Background: The combination of daratumumab (Dara), pomalidomide (POM), and dexamethasone (dex) (DPd) has previously demonstrated deep and durable responses including high rates of minimal residual disease (MRD) negativity, in patients with relapsed/refractory (R/R) MM. Quadruplet regimens may further improve results. We report updated findings from a phase 2 multicenter trial of the addition of ixazomib to DPd (DIPd) in patients with early R/R MM. **Methods:** This is a prospective, multi-center, open-label, single arm phase II trial with a primary objective to evaluate the overall response rate (ORR), safety, and efficacy of DIPd. Secondary endpoints include progression-free survival (PFS), overall survival (OS), and MRD-negativity rate. A Simon's optimal 2-stage design was used, with 14 subjects in stage 1 to assess response and 32 patients for stage 2. Eligible patients may not have had exposure Dara or ixazomib, may not have progressed on POM, and may have received ≥1 and ≤3 prior lines of therapy. The first six patients in the safety run-in received Dara 16mg/kg IV weekly x 8 doses, biweekly x 8 doses, then monthly, POM 4mg orally on days 1-21 of a 28-day cycle, ixazomib 4mg orally on days 1,8,15 every 28 days, and dex 20-40mg weekly. Grade 3-4 neutropenia was observed in 100% of patients, prompting dose reduction to ixazomib 3 mg and POM 3 mg by the DSMB. An amendment allowed subcutaneous Dara administration. MRD assessments are being performed by EuroFlow for patients in VGPR or suspected CR. Pharmacodynamic changes in patients' tumor microenvironments were established by custom panel mass cytometry to include T-cell memory and activated subpopulations, B-cell content, NK-cell subpopulations as well as MDSCs, Tregs and T-exhaustive markers, monocytes and dendritic cells. **Results:** To date, 14 subjects have been treated in stage 1, and 18 patients in stage 2. Median age was 61.5 (range 41-87) years, 50% were female and 72% white. Median number of prior regimens was 1 (range 1-3), all patients were lenalidomide-exposed, and 47% (11/23) had high-risk cytogenetic features. The most common grade 3-4 treatment emergent adverse events included neutropenia (78%), infection (30%), leukopenia (11%), respiratory conditions (7%), psychiatric disturbance (4%), and thrombosis (4%). Median time on treatment was 4 months (1-29), with 11 patients remaining on DIPd and 5 deaths (4 due to progressive disease and 1 due to sepsis). ORR to date was 84% (16/19), and the best responses included: 5 (26%) sCR; 4 (21%) VGPR; 7 (37%) PR. After a median follow up of 12 months, the median OS was 39 months and PFS was 9.5 months. **Conclusions:** The quadruplet regimen DIPd is a well-tolerated combination that has shown early safety, efficacy, and ORR in early R/R myeloma, including patients with high-risk genetic abnormalities. Clinical trial information: NCT03590652. Research Sponsor: Takeda Pharmaceutical Company, Janssen Pharmaceuticals, Bristol Myers Squibb.

Idecabtagene vicleucel (Ide-cel) chimeric antigen receptor (CAR) T-cell therapy for relapsed/refractory multiple myeloma (RRMM): Real-world experience. *First Author: Doris K. Hansen, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Ide-cel, a BCMA directed CAR T-cell therapy, was FDA approved 3/26/2021 for the treatment of RRMM after 4 prior lines of therapy. We evaluated the real-world outcomes of patients treated with standard of care ide-cel under the commercial FDA label. **Methods:** Ten US academic centers contributed data to this effort independent of the manufacturer. As of 1/10/2022, 138 patients were leukapheresed with overall manufacturing failure in 6 (4%). 108 patients were infused ≥ 30 days prior to data-cut off and constitute the study population for this retrospective analysis. **Results:** Table describes the study population compared to the pivotal KarMMa-1 trial (Munshi et al, NEJM 2021). Patients in our study were less likely to have ECOG PS of 0/1 (77%) and more likely to be penta-refractory (41%). 67% of patients would not have met eligibility criteria for KarMMa. Common reasons for ineligibility (> 1 reason in 22% patients) were co-morbidities (28%), cytopenias (22%), prior therapy with alloSCT/CAR-T/other BCMA therapy (19%), CNS myeloma/non-measurable disease/plasma cell leukemia (13%), and fitness (12%). 81% of patients received bridging therapy. Toxicity was comparable to that seen in KarMMa-1. Cytokine release syndrome (CRS) was seen in 82% (> grade 3: 4%) and immune effector cell-associated neurotoxicity syndrome (ICANS) in 15% (> grade 3: 5%) of patients, respectively. Tocilizumab and steroids were used in 72% and 25% of patients, respectively. Infections were seen in 34% of patients. Day 30 response was evaluable in 104 patients. Response rates were: ≥ partial response, 83%; ≥ very good partial response, 64%; and ≥ complete response (CR), 34%. 11% of patients have died by data cut-off, 7 due to disease progression and 5 due to other causes (1 grade 5 CRS, 1 hemophagocytic lymphohistiocytosis, 1 progressive neurological weakness, 2 COVID-19). **Conclusions:** This multicenter retrospective study delineates the real-world outcomes of ide-cel CAR T-cell therapy for RRMM. Despite more patients being penta-refractory and less fit compared to the pivotal KarMMa trial, safety and 30-day responses in the real-world setting (overall response rate: 83%, CR: 34%) are comparable to the clinical trial population. Follow-up is ongoing and updated data will be presented. Research Sponsor: None.

Patient characteristics and outcomes: Comparison between KarMMa-1 (Munshi et al. NEJM 2021) and commercial standard of care ide-cel treatment at 10 U.S. centers.

	KarMMa-1, N=128	Real world, N=108
Median age, yrs	61 (33-78)	64 (36-78)

Demographic disparities in genomic data and clinical trials for multiple myeloma. *First Author: Nidhi Aggarwal, Medical College of Georgia at Augusta University, Augusta, GA*

Background: There are considerable outcome disparities among patients with multiple myeloma (MM). African-Americans have higher risk of developing MM, earlier age at diagnosis, and higher mortality compared to Whites. While outcomes have multifactorial socioeconomic etiologies, race and ethnicity (R&E) correlate with genomic ancestry, and any role of genetics should be explored. This requires equitable representation in biological databases like The Cancer Genome Atlas (TCGA). Here, we characterize disparities in MM cases of TCGA and clinical trials (CT). **Methods:** MM incidence was obtained from North American Association of Central Cancer Registries (NAACCR) for R&E, sex and age (< 50, 50-64, 65+ years). Race includes White, Black, and Asian, along with Hispanic ethnicity, as TCGA MM is limited to these groups. Genes with oncogenic potential and > 5% mutation were stratified by R&E and age. TCGA MM cases are from USA, Canada, Italy, and Spain. On ClinicalTrials.gov, completed MM CT limited to these countries were identified. Student's t-test and chi-square test were used to analyze disparities and gene mutations. Kaplan-Meier curve was generated to evaluate survival. **Results:** TCGA MM representation is in Table, calculated as (demographic TCGA cases divided by total TCGA cases) divided by (demographic incidence divided by total incidence). Race was not reported in 20% of TCGA, 4% of CT, and 3% of NAACCR. Of cases reporting R&E, Hispanics are underrepresented by 26% in TCGA and 47% in CT relative to incidence, Blacks by 22% in TCGA and 41% in CT, and Asians by 40% in TCGA and 10% in CT. Whites are overrepresented, by 8% in TCGA and 7% in CT. More men are in TCGA than women, in all R&E. Less than 25% of patients age < 50 relative to incidence are in TCGA, in all R&E. *BCL7A* is mutated more in Blacks age < 50 (n = 20, 50%) than Whites (n = 39, 10%) (p < 0.01). *FAT4* is mutated in Whites age 65+ (n = 31, 10%) but not Blacks. In all ages, *KRAS* is mutated more in Blacks than Whites (31-35% vs. 20-25%, p < 0.05). Black patients have lower survival than Whites (p < 0.02). In patients age 65+, *KRAS* mutation is associated with 10% lower 4.5-year survival. **Conclusions:** Substantial disparities in Black, Hispanic, women, and age representation exist for MM cases in TCGA and CT. This stratification by R&E and age offers new insight on BCL7A, FAT4, and KRAS mutation in MM. Mutation status is associated with survival in older patients. Equitable demographic representation should be pursued to improve quality of available data and access to medical resources for all populations. Research Sponsor: None.

Percent of All Demographic Incidence Represented in TCGA	All Ages (TCGA n=1065, NAACCR n=26843)	Age <50 (TCGA n=94, NAACCR n=1723)	Age 50-64 (TCGA n=441, NAACCR n=7749)	Age 65+ (TCGA n=418, NAACCR n=17371)

Time to response, duration of response, and patient-reported outcomes (PROs) with daratumumab (DARA) plus lenalidomide and dexamethasone (D-Rd) versus lenalidomide and dexamethasone (Rd) alone in transplant-ineligible patients with newly diagnosed multiple myeloma (NDMM): Subgroup analysis of the phase 3 MAIA study. *First Author: Thierry Facon, University of Lille, CHU Lille, Service des Maladies du Sang, Lille, France*

Background: In the phase 3 MAIA study, adding DARA to Rd improved progression-free survival (primary endpoint), overall survival, duration of response, and PROs in transplant-ineligible pts with NDMM. We report a MAIA subgroup analysis of time to response, duration of response, and PROs. **Methods:** Transplant-ineligible pts with NDMM received 28-day cycles of Rd (R 25 mg PO on Days 1-21; d 40 mg PO QW) ± DARA (16 mg/kg IV QW in Cycles 1-2, Q2W in Cycles 3-6, and Q4W thereafter) until disease progression or unacceptable toxicity. Secondary endpoints included time to response and duration of response. PROs were measured using the EORTC QLQ-C30, with treatment effects assessed via mixed-effects model with repeated measures. **Results:** In total, 368 pts were assigned to the D-Rd group and 369 pts to the Rd group; 162 (44%) D-Rd pts and 142 (38%) Rd pts had renal impairment (defined as baseline CrCl ≤60 mL/min). At a 56.2-mo median follow-up, median times to very good partial response or better (≥VGPR) and complete response or better (≥CR) were shorter with D-Rd vs Rd in the overall study population and in the subgroups of pts with and without renal impairment (Table). Among pts who achieved ≥CR or partial response or better (≥PR), higher proportions of D-Rd vs Rd pts had not experienced disease progression at 48 mo (Table). Among pts with renal impairment, greater improvements from baseline in pt-reported pain, fatigue, and nausea and vomiting symptom scores were observed with D-Rd vs Rd across most timepoints; a notably greater meaningful reduction in pain symptom score was seen with D-Rd vs Rd as early as Cycle 6 Day 1 (least squares mean change from baseline, –14.9 vs –7.0; *P*=0.0241). Analyses for additional pt subgroups will be presented. **Conclusions:** In transplant-ineligible pts with NDMM, D-Rd showed more rapid deep responses as well as more durable responses vs Rd, regardless of renal function. Improvements in pt-reported symptoms were generally greater with D-Rd vs Rd in pts with renal impairment. Our results support the use of D-Rd in transplant-ineligible pts with NDMM. Clinical trial information: NCT02252172. Research Sponsor: Janssen Research & Development, LLC.

African American patients with smoldering multiple myeloma may have a lower risk of progression compared to White patients. *First Author: Theresia Akhlaghi, Department of Internal Medicine, Icahn School of Medicine, Mount Sinai Morningside and West, New York, NY*

Background: The incidence of multiple myeloma (MM) is two to threefold higher in African Americans (AAs) compared to whites when adjusted for socioeconomics, age, and sex. However, there is limited information on whether racial background affects the risk of progression from smoldering MM (SMM) to MM. **Methods:** Patients with SMM presenting to Memorial Sloan Kettering Cancer Center between the years 2000 and 2019 and who identified as either AA or white were included in the study. Baseline characteristics were collected at the time of diagnosis including laboratory, imaging, and pathology reports. Differences in distributions of continuous and discrete characteristics were assessed by Kruskal-Wallis and chi-square tests. Time to progression (TTP) was assessed using the Kaplan-Meier method with log-rank test for comparisons. Univariate and multivariate Cox proportional hazard models were used to estimate effects of risk factors on TTP with hazard ratios (HR) and 95% confidence intervals (CI). **Results:** A total of 576 patients were included (70 were AA, 12%). Median follow-up time was 3 years in AAs and 4 years in whites. Differences in baseline characteristics between AAs and whites included median age (60 years in AAs vs 64 years in whites, p = 0.01), median hemoglobin level (12.3g/dL in AA vs 12.8g/dL in whites, p = 0.02), and immunoparesis including 1 or 2 uninvolved immunoglobulins (31% and 10% in AAs vs 56% and 27% in whites, p = 0.002). There was no difference in bone marrow plasma cells, M-spike, free light chain ratio, or Mayo-2018 SMM risk score. AA race was associated with a significantly decreased risk of progression in the univariate model (HR 0.57, CI 0.34-0.94). In the multivariate model adjusting for age, sex, and variables associated with an increased risk of progression in the univariate model (bone marrow plasma cells, M-spike, free light chain ratio, immunoparesis and low albumin), AA race remained associated with a decreased risk of progression (HR 0.39, CI 0.16-0.95). Overall, AA patients with SMM had a significantly (p = 0.027) longer median TTP (9.7 vs 6.2 years), and a lower 2-year (12.6% vs 20.1%) and 5-year (34% vs 44.6%) progression rate than whites. Because AA patients were younger at diagnosis, we stratified patients by age group, < 65 vs ≥65 years. In patients < 65 years, there was no difference in progression rate. In patients aged ≥65 years, AA patients continued to have a longer TTP than whites (9.8 vs 5.2 years, p = 0.02). **Conclusions:** In our retrospective single institution experience, AA patients with SMM had a lower risk of progression to MM compared to whites. Both groups had similar Mayo-2018 risk scores, however, AA patients had a lower degree of immunoparesis at baseline. Future studies are needed to better understand if these differences are explained by differences in disease biology including genomic mechanisms, immune microenvironment, and systemic immune response. A patient perspective on cure in multiple myeloma: A survey of over 1,500 patients. *First Author: Ghulam Rehman Mohyuddin, University of Utah, Salt Lake City, UT*

Background: As treatments advance in multiple myeloma (MM) and increasingly deeper and longer responses are achieved, the definition of what a cure is becomes increasingly relevant. While many physicians quote that patients may achieve a "functional cure", understanding the patient perspective on the concept of cure has yet to be explored. **Methods:** HealthTree Cure Hub by the HealthTree Foundation represents an online portal for patients with plasma cell dyscrasias to help navigate their disease. It is the largest single database of patients with multiple myeloma with over 10,200 patients as of January 2022. Using this platform, we surveyed patients online from November 11th 2021 to Feb 7th 2022. Varying scenarios incorporating toxicity, disease status, and being on/off treatment were presented, and participants were asked to rate them from 1-5, with 5 being an ideal cure. Patient awareness of the term functional or operational cure was also. **Results:** A total of 1525 participants completed the survey. Table lists characteristics of the patients who completed this survey. The majority of the patients were female (55.5%), college educated (88.5%) and non-Hispanic White (70.7%). Most patients rated being off treatment permanently and having no evidence of disease as a cure (1116/1469, 75.5%), with a median score of 5 amongst respondents, indicating an ideal version of cure. Continuing to take the same pill or injection with significant toxicity and no evidence of disease had a median score of 1, a score lower than either "continuing to take same pill or injection without significant toxicity even in the evidence of disease" (median score 2) or "stopping treatment permanently even with some detectable disease" (median score 2). The majority of patients (76.3%) reported being unfamiliar with the term functional or operational cure. **Conclusions:** In the first study of patients with plasma cell dyscrasias in which patients were asked about their perceptions of what a cure is, our results highlight that drug toxicity and being on treatment profoundly impacts patient's perception of cure. Furthermore, most patients are not familiar with the term functional or operational cure. Future efforts should recruit more diverse patient populations and incorporate patient preferences in approaches to defining cure in myeloma, as well as explaining cure in easily comprehensible terms to patients. Research Sponsor: None.

Evaluating serum-free light chain ratio as a biomarker for multiple myeloma. *First Author: Theresia Akhlaghi, Department of Internal Medicine, Icahn School of Medicine, Mount Sinai Morningside and West, New York, NY*

Background: In 2014, the definition of multiple myeloma was updated to include serum free light chain (FLC) ratio ≥100 as a myeloma defining biomarker, based on retrospective data indicating a 2-year progression rate of 80% and a median time to progression (TTP) of 12 months associated with this marker. However, two recent studies have reported lower 2-year progression rates, 30-44%, and longer median TTP of 40 months in patients with FLC ratio ≥100. Because of the disparity in risk prediction by FLC ratio across studies, we were motivated to assess the risk of progression in patients with SMM and a FLC ratio ≥100. **Methods:** We performed a retrospective analysis of patients diagnosed with SMM at Memorial Sloan Kettering Cancer Center between January 2000 and December 2017. Diagnosis of SMM and progression to MM was defined according to the International Myeloma Working Group (IMWG) criteria at the time of diagnosis. Kaplan-Meier method was used to assess TTP and generate survival curves, with log-rank test for comparison between groups. **Results:** A total of 438 patients were included in the study, with a median follow-up time of 52 months. While all patients with a FLC ratio ≥100 (n = 66) had elevated involved FLC levels, 35 (53%) had an involved FLC concentration > 100 mg/L. Per current diagnostic criteria, we only included patients with an involved FLC concentration > 100 mg/L in the FLC ratio ≥100 group, and found a median TTP of 31 months (95% confidence interval [CI] 16-59 months) and a 2-year progression rate of 49% (CI 28-63%). In a sensitivity analysis including all 66 cases with FLC ratio ≥100 (independent of involved FLC concentration), we found the median TTP to be 41 months (CI 30-72 months), compared to 101 months for those with a FLC ratio < 100 (CI 78-127 months; p < 0.0001). The risk of progression within 2 years was 35% (CI 22-46%) compared to 18% (CI 14-23%; p < 0.0001). Of note, 22 patients with a FLC ratio ≥100 were monitored expectantly for > 4 years, among whom 12 patients had an involved FLC level > 100 mg/L. Ten patients (7 with involved FLC level > 100 mg/L) were followed over a period ranging from 4 to 8.5 years before eventually progressing, and 12 patients (5 with involved FLC level > 100 mg/L) were followed between 4 and 8 years and did not progress during the study period. **Conclusions:** While FLC ratio ≥100 is associated with a high risk of progression in patients with SMM, it does not infer an imminent risk of progression, defined by the IMWG as median TTP of 12 months and 2-year progression rate of at least 80%. On the contrary, select patients with FLC ratio ≥100 can be followed for many years without progressing and some may never progress despite long-term follow-up. These findings suggest that in patients where FLC ratio ≥100 is the only myeloma-defining event, other high-risk features as well as the evolution of FLCs over time should be considered in the decision to start a patient on treatment. Research Sponsor: None.

Retrospective review of outcomes of patients with multiple myeloma with COVID-19 infection (two-center study). *First Author: Hamid Ehsan, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: Coronavirus-2 has profound effects on patients (pts) with Multiple myeloma (MM). At the beginning of the pandemic, COVID-19 infection resulted an overall mortality around 54% (cook et al. BMJ 2020). Here, we report an updated morbidity and fatality for MM. **Methods:** After obtaining IRB approvals from each participating institute, retrospectively, between January 1, 2021 and August 30, 2021, we identified pts with MM and COVID-19 in two myeloma centers (Levine Cancer Institute (LCI) & the University of Kansas medical center (KUMC). **Results:** We identified 162 MM pts who had COVID-19 (LCI n=132, UKMC n=30), including 57% males, with median age of 64 years. Current or former smoking reported in 40% of pts. Most pts have associated comorbid conditions: hypertension (45%), hypogammaglobulinemia (32%), CKD (30%), DM (22%), obesity (16.6%), CHF (14%), and CAD (13.5%). Within 3 months prior to infection, treatment included immunomodulatory combinations in 35%, proteasome inhibitors in 28 %, and Daratumumab in 26.5%. Symptoms are summarized in table. 69% had Mild symptoms (no need for hospitalization), 20 % had moderate symptoms (requiring hospitalization), and 9.8% had severe symptoms (ICU level of care). The 18% of pts required oxygen: 6 pts required invasive oxygenation and 3 pts needed vasopressors. The 32% of pts had RRMM, 29.5% on maintenance, and 12% was getting induction. Regarding MM response: >VGPR in 45% and PD in 18%. The 78 pts had ASCT prior to COVID-19 infection: only 3 pts < 1 year and 3 pts < 6 months. MM response or ASCT did not affect hospitalization or mortality.The case fatality rate (CFR) was 6%. In the univariate analysis, CKD, DM, HTN and hepatic dysfunction were associated with an increased risk of hospitalization. However, in multivariate analysis, only CKD, hepatic dysfunction, and Hypogammaglobulinemia significantly increased the risk of admission with only age and lymphopenia were associated with increased COVID-19 related fatatlity. **Conclusions:** With implementation of center-specific disease control measures and universal screening, pts might have lower case severity and fatality rate than was initially reported. Kinetics of humoral immunodeficiency with bispecific antibody therapy in multiple myeloma. *First Author: Lindsay Hammons, Mount Sinai Beth Israel, New York, NY*

Background: Bispecific antibodies (bsAb) are a promising class of therapeutics in RRMM. While hypogammaglobinemia (HGG) is anticipated due to plasma cell depletion, there is a lack of information about the degree of secondary immunodeficiency and resultant infectious complications. We investigated the kinetics of HGG in patients with RRMM on bsAb therapy. **Methods:** We identified and followed 42 patients treated on early clinical trials of bsAb at our institution between 2019 and 2021. Serial immunoglobulin levels and infections were obtained from the start of therapy until last follow up or 3 months after study exit. **Results:** 49 treatment courses were included from 42 individual patients. All patients were triple class exposed with a median of 5 prior lines of therapy. The median age was 67 (44-85) years, with 49% females. African Americans accounted for 18% of patients. 96% of patients had at least one prior ASCT. 90% of patients received bsAb targeting BCMA including 7 patients who received more than one line of BCMA targeting therapies. At a median follow up 9.5 (0.9-28.6) months, 40.8% of patients remained on bsAb therapy. At the start of therapy, the median IgG, IgA, and IgM levels were 560 (44-9436), 15 (5-3886) and 6 (5-64) mg/dL, respectively and 50% of patients had severe HGG (≤400mg/dl). Serum IgG levels reached a nadir at 3 months while, IgA and IgM at 1 month, from the start of therapy. The median nadir levels of IgG were 159 (40-2996) mg/dL, while it was < 5 mg/dL for both IgA and IgM. IgG levels were below the detectable range (< 40 mg/dl) in 28% of patients at some point during therapy. IgA and IgM were also below the detectable range (< 5 mg/dl) in 50% and 60% of patients, respectively. At last follow-up, the median IgG levels were 444 (40-1860) mg/dL and IgA 5 (5-254) mg/dL and IgM 5 (5-44) mg/dL. Additionally, 38% of patients remained severely hypogammaglobinemic. 57% (24/42) of patients received IVIG supplements in the current series. About 71% of patients had at least one infectious event and the cumulative incidence of infections progressively increased with increasing duration of therapy with risk at 3, 6, 9 12, 15 months being 41%, 57%, 64%, 67% and 70%, respectively. Among these, 54% of infection were bacterial. Viral infection accounted for 41% of infections. A third of patients had new infectious events during the first 90 days following stopping bsAb treatment. 57% (8/14) of patients did not mount a response to the primary COVID19 immunization series. Among the five patients with repeat antibody titers after the booster dose, 50% were still not able to mount an antibody response. **Conclusions:** bsAb therapy in RRMM can be associated with profound and prolonged HGG. The cumulative risk of infection correlated with the degree of HGG and progressively increases with treatment and persisted months after being off therapy. Additionally, an impaired antibody response to the COVID-19 immunization series was also noted. Research Sponsor: None.

The association of agent orange (AO) exposure with monoclonal gammopathy of undetermined significance (MGUS) to multiple myeloma (MM) progression: A population-based study. *First Author: Lawrence Liu, Department of Medicine, Washington University School of Medicine, Saint Louis, MO*

Background: With limited evidence from a single center study [n=211 (11 with AO exposure)] reporting AO exposure as a risk factor for transformation, whether or not AO exposure increases the rate of transformation from MGUS to MM is unclear. Thus, we aimed to conduct a nationwide study to determine the association between AO exposure and the risk of MGUS to MM progression. **Methods:** A retrospective, matched cohort study using data from the U.S. Veterans Health Administration system was conducted. Based on a power calculation, a random sample of MGUS patients with AO exposure was selected and 1:1 matched to those with MGUS without AO exposure (matching factors: age at MGUS diagnosis, race, body mass index categories). Data abstraction confirmed MGUS and MM diagnoses. In addition, information on date of diagnosis, MGUS subtype, and monoclonal protein (M-protein) values was performed. Patients were considered to have MGUS if they had M-protein detected on serum protein electrophoresis (SPEP) with immunofixation confirmation. The association of AO exposure with progression from MGUS to MM was examined using a multivariable Fine-Gray subdistribution hazard model with death as the competing event. The covariates included M-protein at MGUS diagnosis (>1.5, ≤1.5 g/dL [reference]), MGUS subtype (Immunoglobulin A, light chain, and Immunoglobulin G [reference]), and Charlson comorbidity score at MGUS diagnosis. A sensitivity analysis was conducted using inverse probability treatment weighted survival analysis to evaluate the robustness of the conclusion. **Results:** After excluding individuals with no confirmed MGUS or M MGUS subtype, a total of 563 MGUS patients with AO exposure and 563 matched controls were included. No statistically significant difference was observed in the progression of MGUS to MM between the AO exposed group and control group (adjusted hazard ratio (aHR) 0.78, 95% confidence interval (CI) 0.53 to 1.17). The sensitivity analysis demonstrated consistent results. **Conclusions:** Our carefully designed study does not show an association between AO exposure and progression of MGUS to MM in a national cohort of Veterans. Research Sponsor: U.S. National Institutes of Health.

Multivariable analysis of progression of MGUS to MM.

Parameter	Hazard Ratio	95% Confidence Interval	P-value
AO Exposure	0.78	0.53-1.17	0.23
M-protein >1.5 g/dL	16.29	5.86-45.27	<0.0001
Immunoglobulin A MGUS	1.09	0.58-2.06	0.79
Light Chain MGUS	5.57	1.45-21.41	0.01
Comorbidity	0.99	0.91-1.08	0.78

Daratumumab (DARA) in combination with bortezomib plus dexamethasone (D-Vd) or lenalidomide plus dexamethasone (D-Rd) in relapsed or refractory multiple myeloma (RRMM): Subgroup analysis of the phase 3 CASTOR and POLLUX studies in patients (pts) with early or late relapse after initial therapy. *First Author: Andrew Spencer, Malignant Haematology and Stem Cell Transplantation Service, Alfred Health-Monash University, Melbourne, Australia*

Background: High-risk multiple myeloma (MM) is often defined based on cytogenetic abnormalities (ie, t[4;14], t[14;16], and/or del17p); however, pts who relapse early (12-18 months) after initial therapy are considered a functional high-risk group that is also associated with poor prognosis. DARA, a human IgGκ monoclonal antibody targeting CD38, is approved in combination with standard-of-care regimens for MM. In the phase 3 CASTOR and POLLUX studies, D-Vd and D-Rd significantly improved progression-free survival (PFS), regardless of cytogenetic risk, and achieved higher rates of complete response or better (≥CR) and minimal residual disease (MRD)–negativity vs Vd or Rd alone in pts with RRMM. Post hoc analyses of CASTOR and POLLUX evaluated D-Vd vs Vd and D-Rd vs Rd in pt subgroups with 1 prior line of therapy based on timing of relapse (early or late) after initiation of the first line of therapy. **Methods:** In CASTOR and POLLUX, pts with RRMM and ≥1 prior line of therapy were randomized to D-Vd/Vd or D-Rd/Rd, respectively. The primary endpoint was PFS. In this analysis, the early relapse subgroup included pts with 1 prior line of therapy who relapsed <18 months after initiating their first line of therapy; pts with 1 prior line of therapy who relapsed ≥18 months after initiating their first line of therapy were included in the late relapse subgroup. **Results:** 49 and 186 pts from CASTOR and 99 and 196 pts from POLLUX were included in the early relapse and late relapse subgroups, respectively. Median follow-up was 72.6 months (CASTOR) and 79.7 months (POLLUX). PFS consistently favored the DARA-containing regimens across subgroups (Table). In CASTOR, ≥CR rates were higher with D-Vd vs Vd in the early relapse (21% vs 17%; $P = 0.7360$) and late relapse (51% vs 14%; $P < 0.0001$) subgroups. In POLLUX, ≥CR rates were higher with D-Rd vs Rd in the early relapse (53% vs 12%; $P < 0.0001$) and late relapse (62% vs 38%; $P = 0.0012$) subgroups. MRD-negativity rates (10^{-5}) were higher with D-Vd/D-Rd vs Vd/Rd regardless of relapse timing (CASTOR: early, 13% vs 0%; $P = 0.1476$; late, 23% vs 3%; $P < 0.0001$; POLLUX: early, 30% vs 4%; $P = 0.0006$; late, 34% vs 14%; $P = 0.0009$). **Conclusions:** These post hoc analyses of CASTOR and POLLUX showed PFS and depth of response benefits of DARA-containing regimens in patients with 1 prior line of therapy, regardless of relapse timing (early or late). Our results support the use of D-Vd and D-Rd in RRMM, including in pts who are considered functional high risk. Clinical trial information: NCT02136134 and NCT02076009. Research Sponsor: Janssen Research & Development, LLC.

Median PFS, months	D-Vd	Vd	HR (95% CI); *P* value	D-Rd	Rd	HR (95% CI); *P* value
Early relapse	15.4	9.0	0.51 (0.26-1.00); $P = 0.0488$	36.9	11.7	0.41 (0.26-0.65); $P = 0.0002$
Late relapse	27.7	7.9	0.20 (0.14-0.29); $P < 0.0001$	69.3	29.7	0.53 (0.37-0.77); $P = 0.0007$

Outcomes for transplant-eligible, newly diagnosed Black patients (Pts) with multiple myeloma (MM): The Levine Cancer Institute (LCI) experience. *First Author: Barry Paul, Levine Cancer Institute, Charlotte, NC*

Background: Studies have revealed disparities for Black (B) pts with MM, including more advanced disease at presentation, delayed therapy with novel agents such as immunomodulatory drugs (IMIDs) and proteasome inhibitors (PIs), reduced access to autologous stem cell transplant (ASCT), and under-representation in clinical trials. However, B pts tend to be younger at diagnosis and less likely to harbor high risk disease biology, suggesting outcomes could be better relative to their White (W) counterparts. To better understand outcomes by race in the setting of more optimal treatment access, we pursued a retrospective analysis of pts treated at LCI undergoing ASCT as part of first line therapy. **Methods:** 255 pts (181 W pts, 74 B pts) transplanted between 3/2014 – 12/2018 were included. Analysis was restricted to pts with MM who underwent a single ASCT as part of first line therapy. Pts with < 1 year of follow-up and no overall survival (OS) events were excluded. Proportions were compared between groups with Fisher's exact tests; OS and progression free survival (PFS) were evaluated with Kaplan Meier methods and compared between groups with log-rank tests. **Results:** Median follow-up for B and W pts was 5.0 yrs (0.9 – 7.8 yrs) and 4.1 yrs (0.5 – 8.0 yrs). At initial presentation, median age was 59 yrs (24 – 76 yrs) and 61 yrs (35 – 78 yrs, $P = 0.038$), anemia was present in 81.3% and 64.6% ($P = 0.020$), renal impairment in 41.3% and 33.1% ($P = 0.335$), and high-risk cytogenetics [gain 1q21, t(4;14), t(14;16) or del(17p)] in 25.4% and 35.9% ($P = 0.162$) of B and W pts, respectively. Median time from diagnosis to ASCT was 0.6 yrs (0.3 – 2.4 yrs) and 0.5 yrs (0.3 – 2.0 yrs) for B and W pts. 35.2% of all B pts and 43.9% of all W pts treated at LCI during the study period underwent ASCT (48.3% and 64.4% of pts ≤70 yrs of age, $P = 0.002$), while 63.5% and 80.1% received PI/IMID-based induction therapy ($P = 0.009$) and 90.5% and 93.4% received maintenance therapy post-ASCT ($P = 0.438$), respectively. Although ≥very good partial responses were achieved in fewer B pts than W pts after induction (65.8% and 80.7%,($P = 0.014$), there was no difference after ASCT (95.8% and 93.9%, $P = 0.759$). Median PFS was 5.9 yrs (95% CI 3.4 – 6.6) and 3.6 yrs (95% CI 3.0 – 4.5) for B and W pts ($P = 0.039$). Median OS trended in favor of B pts ($P = 0.163$) with 5-year OS of 83.0% (95% CI 71.2% - 90.3%) and 74.2% (95% CI 65.8% - 80.9%), respectively. **Conclusions:** Despite disparities in optimal induction therapy, Black pts with MM who underwent frontline ASCT enjoyed better PFS relative to W pts. Optimizing access to PI/IMID-based induction therapy and ASCT will be necessary to further improve OS. Research Sponsor: None.

Randomized phase II trial of bortezomib, lenalidomide, dexamthasone with/without elotuzumab for newly diagnosed, high risk multiple myeloma (SWOG-1211). *First Author: Saad Zafar Usmani, Myeloma Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The introduction of immunomodulatory agents, proteasome inhibitors, and autologous stem cell transplantation (ASCT) has improved outcomes for patients with multiple myeloma (MM), but those with high risk MM (HRMM) have a poor long-term prognosis. Herein we provide survival outcomes on the first randomized trial in newly diagnosed HRMM, S1211, to follow-up on the previously reported progression-free survival (PFS) (NCT01668719, Usmani SZ et al, Lancet Haem 2021). **Methods:** S1211 is a randomized phase II trial comparing 8 cycles of lenalidomide, bortezomib and dexamethasone (RVd) induction followed by dose-attenuated RVd maintenance until disease progression with or without elotuzumab (RVd-Elo). Stem cell collection was allowed, but ASCT was deferred until progression. HRMM was defined by one of the following: gene expression profiling high-risk (GEP^{hi}), t(14;16), t(14;20), del(17p), amplification 1q21, primary plasma cell leukemia (pPCL), or elevated serum LDH (> 2X ULN). Median PFS was the primary endpoint, using a one-sided stratified log-rank test at a one-sided significance level of 0.1. Secondary endpoints included overall response rate (ORR), adverse events (AE), serious adverse events (SAE) and OS. Response was assessed using the IMWG 2009 criteria. **Results:** S1211 enrolled 103 evaluable patients, RVd n=54, RVd-Elo n=49. 74% had ISS II/III, 48% amp1q21, 38% del(17p), 11% t(14;16), 9% GEP^{hi} , 7% pPCL, 5% t(14;20) and 4% elevated LDH (17% >1 feature). With median follow-up of 72 months (mos.), no difference in median PFS was observed [RVd-Elo=29 mos., RVd= 34 mos., HR = 1.11 (80% CI=0.82, 1.49, p=0.66]. No difference in OS was observed [RVd-Elo = median not reached (NR), RVd= 68 mos., HR = 0.85 (80% CI: 0.59, 1.23), p-value = 0.58]. 76% pts had >Grade 3 AEs, no differences in the safety profile were observed. Amongst patients with gain/amp 1q21, median PFS was [RVd-Elo=31 mos., RVd= 37 mos., HR = 1.48 (80% CI= 0.95, 2.31), p=0.25], median OS was [RVd-Elo = 61 mos., RVd= 68 mos., HR = 1.23 (80% CI: 0.72, 2.10), p-value = 0.63]. In patients with del(17p), median PFS was RVd-Elo=41 mos., RVd= 30 mos.[HR = 0.98 (80% CI= 0.60, 1.58), p=0.95], median OS RVd-Elo = NR, RVd= 72 mos., [HR = 0.77 (80% CI: 0.40, 1.48), p-value = 0.61]. **Conclusions:** In the first randomized HRMM study reported to date, the addition of Elo to RVd induction and maintenance did not improve PFS and OS with a median follow-up of 6 years. Although the median PFS for Del17p subgroup on RVd-Elo arm is higher than RVd, it did not achieve statistical significance. The PFS and OS observed for gain/amp 1q21 and del17p in the RVd control arm may serve as important benchmarks for future enrichment design HRMM clinical trials. The PFS and OS in both arms of the study exceeded the original statistical assumptions and support the role for PI/IMiD combination induction/maintenance therapy for this population. Clinical trial information: NCT01668719. Research Sponsor: U.S. National Institutes of Health.

Myeloma developing regimens using genomics (MyDRUG) trial: Results from the RAS mutation targeting arm. *First Author: Shaji Kumar, Mayo Clinic, Rochester, MN*

Background: Multiple myeloma (MM) is characterized by somatic mutations involving cancer-associated genes. The most commonly mutated genes are N- and K-Ras, which increase in prevalence as the disease progresses. Case reports and retrospective data suggest efficacy of targeting the MAPK pathway in N/K-Ras mutated MM. The MyDRUG trial was initiated to explore the efficacy of specific molecularly-targeted therapies in combination with standard therapies in MM. **Methods:** MyDRUG (NCT03732703) is a genomically-guided umbrella trial for patients with functional high-risk MM, defined as early relapse following primary therapy (3 years for transplant with maintenance, 18 months without), with specific genetic abnormalities. Subjects undergo molecular profiling of their MM cells and are assigned to a targeted arm if a variant allele frequency (VAF) over 25% is identified. The targeted mutated genes and respective agents (approved for non-MM indications and with a known phase 2 dose) are: KRAS/NRAS/BRAF (cobimetinib), FGFR3 (enasidenib), IDH (erdafitinib), CDKN2C (abemaciclib), *t*(11;14) (venetoclax). Patients receive the investigational drug for 2 cycles as a single agent followed by addition of an active MM combination (ixazomib, pomalidomide and dexamethasone, IPd). Limited dose escalation was performed with the single agent followed by dose assessment in combination with IPd. Here we present the results of the dose escalation portion of C1 arm exploring cobimetinib in patients with N/K-RAS or BRAF mutations. Cobimetinib was administered at 40 mg daily in combination with standard doses of IPd. **Results:** Eleven subjects with BRAF/RAS mutations were screened between August 2019 and October 2020, with 4 screen failures. Seven were enrolled, 5 males, median age 65 years, and median time from diagnosis of 30 months. N-RAS, K-RAS or BRAF mutations were seen in 4, 2, and 1 subject(s), respectively, with VAF ranging from 33-93%. Median number of prior lines of therapy was 1 (1-3), 3 patients had extramedullary disease, and 1 patient had high risk cytogenetics. Median duration of therapy was 12 months. One patient was not evaluable for dose limiting toxicity. All but 1 patient had at least one cycle delayed due to adverse events (AEs), but no dose reductions were required. No dose limiting toxicities were observed across the cycles, either during single agent therapy (Cycles 1-2) or in combination with IPd (Cycles 3 and 4). Six patients responded to therapy (4 PR, 2 VGPR). One patient was not response evaluable. Fatigue was the most common non-hematological AE followed by diarrhea. **Conclusions:** Here we report on the feasibility of genomically-guided, precision medicine therapy in K/N-RAS/BRAF-mutated MM. The MEK inhibitor cobimetinib in combination with IPd appears safe in functionally high-risk patients. Ongoing study will provide more information regarding the efficacy of this approach. Clinical trial information: NCT03732703. Research Sponsor: The Multiple Myeloma Research Foundation.

Clinicopathological characteristics of high-risk multiple myeloma in Hispanic versus non-Hispanic patients in central California. *First Author: Andrew Hwang, University of California-San Francisco, Fresno, CA*

Background: Roughly 37% of Multiple Myeloma (MM) patients in the U.S. are non-white minorities. Advanced stage at diagnosis and specific cytogenetic abnormalities are associated with high-risk disease and poor prognosis. Few studies evaluated these risk factors in ethnic minorities. To further investigate, we analyzed ethnic variations in characteristics and outcomes of high-risk MM patients who were treated at our institution in Fresno, CA (49.6% Hispanic population). **Methods:** Patients diagnosed with high-risk MM at Community Medical Centers from 1-1-2011 to 12-31-2020 were included. High risk was defined by Mayo Clinic mSMART 3.0 classification. Demographic and disease-relevant information were collected. Cytogenetics, R ISS stage, 1st line treatment (doublet vs triplet), and treatment response (IMWG response criteria) were evaluated. Hispanic and non Hispanic comparisons were made by Fisher's exact test where appropriate. Progression Free Survival (PFS) and Overall Survival (OS) were evaluated by Kaplan-Meier estimates and compared via log-rank test. Univariate cox proportional hazard model for survival was used to examine the association of variables with mortality risk after 1st line therapy. **Results:** 147 MM patients were screened. 42 high risk patients were identified: 11 (26%) Hispanic, 31 (74%) non Hispanic (22 white, 8 African American, 1 East Indian). Median age at diagnosis was 65. 26 (61%) were females. 25 (59%) were R ISS stage 3. Hispanic vs non Hispanic median income was $46119 vs $65080 (p=0.035). 6 Hispanics had Medi-Cal insurance vs 2 non-Hispanics (54.6% vs 6.5%, p=0.003). More Hispanics had Lambda light chain disease (73% vs 26%; p=0.01). 13 non Hispanics had del 17p vs 0 Hispanics (p=0.009). 40/42 patients (95%) received triplet therapy. 4 Hispanics received ASCT vs 9 non Hispanics (40% vs 33.3%, p=0.716). Hispanics and non Hispanics did not have significantly different treatment responses per IMWG criteria (p=0.799). No significant difference in PFS was seen between Hispanics and non Hispanics (805 vs 793 days; p=0.089); OS was better in Hispanics (1062 days vs 453 days; p=0.008). Per univariate cox proportional Hazard model, female sex (HR 4.34) and age (HR 1.05) were associated with higher mortality while Hispanic ethnicity was associated with lower mortality (HR 0.19). **Conclusions:** Hispanic and non Hispanic high risk MM patients differed significantly in median income, insurance, and del 17p incidence. These did not translate to a difference in 1st line therapy or treatment response. OS in our study is higher in Hispanic high-risk MM patients compared to other ethnicities and warrants further investigation. Research Sponsor: None.

Impact of second primary malignancy post-autologous hematopoietic stem cell transplantation on outcomes of multiple myeloma: A CIBMTR analysis. *First Author: Brittany K. Ragon, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: Following autologous hematopoietic stem cell transplant (auto HCT), maintenance therapies improve survival, reduce relapse risk in multiple myeloma (MM), and are the *de facto* standard-of-care. However, clinical trials have shown an increased risk of second primary malignancies (SPM) with maintenance therapy, including second hematological malignancies (SHM). We examined data from the Center for International Blood and Marrow Transplant Research (CIBMTR) registry to evaluate the impact of SPM on progression-free (PFS) and overall survival (OS) and the utilization of allogeneic HCT in patients with therapy-related myeloid neoplasms (t-MN). **Methods:** Adult patients (pts) with MM who underwent first auto HCT in the United States with a melphalan conditioning regimen from 2011-2018 and subsequently received maintenance therapy were included (N=3948). The primary endpoint of interest was the impact of SPM and SHM on OS. Multivariate analytic (MVA) modelling was applied, accounting for competing risks while integrating significant covariates to determine the impact of SPM on PFS and OS. Finally, we studied the utilization and survival following allogeneic HCT for SHM. **Results:** Baseline characteristics were similar between the two groups. Maintenance regimens used were lenalidomide (2836, 72%), bortezomib (370,9 %) or lenalidomide + bortezomib (372, 9%) based combinations. At a median follow up of 37 months, 175 (5%) pts developed SPM, including 112 (64%) solid 36 (21%) myeloid, and 27 (15%) lymphoid cancers. In MVA, the development of SPM and SHM was associated with an inferior PFS (HR 2.62, $P<0.001$ and HR 5.01, $P<0.001$, respectively) and OS (HR 3.85, $P<0.001$ and 8.13, $P<0.001$, respectively). The two commonest causes of death were MM (42%) and SPM (30%) for those developing SPM. Similarly, MM (53%) and SHM (18%) were the two commonest causes of death for those developing SHM. Nine (14%,5 t-MDS and 4 t-AML) of 63 patients with SHM underwent an allogeneic HCT. Patients undergoing allogeneic HCT were more likely to have Karnofsky score ≥90 (100% *vs.* 50%, $P=0.02$) compared to those who did not. One year survival from allo SCT was 66.7% (CI 34.6-92%). **Conclusions:** The three-year cumulative incidence of SPM was 3.3 (2.6-4)% in this large contemporaneous CIBMTR cohort. Disease relapse remains the primary cause of death in MM patients who develop SPM or SHM. Given the median OS for MM is now > 10 years, longer follow-up is needed to assess the SPM and SHM risks with maintenance therapy post-auto HCT. Research Sponsor: U.S. National Institutes of Health.

Early intervention for high-risk and low-risk of progression for patients with smoldering multiple myeloma. *First Author: Nathan W. Sweeney, HealthTree Foundation, Lehi, UT*

Background: Previous studies have observed smoldering multiple myeloma (SMM) patients with a biomarker criteria of > 20% bone marrow plasma cells, > 2 g/dL M protein spike, and > 20 free light chain ratio, also known as 20/2/20, are at a higher risk of progressing to multiple myeloma (MM) than others. These findings have ignited interest in pursuing early intervention for these high-risk patients. However, we asked if early intervention would be beneficial for all SMM patients regardless of the progression risk level. **Methods:** We utilized real-world data from HealthTree Cure Hub for Multiple Myeloma to first, determine whether 20/2/20 resulted in a higher risk of progression and second, analyze whether early intervention delayed progression from SMM to MM. A 2-sample t-test was used to compare 20/2/20 to non-20/2/20 patients, as well as in the comparison between SMM patients who received early intervention with treatment to without early intervention. **Results:** We found that patients who met at least two of the criteria of 20/2/20 had a tendency to progress to MM 35% faster than patients who did not meet the criteria (n = 36, p-value < 0.10). While not significant, it's still worth noting that there is a difference in the mean time to progression for these patients. Next, we found SMM patients who do not receive early intervention with treatment develop MM two times faster than those who do receive early intervention with treatment, regardless of progression risk level (n = 129, p-value < 0.001). **Conclusions:** Our results revealed that at least two of the biomarker criteria could aid in the identification of patients with a higher risk of progression. However, a casual approach of "sit and wait" for patients to develop 20/2/20 is not warranted since our findings revealed that all SMM patients benefited from treatment intervention regardless of the progression risk level. Research Sponsor: None.

Analysis of long-term outcomes in R-ISS stage 2 multiple myeloma with and without the presence of high-risk cytogenetics. *First Author: Nisha Joseph, Emory University, Winship Cancer Institute, Atlanta, GA*

Background: The Revised International Staging System (R-ISS) is the current standard for risk-stratification of newly diagnosed myeloma (NDMM), incorporating albumin and β2M with high-risk cytogenetics and/or elevated LDH. (Palumbo et al, JCO 2015) R-ISS stage 2 represents a heterogeneous cohort including myeloma with and without high-risk cytogenetics, a known poor prognosticator. Here, we present a retrospective analysis on outcomes of R-ISS stage 2 NDMM utilizing our institutional database of patients treated at the Winship Cancer Institute of Emory University. **Methods:** From January 2007 to August 2016, 1,000 consecutive newly diagnosed myeloma patients treated with RVD induction therapy were identified . Demographics, clinical characteristics, and outcomes data for the patients were obtained from our institutional review board-approved myeloma database. Responses were evaluated per IMWG Uniform Response Criteria. **Results:** The median age of this cohort was 61 years (range 16-83). Other notable patient characteristics include: M/F 54.6%/45.4%, W/AA 61.8%/35.9%; ISS I/II/III 45.8%/30.8%/23.4%. R-ISS I/II/III 39.9%/48.7%/11.5%; Isotype IgG/IgA/FLC 59.2%/19.0%/15.7%; standard risk (SR)/high risk (HR) 71.2%/15.8%. ISS data was available for 75% of patients; R-ISS was available for 41% of patients. HR disease was defined as the presence of t(4;14), t(14;16), del(17p), and/or complex karyotype by conventional metaphase cytogenetics. Frequency of specific CTG abnormalities were 2.8% with t(14;16), 10% with del(17p), and 4.8% with t(4;14). With a median follow up of 88.4 months, the median PFS (mPFS) for the entire cohort was 68.7 months (95% CI 61.8-75.5) and the median OS was 128.9 months. The median PFS for HR vs SR patients was 42.4 months (95% CI 35.7-48.9) vs 80.3 months (95% CI 72.8-87.8). The median OS for SR patients was not reached, and for HR patients was 86.6 months (95% CI 70.1-103.1). The mPFS for R-ISS 1,2 and 3 was 95.4 months (95% CI 73.4-117.5), 56.6 months (95% CI 44.4-68.7), and 31.1 months (95% CI 16.3-45.9). When the R-ISS 2 cohort was divided into those without HR CTG and with HR CTG, the mPFS was 67.1 months (95% CI 53.3-80.8) versus 40.2 months (95% CI 30.1-50.3), respectively. The mOS for R-ISS I/II/III was NR, 122.7 months (95% CI 101.6-143.9), and 60.6 months (95% CI 11.6-109.5). For R-ISS 2 without and with HR CTG, the mOS was 129.1 months and 94.8 months (95% CI 61.3-128.3), respectively. **Conclusions:** The R-ISS is a validated risk model clearly defining three distinct groups in terms of long-term outcomes. However, these data suggest R-ISS stage 2 can further be characterized into two distinct groups based on the presence or absence of high risk cytogenetics. R-ISS 2 with HR-CTG portends both inferior mPFS and increased risk of death when compared to R-ISS 2 without HR-CTG (HR 2.63 versus HR 1.65), and behaves more similarly to R-ISS 3 disease. Retrospective, single-center, real-world experience of belantamab mafodotin in relapsed/refractory multiple myeloma. *First Author: Melody Becnel, The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX*

Background: Belantamab mafodotin (belamaf) is a BCMA antibody drug conjugate approved for the treatment of relapsed refractory multiple myeloma (RRMM) patients (pts) based on the pivotal phase 2 DREAMM-2 study (Lonial et al, *Lancet Oncology*, 2019), which demonstrated an overall response rate (ORR) of 32%, median progression free survival (PFS) of 2.8 months, and overall survival (OS) of 13.7 months in triple class (proteasome inhibitor, IMiD, and anti-CD38) refractory (TCR) MM. In this single-center retrospective study, we report the efficacy and safety of belamaf in RRMM pts administered in a real-world, standard of care (SOC) setting. **Methods**: All MM pts who initiated therapy with SOC belamaf, either as monotherapy or in combination, between 11/1/2020 and 11/30/2021 at MD Anderson were included in this study. Response and progression were evaluated using International Myeloma Working Group standard criteria. Keratopathy and best corrected visual acuity (BCVA) adverse events (AEs) were graded per the Keratopathy and Visual Acuity (KVA) scale. The Kaplan-Meier method was used to estimate time to event endpoints. **Results**: A total of 39 consecutive pts with a median of 7 prior lines of therapy were included in the analysis, of whom 37 pts (95%) received single agent belamaf. Median age was 66 years (range 39-89), 14 of 37 (38%) pts with available FISH had high risk disease (del 17p, t(4;14, and/or t(14;16)), 14 pts (36%) had extramedullary disease, 37 (95%) pts were TCR, 32 (82%) pts were TCR and alkylator-refractory, and 8 pts (21%) were BCMA-refractory. Notably, the majority (69%) of pts in this analysis would have been ineligible for the DREAMM-2 trial based on key eligibility criteria. Median number of belamaf doses administered was 2 (range 1-9). Among 37 pts with measurable, response evaluable baseline disease, the best ORR (≥ PR) was 27% with ≥ VGPR of 3%. The clinical benefit rate (≥ MR) was 35%. Among 8 BCMA-refractory pts, there was 1 PR and 1 MR. Median PFS was 1.8 months and median OS was 9.2 months with a median follow-up of 10.1 months. Median duration of response has not been reached among 10 responding pts. Among 33 pts with a post-treatment ocular exam, 25 pts (76%) developed any grade keratopathy (Grade 1/2/3/4, 9%/55%/12%/0%, respectively) and BCVA changes (Grade 1/2/3/4, 42%/27%/6%/0%, respectively). Median time to first keratopathy or BCVA AE was 1.3 months. The most common reasons for treatment discontinuation were disease progression (75%) and AEs (9%). **Conclusions**: Our current study in heavily pretreated RRMM pts, of whom the majority would have been ineligible for the DREAMM-2 study, demonstrates an ORR, PFS, and ocular AE profile with SOC belamaf therapy comparable to outcomes reported in the pivotal registration study. Future studies are needed to further define the optimal use and sequencing of belamaf in MM pts, particularly in context of other BCMA-targeting modalities. Research Sponsor: None.

