comparison of cytokines from baseline to on-treatment timepoints reveals no evidence of significant changes, even in pts with IRR. Best response per RECIST thus far was stable disease (SD) in 7 pts or non-CR/non-PD in 2 pts: 1 pt had SD for 12 weeks (wks) (4.5 μg/kg, pancreatic CA); 1 pt (1 μg/kg/dose, BC) had non-CR/non-PD for 30 wks; 1 pt (10 μg/kg/dose, GEA) has ongoing SD for 18 wks. AUC_{last} data match PK simulations in non-human primate studies. C_{max} at 10 μg/kg/dose is ≥5 times the IC_{50} values of high HER2 expressing gastric CA and BC cell lines while approaching the IC_{50} of a moderately HER2 expressing liver CA cell line. **Conclusions:** MT-5111 is well tolerated to-date with no clinically significant immuno/cardiotoxicity. Dose escalation is ongoing at a dose of 13μg/kg, expected to be required for efficacious exposure. Clinical trial information: NCT04029922. Research Sponsor: Molecular Templates, Inc.

Factors associated with acute kidney injury among patients with cancer treated with immune checkpoint inhibitor therapy: A population-based study. *First Author: Phillip S. Blanchette, ICES, London Health Sciences Centre, Western University, London, ON, Canada*

Background: Cancer immune checkpoint inhibitor (ICI) therapy may be associated with kidney immune-related adverse events (IRAEs) and other causes of acute kidney injury (AKI). In clinical trials, the frequency of AKI events was uncommon, however, further real-world study is warranted. **Methods:** We evaluated the proportion of AKI events among patients with advanced cancer (bladder, head and neck, lung, kidney and malignant melanoma) treated with ICI therapy in Ontario, Canada from 2012 - 2018. AKI was defined by a rise in the concentration of serum creatinine as per Kidney Disease: Improving Global Outcomes (KDIGO) criteria. A multivariable regression model was used to identify predictors of AKI while accounting for the competing risk of death. **Results:** A total of 4,380 patients received ICI therapy. In follow-up, 1,283 (29%) had recorded AKI event (any stage AKI) and 289 (7%) had a severe AKI event (≥ stage 2). Median time to AKI was 6 months (Interquartile Range 2-16 months) and ≤ 1 % of patients received dialysis therapy. Within 30 days of any observed AKI event, 853 (58%) discontinued ICI therapy, 372 (29%) were hospitalized and 266 (21%) died. Mortality was significantly higher among patients who experiencing a severe AKI event (≥ stage 2) as compared to patients with a less severe AKI event (stage 1) or no observed AKI event. Among patients alive at 30 days following an AKI event, 14% received an outpatient corticosteroid or immunosuppressive therapy prescription, 7% had a visit with a nephrologist. Characteristics associated with a higher risk of AKI included female sex, bladder or kidney cancer (reference malignant melanoma), history of hypertension or diabetes, higher Charlson comorbidity score, a baseline estimated glomerular filtration rate less than 30 mL/min/1.73 m^2, or outpatient prescription for either a proton pump inhibitor or non-steroidal anti-inflammatory drug. Among patients with an AKI event and treatment discontinuation, re-challenge of ICI therapy was infrequent (16%) with a significant risk of a recurrent AKI event (57%). **Conclusions:** In a population-based study among patients with cancer receiving ICI therapy, the rate of AKI was common (29%) but severe AKI was less frequent (7%). Rates of ICI discontinuation, hospitalization and death are substantial following an AKI event. Kidney function should be monitored carefully among patients undergoing ICI therapy who have common risk factors for developing renal disease. Nephrology consultation may be optimized among patients who develop a severe AKI event, especially among individuals who are considered for ICI therapy re-challenge. Research Sponsor: Medical Oncology Research Fund (MORF) London Regional Cancer Program.

Systematic review and meta-analysis evaluating the impact of antibiotic use on the clinical outcomes of patients with cancer treated with immune checkpoint inhibitors. *First Author: Gerard Zalcman, Department of Thoracic Oncology, CIC INSERM 1425, Université de Paris, Hôpital Bichat, Paris, France*

Background: In recent years, the gut microbiome has increasingly emerged as influencing the response to immune checkpoint inhibitors (ICIs) and antibiotic (ABX) exposure has repeatedly been shown to impair clinical outcomes of patients suffering from different cancer types and treated with ICIs. We published in 2020 a meta-analysis confirming that ABX use hampered survival of non-small cell lung cancer (NSCLC) patients treated with ICIs. The present study aims to determine whether ABX use also reduces survival of patients receiving ICIs for other cancers. **Methods:** PubMed and major oncology conferences' proceedings were systematically searched to identify studies assessing the impact of ABX on the clinical outcomes of cancer patients treated with ICIs. Studies were included when reporting data on Overall Survival (OS), Progression-Free Survival (PFS), Overall Response Rate (ORR) and Progressive Disease Rate (PD), according to ABX exposure. Pooled Hazard Ratios (HRs) for OS and PFS and Odds Ratios (ORs) for ORR and PD were calculated, as well as HRs for OS and PFS according to different cancer types and different ABX exposure time windows (TWs). **Results:** Overall, 94 independent cohorts were included, representing 26,174 patients suffering from various types of cancer. The pooled HRs for PFS (61 cohorts, 13,224 patients) and OS (88 cohorts, 25,480 patients) were 1.47 [95% Confidence Interval (CI) 1.31-1.66] and 1.66 [95% CI 1.50-1.83], respectively, confirming a significant harmful impact of ABX on patient' survival, observed across all cancer types (Table). The analyses of OS and PFS based on ABX exposure TWs suggested a stronger deleterious effect of ABX when taken around ICI treatment initiation. The response to treatment among ABX users was also impaired: the pooled ORs for ORR (30 cohorts, 4,590 patients) and PD (33 cohorts, 4,972 patients) were 0.55 [95% CI 0.39-0.77] and 1.97 [95% CI 1.48-2.64], respectively. **Conclusions:** ABX were shown to impair the clinical outcomes of cancer patients treated with ICIs, regardless of cancer type. Research Sponsor: Da Volterra.

Impact of ABX use on the survival of cancer patients treated with ICIs.

Cancer Type	Number of Patients for OS (ABX Users)	Pooled HR OS [95% CI]	Number of Patients for PFS (ABX Users)	Pooled HR PFS [95% CI]
All Cancer Types	25,480 (6,994)	1.66 [1.50-1.83]	13,224 (4,142)	1.47 [1.31-1.66]
NSCLC	12,674 (2,834)	1.62 [1.38-1.90]	5,463 (1,368)	1.49 [1.26-1.76]
Urothelial Carcinoma	3,371 (1,545)	1.60 [1.09-2.34]	3,232 (1,499)	1.26 [0.84-1.90]
Melanoma	2,812 (339)	1.81 [1.27-2.59]	708 (111)	1.72 [0.95-3.10]
Renal Cell Carcinoma	1,029 (212)	1.84 [1.30-2.62]	529 (127)	2.04 [1.40-2.98]
Other Cancers*	2,285 (766)	1.74 [1.26-2.39]	1,983 (684)	1.55 [0.87-2.75]

Outcomes of responders to PD-1/PD-L1 inhibitors who discontinue therapy after sustained disease control. *First Author: Harsh Sharma, University of New Mexico Hospital, Albuquerque, NM*

Background: PD-1/PD-L1 immune checkpoint inhibitors (ICIs) are widely used in the treatment of metastatic malignancies. Judiciously balancing disease control (DC) against development of immune-related adverse events (irAE) remains a crucial aspect of treatment. The effect of treatment discontinuation after sustained disease control (SDC) is unknown. The purpose of this analysis was to evaluate outcomes of responders to ICI who discontinue treatment after a minimum of 12 months (SDC). **Methods:** We retrospectively reviewed the database of the University of New Mexico Comprehensive Cancer Center between 2014 and 2021 and identified patients who had received ICI. Patients with metastatic solid tumors who had stopped ICI therapy after achieving SDC [stable disease, partial response, complete response (SD,PR,CR)] were selected and outcomes reviewed from their electronic health records. **Results:** We identified 204 patients who were treated with ICI for various solid cancers. Forty-four patients (21.6%) met the criteria, of whom 35 with follow-up data were included in the final analysis; including 11 melanoma, 5 non-small cell lung, 4 head & neck, 8 renal, 4 urothelial, 1 anal, 1 Merkel cell carcinoma, and 1 liposarcoma. Patients were divided into two groups: those who stopped ICI due to an irAE [irAE group, n=14, median treatment time (MTT), 16.6 mo] and those who stopped due to other reasons (eg completion of 2 years of therapy, n=20, non-cancer related surgery, n=1) (non-irAE group, n=21, MTT, 23.7 mo). Among the irAE group, the most common irAE included pneumonitis, rash, transaminitis, and fatigue. As of data cutoff date, 10 of 14 (71%) patients continued to show SDC. Only 4 of 14 (28.6%) patients in this group experienced progression of disease (PD), one of whom was re-challenged with nivolumab and achieved DC (median follow-up of 19.2 mo after last dose of treatment, range 3-50.2 mo). Among the non-irAE group, 13 of 21 (62%) continued to have SDC. Eight of 21 (38%) experienced PD after stopping treatment, 7 of whom received ICI rechallenge, with 2 of 7 achieving DC (median follow-up of 22.2 mo, range 3.6-54.8 mo). At a median follow-up of 21.3 mo from stopping ICI therapy (range, 3-54.8 mo), 10 patients (71%) from the irAE group and 13 (61.9%) from the non-irAE group are in DC and have not experienced PD. **Conclusions:** We demonstrate that 23 (66%) patients experienced SDC, regardless of cancer type or development of irAE. After including patients who were re-challenged with ICI due to PD, 26 (74%) remain in DC. Future prospective malignancy-specific trials such as NCT04637594 are warranted to evaluate optimal treatment duration. Research Sponsor: None.

Outcomes of ICI responders who discontinued therapy after ≥ 12 months.

Response to therapy	Non-irAE Group, n=21 (60%)	irAE Group, n=14 (40%)	Total, N=35 (100%)
Disease control	13 (61.9%)	10 (71.4%)	23 (65.7%)
PD	8	4	12
Rechallenge after PD	7	1	8
Disease control after rechallenge	2	1	3

Efficacy and safety of dostarlimab in patients (pts) with mismatch repair deficient (dMMR) solid tumors: Analysis of 2 cohorts in the GARNET study. *First Author: Thierry Andre, Sorbonne University, Saint-Antoine Hospital, AP-HP, Paris, France*

Background: Dostarlimab is a programmed death 1 (PD-1) inhibitor approved in the US as a monotherapy in pts with dMMR solid tumors that have progressed on or after prior treatment, with no satisfactory alternative treatment options; or dMMR advanced/recurrent (AR) endometrial cancer (EC) that has progressed on or after treatment with a platinum-based chemo; and in the EU as a monotherapy in pts with dMMR/microsatellite instabilityhigh (MSI-H) AR EC that has progressed on or after treatment with a platinum-based chemo. Here we report on efficacy and safety in 2 expansion cohorts that enrolled pts with dMMR solid tumors. **Methods**: GARNET is a multicenter, open-label, single-arm phase 1 study. Cohort A1 enrolled pts with dMMR/MSI-H AR EC; cohort F enrolled pts with dMMR/MSI-H/POLε-mut non-EC solid tumors. Pts received 500 mg of IV dostarlimab Q3W for 4 cycles, then 1000 mg Q6W until PD, discontinuation, or withdrawal. Primary endpoints were ORR and DOR by BICR per RECIST v1.1. Biomarker status was based on local assessment. **Results**: For this third interim analysis, 153 pts with dMMR/MSI-H EC and 210 pts with dMMR/MSI-H/POLε-mut non-EC solid tumors (56% colorectal cancer, 11% gastric) were enrolled and treated. Efficacy analysis was performed for 143 dMMR/MSI-H EC and 204 dMMR/MSI-H/POLε-mut non-EC pts who had measurable disease at baseline and ≥6 mo of follow-up. ORRs were 45.5% (dMMR/MSI-H EC) and 43.1% (dMMR/POLε-mut non-EC solid tumors; Table). Probability of PFS at 6, 9, and 12 mo was 49.5%, 48.0%, and 46.4% in dMMR/MSI-H EC and 51.8%, 48.1%, and 46.4% in dMMR/MSI-H/POLε-mut non-EC. Median (m) DOR and mOS were not reached for either cohort. A total of 13 pts (8.5%) with dMMR/MSI-H EC and 12 pts (5.7%) with dMMR/MSI-H/POLε-mut non-EC solid tumors discontinued owing to a treatment-related adverse event (TRAE). TRAEs occurring in ≥12% of pts were diarrhea, asthenia, fatigue, nausea, and pruritis (dMMR/MSI-H EC) and diarrhea, asthenia, and pruritus (dMMR/MSI-H/POLε-mut non-EC solid tumors). 2 deaths (1 hepatic ischemia, 1 suicide) were attributed by investigators to dostarlimab in pts with non-EC solid tumors. **Conclusions**: Dostarlimab demonstrated durable antitumor activity across 16 tumor types in pts with dMMR solid tumors, confirming efficacy in a larger sample size with extended follow-up. The safety profile was acceptable, with manageable toxicities. Clinical trial information: NCT02715284. Research Sponsor: GlaxoSmithKline.

Extended duration of anti-PD-1 therapy, using reduced frequency dosing, in patients with advanced melanoma and Merkel cell carcinoma. *First Author: Lisa May Ling Tachiki, University of Washington and Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Optimal duration of treatment (DoT) with immune checkpoint inhibitors (ICI) in patients with metastatic melanoma (Mel) and Merkel cell carcinoma (MCC) is unclear. ICI discontinuation in Mel patients, especially those without CR, may be associated with a higher rate of progression over time, as compared to ICI continuation. Thus, extending DoT could improve outcomes. However, indefinite continuation at standard frequency doses (SFD) is not logistically or financially viable. Based on data from phase I studies suggesting sustained PD-1 receptor occupancy beyond 3 months after a single dose of nivolumab, we employed reduced frequency dosing (RFD) of anti-PD-1 antibodies every 2-3 months, to extend ICI duration beyond 2 years. **Methods:** This retrospective study analyzes patients in our skin cancer clinic with metastatic Mel and MCC who experienced initial clinical benefit with anti-PD-1 administered at SFD and then transitioned to RFD. We analyzed safety and efficacy endpoints including progression free survival (PFS) and rates of immune-related adverse events (irAE) with RFD. We also compared the pharmaceutical costs and patient-centered costs between 2 years of treatment at SFD versus extended DoT at RFD. **Results:** From 2014 – 2021, 23 patients with either metastatic Mel (N = 18) or MCC (N = 5) received anti-PD-1 therapy at RFD. Median DoT at SFD in this cohort was 1.1 years (range 0.2 – 2.2) with best objective tumor responses of CR (N =6), PR (N = 11), SD (N = 6). Median DoT at RFD was 1.2 years (range 0.2 – 3.5). The median follow-up for the entire cohort is 3.7 years (range 0.7 – 6.3) after ICI initiation. The 3-year PFS in Mel patients was 100% in those with CR (3/3), 89% with PR (8/9), and 50% with SD (3/6). The 3-year PFS in MCC was 100% in all 5 patients, including patients with CR (3/3) and with PR (2/2). Any-grade irAEs occurred in 43% of patients by 3 years on RFD, and grade 3/4 irAEs presented in 15%. Among the subset of 15 patients with DoT >2 years (median 3.4 yr, range 2.0 – 5.0), total savings amounted to $1.1 million in drugs costs and 384 hours of clinic and travel time despite the increased DoT, as compared to the calculated values for 2-year DoT at SFD. **Conclusions:** RFD may provide an alternative approach to extending DoT in patients receiving ICI without additional logistical and financial burden, while preserving outcomes. Efficacy and safety data suggest sustained biologic activity of ICI with RFD administration. PK/PD analyses on patient samples are ongoing to further characterize the RFD approach. The RFD approach could be utilized to expand ICI access to communities with limited healthcare resources, thereby impacting cancer outcomes at a global scale. The effect of circadian rhythm on clinical outcome in patients receiving pembrolizumab in the INSPIRE pan-cancer trial. *First Author: Helena Jacoba Janse van Rensburg, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: The molecular networks comprising circadian rhythm are expressed in immune cells where they affect immune-related processes. Within the emerging field of chrono-immunotherapy, it has been proposed that immunotherapies should be applied at certain times of day to optimize efficacy. Two recent reports have suggested that earlier administration of immune checkpoint inhibitors (ICIs) in non-small cell lung cancer and melanoma may offer improved survival outcomes (Karaboué et al. ASCO 2021, PMID 34780711). Whether this observation applies to other tumour types, or occurs in geographic regions with differing seasonality, is not known. **Methods:** We retrospectively analyzed the time of administration data from the INSPIRE single-centre, phase II, multi-cohort study of pembrolizumab (200 mg IV over 1 hour, q3w to maximum 35 cycles) in patients with advanced solid tumours (NCT02644369). Kaplan-Meier methods were used to estimate PFS and OS. Cox proportional hazards models were fitted to assess the association between time of administration and PFS or OS, adjusting for cohort. Fisher's exact test was used to test for association with immune-related adverse events (irAEs). **Results:** A total of 106 patients (19 head and neck squamous cell, 22 triple negative breast, 21 epithelial ovarian, 12 melanoma, 32 other solid tumours) were accrued between March 21, 2016, and May 9, 2018. Median time of follow-up was 11.5 months. Start of infusion times were obtained for 806 total doses. The median time of administration was 15h06 for the first dose and 15h11 for all doses (range 09h19 – 18h34). No differences in PFS or OS were observed between patients who received their first dose before or after noon, or before or after 15h06. Furthermore, no differences in PFS or OS were observed between patients who received ≥ 50% of their doses before or after noon, or before or after 15h11. There was also no difference in PFS or OS between patients who did or did not have a significant proportion of doses (≥ 20%) after 16h30 ("evening" in previous reports). There were no differences in the frequency of grade ≥ 2 irAEs amongst the various groups. No differences in efficacy were found when individual cohorts were evaluated separately. Finally, no differences in PFS or OS were observed when participants were grouped by season of first dose. **Conclusions:** Despite previous reports of improved survival with earlier ICI dosing, we did not identify any association of time of pembrolizumab administration with clinical outcomes. Our analysis is limited by small sample size and patient heterogeneity which may hinder identification of smaller associations. It is also unclear whether lower response rates in a pan-cancer population (relative to prior reports in lung cancer and melanoma) might impact correlation analysis. Further studies will be necessary to interrogate this phenomenon and ensure that ICI are optimally applied. Research Sponsor: Princess Margaret Cancer Foundation, Pharmaceutical/Biotech Company.

A phase II study of pembrolizumab for HPV-associated papilloma patients with laryngeal, tracheal, and/or pulmonary involvement. *First Author: Sara I. Pai, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Recurrent respiratory papillomatosis (RRP) is caused by human papillomavirus (HPV) types 6 & 11. RRP proliferates in the squamous epithelium lining the respiratory tract impacting breathing, swallowing, and voice and carries a 3-5% risk of malignant transformation. Given the multi-focality of the disease and tolerized host immune response against HPV, in part through upregulation of the PD1:PDL1 axis, the safety and efficacy of systemic pembrolizumab (pembro) as a novel treatment for this benign tumor patient (pt) population was evaluated in a phase II clinical trial. **Methods:** RRP pts > 12 years of age were treated with pembro 200mg every 3 weeks. Primary endpoints were best overall response (ORR) (measured by endoscopic lesional burden) and safety. Greater than 5 pts with disease response out of 21 (assuming > 1 of first n = 11 with disease in response) provided 86% power to distinguish between a 15% and a 38% ORR (one-sided 8% binomial test). HPV-specific CD8+ T cell frequency and functional states and biomarkers of response and immune resistance are being evaluated in serial tissue and liquid biopsies (up to 8 biopsies/patient over the 24 months of treatment). **Results:** The Simon two-stage, stage 1 criteria was met. A total of 21 patients were enrolled and all are now off treatment. Median age (range) was 45 (19-68), 57% (12/21) were male and 67% (14/21) were white. 48% (10/21) had Juvenile-onset (Jo)-RRP, 57% (12/21) had pulmonary RRP involvement, and 19% (4/21) had SCC derived from their RRP. 62% (13/21) completed 24 months of treatment. Reasons for discontinuation included disease progression (14%, 3/21), treatment related adverse event (TRAEs) (14%, 3/21), and study withdrawal (10%, 2/21). A partial response (≥25% reduction in endoscopic tumor burden score) was observed in 57% (12/21) (95% CI: 34%-78.2%) of pts (7 of 10 with Jo-RRP and 5 of 11 with Adult-onset (Ao)-RRP disease responded). Stable disease was observed in 33% (7/21). No complete responses were observed. Fatigue was the most frequent TRAEs; Grade 3 TRAEs included uveitis and hypophysitis, both of which were reversible upon pembro discontinuation and steroid use. At a median follow-up: 25.6 (6.2-38.1 months), the mean number of surgical interventions was reduced by 7 surgeries/year (p = 0.004) in pts treated on the trial for > 12 months, and, upon treatment completion, durable clinical benefit was observed with no additional treatment needed for the duration of the clinical trial follow-up for some pts. **Conclusions:** Pembro reduces the need for routine surgical interventions based on the durable response rates being achieved. Further study of pembro +/- other agents is warranted to achieve and sustain complete responses in this population. Clinical trial information: NCT02632344. Research Sponsor: Merck, Other Government Agency.

2591 **Poster Session**

Efficacy of immune checkpoint inhibitors in patients with non–small cell lung cancer harboring *ERBB2* exon 20 insertions and non-*ERBB2* exon 20 insertions. *First Author: Hai-Yan Tu, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, School of Medicine, South China University of Technology, Guangzhou, China*

Background: Immune checkpoint inhibitors (ICIs) have suboptimal efficacy in non-small cell lung cancer (NSCLC) patients with *ERBB2* mutations, including *ERBB2* exon 20 insertions. This study aims to investigate the efficacy of ICIs and immune characteristics in NSCLC patients harboring *ERBB2* ex20ins and non-ex20ins mutations. **Methods:** Advanced NSCLC patients harboring *ERBB2* mutations were recruited from January 2016 to December 2020. Pre-ICI tumor tissue samples were collected and performed with targeted next-generation sequencing. Patients received ICIs were followed up every 3 months until November 2021. Genomic features were compared between patients with *ERBB2* ex20ins and non-ex20ins mutations. Progression-free survival (PFS), overall survival (OS), and tumor immune microenvironment (TIME) features characterized by multiplex immunohistochemistry (IHC) were further analyzed in patients receiving ICIs. Two-sample T-tests were performed to compare means; Cox models were fitted to estimate hazard ratios (HRs) and 95% confidence intervals (CIs). Two external datasets of *ERBB2*-mutant NSCLC patients, including TCGA (n = 23) and META (n = 33), were used for validation. **Results:** A total of 117 eligible patients were enrolled (median age: 59 [range: 24-82], males 57.3%, stage IV 68.4%, adenocarcinoma 93.2%), of whom 37 received subsequent ICI treatment. similar PD-L1 tumor proportion score (mean: 8.1% *vs.* 13.2%, $p = 0.25$) and significantly lower mutation number (mean: 3.0 *vs.* 6.2 muts/person, $p < 0.01$) were detected in patients with *ERBB2* ex20ins, compared to patients with *ERBB2* mutations other than ex20ins. Similarly, in the TCGA cohort, tumor mutation burden was significantly lower in *ERBB2* ex20ins patients (mean: 2.2 *vs.* 10.3 muts/Mb, $p = 0.02$). Of 37 patients receiving ICIs, *ERBB2* non-ex20ins patients displayed superior PFS (mPFS: 13.5 *vs.* 4.4 months, HR: 0.31, 95% CI: 0.14-0.71), relatively long OS (mOS: 27.5 *vs.* 8.1 months, HR: 0.47, 95% CI: 0.20-1.14), and a relatively high rate of durable clinical benefit (64.3% *vs.* 34.8%, $p = 0.10$) than ex20ins patients, consistent with what was observed in the META cohort (PFS, mPFS: 13.2 *vs.* 2.5 months, HR: 0.20, 95% CI: 0.06-0.68; OS, mOS: 23.3 *vs.* 8.0 months, HR: 0.32, 95% CI: 0.11-0.90). Moreover, the CD4+ T cell density appeared to be lower in the tumor stroma of *ERBB2* ex20ins patients than that of non-ex20ins patients (300.5 *vs.* 1288.0 /mm^2, $p = 0.08$), even though the general TIME features of ex20ins patients were similar to those of non-ex20ins patients. **Conclusions:** NSCLC patients carrying *ERBB2* ex20ins demonstrated worse clinical outcome under ICI treatment, similar PD-L1 expression and lower mutation number when compared to those with non-ex20ins mutations. Genomic and TIME characteristics should be further investigated to elucidate the efficacy of ICIs in lung cancer patients carrying *ERBB2* mutations. Research Sponsor: Guangdong Provincial People's Hospital Young Talent Project (Grant No. KY012021191 to Yang-Si Li).

Updated efficacy and safety results from the phase 2 study of serplulimab, a novel anti-PD-1 antibody, in patients with previously treated unresectable or metastatic microsatellite instability-high or mismatch repair-deficient solid tumors. *First Author: Jin Li, Shanghai East Hospital, Shanghai, China*

Background: Serplulimab is a novel humanized monoclonal antibody against PD-1. At ASCO 2021, we have presented the results from the phase 2 serplulimab study (NCT03941574) in patients with unresectable/metastatic microsatellite instability-high or mismatch repair-deficient (MSI-H/dMMR) solid tumors who have progressed on or been intolerant to standard therapies with a median follow-up of 7.7 months. Here, we report the updated efficacy and safety results together with the results from sensitivity analysis after another 6-month follow-up. **Methods:** In this single-arm, open-label, multicenter, phase 2 study, patients aged 18–75 years with histologically or cytologically confirmed unresectable or metastatic MSI-H/dMMR solid tumors were enrolled to receive 3 mg/kg of intravenous serplulimab every two weeks for up to two years. The primary endpoint was objective response rate (ORR) assessed by an independent radiological review committee (IRRC) per RECIST v1.1. Secondary endpoints included ORR assessed by the investigators, duration of response (DoR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** As of July 10, 2021, 108 patients had received at least one dose of study treatment and were included in the safety set (SS). Among them, 68 patients with confirmed MSI-H (by local sites or central lab) were included in the main efficacy analysis population (MEAP); 58 patients with confirmed MSI-H (by central lab) and had no major protocol deviations were included in the sensitivity analysis population (SAP). The median follow-up duration was 13.5 months in the MEAP and 14.0 months in the SAP. IRRC-assessed ORR per RECIST v1.1 was 39.7% (95% CI 28.0–52.3; 3 complete response [CR]) in the MEAP and 43.1% (95% CI 30.2–56.8; 2 CR) in the SAP. Investigator-assessed ORRs were 38.2% (95% CI 26.7–50.8; 1 CR) and 41.4% (95% CI 28.6–55.1; 1 CR) in the MEAP and the SAP, respectively. Median DoR, PFS, and OS were not reached; 12-month OS rate was 74.5% (95% CI 62.2–83.3) in the MEAP and 82.4% (95% CI 69.7–90.1) in the SAP. In the SS, 57 (52.8%) patients had grade ≥3 treatment-emergent adverse events, most commonly anemia (9.3%). Thirteen (12.0%) patients had grade ≥3 immune-related adverse events. Three (2.8%) deaths (2 progressive disease and 1 intestinal obstruction) that might be related to serplulimab were reported. **Conclusions:** The encouraging antitumor activity and the manageable safety profile sustained after a longer duration of follow-up, supporting the further development of serplulimab as a potential tissue-agnostic antitumor treatment. Clinical trial information: NCT03941574. Research Sponsor: Shanghai Henlius Biotech, Inc.

2593 **Poster Session**

Preliminary data from an ongoing phase 1 dose-escalation study of CCX559, an orally administered small molecule PD-L1 inhibitor, in patients with advanced solid tumors. *First Author: Gonzalo Tapia-Rico, ICON Cancer Centre, University of Adelaide, Adelaide, SA, Australia*

Background: The novel small molecule CCX559 is a highly potent and selective PD-L1 inhibitor that induces the dimerization and internalization of cell-surface PD-L1. CCX559, when orally administered in animal models, demonstrated anti-tumor efficacy, including the ability to induce complete responses (Li C, et al. Cancer Res 2021;81(13_Suppl): Abstract nr 1274). Safety pharmacology and toxicology studies in animals demonstrated an acceptable safety profile for CCX559. Taken together, the preclinical data supports the initiation of human trials in patients with advanced solid tumors. PD-(L)1 therapies have been shown to increase peripheral T cell activation and cytokines such as IFNγ and CXCL9 in patients (Herbst RS, et al. Nature.2014; 515(7528):563–567). **Methods:** This phase 1, first-in-patient, multicenter, open-label, dose-escalation study evaluates safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary anti-tumor activity of CCX559 in patients with refractory, locally advanced or metastatic solid tumors. CCX559 is dosed orally once daily with a starting dose level of 30 mg. Dose escalation/de-escalation is based on the Bayesian Optimal Interval (BOIN) design. PBMC and plasma samples were collected from patients over the first 2 cycles (6 weeks) of treatment, and PD assays were performed, including measurement of cytokines and T cell proliferation. **Results:** As of February 1, 2022, one patient per cohort was enrolled at the 30 mg and 60 mg levels, and 9 patients were enrolled in the 120 mg dose cohort. Of the 11 patients enrolled, 5 patients (all 120 mg cohort) remain on treatment. No DLTs, treatment-related SAEs, or severe (Grade 3 or higher) treatment-related AEs have been reported. PD assays have been performed with samples from the 30 mg (n=1), 60 mg (n=1), and 120 mg (n=3) cohorts. Patients in all three cohorts showed increased peripheral CD4 and CD8 T cell proliferation starting in the first cycle (21 days) of treatment, as measured by Ki67 positivity. Increases in plasma IFNγ, CXCL9, CXCL10, and CXCL11 levels were observed, in particular in one patient (120 mg cohort) starting 15 days after treatment initiation. **Conclusions:** Initial results from the phase 1 dose-escalation study of CCX559 indicate on-target PD effects consistent with PD-L1 inhibition. Updated PD data, together with the safety and PK profile, will be presented. Clinical trial information: ACTRN12621001342808. Research Sponsor: ChemoCentryx, Inc.

Cancer PD1/PD-L1 inhibitor efficacy as stratified by smoking status: A population large database study. *First Author: Zachary D. Urdang, Departments of Otolaryngology and Clinical/Experimental Pharmacology - Thomas Jefferson University, Philadelphia, PA*

Background: Delineating clinical factors that predict immune checkpoint inhibitor (ICI) cancer therapy response is a pressing need and smoking is a known factor. In this study we leveraged a large international (heavily US) database to perform the largest study to date for all cancers and major cancer sub-sites/types. **Methods:** Utilizing the TriNetX electronic health records database with 84.3M patients we tested the hypotheses that ICI response stratifies based on smoking, and continued smoking after ICI. Queries were constructed using billing codes for all cancer types treated with an ICI with and without smoking. The smoking cohort was subsequently sub-stratified for continuing vs cessation of smoking after ICI. Next, using ICI therapy as the index event, odds ratios (OR) with 95% confidence intervals for death, and treatment related secondary outcomes were calculated between 0.5-5 years after ICI treatment. Statistics were calculated using TriNetX's integrated statistical platform before and after 1:1 propensity score matching (PSM) for smoking related co-morbidities. **Results:** The OR for death after ICI therapy for smokers (*n* 13336) vs non-smokers (*n* 38973) for any cancer type was 1.27(1.21-1.34) and decreased to 1.11(1.04-1.19) after PSM. Further substratifying the smoking cohort for continued vs cessation of smoking yielded ORs of 1.13(1.03-1.24) and 1.12(1.01-1.24) before and after PSM respectively. Secondary outcomes included ablative surgery, chemotherapy, radiation, and secondary neoplasm. ORs for receiving chemotherapy, and developing secondary neoplasm were most consistently statistically significant across comparisons. **Conclusions:** Smoking adversely potentiates cancer outcomes after ICI therapy. PSM for smoking related comorbid conditions decreased the magnitude of this association although the findings remained clinically and statistically significant. This highlights the key role in smoking related co-morbid conditions as prognostic clinical characteristics. Furthermore, this suggests that smoking affects ICI on a mechanistic/biological level beyond increasing burden of medical comorbidities. Lastly, as smoking cessation also improved outcomes after PSM this further suggests that washout of smoke toxins has a mechanistic/biological effect on ICI activity. Research Sponsor: None.

Propensity score matching corrected	Alive	Deceased (between 0.5-5yrs after ICI)
Smoker	9,379	2,754
Non-Smoker	9,337	2,540

Odds ratio = 1.11(1.04-1.19)

Extended interval dosing in patients with cancer receiving immune checkpoint inhibitors: Safety analysis from the EDICI study. *First Author: Luca Cantini, Department of Pulmonary Medicine, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: Healthcare costs and need of frequent patients' (pts) access to oncology departments led to an increasing interest in alternative immune check-point inhibitors (ICIs) administration schedules able to offer longer dose intervals. The extended interval dosing (ED) of nivolumab and pembrolizumab was approved based on pharmacokinetic data, the relationship of exposure to efficacy, and the relationship of exposure to safety. We aimed to investigate real-life immune-related adverse events (irAEs) incidence in pts treated with ED-ICIs. **Methods:** Clinicopathological and treatment characteristics of all consecutive solid cancer pts treated with ICIs (pembrolizumab, nivolumab) monotherapy who received at least one cycle of the ED (pembrolizumab 400 every 6 weeks or nivolumab 480 mg every 4 weeks) were identified from patient electronic records of 37 oncology departments across Europe and entered into a prospectively maintained database. **Results:** Among 756 pts enrolled in the EDICI study, 733 pts (229 treated with pembrolizumab, and 504 with nivolumab) were included in the final safety analysis (median follow up time: 24.7 months). 476 pts were males, with melanoma (441, 60%) and non-small cell lung cancer (151, 20%) being the prevalent tumor types. Median age was 67 years old, and 589 (80%) pts received ICIs in the advanced setting. 501 (68%) of the enrolled pts started ICIs with canonical interval dosing (CD, median number of cycles administered: 13) and subsequently switched to ED after a median time interval of 210 days. During CD-ICI, 197 pts (39%) developed irAEs of any grade and 14 patients (3%) G3/G4 events; after switching to ED-ICI treatment, which was administered for a median of 7 cycles and 336 days, irAEs of any grade and G3/G4 events were experienced by 155 (36%) and 20 (5%) pts, respectively; 73 (47%) cases of any grade-toxicity and 12 (60%) of G3/G4-toxicity were *de novo.* 33 (7%) pts switched back to CD, in 45% of the cases due to toxicity. Pts who started *up-front* with ED (n = 232, 32%) were exposed to the drug for a median of 7 cycles; 56 of them (25%) developed irAEs of any grade and 9 (6%) G3/G4 irAEs. Skin (12% of patients), endocrine (11%), rheumatic (10%) and gastrointestinal (9%) were the most common irAEs during ED; 42% were "multiple-site" irAEs, showing no difference with CD (p = 0.21). Lower creatinine values before switch to ED (adjusted odds ratio [aOR], 1.24; 95%CI, 1.03-1.48; P = 0.02) and previous toxicity during CD (aOR, 1.20; 95%CI, 1.08-1.33; P < 0.01) were independent risk factors for development of irAEs during ED. **Conclusions:** Despite similar exposure time, the safety profile of ED treatment did not differ from CD, confirming that ED-ICI administration is a safe and feasible option also in cancer pts outside of clinical trials. Future investigations are needed to explore efficacy data and economic impact of this strategy. Research Sponsor: None.

Identification of super-exhausted T cells: A novel population predictive of response to immunotherapy. *First Author: Florent Peyraud, Institut Bergonié, Bordeaux, France*

Background: Given that most of cancer patients treated with anti-PD1/PD-L1 immune checkpoint blockers (ICB) do not derive benefit, there is a crucial need to identify reliable predictive biomarker of response. Besides PD-1, several key immune checkpoints, such as CTLA4, LAG3, TIM3 and TIGIT, are associated with a T cell exhausted phenotype and play a crucial role in leading to cancer immune evasion. The impact of simultaneous expression by T cells of distinct inhibitory receptors on outcome of patients treated with ICB is still unknown. **Methods**: We analyzed the tissue samples, collected before ICB initiation, from patients with solid tumors and included in an institutional molecular profiling program (NCT02534649). We used multiplexed-immunohistofluorescence with the following panel CD3/PD1/TIM3/LAG3/TIGIT/CTLA4, and performed immune cell characterization using multispectral images analysis. We then investigated the correlation between coexpression of T cell-associated exhaustion markers, clinical response rate, progression-free survival (PFS) and overall survival (OS) by Cox proportional hazards models. **Results**: Four hundred thirty five patients were included in the analysis (NSCLC: n=207, 47.6%; sarcoma: n=42, 9.7%; urothelial: n=30, 6.9%; others: n=156, 35.9%). Digital pathology analysis allowed us to identify a population of "super-exhausted" T cells characterized by the co-expression of PD1, LAG3, TIGIT and TIM3 which was enriched in 125 cases (28.7%), and was significantly associated with better PFS (HR 1.60, CI95 1.26-2.04, p<0.001) and OS (HR 1.42, CI95 1.07-1.89, p=0.016) in the whole cohort. Patients with super-exhausted high tumors had higher objective response rate (38.4%) compared to super-exhausted low tumors (19.7%, p<0.001). The presence of super-exhausted T cells was significantly higher in responders (10%) versus non responders (4%, p<0.001). Correlation with better outcome was observed whatever the subgroup considered (NSCLC vs other tumors, CD8 T cells density and presence of tertiary lymphoid structure [TLS]). In multivariate analysis (n=372, 85.5%), increased tumor infiltration by super-exhausted T cells (>1 %) was significantly associated with better PFS (HR 0.61, CI95 0.46-0.81, p<0.001, Table) and OS (HR 0.68, CI95 0.48-0.97, p=0.033, Table). **Conclusions**: The presence of super-exhausted T cells may represent a new predictive biomarker of response to ICB and pave the way for the development of effective ICB combinations. Data from an independent validation cohort will be presented at the meeting. Research Sponsor: None.

Patients	Endpoint	PFS			OS

Novel, small molecule inhibitors of PD-1/PD-L1 pathway. *First Author: Luca Rastelli, Jubilant Therapeutics, Bedminster, NJ*

Background: Programmed Cell Death 1 (PD-1) protein plays a key role in inhibiting immune responses and enhancing self-tolerance via modulation of T-cell activity, inducing T-cell apoptosis and inhibiting apoptosis of regulatory T cells. PD-L1 also plays an important role in various malignancies where it can attenuate the host immune response to tumor cells thereby favouring tumor progression and metastasis. High expression of PD-L1 in glioblastoma tumor tissues is associated with poor survival of patients, and PD-L1 may act as a prognostic predictor and an effective therapeutic target for glioblastoma. A number of monoclonal antibodies targeting PD-1/PD-L1 have approved for various malignancies. Still, efficacy of these antibodies in glioblastoma and brain metastasis continues to be moderate potentially owing to lack of or poor brain penetrance of these agents. Therefore, there is still a need for potent, selective small molecule PD-1/PD-L1 inhibitors with enhanced brain penetration in the treatment of such cancers. **Methods:** Rational design approaches were used to design novel small molecule PD-1/PD-L1 pathway inhibitors; potency of these inhibitors was assessed in an *in-vitro* TR-FRET assay. Checkpoints signalling reporter assays as well cell based PD-L1 dimerization assays were used to assess the mechanistic and functional effects. *In vivo* efficacy was assessed in orthotopic GBM as well as in syngeneic and humanized subcutaneous tumor models in mice. **Results:** Our lead PD-L1 inhibitor JBI-2174 showed strong *in vitro* IC50 of ~1 nM in TR-FRET assay that measures interaction between hPD-1 and hPD-L1 and a picomolar IC50 against monkey PD-L1. In selectivity assays for immunooncology targets, JBI-2174 was highly selective for PD-L1. JBI-2174 also inhibited PD-L1/PD-1 mediated signalling essential for T-cell modulation. JBI-2174 induced dimerization of PD-L1 as observed by size exclusion chromatography, which was confirmed by co-crystal structure and recapitulated in cell based dimerization assay. Elucidation of the co-crystal structure, clearly demonstrated that JBI-2174 clearly interacts with multiple amino acids on PD-L1 that are critical for PD-1 binding. JBI-2174 showed excellent oral bioavailability across pre-clinical species and sustained brain exposure. In the in vivo efficacy studies, JBI-2174 showed comparable efficacy to the anti-PD-L1 antibody or Atezolizumab in syngeneic (4T1, CT-26) and in partially humanized models (MC-38/hPD-L1). Further, oral administration of JBI-2174 resulted in statistically significant increase in survival (Day 27 in control vs day 38 in treated, $p < 0.05$) in a mouse glioma orthotopic model. **Conclusions:** The oral bioavailability and brain exposure of this molecule will make it attractive for cancers with unmet medical needs such as GBM and brain metastasis. IND enabling studies are being initiated for this compound. Research Sponsor: Jubilant Therapeutics.

Association between body mass index and treatment efficacy with immune checkpoint inhibitor therapy: A retrospective study. *First Author: Hannah Wang, Baylor College of Medicine, Houston, TX*

Background: Increased body mass index (BMI) has been associated with improved efficacy of immune checkpoint inhibitor therapy (ICI) in cancer patients. We aimed to retrospectively assess the relationship between patient BMI and response to ICI at two unique health care systems in our institution **Methods:** We identified patients treated with ICI from 2015-2021 at the Michael E. DeBakey Veterans Affairs Medical Center (MEDVAMC) Cancer Center and Baylor St. Luke's Medical Center (BSLMC), a private hospital-based cancer center, both academic affiliates of Baylor College of Medicine. Clinical details, including BMI, and treatment efficacy were collected. We defined BMI categories as follows: underweight (< 18.5), normal weight (18.5-24.9), overweight (25-29.9), and obese (≥30). Progression free survival (PFS), overall survival (OS), and overall response rate (ORR) were the primary end points calculated for treatment efficacy. Survival curves were generated using the Kaplan-Meier method, and intergroup comparisons were performed with log-rank test. Cox regression analysis was used to determine whether BMI at ICI initiation was associated with survival. Chi-square testing was used to determine any association between BMI and ORR. **Results:** We identified 430 patients treated with ICI, 257 (60%) from BSLMC and 173 (40%) from MEDVAMC. 341 patients (79%) were male and 89 (21%) female. Cancer types included 127 (30%) lung, 49 (11%) kidney, 40 (9.3%) bladder, 38 (8.8%) melanoma, and 38 (8.8%) mesothelioma, 34 (7.9%) head and neck, and 104 (24%) other. 160 (37%) patients had a normal BMI at ICI initiation, 37 (8.6%) underweight, 132 (31%) overweight, and 101 (23%) obese. Mean BMIs of different cancer types were as follows: lung (24.7), kidney (29.2), bladder (26.0), melanoma (29.9), mesothelioma (25.25), head and neck (23.7). 292 (68%) patients were treated with ICI monotherapy. The ORR for patients with normal vs. obese BMIs treated with ICI were 28% and 42%, respectively ($p = 0.03$). In a subset of patients evaluable for survival ($n = 322$), patients with an obese BMI had a significantly improved median PFS compared to those with normal BMI (36.4 vs. 23.5 months, respectively, $p < 0.0001$). Multivariable analysis demonstrated that patients with an obese BMI had significantly improved overall survival compared to patients with a normal BMI (HR 0.64, 95% CI 0.44-0.91, $p = 0.014$). This relationship was also seen in the subset of patients treated with ICI monotherapy (HR 0.66, 95% CI 0.45-0.95, $p = 0.029$). This association was noted regardless of health care systems. **Conclusions:** Increased BMI in cancer patients treated with ICI may predict better treatment efficacy and survival outcomes. More research is needed to define this relationship more clearly. Research Sponsor: None.

Cisplatin (Cis) combined with sintilimab (Sint) and niraparib (Nir) in advanced solid tumors: Updated results. *First Author: TAO Haitao, Department of Oncology, Chinese PLA General Hospital, Beijing, China*

Background: PARP inhibitors or chemotherapy combined with PD1/PDL1 inhibitors resulting in enhanced antitumor activity. We previously reported the part 1 result of a phase Ib study exploring the safety and efficacy of Cis plus Sint and Nir. Here we presented the updated survival and safety data. **Methods:** Eligible pts will receive Sint and Cis on D1, plus Nir on D1-21, every 21-day for up to 4 cycles, following Sint and Nir until disease progression or intolerable toxicity. Part 1 was dose escalation phase followed 3+3 model, and part 2 was dose expansion phase enrolled more patients based on part 1. The primary objective was to determine maximum tolerated dose (MTD)/ recommended part 2 dose (RP2D). Secondary endpoints include objective response rate (ORR) per RECIST v1.1, and safety based on CTCAE v5.0. **Results:** PR2D of Cis and Nir were 60 mg/m^2 and 100 mg, respectively when combined with sint 200mg. From 7/2019 to 9/2021, 22 pts (13 pts in part2) were enrolled, including 12 small cell lung cancer (SCLC), 7 lung squamous cell carcinoma (LUSC), 2 ovarian cancer (OC) and 1 cervical squamous cell carcinoma (CSCC). Most were male (77.3%, n=17), ECOG=1 (63.6%, n=14), current smoker(68.2%, n=15) and PDL1 < 1(50%, n=11). 36.4% (8/22) and 27.3% (6/22) had brain and liver metastasis at baseline, separately. Median follow-up was 6.2 months (range 2.5-10.8). ORR was 27.3% (6/22), DCR was 59.1% (13/22). Median progression-free survival (PFS) was 3.3 months (95%CI 1.9-3.9), and PFS rates at 6 months and 12 months were 28.8% and 10.8%. Median overall survival (OS) was 8.0 months (95%CI 4.9-14.1), 12 months OS rates was 28.5%. Median treatment duration was 4.7 months (range 1.9-15.1). The most common treatment-related adverse events included anemia (90.9%, 20/22, [5 Grade 3/4]), fatigue (77.3%, 17/22, [1 Grade 3/4), γ-glutamyl transpeptidase increased (72.7%, 16/22, [0 Grade 3/4]), leukopenia (68.2%, n=15, [4 Grade 3/4]) and neutropenia (59.1%, n=13, [5 Grade 3/4]). **Conclusions:** In this updated analysis, Cis combined with Sint and Nir showed clinically meaningful efficacy and an adequate safety profile in previously treated advanced solid tumors. Data need longer follow-up. Clinical trial information: ChiCTR1900024488. Research Sponsor: None.

Study to evaluate intraperitoneal (IP) ONCOS-102 with systemic durvalumab in patients with peritoneal disease who have epithelial ovarian (OC) or metastatic colorectal cancer (CRC): Phase 2 results. *First Author: Dmitriy Zamarin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Locoregional treatment with oncolytic viruses may be used to improve the efficacy of immune checkpoint inhibitors at both treated and distant tumor sites. This study evaluated the combination of IP-administered ONCOS-102, an oncolytic adenovirus encoding for granulocyte macrophage colony stimulating factor (GM-CSF), with systemic durvalumab (durva) in patients (pts) with advanced OC or CRC who have failed prior chemotherapy. **Methods:** This open-label study (NCT02963831) evaluated ONCOS-102 (IP 3 x 10^{11} VP in 500ml saline [recommended phase 2 dose] weekly x 6) + durva (IV 1500 mg every 4 weeks x 12). One dose of cyclophosphamide was given prior to first ONCOS-102 dose. Phase 2 evaluated the activity of the combination using Simon's 2-stage MINIMAX design. In MINIMAX stage 1, if ≥ 5 of 18 OC pts or ≥ 1 of 13 CRC pts met the efficacy criteria (progression free at end of week 24), 15 additional OC pts or 14 additional CRC pts were to be enrolled in stage 2. The efficacy endpoint would be met if ≥ 11 OC pts or ≥ 4 CRC pts remained progression free at 24 weeks. Safety, response rate and progression-free survival (PFS) by RECIST 1.1, overall survival (OS), and immunologic effects in tumors were evaluated. ITT population = all pts who received at least one dose of durva or ONCOS-102; per protocol (PP) population = all pts who received at least 60% of ONCOS-102 doses and at least 1 durva dose in the first 2 cycles. **Results:** In MINIMAX stage 1, the OC cohort did not meet the efficacy criteria and was closed. For CRC, stage 1 efficacy criteria were achieved and the cohort was opened for stage 2. As of the 14 Dec 2021 cutoff, CRC enrollment was complete, and all pts were followed for 24 weeks or until progression or off study. Two pts were progression free at 24 weeks (see table). Treatment-related adverse events (TRAEs) occurring in > 30% pts were vomiting, nausea, fatigue, chills, and pyrexia. There were no grade 4 or 5 TRAEs. Grade 3 TRAEs were reported in 8 pts, 2 in the OC cohort and 6 in CRC. All grade 3 TRAEs occurred in no more than 1 pt for each AE except abdominal pain, which occurred in 2 pts. **Conclusions:** The combination of IP ONCOS-102 and durva was well tolerated. The study did not meet its efficacy endpoint. Evaluation of pre- and on-therapy translational parameters is ongoing. Clinical trial information: NCT02963831. Research Sponsor: Ludwig Institute for Cancer Research, Other Foundation, Pharmaceutical/Biotech Company.

PRaG regimens (PD-1 inhibitor combined with radiotherapy and GM-CSF with or not IL-2) rechallenge for patients with acquiring resistance to PD-1/PD-L1 inhibitors in refractory advanced solid tumors. *First Author: Meiling Xu, The Second Affiliated Hospital of Soochow University, Suzhou, China*

Background: Immune checkpoint inhibitors, especially PD-1/PD-L1 inhibitors can promote tumor regression and long-term survival in patients with advanced solid tumors. Despite the characteristic durability of response to ICI, unfortunately some patients may develop acquired resistance after an initial response. The underlying mechanism and effective measure are remarkably limited, perhaps restraining development of immunotherapies. The PRaG trial as a salvage therapy in patients with refractory metastatic solid tumors has obtained satisfactory results(Yuehong Kong et al. ASTRO 2021). With great surprise we found that patients with PD-1/PD-L1 inhibitors acquired resistance are more likely to benefit from the PRaG regimens. This is the PRaG regimen rechallenge that could represent an attractive option in advanced solid tumors. We retrospectively analyzed the clinical efficacy and safety of PRaG regimen (PD-1 inhibitors combined with radiotherapy and GM-CSF with or not IL-2) rechallenge to treat immunotherapy-refractory patients with advanced solid tumors. **Methods:** This is a retrospective analysis of patients who showed initial resistance to PD-1/PD-L1 inhibitors were retrospectively collected from PRaG serial trails (ChiCTR1900020175 and NCT04892498). Patients received SBRT or HFRT (2-3 doses of 5-8Gy) to a target metastatic site, PD-1 inhibitor was dosing intravenously within one week after completion of SBRT or HFRT, and GM-CSF subcutaneous (SC) injection once daily for 14 days after radiotherapy(the PRaG 2.0 regimen, GM-CSF 200μg SC d1-7, sequentially IL-2 2million IU d8-14.). The specific PRaG regimens had been reported at the meeting of 2020 ASCO. Pooled analysis of response rate (ORR), median progression-free survival (mPFS), and treatment-related adverse events were calculated. **Results:** A total of 15 multi-metastatic patients were enrolled between October 2020 and February 2022. Thirteen patients showed acquired resistance and underwent at least one assessment, 5 patients were lung cancer, 3 patients were renal cancer, 2 patients were liver cancer, 2 patient was colon cancer, 1 patient was sarcoma. The ORR was 18.2%, and the disease control rate (DCR) was 90.9%. The median PFS was 8.87 months (95%CI, 1.41 to 16.33 months). One lung cancer achieved complete remission, with PFS over 17 months. Treatment-related adverse events of any grade occurred in 11 of 15(73.3%) patients, while there was no grade 3 or higher adverse events. **Conclusions:** Our preliminary results suggested that PRaG regimens rechallenge maybe an active and feasible strategy in PD-1/PD-L1 inhibitors acquired resistance. The therapy was well tolerated and had acceptable toxicity. A phase III prospective study is being planned to clarify the role of rechallenge after acquired resistance. Clinical trial information: ChiCTR1900020175 and NCT04892498. Research Sponsor: None.

2602 **Poster Session**

A first-in-human phase I dose escalation of YH001, an anti-CTLA-4 monoclonal antibody (mAb), in combination with toripalimab (anti-PD-1 mAb) in patients with advanced solid tumors. *First Author: Vinod Ganju, PSEHOG, Frankston, VIC, Australia*

Background: YH001 is a humanized anti-hCTLA-4 IgG1 mAb that relieves CTLA-4-mediated immunosuppression, and thereby enhances the T-cell-mediated anti-tumor immune response. Pre-clinical data have shown potent anti-cancer activity when combined with anti-PD-1 mAb. **Methods:** This is an ongoing phase 1 dose-escalation study conducted in Australia. Patients (pts) with advanced solid tumors received YH001 by IV administration at 0.05 to 6.0 mg/kg for 1 cycle (21 days) then in combination with Toripalimab (anti-PD-1 mAb) at 240 mg Q3W for 4 cycles. An accelerated titration method followed by the standard "3+3" design was utilized to evaluate safety, tolerability and preliminary efficacy. **Results:** As of 31-Dec-2021 data cut-off, 24 pts with advanced solid tumors were enrolled and dosed at 0.05 mg/kg (n=2), 0.1 mg/kg (n=3), 0.3 mg/kg (n=3),1mg/kg (n=5), 2mg/kg (n=5), 4mg/kg (n=3) and 6mg/kg (n=3). Baseline ECOG scores were 0 (n=14), 1 (n=10) with all pts progressed after a median of 2 prior lines of available standard therapy (range 1-5) including 5 pts progressed after prior immunotherapy of anti-PD-1 antibody. Overall, 6 cases of Grade(G) 3 or above treatment-related AEs (TRAEs) have been reported in 5 pts at 0.3 mg/kg, 4 mg/kg and 6 mg/kg dose level respectively, including 1 G3 colitis, 1 G4 thrombocytopenia, 1 G3 Enterocolitis, 1 G3 Rash, 1 G3 Pruritus and 1 G3 hepatitis. There were no death events due to TRAEs. 18 pts (75%) had 63 TRAEs of any level, including 28 G1 TRAEs, 29 G2 TRAEs. 2 of the first 3 pts at MAD (6mg/kg) met protocol defined DLT in Combo phase. Among the 23 pts having imaging tumor assessment by RECIST v1.1, 4 achieved PR and 9 achieved SD in Best of Response. 1 subject with gastroesophageal junction carcinoma at 0.3 mg/kg has achieved PR since the 2nd tumor assessment, target lesion decreased by up to 84.5% from baseline. 1 subject with urothelial carcinoma at 2 mg/kg progressed after prior anti-PD-1 antibody has achieved PR since the 2nd tumor assessment, target lesion decreased by up to 74% from baseline. 1 subject with uterine carcinosarcoma at 2 mg/kg has achieved PR since the 1st tumor assessment, target lesion decreased by up to 52.3% from baseline. 1 subject with vulva adenocarcinoma at 6 mg/kg has achieved PR since the 1st tumor assessment, target lesion decreased by up to 71.4% from baseline. ORR (CR+PR) and DCR (CR+PR +SD) were 17.4%, 56.5% respectively. **Conclusions:** YH001 was well tolerated up to 4 mg/kg dose levels when combined with toripalimab and has shown encouraging antitumor activity in patients with advanced solid tumors. Clinical trial information: NCT04357756. Research Sponsor: Eucure (Beijing) Biopharma Co., Ltd.

2603 **Poster Session**

A phase I open-label, dose escalation of YH003, an anti-CD40 monoclonal antibody, in combination with toripalimab (anti-PD-1 mAb) in patients with advanced solid tumors. *First Author: Jermaine Coward, ICON Cancer Centre, South Brisbane, QLD, Australia*

Background: YH003, a recombinant, humanized agonistic anti-CD40 IgG2 monoclonal antibody (mAb) specifically recognizes and agonizes CD40 on the antigen-presenting cells to enhance immune responses. Preclinical data have shown potent anti-cancer activity when combined with anti-PD-1 antibodies. **Methods:** This is an ongoing phase 1 dose-escalation study conducted in Australia using an accelerated "3+3" design. Patients (pts) with advanced solid tumors receive YH003 by IV administration Q3W as monotherapy at 0.03 to 3.0 mg/kg for the first cycle (21 days) then in combination with Toripalimab at 240 mg Q3W for the 4 subsequent cycles. Treatment continuation beyond cycle 4 is possible if subject is deriving an ongoing clinic benefit. The safety, tolerability and preliminary efficacy data will be analyzed. **Results:** Between 29 Jul 2020 and 30 Dec 2021, a total of 20 patients with various advanced solid tumors were enrolled including 0.03 mg/kg (n = 3), 0.1 mg/kg (n = 3), 0.3 mg/kg (n = 3), 1.0 mg/kg (n = 8) and 3.0 mg/kg (n = 3). The median age was 60 years (range 33-75). Baseline ECOG scores were 0 (13 pts) and 1 (7 pts). 8 pts had received prior immunotherapy (anti-PD-1/PD-L1 or anti-PD-1+CTLA-4mAb). Dose escalation has been completed and only one dose-limiting toxicity relating to YH003 was observed at 1.0 mg/kg (grade 3 transaminitis). The maximum tolerated dose (MTD) was not reached. 13 (65%) pts experienced any grade treatment related adverse events (TRAEs). The most common (≥ 10%) TRAEs were infusion reaction, pyrexia, fatigue, nausea, diarrhea, transaminitis. Most TRAEs were grade 1 or 2. Only 3 (15.0%) pts experienced Grade 3 TRAEs including one each of neutropenia (YH003 0.3 mg/kg), transaminitis (YH003 1.0 mg/kg) and elevated lipase (Toripalimab 0.1 mg/kg). Only 2 pts have permanently discontinued treatment due to TRAEs including grade 3 transaminases increased and grade 2 hepatitis. There were no ≥grade 4 TRAEs and drug related serious adverse events (SAEs) were not observed. Among 14 pts assessable for response, the overall response rate (ORR) was 14.3% (2/14) and disease control rate (DCR) was 35.7% (5/14). One partial response (PR) occurred in a pt with anti-PD1/anti-CTLA4 refractory ocular melanoma with liver metastases (YH003 0.1 mg/kg) who continued on treatment for > 1 year. The other PR occurred in a pt with Non-Small Cell Lung Carcinoma (YH003 1.0 mg/kg) who continued on treatment for almost 9 months. **Conclusions:** YH003 was well tolerated up to 3.0 mg/kg dose levels when combined with Toripalimab and has shown encouraging antitumor activity in patients with advanced solid tumors. Clinical trial information: NCT04481009. Research Sponsor: Eucure (Beijing) Biopharma Co., Ltd.

2604 **Poster Session**

A phase 1 multiple-ascending dose study to evaluate the safety and tolerability of XmAb23104 (PD-1 x ICOS) in subjects with selected advanced solid tumors (DUET-3). *First Author: Mehmet Akce, Winship Cancer Institute, Atlanta, GA*

Background: XmAb23104 is a bispecific antibody targeting T cells that simultaneously express PD-1, an immune checkpoint, and ICOS, a costimulatory molecule expressed after T cell activation. DUET-3 is a Phase 1, first-in-human, dose-escalation and expansion study in subjects with advanced solid tumors, designed to assess safety, tolerability and to identify the maximum tolerated dose (MTD) of XmAb23104. Secondary objectives are to assess pharmacokinetics (PK), immunogenicity, and preliminary anti-tumor activity. We report preliminary data from the completed dose-escalation phase. **Methods:** A 3+3 monotherapy dose escalation with 9 dose levels from 0.002 to 15 mg/kg has been completed. Subjects with measurable disease who progressed on prior standard therapy were eligible. A minimum 6-week washout from prior pembrolizumab was required. XmAb23104 was administered biweekly and RECIST 1.1 assessment was performed every 8 weeks. **Results:** Sixty-two subjects were treated in escalation at doses up to 15 mg/kg; no dose-limiting toxicities were observed and an MTD was not reached. These subjects had advanced disease, 92% were Stage IV at screening, the median number of prior therapies was 3, and 37% had previous checkpoint therapy. Thirty-seven subjects (59.7%) experienced a treatment-related adverse event (TRAE); the most common were diarrhea (9.7%), decreased appetite (9.7%), and fatigue (9.7%). The majority of TRAEs were Grades 1 or 2, with 6 subjects (9.7%) having a Grade 3 or higher TRAE. Thirteen immunotherapy-related adverse events (irAEs) occurred in 8 subjects; no individual irAE occurred in more than 1 subject. Most irAEs were mild (Grades 1 and 2) with 1 Grade 3 pruritus and 1 asymptomatic Grade 4 lipase elevation. Partial responses were observed in 3 subjects (sarcoma; prior PD-1 head and neck squamous cell carcinoma [HNSCC] and renal cell carcinoma [RCC]), and stable disease > 12 months was observed in 2 subjects with colorectal cancer (CRC; 1 MSS and 1 MSI-H). A dose of 10 mg/kg was selected after consideration of PK, safety, and clinical activity data in consultation with the investigators and continues to be evaluated in the expansion part of the study. **Conclusions:** The dose escalation part of this study indicates XmAb23104 was generally well tolerated at doses up to 15 mg/kg and has shown clinical activity in subjects with advanced solid tumors. CTLA4 blockade has been found to increase the frequency of ICOS-expressing T cells in prostate cancer, bladder cancer, melanoma, and hepatocellular cancer (Chen, 2009; Liakou, 2008; Wei, 2017) and may be applicable to other immunogenic tumor types. XmAb23104 is currently being studied alone or in combination with ipilimumab in expansion in non-squamous non-small cell lung carcinoma, melanoma, CRC, undifferentiated pleomorphic sarcoma, HNSCC, and RCC. Clinical trial information: NCT03752398. Research Sponsor: Xencor.

2605 **Poster Session**

Retrospective analysis of the effect of angiotensin receptor blockers and angiotensin converting enzyme inhibitors on the efficacy of anti-PD-1/PD-L1 immunotherapy in patients with advanced cancer. *First Author: Jason Suh, Valley-Mount Sinai Comprehensive Cancer Care, Paramus, NJ*

Background: Components of the renin angiotensin system (RAS) are expressed in tumors with activation leading to tumor and stromal cell release of immunomodulatory cytokines promoting an immunosuppressive microenvironment and increased infiltration of tumor associated macrophages. Angiotensin converting enzyme inhibitors (ACEi) and angiotensin receptor blockers (ARB) are anti-hypertensives that inhibit the RAS. It is unknown if ACEi and ARB treatment modulates the efficacy of anti-PD-1/PD-L1 immunotherapy. **Methods:** A retrospective chart review was conducted to identify patients with unresectable malignancies initiating treatment with a PD-1 or PD-L1 inhibitor based regimen between 1/1/13 and 6/1/19 at Valley Hospital in New Jersey. IRB approval was obtained. Efficacy of treatment was measured by medical oncologist documentation of clinical benefit (CB = stable disease / treatment response) versus disease progression. Chi-square tests were performed to assess relationship between ACEi or ARB exposure and immunotherapy benefit. To assess for a broader anti-hypertensive effect, the relationship in patients on a beta-blocker but not ACEi/ARB was assessed. **Results:** 197 patients were identified of which 190 had documentation of clinical outcome. The mean age was 72.8 years with 54% female and 46% male. 56 patients were exposed to ACEi (N = 28) or ARB (N = 28) and 141 patients to neither. 37 patients were exposed to beta blocker but not ACEi or ARB. 60 patients had nonsquamous NSCLC (16 on ACEi or ARB), 26 squamous NSCLC (7 on ACEi or ARB) and 24 melanoma (10 on ACEi or ARB). 71% of ACEi/ARB exposed patients had CB by clinician assessment as opposed to 47% in those not on ACEi or ARB (p = 0.003). In ACEi exposed patients, 71% had CB versus 51% in unexposed patients (p = 0.048). In ARB exposed patients, 70% had CB versus 51% in unexposed patients (p = 0.069). By contrast, 51% of beta-blocker treated patients had CB versus 55% in untreated patients (p = 0.72). 36% of ACEi/ARB exposed patients remained on treatment at 12 months versus 22% of ACEi/ARB unexposed patients. Subset analyses were performed on the 3 largest patient populations: squamous NSCLC, nonsquamous NSCLC and melanoma. ACEi/ARB exposed melanoma patients had CB rate of 70% versus 43% in those unexposed. ACEi/ARB exposed squamous NSCLC patients had CB rate of 86% versus 47% in unexposed patients. By contrast, ACEi/ARB exposed nonsquamous NSCLC patients had a 56% CB rate versus 48% in unexposed patients. **Conclusions:** Based on retrospective analysis, advanced cancer patients treated with anti-PD-1/PD-L1 regimens had a statistically significant increase in clinical benefit if administered in the context of renin angiotensin system blockade. Prospective disease specific trials can further validate these findings and define the degree of clinical benefit. Research Sponsor: None.

2606 **Poster Session**

First-line PD-1 inhibitors immunotherapy and chemotherapy combined with or without radiotherapy for patients with advanced non-small cell lung cancer. *First Author: Peng Ding, Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*

Background: Immunochemotherapy has become a standard first-line regimen for advanced non-small-cell lung cancer (NSCLC). Several studies showed the synergistic effects of immunotherapy and radiotherapy on local and abscopal tumour control. But the data of first-line immunochemotherapy combined with radiotherapy for the advanced NSCLC is still scarce. **Methods:** Patients with advanced NSCLC receiving first-line PD-1 inhibitors immunotherapy plus chemotherapy in a single center were retrospectively analyzed in this study. They were divided into two groups according to whether they had received radiotherapy. The efficacy and safety of first-line immunochemotherapy combined with radiotherapy (ICRT group) and immunochemotherapy alone (ICT group) were investigated. **Results:** A total of 135 patients were included; 65 patients received PD-1 inhibitors plus chemotherapy and radiotherapy, while other 70 patients were treated with immunochemotherapy alone. The median interval time between radiotherapy and PD-1 inhibitors immunotherapy was 5 days (range, 0-96 days). The overall response rate (ORR) was 50.8% in the ICRT group and 40.0% in the ICT group, respectively. Patients in the ICRT group achieved significant longer progression-free survival (PFS, median 16.5 vs 10.4 months, P= 0.043) and overall survival (OS, median not reached vs 21.0 months, P= 0.030) compared with those in the ICT group. The addition of radiotherapy was the only prognostic factor for PFS (HR = 0.617, 95%CI: 0.385-0.989, P= 0.045) and OS (HR = 0.512, 95%CI: 0.277-0.947, P= 0.033) by univariate Cox regression analysis. Patients were well tolerated and the overall incidence of adverse events was similar between the ICRT group and ICT group. One patient in ICRT group stopped immunotherapy because of severe immune-associated pneumonia. 3.1% of grade 3-4 radiation-related adverse events were observed. **Conclusions:** Adding radiotherapy to first-line PD-1 inhibitors immunotherapy and chemotherapy improved outcomes of patients with advanced NSCLC and showed acceptable toxicity. Additional prospective studies exploring the first-line combination of immunochemotherapy and radiotherapy are warranted. Resistance to anti-PD-1/anti-PD-L1: GB1211 reverses galectin-3 induced blockade of pembrolizumab and atezolizumab binding to PD-1/PD-L1. *First Author: Joseph Mabbitt, Galecto, Inc., Stevenage, United Kingdom*

Background: Galectin-3 (Gal-3) is a β-galactoside binding lectin highly expressed across many cancers (Li et al. Biomedicines, 2021) with high expression associated with poor response to the PD-1 inhibitor pembrolizumab (Capalbo et al., Int J Mol Sci, 2019). In addition, it has also been shown preclinically in in vivo mouse non-small cell lung carcinoma (NSCLC) models that inhibition of Gal-3 enhances the performance of checkpoint inhibitors targeting the PD-1/PD-L1 axis (Vuong et al., Cancer Res, 2019; Zhang et al., FEBS Open Bio, 2020). The mechanism by which Gal-3 negatively impacts the effect of PD-1/PD-L1 based checkpoint inhibitors is not fully understood. We investigated the hypothesis that anti-PD1/anti-PDL1 is induced by direct binding and blockade of Gal-3 to the PD-1/PD-L1 complex itself. **Methods:** SPR was used to investigate the effect of recombinant hGal-3 in combination with a Gal-3 inhibitor (GB1211) on the binding of recombinant hPD-L1 to hPD-1 in the absence and presence of either pembrolizumab or atezolizumab. SPR analysis was performed with a BIAcore (Cytiva, USA). hPD-1 was immobilized onto a CM5 Series S sensorchip via amine coupling and proteins, antibodies or small molecules flowed over in various combinations. Observations made at the protein level were further confirmed in cell binding assays using flow cytometry measuring pembrolizumab and atezolizumab binding to cells lines over expressing high levels of either PD-1 (Jurkat cells) or PD-L1 (RAJI-hPD-L1 cells), respectively. **Results:** Gal-3 potentiated the binding of PD-L1 to PD-1 with a 3-fold increase in its K_D observed and the efficiency of pembrolizumab and atezolizumab binding to and blocking the PD-1/PD-L1 axis was reduced. A 6-fold reduction in K_D of pembrolizumab for the PD-1/PD-L1 complex was observed in the presence of Gal-3. In addition, atezolizumab PD-L1 blockade was reversed in the presence of Gal-3 and dramatically improved by GB1211. Similarly, in cell systems expressing high levels of PD-1 or PD-L1, Gal-3 reduced the binding of pembrolizumab and atezolizumab to their respective targets on cell surfaces that was also reversed by GB1211. **Conclusions:** Gal-3 was shown to vastly reduce the binding of the checkpoint inhibitors pembrolizumab and atezolizumab, by potentiating the interaction between PD-1 and PD-L1. GB1211 restored the binding of the anti-PD1/anti-PDL1 therapeutics and may thus reduce tumor resistance to these agents. These findings harmonize excellently with *in vivo* and clinical data showing an association between Gal-3 expression and lack of efficacy of PD-1/PD-L1 targeted checkpoint inhibitors. Galecto is now investigating the safety and efficacy of GB1211 in combination with atezolizumab in NSCLC. Research Sponsor: Galecto, Inc.

Actual immune checkpoint inhibitor drug use in U.S. patients with cancer. *First Author: Alia Rawji, OptumLabs, Minnetonka, MN*

Background: By 2018, seven Immune Checkpoint Inhibitor (ICI) drugs had gained FDA approval in nine cancers and the number of indications has continued to increase. Haslam et al. estimated that between 36.1 and 38.5% of US patients with cancer were eligible for ICI therapy in 2019. We report the use of ICI dugs in the first-line of therapy (LOT1) and second-line (LOT2) among enrollees treated for 9 cancers with an FDA indication approval in or before 2017. **Methods:** A cohort of patients treated for one of the nine most common cancers with an FDA indication for ICI drugs in 2017 was identified using de-identified data from the OptumLabs Data Warehouse, and clinical information from the Optum Cancer Guidance Program's electronic prior authorization (ePA) platform. De-identified administrative claims data were then linked to ePA information (cancer type & diagnosis date) at the patient level to identify details of treatment received. Eligible patients were enrolled in a commercial or Medicare Advantage (MA) plan and initiated treatment within six months of diagnosis, enrolled at least six months prior to diagnosis date (ensuring this was the LOT1) and at least thirty days after start of first identified treatment regimen (to identify the full treatment regimen). LOT1 treatment initiation ranged from 1/1/2017 to 12/31/2020 for those who were diagnosed before 6/30/2020. ICI regimens are defined as those with an ICI drug received within first thirty days of the LOT start date. **Results:** In this population, we identified 17,283 eligible patients treated for non-small cell lung cancer (4654), melanoma (705), renal cell carcinoma (554), bladder cancer (1974), colorectal (4502), hepatocellular carcinoma (673), gastric cancer (1786), head and neck cancer (1923), or Hodgkin lymphoma (512) in 2018, 2019, and 2020. Overall, 3,291 (19%) of these patients received an ICI in LOT1 with rates increasing over time. The highest rates of ICI use in LOT1 are for the treatment of melanoma, remaining consistent over time, while ICI use in LOT2 is highest for the treatment of non-small cell lung cancer although evidence from 2020 suggests this may be waning. Among patients being treated for renal cell carcinoma, ICI use in LOT2 decreased from 43% (2018) to 15% (2020) while LOT1 ICI use increased to 81% in 2020. **Conclusions:** Overall, ICI use has changed over time in both the first- and second-line setting. In particular, we observe a shift in ICI use from LOT2 to LOT1, consistent with the more recent FDA approvals in earlier lines of therapy. Research Sponsor: None.

A prospective, multicenter, single-arm clinical trial of PD-1 inhibitors in combination with radiotherapy and GM-CSF, sequentially followed by IL-2 (PRaG 2.0) therapy in advanced refractory solid tumors. *First Author: Pengfei Xing, The Second Affiliated Hospital of Soochow University, Suzhou, China*

Background: It's been widely recognized that T cells play an essential role in immunotherapy of malignant tumors. Notably, in our previous PRaG trial, we observed that T cell decreasing occurred in some patients with advanced refractory solid tumors during PD-1 inhibitor combined with stereotactic body radiation therapy (SBRT) / hypo-fractionated radiotherapy (HFRT) and granulocyte macrophage-colony stimulating factor (GM-CSF) treatment which might be one of the reasons for their poor efficacy. To further improve the efficacy of immunotherapy combined with radiotherapy, we optimized the PRaG regimen and added interleukin-2 (IL-2), which amplifies and activates T cells. We conducted PRaG 2.0 trial to further explore the effect of T cells on efficacy. **Methods:** Patients with advanced refractory solid tumors who lacked or were intolerant to the available standard of care were enrolled to receive PRaG 2.0 regimen. A treatment cycle consisted of SBRT or HFRT (5 or 8Gy×2-3f) delivered for one metastatic lesion, PD-1 inhibitor dosing within one week after completion of radiotherapy, GM-CSF 200μg subcutaneous (SC) injection once daily for 7 days (d1-7), and then sequentially followed by IL-2 2million IU SC once daily for 7 days(d8-14). PRaG 2.0 regimen was repeated every 21 days for at least 2 cycles until no appropriate lesions for irradiation or reached the tolerance dose of normal tissues. Patients who could not continue radiotherapy and had not yet developed progression disease (PD) allowed PD-1 inhibitors to be continued as maintenance therapy until PD or unacceptable toxicity but no more than one year. The primary endpoint was Progression-Free Survival (PFS). This trial was registered at www.clinicaltrials.gov with identifier number NCT04892498. **Results:** With the cutoff date of 31 December 2021, a total of 34 patients were enrolled, in which 28 patients (82%) completed at least 1 tumor assessment with a median follow-up time of 5.5 months (95%CI: 4.4, 6.6). Median PFS and overall survival (OS) were currently not reached. The objective response rate (ORR) was 21.4%, and the disease control rate (DCR) was 71.4% by RECIST1.1. Compared to baseline, no significant decrease of T cells, including $CD3^+$, $CD4^+$, and $CD8^+$ T cells, have been observed in 19 patients who completed ≥ 4 treatment cycles. Treatment-related adverse events (TRAE) occurred in 28 of 34 (82.4%) patients, Grade ≥ 3 TRAEs occurred in three patients (8.8%). TRAEs leading to treatment interruption occurred in three patients (8.8%). **Conclusions:** These preliminary results of PRaG 2.0 trial demonstrate that PD-1 inhibitors in combination with radiotherapy, GM-CSF, and IL-2 could potentially maintain the T cells and improve clinical outcomes in patients with advanced refractory solid tumors with acceptable toxicity. Clinical trial information: NCT04892498. Research Sponsor: None.

2610 **Poster Session**

A phase 1/2 study of onatasertib, a dual TORC1/2 inhibitor, combined with the PD-1 antibody toripalimab in patients with advanced solid tumors (TORCH-2). *First Author: Pei Shu, Clinical Trial Center, National Medical Products Administration Key Laboratory for Clinical Research and Evaluation of Innovative Drugs, West China Hospital, Sichuan University, Chengdu, China*

Background: Pre-clinical studies suggest synergistic activity of the combination of inhibitors of mTOR with a PD-1 antibody in solid tumors. Here we report initial results of a phase 1/2 open-label, dose escalation and expansion trial of the oral TORC1/2 inhibitor, onatasertib (ATG-008) in combination with toripalimab (tori), a PD-1 monoclonal antibody, in patients (pts) with advanced solid tumors (NCT04337463). **Methods:** This study consists of two phases: dose escalation and dose expansion. The primary objective in the dose escalation phase was to evaluate safety and tolerability of onatasertib combined with tori, followed by a dose expansion phase to assess antitumor efficacy and verify the safety and tolerability profile of the combination therapy. Primary endpoints included maximum tolerated dose (MTD), recommended phase II dose (RP2D) and efficacy of the combination. Other endpoints included pharmacokinetics, and exploratory biomarkers of drug activity. Prior check point (anti-PD-1, anti-PD-L1, CTLA-4), mTOR and/or PI3K/AKT/mTOR inhibitor therapy was excluded, regardless of PD-L1 expression. Onatasertib was administered orally once a day (QD) at three dose levels (15, 20 and 30mg) in combination with tori at the approved dose of 240 mg, once every 21 days (Q3W). Efficacy assessments are reported based on RECIST1.1 criteria. **Results:** As of Dec 20, 2021 cut-off, 28 advanced solid tumor pts were enrolled in the study with 10 pts in the dose escalation phase and 18 pts in the dose expansion phase. Median age was 52 years. Baseline ECOG scores were 0 (4 pts) and 1 (24 pts) with a median of 2 prior lines therapy (0-7), 21 pts had stage IV disease. No dose-limiting toxicities were reported in dose escalation phase. The study did not reach MTD. All pts had ≥ 1 TEAEs; 19 (67.9%) pts had grade ≥ 3 TEAEs. The most common grade ≥ 3 TEAEs included lymphocyte count decreased (21.4%), rash (14.3%) and hyperglycemia (10.7%). AEs lead to discontinuation in 2 pts (7.1%). The RP2D for onatasertib was determined to be 15-20 mg in combination with the recommended dose of tori. Among the 21 efficacy evaluable (EE) pts, the ORR was 28.6% (6 pts, 5 confirmed) and DCR was 71.4% (15 pts). In 5 EE pts with cervical cancer, 1 complete response (CR) and 3 partial responses (PR) were observed (all confirmed). One cervical cancer pt with negative PD-L1 expression achieved CR and remains on treatment after 580 days. Two other PRs were seen (one nasopharyngeal carcinoma, one ovarian carcinoma). Median progression free survival (PFS) in the whole cohort was 3.52 months and 18-month PFS rate was 31.2%. **Conclusions:** Onatasertib in combination with tori is tolerable with encouraging response rates and disease stabilisation in subjects with advanced solid tumors, especially in cervical cancer. Expansion enrolment for cervical cancer is ongoing and updated information will be presented. Clinical trial information: NCT04337463. Research Sponsor: Antengene Corporation.

2611 **Poster Session**

Safety of dual checkpoint-blockade with PSB205, an anti-PD-1/CTLA4 monoclonal antibody combination, manufactured and dispensed as a single product: A phase 1 study. *First Author: Rashmi Chugh, University of Michigan, Ann Arbor, MI*

Background: PSB205 is a new biological agent consisting of two engineered monoclonal antibodies (anti-PD-1 IgG4 and anti-CTLA-4 IgG1) expressed in a fixed ratio (2:1) from a single cell-line, manufactured as one product and dispensed from a single vial. PSB205 was designed to optimally balance efficacy and safety through differential target coverage of PD-1 and CTLA-4: the anti-CTLA-4 antibody was engineered to have a shorter half-life to modulate exposure and lower risk of immune-related adverse events (irAEs). **Methods:** We report safety data from a first-in-human study, conducted in standard 3+3 Phase 1 dose escalation format, enrolling subjects with refractory solid tumors with mixed histologies, who had exhausted available standard treatments. Primary objectives were safety (including Dose Limiting Toxicities), tolerability and selection of a Phase 2 dose. Secondary objectives were PK and preliminary evaluation of effectiveness. Treatment was Q3 wks. Inclusive the 1st week following the 2nd infusion, the DLT-period was 28 days. **Results:**Nine US-centers enrolled 27 subjects, representing 19 tumor histologies, in 5 ascending dose cohorts ranging from 0.1 mg/kg to 5 mg/kg; an additional N = 49 pts were dosed in expansion cohorts at 5 mg/kg and 400 mg (fixed dose). Median number of prior systemic treatments for metastatic disease was 4. No DLT was observed at any of dose level evaluated. The most frequent Treatment-Related Adverse Events (TRAE) reported were diarrhea (9%), Infusion-Related Reaction (IRR) (5%) and fatigue (4%). Among the subset (N = 33) who completed at least 4 cycles of treatment, the most common TRAE were diarrhea (21%), IRR (12%), Fatigue (9%), and irAEs, specifically colitis, rash and arthralgia (6% each symptom). Most TRAEs were Grade 1 /2, with just 1 case each of diarrhea and colitis Graded as G 3/4. Tumor responses (all PRs) were observed at dose levels of 3 mg/kg and 5 mg/kg in 4 pts - 1 each with with RCC, SCLC, HNSCC and gastric cancer. **Conclusions:** PSB205 provides dual checkpoint blockade with a very tolerable side effect profile, with less AEs than typically noted in published studies of anti-PD1 and anti-CTLA-4 combination therapy. Further studies are ongoing to confirm this observation. Dose levels of 5 mg/kg and 400 mg fixed were selected for Phase 2, which has commenced enrollment. Clinical trial information: NCT03986606. Research Sponsor: Sound Biologics.

Predictors of response to immune checkpoint inhibitors (ICI) rechallenge post-disease progression in solid tumors: A systematic review and meta-analyses. *First Author: Hassan Mohammed Abushukair, Jordan University of Science and Technology, Irbid, Jordan*

Background: Rechallenge with the same or different ICI has been proposed as a second line option in patients who progress on an initial ICI course. Considering rechallenge risks of limited benefit and further toxicity, identifying predictors for patients benefiting from rechallenge would provide much needed guidance for practice. We present a systematic review and meta-analyses of response predictors to ICI rechallenge after disease progression in solid tumors. **Methods:** A systematic search of PubMed, Cochrane database and ASCO meeting library was done for studies published up to Jan 2022 evaluating the efficacy of ICI rechallenge in patients with advanced solid tumors after disease progression on initial ICI. Predictors of interest included duration of the initial ICI course using a cutoff point of 6 months, and best overall response (BOR) to initial ICI: stratified into responders (complete or partial response or stable disease) and non-responders (progressive disease). Odds ratios (OR) for ICI rechallenge response were calculated & pooled in reference to initial ICI duration and its BOR using the fixed effects model. ORs with a 95% confidence interval [CI] not overlapping the null value (1) were considered statistically significant. **Results:** A total of 56 studies reporting on ICI rechallenge upon progression, comprising 3579 patients, of which 31 studies have switched their second ICI regimen. Initial ICI was anti-PD-1 in 37 studies, anti-CTLA-4 in 14 studies, and anti-PD-L1 in 10 studies. Involved solid cancers included melanoma (n = 30), NSCLC (n = 15), RCC (n = 6), and others (n = 5). Pooled objective response rate for rechallenge was 18.4% ([15.4-21.4], I^2 = 84.6%), with the highest being among melanoma patients (21.2% [17.2-25.2], I^2= 83.4%). For BOR, no significant difference was found for the entire cohort (OR = 1.34 [0.86 - 2.09], I^2 = 27.1%). In melanoma studies, response to ICI rechallenge was significantly higher in patients responding to the initial ICI prior to progression (OR = 1.87 [1.03-3.39], I^2 = 24.5%). For treatment duration, there was no difference in the entire cohort concerning ICI rechallenge (OR = 1.54 [0.86-2.75], I^2 = 14.2%), yet melanoma patients showed a significant difference favoring those who had longer response durations on initial ICI (OR = 2.05 [1.01-4.16], I^2 = 0.0%). **Conclusions:** Response to rechallenge in advanced melanoma patients was more common in initial ICI responders with a longer course duration (> 6 months). More homogeneous studies are needed to validate our findings and investigate other potential markers for rechallenge such as PD-L1 status & mutational burden. Research Sponsor: None.