Updated survival with extended follow-up on patients with newly diagnosed multiple myeloma treated with lenalidomide, bortezomib, and dexamethasone (RVD) induction therapy and a risk-stratified maintenance approach. *First Author: Rujul H Parikh, Emory University, Winship Cancer Institute, Atlanta, GA*

Background: Lenalidomide, bortezomib, and dexamethasone (RVD) has been established as an effective and well-tolerated induction regimen in patients with newly diagnosed myeloma (NDMM). We have previously published a retrospective analysis of 1000 patients treated with RVD and risk-stratified maintenance therapy showing a median PFS of 65 months and median OS of 126 months for the entire cohort (Joseph et al, *JCO* 2020). This data has served as an important benchmark for evaluating upfront treatment strategies in NDMM. Here, we present updated survival data with extended follow up on this patient population treated at the Winship Cancer Institute of Emory University. **Methods:** From January 2007 to August 2016, 1000 consecutive newly diagnosed myeloma patients treated with RVD induction therapy (R-25 mg/day on days 1-14, V-1.3 mg/m2 on days 1,4,8,11 and D-40 mg once/twice weekly as tolerated) were identified. Demographics, clinical characteristics, and outcomes data for the patients were obtained from our institutional review board-approved myeloma database. Responses were evaluated per IMWG Uniform Response Criteria. **Results:** The median age of this cohort was 61 (range 16-83). Other notable patient characteristics include: M/F 54.6%/45.4%, W/AA 61.8%/35.9%; ISS I/II/III 45.8%/30.8%/23.4%. R-ISS I/II/III 39.9%/48.7%/11.5%; Isotype IgG/IgA/FLC 59.2%/19.0%/15.7%; standard risk(SR)/high risk (HR) 71.2%/15.8%.. High risk disease was defined as the presence of t(4;14), t(14;16), del(17p), and/or complex karyotype by conventional metaphase cytogenetics. 81.8% of patients underwent ASCT, with 16.8% having deferred ASCT. 75.3% of patients were initiated on maintenance therapy. With a median follow up of 88.4 months, the median PFS for the entire cohort was 68.7 months (95% CI 61.8-75.5) and the median OS was 128.9 months. The median PFS for HR patients was 42.4 months (95% CI 35.7-48.9), and the median PFS for SR patients was 80.3 months (95% CI 72.8-87.8). The median OS for SR patients was not reached, and for HR patients was 86.6 months (95% CI 70.1-103.1). **Conclusions:** Updated analysis with long-term follow up of this database of 1000 NDMM patients treated with RVD continues to demonstrate that, in combination with a risk-stratified maintenance strategy, RVD delivers durable remissions and impressive long-term outcomes. This study remains the largest cohort of patients treated with RVD reported to date, and continues to show the efficacy of this upfront treatment approach in newly diagnosed myeloma. Research Sponsor: None.

Clinical features of patients with multiple myeloma harboring t(4;14) and impact on long-term survival. *First Author: Nisha Joseph, Emory University, Winship Cancer Institute, Atlanta, GA*

Background: Translocation (4;14) is a known adverse prognostic factor in myeloma. However, utilization of proteasome inhibitors (PIs) in myeloma has abrogated the negative impact of t(4;14) in myeloma, and some investigators question whether t(4;14) still needs to be considered a high-risk marker. Here, we present a retrospective analysis of 142 patients with t(4;14) and describe disease characteristics, treatment patterns, and long-term outcomes. **Methods:** From January 2007 to August 2016, 42 patients with newly diagnosed myeloma and t(4;14) were identified. Demographics, clinical characteristics, and outcomes data for the patients were obtained from our institutional review board-approved myeloma database. Responses were evaluated per IMWG Uniform Response Criteria. **Results:** The median age of this cohort was 59.6 years (range 33-78). Notable patient characteristics include: W/AA/Asian 25.9%/23.6%/50%; ISS I/II/III 36.4%/22.9%/24.1%; R-ISS I/II/III 0%/27.8%/25.8%. Median lab values at diagnosis include: Hgb 10.4 g/dL, Hct 30.8%, Cr 1.01, and Ca 9.4, Frequency of concurrent cytogenetic abnormalities include del(17p): 19.7%; del(13): 44.4%, and +1q21: 46.5%. A majority of patients (86.7%) were induced with either triplet or quadruplet regimens, with 88% of these regimens including a proteasome inhibitor. 78.9% of patients underwent ASCT. Of those responses captured, 75.3% achieved ≥VGPR (sCR 4.8%, CR 30.5%, VGPR 40%, PR 20%). Post-transplant, 88% achieved ≥VGPR (sCR 35.1%, CR 30.9%, VGPR 22.3%), and 82% received maintenance therapy. The most common maintenance regimens included revlimid (34.8%), bortezomib (16.5%), and RVD (11.3%); one-third of patients received triplet maintenance regimens. With a median follow up of 99.5 months, the overall mPFS and mOS for this cohort of t(4;14) patients was 47.6 m (95% CI 32.3-62.8) and 108.5 months (95% CI 87.9-129.2). In patients with both t(4;14) and del(17p), the mPFS was 20.8 months and mOS was 89.6 months; for concurrent t(4;14) and +1q21, the mPFS was 32.0 months and 89.6 months. In patients that received maintenance therapy versus no maintenance, the mPFS and mOS was 54.9 months (95% CI 47.4-62.4) and 115.3 months (95% CI 96.3-134.3) versus 14.7 months (95% CI 13.1-16.3) and 34.3 months (95% CI 10.1-58.5), respectively. **Conclusions:** Overall, the prognosis of t(4;14) myeloma patients significantly improved compared to the pre-proteasome inhibitor era. In particular, maintenance therapies (predominantly PI- based) have made a clear survival impact (doubling of mPFS to 4.5 years and mOS to 9.5 years) compared to patients that did not receive maintenance therapy. However, presence of other concomitant cytogenetic abnormalities such as +1q21 and del(17p) continues to confer poorer outcomes, and innovative approaches are needed to obtain better outcomes for this subgroup of patients. Research Sponsor: None.

The impact of complex karyotype identified by conventional cytogenetics on survival outcomes of 1,000 patients with newly diagnosed myeloma (NDMM). *First Author: Dabedochukwu Obiekwe, Winship Cancer Institute of Emory Univerisity, Atlanta, GA*

Background: Complex karyotype (CK), defined as two or more cytogenetic abnormalities on conventional metaphase cytogenetics, is not routinely used for the risk-stratification or treatment determination in patients with newly diagnosed myeloma (NDMM). Here, we present a retrospective analysis utilizing our institutional data of NDMM patients treated with RVD and a risk-adapted maintenance strategy at the Winship Cancer Institute of Emory University to assess the impact of CK on long-term outcomes. **Methods**:1000 consecutive NDMM patients treated with RVD induction therapy (R25mg/day, days 1-14; V1.3 mg/m^2, days 1,4,8,11 and D40mg once/twice weekly as tolerated) were identified from January 2007 to August 2016. Demographics, clinical characteristics and outcome data for patients were obtained from our institutional review board-approved myeloma database. Responses were evaluated per IMWG Uniform Response Criteria. **Results**: The median age of this cohort was 61 (range 16-83). Notable patient characteristics include: M/F 54.6%/45.4%, W/AA 61.8%/35.9%; ISS I/II/III 45.8%/30.8%/23.4%. R-ISS I/II/III 39.9%/48.7%/11.5%; Isotype IgG/IgA/FLC 59.2%/19.0%/15.7%; standard risk(SR)/high risk(HR) 71.2%/15.8%. ISS data was available for 75% of patients; R-ISS was available for 41% of patients. HR disease defined as the presence of t(4;14), t(14;16), del(17p) and/or CK. Frequency of specific CTG abnormalities were:14.9% with +1q21, 8.3% with del(1p),12.1% with t(11;14), 25.7% with del(13), 13.9% with CK, 2.8% with t(14;16), 10% with del(17p), and 4.8% with t(4;14). 11.9% of patients were classified high risk by FISH alone, 10.0% of patients were classified as high risk by complex karyotype(CK), and 3.9% of patients were classified as high risk by the presence of both high-risk FISH and CK. With a median follow up of 88.4 months, the median PFS (mPFS) for patients HR by FISH alone was 47.6 months (95% CI 35.2-59.9), for HR by CK alone was 46.9 months (95% CI 28.1-65.7) and for HR by both was 24.0 months (95% CI 8.3-39.7). The mOS for HR by FISH alone was 94.7 months (95% CI 74.4-115.1),HR by CK alone was 105.9 months (95% CI 60.8-151.0) and HR by both was 41.0 months (95% CI 24.2-57.8). **Conclusions:** CK by conventional metaphase cytogenetics is not currently included in the risk-stratification or risk stratification models of NDMM patients. In patients with a complex karyotype at time of diagnosis, mPFS and mOS is essentially the same as patients classified HR by FISH abnormalities. When compared to SR patients, prognosis is significantly worse, therefore the standard treatment approach is likely insufficient. As many centers do not routinely perform chromosome analysis, this highlights a gap in providing appropriate risk-stratified care. Moreover, NDMM with HR features by FISH and CK portends a poor prognosis for which alternative treatment strategies may need to be explored. Research Sponsor: None.

Prognostic impact of t(11;14) on PFS1 among patients with myeloma receiving triplet induction therapy. *First Author: Shama Pirmohammed, Winship Cancer Institute - Emory, Atlanta, GA*

Background: Presence of t(11;14) on plasma cells by FISH or metaphase cytogenetics is considered a standard-risk prognostic factor per IMWG risk-stratification. However, recent studies suggest inferior PFS and OS observed among t(11;14) patients relative to the standard-risk myeloma patients. In the context of the ongoing trials of BCL-2 inhibitors (venetoclax) among t(11;14) relapse/refractory myeloma patients yielding response rates closer to 90%, we review the prognostic impact of t(11;14) on PFS. These results may have implications for earlier incorporation of BCL-2 inhibitors among t(11;14) myeloma patients. **Methods:** Among the 1000 consecutive newly diagnosed myeloma patients uniformly treated with RVD induction therapy from January 2008 until August 2016, we have information on FISH probes for t(11;14) tested for 869 patients [121 - t(11;14) and 748 – no t(11;14)]. First, we explore the frequency of IMWG defined concomitant high-risk cytogenetic characteristics [del 17p, t(4;14), t (14;16)]. Next, we create a synthetic control cohort that received maintenance, and excluded patients exhibiting high-risk features to evaluate the relative prognostication conferred by presence of t(11;14). Median follow up was 91 months. Demographic and outcomes data were collected from IRB approved myeloma database and responses were evaluated per IMWG Uniform Response Criteria. **Results:** Median age is 61.2 years (range 16.3-79.83). 34% of the patients are above the age of 65. Men (14.1% vs 11.7%, p = NS) and blacks had higher rates of t(11;14) (16.1% vs 11.1%, p = 0.028). 17 (14%) had concomitant high-risk features – 4 (3.3%) had t(4;14), 3 (2.5%) had t(14;16) and 11 (9.1%) had del17p. Interestingly, the rates of amplification of 1q (26.1% vs 14.9%, p = 0.002), and del13 (34.7% vs 24.4%, p = 0.015) were higher among t(11;14) patients. Compared to the synthetic cohort, the post-induction and post-transplant responses were lower for t(11;14) patients as summarized in table 1. ≥VGPR for t(11;14) vs no t(11;14) post-induction were 48.2% vs 71.5% p < 0.001 and post-transplant were 83.1% vs 92.8% p = 0.001, respectively. The median progression-free survival for the t(11;14) and non-t(11;14) groups were 61.4 months (95% confidence interval (CI), 49.13-73.67) and 82.56 months (95% CI, 70.47-94.65) months, respectively (p = 0.002). **Conclusions:** Even with the use of modern day induction regimens and transplant, patients with t(11;14) seem to have inferior response rates compared to the other standard-risk myelomas. The lower rates of ≥VGPR post-induction and the shorter median PFS suggests BCL-2 inhibitors such as venetoclax may be incorporated earlier in myeloma treatments to improve the outcomes of t(11;14) patients on par with the other standard-risk myeloma patients. Research Sponsor: None.

Immune cell differences between patients in different stages of monoclonal plasma cell disorders. *First Author: Christine Ho, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Multiple myeloma (MM) is an incurable plasma cell malignancy. Precursor conditions include monoclonal gammopathy of unknown significance (MGUS) and smoldering multiple myeloma (SMM). Immune surveillance is paramount for keeping the malignancy in check, whereas a dysfunctional immune system is suspected to promote disease progression. **Methods:** We performed flow cytometric immune panel analyses including T-cell, B-cell, natural killer (NK) cell and dendritic cell (DC) subsets in MGUS, SMM, and MM patients between 2018-2021. Immune panels were analyzed on fresh peripheral blood samples drawn at diagnosis. The patient population were MGUS (n=28), SMM (n=19) and MM (n=94). Samples from MGUS and SMM patients were combined into a single group (asymptomatic) and were compared to MM patients (symptomatic). Lymphocytes were identified by CD45+ expression resolving against side-scattered light on a bivariate plot. B cell and NK cell antigen expression profiles were assessed from this lymphocyte population. T cell subsets were further determined by CD3+. The percent gated for each marker was summarized by cohort using the appropriate descriptive statistics and compared using the Mann-Whitney U exact test. Analyses were performed in SAS v9.4 (Cary, NC) using a two-sided α=0.05. **Results:** Compared to MGUS/SMM patients, MM patients had a significant lower proportion of naive B cells, NK cells, and cytolytic NK cells, and a significant higher proportion of cytolytic T cells at diagnosis (Table). Consistent with prior studies, we demonstrated an increase in exhaustion markers. There was a trend toward a higher population of CD8+ exhausted T cells in MM patients compared to MGUS/SMM patients. Since the follow up for this study was short, survival data is not mature. **Conclusions:** This study demonstrates the immune imbalance that occurs between myeloma precursor conditions and MM. There is a shift in certain cell subsets in the immune microenvironment that alters tumor immunosurveillance and tumor cell killing favoring disease progression. In data not shown, we are currently analyzing the bone marrow microenvironment and its relation to disease progression. Follow up studies could assess if therapeutic intervention could reverse the imbalance, restore homeostatic equilibrium with the goal of controlling disease long-term. Research Sponsor: None.

Summary of the baseline immune markers by disease group for blood sample.

Population	MGUS/SMM (Median %)	MM (Median %)	p_value
Naïve B cells CD19+ CD27- IgD+	4.85	3.13	0.010
Natural Killer cells CD3- CD16- CD56+	11.46	9.20	0.027
Cytolytic Natural Killer cells CD3- CD16- CD56+ CD57+	6.14	3.71	0.001
Cytolytic T cells CD3+CD16- CD56- CD57+	3.62	7.25	0.025
CD8 Exhausted T cells CD3+ CD8+ TIM3- LAG3- TIGIT+ PD1+	0.01	0.03	0.050

Determinants of overall survival (OS) of primary plasma cell leukemia (pPCL): A National Cancer Database (NCDB) analysis of years 2004 to 2009.

First Author: Kevin Scott Landau, Cleveland Clinic Florida, Weston, FL

Background: Outcome data for pPCL is limited due to the rare & aggressive nature of the disease. In this retrospective analysis, we utilized NCDB to identify factors contributing to 1 & 5-year OS of pPCL patients treated at CoC-accredited facilities across USA. **Methods:** Using the NCDB, we identified N= 325 pPCL patients diagnosed between 2004-2009 after excluding entries missing relevant values. Univariate analysis was used to summarize & assess the potential survival factors individually & multivariate Cox regression analysis with backward elimination (using significance level of p<0.05) was utilized to identify the independent survival factors. Kaplan-Meier (KM) survival curves of patient cohort were also produced. SAS version 9.4 was used to analyze the data. **Results:** Multivariate Cox regression analysis with backward elimination method revealed that there were 4 significant independent survival factors including sex, Charlson-Deyo Comorbidity Index (CCI), facility type, and insurance, while age & year-of-diagnosis were not independent survival factors (Table). Male patients were more likely to die compared to female patients (HR=1.40, p=0.005); patients with CCI ≥1 had higher chance to suffer death compared to patients with CCI= 0 (HR=1.52, p=0.002); patients not treated at an academic center (AC) had lower survival compared to those treated at ACs (HR=1.35, p=0.001); and patients without private insurance (PI) were more likely to suffer death compared to those with PI (HR=1.54, p=0.001). The 1 & 5-year survival rates for whole cohort were 51.3% (95%CI: 45.8%-56.8%), and 18.9% (95%CI: 14.6%-23.2%) using KM estimate, respectively. Only 6/325 =1.8% patients underwent autologous hematopoietic stem cell transplant (HSCT). Detailed analysis will be presented. **Conclusions:** In this large analysis of pPCL patients, we identified that being female, having less comorbidities, getting treatment at ACs, and having PI had significantly greater OS. Overall, pPCL is associated with low survival rates both at 1 & 5-years and HSCT may be enormously under-utilized for pPCL patients in the real world setting. Research Sponsor: Internal hematologic malignancy research fund, Cleveland Clinic Florida.

Multivariate Cox regression model analysis for overall survivorship.

Variable	HR (95%CI)	p-value
Sex (male vs. female)	1.40 (1.11-1.78)	0.005
Charlson-score (≥1 vs. 0)	1.52 (1.16-1.99)	0.002
Facility type (other vs. Academic center)	1.35 (1.13-1.62)	0.001
Insurance (other vs. Private program)	1.54 (1.21-1.96)	0.001

Six significant variables (age, sex, CCI, facility type, insurance, and year-of-diagnosis) being identified by univariate analysis were included in the Cox model as explanatory variables, and finally age (p=0.9146) and year-of-diagnosis (p=0.0910) were eliminated by backward elimination method.

COVID vaccine immune response in patients with plasma cell dyscrasia: A systematic review.

First Author: Unaiza Faizan, Rochester General Health System, Rochester, NY

Background: The defective immune system in plasma cell dyscrasia places patients at a higher risk of developing a severe infection, which is one of the leading causes of death in such patients. In an era of a global pandemic, it is essential to protect them against COVID-19, but fewer effective plasma cells lead to a suboptimal response to vaccines. There is still a lack of evidence whether the seroconversion is truly clinically relevant and if patients with plasma cell disorders would benefit from frequent boosters to maintain antibody levels. **Methods:** Online databases including PubMed, CINAHL, Ovid, and Cochrane were searched (January 11th, 2022), following the PRISMA (Preferred Reporting Items for Systematic Review and Meta-Analysis) guidelines. Only articles published in the English language were included. Abstracts, case reports, and case series were excluded. Out of 40 studies, 5 articles were selected for a systematic review. **Results:** In all 5 studies (N=654), seroconversion post-vaccination was used as a positive response to COVID-19 vaccination. Although patients with plasma cell disorders had a lower seroconversion rate compared to controls, the overall percentage was substantial and ranged between 23-95.5%. Amongst patients on active therapy, lower seroconversion rates were seen in patients on a CD-38 inhibitor, ranging from 20.2-92.1% (N=174). Also, a significantly lower percentage was recorded in patients above 65 years and those who have been treated with multiple therapies previously. Better seroconversion rates were seen in mRNA vaccines compared to J&J. **Conclusions:** Variable seropositive rates are seen in patients with plasma cell dyscrasias, lower rates are reported in patients on active therapy, CD-38 targeting therapy, and elderly patients. Hence, these patients should receive a 4 shot series. Research Sponsor: None.

MagnetisMM-9: An open-label, multicenter, non-randomized phase 1/2 study of elranatamab in patients with relapsed/refractory multiple myeloma.

First Author: Rafael Fonseca, Division of Hematology/Oncology, Mayo Clinic Hospital, Phoenix, AZ

Background: Elranatamab (PF-06863135) is a humanized bispecific antibody that targets both B cell maturation antigen (BCMA) on multiple myeloma (MM) cells and CD3 on T cells resulting in T cell- mediated cytotoxicity. In preclinical studies, elranatamab has demonstrated anti-myeloma activity and delayed disease progression. In the ongoing phase 1 MagnetisMM-1 study, elranatamab has demonstrated clinical efficacy and a manageable safety profile in patients with relapsed/refractory MM (Bahlis et al, J Clin Oncol 2021). Elranatamab maximum tolerated dose has not yet been reached. Subcutaneous (SC) elranatamab at the recommended dose of 76 mg QW on a 28-d cycle with a 2 step-up priming dose regimen administered during the first week is currently being evaluated in a phase 2 study, MagnetisMM-3 (Lesokhin et al, Blood, 2021). **Methods:** MagnetisMM-9 (start date: Oct 2021; estimated completion date: Apr 2025) is an open-label, multicenter, non-randomized phase 1/2 study evaluating an alternative priming regimen to further mitigate cytokine release syndrome (CRS) incidence and severity and to evaluate SC elranatamab Q2W and Q4W dosing regimens in patients with relapsed/refractory MM. In part 1 of the study, patients will receive premedications and 2 step-up priming doses on cycle 1 D1 (4 mg) and D4 (20 mg), followed by elranatamab 76 mg QW for 6 cycles, and a dose Q2W thereafter if partial response or better is achieved and maintained. In part 2, higher doses of elranatamab (> 76 mg) at increased intervals between doses will be evaluated. The primary endpoint is grade ≥2 CRS rate during cycle 1. Secondary endpoints include dose-limiting toxicities (part 2 only), objective response rate, duration of response, progression-free survival, overall survival, minimal residual disease negativity rate, safety, and pharmacokinetics. Eligible patients should be ≥18 years of age with a MM diagnosis and measurable disease according to IMWG criteria, refractory to at least one proteasome inhibitor, one immunomodulatory drug, and one anti-CD38 antibody, relapsed/refractory to their last treatment regimen, and have an ECOG performance status ≤1. Key exclusion criteria are smoldering MM, active plasma cell leukemia, amyloidosis, POEMS syndrome, stem cell transplant within 12 weeks of enrollment, active, uncontrolled bacterial, fungal, or viral infections, or any other active malignancy within 3 years prior to enrollment (except for adequately treated basal cell or squamous cell skin cancer, or carcinoma in situ), or previous treatment with an anti-BCMA bispecific antibody. The study is open at centers in the USA, UK, Japan, and Taiwan. Clinical trial information: NCT05014412. Research Sponsor: Pfizer.

TPS8069 **Poster Session**

CAMMA 1: A multicenter phase Ib trial evaluating the safety, pharmacokinetics, and activity of cevostamab-containing regimens in patients with relapsed or refractory multiple myeloma.

First Author: Ravi Vij, Washington University, St. Louis, MO

Background: Treatment of relapsed/refractory (R/R) multiple myeloma (MM) is challenging, especially in later lines where drug resistance reduces therapeutic options and remission duration. Prognosis is poor (estimated survival: < 1 year) for patients with MM who have received > 3 prior lines of therapy and are triple refractory to immunomodulatory drugs (IMiDs), proteasome inhibitors (PIs) and anti-CD38 agents (Gandhi et al. 2019). Thus R/R MM constitutes a significant unmet medical need. Fragment crystallizable receptor-like 5 (FcRH5) is expressed on myeloma cells with near 100% prevalence (Li et al. 2017), constituting a novel therapeutic target. Cevostamab is an IgG1-based T-cell-engaging bispecific antibody engineered to target the most membrane-proximal domain of FcRH5 on myeloma cells and cluster of differentiation 3 (CD3) on T-cells, resulting in T-cell killing of myeloma cells. Clinical data from the first-in-human Phase I study (GO39775) suggest that cevostamab monotherapy is highly active in heavily pretreated patients with R/R MM, with an overall response rate of 56.7% at the 132–198mg dose level (Trudel et al. ASH 2021 Oral presentation). Thus, cevostamab's activity and safety profile support further development. Due to their stimulatory effects on T-cell activity, combination of cevostamab with anti-myeloma agents (pomalidomide [P] or daratumumab [D]) may be synergistic, offering the potential to further improve efficacy. CAMMA 1 (NCT04910568) is an open-label, multicenter Phase Ib trial evaluating the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics of cevostamab-containing combination regimens (Arm B: cevostamab plus P and dexamethasone [d] [Pd]; Arm C: cevostamab plus Dd) in patients with R/R MM. A modified weekly schedule for cevostamab is also under investigation (Arm A: cevostamab monotherapy). **Methods:** Patients must be aged ≥18 years, have an ECOG performance status of 0 or 1 and a life expectancy of > 12 weeks. Patients in all arms have R/R MM; Arms B and C include patients with prior IMiD and PI exposure. Patients with prior CAR-T therapy may enroll with a washout period of 12 weeks post-CAR-T infusion. Cevostamab is administered by intravenous infusion q1w (C1–2)/q2w (C3–6)/q4w (C7–13) in Arm A, q2w (C1–6)/q4w (C7+) in Arm B, and q3w (C1–8)/q4w (C9+) in Arm C. Each arm consists of a safety run-in and an expansion cohort. Enrolment for Arm A is ongoing, with patients receiving up to 13 treatment cycles. Arms B and C are planned; patients will receive treatment until disease progression or unacceptable toxicity. The primary objective is to evaluate the safety and tolerability of cevostamab plus Pd, cevostamab plus Dd and cevostamab monotherapy. Secondary objectives include assessment of activity, PK, immunogenicity, and pharmacodynamic biomarkers. Clinical trial information: NCT04910568. Research Sponsor: CAMMA 1 is a Genentech, Inc. sponsored study. Third-party medical writing assistance, under the direction of the authors, was provided by Rachel Dobb of Ashfield MedComms, an Ashfield Health company, and was funded by F. Hoffmann-La Roche Ltd., Collaborator: F. Hoffman-La Roche Ltd.

TPS8070 **Poster Session**

CAMMA 3: A multicenter phase Ib trial evaluating the safety, pharmacokinetics, and activity of subcutaneous cevostamab monotherapy in patients with relapsed or refractory multiple myeloma. *First Author: Sosana Delimpasi, Department of Hematology and Lymphoma, Evangelismos Hospital, Athens, Greece*

Background: Multiple myeloma (MM) remains an incurable disease. Although new treatment paradigms have increased survival, most patients relapse and treatment in later lines remains a challenge. Prognosis for patients refractory to immunomodulatory drugs, proteasome inhibitors and anti-CD38 antibodies is extremely poor, with an estimated survival of < 1 year (Gandhi et al. 2019). Therefore, patients with relapsed/refractory (R/R) disease represent a high unmet need, and new targets and treatment modalities are needed. Cevostamab is an IgG1-based T-cell-dependent bispecific antibody engineered to target the most membrane-proximal domain of fragment crystallizable receptor-like 5 (FcRH5) on myeloma cells, and cluster of differentiation 3 (CD3) on T cells. This dual binding results in efficient immunological synapse formation and T-cell-mediated killing of myeloma cells. In the ongoing first-in-human Phase I GO39775 study, intravenous (IV) administration of cevostamab monotherapy continues to show clinically meaningful activity and durable responses in patients with heavily pre-treated R/R MM (Trudel et al. ASH 2021), and uses Cycle (C) 1 step-up dosing for the mitigation of cytokine release syndrome (CRS). Subcutaneous (SC) delivery of antibody therapies has been shown to be effective and well tolerated and offers several advantages over IV administration in regards to improved healthcare utilization, including ease of administration, reduced treatment burden and reduced hospitalization. The slower absorption rate observed with SC versus IV antibody therapies may also support the potential for SC cevostamab to provide a further improved CRS profile (Bartlett et al. ASH 2021). CAMMA 3 (GO43227; ISRCTN26168155) is an open-label, multicenter, Phase Ib dose-escalation and dose-expansion trial evaluating the safety, tolerability, pharmacokinetics (PK) and preliminary activity of SC cevostamab monotherapy in patients with R/R MM. **Methods:** For inclusion, patients must be aged ≥18 years and must have R/R MM for which no established therapies are available or appropriate. Cevostamab is administered by SC injection in 28-day cycles, with step-up dosing in C1, q2w dosing in C2–6, and q4w dosing in C7–13. Patients may receive up to 13 cycles unless there is disease progression or unacceptable toxicity. Patients who respond to cevostamab but develop recurrent or progressive disease after 13 cycles may be eligible for cevostamab re-treatment. Primary objectives are to evaluate the safety and tolerability (including the maximum tolerated dose and dose-limiting toxicities) of SC cevostamab and to identify a recommended Phase II dose. Secondary objectives include assessment of PK, activity, and immunogenicity, and identification of biomarkers associated with response and resistance. Clinical trial information: 26168155. Research Sponsor: CAMMA 3 is a Genentech, Inc. sponsored study. Third-party medical writing assistance, under the direction of the authors, was provided by Rachel Dobb of Ashfield MedComms, an Ashfield Health company, and was funded by F. Hoffmann-La Roche Ltd., Collaborator: F. Hoffman-La Roche Ltd.

TPS8071 **Poster Session**

TTI-622-01: A phase 1a/1b dose-escalation and expansion trial of TTI-622 in patients with advanced hematologic malignancies, including multiple myeloma. *First Author: Krish Patel, Swedish Cancer Institute, Seattle, WA*

Background: CD47 is an innate immune checkpoint that binds signal regulatory protein alpha (SIRPα) and delivers a "don't eat me" signal to suppress macrophage phagocytosis. TTI-622 is a fusion protein consisting of the CD47-binding domain of human SIRPα linked to the Fc region of human IgG4. It is designed to enhance phagocytosis and antitumor activity by preventing CD47 from delivering its inhibitory signal as well as generating a moderate pro-phagocytic signal via IgG4 Fc. CD47 is significantly increased in multiple myeloma (MM) bone marrow mononuclear cells and expression inversely correlates with survival in patients. Relapsed/Refractory (R/R) MM shows particularly high expression of CD47. Preclinical studies demonstrate that the addition of proteasome inhibitors to CD47 blockade significantly increases phagocytosis of MM cells in vitro and anti-myeloma activity in vivo. The ongoing phase 1a part of this study has been previously described. The phase 1b part of the study will determine the safety and efficacy of TTI-622 when given as monotherapy or in combination with selected approved anticancer treatments in patients with hematological malignancies where new treatments with novel mechanism of action are needed. Here we describe 5 RRMM cohorts within phase 1b of the study. **Methods:** TTI-622-01 is a multi-center Phase 1a/1b study. Phase 1a was designed to determine the MTD, pharmacokinetics (PK), pharmacodynamics, and preliminary antitumor activity of QW, Q2W, and Q3W single-agent TTI-622 in R/R lymphoma using a 3+3 dose escalation schema. Phase 1b, ongoing, will determine the safety and recommended dose of TTI-622 to be given as single agent and in combination with carfilzomib + dexamethasone (Kd) in RRMM and will evaluate the preliminary efficacy. Secondary objectives are to further characterize the safety, PK and immunogenicity of TTI-622 when combined with Kd. Patients will be enrolled in 5 separate cohorts: 3 cohorts will explore different doses and administration schedules of TTI-622 combined with the approved dose of Kd; 2 cohorts will explore different doses of TTI-622 monotherapy. Cohorts will be opened in a staggered manner. In each cohort 3 patients will be dosed and followed for 28 days (21 days in the monotherapy) before expanding enrolment to approximately an additional 27 patients. Key eligibility criteria include: relapse or progression following ≥3 prior lines of therapy (including a proteasome inhibitor, an immunomodulatory drug, and an anti-CD38 antibody), carfilzomib-refractory progressive and measurable disease per IMWG at study entry; age ≥18 years; ECOG performance status ≤2; adequate organ functions; no known CNS involvement; no prior anti-CD47 or anti-SIRPα therapy. Patient recruitment is planned or ongoing at 40 sites worldwide. Clinical trial information: NCT03530683. Research Sponsor: Trillium Therapeutics Inc., which was acquired by Pfizer, Inc. in November 2021.

TPS8072 **Poster Session**

MajesTEC-3: Randomized, phase 3 study of teclistamab plus daratumumab versus investigator's choice of daratumumab, pomalidomide, and dexamethasone or daratumumab, bortezomib, and dexamethasone in patients with relapsed/refractory multiple myeloma. *First Author: Maria-Victoria Mateos, Hospital Clinico Universitario de Salamanca, Salamanca, Spain*

Background: Patients (pts) with relapsed/refractory multiple myeloma (RRMM) after prior therapy with a proteasome inhibitor (PI) and lenalidomide are challenging to treat. Daratumumab in combination with pomalidomide and dexamethasone (DPd) or bortezomib and dexamethasone (DVd) are approved for pts with RRMM; however, disease control could be further improved. There is an unmet need for new therapeutic options with different modes of action. Teclistamab (tec; JNJ-64007957) is a B-cell maturation antigen (BCMA) × CD3 bispecific antibody that redirects CD3+ T cells to mediate T-cell activation and subsequent lysis of BCMA-expressing myeloma cells. In the phase 1, MajesTEC-1 study (NCT03145181), tec monotherapy was well-tolerated and showed encouraging efficacy in heavily pretreated pts with RRMM. The combination of tec and daratumumab (tec-dara) in the phase 1b TRIMM-2 study (NCT04108195) was also well-tolerated with promising efficacy. MajesTEC-3 (NCT05083169) is a multicenter, open-label, randomized phase 3 study that will compare the efficacy of tec-dara versus investigator's choice of DPd or DVd in pts with RRMM. **Methods:** Pts (≥18 years old) must have documented MM per International Myeloma Working Group (IMWG) criteria; measurable disease; Eastern Cooperative Oncology Group performance status 0–2; received 1–3 prior treatment (tx) lines, including a PI and lenalidomide (pts with 1 prior tx line must be lenalidomide-refractory); with progressive disease on or after their last tx (or within 60 days of completing lenalidomide). Pts who received prior BCMA-directed tx or who are refractory to an anti-CD38 monoclonal antibody will be excluded. ~560 pts will be randomized 1:1 to receive 28-day cycles of tec-dara or investigator's choice of DPd or DVd (stratified by investigator's choice of DPd or DVd, ISS stage, and number of lines of prior tx). Step-up doses of tec will be given prior to the first tx dose. Dara, DPd and DVd will be administered per approved schedules. Pts will be treated until disease progression, death, intolerable toxicity, withdrawal of consent or end of study, whichever occurs first. Response will be assessed per 2016 IMWG criteria. The primary endpoint will be progression-free survival (PFS). Secondary endpoints include overall response rate, complete response or better, MRD negativity, PFS on next-line tx (PFS2), overall survival, and incidence and severity of AEs. Adverse events (AEs) will be graded by Common Terminology Criteria for AEs v5.0, except for cytokine release syndrome and immune effector cell-associated neurotoxicity syndrome, which will be graded by American Society for Transplantation and Cellular Therapy guidelines. The study opened in October 2021 and enrollment is ongoing. Clinical trial information: NCT05083169. Research Sponsor: Janssen Research & Development, LLC.

TPS8073 **Poster Session**

Exploring alternative dosing regimens of single-agent belantamab mafodotin on safety and efficacy in patients with relapsed or refractory multiple myeloma: DREAMM-14. *First Author: Malin Hultcrantz, Myeloma Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Belantamab mafodotin (belamaf: BLENREP) is a first-in-class, monomethyl auristatin F (MMAF)-containing, B-cell maturation antigen (BCMA)-directed antibody–drug conjugate (ADC). In the DREAMM-2 study, belamaf showed deep responses with a manageable safety profile in patients with relapsed/refractory multiple myeloma (RRMM). At 13 months of follow-up, the median duration of response was 11 months and overall survival was 13.7 months at the 2.5 mg/kg Q3W dose. Corneal events are common and expected with belamaf and other MMAF-containing ADCs. In DREAMM-2, corneal events were managed with dose modifications. Clinical responses were observed even with prolonged dose holds, suggesting alternative dosing regimens may lower corneal event rates without compromising efficacy. The DREAMM-14 study (NCT05064358) will investigate if an improved benefit/risk profile of single-agent belamaf can be achieved by modifying the dose, schedule, or both, relative to the approved dosing regimen (2.5 mg/kg Q3W). **Methods:** This Phase II, randomized, open-label study will include adults with RRMM who had ≥3 prior lines of therapy (LOT), including an anti-CD38 monoclonal antibody, an immunomodulatory agent, and a proteasome inhibitor. Patients with corneal epithelial disease (except nonconfluent superficial punctate keratitis) or with prior exposure to BCMA-targeted therapies, or ADCs will be excluded. Patients will be randomized into Arms A–D (n=40 each) and Arm E (n=20) in parallel and stratified by the International Staging System (I vs II vs III) and prior LOT (3 vs ≥4). Belamaf will be administered as follows—Arm A: 2.5 mg/kg Q3W; Arm B: 1.9 mg/kg Q3W; Arm C: 2.5 mg/kg Q6W; Arm D: 1.9 mg/kg Q6W; Arm E: 1.9 mg/kg Q6W with ocular event-related dose modifications based on oncology staff assessment of ocular symptoms (patient-reported symptoms using the Ocular Surface Disease Index), and visual acuity (Snellen chart or equivalent) in addition to corneal findings assessed by an eye care specialist. Patients in all Arms will have response assessments, safety assessments, and ophthalmic exams performed by an eye care specialist Q3W regardless of dosing schedule. Ocular event-related dose modifications (except in Arm E) will be guided by a modified Keratopathy and Visual Acuity scale. The primary endpoint will be incidence of ocular events. Key secondary endpoints include ocular safety and tolerability, overall safety and tolerability, pharmacokinetics, and efficacy outcomes. Follow-up for progression-free survival will be Q3W until progressive disease, start of new anticancer therapy, withdrawal of consent, end of study, or death. Status: Recruitment is ongoing. Funding: GSK (Study 209628); drug linker technology licensed from Seagen Inc.; mAb produced using POTELLIGENT Technology licensed from BioWa. Clinical trial information: NCT05064358. Research Sponsor: GlaxoSmithKline.

TPS8074 **Poster Session**

MagnetisMM-5: An open-label, multicenter, randomized phase 3 study of elranatamab as monotherapy and in combination with daratumumab in patients with relapsed/refractory multiple myeloma. *First Author: Sebastian Grosicki, Department of Hematology and Cancer Prevention, School of Public Health, Silesian Medical University, Katowice, Poland*

Background: Elranatamab (PF-06863135) is a humanized bispecific antibody that targets both B cell maturation antigen (BCMA)-expressing multiple myeloma (MM) cells and CD3-expressing T cells, with binding resulting in T cell-mediated cytotoxicity. Elranatamab has demonstrated antitumor activity and delayed tumor progression in preclinical studies, as well as promising efficacy and manageable safety in the ongoing phase 1 MagnetisMM-1 study in patients (pts) with relapsed/refractory MM (Bahlis et al, J Clin Oncol 2021). **Methods:** MagnetisMM-5 is an open-label, multicenter, randomized phase 3 study designed to evaluate the efficacy and safety of subcutaneous (SC) elranatamab monotherapy and SC elranatamab + SC daratumumab in pts with relapsed/refractory MM who have received prior therapy, including lenalidomide and a proteasome inhibitor (PI). The study consists of 2 parts. In part 1, a minimum of 20 pts will be enrolled to assess the safety of an elranatamab priming regimen and identify the recommended combination dose for SC elranatamab + SC daratumumab for part 2. The primary endpoint of part 1 is dose-limiting toxicities encompassing the elranatamab monotherapy priming duration (14 d) and the first cycle of SC elranatamab + SC daratumumab dosing (28 d). In part 2, ~450 pts will be stratified by prior lines of therapy (1 vs 2–3 vs ≥4) and prior treatment with anti-CD38 therapy (yes vs no) and enrolled in a 1:1:1 ratio to receive SC elranatamab or SC elranatamab + SC daratumumab or SC daratumumab + oral pomalidomide + oral dexamethasone. The primary endpoint of part 2 is progression-free survival (PFS), according to International Myeloma Working Group (IMWG) response criteria and blinded independent review. Secondary endpoints include PFS and PFS on next-line treatment by investigator per IMWG, overall survival, objective response rate, duration of response, complete response (CR) rate, duration of CR, time to response, overall and sustained minimal residual disease negativity rates, safety, quality of life, immunogenicity, and PK. Key inclusion criteria are age ≥18 y, MM diagnosis with measurable disease according to IMWG criteria, ECOG performance status 0–2, and clinical laboratory values within specified ranges. For part 2, pts should have received ≥1 prior line of anti-myeloma therapy, including treatment with lenalidomide and a PI. Key exclusion criteria include smoldering MM, plasma cell leukemia, amyloidosis, POEMS syndrome, stem cell transplant within 12 wk of enrollment, primary refractory MM, active, uncontrolled bacterial, fungal, or viral infections, previous treatment with BCMA-targeted therapy, anti-CD38 therapy within 6 mo of the first dose of study treatment, and previous pomalidomide therapy. MagnestisMM-5 will include sites in 28 countries. Clinical trial information: NCT05020236. Research Sponsor: Pfizer.

TPS8075 **Poster Session**

Subcutaneous daratumumab (DARA SC) versus active monitoring in patients (pts) with high-risk smoldering multiple myeloma (SMM): Randomized, open-label, phase 3 AQUILA study. *First Author: Meletios A. Dimopoulos, National and Kapodistrian University of Athens, Athens, Greece*

Background: Standard of care for SMM includes active monitoring until progression to multiple myeloma (MM); however, recent evidence suggests pts with high-risk features may benefit from early treatment. DARA is a human IgGκ monoclonal antibody targeting CD38 that is approved as monotherapy for relapsed/refractory MM (RRMM) or in combination with standard of care for RRMM or newly diagnosed MM. Results from the phase 3 COLUMBA study showed that DARA SC demonstrated similar efficacy to intravenous (IV) DARA but with a lower rate of infusion-related reactions and shorter administration time. Based on the promising single-agent activity observed with IV DARA in intermediate- or high-risk SMM pts during the phase 2 CENTAURUS study, we hypothesized that DARA SC may delay progression to MM versus active monitoring in pts with high-risk SMM. **Methods:** AQUILA is an ongoing, randomized, open-label, multicenter phase 3 study of DARA SC versus active monitoring in pts with high-risk SMM. DARA SC (DARA 1,800 mg + recombinant human hyaluronidase PH20 [rHuPH20; 2,000 U/mL; Halozyme]) is administered by manual injection over approximately 5 minutes at alternating locations on the abdomen weekly in Cycles 1 and 2, every 2 weeks in Cycles 3-6, and every 4 weeks thereafter until 39 cycles (28 days/cycle), up to 36 months, or until disease progression. Eligibility criteria include confirmed diagnosis of SMM for ≤5 years, factors indicating high risk of progression to MM (clonal bone marrow plasma cells [BMPCs] ≥10% and ≥1 of the following: serum M protein ≥30 g/L, IgA SMM, immunoparesis with reduction of 2 uninvolved Ig isotypes, serum involved:uninvolved free light chain ratio ≥8 to < 100, or clonal BMPCs > 50% to < 60% with measurable disease), and ECOG performance status ≤1. The primary endpoint is progression-free survival (PFS), assessed by an independent review committee, with disease progression defined according to International Myeloma Working Group diagnostic criteria for MM. Secondary endpoints include time to biochemical or diagnostic (SLiM-CRAB) progression, overall response rate, complete response rate, duration of response, time to response, time to first-line treatment for MM, PFS on first-line treatment for MM (PFS2), overall survival, and incidence of MM with adverse prognostic features. The study completed enrollment on May 6, 2019; 390 pts have been randomly assigned to DARA SC or active monitoring. The primary efficacy analysis will be performed after approximately 165 PFS events have been observed. Clinical trial information: NCT03301220. Research Sponsor: Janssen Research & Development, LLC.

TPS8076 **Poster Session**

Birtamimab in patients with Mayo stage IV AL amyloidosis: Rationale for confirmatory affirm-AL phase 3 study. *First Author: Morie A. Gertz, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Light chain (AL) amyloidosis is a progressive and typically fatal disorder caused by misfolded AL protein produced by plasma cells. Birtamimab is a monoclonal antibody designed to neutralize circulating soluble and deposited insoluble amyloid, thus promoting phagocytic clearance. In 2018, the phase 3 VITAL study in newly diagnosed, treatment-naive patients was terminated based on futility analysis of the primary endpoint (time to all-cause mortality [ACM] or time to cardiac hospitalization > 90 days after first study drug infusion); the final hazard ratio (HR) numerically favored birtamimab + standard of care (SOC) over placebo + SOC (0.835 [95% CI: 0.5799, 1.2011]; p = 0.330). Post-hoc analysis of ACM over 9 months revealed a substantial survival benefit (HR = 0.413 [95% CI: 0.191, 0.895]; p = 0.025) in patients at high risk for early death (Mayo Stage IV). Post-hoc analyses of secondary endpoints in this subgroup indicated meaningful improvements in health-related quality of life (assessed with 36-Item Short Form Health Survey version 2; SF-36v2) and 6-minute walk test (6MWT) distance with birtamimab + SOC (p < 0.05) at 9 months. **Methods:** The phase 3, double-blind, placebo-controlled AFFIRM-AL study (NCT04973137) will enroll up to 150 Mayo Stage IV patients with newly diagnosed, untreated AL amyloidosis. Patients will be randomized (2:1) to 24 mg/kg intravenous birtamimab or placebo every 28 days. Both arms will receive concomitant chemotherapy with a first-line bortezomib-containing regimen, with or without daratumumab (D), at the discretion of the investigator. Patients will be stratified at randomization based on their 6MWT distance (< 300 vs ≥300 meters) and initiation of D. The primary efficacy endpoint is time to ACM. Secondary endpoints are change from baseline to month 9 in the physical component summary of the SF-36v2 and 6MWT distance. This trial is powered at a significance level of 0.1 under a Special Protocol Assessment (SPA) with the U.S. Food and Drug Administration (FDA). Given the > 50% relative risk reduction for ACM observed in the post-hoc analysis of VITAL for patients with Mayo Stage IV disease, the AFFIRM-AL study is designed to confirm this effect of birtamimab. Approximately 130 global sites are planned; site initiation and patient randomization are underway. Conclusion: Treatments that improve survival in AL amyloidosis are needed, particularly for patients with advanced cardiac involvement, as median overall survival for those with Mayo Stage IV disease is ~6–9 months. The AFFIRM-AL study is designed to confirm the survival benefit observed in the VITAL study in patients with Mayo Stage IV AL amyloidosis. Clinical trial information: NCT04973137. Research Sponsor: Prothena Biosciences Ltd.

8500 **Oral Abstract Session**

Two cycles versus three cycles of neoadjuvant sintilimab plus platinum-doublet chemotherapy in patients with resectable non-small-cell lung cancer (neoSCORE): A randomized, single center, two-arm phase II trial. *First Author: Fuming Qiu, Department of Medical Oncology, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: Neoadjuvant immune checkpoint inhibitors (ICIs) plus chemotherapy have a promising efficacy in resectable non-small-cell lung cancer (NSCLC), yet the period of neoadjuvant immunochemotherapy is undetermined. This phase II study compared the efficacy and safety of two cycles with three cycles of neoadjuvant sintilimab plus chemotherapy in resectable stage IB-IIIA NSCLC. **Methods:** This randomized, open-label phase II trial recruited patients aged 18 or older with histologically confirmed, treatment-naïve, American Joint Committee on Cancer-defined stage IB-IIIA, resectable NSCLC. Eligible patients were randomly assigned to two or three cycles of neoadjuvant treatment with intravenous sintilimab (200 mg) plus carboplatin (area under curve 5) and nab-paclitaxel (260mg/m^2, for squamous) or pemetrexed (500mg/m^2, for non-squamous) on day 1 of three-week cycle. After surgical resection, patients received totally four doses of perioperative immunochemotherapy, followed by one-year sintilimab maintenance under patient decision. Randomisation was stratified by tumor PD-L1 expression (≥1% vs < 1%). The primary endpoint was MPR rate. Secondary endpoints included complete pathology response (pCR) rate, objective response rate (ORR), 2-year disease-free survival (DFS) rate, 2-year overall survival (OS) rate and safety. This trial is registered with ClinicalTrials.gov, number: NCT04459611. **Results:** From 6/2020 to 9/2021, 60 patients were enrolled and received neoadjuvant treatment. The patient characteristics of both arms were well balanced. Among 55 patients with successful R0 resection, we observed a higher MPR rate (41.4%, 12/29) in three-cycle group compared with two-cycle group (26.9%, 7/26) (p = 0.260), meanwhile, pCR rate achieved 24.1% (7/29) and 19.2% (5/26) respectively (p = 0.660). Patients of squamous subtype generally achieved a statistically higher MPR rate (51.6%, 16/31) compared with the non-squamous subtype (12.5%, 3/24) (p = 0.002). In squamous subgroup, three cycles neoadjuvant treatment induced a MPR rate of 60% compared with 43.8% after two cycles treatment (p = 0.366).In the meantime, the MPR rate was 21.4% versus 0% in non-squamous subgroup, respectively (p = 0.239). The ORR showed no statistical difference between three-cycle group (55.2%, 16/29) and two-cycle (50%, 13/26) (p = 0.701). Patients were well-tolerated in both groups and 5% (3/60) experienced grade 3 immune related adverse events. **Conclusions:** It is the first randomized study comparing different treatment periods of immuno-chemotherapy in the neoadjuvant setting. Three cycles neoadjuvant treatment achieved a numerically higher MPR rate compared with two cycles. Patients with squamous lung cancer obtained a better MPR rate compared with non-squamous subtype. Clinical trial information: NCT04459611. Research Sponsor: None.