Association of proton pump inhibitor use with survival outcomes in patients with cancer treated with immune checkpoint inhibitors: A systematic review and meta-analysis. *First Author: BaoQing Chen, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Proton pump inhibitors (PPIs) were revealed to regulate gut microbiome alterations and further impact the response to immune checkpoint inhibitors (ICIs). Contradictory impacts on survival were observed in ICI-treated patients when concomitantly use PPI or not. We performed this systematic review and meta-analysis to analyze the association of PPI use with survival outcomes in ICI-treated cancer patients. **Methods:** EMBASE, MEDLINE/PubMed, Cochrane Library databases and major oncology conferences proceedings were comprehensively searched. Studies comparing overall survival (OS) and progression-free survival (PFS) between PPI use and PPI non-use in ICI-treated cancer patients were included. Data regarding the characteristics, ICI and PPI treatments and survival outcomes for patients were extracted. Hazard ratios (HRs) with 95% confidence intervals (CIs) were pooled using random-effect models. Subgroup meta-analyses and meta-regressions were performed to explore possible factors of heterogeneity among study results. **Results:** A total of 20 studies were included, comprising 2812 ICI- and PPI-treated patients and 3990 ICI-treated and PPI-free patients. The pooled HR is 1.30 (95% CI, 1.17-1.45; $P < .001$) for OS and 1.20 (95% CI, 1.08-1.34; $P < .001$) for PFS, indicating a significant negative association between PPI use and survival of ICI-treated patients. Subgroup meta-analyses by factors including cancer types, ICI types and time window of PPI use, revealed such associations were in patients with non-small cell lung cancer (OS: HR = 1.40, 95% CI = 1.23 to 1.59, $P < .001$; PFS: HR = 1.27, 95% CI = 1.16 to 1.40, $P < .001$) or urothelial cancer (OS: HR = 1.50, 95% CI = 1.26 to 1.80, $P < .001$; PFS: HR = 1.37, 95% CI = 1.17 to 1.60, $P < .001$), patients treated with anti-PD-1/PD-L1 (OS: HR = 1.41, 95% CI = 1.30 to 1.53, $P < .001$; PFS: HR = 1.29, 95% CI = 1.20 to 1.38, $P < .001$), patients receiving PPI as baseline treatment (OS: HR = 1.43, 95% CI = 1.21 to 1.69, $P < .001$; PFS: HR = 1.29, 95% CI = 1.16 to 1.44, $P < .001$) or 60 days before ICI treatment initiation (OS: HR = 1.28, 95% CI = 1.11 to 1.48, $P < .001$; PFS: HR = 1.27, 95% CI = 1.16 to 1.40, $P < .001$), rather than concomitantly with ICI initiation. **Conclusions:** PPIs use in patients treated with ICIs is associated with a shorter OS and PFS, especially in several specific subgroups of cancer patients. PPIs should be strictly controlled, and appear to not impact survival if given temporarily after ICIs initiation. These detailed observations could provide basis for clinical guidelines when concomitantly use PPIs and ICIs. A pan-cancer analysis of P21 activated kinase (PAK) family genes as potential biomarkers for immune checkpoint therapy. *First Author: Sun Gang, The Affiliated Cancer Hospital of Xinjiang Medical University, Xinjiang Cancer Center, Key Laboratory of Oncology of Xinjiang Uyghur Autonomous Region, Urumqi, China*

Background: PAK (P21 activated kinase) is a family of serine threonine kinases, that consist of 6 members, PAKs 1-6, which are positioned at an intersection of multiple signaling pathways implicated in oncogenesis. Recent studies have found relationship between mutations of some PAK family genes and antitumor immunity. Here, we explored the associations of PAK family gene mutations with ICI response based on multidimensional data from multiple solid tumors. **Methods:** An immunotherapy cohort (Broad/Dana-Farber, Nat Genet 2018, N = 249) within 7 types of tumors as discovery stage, was used to explore the association of PAK family genes mutations with tumor mutation burden (TMB) and efficacy of immunotherapy. To further validate the predictive value of PAK family genes, we employed another ICI-treated cohort, MSKCC cohort (Samstein, Nat Genet 2019, n = 1661), as a validation cohort. TMB was calculated as the total count of nonsynonymous mutations in coding sequence. **Results:** In discovery cohort, compared to that in the PAK-Wt group, longer OS was observed in the PAK-Mut group (mOS: 31.3 vs 15.4 months, HR = 0.59, 95% CI: 0.36 to 0.96, $P = 0.03$). In addition, PAK-Mut group had higher TMB ($P < 0.001$). Median TMB in PAK-Mut group and PAK-Wt group is 17.79 (IQR, 7.45-36.55) Mut/Mb and 5.47 (IQR, 2.46-9.09) Mut/Mb, separately. In validation cohort, PAK-Mut patients also achieved significant improved OS compared with PAK-Wt patients (mOS: 44.0 vs 17.0 months, HR = 0.51, 95% CI: 0.37 to 0.69, $P < 0.001$). Moreover, multivariable analysis of validation cohort demonstrated that PAK-Mut was associated with better OS (HR = 0.71; 95%CI, 0.52-0.98; P = 0.036), after adjusting for Age, Gender, Metastasis, Treatment, TMB, Cancer type. Compared with PAK-Wt group (median [IQR]: 5.90 [2.95-10.04]), PAK-Mut group (median [IQR]: 21.19 [11.81-43.29]) also had higher TMB ($P < 0.001$). **Conclusions:** The results indicated that PAK family genes mutation was associated with a higher TMB both discovery and validation cohort. Analysis of discover and validation immunotherapy cohort data showed PAK family was associated with better OS. These findings indicate that these genes mutation may serve as a potential predictive biomarker for ICI in solid tumor patients. Research Sponsor: None.

***WDR49* mutation as a novel predictive biomarker in patients with non–small cell lung cancer with immune checkpoint inhibitors.** *First Author: Zhihui Shi, The Second Xiangya Hospital of Central South University, Changsha, China*

Background: Application of Immune Checkpoint Inhibitors (ICIs) has become the first-line therapy for advanced or metastatic non-small cell lung cancer (NSCLC). *WDR49* gene belongs to the WDR (WD40-repeat) protein family which participates in a wide range of biological processes, including DNA damage repair and immune regulation, etc. However, the correlation between *WDR49* mutation and immune efficacy is unclear. **Methods:** A total of three independent cohorts of NSCLC patients treated with immunotherapy were analyzed in this study: the Miao cohort (n = 56), the Rizvi cohort (n = 34), the Hellmann cohort (n = 75). Survival was estimated by Kaplan-Meier curves, with the p value determined by a log-rank test. HR was determined through the univariable and multivariable Cox regression. The CIBERSORT analysis relied on RNA-seq data in The Cancer Genome Atlas (TCGA) database. Two-sided P value < 0.05 was considered statistically significant. All the statistical analyses were conducted with R version 4.0.3. **Results:** In this merged cohort, the frequency of *WDR49* mutation (*WDR49*-mut) was 10.30% (17 in 165), and most patients with *WDR49* mutation were lung adenocarcinoma (LUAD) (11.85%, 16 in 135). Meanwhile, the frequency of *WDR49*-mut in TCGA database was 7.05 % and 3.84% in LUAD and lung squamous cell carcinoma (LUSC), respectively. The Kaplan-Meier curves survival analysis indicated that *WDR49*-mut was associated with longer progression free survival (PFS) (median PFS 23 months vs 5.2 months, hazard ratio [HR] = 0.17 [95% CI, 0.06–0.47], P < 0.001) and higher objective response rate (ORR) (76% vs 27%, P < 0.001). Furtherly, *WDR49*-mut was significantly related to higher tumor mutational burden (TMB) (median TMB 495 vs 149, P < 0.001), but it had nothing to do with the expression of PD-L1 (Proportion of PD-L1 positive 72.7% vs 68.5%, P = 1). The CIBERSORT analysis revealed that CD8+ T cell infiltration was significantly higher in *WDR49*-mut group than *WDR49* wildtype group (p < 0.05). **Conclusions:** Better treatment response and survival benefit in the mutant group suggest that the *WDR49* mutation may serve as a novel predictive biomarker in NSCLC patients with ICIs. The significantly higher TMB and CD8+ T cell infiltration in *WDR49*-mut group may be the potential mechanism. Research Sponsor: None.

Molecular predictors of response among patients with MMRd tumors treated on NCI-MATCH Arm Z1D. *First Author: Jonathan Daniel Schoenfeld, Dana-Farber Cancer Institute, Boston, MA*

Background: On arm Z1D of the NCI-MATCH trial, the PD-1 inhibitor nivolumab was found to have activity among patients with mismatch repair-deficient (MMRd) tumors as defined by complete loss of MLH1 or MSH2 nuclear expression determined by immunohistochemistry, with 6-month progression free survival of 51%. We aimed to identify molecular predictors of response in this population. **Methods:** Among patients treated on NCI-MATCH Z1D, we evaluated genomic and tissue predictors of clinical benefit (CB), defined as patients with RECIST v1.1 complete or partial response or stable disease for ≥ 6months. WES files were processed and filtered using GATK best practices preceding TMB and MSI calculations according to MSI sensor score, a WES-based MSI rating system. Cutoffs were set to define TMB (TMB-Low: ≤10 mutation/Mb; TMB-High: >10) and MSI (MSS: ≤10% unstable loci; MSI-Low: $10 > x \leq 20$; MSI-High: >20). Multiplex immunofluorescence (mIF) used formalin-fixed paraffin-embedded slides stained using a BOND RX automated stainer. Expression analyses followed normalization in DEseq2's median of ratios method. Gene set enrichment analysis was conducted by "empirical phenotype-based permutation test." Additional RNA, WES, and mIF comparisons used the Wilcoxon rank-sum test. **Results:** Among 36 patients accrued to NCI-MATCH Z1D with pretreatment correlative samples available, 7 were unevaluable for response, and 1 was misclassified as having an MMRd tumor. Of the remaining 28, 15 had CB (2 CR, 10 PR, 3 SD ≤ 6 months) and correlative data were available for 26 (WES), 27 (RNAseq), and between 10-20 for mIF based on the marker assessed. According to MSI-sensor score, 11 were MSI-high, 8 were MSI-low, and 7 were MSS. MSI-sensor status, but not TMB was associated with CB (p=0.037 and p=0.185, respectively). Similar results were seen when using CR+PR vs SD+PD evaluation. Using RNAseq gene set enrichment analyses, CB patients had increased expression of interferon alpha (p=0.01), interferon gamma (p=0.03), PI3K-AKT-mTOR (p=0.02), cytotoxicity (p=0.05) and antigen processing (p=0.01) gene sets, while hedgehog signaling genes were increased in non-CB patients (p=0.04). The ESTIMATE immune index and infiltration of CD4+/PD1+/Ki67+ cell populations as determined by mIF were nominally higher in patients with CB (p=0.051 and p=0.075). **Conclusions:** Among patients with MMRd tumors treated with PD-1 checkpoint blockade, correlative analyses demonstrate associations between CB and MSI-sensor score as well as biomarkers indicative of immune infiltration and antigen presentation. This suggests that these measures may help differentiate patient response in MSI tumors. Clinical trial information: NCT02465060. Research Sponsor: U.S. National Institutes of Health.

***PAPPA2* mutation as an indicator stratified patients benefit from immune checkpoint inhibitors in NSCLC and SKCM.** *First Author: Yiting Dong, National Cancer Center/National Clinical Research Center for Cancer/ Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Pappalysin 2 (*PAPPA2*) mutation, most occurring in skin cutaneous melanoma (SKCM) and non-small cell lung cancer (NSCLC), is found to be related to anti-tumor immune response. However, the association between *PAPPA2* and efficacy of immune checkpoint inhibitors (ICIs) therapy remains unknown. **Methods:** Forty-one NSCLC patients receiving anti-PD-(L)1 (China cohort, n = 41) and seven public cohorts with whole-exome sequencing (WES) data were included to analyze the performance of *PAPPA2* mutation as an indicator stratifying patients benefit from ICIs, consolidating a discovery set (n = 34) and two validation sets (NSCLC validation set , n = 172 ; SKCM validation set, n = 210). The mechanism was analyzed in the Cancer Genome Atlas (TCGA) database (n = 1467). **Results:** In the discovery set, patients with *PAPPA2* mutation exhibited a significantly predominant PFS (HR, 0.11 [95% CI, 0.01-0.83]; P = 0.01), ORR (100.0% vs 21.4%; P < 0.001) and durable clinical benefit (DCB, 83.3% vs 32.1%; P = 0.012) compared to those with wide-type *PAPPA2*, consistent in NSCLC validation set (PFS, HR, 0.3 [95% CI: 0.16-0.56], P < 0.001; ORR, 70.8% vs. 20.9%, P < 0.001; DCB, 83.3% vs. 36.5%, P < 0.001) and SKCM validation set (OS, HR, 0.49 [95% CI: 0.31-0.78]; P = 0.002; ORR, 34.1% vs. 16.9%, P = 0.039; DCB, 50.0% vs. 30.7%; P = 0.036). Similar results were observed in multivariable models. In contrast, no association between *PAPPA2* mutation and OS or PFS was observed in TCGA datasets, suggesting that *PAPPA2* mutation may be a predictive but not a prognostic factor in ICI treatment for NSCLC patients. Based on CIBERSORT-inferred tumor infiltrating lymphocytes from TCGA, we found that *PAPPA2* mutation was significantly associated with higher activated CD4 memory T cells and lower Treg cells in tumor immune microenvironment, related with higher TMB ($P < 0.001$) and neoantigen load ($P < 0.001$). In addition, gene set enrichment analysis (GSEA) analysis revealed that *PAPPA2* mutation was correlated with upregulated DNA damage repair (DDR) signaling pathway. **Conclusions:** Our findings indicated that *PAPPA2* mutation could serve as a novel indicator to stratify beneficiaries from ICIs therapy in NSCLC and SKCM, warranting further prospective studies. Predictors of immunotherapeutic benefits in patients with advanced melanoma and other malignancies treated with immune checkpoint inhibitors utilizing ORIEN "real-world" data. *First Author: Ahmad A. Tarhini, Department of Cutaneous Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Despite the significant improvements in treating cancer with immune checkpoint inhibitors (ICIs), many patients (pts) do not achieve disease control. Using Oncology Research Information Exchange Network (ORIEN) Avatar real-world data conducted under the Total Cancer Care protocol we investigate predictive biomarkers of ICI benefits in pts with advanced malignancies. **Methods:** Clinical data were normalized as part of ORIEN Avatar. RNA-seq was performed on tumor samples following the RSEM pipeline and gene expressions were quantified as Transcript Per Million (TPM). Gene expressions (GE) were log2(TPM+1) transformed. Mann-Whitney U-test was used to compute differences between groups, and Kaplan-Meier survival analysis was performed. **Results:** Pts (n=1214) with 27 cancer types treated with ICIs were retrieved from the database, where 1143 and 875 patients were profiled by WES and RNA-seq, respectively. 804 pts had both WES and RNA-seq data. The top six cancer types were renal cell carcinoma (n=206), non-small cell lung cancer (n=173), head and neck cancer (n=157), melanoma (n=154), sarcomas (n=99) and bladder cancer (n=87). The ICI regimens included therapy with atezolizumab (n=87), avelumab (n=12), cemiplimab (n=6), ipilimumab (n=47), nivolumab (n=424), pembrolizumab (n=525) and ipilimumab+nivolumab (n=113). Median overall survival (OS) for the entire cohort was 21.9 months. Patients had significant improvement in OS if ICI was given in the first line ($P<0.0001$). Previously published GE signatures were tested in the melanoma cohort. Signatures related to IFNg, effector T cells, chemokines, MHC II and Tertiary Lymphoid Structures were significantly prognostic and predictive of ICI benefits in advanced melanoma (Table). Analyses in the other cancer types are ongoing. **Conclusions:** GE data analyses validate the predictive value of immune related gene signatures following ICI immunotherapy in melanoma. Ongoing analyses are investigating these signatures in other malignancies and integrating the GE data with data related to TMB, somatic mutations and germline genetic variations. Research Sponsor: ORIEN Foundation and Community Foundation of Tampa Bay.

GE signatures and correlation with survival (>24 versus <24 months and overall survival) in cutaneous melanoma (n=123 pts).

A deep learning approach utilizing clinical and molecular data for identifying prognostic biomarkers in patients treated with immune checkpoint inhibitors: An ORIEN pan-cancer study. *First Author: Payman Ghasemi Saghand, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Immune checkpoint inhibitors (ICIs) have made significant improvements in the treatment of cancer patients (pts), but many continue to experience primary or secondary resistance. Here, we leveraged clinical and genomic data to identify prognostic biomarkers in pts treated with ICIs utilizing a pan-cancer approach. **Methods:** Pts were enrolled to the Total Cancer Care protocol across 18 cancer centers within the Oncology Research Information Exchange Network (ORIEN). RNA-seq was performed on tumors following the RSEM pipeline and gene expressions were quantified as Transcript Per Million (TPM) and were logarithmically normalized. An Auto-Encoder Survival Deep Network (AE-SDN) architecture was developed that combined the reconstruction loss of AE with Cox regression for modeling time to event. For comparison, immunoscore for each pt was calculated based on the estimated densities of tumor CD3+ and CD8+ T cells (Galon, 2020) utilizing CIBERSORTx. The quality of overall survival (OS) predictions was assessed using Harrell's concordance index (C-index). Log-rank test was used to assess stratified group differences (by ICI or cancer histology) along with Kaplan-Meier (KM) survival analysis of AE-SDN and immunoscore. **Results:** Pts (n=522) with 4 cancer types including melanoma (n=125), renal cell carcinoma (n=149), non-small cell lung cancer (n=128) and head and neck cancer (n=120) treated with 6 ICI regimens were included in this analysis. ICI regimens were nivolumab (n=219), pembrolizumab (n=202), ipilimumab+nivolumab (n=69), ipilimumab (n=30), avelumab (n=1) and cemiplimab (n=1). The Table summarizes the overall C-index and associated 95% CIs and log-rank *P* values for the entire cohort (regardless of histology) resulting from our proposed AE-SDN model and the separate estimated immunoscore categorization. AE-SDN top selected genes were mostly related to immunity, carcinogenesis and tumor suppression. The corresponding KM plots showed significantly wider separations of the survival curves in favor of our proposed AE-SDN model relative to the immunoscore with more than 20% improvement in prediction power. **Conclusions:** Deep network machine learning analysis is a promising approach to identifying relevant prognostic biomarkers in cancer pts treated with ICI. This may lead to novel therapeutic predictive signatures and identification of mechanisms of ICI resistance. Our AE-SDN gene expression signature was significantly prognostic and outperformed the estimated CD3+, CD8+ T Cell immunoscore. Further refinements to our prediction power are ongoing along with more advanced neural network architectures to elucidate related functional pathways. Research Sponsor: ORIEN Foundation and Community Foundation of Tampa Bay.

	Avg. C-index	95% CI	Log-rank test p-value

Analysis of the contribution of macrophages to the overall tumor PD-L1 microenvironment using a screening multi-tumor tissue microarray and rapid multiplex fluorescence digital phenotyping approach. *First Author: Marie Cumberbatch, TriStar Technology Group LLC, Washington, DC*

Background: Programmed death ligand-1 (PD-L1) contributes to immune suppression in the tumor microenvironment (TME) by interacting with programmed cell death-1 (PD-1) on infiltrating T lymphocytes leading to tumor immune escape. Application of omics technologies has shed light on the relevance of the TME for response to immunotherapies and development of novel treatment options. Here we have applied a multi-plex immunofluorescence/multi-tumor tissue microarray (TMA) approach to examine the immunobiology of different TMEs with respect to the contribution by tumor cells and macrophages to overall PD-L1 expression. **Methods:** A TMA comprising 11 tumor types and a total of 144 different donors, each represented by two cores [1mm; 1 from invasive margin (IM) and 1 from tumor center (TC)], was stained using Ultivue's Immuno8 FixVUE panel (CD3, CD4, CD8, FOXP3, CD68, PD-1, PD-L1, pan-CK/SOX10). Whole slide images from two rounds of imaging (x20 magnification; four markers in each round) were aligned using Ultivue's UltiStacker software based on the nuclear counterstains from the two imaging rounds, to provide precise marker colocalization data. Cell phenotype data for each core was generated using Visiopharm software. **Results:** Overall PD-L1 positivity was greatest for NSCLC, SCLC, TNBC and gastric cancer ranging from approximately 600-1000 PD-L1+ cells/mm^2/core, compared with CRC, breast, pancreatic, liver, and gastric esophageal junction (GOJ) cancers (approx. 50-300 PD-L1+ cells/mm^2/core). Contribution by macrophages to overall PD-L1 expression (dual CD68+/PD-L1+) varied by tumor type representing 25-35% for NSCLC (SCC and ADC) and gastric cancer, whereas a converse pattern was apparent for SCLC, TNBC, breast (ER+ and Her2+) and pancreatic cancers where PD-L1+ macrophages accounted for a large proportion (approx. 60-85%) of overall tumor PD-L1 expression. Interestingly, as a proportion of total macrophage infiltration, approximately 65% of CD68+ macrophages were PD-L1+ for SCLC and TNBC, compared with less than 10% for pancreatic and liver cancer. Spatial analysis revealed PD-L1+ macrophage infiltration to be generally higher for IM versus TC, and the distribution between tumor (CK+) and stroma (CK-) remained similar despite exclusion of CD3+/CD8+ cytotoxic T cells from CK+ tumor regions for pancreatic and liver cancer. **Conclusions:** Taken together, these data illustrate the benefits of combining multiplexed immunofluorescence staining, with digital analysis of cell phenotypes within well characterized tumor samples to better understand the relative immunobiology of different TMEs. Here we demonstrate that the relative contribution of macrophages to the overall PD-L1 microenvironment varies between tumor types, which may help guide options for successful immunotherapy strategies. The inflamed immune phenotype (IIP): A clinically actionable artificial intelligence (AI)-based biomarker predictive of immune checkpoint inhibitor (ICI) outcomes across >16 primary tumor types. *First Author: Jeanne Shen, Department of Pathology, Stanford University School of Medicine, Stanford, CA*

Background: The IIP, defined by enriched intratumoral tumor-infiltrating lymphocytes (TIL), is a potential tumor-agnostic biomarker of responsiveness to ICI therapy. Here, we validate the IIP, as assessed by Lunit SCOPE IO, an AI-powered spatial TIL analyzer that runs on routine H&E-stained whole-slide images (WSI), for clinical outcome prediction in a large, multi-center international cohort of ICI-treated patients, demonstrating its utility as a practical biomarker to guide ICI treatment planning. **Methods:** Lunit SCOPE IO was developed using 17,849 H&E WSI of multiple cancer types, annotated by 104 board-certified pathologists (13.5×10^9 μm^2 area and 6.2×10^6 TIL). IIP+ tumors were defined as those with ≥ 20% of all 1 mm^2 tumor tiles in a WSI classified as having a high intratumoral TIL density. We evaluated the correlation between IIP and ICI treatment outcomes (overall response rate (ORR) and progression-free survival (PFS), assessed by RECIST v1.1) in a real-world dataset of 1,806 patients (> 16 primary tumor types) retrospectively collected from Stanford University Medical Center, Samsung Medical Center, Chonnam National University Hospital, Seoul National University Bundang Hospital, and Northwestern University. IIP status was sub-analyzed by PD-L1 22C3 tumor proportion score (TPS, n = 798), microsatellite status, and tumor mutational burden (TMB, n = 130). **Results:** The IIP+ phenotype (35.2%, 636 of 1,806) was highly enriched in nasopharyngeal carcinoma (68.0%), melanoma (56.3%), renal cell carcinoma (52.9%), and non-small cell lung cancer (NSCLC, 33.7%). The IIP+ proportion by PD-L1 TPS (< 1% / ≥ 1%) was 21.6% and 40.7%, respectively. While 33.3% of microsatellite unstable (MSI-H) or TMB-high (≥ 10/Mb) tumors were IIP+, a substantial proportion (26.1%) of microsatellite stable (MSS), TMB-low tumors were IIP+. The ORR in IIP+ patients was significantly higher (26.0% vs. 15.8% in IIP-, p < 0.001). Median PFS for IIP+ was 5.3 months (95% CI 4.6-6.9 m), significantly longer than that for IIP- (3.1 m, 95% CI 2.8-3.6 m), with a hazard ratio (HR) of 0.68 (95% CI 0.61-0.76, p < 0.001). The association held after excluding NSCLC patients (n = 909) (HR 0.69, 95% CI 0.59-0.81, p < 0.001). On subgroup analysis, IIP+ correlated significantly with prolonged PFS, regardless of ICI regimen (mono / combo therapy) or PD-L1 TPS (< 1% / ≥ 1%). Of note, IIP+ was predictive of favorable PFS only in the MSS, TMB-low group (n = 88, HR 0.56, 95% CI 0.33-0.96), but not in the MSI-H or TMB-high groups. **Conclusions:** The IIP, as evaluated by Lunit SCOPE IO, may represent a practical, clinically-actionable biomarker predictive of favorable ICI treatment outcomes across diverse cancer patient populations, including those with PD-L1 negative, MSS/TMB-low tumors, in whom predictive biomarkers are urgently needed. Research Sponsor: Lunit Inc.

Dual *CDKN2A/MTAP* loss compared to *CDKN2A* loss alone and response to immune-checkpoint inhibitors (ICI) in advanced solid tumors. *First Author: Elio Adib, The Lank Center for Genitourinary Oncology, Dana-Farber Cancer Institute and Brigham and Women's Hospital, Boston, MA*

Background: We previously showed that *CDKN2A* genomic alterations (GAs) are associated with resistance to ICI (Adib E, Clinical Cancer Research, 2021). The majority of such GAs are homozygous deletions, which commonly (~50-80%) include *MTAP*, located 100kb telomeric of *CDKN2A*. MTAP loss leads to 5′-deoxy-5′-methylthioadenosine (MTA) accumulation and immunosuppressive effects in tumors. We examined combined *CDKN2A/MTAP* deletion vs. *CDKN2A* deletion/mutation alone as predictors of poor ICI response. **Methods:** We curated clinical data for cancer patients (pts) treated with ICI at Dana-Farber Cancer Institute through 6/2021, who had targeted panel sequencing. Inclusion criteria were: ICI in metastatic setting, ≥2 cycles, no concurrent systemic therapy, cancer type with > 50 pts treated. *CDKN2A/MTAP* GAs were defined as a deep deletion affecting both genes; *CDKN2A* only GAs included both homozygous deletions and truncating mutations. Hazard ratios (HR) for overall survival (OS) and time-to-treatment failure (TTF) were derived using multivariable Cox regression, adjusted for prior lines of therapy, treatment type (single vs. combination ICI), tumor mutational burden and ECOG PS. We also used a machine learning approach to quantify the density of tumor-infiltrating lymphocytes (TILs) in digital whole-slide H&E images of 144 melanoma pts with available genomic data. **Results:** 921 pts with 6 cancer types were studied: non-small cell lung cancer (NSCLC, n = 366), melanoma (mel, n = 228), urothelial carcinoma (UC, n = 120), esophagogastric carcinoma (EGC,n = 90), head and neck squamous cell carcinoma (HNSCC, n = 58), and renal cell carcinoma (RCC, n = 59). UC pts with *MTAP/CDKN2A* GAs had shorter OS and TTF than pts without GA in either gene (OS HR = 1.9[1.1-3.4], p = 0.005; TTF HR = 1.8[1.0-3.1], p = 0.0016) after adjusting for covariates. Similar results were seen for melanoma (OS HR = 2.5[1.4-2.6],p = 0.00065; TTF HR = 1.9[1.1-3.2],p = 0.018). There was no significant difference between pts with *CDKN2A* GA only and those without GA in either gene for OS or TTF in either UC or melanoma. *CDKN2A/MTAP* status was not associated with significantly shorter survival for NSCLC and EGC; while the analysis was confounded by HPV events for HNSCC, and underpowered for RCC. ML-based analysis of digital slides for melanoma, showed that tumors with *CDKN2A* GAs only (n = 42) had similar median density of TILs compared to tumors without GAs in either gene (n = 84; 920 vs. 943 TILs/mm2; p = 0.42). In contrast, tumors with co-occurring *CDKN2A/MTAP* GAs had lower TIL density (529 TIL/mm2, n = 17 vs. 925 TIL/mm2, n = 126 (pooled); p = 0.018, Wilcoxon rank sum). **Conclusions:** In this study, we showed that co-occurrence of *MTAP/CDKN2A* GAs, but not CDKN2A GA only, was associated with worse outcomes in pts with UC and melanoma treated with ICI. Lower TIL density was also seen in melanoma tissue samples with combined *MTAP/CDKN2A* GA. Research Sponsor: None.

Comprehensive genomic and immune profiling defines immunotherapy treatment in patients with NSCLC with low PD-L1 IHC. *First Author: Sarabjot Pabla, OmniSeq, Inc., Buffalo, NY*

Background: Immune checkpoint inhibitors (ICIs) have emerged as effective treatments in non-small cell lung cancer (NSCLC). While the clinical utility of single agent ICI or in combination with chemotherapy has been well established, there remains an unmet need for the development of biomarkers that can better predict response. To address this need, we developed and applied a combination genomic and immune biomarker strategy to ICI-treated NSCLC patients which identified distinct patient subgroups with differential benefit among single agent or combination ICI treatment strategies. **Methods:** A discovery cohort (DC) of 5450 tumors across 37 histologies were evaluated by comprehensive genomic and immune profiling of the tumor immune microenvironment. Individual and combination biomarker assessment included PD-L1 IHC, TMB, tumor inflammation (TIGS), cell proliferation (CP) and cancer testis antigen burden (CTAB). From this cohort, combinations of molecular and immune biomarkers were identified and applied to a retrospective cohort (RC) of 225 metastatic NSCLC patients treated with pembrolizumab + chemo or pembrolizumab alone to correlate with response. Comparison of objective response rates (ORR) was performed using Chi-square test. Kaplan-Meir analysis was performed to test for differences in overall survival (OS) and 1-year OS. **Results:** Unsupervised analysis of the DC revealed four distinct biomarker combination groups that describe underlying tumor immunobiology: tumor dominant (CTAB, TMB, CP High), proliferative (CP High), inflamed (TIGS High), and checkpoint (PDL1, TIGS and TMB High). Application of these biomarker groups to the RC demonstrated significant differences in response to ICI regimens between groups (p = 0.04). Patients in the proliferative group (35.1%, 79/225; median PD-L1 = 20% TPS) treated with single agent pembrolizumab showed a significantly higher ORR (59%; 16/27) compared to pembrolizumab + chemo (27%; 14/52; p = 0.005), significantly improved 1-yr OS (p = 0.03), and trend towards better OS (p = 0.14). Importantly, patients in the inflamed group (16%, 36/225; median PD-L1 = 1% TPS), suggested that pembrolizumab + chemo (ORR 26.1%; 6/23) was not associated with ORR compared to pembrolizumab (ORR 31%; 4/13, p = 0.76), or OS (p = 0.37) and 1-yr OS (p = 0.57). **Conclusions:** Comprehensive genomic and immune profiling may identify PD-L1 low NSCLC patients who benefit from single agent pembrolizumab. PD-L1 low NSCLC patients with a proliferative phenotype may benefit from single agent pembrolizumab, whereas PD-L1 low cases with an inflamed phenotype may benefit from both single agent and combination pembrolizumab. Although further clinical validation of these predictive biomarker combinations is required, this data-driven approach demonstrates the potential to provide treatment decision support when selecting an ICI therapeutic strategy in lung cancer. Correlation between MSI, TMB, and RAS gene mutation in solid tumors. *First Author: Qingchang Li, The First Affiliated Hospital of China Medical University, Shengyang, China*

Background: RAS gene family encodes a protein that is a member of the small GTPase super family and plays an important role in the regulation of cell proliferation and promoting oncogenic events. Studies have reported that RAS gene shows a high mutation frequency in lung cancer, colorectal cancer and pancreatic cancer. However, the relation between RAS-mutant and RAS-wild type tumors in tumor mutation burden (TMB) and microsatellite instability (MSI) remain unclear in pan-cancer. **Methods:** We retrospectively analyzed 15188 Chinese patients with pan-cancer from laboratory of Simcere Diagnosis (Nanjing, China) during 2019-2021. Somatic mutations in tumor samples were assessed by next-generation sequencing (NGS). We evaluated RAS (KRAS, NRAS and HRAS) mutation frequency, TMB and MSI in RAS-mutant and RAS wild-type tumors. **Results:** RAS mutations were detected in 2663 (17.5%) samples, including 88.7% of KRAS mutations, 9.1% of NRAS mutations and 3.5% of HRAS mutations. The top 6 frequently cancers were colorectal cancer (829, 31.1%), lung cancer (747, 28.1%), pancreatic cancer (358, 13.4%), biliary tract cancer (210, 7.9%), liver cancer (78, 2.9%), and gastric cancer (73, 2.7%). We found that the incidence of MSI-H in patients with RAS-mutant solid tumors was 3.3% and the frequency of MSI-H was significantly higher in RAS-mutant gastric cancer than that in RAS wild-type (RAS-MUT vs RAS-WT, 20.5% vs 3.5%, p < 0.001). Contrary to our assumption, it was not observed in colorectal cancer (RAS-MUT vs RAS-WT, 5.8% vs 6.9%). In the analysis of TMB, RAS gene mutation was associated with higher TMB (P < 0.01). 27.4% of RAS-mutant gastric cancer and 10.8% RAS wild-type gastric cancer were classified as TMB-H (TMB ≥10 muts/Mb) (P < 0.01), while 13.4% of RAS-mutant colorectal cancer was TMB-H, with no significant difference between RAS wild-type. However, we did not observe a close association between MSI, TMB and RAS gene mutations in lung cancer, pancreatic cancer, biliary tract cancer, and liver cancer. **Conclusions:** We analyzed RAS gene mutations in Chinese patients with solid tumor. Our data showed that RAS mutations were associated with TMB-H and MSI-H in solid tumors, especially gastric cancer. In colorectal cancer, RAS mutations were associated with higher TMB, but not TMB-H. It was showed that RAS mutations in specific cancer types, such as gastric cancer and colorectal cancer, may be related to the efficacy of immunotherapy. Research Sponsor: None.

Prevalence of high tumor mutational burden (TMB-H) and microsatellite instability-high (MSI-H) status in neuroendocrine neoplasms. *First Author: Sukhmani Kaur Padda, Samuel Oschin Cancer Center, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Neuroendocrine neoplasms (NENs) encompass a rare group of tumors arising in nearly any organ site. Patients with advanced-stage NENs have limited treatment options, and molecular profiling is not routinely performed in NENs. However, given tissue-agnostic FDA approvals for immunotherapy in biomarker-selected solid tumors, we sought to assess the frequency of TMB-H and MSI-H in NENs by organ site and in comparison to non-NEN counterparts. **Methods**: We retrospectively analyzed de-identified records from the Tempus database of NENs sequenced with the Tempus xT assay (DNA-seq of 595-648 genes at 500x coverage). Patients were included if their primary cancer arose in the lungs, GI tract (esophagus, stomach, small bowel, colon, rectum), pancreas, or prostate. Histologic diagnoses were grouped as NENs (including high grade or low/intermediate grade), and non-NENs (e.g. adenocarcinoma, squamous cell carcinoma) based on data abstracted from pathology reports. TMB-H was defined as ≥ 10 mutations/megabase. MSI-H was calculated as previously published (PMID: 31570899). Statistical comparisons were limited to groups of 10 or larger. **Results**: We characterized a total of 1,477 NENs from the following anatomic sites: lung (64%, N=951), pancreas (15%, N= 220), GI (15%, N= 224) and prostate (6%, N=82). TMB-H was most common in NENs arising in the lungs (17%, N=155), followed by the pancreas (5.4%, N=11), GI tract (4.8%, N=10), and prostate (3.8%, N=3) (p< 0.001). Overall, TMB-H was more common in high-grade NENs compared to low/int-grade NENs [17% (N=147) vs. 6.2% (N=31), P<0.001]. This was also observed in lung NENs [high-grade 19% (N=135) v low/int grade 10% (N=19), P=0.006], with other organ site analyses limited by sample size (although a similar trend was noted for GI NENs). The majority of patients with TMB-H lung NENs had a current or prior smoking history (94%, N=119). Overall, TMB-H was similar in NENs compared to non-NENs [13% (N=179) vs. 12% (N=3018), P=0.4]. However, in the pancreas, TMB-H was more common in NENs vs. non-NENs [(5.4% (N=11) v 1.6% (N=59), P<0.001] while the reverse was true in lung NENs [17% (N=155) v 22% (N=2006), P=0.001]. MSI-H was observed in only 0.9% (N=12) of NENs overall, including in 0.4% (N=4) of lung, 1.4% (N=3) of pancreas, 1.9% (N=4) of GI, and 1.2% (N=1) of prostate NENs. MSI-H status was less common in NENs compared to non-NENs [0.9% (N=12) vs. 2.5% (N=614), P<0.001]. **Conclusions**: In this real-world NEN cohort, the actionable molecular alterations of TMB-H (13%) and MSI-H (0.9%) were observed. Taken together, the data suggest that molecular profiling (regardless of grade) may help identify a small but meaningful subset of patients with NENs who may benefit from immunotherapeutic treatment approaches. Furthermore, the identification of MSI-H NENs has important implications related to germline testing. Research Sponsor: None.

Automated tumor immunophenotyping and response to immunotherapy in non-small cell lung cancer using a spatial statistics approach. *First Author: Darya Orlova, Genentech, Inc., South San Francisco, CA*

Background: Based on the clinical success of immuno-oncology therapeutics, tissue-based, biomarker analyses have shifted from a focus on tumor cell phenotypes to spatial and functional analyses of the tumor immune environment. Distribution and composition of immune infiltrates have shown prognostic or predictive value in various studies; however, standardized approaches to categorize tumors into "Desert", "Excluded" or "Inflamed" immunophenotypes based on the density and pattern of immune infiltrates are missing. This categorization is typically based on visual inspection of a stained tissue section; it is labor-intensive and associated with poor inter-observer concordance. To eliminate these barriers we developed an automated approach that relies on a set of derived spatial features and named this analysis pipeline LATIS (metric Learning based Automated Tumor Immunophenotyping with Spatial statistics). **Methods:** We used two clinical trials, POPLAR (phase II; n=258) and OAK (phase III; n=623) that compared anti-PD-L1 treatment vs chemotherapy in patients with advanced non-small cell lung cancer to develop and validate this approach. LATIS utilizes scans of slides stained immunohistochemically for CD8 and cytokeratin (CK); images were tiled and classified according to CK status (positive/negative). First, CD8 positive and CK density was calculated for each tile. Twenty six spatial features were then extracted for each tiled image scan. We used a labeled (manual immunophenotype calls) POPLAR dataset to learn a metric that separates classes of labeled data best with respect of spatial features provided for each data point. Then, to co-embed OAK dataset with POPLAR dataset into the same space, we used that learned metric as a measure of distance between new unlabeled points (OAK data set). K-means clustering in the embedded space was used to identify clusters of data points followed by QFMatch to assign class labels ("Inflamed", "Excluded", "Desert") to each data point. **Results:** LATIS successfully relates spatial features to both, manual reads and patient response to therapy. In OAK, anti-PD-L1 treated patients experienced longer median overall survival (OS) when tumors showed intra-epithelial CD8+ cells (Inflamed) compared to tumors with a stromal pattern of CD8+ cells (Excluded) or a low density of CD8+ cells (Desert): 17.6 months vs 10.3 (Excluded) vs 12.1 (Desert) [p=0.0061]. Median progression-free survival (PFS) was 3.2 months (Inflamed) vs 2.6 (Excluded) vs 1.4 (Desert) [p=0.00058]. OS and PFS were not significantly different for the three categories in chemotherapy only arm. **Conclusions:** We suggest that tumor immunophenotype categories generated in an automated fashion by LATIS can serve as predictive biomarker for cancer immunotherapy. Research Sponsor: Roche/Genentech.

Immuno-multiple reaction monitoring (iMRM) for quantitation of PD-L1 and PD-1-signaling proteins in non-small cell lung carcinoma (NSCLC). *First Author: Vincent Lacasse, Lady Davis Institute & McGill University, Montreal, QC, Canada*

Background: More accurate predictive biomarkers of response to checkpoint inhibitors (CPIs) still is a major unmet need in oncology. PD-L1 immunohistochemistry (IHC) limitations include its analytical variability and the post-translational modifications of PD-1 signaling-associated proteins like glycosylation. Moreover, PD-L1 IHC is an imperfect surrogate of the tumor immune microenvironment, and immunoscoring is important but difficult to assess in a clinical setting. Proteomic based technologies can overcome these challenges, but the low concentration of these proteins and the presence of high background noise in formalin-fixed paraffin embedded (FFPE) tumors were limiting obstacles. In this study, we evaluate the benefit of a new approach we used with anti-peptide antibodies to purify surrogate peptides, while liquid chromatography (LC) was coupled to multiple reaction monitoring mass spectrometry (iMRM) to improve specificity and precision of protein quantitation. **Methods:** To determine the concentration of PD-L1, PD-1, PD-L2, NT5E, LCK and ZAP70, we used unique and well detectable proteolytic peptides as surrogates. In a refined protocol, we optimized protein extraction and digestion, peptide immunoenrichment, LC and MRM parameters to maximize recovery, increase target-specific signal and reduce noise. Plus, we assessed the glycosylation status of PD-L1, PD-L2, and PD-1. The entire workflow was fully validated using 31 NSCLC FFPE tumors. PD-L1 quantitation by iMRM was compared to PD-L1 IHC clone 22C3. **Results:** On average, 71±29 μg (n = 52) of protein could be extracted from each 1–3 mm^3 NSCLC tumor FFPE core. The optimized iMRM method allowed the quantitation of PD-L1 and PD-1 down to 21 amol on-column. Inter- and intra-day repeatability were well below FDA guidelines (coefficients of variation [CV] < 20%) with average CVs of 5.2±4.0% (intra-day) and 4.5±2.6% (inter-day). Sample storage had no significant effect on peptide quantitation. The final multiplexed iMRM assay enables quantitation all targets and glycosylation states for > 40 samples in only 3 days (including external calibration and quality controls) and was used to quantify the PD-1/PD-L1 axis proteins successfully in all 31 NSCLC FFPE tumors. PD-L1 expression ranged from 2 amol/μg to 61 amol/μg of total protein. As expected, iMRM results correlated moderately ($R = 0.56$, $\rho < 0.001$) with PD-L1 IHC. PD-L1 glycosylation status ranged from 99.9±0.2%, and therefore did not explain the discrepancies between IHC and iMRM for these samples. **Conclusions:** Herein a robust iMRM workflow was developed for the quantitation of the PD-1/PD-L1 axis in FFPE. This proof-of-concept supports that MS-based assay can provide otherwise unavailable data (e.g., PD-L1 concentration, glycosylation status). CPI treated patient tumors are being currently processed to validate the predictive value of the assay. Research Sponsor: Genome Canada, Other Government Agency.

The expression of aryl hydrocarbon receptor predicts responses to anti-PD-1 antibodies in non-small cell lung cancer. *First Author: Si-Chong Han, State Key Laboratory of Molecular Oncology and Department of Internal Medicine, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Blockade of programmed cell death receptor 1 (PD-1) by antibodies such as pembrolizumab has revolutionized treatment for patients with non-small cell lung cancer (NSCLC). However, a significant number of patients achieve only marginal benefit. The predictive abilities of the frequently used biomarkers, including programmed cell death 1 ligand (PD-L1) and tumor mutation burden (TMB), are yet limited, highlighting the urgent need for more reliable biomarkers. Aryl hydrocarbon receptor (AhR) is a ligand-dependent transcription factor that controls the transcription of its targets including PD-L1. Whether AhR could be used as a predictive biomarker for response to PD-1 blockade immunotherapy in NSCLC warrants further investigation. **Methods:** We collected formalin-fixed, paraffin-embedded (FFPE) slides from 104 NSCLC patients before PD-1 blockade immunotherapy treatment, who had sufficient follow-up data for progression-free survival (PFS), and detected the expression of nuclear localized AhR (AhR^N) and membrane localized PD-L1 ($PD\text{-}L1^M$) with multiplex immunohistochemistry (mIHC). H-score was applied to characterize the specific value with the following formula [1 × (% cells intensity =1) + 2 × (% cells intensity = 2) + 3 × (% cells intensity = 3)]. Survival curve for each group was estimated by the Kaplan–Meier method and log-rank test. The diagnostic performance was assessed with the area under the receiver operating characteristic (ROC) curve (AUC), which was calculated based on the Wilcoxon rank-sum test. All statistical tests were two-sided and *P* values less than 0.05 were considered statistically significant. **Results:** Both AhR^N and $PD\text{-}L1^M$ could distinguish responders from non-responders, and patients with higher H-score had longer PFS than those with lower H score. The AUC of AhR^N was 0.804 (95 % CI: 0.721-0.881), higher than that of $PD\text{-}L1^M$ (0.714; 95 % CI: 0.618-0.811) and AhR^N+$PD\text{-}L1^M$ (0.743; 95 % CI: 0.649-0.837), indicating AhR^N might show better predictive capacity to the efficacy of PD-1 blockade immunotherapy than $PD\text{-}L1^M$. Besides, AhR^N exhibited the most significant accuracy in prognosis prediction, since the hazard ratio (HR) of AhR^N was 0.1529 (95 % CI: 0.07704-0.3033, *P*<0.0001), significantly higher than that of $PD\text{-}L1^M$ [HR:0.283 (95 % CI: 0.1525-0.525, *P*<0.0001)] and AhR^N+$PD\text{-}L1^M$ [HR: 0.2456 (95 % CI: 0.1309-0.4607, *P*<0.0001)]. Yet, among the 54 smokers, AhR^N+$PD\text{-}L1^M$ was the best classifier for the efficacy of immunotherapy, of which the AUC was 0.8937 (95 % CI: 0.816-0.971) and HR was infinitely approaching 0 (*P*<0.0001). **Conclusions**: AhR might be a reliable predictive biomarker for PD-1 blockade immunotherapy in NSCLCs. Research Sponsor: National Natural Science Foundation of China.

2629 **Poster Session**

Pan-cancer analysis of YAP1 expression as a predictive biomarker for cancer immunotherapy. *First Author: Taofeek K. Owonikoko, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: High YAP1 expression correlates with the 'T-cell inflamed' expression phenotype in small cell lung cancer (SCLC), but its association with other biomarkers of immune checkpoint vulnerability and in tumor types beyond SCLC is not known. We examined whether YAP1 expression correlates with other established markers of immune checkpoint blockade (ICB) efficacy (PDL1 expression and TMB) in a tumor agnostic manner to determine clinical relevance. **Methods:** Next-generation sequencing of DNA (592 gene panel or whole exome) and RNA (whole transcriptome) was performed for patient samples (n = 57,134), representing 13 cancer types, submitted to a CLIA-certified laboratory (Caris Life Sciences, Phoenix, AZ). The 'T-cell inflamed' signature (TIS) score was calculated as an 18-gene weighted coefficient composite value (Cristescu, 2018). PDL1 expression was assessed by immunohistochemistry (IHC) with cancer type-specific antibodies and thresholds, and high tumor mutational burden was defined as ≥10 mut/Mb. Patients were stratified into subgroups based on median YAP1 expression (YAP1-High/YAP-Low) within each cancer type. Significance was tested by Chi-square, Fisher's exact test, or Mann-Whitney U test. **Results:** YAP1-High tumors were associated with significantly increased TIS scores compared to YAP1-Low across all 13 cancer types examined, with the largest fold increase observed in SCLC (1.33-fold, $p < 0.0001$), followed by pancreatic cancer (1.28-fold, $p < 0.0001$), while the smallest occurred in melanoma (1.13-fold, $p < 0.0001$). Spearman correlation strength (range 0.23-0.57) between YAP expression and TIS scores was consistent with increased TIS scores in YAP1-High samples. TMB-High rates were similar in YAP-High and YAP1-Low subgroups for most cancer types, with slightly lower rates in YAP1-High tumors observed for endometrial (23.0 vs 26.6%, $p < 0.001$) and esophageal (7.0 vs 9.5%, $p < 0.05$) cancers. YAP1 expression was not significantly increased in PDL1+ (IHC) tumors for most cancer types. However, significantly decreased YAP1 expression was associated with PDL1+ samples in RCC (Renal Cell Carcinoma) (0.91-fold change, $P < 0.05$), MM (0.90-fold change, $P < 0.001$), and ENCA (0.80-fold change, $P < 0.0001$) **Conclusions:** Our analyses provide confirmation that YAP1 expression positively correlates with the 'T-cell inflamed' phenotype across many cancer types, including those with approvals for (ICB) therapy. YAP1 expression was independent of established markers of ICB response, including TMB and PDL1. Further analysis of YAP1 expression as an additional tumor agnostic predictive biomarker is warranted. Research Sponsor: None.

A pancancer analysis of impact of *MDM2*/*MDM4* on immune checkpoint blockade (ICB). *First Author: Wafik S. El-Deiry, Cancer Center at Brown University, Providence, RI*

Background: *MDM2/MDM4* are implicated in hyperprogression after immune checkpoint blockade (ICB). Our preclinical studies showed reduced T-cell killing of *MDM2*-amplified tumor cells that was overcome by an MDM2 antagonist or gene knockdown, and we observed additional tumor killing by T-cells with MDM2 inhibition plus anti-PD1. We hypothesized that *MDM2/4* gene amplification/overexpression correlates with resistance to ICB and investigated the association of MDM2/4 alterations to overall survival (OS) following ICB across multiple solid tumors. **Methods:** Solid tumors tested at Caris Life Sciences (Phoenix, AZ) with NextGen Sequencing on DNA (NGS) were analyzed. *MDM2/4* amplification (amp) was tested by NGS and determined as either amp4 (cutoff of >=4.0 copies) or amp6 (>=6.0) or amp8 (>=8.0). Real-world OS was obtained from insurance claims data and calculated from treatment start or tissue collection to last contact. Kaplan-Meier estimates were calculated for molecularly defined groups. X^2/Fisher-Exact were used and significance determined as P-value adjusted for multiple comparisons ($q<0.05$). **Results:** In a large cohort of TP53-wild type solid tumors, 2785 had *MDM2* amp4 (262 were ICB-treated), 2108 had *MDM2* amp6 (ICB: 192), 1721 had *MDM2* amp8 (ICB: 149); 1040 tumors had *MDM4* amp4 (ICB: 59), 293 had *MDM4* amp6 (ICB: 8) and 217 had amp8 (ICB: 4). NSCLC, GBM, breast, bladder cancer and liposarcoma had the highest *MDM2* amp and breast cancer, GBM, uterine, NSCLC and ovarian cancers had the highest *MDM4* amp. When all tumors were considered, *MDM2* amp4, 6 and 8 significantly associated with shortened OS (amp4: HR 1.31; amp6: HR 1.31; amp8: 1.29, all $p<0.0001$); similar results were seen with *MDM4* (amp4: HR 1.14, $p=0.004$; amp6: HR 1.51, $p<0.00001$ and amp8: HR 1.6, $p<0.00001$). Of note, *MDM4* amp4 but not *MDM2* amp4 was associated with significantly worse post-ICB survival (HR: 1.55, $p=0.009$).When comparing molecular differences between *MDM2* amp4 and *MDM4* amp4, significantly higher PDL1 expression was associated with *MDM2* amp (Ab clone 28.8: 58% vs. 28%; clone 22c3: 48% vs.25%, $q<0.05$); while higher mutation rates of *ARID1A*, *PIK3CA*, *PTEN*, *KRAS* and *CTNNB1* were associated with *MDM4* amp (all $q<0.05$). When investigating NSCLC, *MDM4* amp4 was associated with decreased post-ICB survival in NSCLC (HR: 2.59, $p=0.001$) but not *MDM2*; when comparing the molecular alterations, *MDM2* amp was associated with significantly higher PDL1 (22c3) (54% vs. 27%), *EGFR* mutation (36% vs. 14%) but less prevalent *KRAS* (15% vs. 50%), *STK11* (11% vs. 41%), *KEAP1* (2.5% vs. 27%) and *BRAF* (2% vs. 16%) mutations. The association with poor prognosis of *MDM2* amp4/6 (HR: 1.2 and 1.3, $p<0.05$) and *MDM4* amp4/6 (HR: 1.3 and 1.6, $p<0.05$) was seen in breast cancer, but not in NSCLC, GBM, bladder or uterine cancers. **Conclusions:** *MDM2* and *MDM4* amplification are negative prognostic factors in TP53-WT breast cancer while *MDM4* amp is associated with reduced survival in ICB-treated NSCLC. Research Sponsor: None.

2631 **Poster Session**

Systematic assessment of tumor mutational burden calculation across different sequencing platforms and cancer types and its implication in clinical decision-making. *First Author: Daqiang Sun, Tianjin Chest Hospital, Tianjin, China*

Background: Tumor mutation burden (TMB) has been validated as a biomarker to predict the response of immune checkpoint inhibitors (ICIs) treatment in various cancers. However, the effects of different sequencing platforms, cancer types and calculation methods on TMB as well as its cut-off value for predicting immunotherapy efficacy are still need to be further investigated. **Methods:** 4140 tumor samples were performed with targeted panel sequencing or whole exome sequencing (WES) in different platforms such as illumina and MGI. Public sequencing data from 3680 samples which contained targeted panel sequencing, WES and whole genome sequencing were obtained. The impact of different sequencing platforms, sequencing methods and calculation methods on the calculation of TMB were assessed. Further, targeted panel sequencing data from 71 sample of lung cancer patients treated with ICIs were used to determine the best cut-off value of TMB for predicting immunotherapy response. **Results:** TMB values calculated by different platforms and different sequencing methods were similar and there was no significant difference. The distribution of TMB at different sequencing depths and tumor purity were analyzed. We found that there was no significant difference in the distribution of TMB when the sequencing depth was greater than 500, the HE purity was greater than 0.1 or NGS purity was greater than 0.3. In addition, the correlation of TMB calculated from single-sample and paired-sample is 0.95. Further, the optimal cut-off value of TMB in lung cancer treated with ICIs was determined to be 8 through ROC curve analysis, and patients with TMB ≥ 8 had better outcomes than patients with TMB < 8. **Conclusions:** This study systematically analyzed the factors which influenced the TMB calculation, and verifies the feasibility of TMB calculation from single-sample. More importantly, the cut-off value of TMB for predicting immunotherapy efficacy in lung cancer was defined as 8 in East Asian populations, which can help in clinical decision-making. Association between tumor mutational burden (TMB) and mutational profile and its effect on overall survival: A post hoc analysis of patients with TMB-high and TMB-low metastatic cancer treated with immune checkpoint inhibitors (ICI). *First Author: Camila Bragança Xavier, Hospital Sírio-Libanês, São Paulo, Brazil*

Background: High-TMB was recently approved as an agnostic biomarker for pembrolizumab in advanced cancers. Still, several patients with high-TMB do not respond to ICI, while some patients with low-TMB benefit from immunotherapy. **Methods:** We collected genomic (MSK-IMPACTassay) and survival data from 1,661 patients and assessed OS (Kaplan-Meier method) according to the mutational status. To better qualify patients with TMB ≥ 10 mut/Mb (TMB-H) (N = 488, 29%) and TMB < 10 mut/Mb (TMB-L) (N = 1,173, 71%) for ICI treatment, we analyzed single gene alterations impacting OS ($P < 0.05$). For all genes exhibiting a correlation with OS, we conducted a Cox multivariate analysis stratified by median TMB, sex, median age, microsatellite instability (MSI) status, and histology. **Results:** Survival to ICI increased with higher TMB. Median OS was 42 and 15 months for TMB-H and TMB-L ($P < 0.05$), respectively. For TMB-H tumors, 5 genes (*STK11, KEAP1, CIC, E2F3, TP53*) exhibited reduced OS on ICI, and 22 genes (*NTRK3, TERT, NOTCH3, RNF43, TET1, PTPRD, NCOA3, TENT5C, ZFHX3, RIT1, CCNE1, PPM1D, GATA2, ALK, DNMT1, PTPRT, MET, EPHA7, BCL6, SMO, CDK6, MED12*) were associated with better OS, $P < 0.05$. Cox multivariate analysis confirmed a correlation between mutations in *STK11* and *E2F3* with worse OS, while mutations in *NTRK, PTPRD, RNF43, TENT5C, TET1,* and *ZFHX3* were associated with better OS ($P < 0.05$). Histology did not play a relevant role in ICI response except for melanoma (better OS; $P < 0.05$). MSI status did not significantly affect OS. For TMB-L tumors, 20 genes were related with reduced OS (*TP53, H3C2, DAXX, SMARC4, STK11, SOX17, RB1, PIK3CA, CTNNB1, KMT2D, HLA-A, FBXW7, CDH1, RBM10, KEAP1, IGF1R, H3C11, EGFR, RUNX1, B2M*), while 8 genes were associated with better OS (*VHL, SETD2, PBRM1, BRAF, KDM5C, MAP2K1, CSF1R, RET),* $P < 0.05$. Cox multivariate analysis confirmed 15 genes associated with superior (*KDM5C, PBRM1,* and *VHL*) and inferior (*CTNNB1, DAXX, FBXW7, H3C2, H3C1, IGF1R, KMT2D, PIK3CA, RB1, SMARC4, SOX17, TP53*) OS ($P < 0.05$). In the TMB-L context, melanoma histology and MSI status (except among VHL-mutated tumors) were independently associated with better OS. **Conclusions:** This pan-cancer analysis demonstrates that genomic alterations in single cancer genes can help define outcomes of TMB-H and TMB-L patients treated with ICI. Research Sponsor: None.

Age-associated differences in transcriptional expression and tumor immune microenvironment composition among older patients with cancer. *First Author: Khalil Choucair, University of Kansas School of Medicine, Wichita, KS*

Background: Older patients (pts) with cancer are underrepresented in registrational clinical trials for immune checkpoint inhibitor (ICI) therapies. There may be relevant differences in the makeup of the tumor microenvironment (TME) and in genomic signatures of cancer in older pts. This analysis explores differences in the genomic makeup of common cancers and their TME in pts ≥ 80 years (yr) of age, compared to younger pts. **Methods:** Next-generation sequencing of DNA (592 gene panel, NextSeq or whole-exome sequencing, NovaSeq) and RNA (whole transcriptome sequencing, NovaSeq) was performed for non-small cell lung carcinoma (NSCLC; n = 19,891), melanoma (MEL n = 2,899), and renal cell carcinoma (RCC; n = 1,333) pt samples submitted to a CLIA-certified laboratory (Caris Life Sciences, Phoenix, AZ). PD-L1 expression was assessed by immunohistochemistry (IHC), and high tumor mutational burden (TMB-H) was defined as ≥10 mut/Mb. Pts were stratified into age subgroups of ≥80 and < 80 yr for comparison of DNA damage response (DDR) gene alterations, gene expression profiling, and TME analysis (MCP-counter; Becht, 2016). *P-values* were adjusted for multiple hypotheses testing (Benjamini-Hochberg) unless noted as exploratory. **Results:** Pts ≥80 yr accounted for 16.0%, 19.9% and 5.3% of NSCLC, MEL and RCC pts, respectively. Compared to pts < 80 yr, NSCLC and MEL pts ≥80 yr had similar DDR gene mutation rates, while *BRCA1* mutations were more common in MEL pts ≥80 yr (2.1 *vs* 0.8%; exploratory-$p < 0.05$). NSCLC ≥80 yr TMEs had increased abundance of fibroblasts (1.09-fold, $p < 0.01$), dendritic cells (1.07-fold, $p < 0.01$) and macrophages (1.04-fold, $p < 0.01$), and MEL≥80 yr TMEs had fewer infiltrating T-lymphocytes (0.87-fold, $p = 0.02$). Increased expression of immune checkpoint (IC) genes *PDCDL1G2* (PD-L2; 1.11-fold), *HAVCR2 (*TIM-3; 1.11-fold*)*, and *CD80/86* (1.07/1.08-fold, $p < 0.05$) was seen in NSCLC pts ≥80 yr, while *IL-6* expression was decreased (0.88-fold; $p < 0.05$). The largest change in IC gene expression was for *IL-6* (1.24-fold, $p = 0.78$) in MEL, and *GZMB* (0.56-fold*;* $p = 0.17$) in RCC ≥80 yr. TMB-H was less common in NSCLC (29.7 vs 36.5%, $p < 0.001$) and more common in MEL pts ≥80 yr (65.7 vs 49.0%, $p < 0.01$), and PD-L1 (IHC-SP142, ≥2+l5%) expression was less frequent in RCC pts ≥80 yr (9.1 vs 19.4%, exploratory $p < 0.05$). Profiling of glutamine and glucose metabolism-related genes revealed increased *SLC38A5* (1.17-fold; $p < 0.0001$) and decreased *G6PC* (0.65-fold, $p < 0.01$) expression in NSCLC ≥80 yr. While not statistically significant, MEL and RCC pts ≥80 yr had opposite trends for *SLC38A5* and *G6PC* expression. **Conclusions:** Our analysis provides new insights to immune landscape of NSCLC, MEL, and RCC pts ≥80 yr. Differential gene expression and TME composition changes in this population suggest unique, cancer-specific therapeutic opportunities, and a potential to explore biomarkers of response to ICIs. Microsatellite-stable tumors with high tumor mutational burden in association with tumor response to immune checkpoint inhibitor therapy across solid tumors and correlation with specific oncogenic alterations. *First Author: Imran Nizamuddin, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: High tumor mutational burden (TMB-H) has shown promise as a predictive biomarker in certain tumors, but broad applicability across tumors is unclear. In 2020, pembrolizumab was approved for treatment refractory metastatic or unresectable solid tumors with TMB ≥10 mutations/megabase based on exploratory analysis of the KEYNOTE-158 study. Growing evidence suggest limitations of TMB-H across tumors. Our aim is to evaluate outcomes of patients (pts) with advanced microsatellite-stable (MSS) solid tumors with TMB ≥10 mutations/megabase treated with immune checkpoint inhibitors (ICIs) and identify genetic alterations that predict poor response to therapy. **Methods:** Pts treated between 01/2015 to 12/2020 at Robert H Lurie Cancer Center, Northwestern University, with ICIs and TMB ≥10 mutations/megabase on next generation sequencing by FoundationOne CDx, Tempus xT or Guardant360 CDx platforms were identified. Tumors other than carcinomas and microsatellite instability were excluded. Radiologic response was assessed using iRECIST criteria. Responders (CR/PR) were compared with non-responders (SD/PD). Subgroup analyses were conducted based on tumor type, genetic alterations within signaling pathways. Survival curves were calculated using Kaplan-Meier method. Multivariate analyses were performed to determine impact of clinical variables on response. **Results:** Of 119 pts, median age was 68 yrs, and 61% of pts were male. 15 tumor types were represented, most commonly melanoma (33%), NSCLC (28%), small cell lung carcinoma (5.9%), colorectal carcinoma (5%), and pancreatobiliary carcinoma (5%). When evaluating for efficacy (n = 106), ORR was 36% with CR 14%. Median PFS and OS overall were 10.9 mo and 29.9 mo. Lack of exposure to previous therapy was associated with response (p = 0.039). PD-L1 status, specific ICI regimen, age, and sex did not have prognostic significance. When comparing melanoma/NSCLC (n = 66) and other tumor types (n = 40) there was no significant difference in response (p = 0.3). When comparing response by specific gene mutations, *TP53* (p = 0.026) and *PIK3CA* (p = 0.025) were associated with worse response. Similarly, *ROS1* alteration trended to poorer response (p = 0.057). When evaluating genetic pathways, mutations within TP53 pathway were associated inferior response (p = 0.018). There was no significant difference in RTK/RAS, NRF2, PI3K, TGFβ, WNT, MYC, Cell Cycle, and Notch pathways. **Conclusions:** Growing evidence shows limitations of TMB-H as a predictive biomarker for ICI therapy in MSS tumors. Our data suggests alterations within *TP53* and its signaling pathway, *PIK3CA* mutations, and likely *ROS1* alterations are associated with non-responders in MSS TMB-H solid tumors. Further analysis of tumor-specific cohorts and genetic alterations will be presented. Research Sponsor: None.

PD-L1 expression and microsatellite instability in tumors of unknown primary site. *First Author: Joao Neif, Barretos Cancer Hospital, Barretos, Brazil*

Background: Cancer of unknown primary site is a heterogeneous group of tumors for which the origin remains unknown, despite detailed investigation. Its clinical presentation occurs due to symptoms resulting from metastasis, which can be influenced not only by biological processes of the tumor, but also due to regulatory processes in the tumor microenvironment such as PD-L1. Microsatellite instability (MSI) is a predictive biomarker for cancer immunotherapy and its status as well as co-occurrence with PD-L1 expression is poorly evaluated. The aim of this study was to evaluate the expression of PD-L1 and the status of MSI in tumors of unknown primary site and their possible associations with clinical-pathological characteristics and clinical outcomes in patients with this type of tumor. **Methods:** The PD-L1 expression was evaluated using the immunohistochemistry technique and measured by CPS and TPS scores. MSI status was assessed using a hexa-plex marker panel by polymerase chain reaction followed by fragment analysis. Overall survival was analyzed using the Kaplan Meier method and comparisons of the curves using the log rank test. **Results:** Of the 121 conclusive cases for MSI status, only two cases (1,6%) were MSI-High. PD-L1 expression, assessed by both TPS and CPS, was positive in approximately 18% of 108 conclusive cases. PD-L1 expression is significantly less frequent in patients with a predominance of hepatic or bone metastasis and more frequent in patients with a predominance of nodal metastasis. The median overall survival was about 4 months, and the predominance of liver metastases was associated with a worse prognosis, while the use of chemotherapy and low ECOG-PS were associated with better survival. PD-L1 expression was associated with better overall survival. **Conclusions:** PD-L1 is expressed in a subset of patients with cancer of unknown primary site, while MSI is a rare event. It is necessary to better explore the microenvironment of this type of tumor as well as the role of immunotherapy to change such a dismal clinical outcome. 14-gene immunoglobulin (IGG) and proliferation signatures and association with overall survival across cancer-types. *First Author: Francesco Schettini, Hospital Clinic of Barcelona, Barcelona, Spain*

Background: The HER2DX prognostic assay in early-stage HER2-positive breast cancer integrates clinical variables and 4 gene expression signatures (GES) tracking IGG, tumor proliferation, luminal cell differentiation, and the expression of the HER2 amplicon. Here, we assessed the prognostic value across cancer-types of each of these four individual GES and a research-based version of the HER2DX risk-score. **Methods:** RSEM batch normalized RNA-sequencing gene expression data from The Cancer Genome Atlas (TCGA) project were downloaded from cBioPortal. The association between a research-based version of the HER2DX risk-score, and each GES, with overall survival (OS) was assessed as continuous variables using univariate Cox regression model. The research-based version of the HER2DX risk-score tested did not include clinical variables. The Cox model was applied to estimate hazard ratios (HR) with 95% confidence intervals. The threshold for statistical significance was set at $p< 0.05$. **Results:** Gene expression data from 9,852 patients representing 30 different cancer-types were evaluated. The proliferation, IGG, luminal and HER2 amplicon GES were significantly associated with OS in 40.0%, 33.3%, 23.0% and 6.7% of the cancer-types tested, respectively. The IGG GES was found significantly associated with a favorable OS in breast cancer (HR: 0.73, p < 0.001), cervical and head & neck squamous cell carcinomas (HR: 0.75, p = 0.021 and HR: 0.78, p < 0.001), lung adenocarcinoma (HR: 0.84, p = 0.020), skin melanoma (HR: 0.73, p < 0.001) and sarcomas (HR: 0.78, p = 0.029). Conversely, association of IGG GES with unfavorable OS was observed in uveal melanoma (HR: 1.74, p = 0.008), kidney clear cell and papillary cell carcinomas (HR: 1.29, p < 0.001 and HR: 1.44, p = 0.017, respectively), as well as brain low-grade gliomas (LGG) (HR: 1.56, p < 0.001). Finally, the research-based HER2DX risk-score was found significantly associated with OS in 11 of 30 (36.7%) cancer-types, including breast (HR: 1.42, p < 0.001) cervical and head & neck squamous cells cancers (HR: 1.36, p = 0.018 and HR: 1.30, p < 0.001), lung adenocarcinoma (HR: 1.34, p < 0.001), skin melanoma (HR: 1.34, p < 0.001), sarcomas (HR: 1.41, p = 0.003), adrenocortical carcinoma (HR: 2.31, p < 0.001), endometrial carcinoma (HR: 1.36, p = 0.005), hepatocarcinoma (HR: 1.26, p = 0.012), LGG (HR: 1.37, p = 0.001) and mesothelioma (HR: 1.48, p = 0.005). **Conclusions:** The 14-gene IGG and proliferation signatures are strong prognostic biomarkers across cancer-types. The opposite association of IGG with OS depending on the cancer-type warrants further investigation. Research Sponsor: None.

Phase 1 studies of personalized neoantigen vaccine TG4050 in ovarian carcinoma (OC) and head and neck squamous cell carcinoma (HNSCC). *First Author: Jean-Pierre Delord, Department of Oncology, Institut Claudius Regaud, IUCT-Oncopole, Toulouse, France*

Background: Mutation-associated neoantigens (MANAs) constitute attractive antigens for the design of cancer vaccines. However, clinical implementation remains challenging because of the patient specific nature of MANAs, hereby requiring that a bespoke vaccine is designed for each subject. We developed a pipeline for the genomic characterization and the design of tailored vaccine using a modified vaccinia Ankara viral vector. **Methods:** Immunogenicity, safety and early clinical activity of personalized cancer vaccines are being assessed in two phase I trials, respectively in high grade serous OC and HPV-negative HNSCC. Patients (Pts) at high risk of relapse are enrolled in the study being in remission following surgical primary treatment. High risk is defined as stage IIIC or IVA for OC and stage III or IVA for HNSCC. A vaccine is manufactured for each patient. OC pts are treated at asymptomatic relapse based on radiological finding or elevation of CA-125 with the vaccine alone; HNSCC pts in complete remission after surgery and adjuvant therapy are randomized to receive the vaccine either at the end of locoregional treatment or in combination with standard of care at relapse. The vaccine was administered weekly for 6 weeks and a booster dose every three weeks over a year or until progression, whichever occurred first. **Results:** At the time of the data cut-off, a total of 8 pts were treated: 4 relapsing OC pts, 3 HNSCC pts in complete remission and 1 relapsing HNSCC pt. AE attributable to the vaccine were mainly grade 1 injection site reactions and fatigue. One OC pt displayed an objective response 6 weeks after initiation of vaccine and for 9 months with a normalization of CA-125 until death from an unrelated cause; 1 other OC pt remains on treatment with a stable radiological disease for 11 months. The 2 other OC progressed at the first evaluation on day 43. HNSCC pts treated in complete remission received respectively 20, 15 and 4 doses, and remain on treatment and disease free. One HNSCC patient received 9 doses of vaccine after relapse in conjunction with chemotherapy and anti-PD-1 therapy and remains on treatment with stable disease after 5 months. Immune monitoring demonstrates priming of a polyepitopic T cell response against class I and II antigens. Responses were observed regardless of HLA and without cross-reactivity to the germline protein. Adaptive response was associated with a shift of CD4 and CD8 T cells toward an effector phenotype and innate cellular immunity was activated with a strong maturation and activation of NK cells. Immune changes were stronger in pts with controlled disease versus progressors. **Conclusions:** Data demonstrate that TG4050 is safe, well tolerated and able to induce T cell responses whatever the HLA haplotype. Early signs of clinical activity were observed in OC pt. These data pave the way for further development and synergistic immunotherapeutic combinations. Clinical trial information: NCT04183166. Research Sponsor: TRANSGENE.

Personalized neoantigen DNA vaccines expand tumor-specific T cells in the periphery which infiltrate the tumor in hepatocellular carcinoma. *First Author: Renzo Perales, Geneos Therapeutics, Plymouth Meeting, PA*

Background: Tumor neoantigens are epitopes derived from tumor-specific mutations that can be incorporated in personalized vaccines to prime T cell responses. DNA vaccines delivered with electroporation have recently shown strong CD8 and CD4 T cell responses in clinical trials. In preclinical studies, DNA-encoded neoantigen vaccines have shown induction of CD8 T cells against 50% of predicted high affinity epitopes with the ability to impact tumor growth. **Methods:** Paired blood and tumor biopsy samples were collected from a patient with hepatocellular carcinoma before and after treatment with GNOS-PV02 (DNA neoantigen targeted vaccine) + plasmid IL-12 + pembrolizumab. Treatment resulted in a partial response with a decrease in tumor size of 44% by RECIST (168 mm to 94 mm). TCRbeta sequencing was performed on all 4 samples and single cell TCR and transcriptome sequencing was performed from T cells isolated from the post-treatment blood sample. Newly identified TCRs in blood and tumor after vaccination were inserted into an expression vector and used to generate engineered TCR T cells. Engineered TCR T cells were tested against the neoantigens included in the vaccine and their responses characterized by flow cytometry. **Results:** We identified 67,893 new clones in PBMC after vaccination, 3 of which comprised between 0.1 to 1% of the total T cell clones. Moreover, we identified 5126 new clones in the tumor post vaccination, out of these, 3878 (75.68%) were not found within the patient's pre vaccination PBMCs and 556 (10.86%) were identified within the pre vaccination PBMC pool. Importantly, of the newly identified T cells infiltrating the tumor post vaccination, we observed high frequency TCR clones of which 44 and 7 clones were above 0.1% and 1%, respectively. The majority of the newly identified T cell clones were CD8 T cells (68.75%) with an activated phenotype. Importantly, the 6 most expanded clones in blood were identified to be activated CD8+CD69+ T cells (81.82%). Engineered TCR T cells generated encoding the TCRs of these newly identified CD8 T cells showed activation when exposed to the tumor neoantigens encoded in the neoantigen DNA vaccine GNOS-PV02. **Conclusions:** GNOS-PV02, a neoantigen DNA vaccine, in combination with plasmid IL-12 and pembrolizumab resulted in expansion of newly identified T cells, primarily activated CD8, which trafficked to the tumor. These new tumor infiltrating T cells showed TCR specificity against tumor neoantigens encoded in GNOS-PV02 and may account for the observed objective decrease in tumor size. Research Sponsor: Geneos Therapeutics.

Preliminary results from an early phase trial of in situ immunization of lymphoma with a virus likeparticle containing a TLR9 agonist combined with anti-PD1 therapy (NCT03983668). *First Author: Umar Farooq, University of Iowa Hospitals and Clinics, Holden Comprehensive Cancer Center, Iowa City, IA*

Background: *In situ* immunization involves intratumoral (IT) injection of immunostimulatory agents to modify the tumor microenvironment with the goal of inducing an anti-tumor T cell response. Here, we report preliminary results of a clinical trial exploring *in situ* immunization with a virus like particle (VLP) combined with systemic pembrolizumab (Pembro) in lymphoma. The VLP, known as CMP-001 or vidutolimod (Vidu), is composed of the bacteriophage Qb capsid encapsulating the TLR9 agonist G10. Preclinical studies demonstrated generation of antibodies against the Qb capsid (anti-Qb) is necessary for Vidu to induce an anti-tumor response. In other cancers, early phase clinical trials of *in situ* immunization with Vidu, with and without systemic anti-PD1 therapy, have revealed early promising results. **Methods:** This trial included patients with relapsed lymphoma that have failed at least 1 line of therapy. The first dose of Vidu is given subcutaneously to stimulate anti-Qb that opsonizes the VLP. This is followed by IT Vidu administered weekly for seven doses, then at 3-week intervals. Pembro (200 mg fixed dose) is given intravenously every 3 weeks. Subjects continue treatment if they do not experience unacceptable toxicities and in the investigator's opinion continued treatment is in the subject's best interest. Fine needle aspirates for flow cytometric analysis are obtained prior to therapy and 4-6 weeks following initiation of therapy. **Results:** Six patients have enrolled to date (1 CR, 2 PR, 1 SD, 2 PD). The first 3 patients received 5mg Vidu per dose and the second cohort 7.5 mg per dose. Common side effects included chills, rigors, mild headache, and fatigue. These typically resolved within 4 hours after receiving the injection. **Conclusions:** *In situ* immunization with Vidu plus systemic anti-PD1 is a promising therapy in lymphoma. The ability to generate anti-Qb that opsonizes the VLP appears to be necessary for Vidu to induce an immune and therapeutic response. Accrual and correlative studies are continuing with the modification that generation of functional-Qb after the first dose of Vidu is required before patients receive IT therapy. Clinical trial information: NCT03983668. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Pt.	Diagnosis and key prior Rx	Clinical and correlative findings	Preliminary interpretation
1	DLBCL Post CAR-T	No benign B cells, toxicity, or anti-Qb generated - Progression	Anti-Qb is required for therapeutic response
2	FL < 1 yr post rituximab		
3	FL > 2 yrs post rituximab	Flare reaction on PET but achieved CR	Vidu can cause PET pseudo-progression
4	ALK + ALCL	- PR	T cell lymphomas can respond
5	FL ~ 1.5 yrs post obinutuzumab	Generated very low, but functional levels of anti-Qb, Low grade toxicity - SD	Low levels of anti-Qb are adequate for opsonization of VLP
6	FL > 2 yrs post rituximab	Regression of injected and contralateral (un-injected) nodes - PR	Anti-tumor effect is systemic

First-in-human/phase I trial of PE0116 (4-1bb Ig G4 McAb) as single agent in patients with solid tumors progressed after lines of therapies in China. *First Author: Hui Zhao, Departments of Internal Oncology, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiaotong University, Shanghai, China*

Background: The 4-1BB co-stimulatory protein is an important modulator of the adaptive T Cell immune responses, and potentially a vital target for immunotherapies in oncology. HE0116 is a humanized agonist antibody to 4-1BB that promotes proliferation and activation of T cells. The FIH/phase Ia/Ib study was conducted to establish a maximum tolerated dose, identify dose-limiting toxicities (DLTs) and to assess safety, tolerability, and pharmacokinetics of HE0116 as single agent in patients with solid tumors who have progressed on standard of care (SoC) and experimental therapies. **Methods:** Patients (pts) with histologically confirmed solid tumors who progressed after prior SoC and experimental therapies were enrolled. A Fibonacci 3+3 design was employed for the phase 1a dose escalation of 9 dose levels. HE0116 was administered intravenously once in first 28-day cycle for PK analysis and DLT assessment. Pts continued HE0116 treatment every 3 weeks until experiencing an intolerable toxicity, disease progression or withdrawing consent. **Results:** As of January 25, 2022, 19 pts were enrolled in the dose-escalation phase). All pts had progressed on multiple lines of therapies, including but not limited to, chemotherapy, hormonal therapy, or/and immunotherapy. As defined in study protocol, pts received HE0116 intravenously at least once at six dose levels: 0.03 mg/kg (n = 1), 0.1 mg/kg (n = 3), 0.3 mg/kg (n = 3), 1 mg/kg (n = 4), 2 mg/kg (n = 3), and 3 mg/kg (n = 5). One DLT of Grade (g) 4 platelets decrease was reported at 3 mg/kg, thus 3 new pts were added at this dose. The grade1 and grade2 HE0116 related adverse events (AEs) per CTCAE v5 that occurred (< 10% frequency) were ALT and AST increase, platelet decrease, WBC decrease, anemia, hypokalemia, hyponatremia, hypoalbuminemia, hypothyroidism, or bone pain. Three SAE were reported: 1 g2 ascites, 1 g4 dyspnea, 1 g2 fever. To date there was one iPR at 1 mg/kg for a pt with advanced ovarian cancer with liver met after 6 cycles of treatment, and 4 iSD (1 in 2 mg/kg, 3 in 3 mg/kg) were recorded. **Conclusions:** HE0116 administrated intravenously every 3 weeks is well tolerated with minimal toxicities. Preliminary data are very encouraging as single agent HE0116 showed durable responses with 1 iPR, 4 iSD in several difficult to treat late-stage cancer pts. Dose escalation is ongoing as per study protocol. Phase II in select patient populations, and clinical investigation of the combination of HE0116 with CTLA-4 or PD-1 are warranted. Clinical trial information: CTR20201794. Research Sponsor: HyaMab Biotech.

A phase I dose-escalation and expansion study of HBM4003, an anti-CTLA-4 heavy chain only monoclonal antibody, in patients with advanced solid tumors. *First Author: Shanzhi Gu, Department of Interventional Radiology, Hunan Cancer Hospital, Changsha, China*

Background: HBM4003 is a fully human heavy chain only monoclonal antibody (HCAb) to CTLA-4, which has been engineered to deplete Treg cells by enhanced antibody-dependent cellular cytotoxicity (ADCC) activity. In the Phase 1 dose escalation part, HBM4003 showed favorable safety and efficacy profile in patients (pts) with advanced solid tumors. Here, we present the updated data from the dose escalation part and most recent safety and clinical activity data from three expansion cohorts of pts with advanced hepatocellular carcinoma (HCC), melanoma, and renal cell carcinoma (RCC). **Methods:** In the dose-escalation part, pts were enrolled into 3 dose levels (DL): 0.3mg/kg QW (28-day cycle), 0.45mg/kg Q3W (21-day cycle), and 0.6mg/kg Q3W (21-day cycle). In the dose-expansion part, pts with advanced HCC, melanoma, and RCC received 0.45 mg/kg Q3W (21-day cycle). Tumor measurements were performed every 6 weeks for up to 12 months and subsequently every 12 weeks per RECIST v1.1. **Results:** In total 60 pts were included for this analysis, including 24 pts with advanced solid tumors in the dose escalation part and 36 pts in the dose expansion part: 18 pts with HCC, 4 pts with melanoma, and 14 pts with RCC, from 12 sites in mainland China, 5 sites in Australia, and 1 site in Hong Kong. 46 pts (77%) received ≥ 2 lines of previous systemic therapies and 37 pts (62%) received previous PD-1/PD-L1 treatment. For the HCC cohort, 19 pts were treated in dose-escalation (1 pt, 0.45 mg/kg Q3W) and dose-expansion parts. All 19 pts received previous PD-1/PD-L1 therapy. 12 pts were evaluable for efficacy. Two had stable disease (SD), 2 pts had partial response (PR) as best response. For 12 evaluable pts, ORR was 16.7% and disease control rate (DCR) was 33.3%. For the RCC cohort, 19 pts were treated in dose-escalation and dose-expansion parts; 18 pts were evaluable for efficacy. Eight had SD as best response; the DCR was 44.4%. Overall, the most common treatment-related adverse event (TRAE) (incidence ≥ 10%) of all grades was rash (16 [26.7%] pts). At the 0.45 mg/kg Q3W DL, the most common TRAE of all grades was hepatic function abnormalities (12 [27.9%] pts) and rash (12 [27.9%] pts). 30 (69.8%) pts reported Gr 1 or 2 TRAEs. Gr ≥3 TRAEs occurred in 4 (9.3%) pts. 1 pt reported Gr 4 TRAE: blood creatine phosphokinase increased. No Gr 5 TRAE was reported. TRAE leading to discontinuation occurred in 4 pts. In mouse model, only tumor infiltrating lymphocytes Treg was depleted upon HBM4003 treatment while no Treg change in blood and spleen. In pts, Treg depletion was observed only in tumor tissue on day 21 post dosing. Overall, HBM4003 demonstrated dose proportional pharmacokinetics and low immunogenicity. **Conclusions:** HBM4003 showed a favorable safety profile, promising antitumor activity and intratumoral Treg depletion in pts with advanced solid tumors at the 0.45 mg/kg Q3W DL. Clinical trial information: NCT04135261. Research Sponsor: Harbour BioMed US, Inc.