8501 **Oral Abstract Session**

Nivolumab + chemotherapy versus chemotherapy as neoadjuvant treatment for resectable stage IIIA NSCLC: Primary endpoint results of pathological complete response (pCR) from phase II NADIM II trial. *First Author: Mariano Provencio-Pulla, Instituto Investigacion Sanitaria Puerta de Hierro-Segovia de Arana, Hospital Universitario Puerta de Hierro-Majadahonda, Madrid, Spain*

Background: Non-small cell lung cancer (NSCLC) is incurable in most patients with locally advanced stage IIIA disease. Previous results indicate that the use of neoadjuvant chemoimmunotherapy could increase the percentage of cured patients being a promising therapeutic option that has to be tested in randomized clinical trials. **Methods:** NADIM II (NCT03838159) is an open-label, randomized, two-arm, phase II, multi-center clinical trial. Patients with resectable clinical stage IIIA (per AJCC 7th ed) NSCLC, ECOG PS 0-1, and no known EGFR/ALK alterations were randomized to receive Nivolumab (NIVO) 360mg + Paclitaxel 200mg/m^2 + Carboplatin AUC5 for 3 cycles every 21 days (+/- 3 days) as neoadjuvant treatment followed by surgery, or Paclitaxel 200mg/m^2 + Carboplatin AUC5 for 3 cycles every 21 days (+/- 3 days) followed by surgery. Patients with R0 resection confirmed by pathological evaluation initiated adjuvant administration of NIVO within the 3rd to 8th week (+7 days) from surgery and for 6 months. The primary endpoint was pathological complete response (pCR) by blinded independent pathological review (BIPR) in the intent-to-treat population (ITT). pCR was defined as 0% viable tumor cells in resected lung and lymph nodes; patients who did not undergo surgery were classified as non-responders. Major pathological response (MPR; ≤ 10% viable tumor) per BIPR, overall response rate (ORR), toxicity profile, and potential predictive biomarkers are secondary endpoints. **Results:** Between February 8, 2019, and November 11, 2021, 90 patients were enrolled, of whom 87 patients were valid. Neoadjuvant NIVO + chemo significantly increased the pCR rate compared to chemo in the ITT (36.2% vs 6.8%; Relative Risk (RR) 5.25 [99% CI 1.32-20.87]; P = 0.0071). NIVO + chemo also improved MPR rates vs chemo in the ITT (52 % vs 14 %), as well as ORR (74 % vs 48%). Definitive surgery occurred for 91% of pts treated with NIVO + chemo and 69% with chemo; surgery was cancelled rarely due to AEs (1 pts/experimental arm) and due to disease progression in 1 and 4 pts in the experimental and control arm respectively. Grade 3-4-related AEs were reported in 24 % vs 10% in the NIVO + chemo vs chemo arms, respectively. In the ITT experimental arm, patients with pCR had higher PD-L1 TPS (median 70%, IQR 5-90%) compared to non-responders (median 0%, IQR 0-37.5%, P = 0.0035). AUC to predict pCR was 0.734 (95% CI 0.59-0.88; P = 0.005). The pCR rate rises across increasing categories of PD-L1 TPS (< 1% 14.3%; 1-49% 41.7%; ≥50% 61.1%; P = 0.008). **Conclusions:** This study confirms the superiority of the chemo-immuno combination in patients with resectable stage IIIA NSCLC in terms of pCR, as well as the feasibility of surgery, with a moderate increase in grade 3-4 toxicity. Thus, this treatment should become the standard of care in these patients. Clinical trial information: NCT03838159. Research Sponsor: BMS.

Intraoperative quality metrics and association with survival following lung cancer resection. *First Author: Brendan Heiden, Washington University School of Medicine, St. Louis, MO*

Background: Surgical resection remains the preferred treatment for functionally fit patients with clinical stage I non-small cell lung cancer (NSCLC). Process-based intra-operative quality metrics (QMs) are important for optimizing long-term outcomes following curative-intent resection. We sought to characterize overall survival using a novel surgical quality score. **Methods:** We performed a retrospective cohort study using a uniquely compiled dataset of US Veterans with clinical stage I NSCLC receiving definitive surgical treatment. Based on contemporary treatment guidelines, we defined five surgical QMs: timely surgery (within 12 weeks of diagnosis), minimally invasive approach, anatomic resection via lobectomy, adequate nodal sampling (≥10 nodes), and negative margin. Using a multivariable Cox proportional hazards model, we developed a surgical quality score reflecting the relationship between these QMs and overall survival (OS). We also examined the relationship between this score and disease-free survival (DFS). **Results:** The study included 9,628 Veterans undergoing surgical treatment between 2006 and 2016. QMs were met as follows: timely surgery (n=6,633, 68.9%), minimally invasive approach (n=3,986, 41.4%), lobectomy (n=6,843, 71.1%), adequate nodal sampling (n=3,278, 34.1%), and negative surgical margin (n=9,312, 96.7%). The median (IQR) follow-up was 6.2 (2.5-11.4) years. A normalized score from 0 (no QMs met) to 100 (all QMs met) was constructed, with higher scores reflecting progressively improved risk-adjusted OS (Table). The median (IQR) OS was 86.8 (37.8-149.6) months in the highest score quintile versus 25.3 (7.1-45.8) months in the lowest score quintile. Recurrence was detected in 2,268 (23.6%) patients. Higher surgical quality score was associated with improved DFS (multivariable-adjusted hazard ratio, aHR 0.494, 95% CI 0.245-0.997). **Conclusions:** Adherence to intra-operative QMs is associated with markedly improved overall and disease-free survival. Efforts to improve adherence to surgical QMs can dramatically improve patient outcomes following curative-intent resection of early-stage lung cancer. Research Sponsor: U.S. National Institutes of Health.

Association between surgical QMs and overall survival.

Variable[a]	aHR, 95% CI	β	p-value	Score[b]
Delayed surgery (≤12 vs >12 weeks)	0.90 (0.85-0.95)	-0.11	<0.001	2
Surgical approach (minimally invasive vs open)	0.91 (0.86-0.97)	-0.09	0.002	2
Extent of resection (vs wedge)				
Lobectomy	0.79 (0.74-0.84)	-0.24	<0.001	5
Segmentectomy	0.80 (0.70-0.92)	-0.22	0.001	4
Pneumonectomy	1.18 (0.96-1.46)	0.17	0.13	0

8503 **Oral Abstract Session**

Neoadjuvant chemoradiotherapy versus neoadjuvant chemotherapy for patients with stage III-N2M0 non-small cell lung cancer (NSCLC): A population-based study. *First Author: Marah Akhdar, Department of General Surgery and Urology, Faculty of Medicine, Jordan University of Science and Technology, Irbid, Jordan*

Background: Stage III-N2 non-small cell lung cancer (NSCLC) is a heterogeneous disease with controversial management options. Induction therapy as part of multimodal treatment is the standard of care for Stage III-N2 NSCLC. We aim to investigate the effect of adding radiotherapy to neoadjuvant chemotherapy on survival outcomes. **Methods:** All adult NSCLC patients diagnosed between 2004 and 2015 were identified in the Surveillance, Epidemiology, and End Results (SEER) database using ICD-O-3 histologic type coding. Inclusion criteria involved stage III NSCLC patients with ipsilateral lymph node involvement (N2), of any T stage, and with no known distant metastasis (M0). Our main sub-cohorts were patients who either underwent chemoradiotherapy (CRT) or chemotherapy (CT) in neoadjuvant settings. Our primary outcomes were overall survival (OS) and cancer-specific survival (CSS) in months. Cox proportional hazards model was used to analyze the effect of each treatment modality on OS and CSS in univariate and multivariate fashions. Multivariate analysis was adjusted for age, sex, marital status, T stage, resected lymph node status, tumor histology, primary site, laterality, and surgical procedure. Inverse probability treatment weighting (IPTW) was applied to create weighted samples based on study covariates. **Results:** Our analysis included 1175 patients; 799 (68.0%) underwent neoadjuvant CRT and 376 (32.0%) underwent neoadjuvant CT. Sample median age was 63 (IQR:56-69) years. T2 stage was the most prevalent (N =561, 47.7%), followed by T4 (N=243, 20.7%), T1 (N=228, 19.4%), and T3 (N=143, 12.2%). The main tumor histology was non-squamous cell carcinoma in 773 (65.8%) patients. The upper lobe was the most common primary tumor site (N =788, 67.1%). Patients underwent lobectomy (N=917, 78.0%), pneumonectomy (N=184, 15.7%), or sub-lobar resection (N=69, 5.9%). Adding radiotherapy to chemotherapy showed a slightly higher median OS than chemotherapy alone in neoadjuvant settings (51 vs. 47 months, respectively), and a higher median CSS (75 vs. 59 months, respectively). However, these differences were not statistically significant for OS or CSS (HR = 1.08, 95% CI: 0.91-1.28 and HR = 1.04, 95% CI: 0.89-1.21, respectively). After adjustment, age, T3-T4 stage, non-squamous histology, lower lobe primary site, positive resected lymph nodes, and pneumonectomy were all significant independent predictors for worse OS and CSS. IPTW analysis showed no remarkable survival advantage for CRT patients (HR = 1.15, 95% CI: 0.95-1.40 and HR= 1.12, 95% CI: 0.90-1.39) for OS and CSS, respectively. **Conclusions:** Adding radiotherapy to neoadjuvant CT did not result in significant survival benefits. Multiple prognostic factors should be taken into consideration when identifying the optimal choice and sequence of multimodal treatment for stage III-N2M0 NSCLC patients. Research Sponsor: None.

8504 **Oral Abstract Session**

Comparison of quality of life in patients randomized to high-dose once daily (QD) thoracic radiotherapy (TRT) with standard twice daily (BID) TRT in limited stage small cell lung cancer (LS-SCLC) on CALGB 30610 (Alliance, Sub-study CALGB 70702). *First Author: Apar Kishor Ganti, University of Nebraska Medical Center, Omaha, NE*

Background: The CALGB 30610 trial demonstrated that 70Gy QD TRT was not associated with a superior overall survival compared to standard BID 45Gy TRT in limited stage small cell lung cancer. Since both arms appeared to provide similar clinical benefit, other factors such as quality of life may help oncologists decide on the best treatment approach for their patients. The present analysis was conducted to compare patients' quality of life between these regimens in terms of their physical symptoms, physical functioning and psychological state. **Methods:** In the CALGB 30610 planned sub-study CALGB 70702, patients were administered the FACT-L, FACT Trial Outcome Index-Lung Cancer (FACT-L TOI), FACT-Esophageal Cancer Eating and Swallowing Indices, ECOG Acute Esophagitis Scale, Hospital Anxiety and Depression Scale (HADS), the EQ-5D at baseline and a single item assessing difficulty swallowing at baseline, 3, 5, 7, 12, 26, and 52 weeks after starting radiation therapy. Patients were also asked to assess treatment inconvenience at these time points. The primary endpoints of CALGB 70702 were FACT-L TOI and FACT eating and swallowing subscales at 12 weeks. Mean changes from baseline were compared between arms using general linear mixed models. **Results:** 417 patients consented to participate in the patient-reported outcomes substudy. The completion rate of the questionnaires was 87% at baseline and 71% at week 52. The FACT-L total score mean worsening was significantly less in the QD arm compared to the BID arm at week 3 (-1.0 vs -7.0; P=.003), and marginally less at week 5 (-5.3 vs -11.0; P=.06). The FACT-L TOI mean worsening was significantly less in the QD arm than in the BID arm at week 3 (-2.9 vs -7.6; P=.003) and greater at week 12 (-7.6 vs -2.8; P=.03). The QD arm also had a lesser EQ-5D index mean worsening at 3 weeks (-0.04 vs 0.03; P=.002). Mean increase in the acute esophagitis score (1.06 vs 2.89; P<.001) and difficulty swallowing (0.39 vs 1.14; P<.001) were significantly greater in the BID arm at week 3. Mean worsening in HADS anxiety was significantly less in the QD arm at week 5 (-1.99 vs -0.95; P=.03). There were no other significant differences at the remaining timepoints between the two arms. Across visits on the QD arm, patients felt that treatment was inconvenient at 26% (96/376) assessments, compared to 33% (116/352) in the BID arm (chi-sq P=.03). **Conclusions:** Both radiation regimens were well tolerated. However, the QD arm had better quality of life scores at week 3 and was perceived to be less inconvenient. Clinical trial information: NCT00632853. Research Sponsor: U.S. National Institutes of Health.

8505 **Oral Abstract Session**

Serplulimab, a novel anti-PD-1 antibody, plus chemotherapy versus chemotherapy alone as first-line treatment for extensive-stage small-cell lung cancer: An international randomized phase 3 study. *First Author: Ying Cheng, Department of Medical Thoracic Oncology, Jilin Cancer Hospital, Changchun, China*

Background: Monoclonal antibodies against programmed death-ligand 1 (PD-L1) have been approved for the first-line treatment of extensive-stage small-cell lung cancer (ES-SCLC) in combination with chemotherapy. However, whether a programmed death 1 (PD-1) inhibitor provides similar survival benefit in this patient population remains unclear. In this study, the efficacy and safety of serplulimab, a novel humanized monoclonal anti-PD-1 antibody, were assessed in combination with chemotherapy in previously untreated ES-SCLC patients. **Methods:** In this international, randomized, double-blind, multicenter, phase 3 trial (NCT04063163), patients with ES-SCLC who had not received prior systemic therapy were randomized (2:1) to receive serplulimab 4.5 mg/kg or placebo intravenously every 3 weeks. All patients received intravenous carboplatin and etoposide every 3 weeks for up to 4 cycles. The primary endpoint was overall survival (OS). Secondary endpoints included progression-free survival (PFS), objective response rate (ORR), duration of response (DoR), and safety. **Results:** Between September 12, 2019 and April 27, 2021, 585 patients were randomized (serplulimab group, n = 389; placebo group, n = 196). At interim analysis, the median follow-up duration was 12.3 months. Median OS was significantly prolonged in the serplulimab group than the placebo group (15.4 *vs.*10.9 months; hazard ratio [HR] 0.63, 95% CI 0.49–0.82; P < 0.001). Median PFS assessed by the independent radiology review committee (IRRC) per RECIST v1.1 was significantly longer in the serplulimab group than the placebo group (5.8 *vs.* 4.3 months; HR 0.47, 95% CI 0.38–0.59; P < 0.001). Efficacy improvements were also observed in ORR (80.2% *vs.* 70.4%) and DoR (5.6 *vs.* 3.2 months) as assessed by IRRC per RECIST v1.1. Grade ≥3 treatment-emergent adverse events (TEAEs) related to serplulimab or placebo were reported in 129 (33.2%) and 54 (27.6%) patients in the respective groups. Incidence of immune-related TEAEs was higher in the serplulimab group compared to the placebo group (37% *vs.* 18.4%), with the largest difference in endocrine disorders (18.3% *vs.* 4.6%), which are commonly reported with anti-PD-1/PD-L1 therapies. Four deaths (1 acute coronary syndrome, 1 pyrexia, and 1 platelet count decreased in the serplulimab group; 1 thrombocytopenia in the placebo group) that might be related to study drugs were reported. **Conclusions:** Serplulimab plus chemotherapy as first-line treatment provided significant benefits and a manageable safety profile compared with chemotherapy alone in ES-SCLC patients. For the first time, OS benefits was demonstrated with a PD-1 inhibitor in a global phase 3 study among previously untreated ES-SCLC patients. Clinical trial information: NCT04063163. Research Sponsor: Shanghai Henlius Biotech, Inc.

SKYSCRAPER-02: Primary results of a phase III, randomized, double-blind, placebo-controlled study of atezolizumab (atezo) + carboplatin + etoposide (CE) with or without tiragolumab (tira) in patients (pts) with untreated extensive-stage small cell lung cancer (ES-SCLC). *First Author: Charles M. Rudin, Memorial Sloan Kettering Cancer Center, New York, NY*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

8508 **Poster Discussion Session**

Two-year update from KEYNOTE-799: Pembrolizumab plus concurrent chemoradiation therapy (cCRT) for unresectable, locally advanced, stage III NSCLC. *First Author: Martin Reck, LungenClinic, Airway Research Center North, German Center for Lung Research, Grosshansdorf, Germany*

Background: Primary analysis (database cutoff, Oct 28, 2020) of the global KEYNOTE-799 study (NCT03631784) in patients (pts) with unresectable, locally advanced stage III NSCLC, showed that pembrolizumab (pembro; anti–PD-1) plus cCRT resulted in an ORR of 70.5% in cohort A (n = 112; squamous and nonsquamous) and 70.6% in cohort B (n = 102; nonsquamous only) and grade ≥3 pneumonitis in 9 (8.0%) and 7 (6.9%) pts, respectively. We present updated outcomes with 1 y of additional follow-up. **Methods:** In this nonrandomized, phase 2 study, eligible pts were aged ≥18 y with previously untreated, unresectable, pathologically confirmed, stage IIIA-C NSCLC with measurable disease per RECIST v1.1. Pts in cohort A (squamous and nonsquamous) received carboplatin AUC 6 plus paclitaxel 200 mg/m^2 and pembro 200 mg for one 3-wk cycle, followed by carboplatin AUC 2 plus paclitaxel 45 mg/m^2 QW for 6 wks plus 2 cycles of pembro 200 mg Q3W plus standard thoracic radiotherapy (TRT). Pts in cohort B (nonsquamous) received 3 cycles of cisplatin 75 mg/m^2, pemetrexed 500 mg/m^2, and pembro 200 mg Q3W plus standard TRT in cycles 2 and 3. All pts received 14 additional cycles of pembro 200 mg Q3W. Primary endpoints were ORR per RECIST v1.1 by blinded independent central review (BICR) and the incidence of grade ≥3 pneumonitis (per NCI CTCAE v4.0). **Results:** Of 216 pts enrolled in this study, 112 in cohort A and 102 in cohort B received treatment. Median (range) time from first dose to database cutoff (Oct 18, 2021) was 30.2 (25.3–35.5) mo in cohort A and 25.4 (14.5–35.2) mo in cohort B. ORR (95% CI) was 71.4% (62.1%–79.6%) in cohort A and 75.5% (66.0%–83.5%) in cohort B. Median duration of response (DOR) and OS were not reached (NR) in both cohorts; median PFS was 30.6 mo in cohort A, and NR in cohort B (Table). ORR was 66.7% in pts with PD-L1 TPS <1% and 77.3% in pts with PD-L1 TPS ≥1% in cohort A and 78.6% and 72.5%, respectively, in cohort B. ORR was similar by histology (squamous, 72.0%; nonsquamous, 74.1%). Grade ≥3 pneumonitis occurred in 16 pts (7.5%) overall; 9 pts (8.0%) in cohort A and 7 (6.9%) in cohort B. Treatment-related grade ≥3 AEs occurred in 64.3% and 51.0% of pts in cohort A and B, respectively. **Conclusions:** With the accrual of additional responses after >2 y of follow-up, pembro plus cCRT continues to demonstrate robust and durable responses, regardless of PD-L1 TPS and tumor histology, promising survival outcome and manageable safety in pts with previously untreated, locally advanced stage III NSCLC. Clinical trial information: NCT03631784. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

8509 **Poster Discussion Session**

Consolidation nivolumab plus ipilimumab or nivolumab alone following concurrent chemoradiation for patients with unresectable stage III non-small cell lung cancer: BTCRC LUN 16-081. *First Author: Greg Andrew Durm, Indiana University Melvin and Bren Simon Comprehensive Cancer Center, Indianapolis, IN*

Background: The PACIFIC trial demonstrated that a year of consolidation PD-(L)1 inhibition following concurrent chemoradiation (CRT) for unresectable stage III NSCLC improves overall survival (OS). The optimal duration of consolidation IO therapy in this setting is undefined. Studies in metastatic NSCLC demonstrate that combination PD-(L)1/CTLA-4 inhibition improves OS over chemotherapy alone. This trial evaluated the use of combination Nivolumab (N) plus Ipilimumab (IPI) or N alone for up to 6 months in unresectable stage III NSCLC after concurrent CRT. **Methods:** This is a randomized phase II, multicenter trial of 105 pts with unresectable stage IIIA/IIIB NSCLC. All pts received concurrent CRT and were then enrolled and randomized 1:1 to receive N 480mg IV q4wks (Arm A) for up to 24 weeks or N 3mg/kg IV q2 wks + IPI 1mg/kg IV q6 wks (Arm B) for up to 24 weeks. The primary endpoint is 18-month PFS compared to historical controls of CRT alone for arm A (30%) and CRT followed by Durva for arm B (44%). Secondary endpoints include OS and toxicity. **Results:** From 9/2017 to 4/2021, 105 pts were enrolled and randomized, 54 to N alone (A) and 51 to N + IPI (B). The baseline characteristics for arm A/B: median age (65/63), male (44.4%/56.9%), stage IIIA (55.6%/56.9%), stage IIIB (44.4%/43.1%), non-squamous (57.4%/54.9%), and squamous (42.6%/45.1%). The percentage of pts completing the full treatment was 70.4% on A and 56.9% on B ($p = 0.15$). Median f/u was 24.5 and 24.1 months on A and B, respectively. The 18-month PFS was 62.3% on A ($p < 0.1$) and 67% on B ($p < 0.1$), and median PFS was 25.8 months and 25.4 months, respectively. Median OS was not reached on either arm, but the 18- and 24-month OS estimates were 82.1% and 76.6% for A and 85.5% and 82.8% for B, respectively. Treatment-related adverse events (trAE) on arm A/B were 72.2%/80.4%, and grade ≥3 trAEs on arm A/B were 38.9%/52.9%. There was 1 grade 5 event on each arm (COVID19-A, Cardiac Arrest-B). The number of pts with grade ≥2 pneumonitis were 12 (22.2%) on A and 15 (29.4%) on B, with 5 (9.3%) and 8 (15.7%) grade ≥3 events, respectively. The most common (> 10%) non-pneumonitis trAEs on A were fatigue (31.5%), rash (16.7%), dyspnea (14.8%), and hypothyroidism (13%), and on B were fatigue (31.4%), diarrhea (19.6%), dyspnea (19.6%), pruritus (17.7%), hypothyroidism (15.7%), rash (15.7%), arthralgia (11.8%), and nausea (11.8%). **Conclusions:** Following concurrent CRT for unresectable stage III NSCLC, both N and N + IPI demonstrated improved 18-month PFS compared with historical controls despite a shortened interval (6 months) of treatment. OS data are still maturing but 18- and 24-month OS estimates compare favorably to prior consolidation trials. Toxicity for N alone was similar to prior single-agent trials, and the combination of N + IPI resulted in a higher incidence of trAE's, although consistent with prior reports. Clinical trial information: NCT03285321. Research Sponsor: Bristol Myers Squibb.

The Selective Personalized Radio-immunotherapy for Locally Advanced NSCLC Trial (SPRINT): Initial results. *First Author: Nitin Ohri, Montefiore Medical Center and Albert Einstein College of Medicine, Bronx, NY*

Background: Standard therapy for unresectable locally advanced non-small cell lung cancer (LA-NSCLC) is concurrent chemoradiotherapy followed by adjuvant durvalumab. We performed a prospective trial testing sequential pembrolizumab and risk-adapted radiotherapy without chemotherapy for biomarker-selected LA-NSCLC patients. **Methods:** Patients with stage III NSCLC or unresectable stage II NSCLC, ECOG performance status 0-1, and no contraindications to protocol-specified therapy were eligible for this trial. Subjects with PD-L1 tumor proportion score (TPS) ≥ 50% underwent baseline FDG-PET/CT, received three cycles of induction pembrolizumab (200 mg, every 21 days), underwent restaging FDG-PET/CT, received risk-adapted thoracic radiotherapy (55 Gy delivered to tumors or lymph nodes with metabolic tumor volume exceeding 20 cc and 48 Gy delivered to smaller lesions, all in 20 daily fractions), and then received up to 13 cycles of additional pembrolizumab. The primary study endpoint was one-year progression-free survival (PFS). Here we report response rates following induction pembrolizumab, PFS and overall survival (OS) rates, and adverse event rates (CTCAE v. 4.03). **Results:** Twenty-five subjects with PD-L1 TPS ≥ 50% from three institutions were enrolled between August 2018 and November 2021. Median age was 71 (interquartile range [IQR] 62 to 77). One subject had stage II disease, 13 had stage IIIA disease, nine had stage IIIB disease, and two had stage IIIC disease. Median PD-L1 TPS was 75% (IQR 60 to 80%). Two subjects (8%) developed disease progression during induction pembrolizumab, and two subjects discontinued pembrolizumab after one infusion due to immune-related adverse events. Using RECIST 1.1 criteria, 12 subjects (48%) exhibited a partial (n = 11) or complete (n = 1) response following induction pembrolizumab on CT. Using PERCIST criteria, 12 subjects (48%) exhibited a partial response following induction pembrolizumab on PET. Four subjects had responses on PET but not on CT, and four had responses on CT but not on PET. With a median follow-up duration of 13 months, the actuarial 1-year PFS rate is 74%, and the actuarial 1-year OS rate is 95%. Grade 3 adverse events have been limited to single cases of anemia, arthritis, diarrhea, esophagitis, and pneumonitis, and no grade 4-5 adverse events have occurred. Exploratory analyses suggest that response to induction pembrolizumab on PET predicts efficacy of this treatment approach, with a 1-year PFS rate of 100% for responders, compared to 61% for non-responders (logrank p = 0.007). **Conclusions:** Treatment with pembrolizumab and risk-adapted radiotherapy is a promising treatment approach for LA-NSCLC patients with PD-L1 TPS ≥ 50%. Response on PET following induction pembrolizumab may be useful for identifying patients who can be treated successfully without chemotherapy. Clinical trial information: NCT03523702. Research Sponsor: Merck.

8512 **Poster Discussion Session**

EORTC-1416-LCG/ETOP 8-15 – PEARLS/KEYNOTE-091 study of pembrolizumab versus placebo for completely resected early-stage non-small cell lung cancer (NSCLC): Outcomes in subgroups related to surgery, disease burden, and adjuvant chemotherapy use. *First Author: Mary E.R. O'Brien, The Institute of Cancer Research and the Royal Marsden NHS Foundation Trust, Surrey, United Kingdom*

Background: At the second interim analysis (IA2) of the triple-blind, phase 3 PEARLS/KEYNOTE-091 study (NCT02504372), pembrolizumab significantly improved DFS compared with placebo in patients (pts) with completely resected stage IB (T ≥4 cm) to IIIA NSCLC per AJCC v7, regardless of PD-L1 expression (N = 1177, HR 0.76, 95% CI 0.63-0.91, $P = 0.0014$). We present DFS in subgroups related to surgery, disease burden, and adjuvant chemotherapy use. **Methods:** Pts had pathologically confirmed, completely resected stage IB (T ≥4 cm) to IIIA NSCLC of any PD-L1 expression and ECOG PS 0-1. Systematic complete or lobe-specific mediastinal lymph node dissection was recommended; minimally, the subcarinal and 1 lobe-specific lymph node must have been examined. Adjuvant chemotherapy of ≤4 cycles was given as indicated by local guidelines. Eligible pts were randomized 1:1 to pembrolizumab 200 mg or placebo Q3W for 18 doses (~1 y). Treatment effects on DFS were assessed in prespecified subgroups of with and without adjuvant chemotherapy and in exploratory subgroups defined by surgery type, pN stage, tumor size, no. of adjuvant chemotherapy cycles, and adjuvant regimen; only subgroups of > 50 pts were analyzed. Data cutoff for IA2 was September 20, 2021 (median time from randomization to cutoff, 35.6 mo). **Results:** By surgery type, the HR (95% CI) for DFS was 0.78 (0.64-0.96) for lobectomy (n = 925), 0.85 (0.43-1.69) for bilobectomy (n = 92), and 0.71 (0.40-1.24) for pneumonectomy (n = 127). For subgroups based on nodal status, HR (95% CI) for DFS was 0.63 (0.46-0.86) for pN0 (n = 490), 0.77 (0.57-1.03) for pN1 (n = 456), and 1.00 (0.71-1.41) for pN2 (n = 231). By tumor size, and irrespective of nodal status, the HR (95% CI) for DFS was 0.91 (0.69-1.20) for size ≤4 cm (n = 491) and 0.70 (0.55-0.89) for size > 4 cm (n = 685). The HR (95% CI) for DFS was 0.73 (0.60-0.89) in pts who received adjuvant chemotherapy (n = 1010) and 1.25 (0.76-2.05) in those who did not (n = 167). Among pts who received adjuvant chemotherapy, HR (95% CI) for DFS by number of cycles was 0.59 (0.28-1.26) for 1-2 (n = 67) and 0.74 (0.61-0.91) for 3-4 (n = 943); by regimen, it was 0.74 (0.55-0.98) for cisplatin + vinorelbine (n = 491), 0.51 (0.31-0.83) for carboplatin + vinorelbine (n = 151), 1.21 (0.73-1.98) for carboplatin + paclitaxel (n = 135), 0.65 (0.30-1.40) for cisplatin + gemcitabine (n = 57), and 0.68 (0.41-1.14) for other regimen (n = 176). **Conclusions:** Pembrolizumab generally improved DFS versus placebo regardless of type of surgery, lymph node involvement, tumor size, and type and extent of adjuvant chemotherapy in pts with completely resected stage IB (T ≥4 cm) to IIIA NSCLC. These data support the benefit of pembrolizumab as adjuvant therapy for early-stage NSCLC following complete resection and, if indicated, adjuvant chemotherapy. Clinical trial information: NCT02504372. Research Sponsor: Merck Sharp & Dohme Corp, a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Safety results of NRG-LU004: Phase I trial of accelerated or conventionally fractionated radiotherapy combined with durvalumab in PD-L1–high locally advanced non-small cell lung cancer. *First Author: Steven H. Lin, Department of Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In advanced non-small cell lung cancer (NSCLC), high Programmed-Death-1 Ligand (PD-L1) (>50%) expression demonstrate superior response and survival with immune checkpoint inhibitors compared to chemotherapy. We hypothesize that it is safe and feasible to substitute durvalumab instead of chemotherapy concurrently with radiotherapy (RT) in patients with Locally Advanced-NSCLC (LA-NSCLC) and high PD-L1. **Methods:** NRG-LU004 (NCT03801902) is a Phase I study for patients with stage II-III unresectable or inoperable, LA-NSCLC with PD-L1> 50% (Dako 22C3 or Ventana SP263) expression. There were safety and expansion phases with a primary endpoint of safety. Patients started with 1500 mg durvalumab Q4 weeks and thoracic RT within 2 weeks from 1st infusion. Durvalumab continued once a month up to 1 year. In the safety cohort, 6 patients in cohort 1 were treated with accelerated fractionated RT (ACRT) to 60 Gy in 15 fractions, followed by a required safety hold for 90 days. During cohort 1 safety hold, cohort 2 patients were treated with conventional RT 60 Gy in 30 fractions (CONV) followed by a 60-day safety hold. A cohort advanced to the expansion phase to enroll 6 more patients if safety criteria (0-1 patients with a dose limiting toxicity [DLT]) were met. If both cohorts were deemed safe, patients would be randomized 1:1 to ACRT or CONV with safety defined as < 4 of 12 evaluable patients per arm experiencing a DLT. Feasibility was defined as at least 80% of patients in each arm receiving at least 80% of the planned dose of durvalumab during the first 8 weeks. **Results:** 24 evaluable patients enrolled between January 2019 and June 2021. No DLTs were reported in cohort 1, and 1 (unrelated bronchopulmonary hemorrhage leading to discontinuation of durvalumab) in cohort 2. Both safety cohorts advanced to the expansion phase. All but one patient (CONV) received RT per protocol/with an acceptable variation. At the time of analysis, 24% had received all 13 cycles of durvalumab. For the ACRT cohort, there were 4 grade 3, 1 grade 4 (lymphopenia), and 1 grade 5 AE (lung infection, assessed as unrelated to therapy). For CONV, there were 8 grade 3, 0 grade 4, and 1 grade 5 AE (respiratory failure, unrelated to therapy). For feasibility, 10 of 12 (85%) patients in the ACRT cohort received the second dose of durvalumab (2 not received due to shingles and unrelated death), while 9 of 12 (75%) of the CONV cohort received the second dose (reasons for not receiving: viral hepatitis, bronchopulmonary hemorrhage, and respiratory failure, all assessed as unrelated to therapy). **Conclusions:** Chemotherapy-free thoracic RT approaches (ACRT or CONV RT) are safe, when given with concurrent durvalumab in patients with PD-L1 high LA-NSCLC. A trial to compare immunoradiotherapy and consolidation durvalumab to standard chemoradiation and consolidation durvalumab is planned. Clinical trial information: NCT03801902. Research Sponsor: U.S. National Institutes of Health.

8514 **Poster Discussion Session**

Distinct genomic and immunophenotypic features of solid-predominant versus nonsolid-predominant stage I lung adenocarcinomas and association with disease recurrence after surgical resection. *First Author: Joao Victor V. Alessi, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Compared to lung adenocarcinomas (LUAD) with nonsolid-predominant histology (lepidic, acinar, papillary, micropapillary), those with predominantly solid features have a higher risk of disease recurrence after surgical resection. However, little is known about the genomic landscape and immunophenotype of solid vs nonsolid stage I LUAD. **Methods:** We collected clinicopathologic data from patients with resected stage I NSCLC (AJCC 8th Edition), which underwent next-generation sequencing to identify genomic alterations and tumor mutational burden (TMB). A subset of these samples also had multiplexed immunofluorescence for CD8+, FOXP3+, PD-1+, and PD-L1 to determine differences in tumor immune cells subsets according to histologic subtype. Disease free-survival (DFS) was compared in patients based on their predominant histologic subtype (solid vs nonsolid). **Results:** Among 658 LUADs, 11.4% (N = 75) had solid-predominant and 88.6% (N = 583) nonsolid-predominant histology. After a median follow-up of 50 months from the time of surgery, 145 patients (22.0%) experienced recurrence. Compared to nonsolid-predominant LUAD, those with solid predominance had a significantly lower prevalence of activating *EGFR*, *BRAF*^{V600E}, and *METex14* mutations as well as *ALK*/*RET*/*ROS*1 rearrangements (9.3% versus 31.6%, P < 0.001), no difference in *KRAS*^{G12C} frequency (24% versus 16.8%, P = 0.14), a higher TMB (median 12.2 versus 7.2 mutations/megabase; P < 0.001), and a shorter median DFS from the time of surgical resection (43.2 months versus not reached, HR: 3.3 [95% CI: 2.2-4.9], P < 0.001). The detrimental effect of solid-predominant LUAD in DFS remained significant after adjusting for other factors such as tumor stage, surgery type, smoking status, and TMB (HR: 2.66 [95% CI: 1.71-4.11], P < 0.001]. Among LUADs profiled by multiplex immunofluorescence, compared to tumors with nonsolid-predominant subtype (N = 197), those with solid predominance (N = 23) had significantly higher numbers of CD8+, FOXP3+, PD-1+ immune cells, and PD-1+ CD8+ T cells, both intratumorally (P < 0.001) and at the tumor-stroma interface (P < 0.001). Solid-predominant subtype was also associated with a higher median PD-L1 expression level on tumor (5% versus 1%; P = 0.01) and immune cells (16% versus 7%, P = 0.02). **Conclusions:** Among patients with surgically-resected stage I LUAD, solid-predominant histology was associated with distinct genotypic and immunologic characteristics. These findings may aid in identifying patients at greater risk of recurrence after surgery. Research Sponsor: None.

Surfaceome profiling to reveal unique therapeutic vulnerabilities in transcriptional subtypes of small cell lung cancer (SCLC). *First Author: Taofeek K. Owonikoko, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Effective treatment options for SCLC remain limited and new treatment approaches are needed to improve outcome. We sought to validate the initial observation in cell lines and limited tissue samples of SCLC of a differential expression of cancer/testis (CT) antigens and TACSD2 gene that encodes surface protein, Trop2 across various subtypes of SCLC. We also tested whether overall surfaceome profile as previously described in other tumor types will show hierarchical priority of expression between transcriptionally defined SCLC subtypes. **Methods:** We conducted a comprehensive surfaceome profiling of SCLC samples using data generated by RNA sequencing (whole transcriptome) at Caris Life Sciences (Phoenix, AZ). SCLC tumors were stratified into 5 subgroups (SCLC-A/N/Y/P and -mixed) based on the relative expression of the four transcription factors. Expression values were converted to z-scores (the expression value for each gene is normalized to the average expression of that specific gene such that the z-score reflects the number of standard deviations above or below the average). The highest positive z-score among the 4 transcription factors determined subgroup. If all transcription factor z-scores for a given sample were negative, the sample was assigned to 'Mixed' subgroup. Significance was tested by Chi-square, Fisher's exact test, or Mann-Whitney U test. **Results:** We employed data generated from 674 SCLC samples; median age of 66 years and male (48.7%). The SCLC subtype distribution was 241 (35.8%), 120 (17.8%), 40 (5.9%), 143 (21.2%), 130 (19.3%) for types A, N, P, Y and mixed respectively. Supervised analysis for TACSTD2 expression showed highest levels in YAP1 subtype and was overall significantly increased in SCLC-Y (~3-fold) and SCLC-P (~2-fold) subtypes compared to A, N and mixed subtypes. Similarly, SCLC-Y subtype showed the highest median expression as well as the strongest correlation with most TACSTD2-interacting and regulatory genes. A top 10 list of candidate surface protein gene out of 3699 surfaceome genes was defined for each subtype based on the strength of correlation. The top candidate surface protein gene and CT antigen gene respectively by subtype were: SCN3A (r = 0.7033, p = 1.08^{E-101}) and NOL4, (r = 0.574, p = 2.46^{E-60}) for SCLC-A; SSTR2, (r = 0.742, p = 8.18^{E-119}) and TMEFF1, (r = 0.3601, p = 4.53^{E-22}) for SCLC-N; TMPRSS13 (r = 0.5699, p = 2.64^{E-59}) and LY6K (r = 0.4778, p = 9.80^{E-40}) for SCLC-P; and CYBRD1 (r = 0.8559, p = 1.18^{E-194}) and CTAGE5 (r = 0.5521, p = 4.95^{E-55}) for SCLC-Y. **Conclusions:** SCLC-Y subtype showed the highest expression of TACSTD2 and its interacting and regulatory genes. This subtype could serve as an enrichment factor for antibody-drug-construct targeting TROP2. Several candidate CT antigens and surfaceome genes showing strong correlation with lineage-defining transcription factors offer additional therapeutic targets in SCLC. Research Sponsor: None.

Sintilimab plus anlotinib as second or further-line therapy for small cell lung cancer: An objective performance trial. *First Author: Shuxiang Ma, Henan Cancer Hospital, Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou, China*

Background: Small cell lung cancer (SCLC) tends to progress rapidly on first-line therapies, with limited subsequent-line treatment options. **Methods:** In this single-arm objective performance trial, adult patients with extensive-disease SCLC (ED-SCLC) received intravenous sintilimab 200 mg on day 1 and oral anlotinib 12 mg on days 1-14. Treatment lasted for 3 weeks per cycle and was continued until disease progression, unacceptable toxicities, or death. The primary endpoint was the superiority of progression-free survival (PFS) *versus* a PFS of 2.8 months with historical topotecan control. **Results:** Forty-two patients were enrolled, and 39 patients were evaluable for efficacy. Twenty-six patients (66.7%) had ED-SCLC, and 13 (33.3%) relapsed after concurrent chemoradiotherapy. The median follow-up was 11.9 months. The median PFS was 6.0 months (95%CI: 4.8-7.2). The 6- and 12-month PFS rate was 50.5% and 27.8%, respectively. Fourteen patients died by the data cut-off date, and overall survival (OS) was immature (16.1 months, 95%CI: 9.4-22.7). The 12- and 18-month OS rate was 56.7% and 42.5%, respectively. Three patients attained complete response and 16 achieved partial response, and 12 patients had stable disease; the objective response rate was 48.7% and the disease control rate was 79.5%. Forty patients (95.2%) had at least one treatment-related adverse event (TRAE). The most frequent TRAEs were hypothyroidism (45.2%), hypoproteinemia (40.5%) and elevated gamma-glutamyl transpeptidase (38.1%). **Conclusions:** Immunotherapy with sintilimab plus antiangiogenic drug anlotinib demonstrated promising antitumor activities as second or further-line therapy for ED-SCLC and had manageable toxicities. The findings support further development of this combination regimen for ED-SCLC. Clinical trial information: NCT04055792. Research Sponsor: None.

8517 **Poster Discussion Session**

Primary analysis from the phase 2 study of continuous talazoparib (TALA) plus intermittent low-dose temozolomide (TMZ) in patients with relapsed or refractory extensive-stage small cell lung cancer (ES-SCLC). *First Author: Jonathan W. Goldman, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA*

Background: TALA exhibits cytotoxic effects by inhibiting poly (ADP-ribose) polymerase (PARP) proteins 1 and 2 in addition to "trapping" PARP on DNA. TMZ has been shown to increase anti-tumor response when combined with TALA in SCLC models (Wainberg AACR 2016). TALA plus TMZ as second-line therapy for ES-SCLC may improve disease-related outcomes. **Methods:** This is a phase 2, open-label, single-arm study of the safety and efficacy of TALA plus TMZ in patients with ES-SCLC, relapsed or refractory to a first-line platinum-based regimen. Participants receive TALA 0.75 mg (or 0.5 mg if creatinine clearance < 60 mL/min) po daily on 28-day cycles with TMZ 37.5 mg/m2 po on days 1-5. The primary endpoint is objective response rate (ORR) based on RECIST 1.1 criteria, versus a historical control of 15% ORR in second-line topotecan, with the null hypothesis rejected for 8 or more confirmed responses among 28 evaluable subjects (29% ORR). Secondary endpoints include progression-free survival, overall survival, duration of response, and time to response. Exploratory endpoints include biomarker studies such as status of DNA damage response genes (DDR) and patient reported outcomes. A Simon two-stage design was utilized to reach a total accrual of 28 evaluable patients. **Results:** Thirty-one subjects were enrolled, of which 3 were non-evaluable due to ineligibility (1) or early withdrawal of consent prior to first disease assessment (2). Eleven of 28 evaluable subjects (39.3%) achieved a confirmed partial response. The ORR was similar among platinum-refractory (3/6), -resistant (4/9), and -sensitive subgroups (4/13). The median time to response was 1.8 months (m), duration of response 5.8 m, progression free survival 4.5 m, and overall survival 11.9 m. Adverse events (AEs) were manageable, with grade ≥ 3 AEs being thrombocytopenia (61.3%), anemia (54.8%), neutropenia (41.9%), and atypical pneumonia (3.2%), which responded well to dose-hold or dose-reduction and transfusion or growth factor support as needed. Cell free DNA and tissue analysis demonstrated no germline DDR mutations among the trial subjects, but somatic DDR mutations at baseline and acquired during treatment were common. Three subjects remain on study treatment. **Conclusions:** The study exceeded its target response rate. This is the second trial to demonstrate a benefit of PARP inhibition with low-dose TMZ in SCLC (see Farago Cancer Discovery 2019). A phase 3 study is appropriate to confirm the benefit of this approach compared to currently approved options. Clinical trial information: NCT03672773. Research Sponsor: Pfizer.

8518 **Poster Discussion Session**

Targeting genomic instability in extrapulmonary small cell neuroendocrine cancers: A phase II study with ATR inhibitor berzosertib and topotecan. *First Author: Nobuyuki Takahashi, National Cancer Institute, Bethesda, MD*

Background: Extra-pulmonary small cell neuroendocrine cancers (EP-SCNC) are rare cancers with no standard treatments at relapse that share molecular similarities with small cell lung cancer (SCLC). Concurrent inhibition of ataxia telangiectasia and Rad3 related (ATR) and topoisomerase 1, key enzymes for maintaining genomic stability, exacerbated replication stress in SCLC cells and produced durable antitumor responses in patients with relapsed SCLC (Cancer Cell 2021; PMID: 33848478). **Methods:** Combination of berzosertib and topotecan was evaluated in patients with relapsed EP-SCNC (NCT02487095). Berzosertib was administered at 210 mg/m^2 on days 2 and 5 and topotecan 1.25 mg/m^2 on days 1-5 in 21-day cycles. Whole exome sequencing (WES) and transcriptome analyses were performed to assess the genomic features associated with response. **Results:** Fifteen patients with EP-SCNC involving various primary sites were enrolled [three each: cervix, transformed SCLC; two each: bladder, breast, prostate; one each: gallbladder, ovary, rectum]. Two patients (13.3%: breast and rectum) achieved a confirmed partial response (PR; -72.2% and -48.5% tumor reduction in size) lasting 6.9 and 5.8 months. Responses occurred irrespective of platinum-sensitivity or prior treatment with topotecan or immunotherapy. Pre-treatment tumor gene expression profiles of EP-SCNC patients who achieved clinical benefit revealed enrichment of neuroendocrine differentiation (normalized enrichment score and p-value of a gene set enrichment analysis: 2.1 and 2.1 x 10^{-4}). Principal component analysis showed convergent gene expression profiles of both SCLC and EP-SCNC patients who achieved PR. Pre-treatment tumor of a breast small cell cancer patient who achieved durable response revealed amplifications of multiple genes driving replication stress such as *KRAS* and *CCND1*. Longitudinal tumor sampling of the patient through treatment course revealed increasing intratumor heterogeneity as a potential resistant mechanism. **Conclusions:** Combination of berzosertib and topotecan is a novel therapeutic paradigm for patients with EP-SCNCs. Both SCLCs and EP-SCNCs responding to this approach show a similar transcriptional phenotype characterized by high replication stress. Clinical trial information: NCT02487095. Research Sponsor: U.S. National Institutes of Health.

Adjuvant icotinib versus observation in patients with completely resected, EGFR-mutated, stage IB non–small cell lung cancer (GASTO1003, CORIN): A randomized phase II trial. *First Author: Ning Li, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: The role of adjuvant therapy in patients with completely resected stage IB non-small-cell lung cancer (NSCLC) remains to be determined. Icotinib is standard-of-care therapy for patients with advanced NSCLC harboring epidermal growth factor receptor (EGFR) mutation. This phase II study investigated whether adjuvant therapy with icotinib improves the clinical outcome compared with observation in patients with EGFR mutation-positive resected stage IB NSCLC. **Methods:** This phase II, open-label, randomized study (GASTO1003, CORIN) was conducted at Sun Yat-sen University Cancer Center. From May 2013 to December 2020, patients with completely resected, EGFR mutation-positive, stage IB (7th TNM staging for NSCLC) NSCLC without adjuvant chemotherapy according to physician and patient choices were enrolled. The patients were assigned in a 1:1 ratio to receive adjuvant therapy with icotinib (125mg, three times daily) for 12 months or to undergo observation. Therapy continued until disease progression or intolerable toxicity. The primary endpoint was disease-free survival (DFS). Secondary endpoints included overall survival (OS) and toxicity. Survival endpoints were assessed in the intention-to-treat population. **Results:** Three patients withdrew consent and were excluded. A total of 128 patients were enrolled and randomized, with 63 patients in the icotinib group and 65 patients in the observation group. Baseline characteristics were well balanced between the groups. The median duration of follow-up was 34.9 months. A total of 13 recurrence events occurred, including 2 in the icotinib arm and 11 in the observation arm. DFS was significantly longer among those in the icotinib arm than among those in the observation arm (hazard ratio: 0.20, 95% confidence interval, 0.04-0.89; P = 0.018). The 3-year DFS for the icotinib and observation arms were 95.3% and 86.7%, respectively. The OS data were immature with 3 deaths in the observation arm. The safety profile was consistent with the known safety profile of icotinib. Icotinib was well tolerated with no unexpected adverse events. No treatment-related death occurred. **Conclusions:** Adjuvant icotinib shows prolonged DFS and acceptable toxicity in patients with completely resected EGFR-mutated stage IB NSCLC. Ajuvant icotinib provides a treatment option for these patients. Clinical trial information: NCT02264210. Research Sponsor: Betta pharmaceuticals.

8520 **Poster Session**

Patients' preferences for adjuvant osimertinib in non–small cell lung cancer (NSCLC) after complete surgical resection: What makes it worth it to patients? (PATT)—The Roswell Park (RP) Comprehensive Cancer Center experience. *First Author: Angel Mier-Hicks, Roswell Park Comprehensive Cancer Center, New York, NY*

Background: There are clinical controversies surrounding the US FDA approval of Osimertinib in December 2020 as adjuvant therapy, based on disease-free survival (DFS) improvement in patients (pts) with surgically resected stage IB-IIIA EGFRm NSCLC. We initiated a survey study to investigate our hypothesis that DFS benefit alone even without significant OS maybe deemed a valuable endpoint to pts after considering trade-offs. **Methods:** Participants were recruited from pts seen at the RP Thoracic Clinic from 01/21 to 12/21. Eligible pts who were being evaluated for adjuvant systemic therapy following surgical resection were given a self-administered survey based on the validated questionnaire by Blinman et al, which was modified to provide explanation of the differences between OS and DFS and the ADAURA trial results. Survey responses were collected in an online repository. Associations between survey responses and demographics were assessed using Fisher's exact test. Changes in preference responses were assessed using McNemar's test. **Results:** A total of 524 pts with NSCLC were screened, of which 101 pts were eligible to receive the survey. 51 pts (50%) responded to the survey. Median age of respondents was 69yrs (37-83), majority were female (69%, n = 35,), married (61%, n = 31), retired (63%, n = 32), had at least some college or higher education level(54%, n = 28), with history of smoking (84%, n = 43) and with stage IIIA (43%, n = 22) adenocarcinoma (80%, n = 41). To evaluate toxicity-related tradeoffs (Q1), a ≥12 mo. improvement in OS benefit was needed for 66% of pts to consider adjuvant Osi. However, an increase of ≥ 6 mo. of DFS was enough for 66% of pts to justify taking a daily medication (Q2). One mo. increase in DFS or OS was not enough for 60% and 78% of pts respectively to justify taking the medication. A threshold 1% increase in 5-year OS was sufficient to persuade patients to take Osi for three years, even with respect to toxicity side effects (p = 0.023). (Q3). Finally, in the hypothetical cost-based scenario (Q4), there was no indication that pts were willing to pay more for each incremental increase in OS. There appears to be some association between employment status (p = .033) or educational degree (p = .049) for tolerance of side effects if there is at least 1 additional year of DFS or OS. **Conclusions:** We observed that the value patients ascribe to adjuvant Osimertinib is influenced by factors besides efficacy. Knowing pts' preferences for cancer treatments can better inform regulatory bodies in formulating cost-sharing structure for cancer therapies. Our study highlights the importance of shared decision making based on individual pts' preferences. Research Sponsor: None.