2643 **Poster Session**

Phase Ia dose-escalation study of the anti-BTLA antibody icatolimab as a monotherapy in patients with advanced solid tumor. *First Author: Russell J. Schilder, Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA*

Background: The B- and T-lymphocyte attenuator (BTLA) is an inhibitory receptor expressed on B, T and NK cells. Icatolimab (TAB004 or JS004) is a humanized IgG4 monoclonal antibody (mAb) with a hinge mutation (S228P) that binds BTLA and blocks its interaction with its ligand HVEM. In preclinical studies, icatolimab monotherapy suppressed tumor growth in murine tumor models using human BTLA knock-in mice. In this first-in-human dose-escalation study, we report the preliminary safety and efficacy of icatolimab as a single agent in patients with advanced solid tumors. **Methods:** Eligible patients with advance solid tumors refractory to standard therapies were enrolled in this study. Icatolimab was administered at escalating doses of 0.3, 1, 3 and 10 mg/kg intravenously Q3W and followed by dose expansion in 3 and 10 mg/kg cohorts until disease progression or intolerable toxicity. Dose-limiting toxicity (DLT) was evaluated by a safety monitoring committee. Study objectives included safety, pharmacokinetics, pharmacodynamics, and anti-tumor activity. **Results:** A total of 25 patients with solid tumor were enrolled in the Part A of this phase I study (NCT04137900). The median age was 62 (range 32-85) years with 16 (64%) male patients. Patients were heavily pretreated with a median of 4 prior lines of therapy. Fifteen (60%) patients received and progressed upon prior anti-PD-1/L1 therapy. By the data cutoff date of December 31, 2021, the median follow-up was 32 weeks. No DLT was observed. 24 (96%) patients experienced treatment emergent adverse event (TEAEs), with 7 (28%) experienced grade 3 TEAEs. No grade 4 or 5 TEAE occurred. The incidence or severity of AE was not associated with the dose. The most common TEAEs were fatigue (32%), abdominal pain (20%), diarrhea (16%), arthralgia (16%), aspartate aminotransferase increased (16%), constipation (16%), and contusion (16%). One (4%) TEAE led to discontinuation of study drug. Four (16%) patients experienced immune related AE. Among 19 evaluable patients by the cutoff date, 1 confirmed PR (melanoma) and 6 SD were observed as assessed by the investigator per RECIST v1.1. The response was still ongoing over 12 months in the melanoma patient who had progressed upon prior nivolumab and BRAF/MEK inhibitors treatments. BTLA receptor was fully occupied in the 3 and 10 mg/kg cohorts. The mean elimination half-life of icatolimab was 7.5 to 19.2 days in four dose cohorts. Biomarker analysis indicated co-expression of HVEM and CD8 was associated with favorable response. **Conclusions:** Icatolimab monotherapy were well tolerated in all doses evaluated and showed preliminary clinical efficacy as a monotherapy. Icatolimab in combination with toripalimab (anti-PD-1) for the treatment of patients with advanced solid tumors is currently ongoing. Clinical trial information: NCT04137900. Research Sponsor: Shanghai Junshi Biosciences and TopAlliance Biosciences.

2644 **Poster Session**

Preliminary analysis of a phase I study of SNK01 (Autologous Non-genetically Modified Natural Killer Cells With Enhanced Cytotoxicity) monotherapy in patients with advanced solid tumors. *First Author: Victoria S. Chua, Sarcoma Oncology Research Center, Santa Monica, CA*

Background: Natural killer (NK) cells play a key role as the main effector cells toward cancer in innate immunity. Thus, a leading approach is to boost NK-cell mediated anti-tumor activity using adoptive transfer of ex vivo activated NK cells. NK cells have always been challenging to grow ex vivo especially when derived from heavily pretreated donors, thus most have focused on universal allogenic donor derived products. SNK01 is a first-in-kind, autologous non-genetically modified NK cell product with significant anti-tumor cytotoxicity and over 90% expression of CD16, NKG2D, NKp46, and DNAM-1, that can be consistently produced even from heavily pre-treated cancer patients (pts). While most if not all NK cell therapy has focused on liquid malignancies, SNK01 has been found to have strong activity against both liquid and solid tumors preclinically. We hypothesized that SNK01 would be safe without need for lymphodepletion and may demonstrate activity against heavily pre-treated solid tumors. **Methods:** In this Phase 1 dose escalation study (NCT03941262), SNK01 was administered intravenously (IV) weekly for 5 consecutive weeks using a 3+3 design in pts with advanced solid tumors. The starting dose was 1 x 10^9SNK01 cells and the highest dose was 4 x 10^9 SNK01 cells. Primary endpoint was safety based on AEs, vitals, laboratory tests, and PEs. Individual NK cell expansion was characterized for increases in cytotoxicity and changes in activating receptor expression. **Results:** As of Feb 1, 2022, 10 pts with advanced refractory solid tumors have been enrolled. Median age is 50 (range 32 – 75) and 6 were male. Pts had a median 5.5 lines of prior therapy (range 2-10). The subtypes were 4 leiomyosarcoma, 1 chondrosarcoma, 1 NSCLC, 1 small round cell tumor, 1 colorectal, 1 synovial cell sarcoma, 1 angiosarcoma. NK cells were successfully activated and expanded, even from heavily pre-treated pts. Average cytotoxicity was increased over 400% and average activating receptor expression was greater than 90%. There were only two Grade 1 adverse events reported in the 50 total doses given. Best objective response of SD was demonstrated in 7 pts. Of patients who progressed in the dose escalation cohorts, several reported an overall improvement in their QOL. Based on this improvement, patients then became eligible to be treated with additional salvage chemotherapy to which some then showed additional response. **Conclusions:** SNK01 with high cytotoxicity and activating receptor expression can be consistently produced from heavily pretreated patients. SNK01 was very safe and appears to have some clinical activity against heavily pretreated solid tumors and may even sensitize tumors to additional chemotherapy. SNK01 will be studied further as monotherapy and in various combination regimens. Clinical trial information: NCT03941262. Research Sponsor: NKGen Biotech.

2645 **Poster Session**

Promising clinical benefit rates in advanced cancers alongside potential biomarker correlation in a phase I/II trial investigating bexmarilimab, a novel macrophage-guided immunotherapy. *First Author: Petri Bono, Terveystalo Hospital and University of Helsinki, Helsinki, Finland*

Background: Clever-1 is an immunosuppressive scavenger receptor expressed on tumor associated macrophages. High levels of Clever-1 are associated with poor survival and immunotherapy resistance. Bexmarilimab (FP-1305) is a novel humanized anti-CLEVER-1 IgG4-antibody capable of inducing a phenotypic M2 to M1 immune switch of tumor-associated macrophages. **Methods:** MATINS (Macrophage Antibody To INhibit immune Suppression) trial is a first-in-human phase I/II study (NCT03733990) to assess safety and preliminary efficacy of Bexmarilimab in patients with refractory advanced solid tumours. Part I has been completed with initial good safety profile of the IMP, preliminary signs of efficiency, and recommended dose of 1mg/kg Q3W for part II (ESMO 2020). In Part II (ESMO 2021), 10 distinct solid tumour types were enrolled to assess preliminary efficacy (overall survival (OS), progression free survival (PFS), and clinical benefit rate (CBR). Clever-1 IHC in pre-treatment biopsies with Ventana platform using a primary antibody 4G9 (Santa Cruz) was scored by % of positive cells compared to the viable tumor cells. **Results:** At the Jan 2022, a total of 193 patients have been enrolled to the study. In the completed cohorts, 138 patients have received 1-21 doses (median 3) of Bexmarilimab Q3W. Bexmarilimab was well tolerated, and no new safety signals were detected. Part I and Part II fully enrolled 11 cancer cohorts, the median PFS was 2.0 months (95% CI 1.9 – 2.0) and the median OS was 5.2 months (95% CI 4.3 – 6.4). CBR for Part II was 17.3% (19/110) at cycle 4 of treatment (by RECIST v.1.1). Notably, 30-40% CBR at cycle 4 was seen in cutaneous melanoma (30%), gastric cancer (30%), cholangiocarcinoma (30%), hepatocellular cancer (40%), and ER+ breast cancer (40%). Six-month survival rates (landmark analysis) were 70.1% for CBR compared to 34.7% for non-CBR patients, with a similar duration of prior therapy in both groups. Preliminary biomarker analysis (n = 77) demonstrated positive trend (p = 0.038) between CBR and higher intratumoral Clever-1 positivity (median of 15% positivity (range 0-25) in CBR and 3% (range 0-85) in non-CBR patients) **Conclusions:** Bexmarilimab continues to demonstrate promising anti-tumour activity as a monotherapy in several refractory solid tumours. Furthermore, preliminary biomarker analysis suggests a possibility for patient selection based on tumour Clever-1 expression. Further expansion of the study will investigate optimal dosing and biomarkers of efficacy. Clinical trial information: NCT03733990. Research Sponsor: Faron Pharmaceuticals.

Phase I study of the efficacy and safety of IBI319 in patients with advanced malignant tumors. *First Author: Yi-Long Wu, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: IBI319 is a recombinant fully human anti-CD137/PD-1 bispecific antibody. In preclinical studies, IBI319 demonstrated a better anti-tumor efficacy and safety. Here we report the initial results from the first-in-human study of IBI319 in patients with advanced malignancies. **Methods:** Enrolled patients (pts), ECOG PS ≤ 1, had advanced solid tumors or hematological malignancies and failed standard treatment. This phase 1 monotherapy dose-escalation includes accelerated titration (0.03 and 0.1mg/kg) and conventional 3+3 dose escalation (0.3, 1.0, 3.0, 6.0 and 10.0 mg/kg). IBI319 is administered intravenously every 14 days after dose-limiting toxicity (DLT) evaluation. Objectives include evaluation of safety, DLT, pharmacokinetic (PK) and antitumor activity. Adverse events (AEs) were reported per CTCAE v5.0 and DLTs evaluated within a 28-day window. **Results:** At cutoff date of February 10, 2022, 21 pts were enrolled (median age 55 years; 81.0% male; 19.1% ECOG PS 1; 52.4% advanced solid tumors). The following dose levels have been evaluated; 0.03 mg; 0.1 mg; 0.3 mg; 1 mg; 3 mg and 6 mg. Dose escalation is ongoing. The maximum tolerated dose has not been reached. Treatment-emergent adverse events (TEAEs) was reported in 15 out of 21 (71.4%) pts, among which 1 pts had back pain and nausea of grade 3. The most common TEAEs (> 10%) were interleukin level increased (6 pts, 28.6%) and C-reactive protein increased (3 pts, 14.3%). Eleven pts (52.4%) experienced treatment-related AEs; none were grade 3 or higher. The most common TRAEs (> 10%) were interleukin level increased (6 pts, 28.6%) and C-reactive protein increased (3 pts, 14.3%). Importantly, no drug-related elevations in transaminases (ALT, AST) or bilirubin have been seen. No DLT was observed. PK analysis of IBI319 demonstrated consistent exposure with linear PK. For 14 evaluable pts, 1 classical Hodgkin lymphoma patient achieved PR as best response. **Conclusions:** IBI319 demonstrates good tolerability in patients with advanced solid tumors or hematological malignancies, with a safety profile characterized by a lack of hepatotoxicity frequently observed with CD137-targeting antibodies. Clinical trial information: NCT04708210. Research Sponsor: Innovent Biologics Inc.

2647 **Poster Session**

Phase 1 dose escalation study of DSP107, a first-in-class CD47 and 4-1BB targeting multifunctional immune-recruitment protein, in patients with advanced solid tumors. *First Author: Jason J. Luke, University of Pittsburgh, Pittsburgh, PA*

Background: DSP107 is a bi-functional, trimeric, fusion protein composed of sequences from the extracellular domain of SIRPα and 4-1BBL. The SIRPα arm targets CD47 overexpressed on tumor cells, blocking the "don't eat me" checkpoint and triggering tumor cell phagocytosis. The trimeric 4-1BBL arm, once cross-presented and immobilized by SIRPα binding to CD47, interacts with 4-1BB expressed on activated immune cells, mainly T- and NK cells in the tumor microenvironment, and stimulates their proliferation and activation. Thereby, DSP107 triggers both an innate and an adaptive immune response. Here we describe data from the completed DSP107 monotherapy dose escalation portion of study NCT04440735. **Methods:** Adult patients with advanced solid tumors were treated with weekly intravenous DSP107 infusions (0.01 - 10 mg/kg) during 3-week treatment cycles. An accelerated dose escalation in single patient cohorts (dose levels 1-3) was followed by a standard 3 + 3 design. The primary objective was to determine safety, tolerability and pharmacokinetic (PK) parameters. Paired biopsies were obtained from 8 patients (screening, after cycle 2). Restaging imaging was performed every two months and evaluated by RECIST criteria. **Results:** In 23 patients, DSP107 demonstrated no treatment related hematologic or hepatic adverse events (AEs) and no dose limiting toxicities. Grade 1-2 treatment related AEs were observed in 70% of patients (16/23). The most frequent AEs included infusion related reaction (IRR; 26%), diarrhea (17%), fatigue (17%), nausea (13%) and constipation (9%). IRRs were managed during subsequent infusions by reducing the infusion rate and administering IV fluids. No significant systemic cytokine release was measured at any dose level using a 10-plex, pro-inflammatory panel. PK analysis revealed 100% CD47 receptor engagement on peripheral T and NK cells at doses of 3 mg/kg and above. DSP107 did not bind CD47 on red blood cells at any dose. Preliminary histologic assessment of paired biopsies by an independent, blinded pathologist demonstrated increased tumor necrosis compared to screening in 3 out of 4 patients associated with immune cell infiltration. Immuno-profiling of tumor by immunofluorescence is on-going. Stable disease as best response was observed in 11/22 patients with treatment duration up to 26 weeks. **Conclusions:** DSP107 is a novel, CD47 and 4-1BB targeting fusion protein with a differentiated safety, binding and pharmacodynamic profile compared to other CD47 and 4-1BB targeting agents. Clinical trial information: NCT04440735. Research Sponsor: KAHR Medical Ltd.

2648 **Poster Session**

A phase 1a dose-escalation study of PY314, a TREM2 (Triggering Receptor Expressed on Macrophages 2) targeting monoclonal antibody. *First Author: Amita Patnaik, START San Antonio, San Antonio, TX*

Background: To characterize the safety and tolerability of PY314, an immunosuppressive macrophage depleting antibody, as a single agent and in combination with pembrolizumab in subjects with advanced refractory solid tumors including subject's refractory to checkpoint inhibitors if approved for that indication. **Methods:** Two were evaluated in subjects with advanced solid tumors, single agent PY314 and PY314 in combination with 200 mg of pembrolizumab using a 3+3 dose escalation study design. Dosing was intravenous and administered once every 3-weeks, a defined cycle. Disease assessment by RECIST 1.1 was performed every 6 weeks. Each stratum included 4 dose levels of PY314 (1, 3, 10, and 20 mg/kg). Pharmacokinetics were evaluated at specified time points. Archival tumor tissue was analyzed for TREM2 expression by immunohistochemistry. Based on preclinical evaluation of TREM2 expression, HR+ HER2- and triple negative breast cancer, colorectal cancer, renal cell cancer, non-small cell lung cancer and gynecologic cancers were studied. **Results:** 28 subjects (median age 60 years [range 26-76], 22 females and 6) with an ECOG PS <2 were enrolled and all, but one was (1 subject withdrew consent after dosing). 15 subjects were treated with single agent PY314 and 13 were treated with the combination. No infusion-related reactions, dose limiting toxicities, suspected unexpected serious adverse reactions or high-grade treatment related adverse events (TRAEs) that resulted in treatment discontinuance was seen. 12 subjects experienced at least one TRAE, and in all but one subject, these were low grade. One subject experienced a treatment-related immune system disorder. serious adverse events, all unrelated to treatment. TREM2 expression in archival tumor ranged from 0.0-20%. PY314 pharmacokinetics were linear, dose proportional, unaffected by concomitant pembrolizumab and with a half-life of 8-9 days. Best radiographic response was stable disease seen in 11 subjects (39.3%) ranging in duration from 9-42 weeks. 6 subjects with stable disease have progressed and 5 remain on treatment. **Conclusions:** PY314 was well tolerated and has an excellent safety profile both as a single agent and in combination with pembrolizumab. A recommended dose for expansion was derived and enrollment in five prespecified cancers is ongoing. Clinical trial information: 04691375. Research Sponsor: Pionyr Immunotherapeutics.

2649 **Poster Session**

Pan-cancer (ca) analysis of the safety and efficacy of immune checkpoint inhibitors (ICI) in patients (pts) living with HIV (PLWH): Results from the international CATCH-IT consortium. *First Author: Talal El Zarif, Dana Farber Cancer Institute, Boston, MA*

Background: PLWH and ca are inadequately represented in clinical trials evaluating ICI especially in the setting of low CD4 counts (ct) and elevated HIV viral loads (VL). We assembled an international cohort of PLWH and ca treated with ICI to evaluate toxicity profiles and clinical outcomes. **Methods:** We retrospectively collected data on 204 PLWH and ca receiving ≥ 1 cycle of ICI between 2015-2021 at 14 academic medical centers in the US and Europe. Immune-related adverse events (irAEs) were graded per the Common Terminology Criteria for Adverse Events (CTCAE) V5.0. Baseline CD4 ct, CD8 ct and HIV VL were collected within 3 months (mo) of ICI initiation when available. Fisher's exact test was performed to compare categorical variables. Median (med) Overall Survival (OS) and Objective Response Rate (ORR) were calculated for 186 pts treated in the metastatic (met) setting. **Results:** Among 204 PLWH treated with ICI, 174 (85%) were cis-gender males. 61 (31%) were Black and 34 (18%) were Hispanic/Latinx. Pts were treated with pembrolizumab (n=93), nivolumab (n=71), atezolizumab (n=20), nivolumab and ipilimumab (n=13), durvalumab (n=6), or avelumab (n=1). Med number of prior lines of systemic therapy was 1 (range: 0-5). Among pts with available baseline data, 36/133 (27%) had CD4 ct <200 cells/μL while 12/136 (9%) had VL ≥400 copies/mL. irAEs of any grade occurred in 43 (21%) pts and 13 (7%) were grade ≥3 while 19 (9%) required steroids. Pts with CD4 ct <200 cells/μL experienced fewer irAEs than pts with CD4 ct ≥200 cells/μL (2/36 vs 26/97; p<0.01). The incidence of any grade irAEs was similar between pts with CD4/CD8 ratio <0.4 vs ≥0.4 (8/54 vs 18/72; p=0.16) and between pts with HIV VL ≥400 vs <400 copies/mL (1/12 vs 28/124; p=0.46). Clinical outcomes are shown in the table below. Among 29 pts with met non-small cell lung ca (NSCLC) with available CD4 ct, the ORR of pts with CD4 ct <200 cells/μL was 13% (95% CI:0-53) vs 38% (95% CI:18-62) in pts with CD4 ct ≥ 200 cells/μL (1/8 vs 8/21; p=0.38). **Conclusions:** In the largest dataset to our knowledge, we demonstrate tolerability and activity of ICI among PLWH regardless of CD4 ct and HIV VL levels. CD4 ct <200 cells/μL may be associated with a lower incidence of irAEs. An analysis of a larger cohort is underway. Research Sponsor: None.

IBI110 (anti-LAG-3 mAb) as a single agent or in combination with sintilimab (anti-PD-1 mAb) in patients with advanced solid tumors: Updated results from the phase Ia/Ib dose-escalation study. *First Author: Nong Xu, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China*

Background: Lymphocyte-activation gene 3 (LAG-3) is an immune checkpoint receptor protein that functions to control T cell response, activation and growth. Dual inhibition of PD-1 and LAG-3 may improve anti-tumor effect synergistically. A phase Ia/Ib dose-escalation study evaluated IBI110 ± sintilimab in patient with advanced solid tumors; initial efficacy and safety data were previously presented (C Zhou et al. ASCO 2021; NCT04085185). Here, we reported the updated results. **Methods:** Eligible patients were ECOG PS 0-1 and had locally advanced, recurrent or metastatic solid tumors for whom standard therapy had failed. Patients received escalating doses of IBI110 (0.01/0.1/0.3/1/3/10/20mg/kg) IV Q3W in phase Ia and escalating doses of IBI110 (0.3/0.7/1.5/3/5/8/10 mg/kg) in combination with sintilimab 200 mg IV Q3W in phase Ib. Crossover from monotherapy to combination therapy was allowed at progression. The primary objectives were safety, tolerability, and anti-tumor activity of IBI110 alone or IBI110+sintilimab (per RECIST v1.1). **Results:** Phase Ia: 28 patients (median age of 60.5 years [range 35-72], ECOG PS of 0 [n = 14] and 1 [n = 14]) were enrolled. Dose escalation was completed and no dose-limiting toxicity (DLT) was observed in all dose cohorts. The safety profile was generally consistent with the initial. By investigator-assessment, best response was 1 confirmed partial response (PR) and 6 stable diseases (SD) with monotherapy. After crossing to combination therapy at progression, 8 patients who failed prior anti-PD-(L)1 mAb therapy achieved SD. Phase Ib: Overall, 45 patients (median age: 60.0 yr [range 33-74]; ECOG PS: 0 [n = 14], 1 [n = 31]) were enrolled in all dose levels. Dose escalation was completed and no DLT was observed. The most common treatment-related adverse events (TRAEs) were aspartate aminotransferase increased (28.9%), anaemia (24.4%), and alanine aminotransferase increased (22.2%). TRAEs ≥ grade 3 occurred in 10 (22.2%) patients. Immune-related AE (irAE) incidence was 31.1%, and the most common irAE was hypothyroidism (15.6%). In 43 patients who had undergone at least 1 post-baseline tumor assessment, the investigator-assessed best response included 6 PRs (1 endometrial cancer, 4 NSCLC, and 1 SCLC patients) and 23 SDs. Three patients showed a progression-free survival > 1 year and continued treatment. **Conclusions:** IBI110 alone or plus sintilimab demonstrated acceptable safety profile and promising antitumor activity in patients with advanced solid tumors. Clinical trial information: NCT04085185. Research Sponsor: Innovent Biologics, Inc., China.

2651 **Poster Session**

Safety and efficacy of etigilimab in combination with nivolumab in select recurrent/advanced solid tumors. *First Author: Meredith McKean, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: Etigilimab (etig), a humanized IgG1 monoclonal antibody, blocks TIGIT interaction with PVR (poliovirus receptor) and inhibits downstream signalling with target cell killing. Etig +/- nivolumab (nivo) showed acceptable safety and preliminary activity in a FIH Phase 1a/b study in solid tumors. ACTIVATE, an open-label Phase 1b/2 basket study is evaluating further efficacy, safety, tolerability and PK/PD of etig+nivo. This is a preliminary efficacy and safety analysis from ACTIVATE. **Methods:** Subjects with advanced/metastatic solid tumors without curative/standard of care therapies are given IV etig+nivo Q2W until disease progression or intolerable toxicity. Six open cohorts are enrolling in parallel: endometrial cancer (post-front-line platinum), endometrial cancer (2-3 prior lines), PD-L1+ checkpoint-inhibitor-naïve (CPI-n) cervical cancer, rare cancers (germ cell tumor (GCT), sarcoma, uveal melanoma), ovarian cancer (post-front-line platinum) and TMB-h/MSS, (TMB >10mut/mb) tumors. Tumor assessments are done every 8 weeks following baseline scan. Primary endpoint is investigator-assessed ORR by RECIST 1.1. Secondary endpoints include duration of response and safety. **Results:** Of 27 efficacy-evaluable subjects enrolled in the 6 open cohorts with minimum 1 staging scan or radiological/clinical progression at data cut-off of 02/10/22, 12 had clinical benefit with 1 complete response (CR), 2 partial responses (PRs) and 9 stable diseases (SDs) and 15 had radiological/clinical progressive disease (PD), with an overall response rate (ORR) of 11% and disease control rate (DCR) of 44%. **Conclusions:** Etig+nivo is safe and well tolerated with no new safety signals. Early efficacy was noted in cervical cancer (1CR, 1PR and 1SD) and uveal melanoma (3 SDs >20 weeks). Encouraging activity was also noted in ovarian cancer and post-CPI treated TMB-H/MSS NSCLC. These early data support continued evaluation of the combination of etig+nivo. Clinical activity was notable as below. Clinical trial information: NCT04761198. Research Sponsor: Mereo BioPharma 5 Inc.

[1]BOR at data cut-off,*On-study, ^Off-study. [2]Off study, withdrew consent with ongoing CR. [3]Unrelated death with ongoing SD. [4]NSCLC, CPS <1%. Treatment-related adverse event (TRAE) rate was 25% (safety analysis set n=41, ≥ 1 dose of etig+/-nivo). Two G3 TRAEs (immune-related diabetes mellitus and maculopapular rash), and 3 G2 infusion-related AEs occurred. There were no >G3 TRAEs and no treatment-related SAEs/discontinuations. Most common TRAEs were G1-2 skin rashes (36% of TRAEs); 1 G3 rash AE required systemic steroids for resolution.

Enhanced tumor control with a combination of APG-157 and immune checkpoint inhibitors for head and neck cancer. *First Author: Daniel Sanghoon Shin, University of California Los Angeles Medical Center/Veterans Affairs, Los Angeles, CA*

Background: Natural botanical drugs containing flavonoids are under clinical investigation for the treatment of malignancies. A phase I clinical study for patients with locally advanced head and neck cancer with a new class of botanical drug APG-157 showed excellent tolerability, systemic absorption via sublingual administration, and enhanced immune cell infiltration into the tumor microenvironment and suppression of T cell inhibitory inflammatory cytokine production. We sought to evaluate the efficacy of tumor control for the combination of APG-157 and checkpoint blockade immunotherapy using a head and neck cancer mouse model. **Methods:** SCCVII (HPV-) and MEER (HPV+) head and neck cancer murine cell line models were utilized in *in vivo* tumor growth study. After optimization for route and cell number, we measured tumor growth after treating mice with following groups: i) control, ii) APG-157, iii) anti-PD-1, iv) anti-CTLA-4, v) APG-157 + anti-PD-1, vi) APG-157 + anti-CTLA-4, vii) anti-PD-1 and anti-CTLA-4 , viii) APG-157 + anti-PD-1 + anti-CTLA-4. Tumors were collected after 2 injections of immune checkpoint inhibitors and characterized for immunophenotype by multi-color flow cytometry, immunohistochemistry, and RNA-sequence analysis. Fecal microbiome was analyzed by 16S rRNA sequence for SCCVII model to assess the impact of APG-157 on the microbiome as we observed the shift of oral microbiome species in the human trial. **Results:** We confirmed by serum concentration of APG-157 metabolites that the best route of administration is via oral route by mixing with APG-157 with mouse chow. Tumor growth optimization experiments determined that 100,000 cells of SCCVII is the ideal number of cells to inject and day 5-6 is the time to initiate treatment. Among 8 treatment groups, APG-157 + anti-CTLA-4 demonstrated best tumor control (p = 0.0065 compared to control), followed by anti-PD-1 + anti-CTLA-4 treatment group (p = 0.48 compared to control). The immunophenotype assessment by flow cytometry showed over 30% of CD8+ T cell in APG-157 + anti-CTLA-4 group compared to 4-5% of CD8+ T cell for the control group. GSEA analysis from the SCCVII tumors revealed that APG-157 + anti-CTLA-4 group showed an enriched set of genes for inflammatory response, apoptotic signaling pathways. The fecal microbiome analysis showed a substantial difference of lactobacillus genus among groups, highest in the group of APG-157 + anti-CTLA-4 treatment group. The MEER model (HPV positive) tested with same immunotherapy as single or in combination with APG-157 did not grow the tumor, thus we were unable to collect the tumor for immunophenotyping and other studies. **Conclusions:** These study results indicate that APG-157 is able to modulate the immune system and fecal microbial species that could potentially lead to improved anti-tumor immunity and warrants further studies to define mechanism and the potential for human clinical trial. Immune checkpoint inhibitor-related endocrinopathies: A nationwide population-based study. *First Author: Dina Elantably, Metrohealth Medical Center Case Western Reserve University, Cleveland, OH*

Background: Immune checkpoint inhibitors (ICIs) have revolutionized cancer therapy. However, unleashing the body's immune system against cancer is not without consequences and may trigger immune-related adverse events (irAEs), such as endocrinopathies. Real-world data of these endocrinopathies is lacking. This study aims to obtain the prevalence of endocrine irAEs and identify possible underlying demographic risk factors or disparities. **Methods:** A cross-sectional study was performed using a US-based population database (Explorys) that aggregates records from 26 healthcare systems and includes over 79 million patients. Our sample included all patients on an ICI, and we further identified patients who developed endocrinopathies while on different ICI regimens. The demographic data extracted was categorical, hence presented as counts and percentages. The odds ratio (OR), standard error, and 95% confidence interval were calculated with the use of SPSS software version 28.0 (IBM). **Results:** There were 20,950 patients on an ICI; 58% males, 83% Caucasians, 10% African-Americans (AA), 38% aged between 18-65, and 63% were over 65 years. The prevalence of the studied endocrinopathies is listed in the table. The most prevalent ICI-induced endocrinopathy was hypothyroidism (7.9-13%). Combination therapy with ipilimumab and nivolumab showed the highest prevalence of ICI-induced endocrinopathies, followed by durvalumab. The odds of developing ICI-induced endocrinopathy were significantly higher with combination therapy than nivolumab monotherapy (OR 1.6; 95% CI 1.4-1.9). There was no statistically significant difference in endocrinopathy prevalence when comparing Caucasians to AA and adults18-65 years to seniors over 65 years. **Conclusions:** This is the largest epidemiological study of ICI-related endocrinopathies. We find an intriguing divergence from endocrinopathy prevalence reported in the literature and real-world data we are presenting here. Over diagnosis of overt hypothyroidism, as opposed to subclinical hypothyroidism, is concerning as the former necessitates levothyroxine therapy. More alarming is the under diagnosis of hypopituitarism and PAI, in which delay in treatment can be fatal. The diagnosis of these conditions can be challenging. Raising awareness, setting protocols for testing, and involving endocrinologists are crucial. Further studies are needed to clarify our findings. Research Sponsor: None.

Prevalence of immune checkpoint related endocrinopathies.

ICI (Total patients on ICI)	ICI-induced endocrinopathy	Acquired hypothyroidism	Subclinical hypothyroidism	Hyperthyroidism	Hypopituitarism	PAI	Type 1 DM
Nivolumab (6700)	10.4%	8.2%	1%	2.2%	0.3%	0.07%	1.19%
Pembrolizumab (9580)	11%	8.9%	2%	2.5%	0.4%	0.3%	1.04%
Atezolizumab (2020)	10.4%	7.9%	0.2%	2.97%	0.24%	0.24%	1.48%
Durvalumab (940)	17%	13.8%	0.5%	6.38%	0.5%	0.5%	0 %
Ipilimumab & nivolumab (1760)	17.6%	13%	0.3%	3.4%	1.13%	1.7%	1.7%

Immune-related adverse events and immunotherapy efficacy in patients with cancer: A retrospective study. *First Author: Lyndsey L. Prather, Baylor College of Medicine, Houston, TX*

Background: Immune checkpoint inhibitors are revolutionizing cancer care and providing new treatment options with promising outcomes for many cancers. However, immune-related adverse events (irAEs) are not infrequent and can be severe. An intriguing relationship between the presence of irAEs and treatment efficacy has been described but lacks thorough characterization. We aimed to further elucidate a relationship between immune checkpoint inhibitor (ICI) irAEs and efficacy. **Methods:** We identified cancer patients treated with ICI from 2015-2021 across two institutions: Michael E DeBakey Veterans Affairs Medical Center (MEDVAMC) and Baylor St. Luke's Medical Center (BSLMC). Clinical data including cancer type, irAEs type and grade, ICI response, progression free survival (PFS) and overall survival (OS) was collected. Using the Kaplan Meier method, survival curves were generated and comparisons were made amongst groups using the log-rank test. Fisher's exact test was used to compare progression of disease between groups. To determine if variables were associated with survival, multivariable Cox regression analysis was used. **Results:** Of the 456 patients treated with ICI, irAEs were seen in 165 (36%) patients. Of these, 81 (49%) patients had grade 1 toxicities, most commonly arthritis, diarrhea, and dermatitis. 47 (28%) patients had grade 2 toxicities (colitis, hypothyroidism, adrenal insufficiency). 34 (21%) patients had grade 3 toxicities (pneumonitis, pancreatitis, hepatitis). 3 patients had grade 4 toxicities (pneumonitis, DRESS syndrome, and hepatorenal syndrome). 1 patient expired and 24 (15%) patients discontinued ICI due to irAEs. 55 (33%) of patients with irAEs were treated with steroids. For patients assessed for efficacy, objective response rate (ORR) to ICI was higher in patients with irAEs [47% (12% CR) vs 33% (11% CR)]. In fact, the presence of any irAEs was significantly likely to predict response to ICI (OR 1.90, 95% CI 1.25 - 2.86, p = 0.0026). In a subset of patients evaluable for survival (n = 375), patients with any irAEs had a significantly improved median PFS compared to those without irAEs (9.0 vs. 4.8 months, p = 0.0018). Multivariable analysis demonstrated that the development of any irAEs was related to a significantly improved OS (HR 0.63, 95% CI 0.43-0.89, p = 0.01). **Conclusions:** The development of irAEs in cancer patients treated with immunotherapy may predict better treatment efficacy and overall survival. Further prospective studies are needed to confirm these associations and mechanism of action. Research Sponsor: None.

Comparison of the checkpoint inhibitor pneumonitis incidence between immunotherapy alone or in combination with chemotherapy for lung cancer: An observational, retrospective pharmacovigilance study. *First Author: Pei-Hang Xu, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: Clinical trials lack direct cross-comparison in safety between immune checkpoint inhibitor (ICI) as monotherapy and in combination with chemotherapy. The adverse event of checkpoint inhibitor pneumonitis (CIP) is an important factor influencing the treatment decision making. We performed a real-world pharmacovigilance study in the US Food and Drug Administration Adverse Event Reporting System (FAERS) to determine if ICI combination therapy is superior to monotherapy for lung cancer patients in terms of CIP incidence. **Methods:** The database of lung cancer patients receiving ICI between 2015 and 2020 was extracted for this study. The strategy-specific durations of the pneumonitis event were compared using the Kaplan-Meier method. Reporting odds ratio (ROR), a surrogate measure in disproportionality analysis, was used to assess the signal of CIP between ICI treatment strategies. **Results:** A total of 27,882 lung cancer patients with reported adverse events were involved. Among them, 1763 (6.3%) CIP after ICIs therapy were identified. In general, ICI usage was associated with over-reporting frequencies of CIP, but this association was no longer significant after adjustment (ROR: 1.14, 95%CI 0.86-1.49). The median times to CIP occurred early after therapy onset, either in ICI monotherapy or in combination with chemotherapy (41 days and 37 days, log-rank $p>0.05$). Different reporting frequencies emerged when we further compared different ICI strategies. Combination therapy with anti-PD-1 and chemotherapy was associated with a higher CIP incidence compared with anti-PD-1 monotherapy (ROR: 1.86, 95%CI 1.37-2.51), whereas anti-PD-L1/ CTLA-4 medications had lower risks in combination with chemotherapy (ROR: 0.31, 95%CI 0.16-0.56 and ROR: 0.41, 95%CI 0.09-1.22). Subgroup analyses on those with recorded therapy duration also indicated that reports of CIP were significantly lower with combination therapy of PD-L1 and CTLA-4 (ROR: 0.52, 95%CI 0.36-0.74 and ROR: 0.22, 95%CI 0.09-0.51 respectively). **Conclusions:** Compared with ICI monotherapy, the combination with chemotherapy might have an acceptable risk of CIP. Anti-PD-1 medications with additional chemotherapy could increase the risk of pneumonitis, whereas the risk was lower in the combination strategy with anti-PD-L1/CTLA-4. The combination might be a better therapeutic strategy than ICI monotherapy in treating lung cancer, regarding the CIP incidence. Research Sponsor: Guangzhou Science and Technology Planning Program (202002030023).

Disproportionality of checkpoint inhibitor pneumonitis in those treated with ICI combination therapy versus monotherapy.

	Crude ROR (95%CI)		Adjusted ROR (95%CI)	
All ICIs	0.91	(0.78-1.05)	1.14	(0.86-1.49)
Anti-PD-1	1.21	(1.02-1.44)	1.86	(1.37-2.51)
Anti-PD-L1	0.41	(0.31-0.54)	0.31	(0.16-0.56)
Anti-CTLA-4	0.28	(0.13-0.54)	0.41	(0.09-1.22)

Comparing rate of immunotherapy treatment change due to toxicity by gender. *First Author: Kevin Joseph Chua, Section of Urologic Oncology, Rutgers Cancer Institute of New Jersey and Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ*

Background: Immunotherapy (IO) is associated with a variety of treatment related toxicities. However, the impact of toxicity on the treatment discontinuation rate between males and females is unknown. We hypothesized that immune related adverse events would lead to more frequent treatment changes in females since autoimmune diseases occur more frequently in females **Methods:** The Oncology Research Information Exchange Network (ORIEN) Avatar Database collects clinical data from ten different United States cancer centers, where patients receive IO. Of 1,035 patients receiving IO, 447 patients were analyzed, excluding those (N = 573) who did not have documentation noting if a patient changed treatment. 15 additional patients with an unknown or gender-specific cancer were excluded. All cancer types and stages were included. Primary endpoint was documented treatment change due to toxicity. Significance was calculated with logistic regression, linear regression, chi-squared test for categorical variables and Mann-Whitney U test for continuous nonparametric variables. **Results:** 447 patients (281 males and 166 females) received IO treatment for cancer. The most common cancers treated were kidney, skin, and lung for 99, 84, and 54 patients, respectively. Females had a shorter IO course compared to males on Mann-Whitney U test (median 3.7 vs 5.1 months, respectively, p=0.02) and multivariable linear regression (Beta -3.87, 95% CI -6.591, -1.149, p=0.005). 54 patients changed IO treatment due to toxicity. There was no significant difference in the rate of treatment change due to toxicity between females and males on chi-square test (11.4% vs. 12.5%, respectively, p = 0.75) and logistic regression (Table). Pembrolizumab, Nivolumab, Ipilimumab/Nivolumab, Ipilimumab, Durvalumab, Avelumab, and Atezolizumab were given to 16, 14, 9, 9, 3, 2 and 1 patients who changed treatment due to toxicity, respectively. The median length of time for IO treatment prior to change for toxicity was 3 months (IQR 1.4 – 5.9 months). Significantly more patients with COPD changed treatment due to toxicity (Table). **Conclusions:** Females received a shorter course of IO than males. However, there was no significant difference in the treatment discontinuation rate due to toxicity between males and females receiving IO. Toxicity related treatment change was associated with COPD. Studies with larger sample sizes with more granular data (i.e., type of adverse effects) are needed to truly characterize if a difference between genders and IO toxicity exists. Research Sponsor: U.S. National Institutes of Health.

Inpatient complications of immunotherapy-associated colitis in solid malignancies: Real-world data analysis. *First Author: Rayli Pichardo, Henry Ford Hospital, Detroit, MI*

Background: Immune checkpoint inhibitors (ICPis) and their containing regimens have been proven beneficial for the treatment of multiple malignancies, while immune-related adverse events (IrAEs) have become constant safety challenges in their clinical management through all ICPi therapies. Diarrhea resulted from immune-mediated colitis has been one of the most common IrAEs. The Aim of this study is to evaluate the real-world incidence and factors that contributed to colitis among patients hospitalized for anti-neoplastic immunotherapy using a large nation-wide database. **Methods:** We performed a retrospective analysis with the National Inpatient Sample (NIS) using ICD10-CM and PCS codes to identify patients with solid tumors hospitalized for immunotherapy between October 2015 and 2018. A comparison analysis was made between patients who developed diarrhea (or colitis) or not during their hospitalizations. Patient characteristics included past medical history, location, charges, length of stay (LOS) and inpatient complications variables, data were compared between the two groups. **Results:** The data from 5,795 admissions for immunotherapy were included, of which 615 (10.61%) inpatient events were complicated by diarrhea (colitis). Patients with diarrhea tended to be males (60%), slightly older at age 57 years, higher percentage of white patients (78%) though not statistically significant from those who did not have colitis. On the other hand, the length of inpatient stay was statistically longer (7 vs 5 days, $p < 0.05$), and associated with higher expenses ($214,612 vs $ 134,195, $p < 0.05$). In addition, inpatient admissions with colitis were more towards larger academic hospitals (80% vs 67%, p = 0.01). ICPi-treated patients with genitourinary (GU) cancers were observed more with colitis among these admissions (27% vs 15%, $p < 0.05$). Though no difference from mortalities observed, serious complications, such as acute kidney injury (AKI) (44% vs 20%, $p < 0.05$) and non-septic shock rates were higher (7% vs 2%, p = 0.01) among colitis admissions. **Conclusions:** This real-world data analysis of inpatient admissions from ICPi-treated cancer patients demonstrated colitis with diarrhea as a common safety concern over ICPi-therapies, a higher risk among patients of GU primaries, higher risk with serious medical complications: acute renal dysfunction and non-septic shock, led to increased length of stays (LOS) and financial burden. Special attention and further study may be placed among ICPi-treated GU cancer patients. Research Sponsor: Henry Ford Cancer Institute.