8521 **Poster Session**

Predictors of adjuvant chemotherapy refusal in lung cancer: A National Cancer Database Study. *First Author: Anjan Katel, Kathmandu University School of Medical Sciences, Kirtipur, Nepal*

Background: Adjuvant chemotherapy (AC) have been shown to improve overall survival in non-small cell lung cancer (NSCLC). Despite showing significant survival benefit across various age groups, patients are known to refuse AC. However, the factors associated with such a decision remain poorly understood in lung cancer. We therefore sought to investigate the factors associated with AC refusal in a nationally representative database in the United States (US). **Methods:** From 2004 to 2017, adults (≥20 years) with histologically confirmed non-small cell lung cancer (NSCLC) who underwent complete resection and were deemed to be chemotherapy eligible (node-positive or size ≥5 cm) were identified in the National Cancer Database (NCDB). Annual trends and factors associated with refusal of AC in chemotherapy-eligible NSCLC patients were evaluated using Joinpoint regression and multivariable logistic regression. **Results:** Among the 44,957 patients who met the inclusion criteria, 18,468 (3,678 (8.2%)) were noted to refuse chemotherapy in the NCDB. Patients refusing adjuvant chemotherapy were more likely to be elderly (OR 1.08, 95% CI, 1.07-1.08; *P*< .001), uninsured when compared with government insurance (OR 1.79, 95% CI, 1.38-2.33; *P*< .001), treated in the Western region of the when compared with patients in the Northeast (OR 1.47, 95% CI, 1.28-1.68; *P*< .001). They were also more likely to have a higher Charlson score versus patients with Charlson score of zero (OR 1.31, 95% CI, 1.18-1.46; *P*< .001), have squamous cell carcinoma versus adenocarcinoma (OR 1.20, 95% CI, 1.11-1.31; *P*< .001), undergo pneumonectomy versus lobectomy (OR 1.31, 95% CI, 1.16-1.47, *P*< .001), and have ≥2 weeks hospital length of stay versus < 2 weeks (OR 2.25, 95% CI, 1.93-2.63; *P*< .001). **Conclusions:** In our analysis, we identified several sociodemographic and clinicopathologic variables that were independently associated with chemotherapy refusal. We saw the number of patients refusing AC increased sharply during the study period. Our study shows that in addition to poor post-operative recovery, underlying sociodemographic factors might predict patients at risk for refusing adjuvant chemotherapy in lung cancer. Further understanding of these factors might help devise effective interventions to motivate patients to undergo potentially life-extending chemotherapy in lung cancer. Research Sponsor: None.

The Lung ART adjuvant radiotherapy phase 3 randomized trial: Impact of quality of resection in stage IIIAN2 patients. *First Author: Pascal Alexandre Thomas, Centre Hospitalier Universitaire Marseille, Marseille, France*

Background: Lung ART is an international phase 3 trial whose main objective was to evaluate the impact of post-operative conformal radiotherapy (PORT) on disease-free survival (DFS) in patients with completely resected pathologically proven N2 non-small cell lung cancer (NSCLC), with or without neo- or adjuvant chemotherapy. Previously communicated results showed no impact of PORT on DFS. However, as quality of surgical resection and extent of lymph node dissection were expected to be critically important in the interpretation of results, surgical and pathological reports were centrally reviewed by a surgical committee. **Methods:** A surgical advisory committee composed of 4 expert thoracic surgeons reviewed anonymized surgical and pathological reports of all included patients. Pre-defined classification rules were defined using published guidelines from the International Association for the Study of Lung Cancer and the European Society of Thoracic Surgeons. Tumor resection was defined as complete (no residual tumor and adequate lymph node assessment), uncertain (highest mediastinal nodal station involved, incomplete nodal exploration, involved N2 removed in fragments) or incomplete (presence of residual tumor). Nodal exploration was classified as sampling, selective dissection or extensive dissection. **Results:** 501 patients were included in the Lung ART trial. Before surgical committee review intervention, all patients except 2 had complete resection. 496 patients' reports were analyzed by the surgical advisory committee. The basic characteristics are specified in the following table: **Conclusions:** Monitoring of the quality of nodal exploration and of resection should be implemented in randomized studies evaluating peri-operative strategies in NSCLC in order to provide reliable and generalizable results. Clinical trial information: NCT00410683. Research Sponsor: French National Cancer Institute, Programme Hospitalier de Recherche Clinique from the French Health Ministry, Gustave Roussy, Cancer Research UK, Swiss State Secretary for Education, Research, and Innovation, Swiss Cancer Research Foundation, Swiss Cance.

Pre-op chemotherapy (n(%))	All included patients (n = 501)	
	96 (19%)	
	Right tumors (n = 281)	Left tumors (n = 218)
Type of surgery (n(%))		
- (bi-)lobectomy	258 (92%)	176 (81%)
- pneumonectomy	19 (7%)	36 (17%)
- other	4 (1%)	6 (3%)
Mediastinal nodes examined (median n(interquartile range))	11 (6-17)	8 (5-13)
Mediastinal nodes involved (median n(interquartile range))	2 (1-3)	1 (1-2)

Nodal dissection was performed according to lobar location specific recommendations in 69% patients. Regarding nodal dissection: 28% patients had sampling, 17% selective dissection and 55% systematic dissection. Resection was considered complete (R0) in 28%, uncertain in 42%, microscopically incomplete (R1) in 30% and macroscopically incomplete (R2) in 2 patients. 3-year DFS according to R0, R(un) and R1 status was respectively, 70% (95%CI 28-not reached (NR)), 24% (17-34) and 26% (15-84) in the PORT arm, and 62% (21-NR), 24% (15-44) and 16% (10-23) in the control arm.

Checkpoint inhibitor consolidation after definitive chemoradiation for stage III non–small cell lung cancer: Real-world experience in a large academic health system. *First Author: Nikhil Yegya-Raman, University of Pennsylvania, Philadelphia, PA*

Background: The PACIFIC trial demonstrated a 10% improvement in 5-year survival with the addition of consolidation durvalumab versus placebo after chemoradiation (CRT) in good performance status patients (pts) with stage III non-small cell lung cancer (NSCLC). However, not all patients who complete CRT go on to receive consolidation durvalumab. We sought to describe real-world use of consolidation durvalumab or other immune checkpoint inhibitors (ICI) in this setting within a single academic health system. **Methods:** We retrospectively identified pts with unresectable stage III NSCLC treated with definitive CRT between October 2017 and October 2020 within the University of Pennsylvania Health System, including two urban hospitals and two satellite centers. Pts either received consolidation ICI (ICI group) or did not (no ICI group). Baseline characteristics of the groups were compared with the Chi-squared, Fisher exact, or Wilcoxon rank-sum test as appropriate. Overall survival (OS), measured from the last day of CRT, was compared using the Kaplan-Meier method and log-rank test. **Results:** Of the 148 consecutively treated pts who completed CRT, 108 (73%) received consolidation ICI; 40 (27%) did not. Within the ICI group, 42% completed 1 year (yr) of treatment. Within the no ICI group, reasons for non-receipt included disease progression (n = 14, 35%), CRT toxicity (n = 7, 18%), comorbidity or decline unrelated to CRT (n = 7, 18%), provider choice (n = 6, 15%) due to EGFR mutation (n = 5) or atypical histology (n = 1), pt refusal (n = 3, 8%), and death without progression (n = 3, 8%). The ICI group had better performance status (ECOG 0/1/2, 46%/49%/5% ICI vs 25%/48%/28% no ICI, p < 0.001) lower Charlson Comorbidity Index (median, 5 [IQR 4-6] ICI vs 6 [IQR 5-8] no ICI, p = 0.02), and lower rates of active autoimmune disease or immunosuppression (5% ICI vs 15% no ICI, p = 0.03). There were no differences between groups in age (median, 68 yrs [IQR 63-73] ICI vs 71 yrs [IQR 65-73] no ICI, p = 0.25), sex (female, 60% ICI vs 50% no ICI, p = 0.27), race (Black, 19% ICI vs 20% no ICI, p = 0.82), stage (IIIA/B/C, 42%/48%/11% ICI vs 40%/50%/10% no ICI, p = 0.96), and PD-L1 expression (< 1%/1-50%/ > 50%/unknown, 36%/25%/29%/10% ICI vs 40%/25%/28%/8% no ICI, p = 0.97). 1- and 2-yr OS were 83% and 61% in the ICI group versus 52% and 34% in the no ICI group, respectively (p < 0.001). Within the no ICI group, OS was worse among those with versus those without disease progression (PD) post-CRT (1-yr OS 24% vs 74%, p = 0.03). **Conclusions:** In this retrospective study within a large academic health system, we found that over one-quarter of pts who completed chemoradiation for stage III NSCLC did not receive consolidation ICI, most commonly due to disease progression, CRT toxicity, or comorbidity. Survival amongst these pts is particularly poor, especially for those who experience PD shortly after CRT. Research Sponsor: None.

Analysis of patients with relapsed small cell lung cancer (SCLC) receiving single-agent lurbinectedin in the phase 3 ATLANTIS trial. *First Author: Alejandro Navarro, Vall d'Hebron University Hospital and Vall d'Hebron Institute of Oncology, Barcelona, Spain*

Background: Lurbinectedin, a selective inhibitor of oncogenic transcription, received accelerated approval from the US FDA in June 2020 as monotherapy (3.2 mg/m^2 IV every 21 days) for adults with metastatic SCLC with disease progression on or after platinum-based chemotherapy. This approval was based on the overall response rate (35.2%) and duration of response (DOR; 5.3 months) observed in 105 patients from a phase 2 trial. The ATLANTIS trial (NCT02566993) investigated the combination of lurbinectedin 2.0 mg/m^2 IV + doxorubicin (DOX) 40.0 mg/m^2 IV versus topotecan or CAV. This *post hoc* analysis explored the efficacy and safety of single-agent lurbinectedin in patients who completed 10 cycles of the combination and then switched to lurbinectedin monotherapy per protocol. **Methods:** Eligible patients were ≥18 years of age with limited-stage or extensive-stage SCLC, 1 prior line of platinum-based chemotherapy (PD-1/PD-L1 inhibitors were also permitted), ECOG PS ≤2, and chemotherapy-free interval ≥30 days. Tumor assessments were per an independent review committee (IRC). **Results:** Patients who completed 10 cycles of lurbinectedin + DOX and switched to lurbinectedin monotherapy (n = 50) had a median age of 61.5 years (range: 43, 77); 62% were male; and 100% had an ECOG PS < 2. The overall median number of cycles was 15 (range: 11, 47) and included a median of 5 (1, 37) cycles on monotherapy. The majority of patients who switched to lurbinectedin monotherapy maintained or improved their tumor response (**Table**). All 3 patients who achieved a complete response (CR) on combination therapy maintained their CR on monotherapy. Of the 26 patients with a partial response (PR) on combination therapy, 3 (12%) achieved a CR and 15 (58%) maintained their PR. Of the 19 patients with stable disease (SD) on combination therapy, 3 (16%) improved from SD to PR (n = 2) or CR (n = 1) and 8 (42%) maintained SD. The median DOR was 8.3 months (95% CI: 7.1, 11.0). The median overall survival (OS) was 20.7 months (95% CI: 15.7, 24.8). Grade 3/4 hematologic abnormalities based on laboratory assessment included lymphopenia (36%), anemia (16%), thrombocytopenia (12%), neutropenia (12%), and leukopenia (10%). Febrile neutropenia was reported in 4% of patients. **Conclusions:** Patients with relapsed SCLC in ATLANTIS who completed 10 cycles of lurbinectedin + DOX combination and switched to lurbinectedin monotherapy tended to maintain or improve their tumor response (including an increase in CRs), with favorable OS and DOR and acceptable tolerability with no new safety signals. Clinical trial information: NCT02566993. Research Sponsor: PharmaMar.

A real-world (rw) evidence study quantifying the clinical value of multi-gene testing in early-stage lung adenocarcinoma (LUAD). *First Author: Nathan A. Pennell, Cleveland Clinic, Cleveland, OH*

Background: Resected early-stage NSCLC has high risk of recurrence, and tyrosine kinase inhibitors (TKIs) and immune checkpoint inhibitors (ICI), each requiring testing for precision biomarkers, have recently been approved in the adjuvant (adj) setting. We assessed the potential value of multi-gene testing in early NSCLC via enabling timely 1L therapy selection at recurrence and through avoidance of adj ICI in pts with driver alterations unlikely to benefit per current guidelines and the label for atezolizumab in first line (1L) NSCLC. **Methods:** Using the nationwide (~280 US cancer clinics) de-identified EHR-derived rw Flatiron Health- Foundation Medicine clinico-genomic database, we selected 6,725 evaluable pts with LUAD who underwent tissue comprehensive genomic profiling (CGP) as part of routine cancer care (01/2011 – 06/2021). We focused on alterations in 4 drivers (*EGFR*, *ALK*, *ROS1*, *RET*) and studied prevalence in early-stage specimens versus advanced (adv) specimens, as well as the rate of timely delivery of 1L therapy at recurrence for pts receiving CGP in early disease. We estimated the cost implications of adj ICI in pts with PD-L1+ LUAD and an *ALK*, *ROS1*, or *RET* fusion with a probabilistic decision tree. **Results:** CGP was performed on 1,490 specimens collected prior to adv disease (stage I 36%, II 27%, IIIA 37%) and ordered prior to adv diagnosis for 981 pts (15% of total, median 10 weeks after initial diagnosis). In specimens collected in early (n = 1,490) or adv (n = 5,130) stage LUAD, CGP identified drivers in *EGFR* (early/adv: 13%/16%), *ALK* (2.0%/4.2%), *ROS1* (0.7%/1.1%), *RET* (1.0%/1.1%), and prevalence was similar when limiting to PD-L1+ cases. Studying 596 pts with recurrence and CGP on samples collected prior to recurrence, pts with CGP results obtained before (n = 196) vs after (n = 400) recurrence had less time between recurrence and start of any 1L therapy (median 3.1 vs 5.9 weeks, $p < 0.001$). In the subset with a targetable driver detected, 32/42 (76%) with CGP before recurrence initiated matched 1L TKI while 43/67 (64%) with CGP after recurrence received matched 1L TKI ($p = 0.2$). Through avoidance of ICI in PD-L1+ early LUAD with an *ALK*/*ROS1*/*RET* driver, we estimate universal CGP (compared to *EGFR* single-gene testing) could reduce per pt expected costs by $875 (an average incremental $4,050 treatment cost reduction compared to a $3,175 increase in diagnostic cost per pt). **Conclusions:** CGP of early-stage LUAD can identify *EGFR*, *ALK*, *ROS1* and *RET* drivers and enable appropriate selection of precision therapies and timely use of effective 1L therapy at recurrence. Assuming adj ICI maintains the lack of activity in *RET*/*ROS1* as seen for *ALK*, CGP could represent a cost-effective approach for avoiding futile adj ICI and reducing the risk of subsequent TKI-associated toxicity. Additional analysis of driver+ pts receiving adj ICI is needed to help balance the risk/benefit for these high risk pts. Research Sponsor: Foundation Medicine.

Racial disparities in the clinical use of durvalumab for patients with stage III unresectable non–small cell lung cancer treated at Veterans Health Administration facilities. *First Author: Amanda Moore, College of Pharmacy, The University of Texas at Austin, Austin, TX*

Background: Evidence from the PACIFIC study and real-world data highlight the benefit of durvalumab in patients with stage III unresectable non-small cell lung cancer (UR-NSCLC). However, limited literature exists regarding disparities in durvalumab treatment patterns such as treatment initiation delays (TID), treatment interruptions (TI), number of doses, duration of therapy (DOT), adverse effects (AEs), and treatment discontinuation (TD) in minority populations. **Methods:** Patients with stage III UR-NSCLC and a self-reported racial identity of Black or White treated with durvalumab following chemoradiotherapy (CRT) at any Veterans Health Administration (VHA) facility from January 1, 2017 to June 30, 2020 were included. Patients were followed from their date of durvalumab initiation through the earliest of their last VHA visit, loss to follow up, death, or end of the study; therefore, all patients had the opportunity to be treated for 12 months. Patients were excluded if durvalumab therapy was ongoing at the end of the study. Patient charts were retrospectively reviewed for baseline characteristics and durvalumab treatment patterns including TID (>42 days from end of CRT to durvalumab start), TI (>28 days between doses), number of doses, DOT, AEs, and TD. Nominal variables were compared using chi-square/Fisher's exact tests. Continuous variables were compared using Student's t-tests/Wilcoxon Rank Sum tests. **Results:** Among 924 patients, Black patients were younger than White patients (median age 67 years [IQR, 63-71] vs. 70 years [IQR, 65-73]; $p<0.01$), more likely to be current smokers (54% vs. 45%; $p=0.03$), with more chronic liver disease (22% vs. 9%; $p<0.01$), but less COPD (63% vs. 72%; $p=0.01$). Black patients experienced more TI (25% vs. 18%; $p=0.03$) but TID, number of doses, DOT, and TD were similar between the groups. Black patients were less likely to have an immune-related AE (irAE) (28% vs. 36%; $p=0.03$) (and less pneumonitis (7% vs. 14%; $p<0.01$)). Toxicity was the reason for TD in 12% of Black patients vs. 20% of White patients ($p=0.01$), with no other significant ($\alpha < 0.05$) differences in reported reasons for TID, TI, or TD between the groups. **Conclusions:** In this real-world study, Black patients experienced similar TID, number of doses, and DOT as White patients. Black patients were less likely to experience an irAE (including pneumonitis) but experienced more TI; TD were similar but more likely to be from toxicity for White patients. Future research is needed to validate these findings. Research Sponsor: AstraZeneca.

Race and durvalumab treatment patterns.

Outcome	White (n=726)	Black (n=198)	P-value
Patients with TID	38%	45%	0.07
Patients with TI	18%	25%	0.03
Number of doses, median (IQR)	15 (7-24)	18 (7-25)	0.25
DOT (months), median (IQR)	8.7 (2.9-11.8)	9.8 (3.6-12.0)	0.08
Patients with irAEs	36%	28%	0.03
Pneumonitis	14%	7%	<0.01
Patients with TD	60%	54%	0.09

PD-L1 score as a prognostic biomarker in Asian patients with early-stage, EGFR-mutated lung cancer. *First Author: Stephanie Saw, National Cancer Centre Singapore, Singapore, Singapore*

Background: Adjuvant Atezolizumab was recently approved in stage II-IIIA non-small cell lung cancer (NSCLC) with PD-L1 ≥1%. However, disease-free survival (DFS) benefit was mainly driven by PD-L1 ≥50% and among *EGFR*-mutated subgroup, atezolizumab did not demonstrate DFS benefit when PD-L1 0% patients were included. We sought to determine the prognostic value of PD-L1 score in early-stage *EGFR*-mutated NSCLC. **Methods:** Consecutive patients with Stage IA-IIIA NSCLC diagnosed 1/1/2010 – 31/12/2019 who underwent curative surgery at National Cancer Centre Singapore with evaluable *EGFR* and PD-L1 status were included. Co-primary endpoints were 2-year DFS and 5-year overall survival (OS) by Kaplan-Meier method. **Results:** 455 patients were included (267 *EGFR*-mutant; 188 *EGFR*-wildtype). Median age at diagnosis was 65 years, 52.3% (238/455) were males and 62.9% (286/455) were never-smokers. Adenocarcinomas comprised 92.1% (419/455) and 92.5% (421/455) had R0 resection. Stage IA comprised 42.4% (193/455), Stage IB 23.1% (105/455), Stage II 15.8% (72/455) and Stage IIIA 18.7% (85/455). Among *EGFR*-mutant, 45.3% (121/267) were Ex19del and 41.9% (112/267) were L858R. PD-L1 ≥1% among *EGFR*-mutant and *EGFR*-wildtype was 55.8% (149/267) and 60.1% (113/188) respectively ($p = 0.361$). PDL1 ≥50% was significantly associated with higher stage at diagnosis among *EGFR*-mutant ($p < 0.001$) but not *EGFR*-wildtype ($p = 0.319$). At median follow up of 47 months, 178 patients had relapsed. Among *EGFR*-mutant, 2-year DFS comparing PD-L1 0% and PD-L1 ≥1% was 79.0% and 68.9% ($p = 0.006$) while 5-year OS was 87.6% and 70.6% ($p = 0.006$) respectively. 2-year DFS and 5-year OS by PD-L1 tertile (as shown in table) revealed that higher PD-L1 score was prognostically worse for both DFS and OS among *EGFR*-mutant. A similar trend was observed among *EGFR*-wildtype but did not reach statistical significance, apart from PD-L1 ≥50% which had significantly inferior DFS. **Conclusions:** Higher PD-L1 score was significantly associated with worse DFS and OS among early-stage *EGFR*-mutated NSCLC, possibly due to higher stage at diagnosis among PDL1 ≥50%. Our study highlights the poor prognosis of PDL1 ≥50% *EGFR*-mutated NSCLC in a pre-osimertinib era and underscores the importance of personalised risk-stratified adjuvant strategies. Research Sponsor: Singapore National Medical Research Council (NMRC; grant No. NMRC/TCR/007-NCC/2013 and NMRC/OFLCG/002-2018).

Pre-existing interstitial lung abnormalities are independent risk factors for interstitial lung disease during durvalumab treatment after chemoradiotherapy in patients with locally advanced non–small lung cancer. *First Author: Wakako Daido, Department of Respiratory Medicine, Hiroshima University Hospital, Hiroshima, Japan*

Background: The standard treatment for locally advanced non-small cell lung cancer (NSCLC) is chemoradiotherapy (CRT) followed by treatment of durvalumab, one of immune checkpoint inhibitors (ICI). Interstitial lung disease (ILD) is a clinically life-threatening toxicity of CRT or durvalumab. The patient-characteristics or dose-volume histogram parameters of radiotherapy have been reported to be the risk factors for radiation-induced pneumonitis. However, the risk factors for ILD during durvalumab therapy has not been established. Interstitial lung abnormalities (ILA) are generated by aging or smoking, and manifest as minor interstitial shadow on lung computed tomography (CT). We previously reported that ILA were risk factors for ICI-induced ILD in patients with advanced NSCLC, as well as non-lung cancer. Therefore, we investigated whether ILA could be risk factors for ILD during the durvalumab therapy. **Methods:** We retrospectively enrolled NSCLC patients who received durvalumab after CRT at 10 institutions from July 2018 to June 2021. Patient-information, patient-characteristics, dose-volume histogram parameters, chest CT findings, and laboratory data, were obtained. CT findings were examined using CT obtained after CRT and prior to durvalumab therapy. **Results:** A total of 153 patients were enrolled, and the prevalence of ILA was 37.8% (56 patients) before durvalumab treatment. Among the enrolled patients, 94 (63.5%) developed ILD during durvalumab therapy. The proportion of patients with grade 1, grade 2, or grade 3 ILD was observed to be 29.7% (44 patients), 25.7% (38 patients), and 8% (12 patients), respectively. Univariate logistic regression analysis revealed that higher age, higher dose volume histogram parameters (V5, V20, mean lung dose), and the presence of ILA were significant risk factors for grade 2 or more ILD. Multivariate logistic regression analysis showed that ILA, especially ground grass attenuation in ILA, was an independent risk factor for grade 2 or more ILD (odds ratio: 7.02, 95% CI: 2.95-16.69, $p < 0.0001$). **Conclusions:** Pre-existing ILA are risk factors for ILD during durvalumab treatment after CRT. This observation is consistent with previously reported findings in patients with advanced lung cancer and non-lung cancer. Therefore, we should pay more attention to the development of grade 2 or more ILD during durvalumab treatment in patients with ILA. Research Sponsor: None.

Observer performance study to examine the feasibility of the AI-powered PD-L1 analyzer to assist pathologists' assessment of PD-L1 expression using tumor proportion score in non–small cell lung cancer. *First Author: Seokhwi Kim, Department of Pathology, Ajou University School of Medicine, Suwon, South Korea*

Background: Programmed death ligand 1 (PD-L1) expression is the standard biomarker for PD-L1 inhibitors in advanced non-small cell lung cancer (NSCLC). However, evaluation of PD-L1 tumor proportion score (TPS) by pathologists causes inter-observer variation and demands time to interpret. This study aimed to evaluate the benefit of the artificial intelligence (AI) algorithm in assisting pathologists to determine TPS on PD-L1 immunohistochemistry (IHC) whole-slide images (WSIs) in NSCLC. **Methods:** Lunit SCOPE PD-L1, an AI-powered PD-L1 TPS analyzer, was developed from 393,565 tumor cells annotated by board-certified pathologists for PD-L1 expression in 802 WSIs stained by 22C3 pharmDx IHC. The AI model was developed based on a region-based convolutional neural network, and the model can detect and count PD-L1 positive or negative tumor cells from WSIs to calculate TPS. Seven independent board-certified pathologists scored ground truth (GT) of PD-L1 TPS from 199 WSI of NSCLC stained by 22C3 pharmDx IHC. TPS from each GT reader was grouped as negative (< 1%), low (1% to 49%), or high (≥ 50%). The GT of each slide was determined by the consensus of GT readers. Another twelve independent board-certified pathologists scored PD-L1 TPS from the same WSIs as observer performance testers (OPT). They scored TPS twice with a washout interval of 4 weeks, with or without AI assistance. TPS accuracy change and reading time of OPT reader according to the presence or absence of AI assistance were analyzed. **Results:** The standalone accuracy of the AI model was 0.809 (95% CI: 0.690–0.941). With AI assistance, the overall accuracy of TPS had been changed from 0.799 (95% confidence interval [CI]: 0.764–0.836) to 0.832 (95% CI: 0.796–0.869) (P = 0.004). AI assistance increased the accuracy rate in 11 out of 12 OPT readers. The result of the generalized linear mixed model revealed that AI assistance and specimen type affected the probability of correct answer, while the order of reading did not (Table). The mean time to read with AI was 195.4±506.5 (mean±standard deviation) seconds, which was significantly shorter than the mean time to read without AI (285.1±1578.4, P <0.001). **Conclusions:** This study demonstrates that an AI-powered PD-L1 TPS analyzer can assist board-certified pathologists in evaluating TPS of NSCLC by improving the accuracy of TPS group evaluation and reducing the time to read slides. Research Sponsor: Lunit Inc.

Driver coexistence characteristics of ALK-fusion in Chinese patients with lung cancer. *First Author: Min Gao, Shandong Cancer Hospital Affiliated to Shandong University, Jinan, China*

Background: *ALK* fusions and other driver mutations are usually mutually exclusive. With the widespread application of genetic testing techniques, the coexistence of *ALK* fusions and other driver mutations could be detected, such as *ALK* fusion and EGFR driver mutations. However, there were no systematical studies about the coexistence of *ALK* fusions and other driver mutations. Here, we retrospectively investigated the coexistence of ALK fusions and other driver mutations. **Methods:** Samples with *ALK* fusions were extracted from a Chinese lung cancer cohort, which from OncoPanscan (Genetron Health) based sequencing of tissue. Driver mutations of *EGFR*, *ROS1*, *RET*, *NTRK1/2/3*, *BRAF*, *MET*, *KRAS* and *ERBB2* could be detected. **Results:** In the cohort, 692 samples with *ALK* fusions contained the intact kinase domain. These samples could be classified into three forms: canonical fusions (only *EML4* partner, n = 601), single non-canonical fusions (only non-*EML4* partner, n = 51) and complex non-canonical fusions (two or more partners, n = 40). Among the 692 samples, only 20 samples (20/692, 2.89%) coexisted with other driver mutations, which indicated that the driver coexistence were rare. 70% (14/20) of driver coexistence were happened on canonical fusions (*EML4-ALK*) samples. They were coexisting with *EGFR* L858R (3), *EGFR* L858R plus *ROS1* fusion (1), *EGFR* L858R plus *MET* amplification (1), *KRAS* G12C/D/*N* (3), *MET* amplification (3), *MET* Exon14 skipping (1), *ERBB2* amplification (1), and *MET* amplification plus *ERBB2* amplification (1), respectively. 20% (4/20) of driver coexistence samples were single non-canonical ALK fusions coexisting with *EGFR* 19del (1) or 20ins (1) or L858R (1) or *MET* amplification (1). Another 10% (2/20) samples were complex non-canonical *ALK* fusions coexisting with *EGFR* G719S (1) or *RET* fusion (1). Most co-mutations have corresponding targeted inhibitors, maybe these patients can be treated by combined or sequential therapies. Among canonical fusions, single non-canonical fusions and complex non-canonical fusions of *ALK*, the frequency of the samples without coexistence of driver mutations was respectively 97.67% (587/601), 92.16% (47/51), 95.00% (38/40), without significant difference (P = 0.056). Maybe single/complex non-canonical fusions are also strong drivers as canonical fusions. **Conclusions:** In this cohort, very few of *ALK* fusion patients coexisted with other driver mutations. Among the co-existence samples, *ALK* fusion were mainly coexisting with the site mutations of *EGFR* and *KRAS*, amplifications of *MET* and *ERBB2*, fusions of *ROS1* and *RET*. These samples maybe obtain more effective outcomes by combined or sequential therapies. Research Sponsor: None.

Spatial meta-transcriptomics reveal intratumor bacterial association with lung cancer cells showing a distinct oncogenic signature. *First Author: Chen Zhao, Thoracic and Gastrointestinal Malignancies Branch, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: The lung intratumor microbiome influences lung cancer tumorigenesis and treatment responses, but detailed data on the extent, location, and effects of microbes within lung tumors is missing, information needed to improve treatment outcomes and prognosis. **Methods:** To address this gap, we developed a novel spatial meta-transcriptomic method simultaneously detecting the expression level of 1,811 host genes and three microbe targets (16S rRNA, 28S rRNA and CMV). After rigorous validation, we analyzed the spatial meta-transcriptomic profiles of tumor cells, T cells, macrophages, other immune cells, and stroma in tumor samples from 12 patients with early-stage lung cancer. **Results:** Bacterial burden was significantly higher in tumor cells compared to T cells, macrophages, other immune cells, and stroma. This burden increased from tumor-adjacent normal lung and tertiary lymphoid structures to tumor cells to the airways, suggesting that lung intratumor bacteria derive from the latter route of entry. Expression of oncogenic β-catenin and epithelial-mesenchymal transition pathway genes was strongly correlated with bacterial burden, as were tumor subtypes, mutation profile, histology and smoking history. **Conclusions:** Intratumor bacteria were enriched with tumor cells and associated with multiple oncogenic pathways, supporting a rationale for reducing the local intratumor microbiome in lung cancer to optimize clinical outcomes. This research was supported in part by the Intramural Research Programs of the NCI and NIAID. Other funding sources included ASCO Young Investigator Award, SITC-AstraZeneca Immunotherapy in Lung Cancer (Early Stage NSCLC) Clinical Fellowship Award, NIH Bench-to-Bedside and Back Program (BtB), NCI R00 award (CA226400), Emerson Collective Cancer Research fund, Lung Cancer Research Foundation (LCRF) pilot grant and W.W. Smith Trust Foundation award. This study was approved by NCI institutional review board (NCT00242723 and NCT02146170) and Animal Use and Care Committee at the University of Pennsylvania (#806875). Low skeletal muscle area and association with toxicity and hospitalization with chemotherapy in advanced non–small cell lung cancer. *First Author: Anurag Saraf, Harvard Radiation Oncology Program, Boston, MA*

Background: Significant toxicity is common in the treatment of advanced non-small cell lung cancer (NSCLC) and can be associated with adverse events, such as unplanned hospitalization, and worse clinical outcomes. Baseline low skeletal muscle (SM) area is a marker of sarcopenia and has been associated with worse survival in other malignancies, but the association of SM area and toxicity in NSCLC is less studied. **Methods:** Patients with locally advanced or oligo-metastatic NSCLC treated with combined chemotherapy and radiotherapy with or without surgery from 2002-2013 at a single institution were reviewed. A deep-learning pipeline utilized existing pre-treatment computed tomography scans to calculate SM area at the 3rd lumbar vertebral level. Gold standard SM index (SMI) was calculated, adjusting for height, sex, and dichotomized per previously validated cut-off values. Grade 3 or higher hematologic (G3+ heme) toxicity, was assessed per NCI CTCAE v5.0, within 21-days of first chemotherapy cycle. Hospital use was defined as unplanned ED visit or inpatient hospitalization during chemotherapy. Multivariate analysis (MVA) of toxicity endpoints with SMI and baseline characteristics were analyzed by logistic regression analysis, and with overall survival (OS) using Cox regression analysis. **Results:** A total of 369 patients met inclusion criteria with median follow-up of 23.0mo (range 1-193mo), median age of 64y (range 29-88y), and were mostly male (51%). Most were clinical stage (AJCC 7th edition) IIIA (44%), IIIB (31%), or IV (10%), while 10% had upfront surgery and adjuvant chemotherapy. Most common regimen was cisplatin-based (48%). Median OS was 25.5mo and PFS was 14.0mo. Patients with low SMI were more likely to be younger (median age 70y vs 62y), ECOG performance status (PS) > 0 (74% vs 59%), lower BMI (median BMI 23.3 vs 27.7), and not receive cisplatin-based regimen (35% vs 53%). There was no difference in histology, stage, surgery, or every 3-week (q3w) chemotherapy dosing. On MVA, low SMI was associated with increased risk of G3+ heme toxicity (OR 1.74, p = 0.04) and increased hospital use (OR 1.79, p = 0.04). G3+ heme toxicity was also associated with surgery and q3w dosing, but not age, PS, BMI, or regimen. Hospital use was also associated with BMI, surgery, and cisplatin-based regimen, but not age, PS, or q3w dosing. G3+ heme toxicity (HR 1.48, p < 0.01), older age (HR 1.02, p = 0.02), and stage 4 (HR 3.32, p < 0.01) were associated with worse survival on MVA, but not low SMI (HR 1.25, p = 0.11), PS, BMI, surgery, or regimen. **Conclusions:** Low SMI predicted higher risk of G3+ toxicity during first cycle of chemotherapy. High-risk patients with low SMI experienced significant adverse events and should be considered for more aggressive symptom management or alternative treatment strategies. Postoperative ctDNA in indicating the recurrence risk and monitoring the effect of adjuvant therapy in surgical non–small cell lung cancers. *First Author: Xiaoru Tian, Xuanwu Hospital Captical Medical University, Beijing, China*

Background: Circulating tumor DNA (ctDNA) has emerged as a potential novel biomarker to predict molecular residue disease in lung cancer after definitive treatment. Herein, we investigated the value of ctDNA in prognosing risk of relapse and monitoring the effect of adjuvant therapy in surgical non-small cell lung cancer (NSCLC) patients. **Methods:** Forty-one surgical NSCLC patients were enrolled. Tumor tissues were collected at surgery and subjected to targeted NGS of 1021 cancer-related genes. The serial peripheral blood samples were collected at postoperative one month and then at every third or sixth month and subjected to ultra-deep targeted NGS covering 338 genes. **Results:** From 41 eligible patients including 18 patients with stage I disease, 2 with stage II and 21 with stage III, 41 tumor tissues and 137 plasma samples were enrolled and successfully tested. In tissue samples, 323 somatic variations were identified, with a median of 8 (range, 1-21) gene variations detected in each patient. *TP53* was the most common mutation (63.41%), followed by *EGFR* (58.53%), *LRP1B* (17.07%) and *KRAS* (14.63%). The first-postoperative ctDNA positive was found in 13 of 41 patients (31.71%), 9 stage III, 2 stage II and 2 stage I. During a median 9.47 months follow-up, 38.46% (5/13) patients with detectable ctDNA in the first postoperative blood sample experienced recurrence, while 3.57% (1/28) patients with undetectable ctDNA ultimately recurred. The DFS can be stratified by the first-postoperative ctDNA status, with ctDNA-positive groups having significantly reduced DFS ($p < 0.05$). We detected ctDNA in at least one time point after surgery in 17 patients (41.46%), 5 of them (29.41%) experienced recurrence. Twenty-four patients without ctDNA detection during postoperative surveillance, one (4.17%) of them ultimately recurred. Serial ctDNA detection revealed disease recurrence ahead of radiologic imaging by a median of 5.25 months (range, 0.98-14.19). Among the 41 patients, 6 patients had surgery alone, 35 patients received adjuvant therapy. For these 35 patients, ctDNA analysis can stratify patients before and after adjuvant therapy. Recurrence ratio was 33.33% (4/12) in patients with detectable and 4.34% (1/23) in patients with undetectable ctDNA before adjuvant therapy. For ctDNA analysis after adjuvant therapy, no patients (11/11) with negative ctDNA had disease-recurrence while 33.33% (1/3) patients with positive ctDNA experienced recurrence. All four patients with clearance ctDNA by adjuvant therapy remained disease free. **Conclusions:** For NSCLC patients, postoperative ctDNA is a prognostic marker, which reveals disease recurrence ahead of radiographic examination. Importantly, ctDNA-detecting may facilitate personalized adjuvant therapy, and applying adjuvant therapy to the patients with detectable ctDNA could bring clinical benefits for them. Analysis of circulating tumor DNA in the phase 2 BTCRC LUN 16-081 trial of consolidation nivolumab with or without ipilimumab after chemoradiation in stage III non–small cell lung cancer. *First Author: Soyeong Jun, Stanford Cancer Institute, Stanford University, Stanford, CA*

Background: The current standard of care for patients with inoperable stage III non-small cell lung cancer (NSCLC) includes chemoradiation (CRT) followed by up to 1 year of checkpoint inhibitor (CPI) therapy. However, many patients are not able to complete 1 year of treatment and the optimal duration of consolidation therapy remains unknown. Identifying minimal residual disease (MRD) via detection of circulating tumor DNA (ctDNA) may help inform the optimal duration of treatment. Here we report the results of a preplanned correlative study evaluating the association between detectable ctDNA and survival outcomes from the BTCRC LUN 16-081 phase 2 trial of consolidation nivolumab or nivolumab plus ipilimumab following CRT in patients with unresectable Stage III NSCLC (NCT03285321). **Methods:** Following CRT, patients with unresectable stage IIIA/B NSCLC were randomized 1:1 to receive nivolumab 480 mg IV Q4weeks for up to 6 cycles or nivolumab 240 mg IV Q2weeks plus ipilimumab 1 mg/kg IV Q6weeks for up to 4 cycles. Plasma samples for ctDNA analysis were collected after completion of CRT, prior to C2D1 of CPI, and at the end of treatment or withdrawal from the study. Tumor genotyping and ctDNA analysis were performed using CAPP-Seq with a panel targeting 260 genes recurrently mutated in NSCLC. Patient-specific tumor variants were identified using tumor tissue or baseline plasma and matched leukocyte DNA samples. Tumor variants were then monitored in plasma samples using a tumor mutation-informed bioinformatic strategy. **Results:** Thirty-nine patients received either nivolumab (n = 25; cycles: median = 6, range 1-6), or nivolumab plus ipilimumab (n = 14; cycles; median = 2, range = 1-6). Patients with detectable ctDNA MRD after completion of CRT demonstrated significantly inferior progression free survival (PFS) than patients who were MRD-negative (12-month 29% vs 76%, 24-month 29% vs 68%, $P = 0.003$), prior to C2D1 of CPI (12-month 0% vs 85%, 24-month 0% vs 72%, $P < 0.0001$) and at the end of CPI (12-month 14% vs 90%, 24-month 14% vs 79%, $P < 0.0001$). Patients with undetectable ctDNA MRD at the end of CPI (median cycles = 5.5; range 1-6) demonstrated 24-month overall survival of 91%. Additionally, patients with decreasing or undetectable ctDNA levels after one cycle of CPI had improved outcomes compared to patients with increasing ctDNA levels (24-month PFS 73% vs 0%, $P < 0.0001$). Progression of disease occurred within 10.8 months of starting CPI in all patients with increasing ctDNA levels at C2D1. **Conclusions:** Detectable ctDNA before, during, and after consolidation CPI is strongly associated with inferior survival outcomes. Furthermore, less than 12 months of CPI consolidation can result in MRD negativity and high rates of long term PFS. Clinical trial information: NCT03285321. Research Sponsor: U.S. National Institutes of Health.

Monitoring PD-L1 expression on circulating stromal cells in blood predicts PFS and OS in patients with metastatic NSCLC treated with PD-L1/PD-1 immunotherapy. *First Author: Jillian Moran, Creatv MicroTech, Inc., Monmouth Junction, NJ*

Background: Cancer Associated Macrophage Like cells (CAMLs), a circulating stromal cell found in cancer patients (pts) blood, are phagocytic giant macrophages that appear to parallel the inflammatory PD-L1 state of the tumor microenvironment. Previously, we demonstrated in local non-small cell lung carcinoma (NSCLC), CAML PD-L1 expression is dynamic and predicts response to PD-L1/PD-1 immunotherapies (IMTs) following sequential sampling before and after chemotherapy (chemo) induction (~30days) based on progression free (PFS) & overall survival (OS). However this has not been tested in metastatic NSCLC (mNSCLC). Here,we report the results of monitoring PD-L1 expression in CAMLs before and after chemo induction (~30 days) to evaluate its predictive value in mNSCLC pts treated with or without IMT. **Methods:** A single blind multi-year prospective study was undertaken to test the relationship of PD-L1 expression in CAMLs to PFS & OS, pre & post chemo induction, in recurrent mNSCLC with (n = 41) or without (n = 41) additional anti-PD-L1/PD-1 IMTs. This included three IMTs: atezolizumab (n = 4), nivolumab (n = 8) or pembrolizumab (n = 29). We recruited 82 pts with pathologically confirmed recurrent mNSCLC prior to treatment for newly recurrent metastatic disease. Blood samples (15 mL) were taken at Baseline (BL), prior to chemo, and ~30 days after chemotherapy (T1). Blood was filtered by CellSieve filtration & CAMLs' expression scored as a binary high/low, to evaluate PFS & OS hazard ratios (HRs) by censored univariate & multivariate analysis at 18 months. **Results:** CAMLs were found in 97% of all tested samples, 94% at BL & 100% at T1. CAML PD-L1 at BL was found not to be associated with PFS or OS in pts treated with chemo alone (PFS p = 0.620 & OS p = 0.673) or chemo+IMT (PFS p = 0.353 & OS = 0.477) at 18 months. At T1, high CAML PD-L1 in pts treated with chemo alone had no significantly different PFS (HR = 1.3, p = 0.694) or OS (HR = 1.6 p = 0.503). However, high CAML PD-L1 at T1 in pts treated with chemo+IMT had significantly better PFS (HR = 3.1, 95%CI = 1.3-7.3, p = 0.019), and OS (HR = 3.4, 95%CI = 1.4-8.3, p = 0.014). Further subtyping & analysis is ongoing to evaluate PFS and OS at 24 months. **Conclusions:** Our data suggests that in mNSCLC, PD-L1 expression in circulating CAMLs dynamically upregulates after induction with chemotherapy and appears to predict patients with increased benefit to PD-L1/PD-1 IMTs, though additional studies are needed to validate these findings. A phase II study of durvalumab (MEDI4736) immediately after completion of chemoradiotherapy in unresectable stage III non–small cell lung cancer: TORG1937 (DATE study). *First Author: Shinji Nakamichi, Department of Pulmonary Medicine and Oncology, Graduate School of Medicine, Nippon Medical School, Tokyo, Japan*

Background: Concurrent chemoradiotherapy followed by durvalumab maintenance for up to 12 months is the standard of care for patients with unresectable stage III non-small cell lung cancer (NSCLC). However, the best timing of starting durvalumab after completion of chemoradiation has not been identified. Progression-free survival (PFS) and overall survival (OS) were better in the subgroup of patients administered durvalumab within 14 days after last radiation to randomization according to the PACIFIC study (Antonia SJ, et al. 2017, 2018 NEJM). **Methods:** This study was a prospective, single-arm, multicenter, phase II clinical trial. Eligibility criteria included patients with unresectable stage III NSCLC, ECOG PS 0-1, age < 75 years old. Patients who did not have disease progression after definitive concurrent chemoradiotherapy (CCRT) (chemotherapy: 2 cycles of platinum-based doublet chemotherapy, radiotherapy: 60 Gy/30 Fr) received durvalumab (10 mg/kg, every 2 weeks for up to 12 months) from the next day (allowed up to 5 days) after last radiation. The primary endpoint was 1-year PFS rate from registration assessed by an independent review committee. The planned sample size was 47 with a threshold value of 50% based on results of the PACIFIC study, an expected value of 63%, one-sided alpha of 20% and power of 80% in 1-year PFS rate. **Results:** From January 2020 to August 2020, 50 patients were enrolled from 16 institutions and 47 patients were evaluable for efficacy and safety. Forty-two patients received durvalumab maintenance therapy. Patient characteristics were: male/female 41/6; median age 65 (range 42-75); ECOG PS 0/1 28/19; IIIA/IIIB/IIIC 19/21/7. The 1-year PFS rate from registration was 75.0% (60% CI: 69.0 to 80.0). The 1-year OS rate from registration was 97.7% (95%CI: 84.6 to 99.7). ORR, median PFS and median OS were 78.7%, 14.2 months (95%CI: 13.4 to not reached (NR)) and NR, respectively. Grade 3/4 adverse events were pneumonitis (4.3%), neutropenia (44.7%), febrile neutropenia (4.3%). There was no treatment-related death. **Conclusions:** Our study met the primary endpoint. Durvalumab can be safely administered immediately after completion of CCRT for patients with unresectable stage III NSCLC, no additional or unexpected toxicity occurred as a reference to the PACIFIC study. Clinical trial information: jRCTs031190117. Research Sponsor: AstraZeneca.

Neoadjuvant nivolumab in early-stage non–small cell lung cancer (NSCLC): Five-year outcomes. *First Author: Samuel Rosner, Johns Hopkins University, Baltimore, MD*

Background: Neoadjuvant (neoadj) immune checkpoint blockade (ICB) with anti-PD-1 therapy has shown increasing promise for early stage NSCLC, with long-term clinical outcomes still maturing. Our group reported the first phase I/II trial of neoadj nivolumab (nivo) in resectable NSCLC, finding therapy to be safe and feasible. We now present final clinical results from this cohort, representing the longest follow up data for neoadj anti-PD-1 to date. **Methods:** Two doses of neoadj nivo (3 mg/kg) were given prior to resection in 21 patients (pts) with resectable NSCLC. 5-year (yr) follow-up data, including recurrence-free survival (RFS), overall survival (OS) and association with pathologic response were tabulated. Event time distributions were estimated with the Kaplan-Meier method. All p-values are two-sided with 0.05 significance level. **Results:** At a median follow up of 63 months, 3-, 4- and 5-yr survival rates were 85, 80, and 80% respectively. RFS rates at 3-, 4- and 5-yrs were 65, 60, and 60% respectively. As previously reported, major pathologic response (MPR: ≤10% viable tumor) was 45%, and pathologic complete response (pCR) rate was 10%. The hazard ratio (HR) for pathologic down-staging was in the direction of improved RFS, without meeting statistical significance (HR 0.36, 95% CI 0.07-1.75, p = 0.2). RFS HR estimates for MPR and an alternative pathologic cut-off of less than 50% residual tumor (RT), were 0.61, (95% CI 0.15-2.44, p = 0.48) and 0.36, (95% CI 0.09-1.51, p = 0.16) respectively. The direction of the effect of pre-treatment PD-L1 positivity (≥1%) was to improve RFS (HR 0.36, 95% CI 0.07-1.85, p = 0.22). At 5-yr follow up, 8 of 9 (89%) pts with MPR were alive and no cancer deaths have occurred. Amongst pts with MPR, 1/9 pts had a cancer recurrence in the mediastinum treated successfully with definitive chemoradiotherapy. Both pts with pCR are alive and without recurrence. Patterns of all recurrences in this cohort are summarized in table 1. No long-term immune-related adverse events have occurred other than one G3 dermatologic event. **Conclusions:** The 5-yr clinical outcomes for neoadj nivo in resectable NSCLC compare favorably to historical trends. MPR trended toward improved RFS, while definitive conclusions are limited by our cohort size and overall low recurrence rate. Thresholds of %RT beyond pCR and MPR in this setting should be explored in larger prospective studies. PD-L1 expression may play a role in predicting long-term response, but larger prospective studies are needed. Clinical trial information: NCT02259621. Research Sponsor: Cancer Research Institute and Stand Up 2 Cancer.

Prognostic role of preoperative chemosensitivity in patients with non–small cell lung cancer (NSCLC) treated with preoperative chemotherapy: A study of National Cancer Database (NCDB). *First Author: Lei Deng, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Response to preoperative systemic therapy may provide valuable information regarding tumor biology and prognosis. This is increasingly relevant nowadays considering the promising results from preoperative chemoimmunotherapy. This study aims to examine the prognostic role of preoperative chemosensitivity defined by TNM stage change in NSCLC. **Methods:** Patients with histologically confirmed clinical stage II-III NSCLC who have received preoperative chemotherapy followed by R0 curative surgery were identified in the NCDB between 2006 and 2017. Patients who have developed metastasis at the time of surgery, received any perioperative radiotherapy or single agent chemotherapy, or died within 90 days of surgery, were excluded. Preoperative chemosensitivity is categorized as ypT0N0, downstaged (pTNM < cTNM, excluding ypT0N0), and not downstaged (pTNM ≥ cTNM). Logistic regression was used to evaluate associations between chemosensitivity and demographic, clinical, and pathological factors. Log-rank was used for survival analysis and adjusted by cox regression for age, gender, race, year of diagnosis, academic center, insurance, comorbidity, histology, and clinical stage. **Results:** A total of 1266 patients were included, of whom 104 (8.2%) had ypT0N0, 575 (45.4%) were downstaged, while 587 (46.4%) were not. Female, diagnosis in recent years, treatment at academic centers, and squamous histology were significantly associated with better chemosensitivity, while clinical TNM stage, age, race, and comorbidity were not. Five-year overall survival rate is 81.2%, 57.7%, and 46.2%, respectively (log-rank p < 0.001). After Cox regression adjustment, compared with not downstaged, ypT0N0 (HR 0.28, 95% CI 0.17 – 0.45) and downstaged (HR 0.61, 95% CI 0.51 – 0.74) were independently associated with improved postoperative survival. **Conclusions:** Preoperative chemosensitivity defined by TNM stage change before and after chemotherapy may prognosticate NSCLC after curative surgery. It may be a useful clinical tool to identify patients with high risk of treatment failure after neoadjuvant chemoimmunotherapy in the future. Research Sponsor: U.S. National Institutes of Health.

Cox regression model of variables significantly associated with postoperative survival.