Association between germ-line HLA and immune-related adverse events. *First Author: Ning Jiang, Department of Radiation Oncology, The Affiliated Cancer Hospital of Nanjing Medical University, Jiangsu Cancer Hospital, Jiangsu Institute of Cancer Research, Nanjing, NC, China*

Background: In recent years, great progress has been made in immune checkpoint inhibitors (ICIs), opening a new chapter for cancer treatment. However, accompanied by remarkable efficacy, immune-related adverse events (irAEs) also arose. Though some pilot studies have explored the possible factors that may influence the development of irAEs, the mechanism of irAEs remains unclear. Previous studies indicated a positive association between certain HLA types and irAEs. To uncover the relationship between irAEs and divergent HLA types, we initiated a large cohort study. **Methods:** We screened 626 patients who have been treated in the clinical research ward, Cancer Hospital of Chinese Academy of Medical Sciences. All participants included should be diagnosed with malignant tumors and have received at least 2 cycles of ICIs with complete security follow-up data in the original electronic medical records. The blood samples were collected before the first cycle of treatment. Sequencing libraries were generated using a customized panel. Six digit formatted HLA alleles were extracted from HLA-HD (v1.4.0) results for further analysis. Fisher-exact test was used to perform association analysis between HLA and different irAEs. To control the type I error, we introduce two external reference groups as well as the non-irAE control group. In addition, false discovery rate (FDR) correction was performed with the resulting p-values when comparing the HLA allele frequency between patients with irAEs and the MHC-han Chinese reference cohort. We also explored the relationship between zygosity of HLA genes, evolutionary divergence of HLA class I genotype (HED) and irAEs. **Results:** Of the 626 participants, 530 received at least 2 doses of ICIs. The median follow-up time was 10.3 months. 97% patients received anti-PD-1/PD-L1 treatment. Of all participants, 78% reported irAEs of any grade, with 10.2% reporting grade 3 and above irAEs. The occurrence of overall irAEs showed no significant difference between homozygous group and heterozygous group. We did not find any significant association between irAEs and HED. We found that some HLA types are associated with irAEs of different organs, including the significant association between HLA-DRB3*01:01 and thrombocytopenia (OR 3.48 (1.19,9.42), p = 0.011), HLA-DPB1*04:02 and hypokalemia/ hyponatremia (OR 3.44 (1.24,9.1), p = 0.009), leukopenia (OR 2.1 (0.92,4.8) , p = 0.037) as well as anemia (OR 2.33 (1.0,5.41) , p = 0.026), HLA-A*26:01 and bilirubin elevation (OR 2.67 (0.92,8.31) , p = 0.037). **Conclusions:** IrAEs in specific organs and tissues may be associated with certain HLA types, while HLA heterogeneity have no significant influence on the happening of irAEs. More research is needed to explore the role of germline genetic changes in the risk assessment of irAEs, and potential therapies targeting irAE-inducing HLA types without influencing the anticancer effect may be considered to benefit the patients. Research Sponsor: None.

Dysthyroidism during immune checkpoint inhibitors is associated with improved overall survival in solid tumors: Data-mining of 1,382 electronic patient records. *First Author: Mathilde Beaufils, Institut Paoli-Calmettes, Marseille, France*

Background: Medical treatment of solid tumors cancer has irreversibly changed since the development of immune checkpoint inhibitors (ICI). However, immune-related adverse events (irAE) are challenging in routine practice. Dysthyroidism is the most common endocrine irAE and small series suggest that dysthyroidism might be associated with ICI efficacy. This led us to explore the association between ICI-induced dysthyroidism and overall survival (OS) in a large cohort of solid tumor patients (pts) using data mining of electronic patient records (EPR). **Methods:** ConSoRe is a new generation data analytics solution using natural language processing to search aggregated data and perform advanced data mining. It was used for data extraction from EPR of pts treated with ICI for solid tumors in Institut Paoli-Calmettes (Marseille Cancer Center, France), with validation using manual screening of 28.8% EPR. All dysthyroidism were verified and only dysthyroidism ICI-induced were retained. Survival analyses were performed by Kaplan-Meier method and compared using the log-rank test (survminer R package). In the uni/multivariate analysis, the Cox proportional-hazards model was used to estimate the variables associated with OS, using hazard ratio (HR) and its associated 95% confidence interval. **Results:** Data extraction identified 1,385 pts treated with ICI in 2011-2021. Dysthyroidism was observed in 90 pts (6.5%), including 22 hyperthyroidism (24%), 36 hypothyroidism (40%) and 32 hyperthyroidism and hypothyroidism (36%). In this cohort, 81 % of the dysthyroidism were related to PD(L)-1 inhibitors and 19 % to CTLA-4/ PD(L)-1 inhibitors combination. No statistical difference was observed in term of tumor location between patients with or without dysthyroidism. Dysthyroidism was associated with improved OS (HR=0.46, 95%CI 0.29-0.70, p=0.0005) with a median OS of 65 months (mo) *vs.* 30 mo in patients without dysthyroidism. Survival impact of dysthyroidism was consistent using a 2-mo landmark analysis, fixed on median time to dysthyroidism. In multivariate analysis including sex, age, tumor localization, line numbers and type of ICI, dysthyroidism was independently associated with an improved OS (HR=0.49, 95%CI 0.32-0.75, p=0.001), as presented in the Table. **Conclusions:** Data mining identified a large number ICI-induced dysthyroidism, associated with an improved OS. The onset of dysthyroidism might help oncologist detecting patients more likely to benefit from ICI. Research Sponsor: None.

The impact of pembrolizumab on patients with pre-existing autoimmune diseases. *First Author: Noor Bazerbashi, Houston Methodist Hospital, Houston, TX*

Background: Immune checkpoint inhibitors (ICI) have changed the therapeutic landscape across a range of solid and hematologic malignancies. With the mechanistic activation of the adaptive immune response and known unique development of immune-related adverse effects (irAE), there is a theoretical risk of causing detrimental effects on patients with pre-existing autoimmune diseases (AID). However, this patient population was excluded from many clinical trials, and there is limited and conflicting retrospective data speculating upon the impacts of using ICI therapy in patients with AID. This study aims to report the impact of pembrolizumab in patients with AID. **Methods:** Patients who received pembrolizumab for treatment of any type of cancer between 1/1/2017-8/1/2021 were retrospectively reviewed, and patients with AID (rheumatologic or non-rheumatologic) were identified. Data including age, gender, race, ECOG, and primary cancer diagnosis were collected. AID was characterized by type, activity (symptomatic vs. asymptomatic at ICI initiation), and immunosuppressive treatment (IST) use. Outcomes included flare of AID, irAE, and ICI discontinuation. **Results:** Out of 810 patients, 12 with pre-existing AID were found and being treated for non-small cell lung cancer (NSCLC) (58% N=7), renal cell carcinoma (RCC) (16.6% N=2), colorectal cancer (CRC) (8% N=1), head and neck cancer (8% N=1), and cervical cancer (8% N=1). Around 67% of these patients were females with a median age of 65 years (50-77). Median ECOG was 1 (0-2). 9 patients (75%) had rheumatologic disease (5 rheumatoid arthritis (RA), 1 systemic lupus erythematosus (SLE), 2 psoriatic arthritis, and 1 systemic sclerosis (SS)). 3 patients (25%) had non-rheumatologic AID (1 multiple sclerosis (MS), 1 autoimmune hepatitis, and 1 Evan's syndrome). All patients were asymptomatic prior to initiation of therapy. At the time of ICI initiation, 11 patients (92%) were on therapy, including steroids, methotrexate, and other IST. Due to concern for severe flare, pembrolizumab was discontinued in 3 (25%) MS, RA, and SS patients treated for RCC, CRC, and NSCLC, respectively. 3 patients (25%) developed irAE unrelated to their AID (pneumonitis, dermatitis, arthritis, gastritis) and received steroids. 4 patients (33.3%) had documented flares while on pembrolizumab requiring escalation of their ongoing therapy, and 1 NSCLC patient had a severe exacerbation of SS requiring cyclophosphamide and rituximab infusions. **Conclusions:** This analysis adds to the limited available literature that patients with an AID and on IST appear to have minimal AID-associated flares requiring intervention and tolerate pembrolizumab with a similar rate of irAE compared to patients without AID. Additional larger studies are needed to assess the efficacy of treatment in this population. Research Sponsor: None.

Immune-related adverse effects of long-term PD-1/PD-L1 inhibtor treatment. *First Author: Sarah Kim, Stanford Health Care, Stanford, CA*

Background: Immune-related adverse effects (irAE) are autoimmune-like toxicities caused by immune checkpoint inhibitor (ICI) treatment and often necessitate interventions such as corticosteroids, treatment interruptions/discontinuation, or hospital admission. Although ICI related irAEs are well described in literature, data on the toxicity profile associated with long-term ICI use remains limited. Since the optimal duration of therapy with ICI agents is currently unknown, it is crucial to assess the risks of long-term ICI use. **Methods:** This was a retrospective, observational, single-center study of adult oncology patients who received at least 1 year of programed death 1 (PD-1) inhibitor or programmed death ligand-1 (PD-L1) inhibitor treatment. The objective of this study was to characterize late-onset irAEs defined as greater than 1 year with long-term ICI treatment. Clinically significant irAEs were defined as those requiring corticosteroid treatment, hospital admission, treatment interruption or treatment discontinuation. This study included patients who received at least 1 year of nivolumab, pembrolizumab, atezolizumab or durvalumab between January 2016 and September 2021. Disease states included head and neck cancer, renal cell carcinoma, non-small cell lung cancer, and melanoma. Patients with concurrent exposure to other treatment such as chemotherapy, radiation, surgery, tyrosine kinase inhibitors and monoclonal antibodies while on ICI treatment were included in the study. Exclusion criteria included patients with treatment breaks of greater than 6 months, two malignancies undergoing active treatment, and treatment administration outside of the study center. **Results:** Of 282 patients assessed, 143 met study inclusion criteria. The median ICI treatment duration was 19 months (IQR 14-27). There was a 30% incidence of late-onset irAEs, of which 22% were clinically significant. Most late-onset irAEs were low in severity, as 45 (90%) were grade 1-2 and 5 (10%) were grade 3. The most common late-onset irAEs were pulmonary (8%) and gastrointestinal (7%). Univariate analysis suggests risk factors potentially associated with late-onset irAEs include concurrent exposure to additional therapies during ICI treatment and past medical history of rheumatologic disease. **Conclusions:** Although the optimal duration of ICI therapy is unknown, this study suggests that long-term ICI use was associated with a low but notable incidence of toxicities, of which most were low in severity. Research Sponsor: None.

Characterization of late-onset irAEs.

irAE	Incidence N=143 (%)	Median time to onset (months)
Dermatologic	7 (5)	15
Endocrine	7 (5)	17
Gastrointestinal	10 (7)	15
Hematologic	1 (1)	17
Hepatic	6 (4)	22
Ocular	2 (1)	19
Pulmonary	12 (8)	18
Rheumatologic	5 (4)	19

There were no incidences of late-onset cardiovascular, renal, neurologic, or pancreatic irAEs. Seven patients experienced multiple irAEs.

Density patterns of tumor-infiltrating lymphocytes and association with objective response to nivolumab in patients with lung adenocarcinoma from CheckMate 057. *First Author: Germán Corredor, Case Western Reserve University, Cleveland, OH*

Background: Immune checkpoint inhibitors (ICIs) are currently approved for use as therapy in advanced stage lung adenocarcinoma (LUAD). ICIs can decrease risk of progression by up to 60% when compared to chemotherapy, but only about 20% of patients (pts) show response. Given that high levels of tumor-infiltrating lymphocytes (TILs) have been shown to be associated with better prognosis, here, we assess whether computationally derived TIL density measures on digitized H&E images can predict RECIST derived response to nivolumab in LUAD in Checkmate 057 (CM057). CM057 is a clinical trial designed to compare the overall survival of metastatic non-squamous non-small cell lung cancer subjects treated with either nivolumab or docetaxel after failing platinum-based chemotherapy. **Methods:** H&E-stained samples of 683 LUAD pts were collected from TCGA (n = 421), University of Bern (UBern) (n = 100), and CM057 (n = 162). Tumor response was assessed using RECIST v1.1. Samples were digitized as whole slide images. 294 pts randomly selected from TCGA formed the training set. The remaining 389 pts were used for validation in response to nivolumab in CM057 and prognosticating overall survival (OS) in UBern and TCGA. Computerized algorithms automatically identified TILs and extracted features related to quantity and compactness of TILs with respect to other surrounding nuclei. The top 6 features, determined by least absolute shrinkage and selection operator, were used to train Cox regression models that assign a death risk score to each patient. Pts with risk scores higher than the training median score were considered "high risk" or "non-responders" while pts with lower scores were considered "low risk" or "responders". **Results:** The classifier predicted objective response in CM057 with an AUC = 0.61. Additionally, survival analysis showed that the model was prognostic for OS with hazard ratios of 2.38 (confidence interval (CI): 1.32-4.29, p = 0.01, n = 127) in TCGA and 2.37 (CI: 1.32-4.25, p < 0.01, n = 100) in UBern. **Conclusions:** A computerized image analysis model based on measurements of TIL density showed association with response to treatment in LUAD pts who received nivolumab and was prognostic of OS. Although the AUC was not high, the results suggest analysis of TILs has potential to identify pts who will respond to treatment. Future work will include training a classifier using response to treatment as endpoint and combining the TIL measures with other biomarkers like TMB or PD-L1. Tumor-infiltrating lymphocyte enrichment predicted by CT radiomic analysis is associated with clinical outcomes of immune checkpoint inhibitor in non–small cell lung cancer. *First Author: Changhee Park, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea*

Background: Enrichment of tumor-infiltrating lymphocytes (TIL) in the tumor microenvironment (TME) is a reliable biomarker of immune checkpoint inhibitors (ICI) in non-small cell lung cancer (NSCLC). Phenotyping through CT radiomics has the overcome the limitations of tissue-based assessment, including for TIL analysis. Here, we objectively assess TIL enrichment using an artificial intelligence-powered H&E analyzer, Lunit SCOPE IO, and analyze its association with advanced quantitative imaging features extracted via radiomic analysis. Clinical significance of the selected radiomic features (RFs) is then validated in independent NSCLC patients who received ICI. **Methods:** In the training cohort, which included 235 NSCLC patients with both tumor tissue and corresponding CT images obtained within 1 month, we extracted 86 RFs from the CT images. From tissue, a patient's TIL enrichment score (TILes) was defined as the fraction of tissue area with high intra-tumoral or stromal TIL density, divided by the whole TME area, as measured on an H&E slide. From the corresponding CT images, the least absolute shrinkage and selection operator model was then developed using features that were significantly associated with TIL enrichment. The CT model was then applied to CT images from the validation cohort, which included 242 NSCLC patients who received ICI as ≥ second line. **Results:** Among the extracted RFs, 22 features were significantly associated with TILes ($p < 0.005$). After excluding features of multicollinearity and/or zero-coefficient, two features, gray level variance (coefficient 1.71×10^{-3}) and low gray level emphasis (coefficient -2.48×10^{-5}), were finally included in the model. The two features were both computed from the size-zone matrix (SZM), the idea of which is to break down a given tumor volume into smaller spatially contiguous compartments of different sizes. In the validation cohort, the patients with high predicted TILes (≥ median) had significantly prolonged progression-free survival compared with those with low predicted TILes (median 3.81 months [95% CI 2.14 – 5.69] versus 1.94 months [95% CI 1.58 – 2.93], hazard ratio 0.69 [95% CI 0.53 – 0.90], p = 0.007). **Conclusions:** This CT radiomics model is able to assess TIL enrichment in TME, which is significantly associated with favorable ICI outcomes in NSCLC. Analyzing the TME through radiomics may overcome limitations of tissue-based analysis and inform clinical decisions, particularly related to use of ICI. Research Sponsor: None.

Increased incidence of immune-mediated myocarditis in advanced skin malignancies treated with immune checkpoint inhibitors in the COVID-19 era. *First Author: Allison Gradone, University of Michigan, Department of Internal Medicine, Ann Arbor, MI*

Background: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of advanced stage skin malignancies. Immunotherapy related adverse events (irAE) are toxicities associated with ICI therapy. Myocarditis is a rare life-threatening irAE. We attempt to characterize cases of myocarditis related to ICI therapy that have occurred since the start of the COVID-19 pandemic. **Methods:** We performed a single-center, retrospective cohort analysis of patients with advanced stage skin cancers who were treated with ICIs and identified cases of ICI-mediated myocarditis. ICI-mediated myocarditis was defined as evidence of myocardial injury in the setting of irAEs and exclusion of cardiovascular causes. Clinicopathologic variables and clinical outcomes were assessed in these patients. **Results:**A review of 361 patients that received ICI from 9/2014 – 10/2019 found 0 cases of ICI-mediated myocarditis. From 11/2019 – 12/2021, an additional 425 patients were identified of whom 11 (2.6%) developed ICI-mediated myocarditis. 10 patients had melanoma and 1 patient had Merkel cell carcinoma. 10/11 patients were male. 9/11 were treated with anti-PD-1 monotherapy and 2/11 were treated with ipilimumab with nivolumab. All patients had elevated high sensitivity troponin (median 361 pg/mL on presentation, reference range 0-19 pg/mL). 11/11 patients presented with elevated CPK (median 1734 IU/L, reference range 38-240 IU/L) and 8/11 presented with elevated AST:ALT ratio (median 1.58:1) on routine screening which prompted further investigation. 1 patient tested positive for COVID-19 13 days after initial biochemical concern for myocarditis, and 5 patients had received COVID-19 vaccines between 2.5-11 months prior to myocarditis onset. All patients were treated with high dose steroids, and 4 were treated with abatacept. 2 patients died within 30 days after diagnosis of myocarditis and 2 patients later died from malignancy progression. 2 patients developed progressive disease and 1 was successfully rechallenged with ICI with no myocarditis recurrence. 2 patients remain on active surveillance, 2 continue on a steroid taper, and 1 was lost to follow up. All patients with at least 5 months of follow up from myocarditis onset (n = 5) had persistently elevated HS-troponin despite normalization of CPK levels. **Conclusions:** In this single center study, we noted an increase in the frequency of ICI-mediated myocarditis in patients with advanced skin cancers during the pandemic era (2.6% vs 0% pre-pandemic) which is higher than reported in the literature (0.04-1.14%). The impact of COVID-19 during this time is suspicious and warrants further investigation. Therefore, we suggest heightened awareness in the COVID-19 era that elevated CPK levels and AST:ALT ratios merits further diagnostic investigation of ICI-mediated myocarditis. Management of infliximab-refractory immune checkpoint inhibitor gastrointestinal toxicity: A multicenter case series. *First Author: Catriona Harvey, Royal North Shore Hospital, Sydney, Australia*

Background: Immune checkpoint inhibitor (ICI) GI tox (gastritis, enteritis, colitis) is a major cause of morbidity and treatment-related death. Guidelines agree steroid-refractory cases warrant infliximab (IFx); however not all pts respond and best management of IFx-Refractory ICI GI toxicity (IRIGItox) is not clear. **Methods:** We conducted an international multi-centre retrospective case series. IRIGItox was defined as failure of symptom resolution ≤ Gr 1 (CTCAE v5.0) following ≥ 2 IFx doses *or* failure of symptom resolution ≤ Gr 2 after 1 dose. Data were extracted regarding demographics, steroid use, response and survival. Tox was graded at symptom onset and time of IFx failure. Efficacy of IFx refractory therapy was assessed by symptom resolution, time to resolution and steroid wean. **Results:** 78 pts were identified; med age 60 yrs (95% CI 56-65), 56% male. 70 (90%) had melanoma, 55 (71%) had advanced-stage, 60 (77%) received anti-CTLA-4 (with anti-PD1 50, single agent 10). Most had colitis (N=75, 96%) and ≥ Gr 3 tox (N=74, 95%) at symptom onset. Pre-IFx investigation varied: imaging 37%; faecal calprotectin 29%; endoscopy 59%. All pts received Med time to steroid initiation was 3 days (95% CI 2-4). 46 (59%) had primary steroid refractory disease, . Med time from symptom onset to IFx was 18 days (95% CI 12-23), a med 2 (range 1-6) doses of IFx were given, 69 (88%) pts received > 1 IFx dose. Across 78 pts, 105 post IFx treatments were given: calcineurin inhibitors (ciclosporin, tacrolimus, 32); antimetabolites (mycophenolate, azathioprine, 26); non-TNF-α MABs (vedolizumab, ustekinumab, 20); non-targeted anti-inflammatory (mesalazine, 16); non-pharmacological (colectomy 5, faecal transplant 1, photophoresis 1). 4 pts did not receive therapy for IRIGItox. Of these, 2 died of melanoma prior to resolution of tox; 1 had resolution after 4 doses IFx, 1 had recurrent melanoma and flare of tox on PD1 re-challenge. IRIGItox outcomes by post IFx treatment are shown in Table. **Conclusions:** This retrospective case series confirms heterogeneous management of IRIGItox. Non-pharmacological interventions and calcineurin inhibitors appear most likely to result in tox resolution. Calcineurin inhibitors have the shortest time to resolution in responders. Further details on post-IFx management and oncological outcomes will be examined. Research Sponsor: None.

Post IFx treatment (n)	Tox resolution n (%)	If resolved, time to resolution (med (95% CI), days)	If resolved, time to physiological steroid (med (95% CI), days)

Evaluating survival following severe immune-related adverse events requiring hospitalization. *First Author: Francis Wright, University of California San Francisco, School of Medicine, San Francisco, CA*

Background: As immune checkpoint inhibitors (CPI) are increasingly approved for the treatment of multiple cancer types, hospitalizations related to severe immune-related adverse events (irAE) will increase in tandem. Here, we identify patients hospitalized due to irAEs and describe survival outcomes across irAE, CPI, and cancer type. **Methods:** We identified patients exposed to CPIs who were hospitalized from 1/2012 to 12/2020 at our tertiary care hospital by computationally extracting data from the electronic health record. We then performed manual chart review to include only confirmed irAE-related hospitalizations. Survival outcomes were analyzed using Kaplan-Meyer survival curves with log-rank tests. **Results:** Of 3137 patients treated with CPIs, 117 were hospitalized for irAEs (cumulative incidence 4%). Of these, 36% had melanoma, 15% had lung cancer, 9% had renal cell carcinoma (RCC), and the rest were distributed across other cancers. The average number of irAE-related hospitalizations per patient was 1.25 (ranging from 1-3). Among 153 irAEs requiring hospitalization, 39% were gastrointestinal (GI) (including hepatitis), 12% endocrine, 12% pulmonary, 12% neurologic, 12% musculoskeletal, 7% cardiovascular, 6% dermatologic, and the rest affected other organs. Across all patients hospitalized for irAEs, median survival following hospitalization was 980 days. Patients with GI and endocrine irAEs had longer median survival (1474 days and median not reached [NR], respectively), while patients with pulmonary irAEs had shorter median survival (64 days) [p=0.002]. Patients with melanoma and RCC had longer median survival (2796 days and NR, respectively), while patients with lung cancer had shorter median survival (165 days) [p=<0.001]. Survival was not significantly different across CPI type [p=0.20]. **Conclusions:** Although hospitalization for severe irAE was rare, these findings suggest that among these patients, survival differs by irAE and cancer type. This real world data can contribute to clinical models that predict the risk of hospitalization and the risk of death due to severe irAEs, which may inform patient counseling and treatment decision-making. Research Sponsor: U.S. National Institutes of Health.

Frequency, survival, and follow up across irAE, cancer, and CPI type for sample sizes greater than ten.

irAE, Cancer & CPI type	Frequency (n)	%	Median Survival (days)	Time at Risk (days)	Survival IQR (days)	Median follow up (days)	Median follow up range (days)

Landscape of tumor mutation burden and correlation to clinical outcomes in 1,744 solid cancers. *First Author: Jaeyun Jung, Samsung Medical Center, Seoul, South Korea*

Background: Tumor mutation burden (TMB) has proven clinical utility and efficacy related to immune checkpoint inhibitor (ICI) treatment in different tumor types. However, limited data were available to understand the landscape and matched clinical outcomes to a pan-cancer extent. **Methods:** Target sequencing results, using TruSight Oncology 500, from 1,744 solid cancer between 2019 and 2021 as a part of real-world clinical practice were collected. Matched clinical and histological outcomes, including PD-L1 expression (n= 798) and immunotherapy treatment (n= 400), were analyzed. **Results:** Among the 33 different cancer types, high TMB was observed in 257 patients (14.7%) with a significantly higher incidence observed in carcinoma of unknown origin (33.3%), bladder cancer (32.3%), and small bowel cancer (30.0%). TMB was positively correlated with the degree of mutation in homologous recombination genes (HRD, 0.76) and microsatellite instability (MSI, 0.51). The predictive value of high TMB to ICI treatment seemed to be enhanced when it was combined with PD-L1 expression, showing higher response rates in the PD-L1 high group (63.3%) than in the low group (22.2%). In the patients with high TMB, both longer overall survival (p = 0.015) and progression-free survival (p = 0.020) were observed compared to the patients with low TMB. **Conclusions:** We examined the landscape of TMB in a different type of cancer using clinical-level target sequencing outcomes. High TMB seems to be a promising predictive biomarker of ICI, showing a positive correlation with alteration in other DNA damage response and repair-related genes and additive value to PD-L1, which needs to be validated through further prospective trials. Research Sponsor: None.

2668 **Poster Session**

Immune checkpoint inhibitor–induced diabetes mellitus across NCI trials. *First Author: Zoe E. Quandt, University of California-San Francisco, Division of Endocrinology, San Francisco, CA*

Background: Immune checkpoint inhibitors (CPI) are known to rarely cause new onset diabetes (CPI DM). While rare, this adverse event is quite challenging for patients and clinicians to manage. Therefore, it is important to identify risk factors and clinical characteristics. This is the first comprehensive, multi-institutional study of CPI-DM across multiple agents and cancer types. **Methods:** The NCI Cancer Therapy Program (CTEP) database of adverse events (AEs) was queried for AEs related to diabetes (Grade 3 or 4 hyperglycemia, Acidosis including Diabetic Ketoacidosis (DKA), glucose intolerance and diabetes mellitus) among 6,925 patients who had been treated with a PD-(L)1 inhibitor alone or in combination from 6/2015 to 12/2019. Each AE report was reviewed and classified as due to CPI DM, new onset type 2 diabetes mellitus (T2DM), T2DM exacerbation without medication non-compliance, existing DM with medication non-compliance, or association with steroids (SDM). CPI DM was diagnosed based on: evidence of insulin deficiency either through presentation in DKA or low c-peptide with need for long term basal bolus insulin to maintain euglycemia and/or positive islet autoantibodies. **Results:** In total, there were 82 cases with at least one of these AEs; 41 had CPI-DM, 22 had SDM, 1 had new T2DM, 4 had T2DM exacerbation, 3 had medication noncompliance and 11 had acidosis not attributable to diabetes or had insufficient data. After excluding non-hyperglycemic acidosis, 57.8% had CPI-DM. Furthermore, if not on steroids and in good compliance with diabetes medications, 89.1% had CPI-DM. The incidence of CPI-DM was 0.59%; it was most common on combination PD-1/CTLA-4 inhibitor therapy (0.85%, 15/1767), followed by PD-(L)1 inhibitor monotherapy (0.54%, 18/3354), followed by CPIs combined with additional agents including chemotherapy and targeted agents (0.44%, 8/1804)(p = 0.25). Hospitalization was required for 87.5% of CPI-DM cases with 74.3% of those requiring an inpatient endocrine consult. All but one CPI-DM case had an endocrine consult at as either an inpatient or outpatient. **Conclusions:** While rare, this cohort shows the large health care burden of CPI-DM and that any hyperglycemia, and especially marked hyperglycemia, should be treated as CPI-DM until proven otherwise. Research Sponsor: American Diabetes Association.

A systematic review and meta-analysis of early death (ED) upon immune checkpoint inhibitors (ICI) alone or combined with other non-ICIs treatments as first-line treatment of advanced solid tumors. *First Author: Giuseppe Viscardi, Medical Oncology, Precision Medicine Department, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy*

Background: An early crossing of the Kaplan-Meier overall survival curves in randomized clinical trials (RCTs) comparing ICI alone to standard treatments has been observed across different cancer types, suggesting the existence of an excess of mortality upon ICI. Whether ED reflects the natural history of the disease or it is a treatment specific phenomenon remains unclear. Therefore, we conducted a metanalysis of RCTs to analyze the association of ICI treatment with ED. **Methods:** PubMed, Embase and Cochrane were searched (until 12/2021) for RCTs comparing 1st-line PD-1/PD-L1 inhibitors +/- CTLA-4 inhibitors (ICI-only group) or the same drugs in combination with other non-ICI therapies (ICI+OT group) (experimental arms) vs non-ICI treatments (control arm) in patients (pts) with advanced solid cancers. ED was defined as death within the first 3 months of treatment. RCTs providing the number of pts in the intention-to-treat (ITT) population who were alive within 0-3 months from randomization were considered eligible. Primary outcome was ED rate both in the ICI-only and in the ICI+OT groups vs control arm. Secondary outcome was to compare ED risk between ICI-only group and ICI+OT group. Further analysis according to PD-L1 level were performed. The ED rates were estimated by risk-ratio (RR) with 95% confidence intervals (CI) and pooled by random effect model. Heterogeneity was assessed by I^2 statistics. **Results:** 56 RCTs (n = 38697 pts) were eligible, 48.2% included pts with thoracic malignancies. In the ICI-only group (18 RCTs, n = 6638 pts) 50.5% of pts received anti-PD-1/PD-L1 monotherapy and 43.4% anti-PD-1/PD-L1 + anti-CTLA-4 agents. In the ICI+OT group (43 RCTs, n = 15421 pts) 80.1% of pts received ICI + chemotherapy. Compared to control arm, risk of ED was significantly higher for pts who received ICI-only therapies (RR 1.27, 95% CI 1.04-155, p = 0.02, I^2: 73%), but significantly lower in ICI+OT group (RR 0.80, 95% CI 0.71-0.89, p < 0.00001, I^2: 36%). Risk of ED was also significantly higher with ICI-only compared to ICI-OT (RR 1.59, 95% CI 1.26-2.00). ED risk was higher upon ICI-only also in pts with high PD-L1 expression (TPS ≥50%, TC or IC 3, CPS ≥10) and, after excluding Keynote-024, this result became statistically significant (7 RCTs, RR 1.54, 95% CI 1.13-2.10, p = 0.007) with I^2 reducing from 63 to 46%. **Conclusions:** Across cancer types ED is a treatment specific phenomenon, increasing with first-line anti-PD-1/PD-L1 +/- CTLA-4 inhibitors and occurring also in pts with high PD-L1 expression, whereas it can be prevented by combining ICI with other non-ICI treatments. Research Sponsor: None.

TPS2670 **Poster Session**

Phase I study of HFB200301, a first-in-class TNFR2 agonist monoclonal antibody in patients with solid tumors selected via Drug Intelligent Science (DIS). *First Author: Alexander I. Spira, Virginia Health Specialists, Fairfax, VA*

Background: Tumor necrosis factor receptor-2 (TNFR2) is expressed on effector CD8+ T cells, CD4+ T cells, T regulatory cells, natural killer cells, and myeloid cells. Targeting TNFR2 is anticipated to yield effective anti-tumor immunity by stimulating T-cell and NK-cell activation and proliferation in the tumor microenvironment. HFB200301 is a first-in-class anti-TNFR2 agonistic monoclonal antibody that triggers both innate and adaptive immune stimulation by binding to a specific epitope on TNFR2. HFB200301 has demonstrated dose-dependent anti-tumor activity in human TNFR2 knock-in mice bearing MC38 and Hepa1-6 syngeneic tumors. **Methods:** HFB200301 is being evaluated in a first-in-human, open-label, multi-center, dose escalation and expansion study in adult patients with advanced solid tumors. A single-cell immune profiling platform, DIS, was deployed to identify unique tumor-infiltrating T cell signatures that could help optimize patient selection for HFB200301 treatment. It is hypothesized that the presence of an effector T cell subpopulation that express both TNFR2 and CD8A in solid tumors may represent a tumor microenvironment favorable to TNFR2 agonism. The following cancer indications have been identified based on the prevalence of a TNFR2 high/CD8 high signature: Epstein-Barr Virus positive (EBV+) gastric cancer, clear cell renal cell carcinoma (ccRCC), cutaneous melanoma, testicular germ cell tumor (TGCT), soft tissue sarcoma (STS), and PD-L1+ cancers: cervical cancer, pleural mesothelioma, lung adenocarcinoma, and head and neck squamous cell carcinoma (HNSCC). The escalation portion of the study explores increasing doses in cohorts of up to six patients, utilizing mTPI-2 design to determine recommended dose(s) for expansion (RDE(s)). Based on pharmacokinetic modeling to maximize HFB200301 activity, 60-minute intravenous infusions of HFB200301 are administered every 4 weeks. Once RDE(s) is determined, expansion into three indication-specific cohorts is planned to determine the recommended phase 2 dose (RP2D). Key eligibility criteria include histologically documented advanced or metastatic solid tumors in the above listed indications. Patient enrollment opened in February 2022 in the USA, with plans for additional clinical sites in Spain and China. The primary objective is to identify the RDE, characterize safety and tolerability of HFB200301, and determine RP2D. Secondary objectives include pharmacokinetic parameters, preliminary evidence of anti-tumor efficacy (e.g., ORR, DCR, DOR) and pharmacodynamic evaluation (e.g., T cell subsets) in the blood and in the tumor. Furthermore, a potential predictive biomarker signature derived based on the DIS single-cell immune profiling approach will be investigated retrospectively. Clinical trial information: NCT05238883. Research Sponsor: HiFiBiO Inc.

TPS2671 **Poster Session**

Trial in progress: A phase 1-2, first-in-human, open label, dose escalation and expansion study of AU-007, a monoclonal antibody that binds to IL-2 and inhibits IL-2Rα binding, in patients with advanced solid tumors. *First Author: James Robert Vasselli, Aulos Bioscience, Larkspur, CA*

Background: AU-007 is a computationally designed, monoclonal antibody that binds to IL-2 on its CD25 binding epitope. AU-007 bound IL-2 (A/IL-2) cannot bind to high affinity trimeric IL-2 receptors (IL-2R) consisting of CD25, CD122, and CD132 expressed on Tregs and vascular endothelium, but its binding to low affinity dimeric IL-2Rs (CD122 and CD132) expressed on T effector and NK cells is unhindered. Thus, AU-007 redirects endogenously produced or exogenous IL-2 (aldesleukin) towards activation of immune stimulating T effector and NK cells, while diminishing Treg activation and expansion. AU-007 will also bind and redirect newly secreted endogenous IL-2 resulting from A/IL-2 driven T cell expansion in the tumor, converting a Treg mediated autoinhibitory loop into an immune stimulating loop. AU-007 is unique in the IL-2 therapeutic field as engineered exogenous, recombinant "non-CD25" IL-2s in development cannot address the autoinhibitory effect of endogenous IL-2. Preclinically, AU-007 has been demonstrated to capture endogenous human IL-2 *in vivo*. AU-007 with a single low dose of IL-2 has demonstrated efficacy in multiple cancer models and has an excellent safety profile in non-human primates. **Methods:** This first-in-human, multicenter, open label Phase 1- 2 study evaluates the safety, tolerability, and initial efficacy of AU-007 +/- aldesleukin in patients with advanced solid tumors (CT-2021-CTN-03938-1). Phase 1 consists of 3 escalation arms each starting with a single 1+2 escalation cohort followed by 3+3 escalation cohorts to define the recommended Phase 2 dose (RP2D) or maximum tolerated dose (MTD). Patients with melanoma, renal cell carcinoma (RCC) and 17 selected solid tumors are eligible. Prior treatment with check point inhibitors is allowed. In Arm A, escalating doses of Q2w AU-007 are evaluated in sequential escalation cohorts. In Arm B, a single dose of aldesleukin is given with the initial AU-007 dose. AU-007 is given at a fixed dose Q2w with an escalating single aldesleukin dose in sequential escalation cohorts. In Arm C, AU-007 is evaluated in combination with aldesleukin, both given Q2w. AU-007 is administered at a fixed dose with an escalating dose of aldesleukin in sequential cohorts. The Phase 2 cohort expansion portion of the study evaluates the initial efficacy at the RP2D defined in escalation cohorts A, B, and C in 3 matching expansion cohorts of up to 20 patients each. Patients with advanced melanoma, RCC and other tumors including, but not limited to, Merkel Cell Carcinoma, NSCLC, and urothelial cancer are eligible. Enrolment to the study commences in Australia, with US sites planned to open later in 2022. Clinical trial information: CT-2021-CTN-03938-1. Research Sponsor: Aulos Bioscience.

TPS2672 **Poster Session**

A phase 1/2a open label, multicenter study to assess the safety, tolerability, pharmacokinetics, and efficacy of AFM24 in patients with advanced solid cancers: Study design and rationale. *First Author: Omar Saavedra Santa Gadea, Vall d'Hebron University Hospital and Institute of Oncology (VHIO), Barcelona, Spain*

Background: AFM24 is a first-in-class, tetravalent, bispecific, fragment crystallizable-silenced antibody that targets epidermal growth factor receptor-expressing (EGFR+) solid tumors. Of its 4 binding sites, 2 are specific for EGFR, and 2 are specific for CD16A, the Fcγ receptor expressed by natural killer (NK) cells and macrophages. The primary mode of action of AFM24 is not to inhibit EGFR signaling, but to redirect NK cells and macrophages to EGFR+ tumor cells to induce antibody-dependent cellular cytotoxicity (ADCC) and antibody-dependent cellular phagocytosis (ADCP), respectively. Preclinical studies showed AFM24 induced killing of EGFR+ tumor cell lines, and the activity was independent of EGFR cell surface expression level. A favorable safety profile was also demonstrated in cynomolgus monkeys. Therefore, AFM24 may utilize the patients' innate immunity to redirect and activate immune cells, overcoming resistance to current therapies and offering a favorable safety profile. An ongoing Phase 1/2a, first-in-human study (NCT04259450) is evaluating AFM24 in patients with locally advanced or metastatic, treatment refractory solid tumors that are known to express EGFR. The Phase 1 dose escalation study was designed to establish the maximum tolerated dose and/or the recommended Phase 2 dose (RP2D) of AFM24 and evaluated the safety, efficacy, immunogenicity, pharmacokinetic (PK) and pharmacodynamic (PD) responses. AFM24 was administered intravenously once weekly until disease progression, intolerable toxicity, patient withdrawal, or termination at the investigator's discretion. AFM24 had a well-managed safety profile and the RP2D was established. **Methods:** In parallel to the continuing dose escalation phase, the Phase 2a dose expansion study was initiated, and the first patient was enrolled in January 2022. This study will assess AFM24 at the RP2D of 480 mg in patients with different EGFR-expressing tumors and will follow a Simon's two-stage design; the trial will progress to the second stage unless the null hypothesis, that the true tumor response rate is below a specified value, is confirmed at the end of stage one. Eligible patients must have positive histological or cytological staining of EGFR in > 1% of tumor cells. The primary endpoint is to establish the overall response rate (assessed by the investigator per RECIST v1.1) in three disease-specific cohorts. These comprise patients with clear cell renal cell carcinoma (ccRCC), KRAS wild-type colorectal cancer (KRASwt CRC), and EGFR-mutant non-small cell lung cancer (EGFRmut NSCLC). Secondary endpoints include treatment-emergent adverse events, serious adverse events, PK, PD, and immunogenicity. Clinical trial information: NCT04259450. Research Sponsor: Affimed GmbH.

TPS2673 **Poster Session**

AFM24 in combination with atezolizumab in patients with advanced EGFR-expressing solid tumors: Phase 1/2a study design and rationale. *First Author: Omar Saavedra Santa Gadea, Vall d'Hebron University Hospital and Institute of Oncology (VHIO), Barcelona, Spain*

Background: Innate Cell Engagers (ICE) are bispecific molecules that bind both a tumor cell-surface antigen and to CD16A expressed on natural killer (NK) cells and macrophages, inducing antibody-dependent cellular cytotoxicity (ADCC) and antibody-dependent cellular phagocytosis (ADCP), respectively. As epidermal growth factor receptor (EGFR) is often overexpressed in several types of solid tumors, this provides an ideal tumor-cell surface antigen which may be targeted using ICE molecules. AFM24 is a first in class, tetravalent, bispecific, novel ICE targeting EGFR. By binding to EGFR on tumor cells and CD16A on innate immune cells, AFM24 may utilize a patient's innate immunity to induce ADCC/ADCP towards tumor cells. Anti-programmed death-ligand 1 (PD-L1) immune checkpoint inhibitors, which enhance the anti-tumor activity of a patient's adaptive immunity, have also demonstrated efficacy as monotherapy and are playing an increasingly prominent role in treatments. The combination of AFM24 and the PD-L1 inhibitor, atezolizumab, may therefore represent a rational new treatment modality, enhancing both the innate and adaptive immune responses to target EGFR+ tumor cells. **Methods:** An ongoing Phase 1/2a open-label, non-randomized, multicenter, dose escalation (Phase 1) and dose expansion (Phase 2a) study was initiated in November 2021 (NCT05109442) to evaluate the safety, tolerability and efficacy of AFM24 in combination with atezolizumab. The primary aim of the Phase 1 study is to determine the maximum tolerated dose and the recommended Phase 2 dose (RP2D) of AFM24. Eligible patients must have advanced histologically confirmed EGFR+ disease and confirmed disease progression after treatment with ≥1 prior therapy. Patients undergo a safety lead-in phase with AFM24 as a single agent 7 days before receiving the combination therapy. A standard 3+3 design will be used to determine the RP2D. Escalating doses of AFM24 will be given to each cohort as weekly intravenous (IV) infusions; the starting dose and at least two planned dose escalations are based on results from the ongoing AFM24 monotherapy trial (NCT04259450). Atezolizumab will be given at a fixed dose of 840 mg as a biweekly IV infusion. Patients will receive AFM24 and atezolizumab treatment until disease progression, intolerable toxicity, patient withdrawal, or termination at the investigator's discretion. The Phase 2a study will then establish the overall response rate (as per RECIST v1.1) and safety of combination therapy in patients with advanced/ metastatic, or treatment refractory gastric, esophagogastric, hepatocellular, hepatobiliary, pancreatic, or non-small cell lung cancer. For both phases, secondary endpoints include treatment-emergent adverse events, serious adverse events, pharmacokinetics, pharmacodynamics, and immunogenicity. Clinical trial information: NCT05109442. Research Sponsor: Affimed GmbH.