Characteristic	HR	95% CI	p-value

Racial disparities in receipt of curative surgery for early-stage non–small cell lung cancer in Florida. *First Author: Qinran Liu, Department of Public Health Sciences, Miller School of Medicine, University of Miami, Miami, FL*

Background: Lung cancer is the leading cause of cancer death in the United States. Receipt of curative-intent surgery for early-stage non–small cell lung cancer (NSCLC) is associated with disparities in race and socioeconomic status, which is subsequently related to the outcome of NSCLC. This study aimed to examine the racial disparity in receipt of curative-intent surgery among early-stage NSCLC in Florida. **Methods:** A total of 80,458 patients with early-stage NSCLC diagnosed from 2005 to 2017 were identified from the statewide cancer registry, Florida Cancer Data System (FCDS). Percentage of patients receiving curative-intent surgery was calculated for each race/ethnicity. FCDS data was linked to discharge data containing comorbidity information for each lung cancer patient. There was a 94% match between FCDS and discharge data. Multivariable logistic regression was used to determine the impact of race on receipt of curative-intent surgery for early-stage NSCLC. **Results:** Among 80,458 patients with early-stage NSCLC, 66,761 (83.0%) were White, 5,503 (6.8%) were Black and 6,981 (8.7%) were Hispanic. Of note, 69.5% Hispanic patients lived in South Florida. Asian patients (59.9%) had the highest proportion of curative surgery, followed by Hispanics (57.8%), Whites (52.9%) and Blacks (42.6%). In the multivariable model, patients with Charlson Comorbidity Index (CCI)≥3 had 34% lower odds of having curative surgery (OR, 0.66; 95% CI, 0.62 to 0.7) compared to patients who did not have any comorbidity (CCI=0). Highest poverty levels had 27% lower odds of receiving curative-intent surgery compared to lowest (OR: 0.73; 95% CI: 0.68 to 0.78). After adjusting for sociodemographic factors (i.e., age, sex, race, insurance, region) and clinical factors (i.e., histology, AJCC stage, CCI, smoking status), Blacks had 27% lower odds of receiving curative-intent surgery (OR, 0.73; 95% CI, 0.68 to 0.79), whereas Hispanics had 22% (OR, 1.22; 95% CI, 1.14 to 1.30) and Asians had 19% (OR, 1.19; 95% CI, 0.98 to 1.46) higher odds than Whites. In the stratified analysis by regions, Blacks had lower odds of receiving curative-intent surgery than Whites in all regions across Florida while Hispanics had higher odds of receiving surgery than Whites only in South Florida (OR, 1.29; 95% CI, 1.18 to 1.41). **Conclusions:** There are persistent racial disparities in receipt of curative-intent surgery for early-stage NSCLC in Florida. Specifically, Blacks are receiving less curative-intent surgery, despite adjustments for comorbidities, socio-economic status, and insurance. Ethno-regional differences within different regions of Florida are evident with Hispanics surpassing all other races in receipt of curative treatment in heavily Hispanic South Florida. Minimal residual disease (MRD) detection by ctDNA in relation to radiographic disease progression in patients with stage I-III non–small cell lung cancer (NSCLC) treated with definitive radiation therapy. *First Author: Emily S. Lebow, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The standard of care for patients with inoperable early stage or locally advanced NSCLC is definitive stereotactic body radiotherapy (SBRT) or conventional radiation therapy (RT) with systemic therapy. Circulating tumor DNA (ctDNA) testing can be used for the assessment of MRD and predict risk of recurrence. Few studies have prospectively evaluated MRD detection and ctDNA dynamics specifically among patients with early or locally advanced NSCLC receiving definitive RT. **Methods:** In a prospective clinical cohort of patients with stage I-III NSCLC (n = 17), serial plasma samples (n = 70) were collected before and after SBRT as well as before, during, and after conventional RT with or without concurrent systemic therapy and adjuvant durvalumab. Patients were followed-up for a median of 29 months (range: 4 to 54 months) with the last serial plasma collected at a median of 5 months from completion of RT (range: 1 – 26 months). A personalized, tumor-informed multiplex PCR assay (Signatera™ bespoke mPCR NGS assay) was used for the detection and quantification of ctDNA and tracked 16 tumor variants among 16 patients and 15 tumor variants in one patient. This study evaluated the prognostic value of ctDNA, correlating MRD status with clinical outcomes, in addition to ctDNA clearance kinetics during RT. **Results:** Among 17 patients with early-stage and locally advanced NSCLC, baseline ctDNA was detected in 82% of patients (14/17). Clinical progression was confirmed radiographically for 53% (9/17). All events of clinical progression were detectable by ctDNA (sensitivity 100%, 0.63 – 1.0), with a median lead-time of 5.5 months for MRD detection compared to radiographic disease progression. Durable ctDNA clearance was observed in 29% (5/17) of patients, all of whom then remained recurrence-free until the end of follow-up (median 12 months; specificity 100%, 95% CI 0.6 – 1.0). Transient ctDNA clearance was observed in 3 patients, and recurrent ctDNA was detected before or at the time of disease progression in all 3. ctDNA status after treatment at a single time point and longitudinally were highly predictive of disease recurrence (p < 0.0001). **Conclusions:** ctDNA detection is feasible for patients with stage I-III NSCLC undergoing definitive chemoradiation. and can serve as a powerful predictive biomarker for disease recurrence. High baseline detection rate is essential for feasibility of a ctDNA-based MRD assay. Residual detectable ctDNA represents a powerful predictive tool to identify patients who might benefit from intensification of adjuvant therapy following definitive RT. Research Sponsor: Natera Inc.

Durvalumab (durva) after chemoradiotherapy (CRT) in unresectable, stage III, EGFR mutation-positive (EGFRm) NSCLC: A post hoc subgroup analysis from PACIFIC. *First Author: Jarushka Naidoo, Department of Oncology, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: Standard of care for patients (pts) with unresectable (UR) stage III NSCLC is the 'PACIFIC regimen', based on data from the phase 3 placebo (pbo)-controlled trial where consolidation durva following CRT improved overall survival (OS; hazard ratio [HR], 0.68 [95% CI, 0.53, 0.87]) and progression-free survival (PFS; HR, 0.52 [95% CI 0.42, 0.65]), in an all-comer population. However, the benefit of immunotherapy (IO) in pts with EGFRm stage III NSCLC is unclear. We report a *post hoc* exploratory efficacy and safety analysis from 35 pts with EGFRm NSCLC from the PACIFIC trial (NCT02125461). **Methods:** Pts with stage III UR-NSCLC, WHO performance status (PS) 0/1 and no progression after ≥2 cycles platinum-based concurrent CRT were randomized 2:1 (1–42 days post CRT) to receive durva (10mg/kg IV q2w for up to 1 year) or pbo, stratified by age, sex, and smoking history; enrollment was not restricted by oncogenic driver gene mutation status or PD-L1 expression. Primary endpoints: PFS (BICR; RECIST v1.1) and OS; key secondary endpoints: objective response rate (ORR) and safety. Treatment effects for the EGFRm subgroup were estimated using an unstratified Cox proportional hazard model; medians were estimated using the Kaplan–Meier method. Statistical analyses were exploratory. Data cut-off (DCO) for the EGFRm subgroup efficacy analysis was 11 January 2021. **Results:** Of 713 pts randomized, 35 had EGFRm NSCLC based on local testing (durva n = 24, pbo n = 11). In the EGFRm subgroup, more pts in the pbo vs durva arm were male (73% vs 54%), had stage IIIA disease (64% vs 46%), PS 0 (64% vs 54%) and received pre-CRT induction chemotherapy (36% vs 8%). More pts in the durva arm were Asian (63% vs 55%) and had PD-L1 on < 25% tumor cells (67% vs 36%); median age was consistent across arms. At DCO, median duration of follow-up for survival was 42.7 months (range, 3.7–74.3 months) for all randomized pts in the subgroup. Median PFS was 11.2 months (95% CI 7.3, 20.7) with durva vs 10.9 months (95% CI 1.9, not evaluable [NE]) with pbo; HR 0.91 (95% CI 0.39, 2.13). Median OS was 46.8 months (95% CI 29.9, NE) with durva vs 43.0 months (95% CI 14.9, NE) with pbo; HR 1.02 (95% CI 0.39, 2.63). ORR was 26.1% (95% CI, 10.2, 48.4) and 18.2% (95% CI 2.3, 51.8) with durva and pbo, respectively. The safety profile for durva was consistent with the overall population. In the durva and pbo subgroup arms, radiation pneumonitis was reported in 42% vs 36% of pts, and pneumonitis was reported in 17% vs 18% of pts (1 grade 3, pbo arm), respectively. **Conclusions:** In this *post hoc* exploratory analysis of 35 pts, PFS and OS outcomes with durva were similar to pbo in the EGFRm population, with wide CIs. The benefit of IO in this population remains unclear. The ongoing LAURA study (NCT03521154) is investigating the efficacy and safety of maintenance osimertinib in pts with locally advanced EGFRm stage III UR-NSCLC with no progression after CRT. Clinical trial information: NCT02125461. Research Sponsor: AstraZeneca.

Multimodal prediction of response to neoadjuvant nivolumab and chemotherapy for surgically resectable stage IIIA non–small cell lung cancer. *First Author: Loïc Ferrer, SOPHiA GENETICS, Pessac, France*

Background: The NADIM trial (NCT03081689), led by the Spanish Lung Cancer Group, assessed the antitumor activity and safety of neoadjuvant chemoimmunotherapy for resectable stage IIIA NSCLC. Patients received neoadjuvant nivolumab and paclitaxel-carboplatin for three cycles before surgical resection, followed by one year of adjuvant nivolumab. At 24 months, progression-free survival (PFS) was 77%, suggesting that neoadjuvant chemoimmunotherapy represents a promising option in this setting. Pathological complete response (pCR) could potentially be used as an important surrogate endpoint for survival. We present here a re-analysis of the NADIM cohort aiming to develop a machine learning algorithm to predict the pCR status based on multimodal baseline data. **Methods:** We combined baseline clinical data (e.g., age, smoking status), biological data (e.g., tumor histology, mutations), radiology reports and radiomics analysis of the baseline CT scan in a multimodal analysis. While 46 patients were enrolled in the NADIM trial, only 28 had a complete set of data available for this retrospective study. For each patient, tumors were segmented on the baseline CT-scan in 3D by a Deep Learning algorithm. Radiomics features were extracted following the IBSI standards and combined with the other data modalities. A filter-based variable selection method was applied before training several machine learning algorithms. The optimization criterion was the Area Under the ROC Curve (AUC). Due to the small size of the cohort, a leave-one-out cross-validation approach was used to properly estimate the model performance. For a sub-cohort of 20 patients for which data have been collected longitudinally during the neoadjuvant treatment, an additional Delta-radiomics model was used to predict the pCR status. **Results:** An XGBoost algorithm with a linear base learner displayed an AUC of 0.69, a precision of 75%, a sensitivity of 83% and a specificity of 50%. Features with highest weight in the algorithm were a mix of radiological, radiomics, biological and clinical features (including the neutrophils to lymphocytes ratio, mutations and histology) highlighting the importance of a truly multimodal analysis. Indeed, withdrawing a specific data modality (e.g., radiomics or biological features), led to a decrease of ~15% of the AUC. Inclusion of the Delta-radiomics analysis on the data collected longitudinally prior to surgery led to an improved AUC of 0.76 in that patient sub-cohort. **Conclusions:** This study is, to our knowledge, the first to offer a multimodal analysis of the response to neoadjuvant treatment for surgically resectable stage IIIA NSCLC and is a proof of concept that a machine learning algorithm can be used to predict the pCR in this context. These preliminary results are being confirmed in the ongoing NADIM II trial. Clinical trial information: NCT03838159. Research Sponsor: None.

Identifying biomarkers associated with disease-free survival in stage I non–small cell lung cancer. *First Author: Christopher W. Seder, Rush University Medical Center, Chicago, IL*

Background: Patients with early stage, non-small cell lung cancer (NSCLC) with solitary pulmonary lesions ≤4 cm typically have favorable outcomes. However, disease recurrence impacts up to 30% of patients, leading to either additional surgical or systemic interventions. New methods to risk stratify patients based on clinical and molecular parameters may improve our ability to select cases that would benefit from more frequent surveillance or enrollment in clinical trials evaluating systemic therapy. **Methods:** We retrospectively analyzed data from 179 patients with early stage ($T_{1a\text{-}2a}N_0M_0$) NSCLC from a single institution. All patients had anatomic resection, negative margins, and systematic nodal sampling. Clinical and demographic data were abstracted from patient charts and tumor samples were molecularly profiled using the Tempus xT solid tumor assay (DNA-seq of 595-648 genes at 500x coverage, whole exome-capture RNA-seq). Pathogenic alterations (single nucleotide variants and insertion/deletions) and RNA expression were examined. Bivariate Cox-proportional Hazards models were used to assess the association of individual clinical, demographic, and molecular variables with recurrence-free survival, defined as the time from surgery until recurrence or death. **Results:** Our dataset included 166 stage IA1-3 patients and 13 stage IB patients, of which 36 patients experienced a recurrence or death event after surgery. Clinical and DNA-seq data was available for all patients, and RNA expression data was available for 172 patients. Across all patients, the most common somatically mutated genes were *TP53* (33% of tumors) and *KRAS* (16% of tumors), consistent with previous studies. Increasing $\log_{10}$.RNA expression for *NTRK1* (HR: 5.95; 95% CI, 1.16-30.4; p = 0.027) and CD274 (PD-L1) (HR: 7.88; 95% CI, 1.61-38.6; p = 0.013) and decreasing $\log_{10}$.RNA expression for *EGFR* (HR: 0.24; 95% CI, 0.05-1.21; p = 0.071) and *ERBB2* (Her2) (HR: 0.20; 95% CI, 0.04-0.97; p = 0.042) were associated with increased risk of recurrence or death. **Conclusions:** Increased expression of *NTRK1* and *CD274* (PD-L1) and decreased expression of *EGFR* and *ERBB2* (Her2) were associated with a increased risk for recurrence following surgery. This may have mechanistic implications for heightened tumor aggressiveness and/or metastatic potential. Future work will expand our cohort and validate our findings in a broader set of early-stage NSCLC patients. Research Sponsor: Swim Across America.

Multi-omic and spatial dissection of immunotherapy response groups in non–small cell lung cancer (NSCLC). *First Author: Kenneth John O'Byrne, Princess Alexandra Hospital Brisbane, Queensland, Australia*

Background: Immune checkpoint inhibitors (ICI) have shown durable benefit in a subset of non-small cell lung cancer (NSCLC) patients. The composition of the tumour microenvironment (TME) is becomingly increasingly recognised as an important factor to predict response to therapy. **Methods:** Here, we applied digital spatial profiling of the tumour and stromal compartments from a 2nd line NSCLC ICI-treated cohort (n = 41 patient) and standard of care (SOC), platinum treated NSCLC cohort (n = 47), to identify tissue-based signatures of response to therapy. **Results:** We demonstrate by mIHC that the interaction of $CD68^+$ macrophages with $PD1^+$, $FoxP3^+$ cells is significantly enriched in ICI refractory tumours (p = 0.012). Patients sensitive to ICI therapy expressed higher levels of IL2 receptor alpha (CD25, p = 0.028) within the tumour compartments, which corresponded with the increased expression of *IL2* mRNA (p = 0.001) within their stroma. Immuno-inhibitory markers CTLA-4 (p = 0.021) and IDO-1 (p = 0.023) were supressed in ICI-responsive patients. Tumour CD44 (p = 0.02) was depleted in the response group and corresponded inversely with significantly higher stromal expression of one of its ligands, *SPP1* (osteopontin, p = 0.008). Analysis of dysregulated transcripts indicated the potential inhibition of stromal interferon-gamma (IFNγ) activity, estrogen-receptor and Wnt-1 signalling activity within the tumour cells of ICI responsive patients. Cox survival analysis indicated tumour CD44 expression was associated with poorer prognosis (HR = 1.61, p = 0.01), consistent with its depletion in ICI sensitive patients. Similarly, stromal CTLA-4 (HR = 1.78, p = 0.003) and MDSC/M2 macrophage marker ARG1 (HR = 2.37, p = 0.01) were associated with poorer outcome while BAD (HR = 0.5, p = 0.01) appeared protective. The SOC cohort paralleled similar roles for immune checkpoints and pro-apoptotic markers, with LAG3 (HR = 3.81, p = 0.04) indicating poorer outcome, and BIM (HR = 0.16, p = 0.014) with improved outcome. Interestingly, stromal mRNA for E-selectin (HR = 652, p = 0.001), CCL17 (HR = 70, p = 0.006) and MTOR (HR = 1065, p = 0.008) were highly associated with poorer outcome in ICI treated patients, indicating pro-tumourigenic features in the tumour microenvironment that may facilitate ICI resistance. **Conclusions:** Through multi-modal approaches, we have dissected the characteristics of NSCLC treatment groups and provide evidence for the role of several markers including *IL2,* CD25, CD44 and *SPP1* in the efficacy of current generations of ICI therapy. Association of the KRAS genotype and clinicopathologic findings of resected non–small cell lung cancer. *First Author: Yuko Oya, Department of Thoracic Oncology, Aichi Cancer Center Hospital, Nagoya, Japan*

Background: This study assessed the clinicopathological background of early-stage KRAS-mutated non-small-cell lung cancer and analyzed the biological process of KRAS-mutated tumor using an RNA sequencing procedure. **Methods:** We used a cohort of consecutive series of 179 surgically resected early-stage non-small-cell lung cancers harboring *KRAS*mutations and analyzed the clinicopathological features, including the KRAS genotypes, affecting the recurrence-free survival and prognosis. Consequently, we performed RNA sequencing to determine the gene expression profiles of nineteen *KRAS*-mutated non-small-cell cancers. **Results:** The most common *KRAS* genotype was p.G12C (57; 31.8%). A high p-stage (hazard ratio [HR], 4.181; P < 0.0001) and solid predominant adenocarcinoma histology (HR, 2.343; P = 0.0076) were significant independent prognostic factors for the recurrence-free survival. A high p-stage (HR, 3.793; P < 0.0001), solid predominant adenocarcinoma histology (HR, 2.373; P = 0.0147), and *KRAS* p.G12V genotype (HR, 1.975; P = 0.0407) were significant independent prognostic factors for the overall survival. A gene expression analysis of the two factors revealed the p.G12V genotype to be closer to those of stem cells, and the traits of e an enhanced fatty acid and amino acid metabolism as well as a solid predominant phenotype were shown to an acquired a trait that can withstand hypoxia and the effect of prostaglandin-endoperoxide synthase **Conclusions:** The *KRAS* p.G12V genotype and solid predominant adenocarcinoma phenotype may be independent predictive factors of a poor clinical course in resected early-stage non-small-cell lung cancers, possibly due to the differentiation tendency observed in stem cells, the trait of an enhanced fatty acid and amino acid metabolism, and the effect of prostaglandin-endoperoxide synthase. Molecular characteristics of ERBB2-activating mutations in Chinese patients with NSCLC. *First Author: Fan Xu, Affiliated Hospital of Chengde Medical University, Chengde City, China*

Background: Activating mutations in the ERBB2 gene were shown to play an oncogenic role similar to that of ERBB2 amplification. Thus, ERBB2 mutations have emerged as therapeutic targets in non-small cell lung cancers (NSCLC). However, Activating ERBB2 mutations have not been described in detail like other driver gene mutations, such as epidermal growth factor receptor (EGFR)-activating mutations. **Methods:** In this study, we retrospectively analyzed activating ERBB2 mutations using next-generation sequencing(NGS). From May 2019 to January 2022, 21745 patients who were diagnosed with NSCLC were detected. **Results:** A total of 686 activating ERBB2 mutations were found, and 12 patients carried double ERBB2-activating mutations. In this cohort, the average age of patients was 58 years (range, 13-90 years). 59.6% of the patients were female and 88.2% were diagnosed with lung adenocarcinoma .A total of 47 ERBB2-activating mutation subtypes were defined in 674 patients. The most common activating mutations were Y772_A775dup (55.0%, 371/674), followed by G776delinsVC (8.3%, 56/674), S310F (7.7%, 52/674), G778_P780dup (5.6%, 38/674) and V659E (4.1%, 28/674). All other mutations occurred in 14 or fewer patients. ERBB2-activating mutations occurred most frequently in the tyrosine kinase domain (TKD) (80.1%), which included mutations in exon 20 (76.2%), exon 19 (3.0%), and exon 21 (1.2%),In addition, 13.2% of activating ERBB2 mutations occur in the extracellular domain, and 5.5% in the Transmembrane domain. 23.1%(156/674) patients with ERBB2 activating mutations could be evaluated for concurrent mutations, tumor mutational burden (TMB) and microsatellite instability (MSI) status. Among these patients, ERBB2-activating mutations were most frequently co-mutated with TP53(54/156) and EGFR(21/156). The frequency of EGFR mutations was much higher in non-TKD mutation patients than in TKD mutation patients (56.7% vs. 3.2%, P < 0.001), but no difference was observed for TP53. All these patients were microsatellite stable (MSS) and low TMB (< 10 mutations/megabase). **Conclusions:** We report mutational landscape and characteristics of ERBB2 in Chinese NSCLC patients .The prevalence of activating ERBB2 mutations was 3.1% in Chinese NSCLC patients. 80.1% of ERBB2 activating mutations were in TKD and 19.9% were in the non-TKD. The non-TKD mutations might also be used as a therapeutic target in ERBB2-directed target therapy. Research Sponsor: None.

Dynamic monitoring circulating tumor DNA in plasma samples by PEAC technology for patients with early-stage non–small cell lung cancer after surgery. *First Author: Ning Li, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Local recurrence or distant metastasis after surgery is not rare for early-stage Non-Small Cell Lung Cancer (NSCLC) patients. Present clinicopathological parameters, such as TNM stages and pathological subtype, are limited effective, as Positive Predictive Value (PPV) is low while Negative Predictive Value (NPV) is high. In recent years, circulating tumor DNA (ctDNA) has emerged as a noninvasive method for early diagnosis, prognostic stratification, disease surveillance, and treatment response evaluation. We assessed whether circulating tumor DNA (ctDNA) detected by PEAC technology could be a biomarker for minimal residual disease (MRD) and prediction of postoperative relapse in early-stage NSCLC. **Methods:** We enrolled 132 NSCLC patients with EGFR, KRAS, NRAS, BRAF and PIK3CA mutations, and obtained plasma samples at five perioperative time points (before surgery, 3-7 days, 6-months, 12-months and 18-months after surgery). Using PEAC technology, somatic mutations in plasma samples were identified and utilized for ctDNA-based MRD analysis. Clinical follow-ups were collected. **Results:** Our data showed that 32.0% (8 of 25) of patients with positive preoperative ctDNA experienced postoperative relapse, compared with 7.2% (6 of 83) in ctDNA negative patients, demonstrating that preoperative ctDNA status is an effective prognosis factor for NSCLC. In time point of 3-7 days after surgery, plasma samples were obtained from 47 patients, of which 33.3% (2 of 6) with positive ctDNA experienced postoperative relapse, while only 4.9% (2 of 41) in ctDNA negative patients. The result suggests that ctDNA positive in plasma samples of 3-7 days after surgery might be a strong biomarker for MRD detection and relapse prediction. For ctDNA surveillance, plasma samples from 6-months, 12-months and 18-months after surgery were collected and detected. At any one of the three tests ctDNA is positive, 20.0% (8 of 40) patients experienced clinical relapse, while 5.1% (3 of 59) patients with ctDNA negative status at all times relapse. A total of 14 recurrence events had occurred, ctDNA positivity precedes radiological recurrence by a median of 150.5 days (90.5 – 182, P = 0.006). **Conclusions:** Perioperative ctDNA analysis using PEAC technology is effective in early detection of MRD and relapse prediction, and hence could benefit NSCLC patient management in clinical settings. Clinical trial information: NCT03465241. Research Sponsor: Sun Yat-sen University.

Optimization of treatment options for EGFR-mutant, stage III, unresectable NSCLC: A systematic review and meta-analysis. *First Author: Lian Liu, Qilu Hospital of Shandong University, Jinan, China*

Background: The PACIFIC study established a new treatment standard for Stage III unresectable NSCLC, but CRT followed by durvalumab failed to bring survival benefit to patients with EGFR mutations. EGFR-TKIs have been successful in the setting of first-line treatment of advanced NSCLC and postoperative adjuvant treatment of NSCLC. We explored whether locally advanced inoperable patients with EGFR mutations can benefit from EGFR-TKIs and the possibly best treatment regimen through meta-analysis. **Methods:** Studies involving unresectable stage III NSCLC with EGFR mutations published in PubMed, Embase, Cochrane, ClinicalTrials.gov, and abstracts of important international conferences (ASCO, ESMO, WCLC) from January 1, 2000 to September 30, 2021 were screened. An integrative analysis was performed using STATA (version 16.0), and a network meta-analysis based on a Bayesian framework was performed using R (version 3.6.1) for the studies with a control group. The primary endpoints were progression-free survival (PFS) and overall survival (OS). **Results:** A total of 3291 patients were identified in 17 studies, including 5 treatment measures including concurrent chemoradiotherapy (CRT), CRT followed by durvalumab (CRT+Durva), TKI monotherapy, radiotherapy combined with TKI (RT+TKI), and CRT combined with TKI (CRT+TKI). PFS with TKI-free treatments (CRT, CRT+Durva) was significantly shorter than TKI-containing ones (TKI, RT+TKI, CRT+TKI) (HR 2.17, 95%CI 1.47-3.19), but its advantage only translated into borderline OS benefit (1.27, 0.99-1.63). In detail, the PFS with TKI-containing measures, including TKI monotherapy (0.66, 0.50-0.87), RT+TKI (0.37, 0.28-0.50), or CRT+TKI (0.14, 0.03-0.75) were all significantly longer than CRT. Furthermore, the PFS with both RT+TKI (0.40, 0.21-0.76) and CRT+TKI (0.15, 0.03-0.74) were significantly longer than CRT+Durva, while no statistical difference existed in PFS between RT+TKI and CRT+TKI. However, TKI alone had significantly shorter PFS than RT+TKI (1.78, 1.17-2.67). There was no statistical difference in OS among all the treatments, with RT+TKI ranking first in the Bayesian ranking. The integrated analysis found that RT+TKI had the longest OS (65.7 months, 55.5-76.0 months) and PFS (21.8 months, 18.0-25.7 months) and the highest response rate (77.7%, 68.8%-86.6%). Severe neutropenia was the most common with CRT+TKI, while RT+TKI brought the highest incidences of radiation pneumonitis and esophagitis. **Conclusions:** For EGFR mutant Stage III unresectable NSCLC, RT and TKI are both essential. RT+TKI and CRT+TKI have significantly longer PFS than CRT±immunotherapy, and RT+TKI has OS benefit trends. Due to the lack of sufficient studies on CRT+TKI, it is urgent to conduct large randomized clinical trials to explore the optimal treatment for these patients. Research Sponsor: None.

The use of artificial intelligence with uncertainty estimation to predict lung cancer relapse from histopathology. *First Author: James M Dolezal, University of Chicago, Chicago, IL*

Background: First-line treatment of early stage non-small cell lung cancer (NSCLC) is surgical resection, but with a 5-year survival of only 54%, rates of future relapse are high. Identifying patients at high risk of relapse can help guide adjuvant treatment decisions. Deep convolutional neural network (DCNN) AI models trained on tumor histology have shown incredible flexibility as potential biomarkers, both in lung cancer and more generally across many malignancies. While DCNN models can obtain extremely accurate results when used for routine purposes such as diagnosis, subtyping, and grading of malignancies, most models trained for prognostication or treatment response prediction do not reach performance sufficient for clinical application. Uncertainty quantification (UQ) – a family of techniques that give DCNN models the ability to report confidence alongside predictions – is an underexplored avenue in cancer AI that may help further improve performance and clinical application of models designed to provide clinicians with estimations of risk. **Methods:** To explore the potential use of UQ in clinically-oriented DCNN models, we trained models on a single-institution, retrospective digital tumor histology slide cohort from patients with Stage I-III NSCLC who underwent surgical resection to predict risk of future relapse. Estimation of uncertainty was performed using dropout as a Bayesian approximation, and uncertainty thresholds were calculated from training sets using a novel method to identify and remove low-confidence predictions. For comparison, a separate multivariate logistic regression was trained in cross-validation using known clinical risk factors. **Results:** We trained DCNN models on slides from 198 patients (40 relapsed, 158 without relapse). In this cohort, 130 patients had stage I disease (65.6%), 42 had stage II (21.2%), and 26 had stage III (13.2%). The average age was 69 years, 85% were current or previous smokers, and 38 received guideline-concordant adjuvant chemotherapy. Without UQ, a DCNN model predicted risk of future relapse with an average area under receiver operator curve (AUROC) of 0.74 across three-fold cross-validation. Using UQ estimation, 63% of slides were reported with high confidence. Relapse prediction was significantly improved in the high-confidence cohort, with an average AUROC of 0.83 in cross-validation. With a specificity of 70%, this corresponds to an average sensitivity of 86.8% across the three cross-folds (79.1%, 85.5%, and 95.7%). In comparison, a clinical-only multivariate regression model predicted relapse with a cross-validated AUROC of 0.67. **Conclusions:** This method of uncertainty quantification appears to be a powerful tool to predict lung cancer recurrence risk from digital histopathology while simultaneously providing clinicians with a measurement of algorithm trustworthiness. Effect of durvalumab in patients with unresectable stage 3 non–small cell lung cancer post-chemoradiotherapy. *First Author: Aswani Thurlapati, Department of Internal Medicine, LSU Health Science Center, Shreveport, LA*

Background: The PACIFIC study (PS) concluded that the use of durvalumab from 1 to 42 days after concurrent chemoradiotherapy (CXRT) in stage 3 unresectable non-small cell lung cancer (NSCLC) increased the median overall survival (mOS) from 29 to 48 months. It also showed a benefit in tumors with PD-L1 <25%. However, a post-hoc analysis of the PS showed no survival benefit with durvalumab in patients with PD-L1 <1% but was not statistically powered. Currently in the US, durvalumab is approved irrespective of PDL-1 percentage, whereas in Europe it is not approved for tumors with PDL-1 <1%. Also, there was no survival benefit in starting durvalumab within and after 2 weeks of CXRT. Our objectives in this study are to analyze the impact of PDL-1 expression and the date of initiation of durvalumab post CXRT on mOS. **Methods:** We conducted a retrospective observational study of stage 3 unresectable NSCLC patients who received durvalumab post CXRT at LSU Health Shreveport from 2018 to 2021. A survival analysis was done including the following variables: age, race, sex, tumor histology, tumor PD-L1 percentage, and date of initiation of durvalumab post CXRT. P-value <0.05 was considered statistically significant. **Results:** We identified 83 patients who received durvalumab after CXRT for treatment of stage 3 unresectable NSCLC. Baseline characteristics are provided in table 1. Among all the tumors, 25% had a PDL-1 <1%. 33% of the study population received durvalumab less than 30 days after CXRT and 67% received it after 30 days. The mOS was not impacted by race, sex, or tumor hisotology. Compared to higher PDL-1 percentage, patients with PD-L1 <1% had a statistically significant lower survival probability. At 14 months, 87% of patients with a PD-L1 <1% were alive compared to 100% in those with a PD-L1 1-50% or a PD-L1 >50%. Less than 35% of patients with PD-L1 <1% survived beyond 30 months compared to 45% for PD-L1 1-50% and 100% for PD-L1 >50% (p-value 0.02). Patients who received durvalumab 30-60 days after concurrent CXRT had a lower OS at 30 months compared to those who started before 30 days (44% versus 90%). However, statistical significance was not reached (p-value 0.45). **Conclusions:** This study demonstrates that patients with a PD-L1 tumor expression of <1% had a statistically significant lower survival probability compared to those with a PD-L1 expression of 1-50% and > 50% in this patient population. Time from CXRT to the start of durvalumab was not shown to affect survival outcomes. Research Sponsor: None.

Equity for under-served populations in lung cancer screening and treatment: Does mobile low-dose CT scanning lead to stage shift and diagnosis with potential cures at 4 years of follow-up? *First Author: Derek Raghavan, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: Randomized trials proved that screening high-risk patients with LDCT of chest reduces lung cancer mortality. Under-served patients have missed this benefit in most studies through access issues. We showed that mobile LDCT improves access and now assess if this translates to equity of survival. **Methods:** We used two coaches with BodyTom © portable 32 slice low-dose CT scanners (Samsung) to screen uninsured and under-served heavy smokers for lung cancer (Oncologist, 2019). All films were reviewed by central panel using LUNG RADS technique. Protocol was approved by Advarra IRB. Medicare pts were excluded as insurance covered them for LDCT (causing negative bias for diagnosis as the elderly are at high risk). **Results:** We initially screened 1200 uninsured/under-insured subjects, mean age 61 years (range 55-64), with average pack year history of 47.8 (30-150); 61% male; 18% Black, 3% Hispanic/Latino; 78% rural. We found 97 pts with LUNG RADS 4 (high risk) lesions, 30 lung cancers (2.5%), including 18 at stage I-III treated with curative intent (60%); 5 incidental non-lung cancers (renal CA 2, head & neck CA 1, pancreas CA 2); > 50% with intercurrent cardiovascular disease and COPD seen on LDCT. Of eligible first-screen subjects, 51% attended 12 month repeat LDCT and 27% attended third LDCT. One pt (6%) treated with curative intent has relapsed to date (median follow up 2.5 years, with 25% beyond 3 years). An additional 288 screened pts revealed 9 lung cancers (5 stage I-III), confirming shift to early stage disease at diagnosis. **Conclusions:** Mobile LDCT yields higher screening rate for under-served pts than prior hallmark trials, with shift to early-stage detection of lung cancer, with sustained treatment-induced remissions beyond 4 years. This approach could be applied to improve national lung cancer survival in the under-served. Research Sponsor: BMS Foundation; Leon Levine Foundation.

Epidemiology and clinical impact of EGFR mutation in patients with lung cancer after radical surgical treatment. *First Author: Maciej Bryl, E.J. Zeyland Wielkopolska Center of Pulmonology and Thoracic Surgery, Poznan, Poland*

Background: The epidemiology of epidermal growth factor receptor (EGFR) mutation in lung adenocarcinoma and its clinical impact are well-known. However, most studies have focused on advanced-stage inoperable cancer. Data on the frequency of EGFR mutation in surgically resected lung cancer are limited. Recent studies have shown a promising effect of Osimertinib in adjuvant settings. Hence, the need to estimate the target population in the real-world data. This study aimed to assess the occurrence of EGFR mutation in patients after radical surgical treatment of lung adenocarcinoma and explore its prognostic impact compared to EGFR negative group. **Methods:** This single-center retrospective analysis included the group of 732 consecutive Caucasian patients with histopathologically confirmed lung adenocarcinoma, evaluated for EGFR mutations expression, who underwent anatomical resection between January 2016, and December 2020. EGFR status was assessed by cobas EGFR mutation test v2. The frequency of EGFR mutations, disease-free survival (DFS) and overall survival (OS) in EGFR positive and EGFR negative groups were analyzed. **Results:** EGFR mutations were found in 65 surgical patients (8.9%) and did not differ from patients with advanced stages of lung adenocarcinoma (7.9%). EGFR mutations occurred more frequently in females than males, 48 out of 344 (14%) and 17 out of 388 (4.4%), respectively. Deletions within exon 19 and the L858R mutation in exon 21 constituted 49.2% and 24.6% of all mutations, respectively, while others comprised 26.2%. One case of L858R mutation coincided with T790M in exon 20 mutation. Detailed results divided by stages are presented in the Table. The occurrence of EGFR mutation had no significant influence on DFS and OS in patients after radical resection. **Conclusions:** The frequency of EGFR mutation in postoperative lung cancer was comparable to the occurrence in the general lung cancer population. EGFR mutation did not affect DFS and OS in patients after radical resection. Research Sponsor: None.

Summary of the EGFR mutation results by stage.

Stage[1]	EGFR mutation-positive patients [n (%)]	Total numer of patients
IA	12 (7.3)	165
IB	20 (10.2)	196
IIA	5 (10.9)	46
IIB	8 (5.9)	136
IIIA	16 (10.8)	148
IIIB	4 (9.8)	41

Lung cancer risk in persons enrolled in low-dose CT screening (LDCT) versus incidental lung nodule programs (ILNP).

First Author: Wei Liao, Baptist Cancer Center, Multidisciplinary Thoracic Oncology Department, Memphis, TN

Background: LDCT screening saves lives, but <10% of eligible persons participate; eligibility criteria are imperfect; geographic, racial and socio-economic disparities have emerged. ILNP may expand access to early detection. We compared rates of lung cancer diagnosis in LDCT and ILNP population subsets. **Methods:** Prospective observational cohort study of enrollees in LDCT and ILNP in a community healthcare system in AR, MS and TN. We compared LDCT vs 4 ILNP cohorts (C) based on USPSTF 2021 LDCT eligibility criteria: <50 years (C1, too young); >80 years (C2, too old); 50 – 80 years (C3, ineligible smoking history); 50 – 80 years (C4, eligible). For certain analyses, we stratified the LDCT cohort by baseline (T0) Lung-RADS score (0-2 v 3-4). We used a Cox model to calculate crude and adjusted hazard ratios (aHR) for lung cancer diagnosis within 24 months of enrollment. **Results:** From 2015-2021, 7050 persons were in LDCT- 6073 (86%) Lung-RADS 0-2 (no/benign lesions), 977 (14%) Lung-RADS 3 or 4 (possibly malignant lesion) on T0 scan; 17,579 were in ILNP, 16%, 10%, 57% and 16% respectively in C1-4. Demographics and tobacco use history of the ILNP cohorts differed strikingly; C4 was very similar to LDCT (Table). Black persons were significantly more in C1 (too young) and C3 (insufficient tobacco use). Diagnosis of lung cancer at 36 months ranged from 1% in C1 to 15% in C4, compared to 3% in LDCT; aHR for lung cancer diagnosis within 2 years ranged from 0.23 to 5.12 (all LDCT ref), but ranged from 0.04 to 1.02 with reference to LDCT Lung-RADS 3-4. Most patients in LDCT and ILNP C2-4 had early stage. There were proportionately more Black lung cancer patients in C1-4, and 3 times more Black patients in C3 and 4 than in LDCT. **Conclusions:** ILNP provides early-detection access to a larger, more diverse population than LDCT, potentially alleviating race and socio-economics-based outcomes disparities. Research Sponsor: None.

Treatment interruptions and discontinuations among patients with stage III unresectable non–small cell lung cancer treated with durvalumab at the Veterans Health Administration.

First Author: Munaf Alkadimi, University of Texas Health science center at San Antonio, San Anonio, TX

Background: The PD-1/PD-L1 pathway is a mechanism of immune evasion and disruption of this pathway with immune checkpoint inhibitors (ICIs) has shown clinical benefit in multiple malignancies. Based on results from the PACIFIC trial, durvalumab is approved as consolidation therapy in patients (pts) with stage III unresectable non-small cell lung cancer (UR-NSCLC) without progression following concurrent chemoradiotherapy (cCRT). Durvalumab has been used extensively in Veterans Health Administration (VHA) facilities, providing an opportunity to evaluate durvalumab treatment interruptions (TI), treatment discontinuations (TD), and the reasons for these on a national scale. **Methods:** Patients with stage III UR-NSCLC receiving durvalumab consolidation immunotherapy at the VHA between January 1, 2017 and June 30, 2020 with a minimum follow up for 12 months were included using ICD-10, HCPCS, and J codes and followed from their durvalumab start date through the earliest of last VHA visit, loss to follow up, death, or end of study (excluded if durvalumab therapy was ongoing at the end of the study, because the full treatment course could not be determined). TI were defined as durvalumab infusions separated by >28 days. Reasons for TI and TD are presented descriptively. Durations are reported using medians and interquartile ranges (IQR). **Results:** 935 pts were included (median age = 69 years; 95% males; 96% current or former smokers; 70% with COPD; histologies [squamous (50%), non-squamous (43%), other/missing (7%)]; and 77% with carboplatin-paclitaxel as their platinum-based CRT). Durvalumab TI were experienced by 19% of pts (median [IQR] number of TI = 1 [1-1], median [IQR] TI duration = 53 days [39-90]). The main reasons for TI were toxicity (8%) and social reasons (3%) (Table). The median duration of treatment (DoT) with durvalumab (TI included) was 9.0 months (IQR 2.9-11.8). Durvalumab TD occurred in 59% of pts. Top reasons for discontinuation across all 935 pts included disease progression (24%) and toxicity (18%) (Table). **Conclusions:** In this real world analysis of national VHA data, durvalumab DoT was similar to PACIFIC despite having a patient population with worse prognostic factors (e.g. more males, squamous, COPD) with 8% of VHA pts experiencing TI and 18% TD due to toxicity. Patients could benefit from additional efforts to prevent, identify, and manage toxicities in the UR-NSCLC population Research Sponsor: Astrazeneca.

Reported reasons* for durvalumab TI and TD.

	TI % of all (N=935) patients	TD % of all (N=935) patients
Progression	<1 %	24%
Toxicity	8 %	18 %
Patient preference	1 %	6 %
Physician preference	1 %	1 %
Death		4 %
Decline in performance status	1 %	2 %
Social reasons	3 %	<1 %

Texture-based CT radiomics distinguishes radiation and immunotherapy induced pneumonitis in stage III NSCLC.

First Author: Lukas Delasos, Cleveland Clinic Foundation, Cleveland, OH

Background: Recent changes to the standard of care for unresectable stage III NSCLC include chemoradiation followed by consolidative immunotherapy (IO). Pneumonitis is a well-known complication of radiotherapy (RT) and has been increasingly reported in association with IO. Although rare, pneumonitis can cause severe morbidity and possibly death in extreme cases. Differentiating RT and IO-induced pneumonitis (RTP vs IOP) is crucial for acute management and future considerations of individualized treatment. However, the clinical and radiological features of RTP and IOP may be similar and often indistinguishable on computed tomography (CT). Texture-based CT radiomics has previously been used to distinguish benign and malignant nodules on lung CT. In this study, we explore if radiomic features extracted from lung CT can distinguish between RTP and IOP. **Methods:** From 236 patients with stage III NSCLC who underwent chemoradiation followed by consolidative durvalumab, we identified 110 cases of treatment-related pneumonitis. IOP cases were identified through a retrospective review of electronic medical records and independently verified by a thoracic oncologist using features such as bilateral lung involvement, inflammatory changes outside the field of RT, temporal relationship to IO, and response to treatment. Inflammatory lesions were manually annotated using Slicer 3D. After excluding cases without discernible cause and non-identifiable lung lesions (n = 61), we included 49 cases in the study (RTP n = 20; IOP n = 29). A total of 555 features from Gabor, Laws, Laplace, and Haralick feature families were extracted on a pixel level from post-treatment CT images. A support vector machine (SVM) classifier was trained with the most discriminating features identified by Wilcoxon rank-sum test feature selection method. The classifier performance for distinguishing RTP vs. IOP was assessed by averaging the area under the receiver operating characteristic curve (AUC) values computed over 100 iterations of threefold cross-validation. **Results:** We identified the top 5 radiomic texture features distinguishing RTP from IOP including Haralick entropy, Haralick info, Laws median, and high- and low-frequency Gabor. Using 3-fold cross-validation, the SVM classifier model built on the radiomic features achieved an AUC of 0.83 (95% confidence interval, 0.78 - 0.86). **Conclusions:** Pneumonitis is a severe complication of both RT and IO that must be taken into consideration when evaluating future risks of IO-based therapies. The distinction between RTP and IOP remains challenging based on CT findings alone. Radiomic texture features analysis of post-treatment CT images can potentially differentiate RTP from IOP in stage III NSCLC patients who received RT followed by consolidative durvalumab. Additional multi-site independent validation of these quantitative image-based biomarkers is warranted. Research Sponsor: None.

Durvalumab treatment initiation delays in patients with unresectable stage III non–small cell lung cancer treated at Veterans Health Administration facilities.

First Author: Paromita Datta, South Texas Veterans Health Care System, San Antonio, TX

Background: Durvalumab is an FDA-approved immunotherapy for the treatment of adults with UnResectable stage III non-small cell lung cancer (UR-NSCLC) without disease progression following concurrent chemoradiotherapy (CRT). There are limited real-world data regarding Durvalumab treatment initiation delays (TIDs) and reasons for them in the UR-NSCLC population. **Methods:** Patients with stage III UR-NSCLC receiving consolidation Durvalumab at the Veterans Health Administration (VHA) between January 1, 2017 and June 30, 2020 were selected from the VHA database using ICD-10, HCPCS, and J codes. All had the opportunity to be treated for 12 months and were followed from Durvalumab initiation through the earliest of their last VHA visit, loss to follow up, death, or the study's end (and excluded if Durvalumab therapy was ongoing at the study's end). Trained data abstractors determined the occurrence and reasons for TIDs (> 6 weeks from end of CRT to initiation of Durvalumab as in the PACIFIC trial) by chart review. **Results:** 935 patients were eligible for analysis (median age = 69 years; 95% males; 16% with ECOG performance status >1). TIDs occurred in 39% of the patients (Table). Durvalumab was initiated 61 days (median) from the end of CRT in TID patients vs. 31 days for those without TIDs. There were no significant (α<0.05) differences in age, race, smoking status, histology, or ECOG performance status and no comorbidity differences (except in patients with a history of cerebrovascular accident, for whom TIDs were more likely) between the TID/No-TID patients. Patients without timely post-CRT scans were more likely to have a TID. Of the 367 patients who experienced TIDs, 200 had documented reasons for the delay, consisting of other (not categorized) (28.5%), physician preference (20%), toxicity (11%), patient preference (10.5%), decline in performance status (10%), system issues (9.5%), social reasons (9%), and progression (0.5%). **Conclusions:** This is one of the largest retrospective cohort studies reporting real-world data in patients with UR-NSCLC receiving Durvalumab. TIDs were associated with increased time to post-CRT scans. This potential issue can be improved with care coordination and involvement of cancer navigators. Additional studies are needed to assess the impact of TIDs on survival outcomes. Research Sponsor: AstraZeneca.

Times to post-CRT scans and treatment patterns among TID vs. No-TID patients.

	TID (n=367)	No-TID (n=568)	P-value
Time from end of CRT to first scan, median days (IQR)	39 (25-56) n=329	28 (18-35) n=478	<0.01

Clinical activity of pembrolizumab monotherapy in diffuse malignant peritoneal mesothelioma. *First Author: Xiao Wang, University of Pennsylvania, Philadelphia, PA*

Background: Among patients with malignant mesothelioma, pembrolizumab has demonstrated activity in diffuse pleural mesothelioma (DPM), with limited data available for those with diffuse malignant peritoneal mesothelioma (DMPM). DMPM represents a clinically distinct entity from DPM and disease specific outcomes data is needed. We present real world data on the efficacy of pembrolizumab in DMPM. **Methods:** In this retrospective study, we identified patients with DMPM treated with pembrolizumab at two tertiary care cancer centers between 1/1/2009 and 1/1/2021. Clinicopathologic features were annotated. Median progression free survival (mPFS) and median overall survival (mOS) were calculated using Kaplan-Meier curves. Best overall response rate (BOR) was determined using RECIST 1.1 criteria. Association of partial response with disease characteristics was evaluated using Fisher's exact test. **Results:** We identified 24 patients with DMPM who received pembrolizumab (median age 62 years, 63% never smokers, 58% female, 75% had epithelioid histology). All patients received systemic chemotherapy prior to pembrolizumab (median prior lines of therapy: 3). BOR was 17% (3 partial responses, 10 stable disease, 5 progressive disease, 6 lost to follow-up). With a median follow up time of 29.2 months, mPFS was 4.9 months and mOS 20.9 months from pembrolizumab initiation. Three patients experienced PFS of > 2 years. Among the 14 patients who underwent next generation sequencing of tumor tissue, there were 8 somatic BAP1 alterations. Among the 17 patients tested for PDL1, 6 had positive PDL1 expression (1-80%). There was no association between partial response and presence of a BAP1 somatic alteration (p = 0.453), PDL1 positivity (p = 0.7) or non-epithelioid histology (p = 0.55). **Conclusions:** Pembrolizumab is active in a PDL1 unselected cohort of patients with DMPM. The overall response rate of 17% and mPFS of 4.9 months in this 75% epithelioid histology cohort warrants further investigation to identify those most likely to respond to immunotherapy, especially among epithelioid histology. Research Sponsor: This research was supported, in part, by the National Institutes of Health/National Cancer Institute (P30 CA008748).

Positive impact of academic center care on overall survival in malignant pleural mesothelioma (MPM): A National Cancer Database (NCDB) socioeconomic factor analysis. *First Author: Logan Roof, Cleveland Clinic, Cleveland, OH*

Background: MPM is a rare cancer with a poor prognosis. Median survival for untreated patients is 4-13 months, and for treated patients is 6-18 months. Despite asbestos regulations in the United States, annual deaths from MPM rose from 2,479 in 1999 to 2,597 in 2015. Given recent treatment advances, including improvements in multimodality therapy and the introduction of immunotherapy as a treatment option in the frontline setting, the impact that patient demographics and treatment factors have on survival outcomes for MPM requires further evaluation. **Methods:** We identified all patients with MPM in the NCDB from 2004 to 2017. Differences in demographic, disease, and treatment characteristics were assessed by year of diagnosis using Chi-square test. The effect of age, race, insurance status, income, distance to treatment center, and education level on overall survival (OS) was assessed by log-rank test. **Results:** There were 15,287 MPM diagnoses in the NCDB between 2004-2010 and 17,059 diagnoses between 2011-2017. OS improved between the two time periods, with median OS of 9.46 months (95% CI: 9.23-9.63) and 5-year OS rate of 8.3% (95% CI: 7.9-8.7%) in patients from 2004-2011 and median OS of 11.33 months (95% CI: 11.01-11.7) and 5-year OS rate of 12.4% (95% CI: 11.8-13.1%) in patients after 2011, despite an increase in stage IV disease in the latter group. Older patients (≥65 years-old), males, patients with stage IV disease, patients with government primary payer insurance, and patients from urban areas all had significantly worse OS. Patients without comorbidities and those treated at an academic center had significantly better OS. OS was found to significantly increase as both income and education level increase. Patients diagnosed after 2011 were significantly older, were more frequently female, had more stage IV disease, were more frequently treated at academic centers, more commonly had government primary payer insurance, and lived significantly further away from their treatment center. Patients' time to treatment was significantly increased after 2011 (from 28 to 31 days). **Conclusions:** Socioeconomic factors play an important role in survival outcomes for patients with MPM. Many of these are linked with access to healthcare resources, which may increase the likelihood of evaluation at academic centers. For a rare malignancy such as mesothelioma, subspecialty care consisting of a comprehensive thoracic surgical evaluation and appropriate multimodality treatment are of great importance. Time to treatment increased during the study period yet OS improved, which our findings suggest are a result of an increase in evaluation and treatment at academic centers by providers skilled in delivering care to MPM patients. Phase I clinical safety and preliminary efficacy of PD-1-mesoCAR-T cells in the treatment of malignant pleural/peritoneal mesothelioma. *First Author: Qing Xu, Department of Oncology, Shanghai Tenth People's Hospital, Tongji University School of Medicine, Shanghai, China*

Background: Malignant pleural/peritoneal mesothelioma (MPM) is an aggressive cancer characterized by poor therapeutic response and poor survival. Programmed cell death protein-1 (PD-1)-mediated immunosuppression is believed to be associated with T cell exhaustion and dysfunction in solid tumors. We generated chimeric antigen receptor (CAR-T) cells that can secret PD-1 nanobodies and target mesothelin (PD-1-mesoCAR-T). After identifying the anti-tumor activity and cytotoxicity of PD-1-mesoCAR-T cells by pharmacokinetics and pharmacodynamics, we conducted a proof-of-concept clinical trial in the Shanghai Tenth People's Hospital affiliated to Tongji University and the Mengchao Tumor Hospital affiliated to Shanghai University to evaluate the safety and efficacy of PD-1-mesoCAR-T cells in a dose-escalation study for malignant pleural/peritoneal mesothelioma. 6 patients received one or more infusions of the CAR-T cells with prior lymphodepletion and the longest survival is up to 18 months. **Methods:** This open-label, single-arm, multicenter, phase 1 study was enrolled patients with pathological diagnosis with malignant mesothelioma whose mesothelin expression in immunohistochemical samples was equal or greater than 50%. Immunohistochemical samples derived from surgical tissue, puncture tissue or pleural effusion. PD-1-mesoCAR-T cells were administered intravenously ranging 1×10^6–1.5×10^7/kg. Safety and efficacy were assessed in response-evaluable patients (ie, patients who received at least one dose of PD-1-mesoCAR-T and had at least one post-baseline response evaluation). **Results:** From July 20, 2020 to January 31, 2022, 9 patients were screened and enrolled and only 6 patients were evaluable. Mesothelin positive rate in the samples of these patients were from 50% to 100%. Three patients of them had PD-L1 positive staining in specimen. All patients underwent lymphodepletion before infusion. Two of patients (33.3%) had cytokine release syndrome, which were grade 1 and grade 3, respectively. Four patients (66.7%) developed fever. Two patients (25%) had grade 3 pulmonary infection. Stable disease was sustained for ≥3 months in 5 patients; 1 exhibited complete response and one partial response on PET or CT scan. The objective response rate (ORR) was 33.3%, but increased to 66.7% in the patients with PD-L1 positive. Only one patient of these patients appeared progression of disease after infusion. All enrolled patients are alive and observed continually. **Conclusions:** The clinical study of 6 patients with malignant mesothelioma shows that PD-1-mesoCAR-T cells are safe and feasible, indicating a promising curative effect. Effect of the CAR-T cells on the long term survival will be observed continually. Clinical trial information: 01722149. Research Sponsor: Shanghai Cell Therapy Group.

Atezolizumab and bevacizumab in patients with relapsed mesothelioma: MIST4—a phase IIa trial with cellular and molecular correlates of efficacy. *First Author: Dean Anthony Fennell, University of Leicester, Leicester, United Kingdom*

Background: Targeting the PD1-PDL1 axis has demonstrated significant efficacy in patients with relapsed malignant mesothelioma (MM) however the factors that determine sensitivity are unknown. Combined inhibition of vascular endothelial growth factor (VEGF) may potentiate efficacy through remodelling of the tumour microenvironment and inhibition of angiogenesis. We therefore developed a multi-centre molecularly stratified phase IIa trial to test this hypothesis and to uncover cellular and molecular determinants of efficacy as arm 4 of the Mesothelioma Stratified Therapy umbrella trial (NCT03654833, MiST4). **Methods:** Patients with any histological subtype or site of MM (pleural or peritoneal) were enrolled. Key inclusion factors: histological confirmation of MM with an available archival tissue block, ECOG performance status 0-1, prior platinum-based 1st line chemotherapy (any line allowed), evidence of disease progression with measurable disease by CT (RECIST 1.1), and adequate haematological/organ function. Patients received Atezolizumab 1200mg iv q3w with bevacizumab 15mg/kg iv q3w (AtzBev). Primary endpoint was disease control rate at 12 weeks (DCR12w). The null hypothesis was rejected if ≥ 11 patients had disease control (A'Hern design). Secondary endpoints: DCR at 24 weeks (DCR24w), best objective response rate and toxicity (NCI CTCAE 4.03). Patients could undergo an optional re-biopsy upon disease progression. Baseline BAP1, p16ink4a, PD-L1 (DAKO22C3), gut microbiome 16s RNA metagenomics, multiplex immunofluorescence, and whole exome and RNA transcriptome sequencing was conducted to explore cellular and molecular correlates of sensitivity. **Results:** Between January 2020 and February 2021, 26 patients with MM started treatment and received at least one dose of AtzBev. The median age of pts was 68 (range, 44-80) years, 69% were male, 77% epithelioid, 85% ECOG PS1, > 1 prior systemic therapy 54%. The median cycles of Atz dosing was 4.5 (IQR, 2-8) and Bev dosing was 4.5 (IQR, 2-7). DCR12w: 53.8% (95% confidence limit (CI), 33.4% – 73.4%), DCR24w: 23.1% (95%CI, 9.0% – 43.6%). Best responses (evaluable within 24w): partial – 3.8% (95%CI, 0.1- 19.6%); stable disease – 69.2% (48.2 – 85.7%); progression – 15.4% (4.4 – 34.9%). Adverse events (any cause): ≥ grade 3 toxicities affected 35% of pts. **Conclusions:** MiST4 met its primary endpoint however responses were heterogeneous. Analysis of cellular and molecular correlates are ongoing and will be presented. Clinical trial information: NCT03654833. Final survival outcomes and immune biomarker analysis of a randomized, open-label, phase I/II study combining oncolytic adenovirus ONCOS-102 with pemetrexed/cisplatin (P/C) in patients with unresectable malignant pleural mesothelioma (MPM). *First Author: Santiago Ponce, Medical Oncology, Hospital Universitario 12 Octubre,, Madrid, Spain*

Background: MPM is an aggressive malignancy without curative treatment. ONCOS-102 is an oncolytic adenovirus expressing GM-CSF (Ad5/3-D24-GMCSF) with a clinically documented ability to stimulate local and systemic immune responses and remodulate the tumor microenvironment, both as a monotherapy and in combination with anti-PD1 blockade. The study objectives included determining safety and tolerability, efficacy and immunological activation in repeat tumor biopsies, and correlations with clinical outcomes. **Methods:** Following a safety run-in of n = 6 pts, 25 patients were randomized to receive ONCOS-102 intratumorally under CT or US guidance at a dose of 3×10^{11} Virus Particles on Day 1, 4, 8, 36, 78 and 120, plus six cycles of P/C starting on Day 22, or control comprising six cycles of P/C only. Both treatment-naïve (1L) and previously treated patients (2L) were enrolled. Imaging was done at baseline, Day 43-64 and 127-148 and tumor biopsy were collected at baseline and at Day 36. Final survival analysis (n = 25) was performed after 30 mo follow up. Multiplex immunofluorescence for immune cell subsets, RNASeq and qPCR was performed on repeat tumor samples. **Results:** The most frequent adverse events were anaemia, neutropenia and asthenia reported by > 50% in both groups with more frequent reports of pyrexia and nausea in the experimental (exp) group. No difference in the rate of severe events (Gr 3/4 acc to NCI CTCAE vs 4.0) were observed. 30-month survival rate (n = 25) was 34.3 % vs 18.2 % (NS) with mOS of 19.3 mo (95% CI: 4.6, NA) vs 18.3 mo (95% CI: 3.1, 28.9) in the exp group vs control. For patients treated in the 1L setting, 30 mo survival was 33.3 % in the exp group (n = 8) and 0% in the control group (n = 6) with mOS of 25.0 months and 13.5 months, respectively (NS). mPFS was unchanged from prior cut-offs; 9.8 months in the exp group and 7.6 in the control (NS). ONCOS-102 + P/C induced a pronounced increase in tumor infiltration by CD4+, CD8+ and granzyme B expressing CD8+ T-cells as well as M1:M2 macrophage polarization in patients with disease control (n = 13) vs progressing patients (n = 3). The data from RNAseq and qPCR analysis will be presented. **Conclusions:** The addition of ONCOS-102 to P/C was well tolerated by MPM patients and resulted in numerically improved 30-month survival rate in the overall population, and improved mOS in chemotherapy-naïve patients, albeit not statistically significant. Substantial immunological activation in tumor associated with ONCOS-102 was demonstrated, correlating with clinical benefit. Further exploration of ONCOS-102 as a treatment option in MPM is warranted Clinical trial information: NCT02879669. Research Sponsor: Targovax ASA.

PD-L1, VISTA, and CD47 expression and prognosis impact in malignant pleural mesothelioma. *First Author: Mercedes Herrera, Department of Medical Oncology, Hospital Universitario 12 de Octubre, Madrid, Spain*

Background: Malignant Pleural Mesothelioma (MPM) has been characterized by an immune suppressive microenvironment. The immune checkpoint (IC) VISTA is notably expressed in MPM, in contrast to other IC proteins such us PD-L1. Recently, CD47 has been described as a possible diagnostic biomarker for MPM, although its impact in prognosis has not been established yet. **Methods:** This is a retrospective observational study of immunotherapy naïve MPM patients. Immunochemistry (IHC) assessment of PD-L1, VISTA and CD47 protein expression was performed on tissue microarray of 46 surgical samples. Means were compared using Mann-Whitney U test. Correlation was estimated using Pearson's coefficients. Overall survival (OS) was assessed using Kaplan–Meier curves and Cox proportional hazard models. A two-sided alpha error of 0.05 was used to assess statistical significance. Statistical analysis was conducted with Stata/SE version 16.1. **Results:** A total of 46 patients, 71.7% (33/46) male, were included in our study. Among them, 77.8% (35/45) had stage IIIB-IV, 84.8% (39/46) had received systemic therapy and 16.7% (7/42) had undergone radical-intent surgery. Asbestos exposure was confirmed in 65,7% (23/35) patients. Regarding the histological subtype, 71.7% (33/46) were epithelioid (Ep) and 13.0% (6/46) non-epithelioid (NEp), including 5 sarcomatoid and 1 biphasic. In IHC analysis, VISTA and CD47 were expressed in 63.0% (29/46) and 58.7% (27/46), respectively, whereas only 28.3% (13/46) patients had positive PD-L1 expression (≥1%). Median expression of VISTA, CD47 and PD-L1 in tumor samples was 41.8 (95% IC 0.5 - 50.7), 26.3 (95% IC 0 - 45.8) and 0 (95% IC 0-0.5), respectively. VISTA and CD47 expression were significantly higher in the Ep subgroup vs. the NEp subgroup (VISTA 39.4% vs 7.2% p = 0.028; CD47 37.3 vs. 0.8 p = 0.01). Additionally, we found a significant positive correlation between VISTA and CD47 protein expression (Pearson's r = 0.55, p < 0.001), which was consistent with the results we found in an independent MPM patient series from TCGA PanCancer Atlas (N = 87) based on RNA expression (r = 0.46; p < 0.001). Median OS, available in 40/46 cases, was 16.6 months (95% CI 12.03-20.43). On multivariate analysis, CD47 ≥1% expression was significantly associated with longer OS (29.7 vs 10.53 months, HR 0.35, [IC 95% 0.14-0.86]; p = 0.02) after adjusting for histological subtype, PDL1 and VISTA expression. In contrast, PD-L1 ≥1% showed a trend towards worse prognosis (10.3 vs 19.3 months), without reaching statistical significance (HR 2.23 [95% IC 0.95-5.23]; p = 0.065). No OS differences were found regarding VISTA expression. **Conclusions:** To our knowledge, this is the first study to describe VISTA and CD47 correlation in MPM. Moreover, we demonstrate CD47 expression to be an independent prognostic marker in MPM, suggesting C47 may play a key role in tumor biology of MPM, for which further validation and functional studies are necessary. Research Sponsor: None.

Safety and efficacy of SHR-1316 combined with chemotherapy and sequential chest radiotherapy as first-line therapy for extensive-stage small cell lung cancer (ES-SCLC): The results from a phase II single-arm trial. *First Author: Dawei Chen, Shandong Cancer Hospital Affiliated to Shandong University, Jinan, China*

Background: Impower133 and CASPIAN studies showed that PD-L1 antibody combined with first-line chemotherapy could prolong the overall survival. Previous studies have shown that radiotherapy could potentially promote tumor antigen presentation and reverse immunosuppressive microenvironment in tumor. The purpose of this study was to explore the efficacy and safety of SHR-1316 (PD-L1 antibody) combined with chemotherapy and sequential chest radiotherapy as first-line therapy for ES-SCLC. **Methods:** Key inclusion factors were 18-75 years old, histologically or cytologically confirmed ES-SCLC, ECOG performance status 0-1, no previous systematic treatment. Patients (pts) included in this study received 4~6 cycles of SHR-1316 (20mg/kg, D1, q3w) combined with EP/EC (cisplatin 75mg/m^2 D1-3 q3w or carboplatin AUC = 5, D1 q3w; etoposide 100mg/m^2, D1-5, q3w), sequentially SHR-1316 combined with chest radiotherapy (≥3Gy*10f or ≥2Gy*25f, involved- field irradiation), and then entered the maintenance treatment stage until disease progression or intolerable side effects. The main endpoints included PFS, ORR and safety. **Results:** From October 2020 to December 2021, 31 pts with ES-SCLC received at least one dose of SHR-1316. The median age was 64 (range: 37-75) with 25(80.6%) male, 22(71%) former smokers and 31 (100%) ECOG performance status 1. 17 (54.8%) pts were with brain metastasis, 8 (25.8%) pts with liver metastasis, 8 (25.8%) pts with kidney/adrenal metastasis, 7(22.6%) pts with bone metastasis. At the data cutoff date, 15 pts remained on treatment, the average number of treatment cycles was 5.19. 24 pts had at least one 1 post-treatment tumor assessment. The median PFS was 7.56 months, the confirmed ORR and DCR in all pts were 50% (12/24) and 87.5% (21/24), respectively. The confirmed ORR and DCR in pts with brain metastasis were 38.5% (5/13) and 76.9% (10/13), and were 63.6% (7/11) and 100% (11/11) in pts without brain metastasis. In pts received chest radiotherapy, the confirmed ORR and DCR were 80% (8/10) and 100% (10/10). During the study period, 23 (74.2%) pts had adverse drug reactions, and 16 (51.6%) pts had grade 3 or 4 adverse drug reactions, including 12 (38.7%) neutropenia 8 (25.8%) leukopenia, 2 (6.5%) thrombocytopenia, 2 (6.5%) anemia, 1(3.2%) lymphocytopenia, 1(3.2%) amylase increased. No grade 5 adverse drug reaction was observed. **Conclusions:** SHR-1316 combined with chemotherapy and sequential chest radiotherapy as first-line therapy for ES-SCLC showed promising efficacy and acceptable safety. It is worthy of further clinical exploration. Clinical trial information: NCT04562337. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co. Ltd.

Preliminary safety and efficacy of camrelizumab plus nab-paclitaxel and carboplatin as frontline setting in extensive-stage small cell lung cancer (ES-SCLC) from a phase II trial. *First Author: Shengxiang Ren, Oncology Department, Shanghai Pulmonary Hospital, Shanghai, China*

Background: Impower133 and CASPIAN studies showed that PD-L1 antibody combined with first-line chemotherapy could prolong the overall survival. Our previous study showed that nab-paclitaxel had a promising efficacy as later line setting in ES-SCLC. This phase II trial aimed to evaluate the efficacy and safety of camrelizumab plus nab-paclitaxel and carboplatin as front-line setting in ES-SCLC. **Methods:** Key inclusion factors were18-75 years old, histologically or cytologically confirmed ES-SCLC, ECOG performance status 0-1, no previous systematic treatment. Patients (pts) received 4 ~ 6 cycles of camrelizumab (200mg, D1, q3w) combined with nab-paclitaxel (230mg/kg, D1, q3w) plus carboplatin (AUC = 5, D1, q3w), then camrelizumab maintenance until disease progression or intolerable side effects. The primary endpoint was 6 months progression free survival rate. Secondary endpoints included PFS, ORR and safety. **Results:** From April 2021 to December 2021, 36 pts who received at least one dose of camrelizumab were included into this report. The median age was 60.5 (range: 32-73) with 30 (83.3%) males, 19 (52.8%) former smokers, and 36 (100%) ECOG performance status 1. The median drug exposure was 5 cycles, and 18 (50%) pts entered the maintenance stage. 33 pts had at least one 1 post-treatment tumor assessment. Among them, 32 partial responses (5 unconfirmed), 1 progressive disease (new lesion). The confirmed ORR was 81.8% (27/33), the unconfirmed ORR was 97% (32/33), DCR was 97% (32/33). The median PFS was 7.27 months (95% CI: 4.7 – 9.8 months). 24 (66.7%) pts had at least one adverse event, and 10 (27.8%) pts experienced grade 3 or 4 adverse events, including 10 (27.8%) neutropenia, 4 (11.1%) leukopenia, 2 (5.6%) thrombocytopenia, 2 (5.6%) anemia, 2 (5.6%) hepatic function abnormal,1(2.8%) alanine aminotransferase increased, 1(2.8%) hyperglycaemia, 1(2.8%) diabetes mellitus, and no grade 5 adverse event happened. **Conclusions:** Camrelizumab plus nab-paclitaxel and carboplatin had promising efficacy and safety profile as first-line setting in ES-SCLC, further validation is warranted. Clinical trial information: NCT04790539. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co. Ltd.

Phase I/II investigator-initiated study of olaparib and temozolomide in SCLC: Updated analysis and CNS outcomes. *First Author: Catherine Belle Meador, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Temozolomide has activity in small-cell lung cancer (SCLC), including patients (pts) with brain metastases (mets; Pietanza M, Clin Cancer Res 2012). Inhibition of Poly (ADP-ribose) polymerase (PARP) is another therapeutic strategy in SCLC. We hypothesized that olaparib plus temozolomide may be safe and effective for pts with relapsed SCLC and clinically active against CNS disease (Farago A, Cancer Discovery 2019). Here, we present an updated analysis of this combination in pts with relapsed SCLC, including a second cohort testing an alternative dosing strategy and an exploratory analysis of CNS-specific outcomes. **Methods:** In this phase I/II trial of olaparib plus temozolomide in pts with recurrent SCLC, pts were sequentially enrolled into two cohorts defined by dosing schedule. In cohort 1, olaparib was dosed on D1-7 of each 21d cycle. In cohort 2, olaparib was dosed on D1-21. Temozolomide was dosed on D1-7 in both cohorts. Each cohort had a phase I portion (conventional 3+3 dose-escalation) for determination of MTD and RP2D and a phase II portion with primary endpoint of ORR. Per protocol, eligible pts could have untreated asymptomatic brain mets < 1cm and, after mandatory baseline imaging, CNS imaging was performed at investigator's discretion. A post-hoc exploratory analysis of CNS-specific outcomes was performed using modified RECIST criteria (Long GV, Lancet Oncol 2012) in which brain mets ≥5mm were considered measurable, and intracranial response was independently assessed by an attending radiologist. **Results:** 66 pts with median of 2 prior lines of therapy (range, 1-7) were enrolled, 50 pts in cohort 1 and 16 pts in cohort 2. 33/66 (50%) pts had history of brain mets, 15/66 (23%) pts had untreated brain mets at enrollment. The confirmed ORR of cohort 2 was 7% (1/14 evaluable pts, 95% CI: 0.2-33.9%), and the updated confirmed ORR of the entire study population was 34% (21/62 evaluable pts, 95% CI: 22.3-47.0%). The most common adverse events were hematologic toxicities (thrombocytopenia, anemia, and neutropenia). 22/50 (44%) of cohort 1 pts and 4/16 (25%) of cohort 2 pts required dose reduction. Of 15 pts with untreated brain mets, best overall intracranial response (including both confirmed and unconfirmed responses) was CR in 6 pts, PR in 4 pts, SD in 3 pts and PD in 1 for a CNS disease control rate of 87% (95% CI: 59.5-98.3%). Of 10 pts with CR/PR as their best intracranial response, 4 responses were confirmed. With non-CNS progression as a competing risk, the probability of CNS progression among the entire study population was 17% (95% CI: 8.8-26.7%) at 6 months and 21% (95% CI: 12.1-32.0%) at 12 months. **Conclusions:** Olaparib and temozolomide may be an effective therapy for relapsed SCLC, especially for pts with CNS disease where we observed a high rate of intracranial disease control. Ongoing analyses regarding optimal dosing schedule will inform potential for future use of this combination. Clinical trial information: NCT02446704. Research Sponsor: AstraZeneca.

8566 **Poster Session**

Interim results of an ongoing phase 1/2a study of HPN328, a tri-specific, half-life extended, DLL3-targeting, T-cell engager, in patients with small cell lung cancer and other neuroendocrine cancers. *First Author: Melissa Lynne Johnson, Tennessee Oncology, Sarah Cannon Research Institute, Nashville, TN*

Background: HPN328 is a delta like canonical Notch ligand 3 (DLL3)-targeting T-cell engager (TCE) derived from the TriTAC platform, designed to minimize off-target toxicities. HPN328 contains 3 binding domains, engineered to redirect T cells to kill DLL3-expressing cancer cells: anti-DLL3 for target engagement, anti-CD3 for T-cell engagement, and anti-albumin for half-life extension. **Methods:** This ongoing Ph1/2a study is evaluating HPN328 in patients (pts) with metastatic small cell lung cancer (SCLC) and other neuroendocrine (NE) cancers associated with DLL3 expression. Eligible pts must have disease that is relapsed/refractory to standard systemic therapy. Primary endpoints are safety, tolerability, and determination of MTD/RP2D. Secondary objectives are pharmacokinetics (PK), pharmacodynamics, immunogenicity, and preliminary anti-tumor activity (RECIST 1.1). HPN328 is administered IV, once weekly. AEs are graded by CTCAE 5.0, and ASTCT for cytokine release syndrome (CRS). **Results:** As of Feb 3rd, 2022, 16 pts were enrolled in 8 dose-escalation cohorts at doses from 0.015mg to 12.0mg (SCLC n = 10 (62.5%); NE prostate cancer (NEPC) n = 2 (12.5%); other NE neoplasms (NEN) n = 4 (25%)). Median pt age was 61 (43-73) yrs. Pts received a median of 3 (1-5) prior treatments; 75% received a PD-1 blocker. At baseline, 6 pts (37.5%) had treated brain metastases and 8 (50%) had liver metastases. Median treatment duration was 10.6 (3.3-31.3 plus) weeks. Treatment is ongoing in 7 pts (44%; median 16.5 weeks). CRS was reported in 5 pts (31%); events were grade 1 or 2, occurred within 24 hrs of the 1st or 2nd dose and did not recur with rechallenge. No ≥ Grade-3 CRS occurred. No dose-limiting toxicities were observed, and no AEs led to discontinuation. HPN328 exhibited linear PK, with dose-proportional increases in exposure and a median half-life of 71 hrs. Small, transient increases in select cytokines and chemokines were observed up to 24 hrs post dose. T-cell activation and margination were observed, consistent with target engagement. DLL3 expression was confirmed on IHC analysis of most baseline biopsies. 15 pts were efficacy evaluable. 6 of 15 (40%) had decrease in sum of target lesion diameters (4 SCLC, 1 NEPC, 1 NEN). 3 of 9 (33%) SCLC pts across all doses had > 30% decrease (weeks on treatment: 17.2, 16.9 [ongoing], and 25.1 [ongoing, confirmed PR]). At doses ≥1.215mg, 2 of 4 (50%) SCLC pts had > 30% decrease and 1 had > 20% decrease. 4 pts (25%) had stable disease: 2 SCLC, 1 NEPC, 1 NEN (Thymic atypical carcinoid). **Conclusions:** HPN328 is a novel half-life extended DLL3-targeting TCE that is well tolerated and clinically active. AEs have been transient, manageable, and consistent with class. No ≥ Grade-3 CRS occurred. Tumor shrinkage has been observed, including 1 confirmed PR. Dose escalation is ongoing; updated data will be presented. Clinical trial information: NCT04471727. Research Sponsor: Harpoon Therapeutics, Inc.

Impact of underrepresented populations on clinical outcomes of chemo-immunotherapy for extensive-stage small cell lung cancer: Real-world prospective cohort study. *First Author: Motohiro Tamiya, Department of Thoracic Oncology, Osaka International Cancer Institute, Osaka, Japan*

Background: Chemo-immunotherapy is the standard 1st-line therapy for patients with extensive-stage small cell lung cancer (ES-SCLC). Prospective data about underrepresented populations outside the clinical trial such as elderly or poor risk has not been revealed. **Methods:** We conducted a 32-hospitals prospective cohort study of consecutive patients with ES-SCLC who received carboplatin and etoposide with atezolizumab as 1st-line therapy between September 2019 and September 2020. The primary outcome was 6-months progression-free survival (PFS) probability of all patients. The secondary outcomes were overall survival (OS), PFS, time to treatment failure, objective response rate, safety, and differences in efficacy and safety depending on whether or not the key eligible study criteria of previous trials are met. **Results:** In total, 207 patients with ES-SCLC were analyzed. The median age was 72 years, and 64 patients (31%) were elderly (≥75 years). Most patients (89%) had a performance status (PS) of 0 or 1. As a result, 132 (64%) was categorized as eligible patients. The 6-months PFS probability of all patients was 38.8 % (95%CI:32.4-45.7%). Between eligible and ineligible patients, there was significant difference of patients who attained disease control (93% versus 77%, p = 0.002). Median PFS was significantly longer in eligible patients than ineligible patients (5.1 vs. 4.7 months; P = .03, HR 0.72 (95% CI 0.53–0.97)), and median OS was longer in eligible patients than ineligible patients, without any significant difference (15.8 vs. 13.1 months; P = .10, HR 0.73 (95% CI 0.51–1.07)). Survival analysis identified a PS score of 0-1 (HR: 0.60, 95% CI: 0.39-0.97, p = 0.03) as a significant predictor of better PFS, while PS score of 0-1 (HR: 0.51, 95% CI: 0.31-0.89, p = 0.01) and younger patients (< 75 years) (HR: 0.66, 95% CI: 0.45-0.97, p = 0.03) as significant-good predictor of OS. The rate of severe AEs was higher in ineligible patients than in eligible (39% vs. 27%, respectively; p = 0.07), although the difference was not significant. Older age was significantly associated with severe AEs (p = 0.049). **Conclusions:** The real-world efficacy of chemo-immunotherapy for ES-SCLC was similar to that of pivotal clinical trials. However, trial-ineligible patients with ES-SCLC had poor treatment outcome and the higher rates of severe adverse events in this prospective cohort study. Our study suggests that positive results among the trial eligible patients may not translate to ineligible patients. Clinical trial information: UMIN000038064. Research Sponsor: Chugai pharmaceutical.

8568 **Poster Session**

Impact of trilaciclib on multilineage chemotherapy-induced myelosuppression events in patients with extensive-stage small cell lung cancer: Post-hoc analyses of data from randomized clinical trials. *First Author: Jerome H. Goldschmidt, Blue Ridge Cancer Care, Blacksburg, VA*

Background: Trilaciclib is a short-acting CDK4/6 inhibitor administered prior to chemotherapy for multilineage myeloprotection. Reduced occurrence of chemotherapy-induced myelosuppression (CIM) events across neutrophil, red blood cell, and platelet lineages was reported in 3 Phase 2 clinical trials of trilaciclib versus placebo in patients with extensive-stage small cell lung cancer (ES-SCLC). In this post-hoc trial analysis, we further assessed the impact of trilaciclib on the occurrence of single and concurrent multilineage CIM events. **Methods:** Analyses were conducted separately by line of chemotherapy. In the first-line (1L) setting, pooled data from the G1T28-05 and G1T28-02 trials, in which trilaciclib or placebo was administered prior to etoposide, carboplatin, and atezolizumab [E/P/A] and E/P, respectively, were used. In the 2/3L setting, analyses were based on data from the G1T28-03 trial where patients received trilaciclib or placebo prior to topotecan. The proportion of patients with single and concurrent multilineage CIM events and incidence rate were estimated per cycle and during the first 4 cycles of chemotherapy. Severe (grade ≥ 3 per CTCAE definition) CIM events of neutropenia (SN), anemia (SA), and thrombocytopenia (ST) were assessed. Concurrent CIM events were defined as having 2 or 3 lineage-specific CIM events overlap for ≥ 1 day. As sensitivity analyses, the occurrence of CIM events in patients with ES-SCLC receiving 1L treatment in the G1T28-05 and G1T28-02 studies was analyzed separately. **Results:** Compared with placebo, fewer patients receiving trilaciclib had single-lineage CIM events and concurrent events in 2 or 3 lineages during cycles 1–4 of 1L chemotherapy using pooled data from G1T28-05 and G1T28-02 (Table). A similar trend was observed in the 2/3L setting. Generally, SN occurred more frequently in earlier cycles, whereas SA and ST tended to occur later. The sensitivity analysis in each individual 1L trial yielded consistent results with the pooled analysis. **Conclusions:** Patients with ES-SCLC receiving trilaciclib prior to chemotherapy had fewer single and concurrent multilineage CIM events than patients receiving placebo. Clinical trial information: NCT03041311, NCT02499770, NCT02514447. Research Sponsor: G1 Therapeutics, Inc.

CIM events per 21-day cycle among 1L and 2/3L patients with ES-SCLC during cycles 1–4.

Exploratory analysis using cfDNA-based fragmentomics to predict disease recurrence in limited disease small cell lung cancer. *First Author: Sehhoon Park, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: The current standard of care (SOC) for limited disease (LD) small cell lung cancer (SCLC) is definitive concurrent chemoradiotherapy (CCRT). Despite the high response rate to SOC, up to 70% of the patients potentially experience disease recurrence and fail to show the prolonged clinical benefit. We investigated the feasibility of cell-free DNA (cfDNA) based genomic alteration and fragmentomic analysis using pre-and post-treatment samples to investigate the predictive value of disease recurrence in LD-SCLC. **Methods:** The blood sample from fifty LD-SCLC who were treated with definitive CCRT were collected before and after the treatment. Target sequencing, AlphaLiquid scan (IMBdx, Korea), composed of 106 target genes, was conducted using cfDNA and peripheral blood mononuclear cells. Based on the recurrence-free survival (RFS) interval of 12 months, patients were categorized into group with persistent response (PeR, n = 29) and non-PeR (n = 21). Fragmentomics analyses were collected using the proportion of cfDNA fragments sized in P1 (100 – 155 bp) and P2 (160 – 180 bp) ranges. **Results:** Initial analysis was conducted based on the gene of interest. Patients with *RB1* mutation (n = 11) detected in follow-up sample demonstrated significant shorter RFS compared to the *RB1* wild type (WT) patients (n = 39) (7.9 mon. vs. NR, $P = 0.002$). Among the patients who were available for our fragmentomics analysis in follow up samples (n = 19), non-PeR (n = 9) group were significantly high in P1 range ($P = 0.003$) and low in P2 range ($P = 0.002$) compared to PeR group (n = 10). AUCs using the fragment proportion in P1, proportion in P2, and the fragmentation ratio (proportion in P1 / proportion in P2), were 0.889, 0.911, and 0.889, respectively. The survival analysis using fragmentation ratio showed significantly longer RFS in fragmentation ratio low group compared to the high group (7.6 mon. vs. NR, $P = 0.002$). Integrating *RB1* mutation status with fragmentation ratio, patients with both *RB1* WT and fragmentation ratio low (n = 9) showed the most favorable outcomes ($P = 0.006$). On the contrary, patients with either *RB1* mutated or high in fragmentation ratio (n = 10) showed median RFS of rest than 12 months. **Conclusions:** In this study, we investigated the clinical feasibility of cfDNA detected mutation and size of the fragment in disease recurrence of LD-SCLC using the sample collected before and after definitive CCRT. It is observed that patients with either *RB1* mutation or high fragmentation ratio detected from cfDNA after the completion of CCRT are likely to experience early disease recurrence. Our findings suggest that cfDNA could provide supplementary information in predicting early treatment failure and support the clinical decision in selecting high-risk patients who might need intense monitoring and additional consolidative treatment. Stereotactic radiosurgery (SRS) versus whole brain radiation therapy (WBRT) in patients with small cell lung cancer (SCLC) and intracranial metastatic disease (IMD): A systematic review and meta-analysis. *First Author: Karolina Gaebe, University of Toronto, Toronto, ON, Canada*

Background: Patients with SCLC are at high risk for the development of IMD and, subsequently, rapid intracranial progression. SRS has supplanted WBRT as first-line treatment for IMD in most solid cancers, but WBRT remains first-line treatment for IMD in SCLC patients. Data on SRS in SCLC are limited to small retrospective studies. **Methods:** Studies reporting on SRS in SCLC patients with IMD were collected from EMBASE, MEDLINE, CENTRAL, and grey literature sources (n = 3,732 studies). Random-effects meta-analysis pooled hazard ratios (HR) for overall survival (OS) between SRS and WBRT ± SRS boost, as well as medians for OS in months (mo) and risk rates for intracranial local (LC) and intracranial distant control (DC) in single-arm SRS studies. **Results:** OS following SRS was non-inferior compared with WBRT ± SRS boost (HR 0.90; 95% confidence interval (95CI), 0.73-1.10; n = 7 studies; n = 18,130 patients), and superior compared with WBRT alone (HR 0.80; 95CI, 0.66-0.96; n = 7 studies; n = 16,961 patients). Pooled median OS from single-arm studies following SRS was 8.99 mo (95CI, 7.86-10.15; n = 14 studies; n = 1,682 patients). Pooled LC and DC estimates following SRS were 81% (95CI, 67%-99%) and 66% (95CI, 50%- 86%), respectively, at 6 mo, and 78% (95CI, 61%-98%) and 58% (95CI, 46%-75%), respectively, at 12 mo. **Conclusions:** This systematic review and meta-analysis provides evidence that SRS may achieve analogous survival outcomes compared with WBRT in patients with SCLC and IMD, indicating that a subset of SCLC patients may benefit from first-line SRS treatment. Prospective trials should investigate the impact of metastatic burden as well as LC and DC differences between WBRT- and SRS-treated SCLC patients. Research Sponsor: None.

Adverse events self-reported by patients (pts) with extensive-stage small cell lung cancer (ES-SCLC) treated with durvalumab (D) plus platinum-etoposide (EP) or EP in the CASPIAN study. *First Author: Mustafa Özgüroğlu, Istanbul University-Cerrahpaşa, Cerrahpaşa School of Medicine, Istanbul, Turkey*

Background: The CASPIAN phase 3 study established D+EP as a global standard of care in ES-SCLC. Patient-Reported Outcomes - Common Terminology Criteria for Adverse Events (PRO-CTCAE) was developed to complement standard adverse event (AE) reporting in oncology trials. Here we describe patient-reported symptomatic AEs using PRO-CTCAE in CASPIAN, the first time the PRO-CTCAE tool has been piloted in SCLC research. **Methods:** In CASPIAN, treatment-naïve pts (WHO PS 0/1) with ES-SCLC received 4 cycles of D+EP q3w followed by maintenance D q4w until progressive disease (PD), or up to 6 cycles of EP q3w. As part of exploratory analyses, where validated local language versions were available (in English, German, Japanese or Spanish), pts were asked to complete the PRO-CTCAE by e-device at baseline, q3w during EP (in both arms), then q4w until PD, followed by day 28 post-PD, 2 months post-PD, and q8w until second progression/death. Presence/absence, frequency or severity were examined during the first 24 weeks after starting treatment across 11 AEs selected as being relevant to pts with ES-SCLC (Table). **Results:** In total, 164 of the 537 pts randomized to D+EP and EP in CASPIAN (31%; D+EP: 83; EP: 81) were asked to complete the PRO-CTCAE. At baseline, the PRO-CTCAE was completed by 84% of these pts in the D+EP arm and 81% in the EP arm; compliance rates > 60% were achieved up to cycle 32 for D+EP and cycle 6 for EP. Examined AEs were reported by a minority of pts before starting treatment in both arms (range D+EP vs EP: 4% vs 3% for hand-foot syndrome to 34% vs 41% for dry mouth). Baseline AE rates were generally maintained in both arms up to 24 weeks after starting treatment, except for itchy skin, which showed a numerical increase from 13% at baseline to a peak of 34% at cycle 6 in the D+EP arm and 12% at baseline to a peak of 42% at cycle 8 in the EP arm; and dizziness, which showed a numerical increase from 16% at baseline to a peak of 40% at cycle 5 in the D+EP arm, while rates were maintained vs baseline in the EP arm. Most pts reporting these AEs indicated that they occurred rarely or occasionally, or were mild or moderate in severity. **Conclusions:** Self-reported data from pts in CASPIAN showed that the 11 AEs examined during the 24 weeks after starting treatment were reported by a minority of pts, mostly with rare or occasional occurrence, and mild to moderate severity. Rates and patterns of AEs over time were broadly similar in the D+EP and EP arms. These results complement the CASPIAN safety profile and give insight into pts' experience of treatment. Clinical trial information: NCT03043872. Research Sponsor: AstraZeneca.

Primary attribute examined	AEs
Presence/absence	Rash; pain, swelling, or redness at a site of drug injection or IV
Frequency	Arm or leg swelling; pain in the abdomen; shivering or shaking chills
Severity	Itchy skin; numbness or tingling in hands or feet; dizziness; mouth and throat sores; hand-foot syndrome; dry mouth

The efficacy and safety of taletrectinib in patients with TKI-naïve or crizotinib-pretreated ROS1-positive non–small cell lung cancer (NSCLC). *First Author: Wei Li, Oncology Department, Shanghai Pulmonary Hospital, Shanghai, China*

Background: Taletrectinib (AB-106 / DS-6051b) is a next-generation, potent, CNS- penetrant, selective ROS1 tyrosine kinase inhibitor. The ongoing TRUST study (NCT04395677) is a multicenter, open-label, single-arm, Phase 2 study of taletrectinib in Chinese ROS1-positive NSCLC patients who are TKI -naïve or crizotinib-pretreated. Here we present the updated efficacy and safety results of the study. **Methods:** The eligible ROS1-positive NSCLC patients were enrolled into either TKI-naïve or crizotinib-pretreated cohorts, and treated with taletrectinib 600mg once daily. The study endpoints included overall response rate (ORR), duration of response (DOR), disease control rate (DCR), overall intracranial response rate (IC-ORR), progression-free survival (PFS), and safety profile. **Results:** As of the data cutoff date of September 7, 2021, 61 of the 86 stage IV patients enrolled in the study have at least three postbaseline tumor assessment of which 40 patients in the TKI-naïve cohort, and 21 patients in the crizotinib-pretreated cohort (50% patients having at least one prior chemotherapy). In the TKI -naïve cohort, the confirmed ORR by investigators per RECIST 1.1 was 90.0%: [95%CI: 76.3%; 97.2%] (36/40); and the DCR was 95% [95%CI: 83.1%; 99.4%] (38/40). In the crizotinib-pretreated cohort, the confirmed ORR by investigators was 47.6% [95%CI: 25.7%; 70.2%] (10/21); and DCR was 76.2%: [52.8%; 91.8%] (16/21). The mDOR and mPFS are not reached yet for both cohorts. Of 6 patients having brain metastasis and measurable target brain lesions at baseline, the intracranial ORR and IC-DCR were 83.3% and 100%, respectively. Of 4 patients with ROS1 G2032R mutation, 3 patients achieved partial response (PR), and 1 patient achieved stable disease (SD). The most common treatment-related adverse events (TRAEs) include diarrhea, nausea, vomiting, transaminase elevation, anemia, neutrophil count decrease, etc. were Grade 1 or 2, and the most common AEs (below 10%) were ALT/AST increased but reversible. **Conclusions:** Taletrectinib demonstrated meaningful clinical efficacy in both TKI-naïve and crizotinib-pretreated ROS1 positive NSCLC patients. In particular, taletrectinib showed clinical effectiveness in patients with ROS1 secondary G2032 mutations and patients with brain metastasis. Taletrectinib was well tolerated in this patient population. Clinical trial information: NCT04395677. Research Sponsor: AnHeart Therapeutics Inc.

Efficacy and safety of camrelizumab combined with chemotherapy (irinotecan combined with platinum) followed by camrelizumab combined with apatinib in the first-line treatment of advanced small cell lung cancer: A phase II study. *First Author: Jun Ni, Department of Pulmonary and Critical Care Medicine, Peking Union Medical Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China*

Background: The treatment mode of small cell lung cancer (SCLC) is mainly based on the comprehensive treatment of chemotherapy and radiotherapy. IMpower133 study, suggesting that immune checkpoint inhibitors combined with chemotherapy first-line treatment for advanced SCLC may bring new research directions of clinical benefit. Previous study suggested that the combination of anti-PD-1 antibody camrelizumab and VEGFR-2 inhibitor apatinib significantly improved antitumor effects. The aim of this study was to evaluate the efficacy and safety of camrelizumab combined with chemotherapy (irinotecan combined with platinum) followed by camrelizumab combined with apatinib in the first-line treatment of SCLC. **Methods:** Extensive-stage small cell lung cancer patients were enrolled in this single-center, single-arm study. During the induction treatment phase, Patients received camrelizumab (200mg q3w), irinotecan (65 mg/m2, q3w) and platinum (cisplatin: 30 mg/m2, carboplatin: AUC=4~5), after 4-6 cycles, the patient entered the maintenance phase, and then patients received camrelizumab combined with apatinib until disease progression or unacceptable toxicity. Treatment efficacy was assessed every 3 cycles (6 weeks). The primary endpoint is progression-free survival (PFS). Secondary endpoints are objective response rate (ORR), disease control rate (DCR) , duration of response (DoR) and overall survival (OS), which are based on RECIST 1.1. **Results:** At data cut-off (Jan 10, 2022), 20 extensive-stage SCLC patients were enrolled in the study, of which 18 patients were evaluable. Median age was 64 years, male accounts for 85.0% (17/20). Median follow-up was 5.0 months (range 0.4~17.6 months). Of 18 evaluable patients, no one achieved complete response Partial response was achieved by 17 (94.4%) patients and stable disease exhibited by 1 (5.6%) patient. The ORR and DCR were 94.4% and 100%, respectively. mPFS and mDoR have not been reached. In terms of adverse events (AEs), reactive cutaneous capillary hyperplasia (RCCEP) was observed in 10 (47.6%) patients 10 patients. Grade III-IV AEs were observed in 7 (35.0%) patients with neutropenia, thrombocytopenia, hemoglobin reduction, leukopenia, rash. The rest were grade I-II AEs. **Conclusions:** The treatment in this study showed impressive ORR and DCR, and acceptable toxicity, and may be a promising method as a first line treatment. Clinical trial information: NCT04453930. Research Sponsor: Jiangsu Hengrui Medicine Co.,Ltd.

Total metabolic tumor volume on 18F-fluorodeoxyglucose-positron emission tomography ([18F]-FDG-PET) scan: A potential prognostic factor in extensive-stage small cell lung cancer. *First Author: Elisa Andrini, Department of Experimental, Diagnostic, and Specialty Medicine – DIMES, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy*

Background: Small-cell lung cancer (SCLC) is a highly aggressive neuroendocrine lung cancer, accounting for 10-15% of all lung cancers, commonly classified in limited stage (LS-SCLC) and extensive stage (ES-SCLC). Despite the introduction of chemoimmunotherapy as new standard first-line therapy for ES-SCLC, the benefit of addition of the programmed-death ligand 1 (PD-L1) inhibitors is limited to a subset of patients, suggesting the importance to identify predictive biomarkers of response. [18F]FDG-PET/CT is commonly used for the staging and therapeutic planning of SCLC patients. Metabolic parameters derived from [18F]FDG-PET could predict patient outcomes by measuring the extension of metabolically active tumor (metabolic tumor volume [MTV]) or its metabolic heterogeneity (total lesion glycolysis [TLG]). **Methods:** We retrospectively collected patients with pathologically confirmed diagnosis of SCLC, who had undergone an [18F]FDG PET/CT scan within 30 days from the start of first-line treatment for ES-SCLC. Patients with LS-SCLC at diagnosis were included if presenting relapse at pre-treatment scans performed at least 90 days from the end of treatment with radical intent. We calculated metabolic parameters, MTV and TLG, by summing each single lesion's MTV and TLD respectively. The primary endpoint of the study was overall survival (OS), defined as the time from [18F]FDG PET/CT scan acquisition to death from any cause. **Results:** A total of 86 SCLC patients ES-SCLC were included. Patients with hyponatremia, hypoalbuminemia and elevated LDH levels were associated with greater number of lesions, greater total MTV, and higher total TLG at [18F]FDG-PET/CT/CT scan. At a median follow-up of 20.9 months, the median OS was 11.1 months. Median survival was longer among patients with Na + ≥135 mEq/L, with normal albumin levels and in those with normal LDH levels and without bone metastases. Patients with low total MTV had longer OS compared with those with high total MTV (11.9 months vs 4.8 months, respectively). High total MTV was independently associated with the risk of death ($p < 0.001$) but not with the risk of progression. **Conclusions:** Our preliminary data showed that total MTV could provide prognostic information in patients with ES-SCLC, suggesting a potential role as stratification factor in immunotherapy-based clinical trials. Nab-PTX and nab-PTX combined with immune checkpoint inhibitors for relapsed small cell lung cancer. *First Author: Rui Wan, State Key Laboratory of Molecular Oncology, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Despite sensitivity to first-line chemotherapy, most small cell lung cancer (SCLC) patients experience disease progression after initial treatment. Nab-PTX showed comparable anti-tumor activity for relapsed SCLC. Whether immune checkpoint inhibitors (ICIs) combined with nab-PTX could improve clinical outcome for relapsed SCLC has not been fully evaluated. The aim of this study is to evaluate efficacy and safety of nab-PTX and nab-PTX combined with ICIs for relapsed SCLC. **Methods:** We retrospectively reviewed relapsed SCLC patients who were given nab-PTX (130mg/m2, day1,8 /Q3 weeks) or nab-PTX combined with ICIs (PD-1 or PD-L1), from Feb 2017 to Sep 2021. Clinical data were collected from electronic medical records. The clinical outcome, including progression-free survival (PFS) and overall survival (OS) were assessed using the Kaplan-Meier method and standard Log-rank test. **Results:** A total of 56 patients with relapsed SCLC were included, 29 and 27 patients received nab-PTX (group A) and nab-PTX combined with ICIs (group B), respectively. Baseline characteristics were well balanced between the groups. Patient characteristics (group A: group B) were as follows; median age 57: 59, male 25(86.2%): 24(88.9%), heavy smoking 23(79.3%): 18(66.7%), ECOG-PS 1 19(65.5%) :19(70.4%), extensive disease 28(96.6%) :25(92.6%), liver metastasis 10(34.5%) :12(44.4%), brain metastasis 8(27.6%) :10(37%), refractory relapse 10(34.5%) :11(40.7%). ORR in group A and B were 17.2% vs 40.7%, and DCR in group A and B were 72.4% vs 66.7%, respectively. The median PFS and median OS were similar between group A and B (median PFS, 2.8months vs 3.2months; median OS, 9.3 months vs 11.0months). PFS and OS according baseline characteristics were showed in the table. Toxicity profile of group B was tolerable as well as group A. **Conclusions:** This retrospective study indicated nab-PTX combined with ICIs failure to improve clinical outcome for relapsed SCLC when compared with nab-PTX monotherapy. Research Sponsor: None.

Genomic analysis and prediction of therapeutic vulnerabilities of small cell lung cancer from rovalpituzumab tesirine phase III trial (MERU). *First Author: Weilong Zhao, AbbVie Bay Area, South San Francisco, CA*

Background: Predicting variable therapeutic responses that are driven by the genetic and transcriptomic heterogeneity of Small Cell Lung Cancer (SCLC) offers an opportunity for implementing precision therapies within the cancer cells and tumor microenvironment (TME). MERU was a Phase III study of Rovalpituzumab Tesirine (Rova-T) as maintenance therapy following first-line platinum-based chemotherapy in participants with extensive stage SCLC. In this study, we comprehensively analyzed the baseline genomic data in the MERU cohort to interrogate SCLC's heterogeneous TME and tumor-intrinsic molecular and genetic drivers for therapeutic vulnerabilities. **Methods:** RNA-seq and Whole-Exome-Sequencing (WES) data were collected from archival tumor samples of 306 of 740 subjects enrolled in MERU. RNA-seq reads were aligned with STAR and quantified for gene expression by HTSeq. WES reads were analyzed for somatic mutation and copy number variation using AbbVie's tumor-only WES pipeline. TME heterogeneity was evaluated using gene-set variation analysis of pan-cancer TME gene signatures. SCLC subtyping was performed using expression of 4 transcriptional factors (TF): ASCL1, NEUROD1, POU2F3, and YAP1. A computational framework of mapping MERU transcriptome expression profile to Cancer Dependency Map (DepMap) dataset was developed to synthetically screen MERU samples' drug sensitivity. **Results:** TF subtyping reveals high prevalence of SCLC-A and -N subtypes in the MERU cohort, consistent with high expression of DLL3 in these two neuroendocrine subtypes. Correlation of TME gene signature scores identified two distinct clusters in the MERU cohort with correspondingly polarized immune-suppressive and -inflamed phenotypes. The pro-inflammatory score combining IFN-gamma and TGF-beta signatures, predicted prognosis in the MERU cohort better than the previously reported SCLC-I signature (Hazard Ratio: 0.71 [95% CI 0.38-1.3] vs. 1.29 [95% CI 0.65-2.6]). WES analysis identified high prevalence of TP53 and RB1 mutations, in line with the reported prevalence of these genetic drivers in SCLC. The clinical characteristics including gender, smoking status, and prior treatment, are not significantly associated with either TF or TME subgroup. The computational drug screen framework maps 83% of MERU samples to DepMap SCLC cell lines. The correlation of subtype TF expression with drug sensitivity was highly concordant between MERU and DepMap. Collectively, this approach demonstrated that molecular subtyping can be leveraged to broadly predict drug response in SCLC patients. **Conclusions:** Our comprehensive genomic analysis of the MERU cohort provides new insights into SCLC heterogeneity from both tumor-intrinsic and tumor-immune interaction perspectives and shall contribute to the development of predictive biomarkers and therapeutic opportunities for SCLC. Research Sponsor: AbbVie Inc.

The predictive value of YAP-1 for efficacy of immunotherapy among patients with ES-SCLC. *First Author: Yuqing Chen, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: IMpower133 showed benefits in both progression-free survival (PFS) and overall survival (OS) of etoposide/carboplatin plus atezolizumab (ECT) regimen in extensive-stage small-cell lung cancer (ES-SCLC), but the absolute benefit was limited. Previous studies have classified SCLC patients by RNA-seq clustering analysis to explore the dominant population for treatment, but was difficult for clinical application. We aimed to explore whether expressive status of Yes-Associated Protein 1 (YAP-1) can screen dominant population of immunotherapy among ES-SCLC patients. **Methods:** We selected ES-SCLC patients treated in our hospital from Jan, 2018 to Jul, 2021, and enrolled 21 patients with ES-SCLC received ECT regimen whose formaldehyde-fixed, paraffin-embedded sample was reachable. Assessments of complete remission (CR), partial remission (PR), disease stable (SD) and progressive disease (PD) were according to the efficacy evaluation criteria of solid tumor (RECIST) version 1.1. Immunohistochemistry (IHC) of YAP-1 (ET1608-30, 1/100) was conducted. The H-score was calculated by IHC Profiler. All statistical analyses were evaluated using SPSS 22.0, X-tile 3.6.1, and Excel. P values < 0.05 were considered statistically significant. **Results:** Baseline information was provided in table. The median H-score of responders (CR/PR patients) and non-responders were 13.97 (95%CI: 8.97-16.30) and 23.72 (95%CI: 8.13-75.40) that were significantly different ($P < 0.05$). H-score and PFS showed negative correlation by spearman (r = -0.603). Patients were divided into two groups as low expression group (H-score ≤25.00, n = 16) and high expression group (H-score > 25.00, n = 5) according to the cut-off value of H-score. The median PFS of these two groups were 7.1m (95%CI: 2.6-11.6m) and 3.4m (95%CI: 0.9-5.9m), respectively. K-M curves of PFS were significantly different ($P < 0.05$). **Conclusions:** Our preliminary results have indicated a potential efficacy predictive value of YAP-1 protein. And the expression level of YAP-1 protein was negatively correlated with efficacy of ECT in ES-SCLC patients. Research Sponsor: None.