TPS2674 **Poster Session**

A non-inferiority randomized phase III trial of standard immunotherapy versus reduced dose intensity in responding patients with metastatic cancer: MOIO study. *First Author: Gwenaelle Gravis, Department of Medical Oncology, Institut Paoli-Calmettes, Aix-Marseille Universite, CRCM, Marseille, France*

Background: Immunotherapy (IO) is increasingly used for treating various metastatic cancers. With respect to the pharmacologically-active levels of IO drugs and their pharmacokinetics features, standard scheduling lead to plasma exposures largely exceeding the thresholds associated with target engagement. Indeed, phase I studies have shown that saturation of the target can persist far beyond the serum IO drugs half-life. *In silico* modeling has suggested that alternate scheduling (i.e. 3-monthly dosing) could be performed without compromising efficacy. Indeed, prolonged IO half-lives, time-varying clearance plus plasma concentrations far above the threshold associated with maximal target-engagement, suggest that the rhythm of IO administration could be slowed down. A phase II showed that extending IO dosing intervals did not compromise efficacy, while reducing toxicity in metastatic renal cell cancer. **Methods:** This non-inferiority, randomized, French national multicenter (36 centers involved) phase III study (NCT05078047) aims to compare the standard scheduling of a variety of IO drugs VS. 3-monthly scheduling in adult patients with metastatic cancer in partial (PR) or complete response (CR) after 6 months of standard IO dosing (except melanoma in CR). The main objective is to demonstrate the non-inferiority in Progression-Free Survival (PFS) of the reduced intensity group compared to the standard regimen. Secondary objectives are cost-effectiveness, quality of life, anxiety and fear of relapse, response rate, overall survival, and toxicity. A 1:1 randomization by minimization will be conducted on the following stratification factors: therapy line (first line vs others), tumor type, IO type (anti-PD-1 vs anti-PD-L1) and response status (PR, CR). A total of 646 pts will be randomized to get the 498 events necessary to prove non-inferiority between groups. The main analysis will conclude that reduced dose intensity is non-inferior to standard scheduling if the hazard ratio for PFS, estimated by a Cox model after adjustment for stratification factors, is significantly lower than the predefined 1.30 non-inferiority margin. In order to minimize the number of patients exposed to suboptimal treatment, an independent data monitoring committee will specifically review the efficacy data and recommend the early termination of the trial if lack of efficacy is evidenced. Ancillary studies of pharmacokinetics and immune-monitoring will be conducted to provide mechanistic insights supporting the clinical outcomes observed in both groups. **Conclusion** Should the hypothesis of non-inferiority with an IO reduced dose intensity be validated, alternate scheduling could preserve efficacy while being cost-effective and allowing a reduction of the toxicity, with an increase in patient's quality of life. Clinical trial information: NCT05078047. Research Sponsor: Institut National du Cancer France.

TPS2675 **Poster Session**

The combination of CD16A/EGFR innate cell engager, AFM24, with SNK01 autologous natural killer cells in patients with advanced solid tumors. *First Author: Anthony B. El-Khoueiry, University of Southern California, Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: Natural killer (NK) cells are a critical component of the innate immune system involved in the eradication of transformed cells via antibody-dependent cellular cytotoxicity (ADCC). For treatment of solid tumors autologous NK cell transfer represents a promising treatment strategy, with *ex vivo* expansion and activation enhancing the specificity and anti-tumor activity of NK cells. The efficacy of this approach may be enhanced through the addition of tumor-targeting antibodies, augmenting NK cell-mediated ADCC. Innate Cell Engagers (ICE) are bispecific antibodies that target a tumor cell-surface antigen and bind to CD16A expressed on NK cells. AFM24 is a novel ICE that targets epidermal growth factor receptor (EGFR), which is often overexpressed in solid tumors. The Phase 1 study of AFM24 monotherapy showed patients had a manageable safety profile, and SNK01 monotherapy has also shown to be well-tolerated in patients with rapidly progressive solid tumors. This study seeks to investigate AFM24 in combination with SNK01 autologous NK cells in patients with advanced EGFR+ solid tumors. **Methods:** An ongoing Phase 1/2a open-label, non-randomized, multicenter, dose escalation (Phase 1) and dose expansion (Phase 2a) study was initiated in November 2021 (NCT05099549) to evaluate the safety, tolerability and efficacy of AFM24 in combination with SNK01 NK cells in EGFR+ solid tumors. The primary aim of the Phase 1 study is to determine the maximum tolerated dose and/or recommended Phase 2 dose (RP2D) of AFM24 in combination with SNK01 at a fixed dose NK cells using a standard 3+3 design. Eligible patients must have advanced or metastatic disease with positive immunohistochemical staining for EGFR in >1% of tumor cells and be refractory to standard-of-care treatment. Treatment begins with a safety lead-in phase with a single dose of AFM24 7 days prior to combination therapy. AFM24 will be administered at an escalating dose as weekly intravenous (IV) infusions; the starting dose (160 mg) and dose escalations for each cohort are based on results from the ongoing AFM24 monotherapy trial (NCT04259450). SNK01 NK cells will be given at a fixed dose (4.0 x10^9 cells) as a weekly IV infusion concomitantly with AFM24. Patients will receive combination therapy until disease progression, intolerable toxicity, patient withdrawal or termination at the investigator's discretion. Phase 2 will then establish the overall response rate (as per RECIST v1.1) of combination therapy in patients with treatment refractory, advanced or metastatic squamous cell carcinoma of the head and neck, non-small cell lung cancer, or colorectal cancer as the primary endpoint. Efficacy will also be assessed by assessing progression-free and overall survival. Secondary endpoints for both phases include treatment-emergent adverse events, serious adverse events, pharmacokinetics and immunogenicity. Clinical trial information: NCT05099549. Research Sponsor: Affimed GmbH and NKGen Biotech, Inc.

TPS2676 **Poster Session**

BASECAMP-1: Leveraging human leukocyte antigen (HLA) loss of heterozygosity (LOH) in solid tumors by next-generation sequencing (NGS) to identify patients with relapsed solid tumor for future logic-gated Tmod CAR T-cell therapy. *First Author: Diane M. Simeone, Department of Surgery, New York University Langone Health, New York, NY*

Background: Solid tumors comprise > 90% of cancers. Metastatic colorectal cancer, non-small cell lung cancer, and pancreatic cancer are among the leading causes of cancer-related mortality (5-year overall survival: 14%, 6%, and 3%, respectively) (ACS. 2021). Chimeric antigen receptor (CAR) T-cell therapy has demonstrated clinical efficacy in hematologic malignancies (Neelapu S. et al. *N Engl J Med*. 2017). Translating engineered T-cell therapies to solid tumors has proven to be challenging due to a lack of tumor-specific targets that can discriminate cancer cells from normal cells. Previous studies using carcinoembryonic antigen (CEA) T-cell receptors and mesothelin (MSLN) CARs resulted in dose-limiting on-target, off-tumor toxicities (Parkhurst M, et al. *Mol Ther*. 2011; Tanyi J. Cellicon Valley '21). To create a therapeutic safety window, Tmod CAR T-cell therapy utilizes dual-signaling receptors to create a robust NOT logic gate capable of killing tumor cells, while leaving healthy cells intact (Hamburger A, et al. *Mol Immunol*. 2020). The 2 receptors in Tmod CAR T-cell therapy comprise an activator that recognizes an antigen on the surface of tumor cells that may also be present on normal cells, such as CEA and MSLN, and a blocker that recognizes a second surface antigen from an allele lost only in tumor cells. The frequency of HLA LOH among advanced GI solid tumor cancers in the Tempus real-world dataset is 16.3% with a range of 15.6%-20.8% between colorectal, pancreatic, and gastroesophageal tumors (Hecht R. et al. ASCO-GI 2022. Abstract #190). As such, HLA LOH offers a definitive tumor versus normal discriminator target for CAR T-cell therapy. Different activator/blocker combinations can be engineered with the Tmod platform technology and may be applied to T cells and natural killer cells in autologous and allogeneic settings. BASECAMP-1 is a currently enrolling observational study with key objectives of 1) To identify patients with somatic HLA LOH eligible for Tmod CAR T-cell therapy, and 2) To obtain leukapheresis and feasibility for the future EVEREST Tmod CAR T-cell trial. **Methods**: BASECAMP-1 (NCT04981119) patient eligibility has 2 parts: 1) Patients will be initially screened to identify germline HLA-A*02 heterozygosity by central NGS. If HLA-A*02 heterozygosity is confirmed, primary archival tumor tissue will be analyzed for somatic mutations by xT-Onco NGS testing. 2) If the tumor demonstrates HLA-A*02 LOH and the patient is eligible after screening, the patient will undergo leukapheresis. Banked T cells will be available for the autologous EVEREST Tmod CAR T-cell therapy interventional study to reduce waiting time at relapse. Clinical trial information: NCT04981119. Research Sponsor: A2 Biotherapeutics.

TPS2677 **Poster Session**

A phase 1, first-in-human (FIH) study of adenovirally transduced autologous macrophages engineered to contain an anti-HER2 chimeric antigen receptor (CAR) in participants with HER2 overexpressing solid tumors. *First Author: Kim Anna Reiss, University of Pennsylvania Abramson Cancer Center, Philadelphia, PA*

Background: Adoptive T cell therapies have led to remarkable advances among patients with hematologic malignancies, but have had less success in those with solid tumors. Macrophages are actively recruited and abundantly present in the solid tumor microenvironment (sTME). Tumor associated macrophages are predominantly immunosuppressive and support tumor growth (M2), while a subset of proinflammatory macrophages enhance anti-tumor immunogenicity (M1). M1 macrophage function can be augmented by CAR expression to selectively recognize and phagocytose antigen overexpressing cancer cells. Moreover, CAR macrophages can reprogram the sTME and present neoantigens to T cells, leading to epitope spreading and anti-tumor immune memory. Human Epidermal Growth Factor Receptor 2 (HER2) overexpression promotes tumorigenesis in many solid tumors (Table). CT-0508 is a cell product comprised of autologous monocyte-derived proinflammatory macrophages expressing an anti-HER2 CAR. Pre-clinical studies have shown that CT-0508 induced targeted cancer cell phagocytosis while sparing normal cells, decreased tumor burden, prolonged survival, and were safe and effective in a semi-immunocompetent mouse model of human HER2 overexpressing ovarian cancer. **Methods:** This Phase 1, FIH study is evaluating safety, tolerability, cell manufacturing feasibility, trafficking, and preliminary evidence of efficacy of investigational product CT-0508 in 18 participants (pt) with locally advanced (unresectable) or metastatic solid tumors overexpressing HER2. Pt previously treated with available therapies, including anti-HER2 therapies, as indicated, and subsequent progression are permitted. Filgrastim is used to mobilize autologous hematopoietic progenitor cells for monocyte collection by apheresis. CT-0508 is manufactured, prepared, and cryopreserved from mobilized peripheral blood monocytes. Group 1 pt (n=9) receive CT-0508 infusion split over D1, 3, and 5. A Safety Review Committee will review dose limiting toxicities. Group 2 pt (n=9) will receive the full CT-0508 infusion on D1. Pre- and post-treatment biopsies and blood samples will be collected to investigate correlates of safety (immunogenicity), trafficking (RNA scope), CT-0508 persistence in blood and in the tumor, target antigen engagement, TME modulation (single cell RNA sequencing), immune response (TCR sequencing) and others. Radiographic imaging is also being conducted to assess preliminary tumor activity. Clinical trial information: NCT04660929. Research Sponsor: Carisma Therapeutics.

HER2 overexpression across tumor types.

Tumor	HER2 Overexpression (%)
Bladder	8 - 70
Salivary duct / mucoepidermoid	30 – 40 / 17.6
Gastric	7 - 34
Ovarian / Cervical / Uterine	26 / 2.8 – 3.9 / 3
Breast	11 - 25
Esophageal	12 - 14
Gallbladder / Cholangiocarcinoma	9.8 – 12.8 / 6.3 - 9
Colorectal	1.6 - 5
Testicular	2.4

TPS2678 **Poster Session**

A phase I trial of T-cell receptor gene therapy targeting KK-LC-1 for gastric, breast, cervical, lung and other KK-LC-1 positive epithelial cancers. *First Author: Scott Norberg, National Cancer Institute, Bethesda, MD*

Background: T cell receptor (TCR)-T cell therapy is an emerging cancer treatment strategy. Thus far, demonstration of clinical activity has been limited to a subset of solid tumors including melanoma, synovial cell sarcoma and HPV-associated cancer. It is estimated that metastatic epithelial cancers are responsible for approximately 90% of cancer deaths in the United States. The estimated 600,000 cancer deaths each year is driven largely by lung adeno- and squamous cell carcinoma and invasive breast cancer, which account for approximately 30% of all cancer-related deaths. Kita-Kyushu Lung Cancer Antigen 1 (KK-LC-1) is a cancer germline antigen with expression restricted to germ cells in adults and certain epithelial cancers including lung, breast, gastric and cervical. We identified a KK-LC-1 TCR from the tumor-infiltrating lymphocytes (TIL) of a patient with cervical cancer who had a complete tumor response to TIL therapy. The KK-LC-1 TCR was the most dominate clonotype in the infused TIL product and persisted in the peripheral blood following infusion, suggesting that it may have contributed to cancer regression in this patient. **Methods:** We are conducting a phase I cell dose escalation trial to test the safety and efficacy of KK-LC-1 TCR-T cell therapy in patients with metastatic KK-LC-1 positive epithelial cancer. Patients receive a lymphocyte depleting conditioning regimen followed by a one-time infusion of genetically engineered T cells expressing the KK-LC-1 TCR (KK-LC-1 TCR-T cells) and high-dose systemic aldesleukin. KK-LC-1 positivity is determined by RNAscope assay measuring the percentage of cancer cells expressing CT83 (gene encoding KK-LC-1) with a percentage of 25 or greater considered positive. Main inclusion criteria include HLA-A*01:01 allele, prior first-line therapy, ECOG of 0 or 1 and adequate organ and hematologic function. Main exclusion criteria include active major medical illness of the cardiovascular, respiratory or immune system, primary or secondary immunodeficiency and autoimmune disease. Participants will be entered in sequential dose levels and receive escalating doses of cells beginning at $1x10^8$ and ending with $6x10^{10}$. Dose-limiting toxicities will be assessed during the first 30 days of cell infusion. The primary objective is to determine the maximally tolerated dose of KK-LC-1 TCR-T cells. Exploratory objectives include assessing the safety and efficacy of KK-LC-1 TCR-T cells and to conduct immunologic studies to understand and improve the administered treatment. Clinical trial information: NCT05035407. Research Sponsor: U.S. National Institutes of Health.

TPS2679 **Poster Session**

First-in-human phase 1/2 study of autologous T cells engineered using the Sleeping Beauty System transposon/transposase to express T-cell receptors (TCRs) reactive against cancer-specific mutations in patients with advanced solid tumors. *First Author: Marcelo Vailati Negrao, Department of Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In 2022 approximately 1.7 million Americans will die from solid cancers. Recently there have been significant advances in the genetic engineering of T lymphocytes to recognize neoantigens on tumors in vivo, resulting in remarkable cases of tumor regression and remission. Cancer cells frequently harbor *KRAS, TP53,* and *EGFR* somatic hotspot mutations that can be processed and presented by tumor HLA as neoantigens to T cells through their T-cell receptor (TCR). These neoantigens are not present in the normal tissues; thus, they are attractive targets for adoptive T cell therapy. Given the number and complexity of different neoantigen/HLA combinations on solid tumors, a TCR library approach is warranted. Therefore, we have developed a library of TCR-T cell therapies including those targeting shared *KRAS, TP53* and *EGFR* mutations. **Methods:** Patients for whom a TCR matching the subject's somatic mutation(s) and HLA type is available in our TCR library, and have progressive or recurrent disease following standard therapy are eligible for enrollment on this protocol. Patients with the following tumor types will be enrolled: ovarian, endometrial, colorectal, pancreatic, cholangiocarcinoma, and non-small cell lung cancer. This first-in-human study includes Screening, Pre-Treatment, Treatment and Follow-up Periods. During the Pre-Treatment Period, subjects will undergo apheresis for PBMCs isolation. The PBMCs will be transposed using the *Sleeping Beauty* system to express the subject's mutation specific TCR. Bridging therapy after apheresis is allowed once the apheresis product has been accepted. During the Treatment Period, patients will undergo lymphodepletion with cyclophosphamide and fludarabine. After which, the TCR-T cell drug product will be administered to the subject by infusion at the assigned dose level. The starting dose level of Arm A (monotherapy) will be DL1 ($5 x10^9$ TCR+ Cells) administered on Day 0. Dose escalation will continue utilizing the accelerated BOIN design (planned escalation dose levels: $5 x10^9$, $4 x10^{10}$ and $1 x10^{11}$ TCR+ Cells). In Arm B, if initiated by protocol, subjects will also receive aldesleukin (interleukin-2) infusion starting on Day 0 (within 24 hours of TCR-T cell product infusion) at 720K IU/kg, every eight hours for up to 4 days. The Follow-up Period will begin after the subject completes their Day 28 visit. Clinical and radiologic response will be assessed at 6 and 12 weeks after TCR-T cell drug product infusion and every 12 weeks thereafter until up to 2 years or study discontinuation (e.g., disease progression, initiation of new anti-cancer therapy, consent withdrawn), whichever occurs first. All subjects will continue to be followed in the Long-Term Follow-up Protocol for up to 15 years post-TCR-T cell drug product infusion. Clinical trial information: NCT05194735. Research Sponsor: Alaunos Therapeutics.

TPS2680 **Poster Session**

A phase 1/2 study of RTX-224, an engineered red blood cell expressing 4-1BB ligand and membrane-bound IL-12, for the treatment of patients with select advanced solid tumors. *First Author: Alexander I. Spira, NEXT Oncology - Virginia Cancer Specialists, Fairfax, VA*

Background: RTX-224 is a genetically engineered off-the-shelf, allogeneic red blood cell that expresses the costimulatory molecule 4-1BB ligand (4-1BBL) and cytokine interleukin-12 (IL-12) on the cell surface. The use of 4-1BB and IL-12 agonists for cancer immunotherapy has been limited due to systemic toxicities. Unlike agonist antibodies and recombinant cytokines, which are distributed systemically, Red Cell Therapeutics, such as RTX-224, are restricted to the vasculature and spleen, which may limit toxicities previously observed with agonist 4-1BB monoclonal antibodies and recombinant IL-12. RTX-224 is designed to be a broad immune agonist of both adaptive and innate responses that activates and expands effector and memory CD8+ and CD4+ T cells, cytotoxic natural killer (NK) cells and produces inflammatory cytokines and chemokines, leading to enhanced antigen presentation. In preclinical studies, the combined activation of both adaptive and innate immune responses by the murine surrogate of RTX-224 led to antitumor activity while the restricted biodistribution improved the safety profile. **Methods:** The RTX-224-01 study is a Phase 1/2, first-in-human, multi-center, dose-escalation and expansion study of RTX-224 in patients with relapsed or refractory urothelial cancer, squamous cell carcinoma of the head and neck, non-small cell lung cancer, triple negative breast cancer and cutaneous melanoma. Safety, tolerability, pharmacokinetics and pharmacodynamics and anti-tumor activity of RTX-224 will be assessed. Approximately 28 patients will be enrolled across dose level cohorts to identify the recommended Phase 2 dose (RP2D). The starting dose is 100 million ($1x10^8$) cells administered intravenously every 3 weeks (Q3W) and the dose will be escalated by half-log increments following a Bayesian logarithmic regression model (BLRM) with overdose control. Following RP2D selection, each of the 5 expansion cohorts will enroll approximately 20 patients. Pharmacodynamic and exploratory biomarker studies correlative to clinical response will be evaluated on peripheral blood and paired tumor biopsies. Multiple technologies will be employed to profile the innate and adaptive responses following RTX-224 treatment. The study is open and enrolling patients in Phase 1. Clinical trial information: NCT05219578. Research Sponsor: Rubius Therapeutics, Inc.

TPS2681 **Poster Session**

ZENYTH-ESO: Master protocol to assess the safety and recommended phase II dose of next generation NY-ESO-1-specific TCR T-cells in HLA-A*02 patients with synovial sarcoma and myxoid/round cell liposarcoma [Substudy 3, GSK4427296]. *First Author: Dejka M. Araujo, University of Texas MD Anderson Cancer Center, Department of Sarcoma Medical Oncology, Houston, TX*

Background: Letetresgene autoleucel (lete-cel; GSK3377794) is an autologous T-cell therapy expressing an affinity-enhanced T-cell receptor (TCR) to improve recognition of cancer cells expressing NY-ESO-1 and/or LAGE-1a. Next generation NY-ESO-1 TCR T-cell therapy, GSK4427296, utilizes the same TCR as lete-cel, as well as an epigenetic reprogramming process (Epi-R) developed by Lyell Immunopharma to alter the phenotypic T-cell profile of the manufactured product, and is intended to increase the proportion of cells with properties of durable stemness. T cells with properties of durable stemness are able to proliferate, persist, and self-renew with anti-tumor functionality. A first-time-in-human master protocol (NCT04526509) is underway to evaluate the safety, tolerability, and recommended phase II dose (RP2D) of next generation NY-ESO-1 TCR T-cell therapies. Substudy 3 is added to this master protocol to assess GSK4427296 in patients with advanced synovial sarcoma (SS) or myxoid/round cell liposarcoma (MRCLS). **Methods:** This substudy includes a dose confirmation stage to assess RP2D and a dose expansion stage, aiming to dose 10 participants at the RP2D. Key inclusion criteria: age ≥18 years; measurable disease per RECIST v1.1; HLA-A*02:01, A*02:05, or A*02:06 positivity; NY-ESO-1/LAGE-1a tumor expression; advanced (metastatic/unresectable) SS with t(X;18) translocation or MRCLS with a translocation involving *DDIT3* and/or *FUS* and/or *EWSR1* genes; and anthracycline-based therapy receipt/completion/intolerance. Key exclusion criteria: prior malignancy that is not in complete remission or clinically significant systemic illness; prior receipt of gene or allogenic stem cell/solid organ transplant; and central nervous system metastases. Primary endpoints: safety (adverse events) and tolerability (dose-limiting toxicities). Secondary endpoints: investigator-assessed overall response rate, duration of response, maximum transgene expansion (C_{max}), T_{max}, and $AUC_{(0\text{-}t)}$. Analyses will be descriptive. The master protocol is open for recruitment. Clinical trial information: NCT04526509. Research Sponsor: GlaxoSmithKline; GSK4427296 produced by and used in collaboration with Lyell Immunopharma.

TPS2682 **Poster Session**

NEBULA: A multicenter phase 1a/b study of a tumor-selective transgene-expressing adenoviral vector, NG-641, and nivolumab in patients with metastatic or advanced epithelial tumors. *First Author: Thomas Lillie, PsiOxus Therapeutics Ltd, Abingdon, United Kingdom*

Background: Tumor-Specific Immuno Gene Therapy (T-SIGn) vectors are next-generation transgene-armed variants of the adenoviral vector enadenotucirev that selectively replicate in epithelial tumor cells. T-SIGn vectors are blood-stable, allowing IV delivery to be coupled with local transgene expression in the tumor microenvironment (TME), thereby targeting all lesions while limiting systemic exposure. The T-SIGn vector NG-641 encodes four immunostimulatory transgenes: fibroblast activation protein-directed bi-specific T-cell activator antibody to target cancer-associated fibroblasts (CAFs), IFNα2 to promote innate and adaptive immune responses, and CXCL9/10 to induce T-cell infiltration. Through this novel multimodal combination of immunostimulatory effects NG-641 is designed to re-program the TME to allow functional anti-cancer immune responses. In the ongoing STAR study (NCT04053283), NG-641 has been successfully dose-escalated to 1×10^{12} viral particles (vp) on Day 1 and 3×10^{12} vp on Days 3 and 5, with promising preliminary safety/tolerability and pharmacodynamic results. Based on these encouraging preliminary data with NG-641 monotherapy, we designed a new study to assess NG-641 + nivolumab. **Methods:** NEBULA (NCT05043714) is an open-label, dose-escalating, phase 1a/b study of NG-641 + nivolumab in patients (pts) with advanced/metastatic epithelial tumors that have progressed after ≥1 line of systemic therapy and are incurable by local therapy. Pts are eligible for phase 1a if they have received prior PD-1/PD-L1 inhibition as part of any line of therapy. During phase 1a, up to 30 pts will receive escalating doses of IV NG-641 to a maximum dose of 1×10^{12} viral particles (vp) on Day 1 and 1×10^{13} vp on Days 3 and 5 (1 cycle; Bayesian Optimal Interval design). Pts will receive a fixed-dose of nivolumab (480 mg IV) on Day 15 and then every 4 weeks thereafter for up to 8 cycles. In phase 1b, the recommended dose regimen will be further studied in patients with primary resistance to PD-1/PD-L1 inhibition; patients will be enrolled in up to 3 tumor-specific cohorts (Cohorts A-C; Simon 2-stage design). Co-primary objectives are to characterize the safety and tolerability of NG-641 + nivolumab and to identify a recommended dose. Preliminary efficacy and immunogenicity are secondary endpoints. Pharmacodynamic outcomes will also be assessed. Viral replication, transgene expression, immune/inflammatory responses and effects on CAFs by IHC and gene expression analysis will be analyzed using tumor tissue from serial biopsies (taken at baseline and Day 15 of cycles 1-3 [cycles 1-2 only in Phase 1b]). Serial blood samples will be analyzed to study cytokine production and changes in peripheral immune cell subsets. Enrollment to the first dose-escalation cohort is ongoing. Clinical trial information: NCT05043714. Research Sponsor: Funded by PsiOxus Therapeutics Ltd, in collaboration with Bristol Myers Squibb.

TPS2683 **Poster Session**

Davoceticept (ALPN-202), a PD-L1-dependent CD28 costimulator and dual checkpoint inhibitor, in combination with pembrolizumab in patients with advanced malignancies (NEON-2). *First Author: Amita Patnaik, START, San Antonio, TX*

Background: Despite successes with checkpoint inhibition (CPI) in a wide range of tumors, most demonstrate primary or acquired resistance, warranting better therapeutic strategies. PD-1 is now recognized to effect much of its benefit by disinhibiting CD28 signaling – a mechanism expected to require intra-tumoral engagement of CD28 by its ligands CD80/CD86. Davoceticept (ALPN-202), a variant CD80 vIgD-Fc fusion protein, was engineered to provide tumor localizing PD-L1-dependent CD28 agonism, while inhibiting PD-L1 and CTLA-4. Davoceticept has demonstrated superiority to CPI-only therapies in both in vitro and in vivo tumor models, while also demonstrating additional benefit in combination with targeted PD-1 axis blockade (Lewis et al. (2019) J Immunother Cancer 7(S1): P467). The benefit appeared at least additive in models of poorly immunogenic tumors, suggesting the possibility of meaningful clinical benefit where CPI therapeutic efficacy is limited, such as noninflamed tumors. Single agent safety and tolerability of davoceticept has been demonstrated along with pharmacodynamic evidence of CD28 engagement with immune checkpoint inhibition (Moser et al. (2021) J Clin Oncol 39(s15): 2547). **Methods:** NEON-2 is an open-label dose escalation and expansion study of davoceticept combined with pembrolizumab in adults with advanced solid tumors or lymphoma that was initiated in June 2021 (NCT04920383). Eligibility includes tumors where single agent PD-(L)1 antagonists are SOC, are refractory or resistant to standard therapies (including approved CPIs), or have no standard or curative therapy. The study employs a standard 3+3 dose escalation design with two schedules, Q1W and Q3W of davoceticept. Pembrolizumab is given per label at 400 mg IV Q6W. Objectives include evaluation of safety and tolerability, identification of the recommended phase 2 dose(s) (RP2D), PK, PD, exploratory predictive biomarker analysis (i.e., PD-L1, CD28, CD80 and CD86 expression, as well as immunophenotyping of immune cell populations on treatment) and preliminary anticancer activity of davoceticept in combination with pembrolizumab. Disease assessments are evaluated by RECIST v1.1 for solid tumors or by Lugano Classification for lymphoma. Efficacy endpoints include ORR, duration of response and disease control rate. Once the RP2D combination is identified, tumor-specific expansion cohorts of ~ 30- 35 patients will be performed, including histologies that have not been demonstrated to be CPI responsive, as well as those where CPIs are approved SOC. The 0.1 mg/kg cohorts have been completed without DLT. Enrollment to the 0.3 mg/kg cohorts began in September 2021. Clinical trial information: NCT04920383. Research Sponsor: Alpine Immune Sciences.

TPS2684 **Poster Session**

ARTISTRY-3: Effect of nemvaleukin alfa with a less frequent IV dosing schedule as monotherapy and in combination with pembrolizumab and impact on the tumor microenvironment (TME) in patients (pts) with advanced solid tumors. *First Author: Sarina Anne Piha-Paul, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Nemvaleukin alfa (nemvaleukin, ALKS 4230) is a novel engineered cytokine that selectively binds the intermediate-affinity interleukin-2 (IL-2) receptor, preferentially activating and expanding antitumor $CD8^+$ T cells and NK effector cells, with minimal effect on regulatory T cells. Nemvaleukin was designed to leverage antitumor effects of the IL-2 pathway while limiting typical IL-2–associated toxicity. In ARTISTRY-1, the recommended phase 2 dose (RP2D) for nemvaleukin monotherapy of 6 μg/kg IV on days 1 to 5 of a 21-day cycle elicited durable and deep responses in pts with advanced melanoma and renal cell carcinoma (Boni et al. ASCO 2021:abstr 2513). Responses with nemvaleukin plus pembrolizumab were also observed in platinum-resistant ovarian, breast, cervical, gastrointestinal, and genitourinary cancers. ARTISTRY-3 will investigate the effects of nemvaleukin as monotherapy and in combination with pembrolizumab on the TME in pts with advanced solid tumors, and in an additional cohort (Cohort 2), to further assess a less frequent IV dosing schedule for nemvaleukin. **Methods:** The phase 1/2, open-label ARTISTRY-3 (NCT04592653) study will enroll adults (≥18 years) with select advanced solid tumors, ≥1 accessible lesion for biopsy, ≥1 target lesion (per RECIST v1.1), ECOG PS of 0 or 1, estimated life expectancy of ≥3 months, adequate hematologic reserve, and adequate hepatic and renal function. Primary objectives: to evaluate effects of nemvaleukin monotherapy on the TME (Cohort 1) and to determine RP2D for less frequent dosing schedule (Cohort 2). Additional objectives are to evaluate: efficacy, safety, immunogenicity, and pharmacokinetics of nemvaleukin monotherapy; effects of nemvaleukin plus pembrolizumab on the TME; and correlative biomarkers of nemvaleukin as monotherapy and combination. Following the protocol amendment, additional pts enrolled in Cohort 1 will receive lead-in monotherapy at a dose selected based on results from Cohort 2, and pre- and on-treatment biopsies will be collected for TME assessments. Subsequent cycles will be administered in combination with pembrolizumab, and a biopsy may be collected at cycle 4 or 5. Tumor types eligible for Cohort 2 are selected based on activity observed in the ARTISTRY-1 study. A quantitative system pharmacology model was applied to identify a less frequent schedule for nemvaleukin monotherapy and combination. Cohort 2 will initially assess safety and tolerability of nemvaleukin at 1 dose per 21-day cycle. Two doses per 21-day cycle may be implemented to achieve optimal PK/PD parameters. Bayesian optimal interval design methodology with open enrollment will be applied to facilitate dose escalation decisions. Clinical trial information: NCT04592653. Research Sponsor: Alkermes, Inc.

TPS2685 **Poster Session**

BMC128: A rationally designed live bacterial consortium for the potentiation of immune checkpoint therapy in solid tumors. *First Author: Corinne Maurice-Dror, BC Cancer, Vancouver, BC, Canada*

Background: Immune-Checkpoint inhibitors (ICI) have transformed the treatment of solid tumors, specifically in cutaneous melanoma, clear cell renal cell carcinoma (ccRCC) and non-small cell lung cancer (NSCLC). Despite these advances, a significant proportion of patients do not respond to ICI and only a fraction of responding patients will experience durable responses. Recent reports have found that patients showing poor response to ICI are characterized by a reduced gut microbiome diversity, suggesting that the gut microbiome might affect immune activation by ICI. BMC128 is a live bacterial consortium of 4 bacterial strains predicted to induce anti-tumor immune function when given in conjunction with ICI. These strains were identified by analyzing data obtained from NSCLC and ccRCC patients presenting varied responses to ICI, using a proprietary computational discovery platform enabling high-resolution functional microbiome analysis. In pre-clinical studies, treatment with BMC128 potentiated the efficacy of ICI in breast cancer and melanoma mouse models, reducing tumor volume, increasing the number of responders, and demonstrating an increase in infiltrating immunocytes: CD4, CD8 and NK cells. **Methods:** In this phase I, first-in-human trial, patients with ccRCC, cutaneous melanoma and NSCLC-adenocarcinoma (EGFR/ALK wild-type), who previously progressed on PD1/PDL-1 inhibitors will be treated with BMC128 $8*10^8$ CFU BID in combination with Nivolumab at a fixed-dose of 480mg q4weeks in a 3+3 design, followed by a 9 patient expansion phase. No dose escalation is planned. The primary objective is to investigate the safety and tolerability of BMC128 in combination with Nivolumab. Enrollment is intended to start in Feb, 2022. Clinical trial information: 202122207. Research Sponsor: Biomica Ltd.

Overall study design.

	Period		Duration (days)
1	Screening	Screening	
2	DLT period	Native microbiota depletion	1
3		Induction (BMC128 monotherapy)	14
4		Combination treatment, cycle 1: BMC128+Nivolumab	28
5	Cycles 2-4	Combination treatment, BMC128+Nivolumab	84
6	Cycles 5-26	Nivolumab monotherapy	~590
7	Follow up	Follow up	30

TPS2688 **Poster Session**

A phase 1 dose-escalation study to investigate the safety, efficacy, pharmacokinetics, and pharmacodynamic activity of CLN-619 (anti-MICA/MICB antibody) alone and in combination with pembrolizumab in patients with advanced solid tumors. *First Author: John D. Powderly, Carolina BioOncology Institute, Huntersville, NC*

Background: The major histocompatibility complex (MHC) class I-related proteins MICA and MICB are stress-inducible, surface glycoproteins that are up-regulated on human tumors. MICA/MICB are ligands for the activating receptor, Natural Killer Group 2 member D (NKG2D) expressed on Natural Killer (NK) cells, CD8+ T cells, $\gamma\delta$ T cells and iNKT cells. Proteases in the tumor microenvironment cleave MICA/MICB from the cell surface which enables tumor cells to evade immune cell recognition and destruction by NKG2D-expressing cells. Increased concentrations of shed MICA have been observed in serum from patients across multiple tumor types and correlate with poor survival. CLN-619 is a humanized, clinical-stage, MICA/MICB-specific IgG1 monoclonal antibody that prevents the proteolytic release of MICA/MICB thereby exposing tumor cells for immune destruction through both NKG2D-mediated and antibody-dependent cell-mediated cytotoxicity (ADCC). The antibody has been shown to restore the MICA/MICB-NKG2D axis to promote NK-mediated tumor cell lysis (AACR Annual Meeting abstract 3506, April 2022). In mice bearing MICA/MICB-expressing human tumor xenografts, CLN-619 treatment yielded robust anti-tumor activity at low doses. MICA/MICB is expressed in a wide range of solid tumors. Therefore, CLN-619 is expected to have broad anti-tumor activity. **Methods:** CLN-619 is being evaluated in an open-label, non-randomized, dose-escalation (phase 1) study as monotherapy, and in combination with pembrolizumab, in patients with advanced solid tumors. Cohort expansion in patients with specific indications as monotherapy and in combination with pembrolizumab will be conducted. The phase 1 study explores ascending intravenous doses of CLN-619 as monotherapy (0.1, 0.3, 1.0, 3.0, 6.0 and 10.0 mg/kg) and in combination with pembrolizumab (200 mg) in 21-day cycles to identify the maximum tolerated dose (MTD) and recommended Phase 2 dose (RP2D). Key eligibility criteria include 1) histological or cytological diagnosis of cancer and 2) refractory metastatic disease, or locally advanced disease not amenable to local therapy. At the RP2D, CLN-619 monotherapy will be evaluated in non-small cell lung and cervical cancer. In parallel, a cohort of patients will be administered CLN-619 in combination with pembrolizumab. Serum levels of soluble MICA/MICB, identity of MICA/MICB alleles, phenotypes of peripheral blood mononuclear cells, cytokines and tumor biopsies will be investigated for correlative pharmacodynamic and predictive biomarkers. This clinical trial is in progress (NCT05117476) and has completed accrual of three participants at the first dose level. Clinical trial information: NCT05117476. Research Sponsor: Cullinan Oncology, LLC.

TPS2689 **Poster Session**

A combined phase I/II study of a novel bicycle tumor-targeted immune cell agonist BT7480 in patients with nectin-4 associated advanced malignancies. *First Author: Kyriakos P. Papadopoulos, START San Antonio, San Antonio, TX*

Background: BT7480 is a novel, first-in-class, Nectin-4/CD137 *Bicycle* tumor-targeted immune cell agonist (*Bicycle* TICA) that co-ligates cluster of differentiation (CD)137 (on immune cells) and Nectin-4 (on tumor cells). BT7480 comprises 3 bicyclic peptides (*Bicycles*), 1 that binds to Nectin-4 and 2 that bind to CD137. The *Bicycles* are conjugated via a branched trimeric polyethylene glycol linker. Co-ligation of Nectin-4 and CD137 by BT7480 is hypothesized to induce oligomerization and activation of CD137 resulting in a tumor-localized costimulatory signal that leads to an antitumor response in preclinical studies. Nectin-4 is reported to be highly expressed in numerous tumors with unmet medical need including bladder, pancreas, breast, ovary, esophagus, head and neck, stomach, and lung cancers. Many of these tumor types also contain CD137 expressing cells. BT7480 exhibited a favorable preclinical profile supporting initiation of a first-in-human study to investigate safety and efficacy in indications with evidence of Nectin-4 expression. **Methods:** BT7480-100 (NCT05163041) is a PhI/II study to evaluate safety and tolerability of BT7480 administered as an intravenous infusion QW in a 28-day cycle, and to determine a recommended Phase 2 dose to further explore efficacy and safety. Patients will be recruited with advanced solid tumors associated with Nectin-4 expression including urothelial; head and neck squamous cell; non-small cell lung; ovarian, breast, gastric or esophageal carcinoma after exhausting standard of care options. Patients must have available tumor tissue, acceptable hematologic and other critical organ function. Exclusion criteria include uncontrolled brain metastases, uncontrolled hypertension, significant history of autoimmune disease and prior CD137 targeted therapy. Pharmacokinetic and pharmacodynamic analyses will be performed to support dose escalation decisions and increase the understanding of safety and clinical activity signals observed during the study. Tumor response will be assessed per RECIST every 8 weeks. Cohorts 1 and 2 have been completed without DLT. Enrollment in cohort 3 began in January 2022. Clinical trial information: NCT05163041. Research Sponsor: BicycleTx Limited.

TPS2690 **Poster Session**

Phase 1a/1b study design of the novel STING agonist, immune-stimulating antibody-conjugate (ISAC) TAK-500, with or without pembrolizumab in patients with advanced solid tumors. *First Author: Jennifer Robinson Diamond, University of Colorado Anschutz Medical Campus, Aurora, CO*

Background: Tumor resistance to immune checkpoint inhibitors (CPIs), including pembrolizumab, is common. Suggested mechanisms of resistance include reduced interferon (IFN) signaling, immune escape, and immunosuppressive tumor phenotypes. Innate immune cell stimulation in the tumor microenvironment may be a potential pathway to overcome this resistance. Stimulator of interferon genes (STING) is a cytosolic protein critical for initiation of type-1 IFN-dependent innate immunity. TAK-500 is a novel ISAC comprising a STING agonist (based on TAK-676, which is currently in phase 1 clinical trials [NCT04420884, NCT04879849]), an IgG1 anti-cysteine-cysteine chemokine receptor 2 (CCR2) antibody, and a self-immolating maleimide-containing protease-cleavable peptide linker. CCR2-expressing myeloid cells, including tumor associated macrophages (TAMs), promote immune evasion in part by reducing infiltration of CD8+ T cells into the tumor microenvironment. As such, TAK-500 has the potential to mitigate CPI resistance in solid tumors via targeted STING activation of tumor-infiltrating CCR2-expressing myeloid cells, thus leading to stimulation of innate and adaptive immunity within the tumor microenvironment through three potential mechanisms of action: activation of IFN signaling, reprogramming of CCR2-expressing myeloid cells to an inflammatory phenotype, and blockade of suppressive TAM recruitment. **Methods:** Adult patients with a diagnosis of locally advanced or metastatic gastroesophageal adenocarcinoma, pancreatic adenocarcinoma, hepatocellular carcinoma, non-squamous non-small cell lung cancer, squamous cell carcinoma of the head and neck, mesothelioma or triple-negative breast cancer are eligible. All patients must have progressive disease while on, or be intolerant to, all current standard therapies. Approximately 106 patients in total will be enrolled to the dose escalation and expansion cohorts. In the dose escalation phase, intravenous (IV) TAK-500 will be administered over the range 8–480 μg/kg on day 1 of every 21-day cycle (Q3W) to establish the pharmacologically active dose (PAD) range. An additional escalation cohort of patients will receive TAK-500 + IV pembrolizumab 200 mg Q3W, starting at a dose of TAK-500 that is 1–2 dose levels below the lowest PAD range established in the single agent cohort. Dose escalation in both cohorts will be guided by Bayesian Optimal Interval design. In the dose expansion phase, only the combination of TAK-500 + pembrolizumab will be evaluated. Primary objectives of this study are safety and tolerability; secondary objectives include determination of the PAD range, the recommended phase 2 dose, pharmacokinetics, pharmacodynamics, and antitumor activity of TAK-500 as a single agent and in combination with pembrolizumab. Clinical trial information: NCT05070247. Research Sponsor: Takeda Development Center Americas, Inc. (TDCA).