A phase I study of anlotinib with concurrent chemoradiotherapy for limited-stage small cell lung cancer. *First Author: Dingzhi Huang, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*

Background: Concurrent chemoradiotherapy (CCRT) is the standard treatment for limited-stage small-cell lung cancer (LS-SCLC). However, LS-SCLC remains an area of high unmet medical need. Anlotinib is an antiangiogenic multi-target tyrosine kinase inhibitor. In the phase II ALTER-1202 trial, anlotinib significantly improved clinical outcomes in advanced small-cell lung cancer. We report here a phase 1 trial of anlotinib with CCRT for LS-SCLC. **Methods:** This is a prospective, single-arm, phase I clinical trial using a 3+3 design. Patients aged between 18 and 75 with previously untreated LS-SCLC, PS 0-1 and adequate organ function are eligible. Patients received anlotinib (12mg, qd, d1-14, q3w) and chemotherapy (etoposide, 100 mg/m^2, d1-3, q3w and cisplatin, 25 mg/m^2, d1-3, q3w) for cycle 1, then anlotinib [dose escalation at 3 levels (DL1-3) 8mg, 10mg and 12mg, qd, d1-14, q3w], chemotherapy (etoposide, 50 mg/m^2, d1-5, q4w and cisplatin, 25 mg/m^2, d1-3, q4w) and thoracic radiotherapy (60-66 Gy in 30-33 daily 2-Gy fractions starting on day 1 of cycle 2) for cycles 2–3, then anlotinib (12mg, qd, d1-14, q3w) and chemotherapy (etoposide, 100 mg/m2, d1-3, q3w and cisplatin, 25 mg/m^2, d1-3, q3w) for cycles 4-6. Cycles 5-6 were given as appropriate according to the patient's physical condition. Prophylactic cranial radiation was given according to the judgment of the investigator after CCRT. The purpose of this study is to determine the maximum tolerated dose (MTD) of anlotinib when combination with CCRT. **Results:** Twelve patients were enrolled from May 2020 to September 2021. No DLTs were observed in DL1 (3 patients) or DL2 (3 patients). At DL3 (6 patients), 1 patient had a DLT of grade 3 pulmonary embolism. Grade 3 adverse events were white blood cell count decreased, neutrophil count decreased, lymphocyte count decreased, hypertension, albumin decreased and pulmonary embolism. One patient had grade 3 pulmonary embolism and grade 4 neutrophil count decreased in DL3 at cycle 1. One patient had grade 2 radiation pneumonitis after cycle 5 and grade 1 radiation esophagitis at cycle 3 in DL3. One patient had grade 2 radiation esophagitis at cycle 3 in DL2. The MTD was not reached. **Conclusions:** Combined treatment with anlotinib and CCRT for limited-stage small cell lung cancer is well tolerated and further clinical investigation is warranted. Clinical trial information: NCT04882033. Research Sponsor: None.

Efficacy and safety of lurbinectedin as second-line therapy in Chinese patients with small cell lung cancer: Preliminary results of a phase 1 study. *First Author: Ying Cheng, Department of Medical Thoracic Oncology, Jilin Cancer Hospital, Changchun, China*

Background: Lurbinectedin (Zepzelca), a selective inhibitor of oncogenic transcription, was granted accelerated approval on June 15, 2020, by the FDA for adult patients (pts) with metastatic small cell lung cancer (SCLC) with disease progression on or after platinum-based chemotherapy, based on the results from SCLC cohort in PM1183-B-005-14 trial. Here we report the preliminary results of a phase 1 study (LY01017/CT-CHN-101) which aimed to evaluate the safety, tolerability, pharmacokinetics (PK) characters and preliminary efficacy of lurbinectedin in Chinese pts with advanced solid tumors including relapsed SCLC. **Methods:** In the dose-escalation stage, 10 pts with advanced solid tumors received lurbinectedin (2.5-3.2 mg/m^2) as 1-hour i.v. infusion q3wk in a classical 3+3 design, without primary granulocyte colony-stimulating factor (G-CSF) prophylaxis during Cycle 1. In the dose-expansion stage, 22 pts with relapsed SCLC after first-line platinum-based chemotherapy were treated with single-agent lurbinectedin at the recommended dose (RD) defined in the dose-escalation stage, with or without G-CSF support. Endpoints included safety (CTCAE v5.0), tolerability, PK, and confirmed objective response rate (ORR; RECIST v1.1). The data cutoff was January 13, 2022. **Results:** No dose-limiting toxicity (DLT) was observed in the first 3 pts treated at 2.5 mg/m^2, while 1/7 pts treated at 3.2 mg/m^2 had DLT (grade 4 neutropenia lasting ≥3 days) in Cycle 1, thus 3.2mg/m^2 without G-CSF prophylaxis was defined as the RD of the dose-expansion stage. At cutoff, 22 SCLC pts treated in the dose-expansion stage were still ongoing, with 21 and 22 pts evaluable for efficacy and safety, respectively. The investigator-assessed confirmed ORR was 42.9% (9/21, partial responses). The duration of response (DOR) is pending. The most common grade 3-4 treatment-related adverse events (TRAEs) were neutropenia (16 [72.7%]), leukopenia (13 [59.1%]), thrombocytopenia (9 [40.9%]), increased ALT (4 [18.2%]), anemia (3 [13.6%]), and increased AST (2 [9.1%]). Serious treatment-related adverse events, including neutropenia (5 [22.7%]), leukopenia (4 [18.2%]), thrombocytopenia (3 [13.6%]), increased ALT (2 [9.1%]), increased AST (2 [9.1%]), vomiting (2 [9.1%]), febrile neutropenia (1 [4.5%]), and edema (1 [4.5%]), were reported in 10 pts (45.5%). No cases of infection, sepsis and Hy's law were reported. A total of 40.9% (9/22) had dose delay and 31.8% (7/22) had dose reduction, mainly attributed to hematological toxicities. No discontinuations occurred due to AEs. No treatment-related deaths were reported. **Conclusions:** Lurbinectedin at the RD (3.2mg/m^2) shows promising efficacy as second-line therapy in Chinese pts with SCLC, with acceptable tolerability and manageable safety profile. Clinical trial information: NCT04638491. Research Sponsor: Pharma Mar, S.A, Pharmaceutical/Biotech Company.

8581 **Poster Session**

A phase 1/2 trial of lurbinectedin (L) in combination with pembrolizumab (P) in relapsed small cell lung cancer (SCLC): The LUPER study. *First Author: Antonio Calles, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

Background: L is a novel anticancer agent that inhibits trans-activated transcription and modulates the tumor microenvironment. L is approved by the FDA for metastatic SCLC patients (pts) with progressive disease (PD) on or after platinum-based chemotherapy (CT). The LUPER study is assessing the safety, tolerability, and preliminary efficacy of L+P as second-line regimen for SCLC pts after failure of platinum-based CT. Phase 1 data are presented here. **Methods:** In this phase 1/2 trial (NCT04358237), adult pts with histologically confirmed SCLC, PD to a previous CT-containing regimen (≥4 weeks before study initiation), no prior exposure to immunotherapy, ECOG PS of 0-1, and measurable disease as per RECIST 1.1 are eligible. Pts with treated, stable, and asymptomatic brain metastases (BMs) are allowed. A 3+3 dose-escalation was done to determine the recommended phase 2 dose (RP2D) of L+P. L was dosed at 2.4 mg/m^2 and 3.2 mg/m^2 IV Q3W in the dose level (DL)1 and 2, respectively, in combination with fixed dose of P (200 mg IV Q3W). The RP2D was the highest DL at which 0/3 pts or ≤1/6 pts experienced dose-limiting toxicities (DLTs) during the first cycle. Treatment was administered until PD, unacceptable toxicity, or consent withdrawal. Secondary endpoints include safety as per CTCAE 5.0, preliminary efficacy, and pharmacokinetics. **Results:** Thirteen pts were enrolled across 3 hospitals in Spain (DL1, n = 7; DL2, n = 6). Median age was 66 (range 43–78) years, 46.2% were female, 61.5% had ECOG PS of 1, 38.5% had platinum-free interval < 90 days, 30.8% had LDH > upper normal limit, and 15.4% had BMs. One DLT (G3 asthenia) and one G4 neutropenia lasting > 3 days (controlled with G-CSF prophylaxis upon C2, without requiring dose delay or modification) occurred in the DL1. No DLT were reported in the DL2. The RP2D was identified as 3.2 mg/m^2 L and 200 mg P IV Q3W. At data cutoff (Jan 21, 2022), 5 (38.4%) pts remained on treatment (1 pt in DL1 discontinued due to COVID-19 in cycle 1). Median duration of treatment was 2.1 (0–11.8) months, 5 (38.5%) pts had ≥8 cycles, and median relative dose intensity of L and P were 91.1% and 95.7%, respectively. Immune-related AEs (G2 pneumonitis; G3 ALT increased) led to P discontinuation in 2 (15.4%) pts. Responses were shown in both DLs, with ORR of 30.8% (1 confirmed complete response and 3 partial responses); 3 pts had stable disease (SD; including 1 patient with SD > 12 weeks) and 5 (38.5%) pts experienced PD. **Conclusions:** This is the first report to demonstrate a manageable safety profile and preliminary efficacy of second-line L+P for relapsed SCLC pts. This combination warrants further confirmation in the ongoing expansion phase 2. Clinical trial information: NCT04358237. Research Sponsor: PharmaMar, MSD.

Circulating tumor DNA (ctDNA) mutations associate with response in patients (pts) with extensive-stage small cell lung cancer (ES-SCLC) treated with talazoparib (TALA) and temozolomide (TMZ). *First Author: Maria A Velez, David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: Poly (ADP-ribose) polymerase (PARP) inhibition in combination with TMZ is a promising treatment strategy for ES-SCLC. In SCLC models, TALA, a potent PARP inhibitor, exhibits cytotoxic effects by impairing PARP proteins 1/2 and trapping PARP on DNA while TMZ potentiates antitumor response by contributing to genomic instability (Wainberg 2016). A prior analysis of ctDNA in 15 pts treated on trial with TALA and TMZ suggested that mutations in DNA damage repair (DDR) genes occurred with this combination and may associate with response (Mulroy ASCO 2021). **Methods:** Pts with relapsed or refractory ES-SCLC were treated with TALA 0.75 mg po daily with TMZ 37.5 mg/m2 po on days 1-5 of 28-day cycles in a phase 2 clinical trial (UCLA/TRIO-US L-07, NCT03672773). ctDNA was collected and assessed based on allele frequency and plasma copy number at baseline and every 8 weeks during treatment with the Guardant360 assay (Redwood City, CA). DDR status was defined as a mutation known or likely to result in aberrant expression of *ATM* or *BRCA1/2* (other DDR genes not detected by assay) (Pearl 2015). Germline DDR mutations were evaluated with matched-normal (PBMC) whole exome sequencing (WES) with archival specimens by Tempus (Chicago, IL). Response to treatment was defined by RECIST 1.1 criteria. Fisher s exact tests were used to compare proportions of patients, with P-values <0.05 considered statistically significant (www.r-project.org, Vienna, AU). **Results:** For 27 pts with evaluable response, 78 ctDNA samples were collected. The most common baseline somatic alterations were mutations in *TP53* (23 pts), *RB1* (8 pts), *ATM* (5 pts), and *BRCA2* (5 pts). There were no patients with germline DDR mutations. Overall, 22/27 (81.5%) had disease control (DC), including 11 with confirmed partial responses (PR) and 11 with stable disease while 5 had progressive disease. All those with PRs and ctDNA burden >0.2% at baseline experienced a ctDNA decrease at 8 weeks of treatment. DDR mutations were found in 18/27 (66.7%) pts. Of those with ≥ 1 follow-up ctDNA time point collected, 13/17 (76.4%) pts had at least one new mutation detected while on treatment, most commonly in *ATM* (6 pts). The appearance of new mutations associated with DC (P=0.042) and with a trend towards improved progression free survival (PFS, 5.9 m vs 3.6 m, P=0.099). All 5 pts with DDR mutations present at baseline had DC with TALA and TMZ, and 9/11 (81.8%) of those with PR had DDR mutations detected at some point during the trial, although the trend toward DC enrichment with DDR mutations did not maintain statistical significance (P=0.24). **Conclusions:** Mutations in DDR genes occur on treatment with TALA and TMZ and may associate with disease control. Validation in a larger cohort will be pursued. Research Sponsor: Pfizer.

A pilot study of ipilimumab and nivolumab in recurrent extensive-stage small cell lung cancer after platinum-based chemotherapy. *First Author: Anne C. Chiang, Yale Cancer Center, New Haven, CT*

Background: Immunotherapy has shown efficacy in the treatment of recurrent, extensive-stage small cell lung cancer (ES-SCLC). In the Checkmate 032 trial, ipilimumab and nivolumab combination therapy resulted in a 21% objective response rate in relapsed SCLC. At present, there are no biomarkers used in clinical practice to predict treatment responsiveness in SCLC. Ipilimumab and nivolumab act by blocking key co-inhibitory immune pathways of CTLA-4 and PD-1/PD-L1, respectively, leading to reinvigoration of anti-tumor cytotoxic T cell responses and a decrease in immune suppressive tumor infiltrating leukocytes. The ratio of intratumor Teff (CD8+) cells to Treg (CD4+/Foxp3+) cells (Teff/Treg) could be a more reliable biomarker than effector cell infiltration alone. **Methods:** In this open-label, single arm trial, we enrolled patients with ES-SCLC who previously received platinum-based chemotherapy; prior anti-PD-1 /PD-L1 therapy was allowed. Patients were treated with nivolumab 1 mg/kg and ipilimumab 3 mg/kg, for a total of 4 doses each and received nivolumab 480 mg beginning with cycle 5, every 4 weeks until progression, unacceptable toxicity or study discontinuation. On-study biopsies were performed prior to initiation of therapy and during week 4 for the biomarker primary objective—to correlate disease response with intratumor Teff/Treg changes. Secondary objectives include determining ORR, DOR, PFS, and OS. **Results:** Twenty-two patients (median age 63.5 [range 54-80] years, ECOG 0/ 1/2 [41%/50%/9%], sex M/F [45%/55%]) were enrolled and received treatment. Fourteen (64%) had paired biopsies while on treatment. Fifteen patients were evaluable per RECIST with an ORR of 13% (2/15, 2 partial responses [13%]) and DCR was 40% (6/15, 4 stable disease [27%]). Grade 3 treatment-related adverse events (TRAEs) occurred in 9/22 [40%]. Grade 4 TRAEs occurred in 2/22 [9%] (elevated lipase and elevated bilirubin) and Grade 5 TRAEs occurred in 1/22 patients (hepatic failure). Out of the 9 patients previously treated with anti- PD-1/PD-L1 therapy, 1 had a partial response and 2 had stable disease. Multiplexed quantitative immunofluorescence analysis revealed changes of both CD8+ effector T cells and Tregs in the tumor micro-environment associated with clinical benefit to immunotherapy. **Conclusions:** Combination immunotherapy with ipilimumab and nivolumab shows clinical efficacy in relapsed extensive-stage SCLC, including those previously treated with anti-PD-1/ PDL-1 therapy. Obtaining paired biopsies was shown to be successful in this prospective trial to study the tumor microenvironment in SCLC tumors treated with checkpoint inhibitors. Early biomarker evaluation during week 4 shows local immunomodulatory effect of treatment and supports exploration as predictive biomarker in this population. Clinical trial information: 03670056. Research Sponsor: Bristol Myers Squibb.

Trends in treatment patterns associated with small cell lung cancer in a U.S. Medicare population. *First Author: Robert A. Ramirez, Vanderbilt University Medical Center, Nashville, TN*

Background: Characterizing changes in the incident small cell lung cancer (SCLC) patient population and SCLC treatment landscape is essential for understanding drivers of outcomes among patients diagnosed with SCLC. The objective of this study was to examine trends in patient characteristics and treatment patterns for SCLC in a Medicare population. **Methods:** A retrospective analysis was conducted using the Surveillance, Epidemiology, and End Results (SEER)–Medicare linked data. Patients were included if they had a record with a diagnosis of SCLC in the database from 1/1/2007 – 12/31/2017 and were ≥65 years of age at diagnosis. Patients also had continuous enrollment for ≥180 days pre-SCLC diagnosis. Characteristics and treatment patterns were stratified by year of SCLC diagnosis. **Results:** 13,516 patients met the study criteria. Overall, 57.7% were female, mean age was 74 years, 89.5% were white, and 45.6% had a history of tobacco use. The majority (73.1%) were diagnosed with stage IV disease. Just over half (55.4%) of patients initiated first line (1L) treatment and mean time from diagnosis to 1L treatment was 6 weeks. Only 36.7% of those initiating 1L went on to second line (2L). Platinum-based chemotherapy (carboplatin or cisplatin + etoposide) was by far the most common 1L regimen (91.3%). 44.7% of patients received monotherapy in 2L, with topotecan being the most common (28.4%) regimen. Carboplatin + etoposide was used for approximately 20% of 2L patients. Over time, the demographic characteristics of patients diagnosed with SCLC was fairly stable with the exception of patients reporting a history of tobacco use, which more than tripled, increasing from 19.3% to 67.7% between 2007 and 2017. Between 2007 and 2017 the share of SCLC patients initiating 1L treatment increased 8.2% from 53.8% to 58.2% and the share initiating 2L fluctuated between 35% and 39%. Platinum-based chemotherapy was consistently used by the vast majority (88.7%–96.6%) of patients in 1L during the study period. Other chemo monotherapy (e.g., topotecan) and platinum-based chemotherapy with or without irinotecan were the most common 2L regimens from 2007-2014. Use of checkpoint inhibitors (CPIs) in 2L began in 2015 and became the most common 2L treatment following platinum-based chemotherapy by 2017 with 41.5% of patients receiving a CPI in 2L. **Conclusions:** While an increasing share of SCLC patients are pursuing treatment, less than 60% of SCLC patients receive any anticancer therapy. Fewer still receive more than one line of treatment, highlighting the ongoing need for effective therapies for SCLC. Research Sponsor: Ipsen.

Lenvatinib for the treatment of thymic epithelial tumors (TETs): A real-life multicenter experience. *First Author: Jose Carlos Benitez, Gustave Roussy, Villejuif, France*

Background: TETs are rare malignancies of the anterior mediastinum being thymoma (T) B3 and thymic carcinoma (TC) the most aggressive subtypes. There is no standard treatment after platinum-based chemotherapy in refractory or metastatic setting. A phase 2 trial has reported clinical benefit for lenvatinib 24mg (objective response rate [ORR] of 38%), a novel multi-targeted inhibitor of VEGFR, FGFR, RET, c-Kit, and other kinases; significant toxicity grade 3 hypertension was 64%. No real-life data exists. **Methods:** We selected patients (pts) under lenvatinib as a second-line or beyond for refractory TETs from 8 International centers from France (belonging to the nationwide network RYTHMIC) and United States. We analyzed epidemiologic, clinical and pathological characteristics of patients with TET's. The toxicity was evaluated according to CTCAE v4, with a local evaluation of efficacy and we assessed toxicity profile and survival outcomes. **Results:** From March 2020 to December 2021, 29 pts were enrolled. Median age at diagnosis was 49 (24-71), 51.7% were women, 6/29 (20.7%) reported auto-immune disorders (AIDs). TC was the most frequent subtype (n=18, 62.1%), followed by B3 and B2. Lenvatinib was used as a second line for 52% of pts, mainly starting from 14 mg/daily (n=20, 69%) and one pts with concomitant pembrolizumab. The ORR was 17% (95%CI 3.0-32.0) with partial responses only seen in TC, and the disease control rate was 76% (95%CI 59.0-92.0). Response was observed with the dose of 24mg in 3 pts and 14mg in 2 pts, with a median follow-up period of 5 months (m) (95%CI 3.2-6.7), PFS at 6 and 12 m was 64% and 30%, respectively. Toxicity is summarized in table 1. Dose de-escalations were needed in 27.5% of pts. **Conclusions:** We confirm the activity of lenvatinib in pts with advanced or metastatic T and TC, despite the use of lower doses than the phase 2 study. Research Sponsor: None.

CD47 expression patterns in thymic epithelial tumors. *First Author: Thomas Yang Sun, Stanford University, Palo Alto, CA*

Background: Blockade of CD47, an immunoglobulin overexpressed on solid tumor cells that inhibits macrophage phagocytosis, is a promising anti-cancer immunotherapy which has not yet been explored in thymic epithelial tumors (TETs). TETs, including thymomas and thymic carcinomas, are rare tumors with limited immunotherapy treatment options due to the high rates of immune-related adverse effects observed with PD-1/PD-L1 checkpoint inhibitors. This study aimed to examine CD47 protein expression in TETs. **Methods:** A clinically annotated tissue microarray of 67 TETs consisting of 64 thymomas and 3 thymic carcinomas, as well as 14 thymic controls were included. Each sample with an average of 3 cores was stained for CD47 epithelial expression (rabbit monoclonal antibody SP279, Abcam, USA). Samples were scored for intensity as follows: 0 = none, 1 = weak, 2 = moderate, and 3 = strong. An H-score, defined as intensity x percentage of tumor involved, was also assigned and ranged from 0 to 300. Samples with an intensity score of < 2 or an H-score of < 150 were categorized as $CD47^{low}$, while the rest as $CD47^{high}$. Multivariate linear regression analysis accounted for WHO subtype, stage, resection status and presence of paraneoplastic syndrome (Prism 9, Graphpad). **Results:** Compared to normal thymic tissue, TETs were more frequently CD47 positive and had significantly higher levels of CD47 expression. CD47 was present in 91% of TETs, compared to 64.3% of normal thymus. Importantly, the level of expression was significantly higher in TETs by 16-fold (mean H-score 75.0 vs 4.6, p = 0.003). Among tumors, univariate analyses showed that higher CD47 expression was correlated with a lower stage (p = 0.032) and more complete resection (p = 0.058). A multivariate analysis accounting for these factors showed that CD47 expression by both H-score and intensity were each highly correlated with WHO histology subtype (p = 0.0005; p = 0.0017 respectively) with lower grade subtypes more frequently found in $CD47^{high}$ tumors. The most frequent subtype in $CD47^{high}$, when compared to $CD47^{low}$ tumors, was AB (61.5% vs 13.7%) and the least frequent was B2 (0% vs 37.3%). Tumors with the highest grade (subtype C, thymic carcinomas) were exclusively $CD47^{low}$. $CD47^{high}$ tumors were associated with an increased incidence of paraneoplastic syndromes (52.4% vs 12.0%, p = 0.0014). **Conclusions:** CD47 expression was found in the vast majority of TETs, and in significantly higher levels than normal thymic tissue. Among tumors, those with higher CD47 expression tended to have lower grade and stage, as well as higher frequency of paraneoplastic syndromes. This study is the first to examine CD47 expression in TETs. Given the prevalent expression of CD47 found in TETs and current available CD47 targeted agents, this study lends support for further investigation of this novel therapeutic approach. Research Sponsor: None.

Genomic characterization of thymic epithelial tumor from real-world data. *First Author: Kana Kurokawa, Department of Respiratory Medicine, Juntendo University Graduate School of Medicine, Tokyo, Japan*

Background: Thymic epithelial tumors (TETs), including thymic carcinomas and thymomas, are rare neoplasms arising in the mediastinum. Chemotherapy is still the mainstay of treatment and few therapeutic options are available for patients with advanced or metastatic TETs. Due to their rarity, the sample size in the previous reports about the genomic profiles of TETs was small and the results varied from study to study, which hinders the development of treatment. Herein, we investigated the comprehensive genomic characteristics of TETs evaluated in a large genomic database profiled in a real-world setting. **Methods:** Tissue biopsy-based comprehensive genomic profiling was performed in the course of routine clinical care. We included data from two different cohorts: Foundation Medicine Inc. (FMI) in the US (Frampton GM, et al. Nat Biotechnol 2013) and the Center for Cancer Genomics and Advanced Therapeutics (C-CAT) in Japan, which is engaged in a national project for collecting genomic analysis and clinical results from patients. Samples profiled at Foundation Medicine were examined for all classes of alterations in 253 genes targeted across all assays. Tumor mutational burden (TMB) and microsatellite instability (MSI) were calculated as previously described (Chalmers ZR, et al. Genome Med 2017. Trabucco, et al. J Mol Diagn 2019). Patients' background including histology, age, and sex were also investigated, and genetic alteration, TMB, and MSI were stratified by them. **Results:** A total of 794 patients were collected for our study, including 722 cases from FMI and 72 cases from C-CAT. In the FMI data, 414 cases of thymic carcinoma and 308 cases of thymoma were included. *CDKN2A* (39.9%), *TP53* (30.2%) and *CDKN2B* (24.6%) were frequently altered in thymic carcinoma, versus *TP53* (7.8%), *DNMT3A* (6.8%), *CDKN2A* (5.8%) and *CDKN2B* (4.6%) in thymoma. TMB-High (≥ 10muts/Mb) and MSI-High were present in 7.0% and 2.3% of thymic carcinomas, and 1.6% and 0.3% of thymomas, respectively. Comparison of the thymic carcinoma cohort based on age < 60 vs 60+ years found a significant difference in prevalence of *NFKBIA* alterations (2.7% age < 60 vs 11.7% age ≥ 60, p = 0.034), while a similar comparison of the thymoma cohort found no significant differences between age groups. An analysis based on sex did not find any significant differences between groups. 55 cases of thymic carcinoma and 17 cases of thymoma were included from C-CAT data. In thymic carcinoma, *CDKN2A* (27.3%), *TP53* (23.6%) and *CDKN2B* (20.0%) were also frequently altered, while alterations of *TSC1* (23.5%) and *CD22*, *LTK*, *NOTCH1*, *KMT2A*, *SETD2*, *ATM* (17.6% each) were found in thymoma. **Conclusions:** To the best of our knowledge, this is the largest cohort in which genomic alterations, TMB, and MSI status of TETs were investigated. We suggest that several gene mutations, TMB, and MSI status might be potential targets for treatment and lead to therapeutic development opportunities, especially in thymic carcinoma. Research Sponsor: None.

Impaired seroconversion after SARS-COV-2 mRNA vaccine in patients with thymic epithelial tumors. *First Author: Erica Pietroluongo, Department of Clinical Medicine and Surgery, University Federico II, Naples, Italy*

Background: Thymic epithelial tumors (TET) are rare malignancies associated with dysregulation of the immune system and humoral and cell mediated immunity abnormalities. Anti-syndrome coronavirus type 2 (SARS-CoV-2) vaccine is effective at preventing COVID-19 morbidity and mortality. No published data are available regarding the immunization in TET patients (pts). The aim of this study was to evaluate the immunization in TET pts who received two doses of mRNA vaccine, by longitudinal serological detection of SARS-COV-2 spike-binding IgG antibody. **Methods:** Starting from April 2021 to October 2021, consecutive TET pts referred to the Rare Tumors Coordinating Center of Campania Region (CRCTR - Naples, Italy) were enrolled. All study subjects received two doses of COVID-19 mRNA vaccine (BNT162b2 by Pfizer-BioNTech). SARS-CoV-2 spike-binding IgG antibody (Ab) serological levels were analyzed by centralized chemiluminescent immunoassay (CLIA) at different time-points, including before 1^{st} vaccine dose (T0) and 1 month after 2^{nd} dose (T2). Cut-off for Ab titers positivity was > 25 AU/mL. **Results:** Forty pts were enrolled; 23 (57.5%) were female and 17 (42.5%) male. Eleven pts (27.5%) suffered from thymic carcinoma, 28 (70%) thymoma, and 1 (2.5%) thymic hyperplasia. At the time of study enrollment, 20 pts (50%) had no evidence of disease (NED) and were in follow-up; the remaining 20 pts had evidence of disease (ED) by imaging and were receiving systemic treatment (55% oral low-dose etoposide-based therapy, 40% somatostatin analogs + prednisone, 5% supportive care). Immune system disorders were diagnosed in 29 TET pts (72.5%): 19 pts (47.5%) had Good's Syndrome (GS) and 10 (25%) other immune disorders. At T0, all enrolled pts had negative Ab titers and no prior SARS-CoV-2 infection. At T2, Ab data were available for 37 pts (92.5%): 18 pts (48.7%) had positive Ab titers, whereas 19 (51.3%) did not achieve seroconversion. Among pts with ED, seroconversion was achieved only in 2 cases (11.8%). Lack of seroconversion at T2 was significantly associated with ED (Fisher's exact test p: 0.0001) and with the presence of GS (Fisher's exact test p: 0.0489). No significant association of seroconversion with other immune disorders and disease features was found. **Conclusions:** Our data showed that TET pts with ED had substantially higher probability of impaired seroconversion after SARS-COV-2 vaccine as compared with NED pts. We warrant further studies to evaluate the role of disease status, anti-tumor treatments and immune disorders in post-vaccine immunization of TET pts. Research Sponsor: None.

8589 **Poster Session**

Immunological signature of patients with thymic epithelial tumors. *First Author: Rocco Morra, Department of Clinical Medicine and Surgery, University Federico II, Naples, Italy*

Background: Thymic epithelial tumors (TETs) are complex diseases frequently associated with immune disorders, including Good Syndrome (GS). Etiopathogenesis of immune dysregulations in TETs patients is still not totally explained. The aim of this study was to evaluate differences in immune cell phenotype, as well as in the serum expression levels of a panel of cytokines, chemokines, and growth factors in patients with TETs and GS with or without autoimmune disorders (AD). **Methods:** From May 2019 to June 2020, consecutive patients with TETs and GS were recruited at Rare Tumors Coordinating Center of Campania Region (CRCTR – Naples, Italy). We analyzed the immunophenotype from peripheral blood focusing on selected immune cell subsets (monocytes, neutrophils, eosinophils, CD4+T cells, CD8+T cells, B-cells, NK cells and NKT- cells, T regulatory cells) processed for blood cell count and immunophenotyping, according to the 8-color immunophenotyping kit and Treg detection kit (CD4/CD25/CD127), and a panel of cytokines, chemokines, and growth factors from peripheral blood serum screened with pre-formed kits by Bioplex multiplex. D'Agostino-Pearson normality test was used to evaluate whether the continuous data were normally distributed, and a two-tailed t-test for independent samples was used. p-values < 0.05 were considered statistically significant. **Results:** Overall, 29 patients were enrolled [17 (58.6%) with and 12 (41.4%) without AD]. Sixteen patients (55.2%) were female and 13 patients (44.8%) were male. Tumor histology included thymoma in all the patients with AD, whereas there were 10 cases of thymoma and 2 of thymic carcinoma in the group of patients without AD. The analysis of leucocytes by blood cell count showed a statistically significant higher number of leucocytes, ascribable to T lymphocytes (p = 0.023), B lymphopenia (p = 0.003) and decrease of T regulatory cells (p = 0.009) in TET patients with AD, as compared with TET patients without AD. Moreover, TET patients with AD showed significantly higher circulating levels of IL-15 (p = 0.032), VEGF (p = 0.007), IP-10 (p = 0.013), GM-CSF (p = 0.042), IL-6 (p = 0.031), and MIP-1α (p = 0.017) with respect to TET patients without AD. **Conclusions:** To our knowledge, this is the first report describing a profound alteration in B and T lymphocytes in TET patients associated with AD. The observed differences may be potentially important in the clinical management of this complex disease. Additional studies are needed to better understand the immunophenotypic alterations in TETs patients. Research Sponsor: None.

TPS8590 **Poster Session**

Neoadjuvant and adjuvant capmatinib in resectable non–small cell lung cancer with *MET* exon 14 skipping mutation or high *MET* amplification: GEOMETRY-N trial. *First Author: Jay M. Lee, David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: Neoadjuvant therapy is the earliest opportunity to eliminate micrometastatic disease. Emerging data suggest that neoadjuvant therapy in non-small cell lung cancer (NSCLC) can elicit major pathological responses (MPRs) that translate into prolonged survival outcomes, serving as an early surrogate for efficacy. Adjuvant therapy can improve overall and disease-free survival (DFS) in patients with completely resected NSCLC. DFS observed with osimertinib in patients with early-stage *EGFR*-mutated tumors supports evaluation of other tyrosine kinase inhibitors (TKIs) in the neoadjuvant and adjuvant settings. In early-stage NSCLC, *MET* exon 14 skipping mutation (*MET*ex14) and de novo *MET* amplification (*MET*amp) are estimated to occur in up to 2.8% and 1.7% of patients, respectively. Capmatinib, a selective MET TKI, is FDA approved for patients with metastatic *MET*ex14 NSCLC. It was studied in GEOMETRY mono-1 in patients with advanced/metastatic NSCLC with *MET*ex14 or *MET*amp. In 2 treatment-naive *MET*ex14 cohorts, overall response rate (ORR) was 68% and 66%. In a treatment-naive high-level *MET*amp cohort, ORR was 40%. Capmatinib had a tolerable safety profile; most adverse events were reversible with dose adjustments. Based on the ORRs and safety profile observed in treatment-naive patients with advanced/metastatic *MET*-dysregulated NSCLC, GEOMETRY-N (NCT04926831), a Phase II, 2-cohort, 2-stage study, is evaluating the efficacy and safety of neoadjuvant and adjuvant capmatinib therapy in improving the MPR rate and outcomes in patients with *MET*ex14 or high-level *MET*amp NSCLC. **Methods:** Adults with resectable, histologically confirmed NSCLC stage IB-IIIA, N2 and select IIIB (T3N2 or T4N2) with either *MET*ex14 (cohort A) or high-level *MET*amp (gene copy number ≥10; cohort B) are eligible. *MET*ex14 must be determined by a Clinical Laboratory Improvement Amendments (CLIA)-certified lab. *MET*amp must be determined by fluorescence in situ hybridization at a CLIA-certified lab or by FoundationOne CDx next-generation sequencing. Prior systemic anticancer therapy is prohibited. Patients will receive capmatinib 400 mg twice daily for 8 weeks before surgical resection, followed by 3 years of adjuvant capmatinib. In the 2-stage design, stage 1 will enroll 9 patients per cohort, with MPR evaluated in each cohort after 9 patients have completed neoadjuvant therapy; stage 2, enrolling 10 more patients in a cohort, will proceed only if ≥1 of 9 participants has an MPR. About 42 patients will be enrolled, with 19 evaluable patients per cohort. Primary endpoint is MPR rate (local assessment). Secondary endpoints are complete pathological response rate (central and local review), ORR (local assessment), DFS, and safety. Following treatment, there will be a 2-year survival follow-up. Enrollment has started; expected first patient first visit: March 31, 2022. Clinical trial information: NCT04926831. Research Sponsor: Novartis Pharmaceuticals.

TPS8591 **Poster Session**

Phase III study with atezolizumab versus placebo in patients with malignant pleural mesothelioma after pleurectomy/decortication (AtezoMeso study). *First Author: Maria Pagano, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy*

Background: Surgery for malignant pleural mesothelioma (MPM) is indicated mainly in multimodal approaches and in clinical trial settings. Different studies have shown significantly lower complication rates, lower peri-operative morbidity and mortality with pleural/decortication (P/D), with similar overall survival rates. The biology of mesothelioma shows significant heterogeneity. Surgical tumor reduction may create a host environment more amenable to immunotherapy by reducing the ratio of tumor cells versus antitumor effector T lymphocytes, reducing the quantities of intratumor and/or systemic immunosuppressive cells, and ablating tumor-derived paracrine factors that promote local recruitment of immunosuppressive cells. Encouraging clinical data emerging in the field of tumor immunotherapy have demonstrated that therapies focused on enhancing T-cell responses against cancer can result in a significant survival benefit. The AtezoMeso Study evaluates the introduction of atezolizumab-ATEZO in MPM, patients (pts) after P/D and platinum/pemetrexed perioperative therapy. **Methods:** This is a double-blind, placebo controlled, phase III trial, in 20 Italian centers. Main inclusion criteria are P/D without macroscopic residual and ECOG-PS 0-1. Pts who underwent to P/D without macroscopic residual disease and have received at least 4 cycles of perioperative therapy with cisplatin/carboplatin and pemetrexed, will be randomized (2:1) to receive ATEZO or placebo. Therapy will be administered at dose of 1,200 mg iv, every 21 days, for 12 months or until recurrence, unacceptable toxicity or patient/physician decision. Randomization will be done through a centralized system, using histology (epithelioid vs nonepithelioid) and stage (I vs > I) as stratification factors. Pts will be radiologically evaluated after surgical before starting therapy and then every 12 weeks for 24 months or until recurrence. Quality of life (QoL) will be evaluated with the EQ-5D questionnaire administered at baseline and every 12 weeks. Tissue tumor samples will be centrally analyzed to determinate the genomic profile using FoundationOne CDx platform. The primary endpoint is the evaluation of the atezolizumab efficacy in terms of disease free survival (DFS). Secondary endpoints include the safety and efficacy in terms of overall survivall and QoL. Assuming a median DFS equal to 9 months in placebo arm, an accrual time of 24 months and a follow-up time of 24 months, a sample size of 162 pts will allow to detect true hazard ratios of 0.62 with power 0.8, at a confidence level of 95%. At February 14th, 2022, 3 pts have been enrolled. Clinical trial information: 2020-003762-39; GOIRC-02-2019. Research Sponsor: Roche.

TPS8592 **Poster Session**

Assessing the predictive value of ctDNA on relapse in patients with resected stage IB-IIIA NSCLC treated with adjuvant chemotherapy plus concomitant atezolizumab followed by atezolizumab: BTCRC LUN 19-396. *First Author: Fatemeh Ardeshir-Larijani, Indiana University, Melvin and Bren Simon Cancer Center, Indianapolis, IN*

Background: A standard of care treatment for most patients with stage II and III non-small cell lung cancer (NSCLC) and a PD-L1 > 1% is surgery followed by adjuvant (adj) histology-specific chemotherapy followed by 1 year of atezolizumab. The benefit of adding atezolizumab concomitantly to chemotherapy in the adj setting has not been reported. In addition, the optimal duration of adjuvant therapy is undefined. Emerging data have demonstrated the potential for ctDNA to predict clinical recurrence in patients with surgically resected lung, breast, and colon cancer. The current study explores the predictive value of ctDNA for early relapse in patients treated with adj chemotherapy plus atezolizumab. **Methods:** The LUN19-396 is a phase II biomarker study that enrolls pts with resected NSCLC stage IB (tumors ≥ 4cm), IIA, IIB, and select IIIA (T3N1-2, T4N0-2). The ctDNA will be assessed within 60 days post-surgery and then every 3 months up to 12 months. All pts will receive treatment with 4 cycles of Cisplatin 60-75mg/m2 + Docetaxel 60-75mg/m2 + Atezolizumab 1200mg IV on day 1 q 3w (for patients with squamous cell cancer) or Cisplatin 60-75mg/m2 + Pemetrexed 500mg/m2 + Atezolizumab 1200mg on day 1 IV q 3w (for patients with non-squamous cell), followed by up to 13 additional cycles of Atezolizumab 1200mg IV every 3w. This trial will enroll a total of 100 pts to achieve more than 80% power. The primary objective is to estimate the percentage of pts with detectable ctDNA after surgery who have clearance of ctDNA at designated time points during adjuvant therapy. The key secondary objective is to estimate the 1-year disease-free survival in pts with undetectable ctDNA after 4 cycles of adj chemotherapy plus atezolizumab who had detectable ctDNA after surgery. This trial has enrolled 17 pts as of February 8, 2022. Clinical trial information: NCT04367311. Research Sponsor: Genentech.

TPS8593 **Poster Session**

A phase 1/2 study of REGN5093-M114, a METxMET antibody-drug conjugate, in patients with mesenchymal epithelial transition factor (MET)-overexpressing NSCLC. *First Author: Alexander E. Drilon, Department of Medicine, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: MET, also called hepatocyte growth factor receptor (HGFR), is a high-affinity transmembrane protein receptor for HGF. MET is overexpressed in various malignancies, including non-small cell lung cancer (NSCLC). MET overexpression can accompany *MET* exon 14 alteration or de novo/acquired *MET* amplification. REGN5093-M114 is an antibody drug conjugate composed of a novel linker-payload (M114, carrying the maytansine derivative M24, a potent inhibitor of microtubule assembly) covalently bound to lysine residues on a MET-targeting human IgG4p bispecific antibody, REGN5093. In preclinical models of MET overexpressing cancers, REGN5093-M114 demonstrated significant dose-dependent antitumor activity. **Methods:** This is an open label, phase 1/2, first-in-human, multicenter dose-escalation study with cohort expansion evaluating REGN5093-M114 in patients with MET-overexpressing NSCLC (NCT04982224). Patients must have advanced stage NSCLC for which there are no approved therapies available expected to confer clinical benefit, with tumor overexpressing MET (≥75% tumor cell staining at 2+) as centrally confirmed by immunohistochemistry. For the expansion phase, patients must have at least one lesion that is measurable by RECIST 1.1. REGN5093-M114 will be administered intravenously once every 3 weeks over 30 minutes until disease progression, intolerable adverse events, withdrawal of consent, or study withdrawal. The primary objectives in dose escalation are to evaluate safety, tolerability, PK, and maximum tolerated dose and/or recommended phase 2 dosing regimen of REGN5093-M114. PKs will include the assessment of REGN5093-M114, total antibody, and payload M24 concentrations. The primary objective in dose expansion is to assess preliminary anti-tumor activity of REGN5093-M114 in MET-overexpressing NSCLC as measured by the objective response rate. The secondary objectives of both phases of the study include an evaluation of treatment durability, and the immunogenicity of REGN5093-M114. This study is currently open to enrollment. Clinical trial information: NCT04982224. Research Sponsor: Regeneron Pharmaceuticals, Inc.

TPS8594 **Poster Session**

LIBRETTO-001 cohort 7: A single-arm, phase 2 study of neoadjuvant selpercatinib in patients with resectable stage IB-IIIA *RET* fusion-positive NSCLC. *First Author: Ravi Rajaram, Department of Thoracic and Cardiovascular Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Despite definitive surgery and perioperative chemotherapy, many patients with locoregional non-small cell lung cancer (NSCLC) continue to experience recurrent disease and limited survival. Although targeted therapies are standard treatment for metastatic NSCLC with genomic alterations, their use in the early-stage setting is still being characterized. Initial studies examining targeted therapy in neoadjuvant setting for early-stage epidermal growth factor receptor positive NSCLC has shown promise. Selpercatinib is a highly selective, potent, and central nervous system active rearranged during transfection (RET) inhibitor with demonstrated robust and sustained antitumor activity and manageable toxicity in patients with *RET* fusion-positive advanced NSCLC. Cohort 7 of the Phase 2, open-label, single arm LIBRETTO-001 study evaluates efficacy and safety of neoadjuvant selpercatinib in patients with resectable stage IB-IIIA *RET* fusion-positive NSCLC (NCT03157128). **Methods:** Key eligibility criteria include age ≥18 years; histologically confirmed stage IB–IIIA NSCLC (AJCC, version 8); presence of *RET* fusion in tumor (by PCR or NGS) or blood (by NGS) (pre-treatment biopsy confirmed); resectable and operable tumor; measurable disease (RECIST 1.1); and ECOG performance status 0-1. Key exclusion criteria include presence of other known oncogenic drivers; and concurrent investigational anticancer therapy. Eligible patients will undergo full staging including radiographic tumor measurements using CT, PET, and brain MRI at baseline and after two 28-day cycles of neoadjuvant selpercatinib, followed by surgery. Dosing regimen is 160 mg twice daily. Resected tumor specimens will be sent to an Independent Pathology Review Committee (IPRC) for evaluation. Patients may then be treated with stage-appropriate adjuvant therapy/surveillance, based on the treating physician's decision, followed by selpercatinib until disease recurrence, unacceptable toxicity, withdrawal, or death, for a maximum treatment duration of 3 years. The primary endpoint is to determine the rate of major pathologic response (MPR) by IPRC, defined as ≤ 10% residual viable tumor cells in the surgically resected specimen. Efficacy based on the MPR will be assessed using the Simon's 2-stage design. In Stage I, 9 patients will be enrolled; if ≤1 patient achieves an MPR, the study will be stopped. Otherwise, at least 10 additional patients will be enrolled, with a total of 19 patients undergoing surgery. The rate of pathologic complete response (pCR) by IPRC, disease-free survival, and overall survival will be assessed as secondary endpoints. pCR rate will be determined at the time of surgery, indicating no remaining viable tumor cells. Safety of peri-operative treatment will be assessed, including 30- and 90-day post-operative readmission and mortality rates. Clinical trial information: NCT03157128. Research Sponsor: Eli Lilly and Company.

TPS8595 **Poster Session**

A first-in-human phase 1 study of the next-generation RET inhibitor, LOXO-260, in RET inhibitor refractory patients with RET-altered cancers (trial in progress). *First Author: Nathan A. Pennell, Department of Hematology and Medical Oncology, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH*

Background: *RET* fusions are found in 1-2% of lung adenocarcinomas and 10-20% of papillary thyroid carcinomas. Activating *RET* mutations occur in 50-60% of medullary thyroid cancers (MTCs). Selpercatinib was the first selective RET inhibitor approved by the FDA and is indicated for patients (pts) with *RET* fusion-positive NSCLC and thyroid cancer, and *RET* mutant MTC. Despite marked and durable activity, acquired resistance can eventually develop through a variety of mechanisms. These include acquisition of RET G810X mutations at the solvent front of the ATP pocket. LOXO-260 is a highly potent and selective inhibitor of RET designed to have activity against both solvent front and gatekeeper mutations, expressed alone or together, while maintaining potency against *RET* fusions or mutations (Kolakowski GR. et al. 2021 *Cancer Research* 81 (13 Suppl) 1464). **Methods:** LOXO-NGR-21001 is a global, open-label, first-in-human phase 1 study of LOXO-260 in pts with *RET* fusion-positive advanced solid tumors and *RET* mutant MTC who received a prior selective RET inhibitor. Phase 1a dose escalation will utilize a modified i3+3 design, allowing for pt backfill to previously cleared dose levels. Phase 1b dose expansion will evaluate LOXO-260 in specific expansion cohorts: *RET* fusion-positive NSCLC or thyroid cancers and *RET* mutant MTC. The primary objectives in dose escalation are to determine the MTD/RP2D and safety of LOXO-260. Key secondary objectives include characterization of PK and preliminary antitumor activity of LOXO-260 per RECIST v1.1. The primary objective of dose expansion is to assess the antitumor activity of LOXO-260 based on investigator-assessed overall response rate (ORR). Key secondary objectives are to characterize the PK and antitumor activity of LOXO-260 based on progression-free survival (PFS), time to response (TTR), and duration of response (DOR). Eligible pts must have received a prior selective RET inhibitor, have a documented *RET* fusion or *RET* mutation and a diagnosis of locally advanced, unresectable and/or metastatic cancer per disease-specific criteria, and must have progressed or be intolerant to standard therapies or must have refused such a therapy. Pts must be ≥18 years old and have an ECOG PS of 0-2. Key exclusion criteria include presence of serious cardiac conditions, interstitial lung disease, symptomatic CNS metastases, or carcinomatous meningitis. Clinical trial information: NCT05241834. Research Sponsor: Loxo Oncology.

TPS8596 **Poster Session**

LCMC LEADER neoadjuvant screening trial: LCMC4 evaluation of actionable drivers in early-stage lung cancers. *First Author: Boris Sepesi, Thoracic and Cardiovascular Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Comprehensive genomic profiling (CGP) has transformed the care of patients with advanced non-small cell lung cancer (NSCLC), giving many patients access to precision targeted treatment and immunotherapy with remarkable improvements in outcomes. Studies show that patients with lung cancers with oncogenic drivers are the least likely group to benefit from checkpoint inhibitors and are better served by enrollment in studies of targeted therapies. Early-stage NSCLC is now poised to benefit from these precision approaches with the regulatory approval of the first tyrosine kinase inhibitors and checkpoint inhibitors for the adjuvant treatment of resected NSCLC, each requiring testing for precision biomarkers. Neoadjuvant precision therapy for NSCLC has the potential to further improve treatment outcomes. **Methods:** The LCMC4 Evaluation of Actionable Drivers in EaRly Stage Lung Cancer (LEADER) Neoadjuvant Screening Trial (NCT04712877) is a collaborative diagnostic study developed by the Lung Cancer Mutation Consortium (LCMC), supported by the Thoracic Surgery Oncology Group and the Lung Cancer Research Foundation. The primary objective is to determine the proportion of patients with stage IA2-III lung cancers who possess actionable oncogenic drivers, defined as 1 of 11 actionable genomic alterations: mutations in *EGFR, BRAF*^{V600E} , *MET* exon 14, *KRAS* G12C, and *HER2*, rearrangements in *ALK, RET, NTRK, and ROS1,* and amplification of *MET* and *HER2*. The study will also assess the feasibility of CGP to detect actionable oncogenic drivers in patients with suspected early-stage lung cancers scheduled to undergo biopsies to establish the diagnosis of lung cancer. The protocol will enroll 1000 patients with operable stage IA2-III (TNM 8th edition) lung cancer who will undergo CGP utilizing the Foundation Medicine 324 gene assay as well as paired liquid biopsy analysis. Results will enable selection of neoadjuvant therapy and enrollment onto independent therapeutic trials with genomically matched neoadjuvant treatment, standard therapies, or other trials if no driver is detected. The approach will be considered feasible if >35% of non-squamous NSCLCs have 1 of the 11 actionable alterations. Tumor mutational burden and PD-L1 IHC will be assessed. Plasma specimens collected pre- and post neoadjuvant treatment and post-surgery will be used for research to study the ability of circulating tumor DNA to assess neoadjuvant treatment response and minimal residual disease. 26 academic sites in the US plan to enroll patients. Clinical trial information: NCT04712877. Research Sponsor: Genentech, Other Foundation, Pharmaceutical/Biotech Company.

TPS8597 **Poster Session**

Phase 3, randomized, placebo-controlled study of stereotactic body radiotherapy (SBRT) with or without pembrolizumab in patients with unresected stage I or II non–small cell lung cancer (NSCLC): KEYNOTE-867. *First Author: Salma K. Jabbour, Department of Radiation Oncology, Rutgers Cancer Institute of New Jersey, Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ*

Background: Anti–PD-(L)1-directed therapy following radiotherapy or following concurrent chemoradiation is associated with significantly longer PFS and OS in patients with advanced or metastatic NSCLC, including those with locally advanced inoperable tumors. KEYNOTE-867 (NCT03924869) evaluates the efficacy and safety of SBRT with or without pembrolizumab in patients with unresected stage I or II NSCLC. **Methods:** In this phase 3, randomized, placebo-controlled study, approximately 530 adult patients with previously untreated, unresected, histologically/cytologically confirmed stage I or II (T1 to limited T3, N0, M0) NSCLC are randomized 1:1 to receive thoracic SBRT to primary tumors for ≤2 wk (Table) and either pembrolizumab 200 mg or placebo every 3 wk for 17 cycles (approximately 1 year) or until disease recurrence, development of unacceptable AEs, SBRT not started for any reason, or study withdrawal. Randomization is stratified by disease stage (I vs II), ECOG PS (0 or 1 vs 2), geographic region (East Asia vs non-East Asia), and reason for not receiving surgery (medically inoperable vs refused surgery). Imaging assessment by blinded independent central review (BICR) occurs at 12 wk (≥10 wk after SBRT completion), followed by every 16 wk for 3 y, and then every 6 mo. Primary endpoints are event-free survival (EFS) by BICR and OS. Secondary endpoints include time to death or distant metastases and safety; exploratory endpoints are time to subsequent treatment, disease-specific survival, and time to recurrence/progression on subsequent line of therapy. AEs are monitored throughout the trial until 30 d after last dose (90 for serious AEs) and graded according to NCI CTCAE version 4.0. EFS and OS are analyzed by the nonparametric Kaplan-Meier method, treatment differences by stratified log-rank test, and hazard ratios by stratified Cox proportional hazard model with Efron's method of tie handling. Enrollment started on June 17, 2019, and is ongoing at 168 sites around the world. Clinical trial information: NCT03924869. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Stereotactic body radiotherapy regimen.[a]

Unit Dose Strength(s)	
Peripheral tumors	45–60 Gy in 3 fractions (preferred regimen); 48–50 Gy in 4 fractions or 50–55 Gy in 5 fractions (acceptable regimens)
Tumors abutting the chest wall	48–50 Gy in 4 fractions; 50–55 Gy in 5 fractions
Central tumors	50–55 Gy in 5 fractions; 60–70 Gy in 8 fractions

[a]Regimens have been amended since the original protocol.