TPS2691 **Poster Session**

A first-in-human phase 1 trial of nx-1607, a first-in-class oral CBL-B inhibitor, in patients with advanced solid tumor malignancies. *First Author: Adam Sharp, The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: Casitas B-lineage lymphoma proto-oncogene B (CBL-B) is an E3 ubiquitin ligase expressed in multiple immune cell lineages, which in contrast to cell surface immune checkpoints, acts as a regulator of both T and NK cell activation. Inhibition of CBL-B enhances T-cell response, increases response to suboptimal priming, and restores response in exhausted T cells. Thus CBL-B is a promising immune-oncology target and may overcome challenges seen with other T-cell directed therapies. NX-1607 is an oral small molecule inhibitor of CBL-B that has demonstrated anti-tumor activity and long-term survival in murine models as both a single agent and in combination with programmed cell death protein-1 (PD-1) antibodies. Further, NX-1607 elicits dose-dependent increases in cytokine secretion and proliferation in T-cell receptor-stimulated primary human T cells with enhanced tumor antigen-specific T-cell and NK cell anti-tumor responses. Thus, NX-1607 may be effective as a single agent or it may significantly enhance efficacy of other anti-tumor agents. **Methods:** NX-1607-101 is a first-in-human, multicenter, open-label, Phase 1 dose escalation and expansion trial evaluating NX-1607 in a variety of indications including platinum-resistant epithelial ovarian cancer (EOC), gastric cancer, squamous cell carcinoma of the head and neck (HNSCC), metastatic melanoma, non-small cell lung cancer (NSCLC), metastatic castration-resistant prostate cancer (mCRPC), malignant pleural mesothelioma (MPM), triple-negative breast cancer (TNBC), locally advanced or metastatic urothelial cancer, cervical cancer, microsatellite stable colorectal cancer (MSS CRC), and diffuse large B-cell lymphoma with Richter transformation (DLBCL-RT). The main objective is to establish the safety and tolerability of NX-1607, characterize PK/PD, and determine the recommended Phase 1b dose. NX-1607 will be given orally once daily at doses ranging from 5 to 100 mg in up to 6 dose levels. Dose escalation will proceed using an accelerated modified Fibonacci dose escalation design that transitions to a standard 3 + 3 design based on protocol-specific criteria. Up to 8 expansion cohorts in Phase 1b will be composed of patients with subsets of advanced cancers. Key eligibility criteria include patients with metastatic or unresectable disease that have progressed after prior therapy and for whom standard therapy with proven clinical benefit does not exist, is no longer effective, or is not appropriate. Prior treatment with immune checkpoint inhibitors or CAR-T cells with washout is allowed, but a history of active autoimmune disease is not. Up to 336 patients (60 in Phase 1a, 276 in Phase 1b using a Simon 2-stage design) will be enrolled at approximately 20 sites in the UK and US and treated until disease progression or unacceptable toxicity. Dose escalation is ongoing. Clinical trial information: NCT05107674. Research Sponsor: Nurix Therapeutics, Inc.

TPS2693 **Poster Session**

A phase 1/2 dose escalation/expansion study of OR2805 alone or in combination in subjects with advanced solid tumors. *First Author: Anthony W. Tolcher, NEXT Oncology and Texas Oncology, San Antonio, TX*

Background: M2-like macrophages are thought to promote an immunoinhibitory environment and prevent activation and proliferation of T cells, leading to resistance to checkpoint inhibitor (CPI) therapy. OR2805 is a fully human monoclonal antibody identified in a patient who had an exceptional response to CPI. OR2805 recognizes CD163, an immunosuppressive scavenger receptor highly expressed on M2 tumor-associated macrophages (TAMs). OR2805 treatment reprograms M2 macrophages to take on an immunostimulatory, M1-like phenotype. In macrophage/T cell coculture assays, OR2805 treatment relieved the suppressive effect of M2c macrophages as demonstrated by increased T-cell proliferation and stimulation of IFN-γ and perforin release. OR2805 restored the IFN-γ production of exhausted T cells and showed a synergistic effect on cocultures treated in combination with CPI. OR2805 monotherapy demonstrated significant anti-tumor activity in lung cancer xenograft models in NSG-SGM3 mice. Relieving the immune suppression of CD163-expressing TAMs by OR2805 to improve anti-tumor T-cell responses will be evaluated alone and in combination with CPI therapy. **Methods:** This phase 1/2, open-label, multicenter, dose-escalation/expansion study is assessing the safety, tolerability and preliminary activity of OR2805 alone and in combination with anti-PD-1 or chemotherapy in up to 325 adults (≥18 years) with histologically or cytologically confirmed metastatic or locally advanced solid tumors. The study is divided into 3 parts. Part A will enroll subjects with advanced solid tumors of any histology to describe the preliminary safety profile of OR2805 and determine the recommended phase 2 dose (RP2D) of OR2805 alone and in combination with an anti-PD-1 monoclonal antibody. Part B will further characterize the safety and preliminary antitumor activity of OR2805 either alone or in combination with an anti-PD-1 or chemotherapy in previously treated non-small cell lung cancer (NSCLC), melanoma and liposarcoma, as well as in previously untreated NSCLC in combination with an anti-PD-1 antibody. Part C will evaluate OR2805 monotherapy in relapsed squamous cell carcinoma of the head and neck and other tumor types with an emphasis on correlative biomarker analysis. OR2805 will be infused on Day 1 of 21-day cycles. Primary endpoints are adverse events, laboratory abnormalities, dose-limiting toxicities, and dose-level safety and activity. Secondary endpoints are objective response rates, duration of response, complete response, progression-free survival, overall survival, PK, and antidrug antibodies. Exploratory biomarkers of OR2805-mediated pharmacodynamic effects and immune stimulation will be explored. The study was opened September 2021 and is enrolling at sites in the United States with planned expansion within the US and to Europe. Clinical trial information: Clinical trial information: NCT05094804. Research Sponsor: Oncoresponse, Inc.

TPS2694 **Poster Session**

An open-label, non-randomized, multi-center phase I study evaluating the safety, tolerability, pharmacokinetics and preliminary efficacy of bi-ligand-drug conjugate CBP-1018 in patients with advanced solid tumors. *First Author: Kaiwen Li, Department of Urology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*

Background: Folate-receptor 1 (FOLR1) and prostate specific membrane antigen (PSMA) are overexpressed on tumor and angiogenic endothelial cells in solid tumors, including prostate cancer, renal cell cancer and lung cancer. CBP-1018 is a first-in-class bi-ligand drug conjugate targeting to both FOLR1 and PSMA, with a tubulin inhibitor payload, monomethyl auristatin E (MMAE). We herein introduce its first-in-human study which is designed based on the significant anti-tumor potency and acceptable safety profile in nonclinical studies. **Methods:** This study is a phase Ia/Ib, multicenter, open-label study enrolling patients with advanced solid tumor relapsed after previous standard therapies. The primary objective is to assess CBP-1018 safety, tolerability, dose limiting toxicity and maximum tolerated dose. Preliminary efficacy including objective response rate, duration of response and progression-free survival will be observed. Pharmacokinetics, immunogenicity and biomarkers will be also evaluated. This study includes 2 parts: Ia (Dose Escalation) and Ib (Dose Expansion). CBP-1018 is administrated iv Q2W (4 weeks/cycle) in Ia, with accelerated titration at lower doses (0.03 mg/kg and 0.06 mg/kg) and an i3+3 design at following doses (0.08 mg/kg, 0.10 mg/kg, 0.12 mg/kg and 0.14mg/kg, etc.). Subjects will be enrolled in 4 cohorts in Ib: metastatic castration resistant prostate cancer, advanced renal cell cancer, advanced lung squamous cell cancer, and other advanced solid tumors. Efficacy will be assessed every 8 weeks (±7days) according to RECIST 1.1, PCWG3 and PSA assessment (only for prostate cancer). Treatment will be continued untill disease progression or intolerable toxicity. Enrollment has been started in Nov. 2021 and is ongoing. Clinical trial information: NCT04928612. Research Sponsor: Coherent Biopharma (Suzhou) Co., Ltd.

TPS2695 **Poster Session**

IL believe: A phase 1/2, open-label, dose escalation and dose expansion study of TransCon IL-2 β/γ alone or in combination with pembrolizumab or standard-of-care chemotherapy in patients with locally advanced or metastatic solid tumors. *First Author: Alexander Starodub, The Christ Hospital, Cincinnati, OH*

Background: Advances in immunotherapy have led to significantly improved survival and quality of life in some cancer patients, but many with less immunogenic tumor types derive suboptimal clinical benefit. Recombinant human interleukin-2 (IL-2, aldesleukin) can induce a response rate of ~15% in metastatic renal cell carcinoma and metastatic melanoma, yet toxicities (vascular leak syndrome, cytokine storm) have limited its use. TransCon IL-2 β/γ, a novel prodrug with sustained release of a receptor-selective IL-2 (IL-2 β/γ), was designed to optimally address drawbacks of aldesleukin: potent activation of undesired IL-2Rα^+ cell types and high C_{max} with rapid clearance. TransCon IL-2 β/γ comprises 3 main components: IL-2 β/γ, a methoxy polyethylene glycol (mPEG) carrier molecule, and a linker connecting the two. Under physiological conditions, TransCon IL-2 β/γ releases active IL-2 β/γ from the mPEG carrier through cleavage of the TransCon Linker. This results in a lower C_{max} and much longer effective $t_{1/2}$ of free IL-2 β/γ compared to aldesleukin. PD-1 expression at the cell surface of activated cytotoxic T cells and natural killer cells provides a clear rationale to study TransCon IL-2 β/γ alone or in combination with pembrolizumab. **Methods:** IL Believe is a multicenter, first-in-human, Phase 1/2 study in 3 parts in adult patients with locally advanced or metastatic solid tumors. All patients need ≥1 measurable lesion per RECIST 1.1 and an ECOG score of ≤ 2. The primary objectives are to evaluate safety and tolerability, and to define the maximum tolerated dose and recommended Phase 2 dose (RP2D) of TransCon IL-2 β/γ alone or in combination with pembrolizumab. Parts 1 and 2 Dose Escalation (Phase 1) use a standard 3+3 design with increasing doses of intravenous (IV) TransCon IL-2 b/g alone (Part 1) or with 200 mg IV pembrolizumab in solid tumors where pembrolizumab monotherapy may have clinical activity (Part 2). Each part will enroll ~15 patients. Part 3, Combination Dose Expansion (Phase 2) will evaluate preliminary clinical efficacy of TransCon IL-2 β/γ at the RP2D determined in Part 2, combined with chemotherapy. Platinum Resistant Ovarian Cancer is currently planned for dose expansion with other indication specific cohorts to be included in a subsequent amendment. Each cohort will be analyzed using a Simon 2-stage design and will enroll ~56 patients. Other key objectives include the evaluation of pharmacokinetics, pharmacodynamic biomarkers, and antitumor activity according to RECIST 1.1. Recruitment started in January 2022 and is ongoing (NCT05081609). Clinical trial information: NCT05081609. Research Sponsor: Ascendis Pharma.

TPS2696 **Poster Session**

A phase 1 study of TPST-1495 as a single agent and in combination with pembrolizumab in subjects with solid tumors. *First Author: Diwakar Davar, University of Pittsburgh Medical Center, Hillman Cancer Center, Pittsburgh, PA*

Background: Prostaglandin E2 (PGE2) is a bioactive lipid that promotes cancer through diverse mechanisms including stimulating tumor proliferation, enhancing angiogenesis and suppressing immune function in the tumor microenvironment. PGE2 produced by tumor cells through upregulation of cyclooxygenase-2 (COX-2) is also a key mediator of adaptive resistance to immune checkpoint inhibitor therapy. While PGE2 signaling is important in cancer, how best to inhibit PGE2 for cancer treatment is under investigation. Inhibition of COX enzymes (e.g., with NSAIDS) has shown promise in large observational studies, but inconsistent results in prospective studies. Importantly, COX inhibition alters multiple prostanoids beyond PGE2, resulting in toxicity that limits therapeutic dosing for cancer. PGE2 signals through four receptors, EP1-4, that are variably expressed and have distinct activities. The tumor promoting and immunosuppressive activities of PGE2 predominantly arise from signaling through the EP2 and EP4 receptors, while signaling through the EP1 and EP3 receptors generally is pro-inflammatory. TPST-1495 is designed to be an oral, highly specific, antagonist of the EP2 and EP4 receptors, sparing the EP1 and EP3 receptors and the COX enzymes. Preclinical studies suggest that blocking EP2 and EP4 with TPST-1495 inhibits tumor proliferation and stimulates anti-cancer immunity better than inhibiting all 4 receptors together, the EP2 or EP4 receptors singly, or the upstream COX-2 enzyme. **Methods:** TPST-1495-001 is a first-in-human Phase 1 study (NCT04344795). In the Dose and Schedule Optimization Stage, the primary objectives are to characterize the safety and tolerability (including dose limiting toxicities) and determine the recommended phase 2 dose (RP2D) of TPST-1495 as monotherapy and in combination with pembrolizumab in patients with advanced solid tumors. Additional objectives include characterization of PK, PD, and evaluation of potential biomarkers, including through paired (pre- and on-treatment) tumor biopsies. Monotherapy dose-finding employs a modified 3+3 design evaluating BID and QD TPST-1495 schedules along with continuous or intermittent (Days 1-5 every 7 days) dosing. For the pembrolizumab combination, the starting dose and schedule of TPST-1495 are determined by safety, PK and PD of monotherapy. Indication-specific Expansion Stage cohorts will evaluate TPST-1495 at the selected RP2D and schedule for both monotherapy and combination in endometrial cancer, squamous cell carcinoma of the head and neck, and microsatellite stable colorectal cancer (combination only), as well as in a biomarker-specific cohort enrolling patients with pathogenic tumor PIK3CA gene mutation. Dose and Schedule Optimization enrollment (monotherapy and combination) is ongoing at abstract submission while Expansion Stages are planned after identification of the RP2Ds. Clinical trial information: NCT04344795. Research Sponsor: Tempest Therapeutics.

TPS2697 **Poster Session**

A first-in-human, multicenter, phase 1/2, open-label study of XTX202, a masked and tumor-selective recombinant human interleukin-2 (IL-2) protein, in patients with advanced solid tumors. *First Author: Meredith McKean, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: High-dose interleukin-2 (IL-2) has been approved in metastatic renal cell carcinoma (RCC) and metastatic melanoma, and can result in durable complete responses, including cures. Its use has been limited by life-threatening treatment-related multisystem toxicities, consisting mainly of vascular leak syndrome. XTX202 is a masked, tumor-selective IL-2 that is designed to be pharmacologically inactive in non-tumor tissue when circulating systemically and unmasked by matrix metalloproteases (MMPs) found preferentially in the tumor microenvironment (TME). XTX202 is expected, therefore, to achieve a wider therapeutic index resulting in increased efficacy and lower toxicity compared to existing non-tumor selective IL-2 based-therapies. The IL-2 domain of the XTX202 molecule is modified to reduce binding to the high-affinity IL-2 receptor while maintaining binding to the intermediate-affinity IL-2 receptor, thereby decreasing activation of regulatory T-cells relative to wild-type IL-2, while still activating effector T cells. A masking domain is designed to pharmacologically inactivate IL-2 until it is activated by MMPs that are enriched in the TME. Cleavage at a protease cleavage site in the XTX202 linker by MMPs results in an active IL-2 moiety when the masking domain is released. XTX202 is designed with the goal of producing a localized anti-tumor immune response and limiting exposure of the active form of XTX202 in non-tumor tissue. Preclinically, XTX202 exhibited tumor-selective activity in mice without peripheral toxicities in non-human primates [O'Neil et al. ASCO 2021]. **Methods:** XTX202-01 trial (NCT05052268) is a first-in-human Phase 1/2 study to determine a recommended Phase 2 dose of XTX202 (Phase 1) and to evaluate the efficacy of XTX202 monotherapy in patients with metastatic RCC and unresectable or metastatic melanoma (Phase 2). Patients with advanced solid tumors are eligible for Phase 1 and will receive XTX202 monotherapy administered every 21 days in an accelerated and standard 3+3 dose escalation design. Phase 2 will consist of 2 parts: Part 2a will enroll patients with metastatic RCC who have received a prior tyrosine kinase inhibitor therapy and have been treated and progressed on an anti-PD-1 therapy. Part 2b will enroll patients with unresectable or metastatic melanoma who have received immune-checkpoint therapy with an anti-PD-1 therapy and an anti-CTLA-4 therapy to determine the efficacy of XTX202 monotherapy in this population. Enrollment to the study began in January 2022. Clinical trial information: NCT05052268. Research Sponsor: Xilio Therapeutics.

TPS2698 **Poster Session**

TAK-676 in combination with pembrolizumab after radiation therapy in patients (pts) with advanced non–small cell lung cancer (NSCLC), triple-negative breast cancer (TNBC), or squamous-cell carcinoma of the head and neck (SCCHN): Phase 1 study design. *First Author: Benjamin T. Cooper, Perlmutter Cancer Center, New York University School of Medicine, New York, NY*

Background: The cyclic GMP-AMP Synthase (cGAS)–STimulator of INterferon Genes (STING) pathway is an important modulator of the innate immune system via induction of type I interferon (IFN-I). Cytosolic DNA generated as a result of tumor cell death following radiation therapy has been demonstrated to activate the cGAS-STING signaling axis resulting in antitumor immunogenicity. TAK-676 is a novel, synthetic STING agonist and it has been shown in preclinical studies to potently modulate the innate immune system and subsequently activate the adaptive immune system to produce antitumor responses. TAK-676 is designed for prolonged half-life in serum and enhanced tissue permeability compared with other STING agonists designed for intratumoral injection, allowing for systemic IV delivery with access to tumor sites and lymphatic tissue. IFN signaling impairment has been linked to checkpoint inhibitor (CPI) resistance in tumors. Treatment with TAK-676 after radiation therapy has the potential to stimulate T cell-mediated antitumor immunity via STING-mediated IFN-I release, particularly when used with anti-PD-1/PD-L1 therapies. Preclinical data support the addition of STING agonists to reverse resistance in tumors with prior exposure to CPIs. TAK-676 is being investigated (+/- pembrolizumab) in an ongoing first-in-human phase 1 study (NCT04420884). Here, we describe another phase 1 trial to investigate the safety and preliminary antitumor activity of TAK-676 plus pembrolizumab following radiation therapy in pts with advanced or metastatic NSCLC, TNBC, or SCCHN (NCT04879849). **Methods:** Adult pts with progressive disease (PD) following CPI treatment and who have ≥2 lesions, 1 of which can be targeted with radiation, are being enrolled. Pts receive 8 Gy x 3 fractions of image-guided radiation followed (after ≥40 hours) by IV pembrolizumab 200 mg on day 1 plus escalating doses of IV TAK-676 on days 1, 8, and 15 of a 21-day cycle. TAK-676 dose escalation is guided by the Bayesian optimal interval design. Pts receive TAK-676 plus pembrolizumab until PD, intolerance to treatment, or withdrawal. Pts enrolled at TAK-676 dose levels shown to have pharmacodynamic activity, and who have a safely accessible lesion outside the radiation field, will have paired biopsies collected at screening and between days 15 and 21 of cycle 1. The primary objective is to determine the safety and tolerability of TAK-676 plus pembrolizumab following radiation therapy; secondary objectives are to establish the recommended phase 2 dose of TAK-676 plus pembrolizumab following radiation therapy, and to assess preliminary antitumor activity both locally (within the radiation field) and systemically (non-radiated lesions). As of February 2022, we have enrolled ~10% of the planned pts. Clinical trial information: NCT04879849. Research Sponsor: Takeda Development Center Americas, Inc. (TDCA).

TPS2699 **Poster Session**

Phase 2 study of the IDO/PD-L1-targeted immune-modulatory vaccine, IO102-IO103, plus pembrolizumab as first-line treatment for metastatic non–small cell lung cancer (NSCLC), squamous cell carcinoma of the head and neck (SCCHN), or urothelial bladder cancer (UBC). *First Author: Jonathan W. Riess, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Immunotherapy has transformed the treatment of NSCLC and other solid tumors, such as SCCHN and UBC. However, even with standard-of-care anti-PD-1/PD-L1 therapies, few patients achieve durable benefit even when PD-L1 is overexpressed. IO102-IO103 is a potentially first-in-class, dual-antigen, immune-modulatory therapy that stimulates T cells to target tumoral immune escape via key checkpoint molecules IDO and PD-L1. It is thought that activating IDO/PD-L1-specific T cells in cancer patients through vaccination may support anticancer immunity by restricting immunosuppressive signaling and restoring the tumor immune microenvironment to render the tumor more susceptible to anti-PD-1 blockade. Thus there is a rationale for combining IO102-IO103 with anti-PD-1 therapy in the first-line treatment of metastatic tumors, such as NSCLC, SCCHN, or UBC. Combined IO102-IO103 and anti-PD-1 therapy (nivolumab) has already shown a robust signal of clinical activity (overall response rate [ORR], 80%; complete response rate [CRR], 43%; median progression-free survival [PFS], 26 months) and was well tolerated with minimal added toxicity to nivolumab in a Phase 1/2 study of anti-PD1-naïve patients with metastatic melanoma (Kjeldsen, et al. Nat Med 2021). **Methods:** This is a Phase 2, international, multicenter (US and Europe), non-comparative, open-label, multi-arm (basket) trial (EudraCT No. 2021-003026-69; ClinicalTrials.gov No. NCT05077709). Patients with recurrent, unresectable or metastatic solid tumors in 3 indications and no prior treatments for metastatic disease are being enrolled: NSCLC with a PD-L1 Tumor Proportion Score (TPS) ≥50% (Arm A); SCCHN with PD-L1 Combined Positive Scores (CPS) ≥20 (Arm B); or UBC with PD-L1 CPS ≥10 and not eligible for platinum-containing chemotherapy (Arm C). All patients, ~30 in each arm, will receive 3-week cycles of IO102-IO103 (85-85 μg on Day [D] 1 and 8 of Cycle 1 and 2, and D1 thereafter) subcutaneously plus pembrolizumab (200 mg on D1) intravenously, for up to 2 years. Primary endpoints are ORR by RECIST v1.1 or 6-month PFS rate by investigator assessment (to be analyzed either 6 months after last patient started treatment or after target ORR is achieved, whichever is earliest). Secondary endpoints include PFS, duration of response, complete response rate, disease control rate, time to response, overall survival, and safety. Exploratory endpoints include biomarker and immune marker correlative studies, and PFS by iRECIST. The trial will assess the opportunity for a positive risk–benefit based on 2 efficacy boundaries for the ORR and 6-month PFS rate in each arm, with cohort expansion permitted if a clinically relevant efficacy signal is observed. Clinical trial information: EudraCT No. 2021-003026-69; ClinicalTrials.gov No. NCT05077709. Research Sponsor: IO Biotech ApS & Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS2700 **Poster Session**

A first-in-human, phase I, open-label study of a novel cancer vaccine labvax 3(22)-23 and adjuvant GM-CSF in patients with advanced stage adenocarcinomas. *First Author: Weijie Ma, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Adenocarcinoma is the most common histologic type of solid tumors and can arise from almost anywhere in the body. Labyrinthin is a novel tumor-specific protein expressed on the cell surface of the majority of adenocarcinomas of various cancer types. Several therapeutic strategies targeting labyrinthin are under development. We hypothesize that vaccination against labyrinthin can elicit strong immune responses against the labyrinthin-positive adenocarcinomas in cancer patients. LabVax 3(22)-23 is a novel anti-tumor vaccine that contains 4 synthetic labyrinthin-based peptides designed to elicit both B-cell and T-cell responses. Sargramostim, a recombinant granulocyte macrophage colony-stimulating factor (GM-CSF), is given as an immunostimulator with LabVax 3(22)-23 to boost the anti-tumor immune response. Preclinical studies showed that LabVax 3(22)-23 significantly inhibited tumor growth that was augmented by GM-CSF without any significant toxicity in C57/BL6 transgenic mice expressing human PD-1/PD-L1 implanted with the murine colon adenocarcinoma cell line MC-38-huPD-L1. This single institution, first-in-human, phase I trial (UCDCC#296) evaluates LabVax 3(22)-23 and adjuvant sargramostim in patients with labyrinthin-positive metastatic or recurrent adenocarcinoma of any primary tumor site after all standard-of-care therapies. **Methods:** The primary objective is to assess the toxicity of LabVax 3(22)-23 and adjuvant sargramostim according to NCI CTCAE V5.0. The primary endpoint is dose limiting toxicity (DLT), which is defined as grade ≥ 2 allergic and autoimmune reaction, grade ≥ 3 injection site reaction, any grade 3 toxicities lasting >1 week, or any grade ≥ 4 toxicities. With a sample size of 10 patients, there is 89-97% of chance to observe ≥1 DLT if the true event rate is 20-30%. A secondary endpoint is the preliminary assessment of tumor response rate by Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. Exploratory objectives measure the effect of LabVax 3(22)-23 on various immune responses (cytokines, anti-labyrinthin antibody production) and the correlation between the level of labyrinthin expression and the efficacy of LabVax 3(22)-23. Eligible patients are required to have labyrinthin expression on their tumor cells by immunohistochemistry and adequate organ function. Patients receive sargramostim subcutaneously and LabVax 3(22)-23 intradermally on weeks 1, 2, 4, 8, and 12 in the absence of disease progression or unacceptable toxicity. After completion of study treatment, patients are followed every 3 months for 1 year. Two patients are enrolled at the time of submission. Clinical trial information: NCT05101356. Research Sponsor: UC Davis Comprehensive Cancer Center, Pharmaceutical/Biotech Company.

TPS2701 **Poster Session**

First-in-human phase 1 trial of ELI-002 immunotherapy as treatment for subjects with Kirsten rat sarcoma (KRAS)-mutated pancreatic ductal adenocarcinoma and other solid tumors. *First Author: Shubham Pant, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Mutations in KRAS and NRAS occur in one quarter of human solid tumors. The G12D allele is the most commonly occurring variant in pancreatic, colorectal, non-small cell lung, ovarian, biliary and gallbladder cancers. ELI-002 2P is an immunotherapeutic comprised of a lymph-node targeted amphiphile (AMP)-modified G12D and G12R mutant KRAS peptides together with an AMP-modified CpG oligonucleotide adjuvant. In preclinical models, ELI-002 demonstrated increased cytotoxic KRAS-specific T cells compared to non-lymph node targeted controls using the same peptide and adjuvant. Clinical evaluation of adoptively transferred KRAS-specific T cells demonstrated objective antitumor activity (Tran 2016). Circulating tumor (ctDNA) methodology permits identification of patients with minimal residual disease (MRD) following locoregional treatment. In MRD setting, immunotherapy is anticipated to succeed as the ratio of effector T cells to target tumor cells is maximized prior to bulk visible disease. The AMPLIFY-201 study (NCT04853017) is evaluating ELI-002 in patients with KRAS mutated solid tumors with MRD. **Methods:** AMPLIFY-201 is an open-label, dose-escalation and expansion phase I, first in human, trial evaluating ELI-002 2P in patients with KRAS mutated tumors with MRD following standard of care therapy. The initial phase I cohort enrolls patients with colorectal and pancreatic cancer to receive multiple doses of AMP-peptides 70mcg each (1.4 mg total) admixed with AMP-CpG 0.1 mg, administered once every two weeks. Subsequent phase I cohorts will enroll patients with RAS-mutated pancreatic, colorectal, non-small cell lung, ovarian, bile duct or gallbladder cancer, who will receive a fixed dose of AMP-peptides 70 mcg each, together with escalating doses of AMP-CpG. Safety and efficacy will be summarized with descriptive statistics. The maximum tolerated dose (if any) and the recommended phase II dose (RP2D) will be determined with the dose-response activity of ELI-002 2P in eliciting functional KRAS-specific T cells. Preliminary antitumor activity will be characterized using changes from baseline in ctDNA, serum biomarkers appropriate for tumor type, and progression free survival time. Eligibility includes patients who have received standard of care locoregional treatment according to NCCN guidelines and whom have MRD persistence or relapse (ctDNA positive). Patients with colon and pancreas cancer with Stage IV oligometastatic disease (< 3 lesions in one organ) rendered surgically free of disease and with MRD, are also eligible. The dose escalation portion of the study is currently enrolling. Clinical trial information: NCT04853017. Research Sponsor: Elicio Therapeutics.

TPS2702 **Poster Session**

A phase 1 dose-finding and dose-expansion study evaluating the safety, tolerability, pharmacokinetics, and efficacy of a highly selective WEE1 inhibitor (Debio 0123) in adult patients with advanced solid tumors. *First Author: Kyriakos P. Papadopoulos, START San Antonio, San Antonio, TX*

Background: Debio 0123 is an oral, highly selective inhibitor of the tyrosine kinase WEE1. WEE1 is a key regulator of cell cycle progression that modulates the activity of CDK1 (CDC2), influencing entry into mitosis. WEE1 inhibition results in G2 checkpoint abrogation, triggering mitosis with unrepaired DNA leading to cell death. *In vitro* and *in vivo* tumor models have shown Debio 0123 antitumor activity. Continuous exposure seems to be needed to maximize monotherapy efficacy in preclinical models. Preliminary data from an ongoing phase 1 study of intermittent Debio 0123 combined with carboplatin, showed a manageable safety profile, and signals of antitumor activity in patients (pts) with advanced solid tumors. We present the design of a phase 1 study (NCT05109975) of continuous Debio 0123 administered as a single agent in pts with advanced solid tumors. **Methods:** The study comprises a dose escalation part and a dose expansion part. The primary objective of the dose escalation part of the study is to determine the maximum tolerated dose (MTD) and/or the recommended phase 2 dose (RP2D) of continuous Debio 0123 monotherapy in adults with previously treated advanced solid tumors. Key secondary objectives include characterization of safety and tolerability, pharmacokinetics (PK), and preliminary antitumor activity (overall response rate [ORR]). Key inclusion criteria are histologically or cytologically confirmed locally advanced or metastatic solid tumors, and ECOG-PS 0 or 1. Key exclusion criteria are asymptomatic or unstable brain metastases, history of cardiac disorders, inability to swallow oral medication or abnormalities affecting drug absorption. Approximately 30 dose-limiting toxicity (DLT)-evaluable pts are anticipated to be enrolled based on an escalation with overdose control (EWOC) approach for 21-day treatment cycles. When the pts of each cohort become evaluable, a safety monitoring committee will review safety and tolerability and based on EWOC recommendations will decide the next dose level or will declare the MTD and/or RP2D. Pharmacodynamic biomarkers will be correlated with tumor response and/or PK. The dose-expansion part may start after MTD and/or RP2D determination. The primary objective of this part will be to characterize the safety and tolerability (e.g. percentage of pts with DLTs, serious adverse events or discontinuations) of Debio 0123 monotherapy at the MTD/RP2D, and to evaluate the anti-tumor activity (ORR) in pts with selected recurrent/progressive solid tumors. Key inclusion criteria are measurable disease per RECIST 1.1 and specific tumor types. Based on a Simon 2-stage design, up to 34 pts per tumor type cohort may be enrolled. Currently accrual to the dose escalation is ongoing in the United States and Switzerland. Clinical trial information: NCT05109975. Research Sponsor: Debiopharm International SA.

TPS2703 **Poster Session**

CAIRE: A basket multicenter open-label phase 2 study evaluating the EZH2 inhibitor tazemetostat in combination with durvalumab in patients with advanced solid tumors. *First Author: Antoine Italiano, Institut Bergonié, Bordeaux, France*

Background: Recent studies have shown shown that genetic depletion of EZH2 in Tregs (using FoxP3creEZH2fl/fl mice) and pharmacological inhibition of EZH2 elicits phenotypic and functional alterations of Tregs, leading to an effector-like T cell profile. Further, EZH2 inhibition enhances the cytotoxicity of human Teffs in vitro and the proportion of tumor-infiltrating cytotoxic T cells in vivo in murine models. It has been shown that immune checkpoint inhibition (ICI) increases EZH2 expression in human T cells across various tumor types and that increased EZH2 expression in T cells inversely correlate with clinical outcome. Upregulation of EZH2 mediated by immune checkpoint inhibition in T cells modulates T cell responses and diminishes the effectiveness of immunotherapy. Consistent with this mechanism, pharmacologic inhibition of EZH2 has been shown to increase effector-like T cell responses and enhances effectiveness of immune checkpoint therapy in tumor-bearing mice [16-17]. Our group also reported first clinical data from a participant with sarcoma showing strong T cell infiltration after treatment with tazemetostat (Italiano et al Lancet Oncol 2018). Altogether, these findings pave the way for clinical trials combining ICI with the specific EZH2 inhibitor, tazemetostat in solid tumors. **Methods:** CAIRE (NCT04705818) is a multi-cohort, four single-arm phase 2, multicenter, open-label study investigating tazemetostat combined with durvalumab in patients with advanced cancers: pancreatic adenocarcinoma (cohort A), microsatellite stable colorectal cancer (cohort B), solid tumors with presence of tertiary lymphoid structures (assessed centrally) (cohort C), soft-tissue sarcomas (cohort D). Cohort A will enroll ~32 patients and cohorts B, C and D ~47 patients respectively. Eligible patients must have no standard treatment options available or a contraindication to standard treatment options, and ECOG PS 0–1. Patients with prior exposure to EZH2 inhibitor and/or PD1/PDL1 monoclonal antibodies are excluded. Tazemetostat will be administered per-os, twice daily (800 mg x 2), continuously. Treatment by Tazemetostat will start on Day 1 (of cycle 1). Durvalumab will be administered by intravenous infusion (1120 mg) on day 1, every 3 weeks. Treatment by Durvalumab will start on Day 1 of cycle 2. The primary endpoints are disease control rate within 24 weeks of treatment as per RECIST 1.1 in cohort A and B; objective response rate within 24 weeks of treatment as per RECIST 1.1 in cohort C, and 6-months non progression rate for cohort D. Secondary endpoints include adverse events (AEs)/serious AEs, duration of response, and progression-free survival. Pharmacodynamic and other biomarkers will be explored. The first patient received study drug on July, 30, 2022 and 1 site across France are currently enrolling patients. Clinical trial information: NCT04705818. Research Sponsor: Astra Zeneca, Other Government Agency.

TPS2704 **Poster Session**

A phase 1 trial of RP2, a first-in-class, enhanced potency oncolytic HSV expressing an anti-CTLA-4 antibody as a single agent and combined with nivolumab in patients with advanced solid tumors. *First Author: Kevin Joseph Harrington, The Royal Marsden//The Institute of Cancer Research NIHR Biomedical Research Centre, London, United Kingdom*

Background: RP2 is a selective replication-competent herpes simplex virus 1 (HSV-1) that contains a codon-optimized sequence for human granulocyte-macrophage colony-stimulating factor (GM-CSF), the gibbon ape leukemia virus surface glycoprotein (GALV-GP) with the R- sequence deleted (R-), GM-CSF, and an anti–cytotoxic T lymphocyte antigen 4 (CTLA-4) antibody-like molecule. These modifications are intended to increase oncolytic potency, cell-to-cell spread, tumor antigen release, and systemic antitumor immune activation. RP2 has demonstrated antitumor activity in preclinical models using viruses similar to RP2 expressing murine versions of anti-CTLA-4 and GM-CSF, both alone and in combination with PD1-1 blockade. **Methods:** This is a Phase 1 multicenter, open-label, study evaluating RP2 ± nivolumab (NCT04336241). Part 1 evaluated escalating doses of monotherapy RP2 with a modified 3 + 3 design. Patients (pts) received intratumoral (IT) injections of up to 10 mL of RP2 into superficial or visceral tumors Q2W x5 across two dose levels (DL1: 10^5 plaque-forming units (PFU)/mL once, then followed by 10^6 PFU/mL x4; DL 2: 10^6 PFU/mL once, then followed by 10^7 PFU/mL x4). The recommended Phase 2 dose of RP2 was identified as 10^6 PFU/mL once, followed by subsequent doses of 1×10^7 PFU/mL. In Part 2, up to 60 evaluable pts will be enrolled, including 30 pts in Cohort 2a and 30 in Cohort 2b. Cohort 2a was designed to evaluate the safety and antitumor activity of the combination in pts with solid tumors, and is fully enrolled. Cohort 2b is open for enrollment of pts with advanced or metastatic uveal melanoma, NSCLC, breast cancer, head and neck cancer or GI cancers (NSCLC, breast or GI cancers must have at least one liver tumor suitable for injection). Pts in Part 2 receive intra-tumoral RP2 at the RP2D Q2W for up to 8 doses in combination with 240 mg nivolumab IV Q2W or 480 mg nivolumab IV Q4W for up to two years from the first RP2 dose. In Part 3 (not yet open for enrollment), up to 15 evaluable pts are able to be enrolled to evaluate RP2 monotherapy including at least 10 pts with NSCLC, breast or GI cancers with at least one liver tumor suitable for injection. Reinitiation of up to 8 additional RP2 doses is permitted if prespecified criteria are met. Pts are dosed with RP2 by direct visualization or ultrasound-guided injection into superficial, subcutaneous, or nodal tumors and by image-guided injection into deeper lesions, including visceral lesions. Key inclusion criteria include histologically confirmed advanced or metastatic non-neurological solid tumors, at least one measurable and injectable tumor of diameter ≥1 cm, ECOG ≤1, and adequate hematologic, hepatic, and renal function. Exclusion criteria include prior treatment with oncolytic viruses, acute or chronic hepatitis B or C infection, and HIV infections. Clinical trial information: NCT04336241. Research Sponsor: Replimune Group Inc.

TPS2705 **Poster Session**

An open-label, multicenter, phase 1 study of RP3 as a single agent and in combination with nivolumab in patients (pts) with solid tumors. *First Author: Kevin Joseph Harrington, The Royal Marsden//The Institute of Cancer Research NIHR Biomedical Research Centre, London, United Kingdom*

Background: RP3 is a genetically modified herpes simplex virus 1 (HSV-1) that contains insertions for the gibbon ape leukemia virus surface glycoprotein (GALV-GP) with the R- sequence deleted (R-), an anti–cytotoxic T lymphocyte antigen 4 (CTLA-4) antibody-like molecule, CD40 ligand, and 4-1BB ligand. Together, these insertions are expected to increase oncolytic potency, cell-to-cell spread, immunogenic cell death, and systemic immune activation. RP3 has demonstrated antitumor activity in preclinical models using viruses similar to RP3 expressing murine versions of anti-CTLA-4, CD40L, and 4-1BBL both alone and in combination with PD1-1 blockade. **Methods:** This is an open-label, multicenter, Phase 1 study evaluating RP3 as monotherapy or in combination with nivolumab (nivo) in patients (pts) with solid tumors (NCT04735978). Part 1 evaluated escalating doses of RP3. Pts in Part 1 received IT injections of up to 10 mL RP3 into superficial, nodal, or visceral lesions Q2W x 5 across two dose levels (DL1: 10^5 plaque-forming units (PFU)/mL once, then 10^6 PFU/mL x 4; DL2: 10^6 PFU/mL once, then 10^7 PFU/mL x4). The RP2D is 10^6 PFU/mL once, followed by 10^7 PFU/mL IT Q2W. In Part 2, pts are being enrolled into expansion cohorts of 45 patients with GI (including HCC), lung, breast, and squamous cell carcinoma of the head and neck treated with RP1 combined with nivo. Additional cohorts will enroll patients treated with RP3 followed by nivo, RP3 monotherapy to further explore biomarkers in injected and uninjected tumors, and with the potential to also open a cohort in melanoma. Pts in both Part 1 and Part 2 may receive up to 8 additional doses of RP3 if protocol-specified criteria are met. Key inclusion criteria: confirmed advanced or metastatic non-neurological solid tumors, at least one measurable tumor $\geq$ 1 cm and injectable tumors $\geq$ 1 cm in aggregate, ECOG $\leq$1, and adequate hematologic, hepatic, and renal function. In Cohorts 1, 2, and 4, approximately 50% of the pts with lung, breast, and GI cancer must have liver lesions intended for injection. Exclusion criteria include prior oncolytic virus treatment, need for immunosuppressive therapy, an autoimmune disease requiring systemic therapy, active significant herpetic infections or prior complications of HSV-1 infection, active or chronic HBV or HCV infection, known HIV infection, or prior active malignancy within 3 years. Clinical trial information: NCT04735978. Research Sponsor: Replimune.

3000 **Oral Abstract Session**

A phase Ia/Ib study of CBP-1008, a bispecific ligand drug conjugate, in patients with advanced solid tumors. *First Author: Lingying Wu, Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China*

Background: Folate receptor α (FRα) and vanilloid subfamily member 6 of transient receptor potential channels (TRPV6) are overexpressed in many solid tumors hence could be promising therapeutic targets. CBP-1008 is a first-in-class bispecific ligand drug targeting FRα and TRPV6 carrying monomethyl auristatin E (MMAE) as payload. Here we report the first-in-human, multicenter, phase Ia/Ib study designed to explore the safety, pharmacokinetics and efficacy of CBP-1008 in advanced solid tumors. **Methods:** CBP-1008 was administered by intravenous infusion. Phase Ia study included a dose-escalation period initiated by accelerated titration (0.015, 0.03mg/kg d1,15; q28d) and then switched to 3+3 scheme (0.12, 0.15, 0.17, 0.18mg/kg d1,15; q28d) and a dose expansion period. Phase Ib clinical expansion study included 3 cohorts, platinum-resistant ovarian cancer (OC), metastatic triple negative breast cancer (TNBC) and other solid tumors. The primary objective was to assess the safety and preliminary efficacy. **Results:** As of January 13, 2022, 106 patients received at least one dose of study drug were enrolled (phase Ia: n = 30; phase Ib: n = 76) and received median 3 prior regimens. Included tumor species were OC (n = 52), TNBC (n = 20), ER+/Her2+ breast cancer (BC) (n = 16), lung cancer (n = 3), pancreatic cancer (n = 2) and others (n = 13). In phase Ia study, DLTs were observed in 3 patients (0.12, 0.15, 0.18mg/kg, n = 1 each), including grade 4 hypophosphatemia, neutropenia, febrile neutropenia, and grade 3 hyperglycemia, alanine aminotransferase (ALT). MTD was not yet reached. Majority of adverse events were mild to moderate. The most common grade 3/4 treatment-emerging adverse events (TEAEs) were neutropenia (37.7%), AST elevation (6.6%), ALT elevation (5.7%), hyperglycemia (2.8%), hypohemoglobinemia (2.8%) and nausea (1.9%). Drug-related death was not observed. A total of 69 patients at dose of 0.15mg/kg or above were evaluable for efficacy assessment. There were 11 patients achieved partial response (PR) (OC n = 8, ER+/Her2+ BC n = 2, TNBC n = 1) and 30 patients achieved stable disease (SD). In 32 advanced platinum-resistant OC patients with FRα and/or TRPV6-positive expression, 6 PR and 16 SD were observed. Moreover, 6/18 PR (33.3%) and 8/18 SD (44.4%) were observed in enriched OC patients who showed high score of FRα/TRPV6 receptor. **Conclusions:** The preliminary results showed that CBP-1008 has manageable safety profile. Antitumor activity was observed in patients with FRα/TRPV6 receptor expression, especially in platinum-resistant OC cohort with high score of the two receptors. Clinical trial information: NCT04740398. Research Sponsor: Coherent Biopharma (Suzhou) Co., Ltd.