TPS8598 **Poster Session**

Phase 2 randomized trial of neoadjuvant or palliative chemotherapy with or without immunotherapy for peritoneal mesothelioma (Alliance A092001). *First Author: Aaron Scott Mansfield, Mayo Clinic, Rochester, MN*

Background: Peritoneal mesothelioma is a rare and poorly studied disease with few treatment options. For patients who are not surgical candidates, treatment recommendations for systemic therapy have been extrapolated from clinical trials for pleural mesothelioma that commonly exclude patients with peritoneal mesothelioma. Recently, the combination of the PD-1 inhibitor nivolumab and the CTLA-4 inhibitor ipilimumab received FDA-approval for the frontline treatment of non-resectable pleural mesothelioma. Additionally, a prospective, non-randomized phase 2 trial demonstrated activity with combined PD-L1 (atezolizumab) and VEGF (bevacizumab) blockade in peritoneal mesothelioma. In parallel, encouraging activity with combined chemo-immunotherapy has been reported in pleural mesothelioma. Given the benefits observed with immunotherapy, and the potential to improve upon those with chemotherapy and VEGF inhibition, we seek to determine whether the addition of the PD-L1 inhibitor atezolizumab improves outcomes with chemotherapy and bevacizumab in patients with newly diagnosed peritoneal mesothelioma. **Methods:** A092001 is a prospective, randomized phase 2 clinical trial. All patients with newly diagnosed peritoneal mesothelioma will be randomized 1:1 using a dynamic allocation Pocock-Simon procedure to receive carboplatin, pemetrexed, and bevacizumab, with or without atezolizumab, every 21 days for four cycles. Patients who are eligible to proceed with surgery after four cycles of therapy will then do so. Patients who are not eligible to proceed with surgery may receive maintenance bevacizumab and atezolizumab, or second-line atezolizumab with bevacizumab until progression of disease or toxicity. The primary objective is to determine whether frontline treatment with carboplatin, pemetrexed, bevacizumab and atezolizumab results in a superior best response rate (RR) to carboplatin, pemetrexed and bevacizumab as determined by RECIST. With 31 eligible patients per arm (62 eligible total), this randomized design has 80% power to detect an improvement in the RR from 20% to 45%, with a 1-sided significance level of 0.10 where an interim futility analysis will be conducted after 32 patients are enrolled. As stratification factors we have included eligibility for cytoreductive surgery at diagnosis, and histologic subtype. Secondary endpoints include assessment of progression-free survival, overall survival, and adverse events. As integrated biomarkers, we will determine if soluble mesothelin-related peptides and megakaryocyte potentiating factor correlate with responses. This trial was recently approved by the National Cancer Institute Central IRB and is activating at sites across the country. Support: U10CA180821, U10CA180882. Clinical trial information: NCT05001880. Research Sponsor: U.S. National Institutes of Health.

TPS8599 **Poster Session**

DREAM3R: Durvalumab with chemotherapy as first-line treatment in advanced pleural mesothelioma—A phase 3 randomized trial. *First Author: Patrick M. Forde, The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Combination PD1/CTLA4 immune checkpoint blockade and platinum-pemetrexed (CP) chemotherapy are standard first-line options for the treatment of unresectable malignant pleural mesothelioma (MPM). Two recent, single-arm, phase 2 trials (DREAM and PrE0505) combining the PD-L1 inhibitor durvalumab and standard first line CP both exceeded pre-specified efficacy criteria. The Phase 3 DREAM3R trial aims to determine the effectiveness of including durvalumab with first line CP chemotherapy in advanced MPM. **Methods:** Treatment-naïve patients with advanced MPM will be randomized (2:1) to either durvalumab 1500 mg every 3 weeks plus chemotherapy (cisplatin 75 mg/m2 or carboplatin AUC 5 and pemetrexed 500 mg/m2) every 3 weeks for 4-6 cycles (Arm A), followed by durvalumab 1500 mg every 4 weeks until disease progression, unacceptable toxicity or patient withdrawal, versus doublet chemotherapy alone for 4-6 cycles with all patients monitored for progression. The target sample size is 480 patients recruited over 27 months, with follow up for an additional 24 months. This provides over 85% power if the true hazard ratio for overall survival (OS) is 0.70, with 2-sided alpha of 0.05, assuming a median OS of 15 months in the control group. Key eligibility criteria include: MPM of any histological subtype; measurable disease per RECIST 1.1 modified for mesothelioma (mRECIST 1.1); ECOG PS 0-1; and adequate hematologic, renal, and liver function. Exclusions: Prior systemic anticancer treatment for MPM, diagnosis based solely on cytology or fine needle aspiration biopsy, contraindication to immunotherapy or conditions requiring immunosuppressive agents or corticosteroids. Patients will be further stratified at randomization by: Age (18-70 years vs. > 70), sex, histology (epithelioid vs. non-epithelioid), planned platinum (cisplatin vs. carboplatin) and geographic region (USA vs. ANZ). The primary endpoint is OS. Secondary endpoints include progression-free survival; objective tumor response; adverse events; health-related quality of life; and healthcare resource use in ANZ. Tertiary correlative objectives aim to further explore and validate potential prognostic and/or predictive biomarkers (including those identified in the DREAM and PrE0505 studies, PD-L1 expression, tumor mutation burden, genomic characteristics, and HLA subtypes) via tissue and serial blood samples. An imaging databank will be assembled for validation of radiological measures of response, and studies of possible radiomic biomarkers in mesothelioma. The study is active and enrolling in both ANZ and in the US. Clinical trial information: NCT04334759 and ACTRN 12620001199909. Research Sponsor: AstraZeneca.

TPS8600 **Poster Session**

An open-label, multicenter, phase 2 study of the safety and efficacy of navtemadlin (KRT-232) in patients with *TP53* wild-type relapsed/refractory small cell lung cancer. *First Author: Afshin Dowlati, University Hospitals Seidman Cancer Center and Case Western Reserve University, Cleveland, OH*

Background: Small cell lung cancer (SCLC) is a highly aggressive neuroendocrine tumor characterized by early metastasis and a high recurrence rate with currently available treatment options. Although SCLC is generally sensitive to initial chemotherapy, responses are not durable and most patients eventually relapse. Prognosis is poorer in the relapsed/refractory (R/R) setting and currently available treatment options, including checkpoint inhibitors, are associated with a median overall survival of 2-9 months (Chauhan 2020; Trigo 2020; Chung 2020). Approximately 15% of patients have a *TP53* wild-type ($TP53^{WT}$) gene. In patients with extensive-stage SCLC, $TP53^{WT}$ is paradoxically associated with an inferior response to chemotherapy (Dowlati 2016). Thus, the presence of $TP53^{WT}$ may help identify a small subset of patients with an even greater unmet need. Murine double minute 2 (MDM2) is the key negative regulator of the tumor suppressor protein, p53, which can induce apoptosis of malignant cells by shifting the balance between prosurvival and proapoptotic BCL-2 family members. In SCLC cell lines, MDM2 inhibition restored p53 function leading to downregulation of prosurvival Bcl-2 and Mcl-1 proteins, and upregulation of the proapoptotic Bim protein, thereby inducing cancer cell death (Yu 2019). Navtemadlin (KRT-232) is a potent, selective, orally available MDM2 inhibitor that restores p53 function to drive apoptosis of $TP53^{WT}$ malignancies. Treatment with navtemadlin may be an effective strategy for patients with $TP53^{WT}$ SCLC. **Methods:** The open-label, multicenter Phase 2 KRT-232-112 study (NCT05027867) is evaluating navtemadlin in $TP53^{WT}$ patients with R/R SCLC. Eligibility criteria include age ≥18 years, ECOG performance status ≤2, presence of measurable disease and demonstrated radiographic progression after ≥1 prior platinum-containing therapy with no curative therapy available. Patients must have received a checkpoint inhibitor if available and not contraindicated. Patients with symptomatic or uncontrolled central nervous system metastases or those with prior MDM2 inhibitor treatment will be excluded. In part 1 of the study, approximately 20 patients will be randomly assigned to receive oral navtemadlin once daily in 21-day cycles at 240 mg 7 days (D) on/14D off (Arm A) or 180 mg 7D on/14D off (Arm B) until disease progression or unacceptable toxicity. In part 2, an additional 18 patients will be enrolled in each arm selected for expansion. The primary endpoint is objective response rate per RECIST v1.1. Secondary endpoints include duration of response, progression-free survival, overall survival, disease control rate, and safety. This trial is ongoing and will enroll patients at approximately 40 global sites. Clinical trial information: NCT05027867. Research Sponsor: Kartos Therapeutics, Inc.

TPS8601 **Poster Session**

TRUST-II: A global phase II study for taletrectinib in *ROS1* fusion–positive lung cancer and other solid tumors. *First Author: Misako Nagasaka, University of California Irvine School of Medicine and Chao Family Comprehensive Cancer Center, Orange, CA*

Background: Taletrectinib (AB-106/DS-6051b) is a next-generation, brain-penetrant, ROS1/ NTRK tyrosine kinase inhibitor (TKI) and has shown clinically meaningful effect and safety profile in ROS1+ Non-Small Cell Lung Cancer (NSCLC) patients in phase 1 studies (Fujiwara et al, Oncotarget 2018; 9(34): 23729-23737; Ou et al, JTO Clin Res Rep. 2020 Oct 21;2(1):100108). Taletrectinib has also demonstrated activity against ROS1 G2032R resistance mutation and CNS metastases in the ongoing phase 2 TRUST study (NCT04395677) in China. Also, taletrectinib has shown preliminary efficacy against NTRK positive solid tumors in an ongoing phase 2 study (NCT04617054). **Methods:** TRUST-II study (NCT04919811) is a phase 2, global, multicenter, open-label, single-arm multicohort study evaluating the efficacy and safety of taletrectinib for *ROS1* fusion-positive advanced metastatic NSCLC and other solid tumors. Taletrectinib will be given at 600 mg once daily in 21-day cycle. The patients with ROS1 fusions detected by local tests are eligible to enroll with retrospective confirmation by a central laboratory. The study consists of four cohorts: cohort 1: systemic chemotherapy naïve or ≤ one prior line and ROS1 TKI naïve NSCLC (N = 53); cohort 2: previously treated with one ROS1 TKI (crizotinib or entrectinib) and with progression who are either chemotherapy naïve or ≤ one line of platinum and/or pemetrexed based therapy for NSCLC (N = 46); cohort 3: ≤ 2 prior ROS1 TKIs and with progression who are either chemotherapy naïve or ≤ 2 lines of platinum and/or pemetrexed based therapy for NSCLC (N = 10); and cohort 4: systemic chemotherapy naïve or ≤ 2 prior lines of chemotherapy, but ROS1-TKI naïve ROS1 positive solid tumor other than NSCLC (N = 10). The primary endpoint is objective response rate (ORR) (RECIST v1.1) by independent review committee (IRC) assessment for cohorts 1 and 2. Key secondary endpoints include IRC-assessed duration of response, IRC-assessed intra-cranial ORR, progression free survival (PFS), overall survival (OS), and safety. This study is currently recruiting in Japan, Republic of Korea, and USA. Additional accrual is planned in Canada, China, and European Union. Clinical trial information: NCT04919811. Research Sponsor: AnHeart Therapeutics Inc.

TPS8603 **Poster Session**

Phase 2 study of tarlatamab, a DLL3-targeting, half life–extended, bispecific T-cell engager (HLE BiTE) immuno-oncology therapy, in relapsed/refractory small cell lung cancer (SCLC). *First Author: Suresh S. Ramalingam, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: SCLC is characterized by rapid growth and early development of metastases. Platinum-based first-line chemotherapy is associated with a high initial response rate; however, disease recurrence is common. Delta-like ligand 3 (DLL3) is a Notch ligand that is upregulated and aberrantly expressed on the cell surface in most SCLC, making it a compelling therapeutic target. Tarlatamab is an HLE BiTE immuno-oncology therapy designed to bind DLL3 on target cancer cells and CD3 on T cells, forming a cytolytic synapse inducing T cell activation and expansion and T cell-dependent killing of tumor cells. Interim results of an ongoing first-in-human study in patients with relapsed/refractory SCLC (NCT03319940) show preliminary evidence for tarlatamab efficacy in pretreated patients with confirmed partial responses in 20% of patients and duration of response of 8.7 months (Owonikoko TK, et al. Abstract 8510. Presented at: ASCO Annual Meeting, June 4–8, 2021; Virtual). Grade ≥ 3 treatment-related AEs (TRAEs) occurred in 27% of patients and TRAEs resulted in discontinuation in 5% of patients. This promising efficacy/safety profile supports further study of tarlatamab in SCLC. **Methods:** NCT05060016 is a phase 2, open-label study evaluating tarlatamab in patients with relapsed/refractory SCLC after two or more lines of prior treatment. Part 1 is a dose characterization phase in which subjects will be randomized 1:1 to two active doses of tarlatamab. Part 2 will continue enrollment for the selected target dose only based on interim analysis of Part 1. Key eligibility criteria include adults with histologically or cytologically confirmed SCLC whose disease progressed/recurred after two or more lines of prior treatment including at least 1 platinum-based regimen (including a PD-L1 inhibitor, if standard of care, with certain exceptions per protocol), treated brain metastases, ECOG performance status ≤1, and life expectancy ≥ 12 weeks in the opinion of the investigator. The primary endpoint for the primary analysis is ORR per RECIST 1.1 as assessed by blinded independent central review. Secondary objectives are to evaluate antitumor activity by additional measures (duration of response, progression-free survival, disease control rate and duration, overall survival), safety and tolerability, immunogenicity, and pharmacokinetics. Sites in North America, Asia and Europe are participating in the trial with subjects already enrolled and enrollment ongoing. Clinical trial information: NCT05060016. Research Sponsor: Amgen Inc.

TPS8604 **Poster Session**

MC1923 phase II clinical trial of durvalumab (MEDI4736) and topotecan or lurbinectedin in patients with relapsed extensive-stage small cell lung cancer previously treated with chemotherapy and immunotherapy. *First Author: Konstantinos Leventakos, Department of Oncology, Mayo Clinic, Rochester, MN*

Background: Chemoimmunotherapy followed by durvalumab maintenance yields a median overall survival of 12.9 months in patients with extensive stage Small Cell Lung Cancer (ES SCLC), which is an improvement over chemotherapy alone. However, 90% of these patients will have progressive disease. While topotecan and lurbinectedin have established modest activity in the second line, it is unknown whether continuing immunotherapy in this setting confers additional benefit. In preclinical studies lurbinectedin, a DNA minor groove binder, used with immune checkpoint inhibitors has synergistic effects. **Methods:** This phase 2 trial is enrolling patients with ES SCLC who have progressed on platinum based chemoimmunotherapy, to three treatment groups. Group 1 includes patients with platinum sensitive SCLC who will receive durvalumab (1500 mg given as an intravenous [IV] infusion once every 3 weeks) and topotecan (1.25 mg/m^2/day IV for 5 consecutive days every 3 weeks). In Groups 2A and 2B, patients with platinum sensitive and platinum resistant disease respectively, receive durvalumab and lurbinectedin (3.2 mg/m^2 IV on Day 1 of every 21-day cycle). Patients with platinum sensitive disease are assigned to Groups 1 or 2A based on the preferences of the treating physician and the patient. Patients with treated/stable CNS metastases are eligible. The primary endpoint is the proportion of patients who are alive at 6 months (6OS) for Group 1 and the proportion of patients who are alive and progression-free at 6 months (6PFS) in Groups 2A and 2B. Secondary endpoints include safety, adverse event profile, response rate, PFS, and OS. The sample size is based on a 2-stage Simon Optimal Design. For Treatment Group 1, with 22 eligible patients there is 80% power to detect a true 6-month OS rate (6OS) of 75%, with 10% alpha under the null hypothesis that the true 6OS is at most 50%. For Treatment Group 2A, with 20 eligible patients this design has 80% power to detect a true 6-month PFS rate (6PFS) of 65%, with 10% alpha under the null hypothesis that the true 6PFS is at most 40%. For Treatment Group 2B, with 22 eligible patients this design has 80% power to detect a true 6-month PFS rate (6PFS) of 40%, with 10% alpha under the null hypothesis that the true 6PFS is at most 19%. To account for possible drop-outs, accrual targets will be 24, 22, and 24 patients to Groups 1, 2A, and 2B respectively. For the safety analyses, 6 patients will be enrolled at the starting dose level for each treatment group (1, 2) and then briefly closed to accrual to assess adverse events. If we observe 2+ DLTs in these 6 treated patients during Cycle 1 within a treatment group (1 vs. 2), we will declare the combination treatment too toxic and lower the starting dose of chemotherapy for the next 6 patients. The study was open for all 3 groups as of January 2022 and has accrued 2 patients. Clinical trial information: NCT04607954. Research Sponsor: AstraZeneca.

TPS8606 **Poster Session**

KeyVibe-008: Randomized, phase 3 study of first-line vibostolimab plus pembrolizumab plus etoposide/platinum versus atezolizumab plus EP in extensive-stage small cell lung cancer. *First Author: Jacob Sands, Dana-Farber Cancer Institute, Boston, MA*

Background: Current standard of care immunotherapy plus chemotherapy options for first-line extensive-stage small-cell lung cancer (ES-SCLC) are associated with modest improvements in median OS and PFS. In the KEYNOTE-604 study, first-line pembrolizumab plus etoposide/platinum (EP) significantly improved PFS (HR 0.75; 95% CI, 0.61–0.91; $P = 0.0023$) compared with placebo plus EP in ES-SCLC; OS was also longer with pembrolizumab plus EP vs placebo plus EP but did not reach statistical significance (HR 0.80; 95% CI, 0.64–0.98; $P = 0.0164$). Preclinical and clinical data suggest that blocking the interaction between the T-cell immunoreceptor with immunoglobulin and ITIM domains (TIGIT) and its ligands CD112 and CD155 with the anti-TIGIT humanized monoclonal antibody vibostolimab (MK-7684) yields promising antitumor activity when combined with pembrolizumab, with or without chemotherapy, including in patients with lung cancer. The current phase 3 study, KeyVibe-008 (NCT05224141), is comparing the efficacy and safety of first-line treatment with MK-7684A, a co-formulation of vibostolimab plus pembrolizumab, in combination with EP vs atezolizumab plus EP in patients with ES-SCLC. **Methods:** This multicenter, randomized, double-blind, phase 3 study is enrolling patients aged ≥18 years with histologically or cytologically confirmed, previously untreated ES-SCLC. Patients must have measurable disease per RECIST v1.1; ECOG PS of 0 or 1; no active CNS metastases/carcinomatous meningitis, autoimmune disease, neurologic paraneoplastic syndromes, pneumonitis, or interstitial lung disease; and must provide a pretreatment tumor sample. Patients are randomized 1:1 to receive up to 4 cycles of EP (cisplatin or carboplatin) in combination with MK-7684A (vibostolimab 200 mg + pembrolizumab 200 mg) Q3W or atezolizumab (1200 mg) Q3W, followed by MK-7684A or atezolizumab, respectively, until disease progression, unacceptable AEs, intercurrent illness, protocol violation, or investigator/patient decision. Randomization is stratified by ECOG PS (0 vs 1), LDH (≤ULN vs > ULN), liver metastases (yes vs no), and brain metastases (yes vs no). The primary endpoint is OS. Secondary endpoints include PFS, ORR, and duration of response per RECIST v1.1 by blinded independent central review; safety; and patient-reported outcomes (PROs). Tumor imaging occurs at baseline, every 6 weeks until 48 weeks, and every 9 weeks thereafter until disease progression, start of new anticancer treatment, withdrawal of consent, or death. PROs are assessed using validated instruments including the EORTC quality of life and EuroQol questionnaires. AEs are graded according to NCI CTCAE v5.0. Enrollment is ongoing worldwide. Clinical trial information: NCT05224141. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS8607 **Poster Session**

Phase II study of KN046 in patients with thymic carcinoma who failed immune checkpoint inhibitors. *First Author: Barbara Ting-wen Ma, Weill Cornell Medicine, New York-Presbyterian Hospital, New York, NY*

Background: Thymic carcinomas are the most aggressive form of thymic epithelial tumors. They are often not operable and are more resistant to chemotherapy than thymomas. Thymic carcinoma is sensitive to pembrolizumab. However, most patients who respond to pembrolizumab eventually recur. Recently, molecules that combine PD(L)1 and CTLA-4 have been developed for solid tumor patients, with the hope that targeted therapy will be more effective than standard of care. KN046 is a bi-specific antibody against PD-L1 and CTLA-4 with a much higher affinity of the anti-PD-L1 portion and a weaker affinity for anti-CTLA-4, potentially leading to less autoimmune disorders and toxicities. We developed a Phase II study to test the hypothesis that dual PD-L1 and CTLA-4 inhibition with KN046 may represent a safe and tolerable option for patients with advanced thymic carcinoma who have progressed on prior treatment with immune checkpoint inhibitors. **Methods:** Key eligibility criteria include thymic carcinoma with progression after treatment with an immune checkpoint inhibitor with no limit to prior lines of therapy, adequate organ function and performance status. History of prior or current autoimmune disorders are not allowed and history of baseline positive anti-acetylcholine receptor (AChR) autoantibody are not allowed. KN046 will be administered intravenously at 5 mg/kg every 2 weeks until progression or excessive toxicity for up to 2 years. A cycle is defined as 2 treatments (28 days). The primary objective is to evaluate the antitumor activity of KN046 in patients with thymic carcinoma as measured by overall response rate defined by RECIST 1.1 criteria. The secondary objectives are to assess the safety and tolerability of KN046 including safety as measured by the number of adverse events (CTCAE 5.0), duration of response (RECIST 1.1) from first documented response to the date of first documented disease progression, progression-free survival, and overall survival. Exploratory objectives include the association of biomarkers (PD-L1 expression, tumor immune microenvironment determined by multiplex IHC, tumor mutational burden, T-cell inflamed gene expression profile) and clinical efficacy parameters. We will also characterize the safety laboratory results (AChR autoantibodies and creatinine kinase) and the occurrence of adverse events of interest. Simon's two-stage design will be used. The null hypothesis that the true response rate is 5% will be tested against a one-sided alternative of target response rate ≥20%. In the first stage, 10 patients will be accrued. If there are no responses in the first stage, then the study will be stopped. Otherwise, 19 additional patients will be accrued for a total of 29 patients. The null hypothesis will be rejected if ≥4 responses are observed in 29 patients, with a type 1 error rate of 0.05 and power of 80%. The study was activated at Weill Cornell Medicine in December 2021. Clinical trial information: NCT04925947. Research Sponsor: Jiangsu Alphamab Biopharmaceuticals.

9000 **Oral Abstract Session**

Outcomes of anti–PD-(L)1 therapy with or without chemotherapy (chemo) for first-line (1L) treatment of advanced non–small cell lung cancer (NSCLC) with PD-L1 score ≥ 50%: FDA pooled analysis. *First Author: Oladimeji Akinboro, Center for Drug Evaluation and Research, U.S. Food and Drug Administration, Silver Spring, MD*

Background: FDA-approved 1L treatment options for patients with PD-L1-high advanced NSCLC (PD-L1 score ≥50%) include IO ± chemo (± anti-angiogenics) but it is unclear if chemo substantially improves efficacy outcomes when added to IO in this patient population. **Methods:** Data was pooled from 12 randomized controlled trials that investigated anti-PD-(L)1 regimens ± chemo for the 1L treatment of patients with advanced NSCLC. PD-L1 score was defined as the proportion of tumor cells stained by the assay and analysis was conducted for patients with tumor PD-L1 score ≥50%. OS, PFS, and ORR were compared between chemo-IO and IO alone via a pooled analysis. Median survival times were estimated using Kaplan-Meier methods. Hazard ratios were estimated using Cox proportional hazards models stratified by trial; odds ratios were estimated using a logistic regression model with trial as a covariate. All analyses were adjusted for age, sex, race, ECOG, histology and smoking status. **Results:** A total of 3,189 patients with NSCLC and PD-L1 score ≥50% were identified for this analysis. Baseline characteristics were: 38% ages 65-74 years and 11% ages ≥75 years; 69% male; 80% White; 66% ECOG ≥1; and 89% former/current smokers. Median OS in the pooled chemo-IO (*N*=455) and IO-only (*N*=1,298) arms was 25.0 vs 20.9 months (HR 0.82; 95% CI: 0.62, 1.08); median PFS was 9.6 vs 7.1 months, respectively (HR 0.69; 95% CI: 0.55, 0.87). ORR was higher with chemo-IO than with IO alone (61% vs 43%; Odds ratio 1.2, 95% CI: 1.1, 1.3). **Conclusions:** This exploratory, hypothesis-generating pooled analysis suggests that most subgroups of patients with advanced NSCLC with PD-L1 score ≥50% receiving FDA-approved chemo-IO regimens may have OS and PFS outcomes that are comparable with or better than IO-only regimens. Patients ≥75 years of age receiving chemo-IO may not have improved outcomes over IO. These results support shared decision-making that balances potential benefits and risks of adding chemo to IO regimens based on patient factors that may impact tolerability. Research Sponsor: None.

Outcomes of first-line immune checkpoint inhibitors with or without chemotherapy according to KRAS mutational status and PD-L1 expression in patients with advanced NSCLC: FDA pooled analysis. *First Author: Erica C. Nakajima, Center for Drug Evaluation and Research, U.S. Food and Drug Administration, Silver Spring, MD*

Background: While existing data suggest a detriment of immune checkpoint inhibitors (ICI) in other targetable mutations in non-small cell lung cancer (NSCLC), limited retrospective analyses suggest patients with *Kirsten rat sarcoma oncogene* (*KRAS)*-mutated NSCLC benefit from ICI in the front-line (1L). To better define this benefit, pooled data from 12 registrational clinical trials investigating 1L ICI with or without chemotherapy (chemo) in patients with documented *KRAS* status (mutant or wildtype) was evaluated for efficacy of ICI+chemo, ICI alone, and chemo alone. **Methods:** Pooled data was evaluated for objective response rate (ORR) and overall survival (OS) by *KRAS* status (mutant, G12C, or wildtype). ORR and 95% confidence intervals (CI) were estimated using Clopper-Pearson method; median OS was estimated using Kaplan-Meier methods. Subgroup analyses were performed using Cox model stratified by KRAS status and PD-L1 status (Positive (combined positive score (CPS) ≥1), Negative (CPS<1), High (CPS≥50), Low (CPS<50)). **Results:** *KRAS* mutational status was reported in 1430 patients (61% wildtype, 39% mutated). *KRAS G12C* was reported in 11% of patients with a *KRAS* mutation (157/555). Demographics were similar between KRAS mutated, G12C, and wildtype patients. Amongst all patients, 60% were male, 89% white, 60% positive PD-L1, 67% former or current smokers. Table 1 shows outcomes of chemo+ICI, ICI alone, and chemo alone in each population. **Conclusions:** This retrospective, pooled analysis suggests that patients with *KRAS*-mutated NSCLC benefit from 1L chemo-ICI similarly to those with *KRAS* wild-type NSCLC, and should receive combination therapy upfront. Patients with *KRAS*-mutated NSCLC derived the greatest benefit from the combination of chemo-ICI as compared to ICI or chemo alone. The small number of patients with documented KRAS G12C mutation limits interpretation of the data for this subgroup. Clinical trials investigating targeted therapies for *KRAS*-mutated NSCLC in the 1L should include a chemo-ICI comparator arm. Research Sponsor: U.S. Food and Drug Administration.

KRYSTAL-1: Activity and safety of adagrasib (MRTX849) in patients with advanced/metastatic non–small cell lung cancer (NSCLC) harboring a KRAS^{G12C} mutation. *First Author: Alexander I. Spira, Virginia Cancer Specialists Research Institute, Fairfax, VA*

Background: KRAS is a key mediator of the RAS/MAPK signaling cascade that promotes cellular growth and proliferation. KRAS^{G12C} mutation occurs in ~14% of NSCLC. Adagrasib, an investigational agent, is a KRAS^{G12C} inhibitor that irreversibly and selectively binds KRAS^{G12C}, locking it in its inactive state. Adagrasib is optimized for favorable pharmacokinetic (PK) properties, including long half-life (~24 h), dose-dependent PK, and central nervous system penetration; it has demonstrated objective response and favorable tolerability in the Phase 1/1b setting. **Methods:** KRYSTAL-1 (NCT03785249) is a multicohort Phase 1/2 study evaluating adagrasib as monotherapy or in combination regimens in patients with advanced solid tumors harboring a KRAS^{G12C} mutation. Here we report the first disclosure from all patients enrolled in Cohort A, a Phase 2 cohort with registrational intent, evaluating adagrasib given 600 mg orally BID in patients with NSCLC previously treated with platinum-based chemotherapy and anti-PD-1/L1 therapy. Study objectives include evaluating efficacy (objective response rate [ORR], duration of response [DOR], progression-free survival [PFS], overall survival [OS]), safety, PK, and exploratory correlative analyses. Objective tumor response was assessed per RECIST v1.1 by blinded independent central review (BICR). **Results:** As of the 15 October 2021 data cutoff, 116 patients with NSCLC harboring a KRAS^{G12C} mutation were enrolled and treated, with a median follow-up of 12.5 months. Baseline characteristics include median age 64 years, 65% female, and 15.5%/83.6% with ECOG PS 0/1; 98.3% of patients received adagrasib following prior treatment with immunotherapy and chemotherapy, with a median of 2 prior systemic therapies. The ORR (by BICR) was 42.9% (48/112) and the disease control rate was 79.5% (89/112); 31 patients remain on treatment. Median DOR was 8.5 months (95% CI 6.2–13.8), median PFS was 6.5 months (95% CI 4.7–8.4), median OS was 12.6 months (95% CI 9.2–NE). Treatment-related AEs (TRAEs) of any grade occurred in 97.4% of patients, grade ≥3 TRAEs in 45.7%, 2 grade 5 TRAEs, and 8 (6.9%) TRAEs led to discontinuation. The most commonly reported (≥25%) TRAEs (any grade) were diarrhea (62.9%), nausea (62.1%), vomiting (47.4%), fatigue (40.5%), ALT/AST increased (27.6%/25%), blood creatinine increased (25.9%); the most commonly reported (≥5%) TRAEs (grade 3/4) were lipase increased (6%) and anemia (5.2%). Additional subgroup analyses will be presented, including selected demographics, molecular markers and sites of metastases. **Conclusions:** Adagrasib is well tolerated and demonstrates promising efficacy in pretreated patients with NSCLC harboring a KRAS^{G12C} mutation. A Phase 3 trial evaluating adagrasib monotherapy versus docetaxel in previously treated patients with KRAS^{G12C}-mutant NSCLC is ongoing (NCT04685135). Clinical trial information: NCT03785249. A phase II study (TACTI-002) in first-line metastatic non–small cell lung carcinoma investigating eftilagimod alpha (soluble LAG-3 protein) and pembrolizumab: Updated results from a PD-L1 unselected population. *First Author: Enriqueta Felip, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Eftilagimod alpha (E) is a soluble LAG-3 protein binding to a subset of MHC class II molecules to mediate antigen presenting cell (APC)/CD8 T-cell activation. Stimulation of the APCs and subsequent T cell recruitment with E may lead to stronger anti-tumor responses than observed with pembrolizumab (P) alone. We hereby report results of the extended first-line non-small cell lung carcinoma (NSCLC) cohort of the TACTI-002 ("Two ACTive Immunotherapies") phase II trial. **Methods:** Pts with untreated metastatic NSCLC, unselected for PD-L1 expression were recruited. Objective response rate (ORR) by iRECIST was the primary endpoint (EP) and secondary EPs include ORR by RECIST 1.1, tolerability, disease control rate (DCR), progression free survival (PFS), overall survival (OS) and exploratory biomarker. Pts received 30 mg E SC q2w for 8 cycles (1 cycle= 3 weeks) and then q3w for up to 1 year with P (200 mg IV q3w for up to 2 years). Imaging was done every 8 weeks. PD-L1 was assessed centrally. This has been approved by relevant CAs, ECs, and IRBs. **Results:** From Mar 2019 to Nov 2021 114 pts were enrolled. Median age was 67 years (44-85) and 74% were male. ECOG PS was 0 and 1 in 37% and 63% of pts, respectively. Pts presented squamous (35%) or non-squamous (62%) NSCLC with 88% of pts at stage IV at the time of study entry. All PD-L1 subgroups were represented (Table). Pts received median 6.0 (range 1–35) P and 7.0 (1-22) E administrations. 19 (17%) pts discontinued treatment due to adverse events (AEs). The most common (≥15%) AEs were dyspnea (33%), asthenia (30%), decreased appetite (22%), cough (20%), anemia (20%), fatigue (19%), pruritus (18%), constipation (17%) and diarrhea (15%). At data cut-off (Jan 2022), 75 pts with a minimum follow-up of 6 months were evaluated for efficacy. ORR (iRECIST) was 37.3% in the ITT and 41.8%% in the evaluable pts assessed by local read. DCR 73.3% was reported. Response rate for squamous and non-squamous pathology were 33.3 % and 40.3 %, respectively. Results according to RECIST 1.1 were comparable. Responses were observed in all PD-L1 subgroups (Table). 24/28 (86%) responses were already confirmed while median duration of response was not yet reached (5 events). **Conclusions:** E + P is safe and shows encouraging antitumor activity in first-line metastatic NSCLC patients unselected for PD-L1, warranting further investigation. Clinical trial information: NCT03625323. Research Sponsor: Immutep S.A.

9004 **Oral Abstract Session**

Overall survival from a phase II randomized study of ramucirumab plus pembrolizumab versus standard of care for advanced non–small cell lung cancer previously treated with immunotherapy: Lung-MAP nonmatched substudy S1800A. *First Author: Karen L. Reckamp, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Resistance to immune checkpoint inhibitor (ICI) therapy develops in most patients (pts) with advanced non-small cell lung cancer (NSCLC). Tumors that develop resistance to ICI constitute a major unmet need. Combined ICI and VEGF/VEGF receptor inhibition have shown benefit in multiple tumor types through immune modulation. We evaluated pembrolizumab and ramucirumab (P+R) in advanced, ICI-exposed NSCLC, under the aegis of Lung-MAP, a master protocol for pts with stage IV, previously treated NSCLC. Pt characteristics and treatment toxicities were presented at ASCO 2021. **Methods:** S1800A was a randomized phase II trial for pts ineligible for a biomarker-matched substudy with acquired resistance to ICI defined as previous ICI therapy for at least 84 days with progressive disease (PD) on or after therapy. Eligibility stipulated PD on prior platinum-based doublet therapy (sequential or in combination with ICI) and ECOG PS of 0-1. Pts were stratified by PD-L1 expression, histology, and intent to receive ramucirumab in the standard of care (SOC) arm and were randomized to P+R or SOC (investigator's choice of docetaxel+R; docetaxel, pemetrexed, gemcitabine). With a goal of 144 total/130 eligible pts, the primary objective was to compare overall survival (OS) between the arms using a 1-sided 10% level log-rank test upon 90 deaths. Secondary endpoints included response, duration of response, investigator assessed-progression free survival and toxicity. **Results:** From May 17, 2019 to November 16, 2020, 166 pts were enrolled with 137 eligible (69 P+R; 68 SOC [45 +R, 23 w/o R]). Main causes for ineligibility were lack of PD on ICI or chemotherapy (6 SOC, 6 P+R), > 1 line of ICI (2 P+R), ICI discontinued due to toxicity (2 SOC), or lack of measurable disease (2 SOC, 1 P+R). OS was significantly improved with P+R (HR: 0.61 [0.38-0.97], 1-sided p-value = 0.019; median [95% CI] OS of 15.0 (13.2-17) months (mo) for P+R and 11.6 (8.5-13.8) mo in SOC arm). Progression-free survival (PFS) was not different between the arms (HR: 0.86 [0.57-1.31], 1-sided p-value=0.25; median PFS (95% CI) of 4.5 (4.0-6.9) mo for P+R and 5.2 (4.0-6.6) mo in SOC arm). ORR was not different between the arms (p=0.28). OS benefit for P+R was seen in most subgroups. Analysis of survival based on genomic alterations, tumor mutational burden and PD-L1 will be presented. **Conclusions:** Pembrolizumab + ramucirumab in pts with advanced NSCLC previously treated with chemotherapy and immunotherapy led to improved OS compared to SOC. Discordance of ORR and PFS from OS has been reported in prior ICI trials (Rittmeyer et al. Lancet 2017). This is the first trial in the 2nd line setting without a chemotherapy backbone to demonstrate a potential survival benefit compared to SOC regimens including docetaxel and ramucirumab using the Lung-MAP platform. Clinical trial information: NCT03971474. Research Sponsor: NIH/NCI U10CA180888, U10CA180819, U10CA180821, Other Foundation, in part by Eli Lilly and Company and Merck & Co., Inc.

9005 **Oral Abstract Session**

Cabozantinib (C) plus atezolizumab (A) or C alone in patients (pts) with advanced non–small cell lung cancer (aNSCLC) previously treated with an immune checkpoint inhibitor (ICI): Results from Cohorts 7 and 20 of the COSMIC-021 study. *First Author: Joel W. Neal, Stanford University, Stanford Cancer Institute, Palo Alto, CA*

Background: C, a multitargeted receptor tyrosine kinase inhibitor (TKI), promotes an immune-permissive environment that may enhance ICI activity. COSMIC-021 (NCT03170960) is a multicenter phase 1b study evaluating C + A in advanced solid tumors. In COSMIC-021, C + A demonstrated encouraging clinical activity in the cohort of pts with aNSCLC previously treated with ICIs (cohort 7 [C7]) (Neal. ASCO 2020. Abstr 9610). Updated outcomes of C + A in expanded C7 and outcomes for C alone in exploratory cohort 20 (C20) are presented. **Methods:** Pts with stage IV nonsquamous NSCLC without mutations in EGFR, ALK, ROS1, or BRAF V600E who progressed on one prior ICI and ≤2 prior lines of systemic anticancer therapy but no prior VEGFR TKI were eligible. Cohorts were not accrued contemporaneously. Pts received C 40 mg PO QD plus A 1200 mg IV Q3W (C7) or C alone 60 mg PO QD (C20). Primary endpoint was objective response rate (ORR) per RECIST v1.1 by investigator. Other endpoints included safety, duration of response (DOR), progression-free survival (PFS), and overall survival (OS). CT/MRI scans were performed Q6W for the first year and Q12W thereafter. **Results:** A total of 81 and 31 pts received C + A and C, respectively; baseline characteristics were as follows: median age, 67 y, 70 y; male, 57%, 58%; ECOG PS 1, 64%, 71%; liver metastasis, 21%, 23%; refractory to prior ICI (progressive disease [PD] as best response), 32%, 45%; median number of prior systemic therapies, 3 and 3. As of Nov 30, 2021, median follow-up (range) (mo) was 24.7 (10.7, 42.8) and 21.5 (17.3, 27.6) for C + A and C, respectively, with 6 (7%) and 1 (3%) on study treatment. Clinical activity was observed for C + A and C alone (Table). Most common treatment-related adverse events (TRAEs) of any grade for C + A and C, respectively, included diarrhea (40%, 42%), nausea (22%, 45%), decreased appetite (25%, 26%), vomiting (14%, 23%), and fatigue (28%, 19%); grade 3/4 TRAEs occurred in 44% and 52% and one grade 5 TRAE occurred in each cohort (pneumonitis [C + A] and gastric ulcer hemorrhage [C]). **Conclusions:** C + A and C demonstrated encouraging clinical activity with manageable toxicity in pts with aNSCLC previously treated with ICIs. A phase 3 trial (CONTACT-01; NCT04471428) of C + A vs docetaxel is ongoing in NSCLC previously treated with an ICI and platinum-containing chemotherapy. Clinical trial information: NCT03170960. Research Sponsor: Exelixis, Ipsen, Takeda.

Amivantamab and lazertinib in patients with EGFR-mutant non–small cell lung (NSCLC) after progression on osimertinib and platinum-based chemotherapy: Updated results from CHRYSALIS-2. *First Author: Catherine A. Shu, Columbia University Medical Center, New York, NY*

Background: Initial results with the amivantamab (ami) and lazertinib (laz) regimen showed encouraging efficacy in patients (pts) whose disease progressed after standard-of-care osimertinib (osi) and platinum-based chemotherapy (pt-chemo; Shu *Ann Oncol* 2021; 32:S949-1039; 1193MO). We present updated results of this population (Cohort A) from the CHRYSALIS-2 study (NCT04077463). **Methods:** Cohort A evaluated ami and laz in pts with EGFR exon 19 deletion or L858R NSCLC whose disease progressed on 1st/2nd-line osi followed by pt-chemo as last line of therapy (target population, n=106) and among a more heavily-pretreated population (n=56) whose disease progressed after osi and pt-chemo ± other therapies without regard to number and sequence of these therapies. Pts received 1050 mg IV ami (1400 mg, ≥80 kg) + 240 mg oral laz. Investigator (INV)- and blinded independent central review (BICR)-assessed response per RECIST v1.1 is reported for efficacy-evaluable pts, defined as pts who initiated study treatment on or before 17 Mar 2021, allowing for ≥6 mo of follow-up for response durability. **Results:** As of 6 Nov 2021, 162 pts were enrolled in Cohort A (median 62 y, 65% women, 61% Asian, median 3 [range, 2–14] prior lines). Median time between last osi treatment to first dose of ami + laz was 6.3 mo and 2.0 mo for the target and heavily-pretreated populations, respectively. Of 50 efficacy-evaluable pts in the target population, the overall response rate (ORR) by BICR was 36% (95% CI, 23–51), with 1 complete response (CR) and 17 partial responses (PRs), and the clinical benefit rate (CBR) was 58% (95% CI, 43–72); full results for all enrolled pts will be reported at the meeting. Median duration of response (mDOR) was not reached based on BICR. At a median follow-up of 8.3 mo, 7 responders (39%) have achieved a DOR lasting ≥6 mo by BICR. INV-assessed responses were consistent with BICR. Of 56 efficacy-evaluable pts in the heavily-pretreated population (8.7-mo median follow-up), ORR by INV was 29% (95% CI, 17–42), with 1 CR and 15 PRs. CBR was 55% (95% CI, 42–69) and mDOR was 8.6 mo (95% CI, 4.2–NR). BICR results are pending. Preliminary evidence of CNS antitumor activity was reported among 8 pts with baseline brain lesions (7 non-target, 1 target) who had not received radiation within 1 year prior to study enrollment. Most frequent adverse events (AE) were infusion-related reaction (65%), paronychia (49%), rash (41%), and stomatitis (39%). Most common grade ≥3 treatment-related AEs (TRAEs) were infusion-related reactions (7%), acneiform dermatitis (5%), and hypoalbuminemia (4%). TRAEs leading to discontinuation of either or both ami and laz occurred in 12% and 7%, respectively. **Conclusions:** Among an unselected population that has exhausted SOC osi and pt-chemo, ami and laz demonstrates encouraging antitumor activity with a manageable safety profile. Clinical trial information: NCT04077463. Research Sponsor: Janssen.

9007 **Oral Abstract Session**

Phase (Ph) 1/2a study of CLN-081 in patients (pts) with NSCLC with EGFR exon 20 insertion mutations (Ins20). *First Author: Helena Alexandra Yu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: EGFR ins20-mutant NSCLC has historically been challenging to treat. While new agents targeting EGFR ins20 have recently been approved, adverse events (AEs), particularly wild type (WT) EGFR-related AEs are common. CLN-081 is a novel EGFR tyrosine kinase inhibitor (TKI) with broad activity against *EGFR* mutations, including ins20, and increased selectivity for ins20 versus WT EGFR. CLN-081 has been granted FDA Breakthrough Therapy Designation for the treatment of pts with EGFR ins20 NSCLC. We present updated results of the initial multicenter Ph1/2a study of CLN-081 in pts with advanced, EGFR ins20-mutant NSCLC, including 39 pts treated in an expanded cohort at the dose of 100 mg twice daily (BID). **Methods:** Ph1 dose escalation utilized an accelerated titration (AT) and rolling six design. Individual cohorts were expanded in Phase 1 and 2a based on prespecified protocol criteria. Pts were required to have received prior platinum-based chemotherapy. Stable, treated brain metastasis (mets) were allowed. CLN-081 is dosed in 21-day cycles. **Results:** As of 13 December 2021, 73 pts [median age: 65 (36-82), median lines of prior therapy: 2 (1-9), 28 (39%) with a history of brain mets] received CLN-081 at 30 mg (8), 45 mg (1), 65 mg (14), 100 mg (39), and 150 mg (11), all BID. Treatment-related AEs in ≥ 15% of pts were rash (74%), diarrhea (27%), paronychia (25%), fatigue (19%), anemia (18%), dry skin (18%), nausea (16%). Treatment-related Gr ≥ 3 AEs in ≥ 4 % of pts included anemia (10%), increased ALT (4%), and increased AST (4%). Gr 3 rash and Gr 3 diarrhea were observed in 1 and 2 pts, respectively, at 150 mg BID, while no pts treated at ≤ 100 mg BID experienced Gr 3 rash or diarrhea. Treatment-related dose reductions and discontinuations across all dose levels occurred in 10 pts (14%) and 5 pts (7%) respectively. Among 70 response-evaluable pts across all dose levels, 25 (36%) had a confirmed partial response (PR), 34 (49%) had stable disease (SD), and 3 (4%) had progressive disease as a best response. Seven pts (10%) had a PR that remained unconfirmed; 1 (1%) pt was pending a confirmatory scan. Of 36 response-evaluable pts at 100 mg BID, 14 (39%) had a confirmed PR, 17 (47%) had SD, and 1 (3%) had PD. Three pts had a PR that remained unconfirmed (8%); 1 (3%) pt was pending a confirmatory scan. Notably, among Ph1 pts treated at 100 mg BID (N = 13) in whom longer follow-up is available, the mDOR and mPFS (estimated by Kaplan-Meier) was > 15 months and 12 months, respectively. Disease control (SD ≥ 6 months or any PR) was observed in 12/13 pts (92%). Updated data with additional follow-up will be presented. **Conclusions:** In pts with heavily-pretreated advanced EGFR ins20 NSCLC, CLN-081 has a manageable safety profile, with anti-tumor activity across the range of doses tested. Further, CLN-081 has demonstrated a favorable clinical profile at the dose of 100 mg BID, with an encouraging objective response rate, response durability, and no Gr 3 rash or diarrhea. Clinical trial information: NCT04036682. Research Sponsor: Cullinan Oncology, LLC.

9008 **Oral Abstract Session**

Amivantamab in patients with NSCLC with MET exon 14 skipping mutation: Updated results from the CHRYSALIS study. *First Author: Matthew Krebs, The University of Manchester and The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: Amivantamab, a fully human bispecific antibody targeting epidermal growth factor receptor (EGFR) and MET, is approved for the treatment of non-small cell lung cancer (NSCLC) with EGFR exon 20 insertion after prior platinum-based chemotherapy. Given its bispecific nature, amivantamab is being explored in patients (pts) with primary MET exon 14 skipping mutation (METex14) in the MET-2 cohort of the CHRYSALIS study. **Methods:** CHRYSALIS (NCT02609776) is an ongoing phase 1 dose escalation/dose expansion study of amivantamab in pts with advanced NSCLC. Pts with primary METex14 whose disease progressed on or who declined current standard of care therapy were treated with amivantamab 1050 mg (pts <80 kg) or 1400 mg (pts ≥80 kg) weekly in cycle 1 and biweekly thereafter. Response was assessed by investigators using RECIST v1.1. **Results:** As of 2 Dec 2021, 43 pts with METex14 had received amivantamab. Median age was 70 y (range, 43-88), 58% were women, median prior lines of therapy was 2 (range, 0-10) [eg, crizotinib (n=13), capmatinib (n=11), tepotinib (n=5), anti-MET antibody (n=1)], and 23% had history of brain metastases at baseline. In 36 pts with ≥1 postbaseline disease assessment, median duration of follow-up was 5.8 months (range, 0.3-15.8); 6 pts had no prior treatment, 11 had no prior MET inhibitor, and 19 had a prior MET inhibitor. Overall response rate was 33% (50% [3/6] in treatment-naïve pts, 46% [5/11] in pts with no prior MET inhibitor, and 21% [4/19] in pts with prior MET inhibitor therapy). Clinical benefit rate was >54% regardless of prior treatment (Table). Median duration of response (DOR) was not reached (range, 2.1-12.2 months); 67% (8/13) had DOR ≥6 months. Ten of the 12 responders remain on treatment (6.0-14.4 months) with ongoing responses; 2 discontinued after 2 and 12 months, respectively. Safety profile was consistent with previously reported experience of amivantamab (Sabari 2021 *JTO* 16(3):S108-109). Treatment-related adverse events leading to dose reduction or discontinuation occurred in 3 pts, each. **Conclusions:** Amivantamab demonstrates anti-tumor activity in primary METex14 NSCLC including after prior MET inhibitor treatment. Enrollment is ongoing and updated data will be shown. Clinical trial information: NCT02609776. Research Sponsor: None.

9010 **Clinical Science Symposium**

Updated analysis from the ATEZO-BRAIN trial: Atezolizumab plus carboplatin and pemetrexed in patients with advanced nonsquamous non–small cell lung cancer with untreated brain metastases. *First Author: Ernest Nadal, Institut Català d'Oncologia, L'Hospitalet, Barcelona, Spain*

Background: Atezolizumab plus chemotherapy was safe and yielded promising clinical outcome as frontline therapy for patients (pts) with advanced NSCLC with untreated brain metastases (BM) in the ATEZO-BRAIN study (NCT03526900). **Methods:** A multicenter single-arm phase II trial with a Bayesian design for evaluating the safety and efficacy of atezolizumab plus carboplatin with pemetrexed every 3 weeks for 4-6 cycles, followed by maintenance with pemetrexed plus atezolizumab in pts with stage IV non-squamous NSCLC without EGFR or ALK genetic alterations and untreated BM. Pts not presented neurologic symptoms at baseline; but anticonvulsants and dexamethasone (DXM) ≤ 4mg qd were allowed. Co-primary endpoints were safety and investigator-assessed progression-free survival (PFS) at 12 weeks according to RANO-BM and RECIST v1.1 for brain and systemic disease, respectively. Here we present the final data and an exploratory analysis based on PD-L1 expression and corticosteroid treatment at baseline. **Results:** Out of 40 pts included in the study, 22 (55%) were receiving DXM at baseline and 20 (50%) had positive expression of PD-L1. Sixteen (40%) pts had confirmed intracranial response based on RANO-BM (12 PR, 4 CR) and 19 (47.5%) pts achieved systemic response (all PR). Only 4 pts had discordant responses between the body and the brain. No differences were observed in the overall systemic and intracranial response rate according to the PD-L1 expression or the use of corticosteroids at baseline. As of December 31, 2021 (median follow-up, 20 months), the updated median (95% CI) systemic PFS was 8.9 (6.7 to 13.8) and intracranial PFS was 6.9 (4.7 to 11.9). Median (95% CI) OS was 13.6 (9.72 to not reached) and estimated 2-year OS rate (95% CI) was 30.5% (18.4 to 50.4). Median (95%CI) OS was longer for PD-L1 positive pts (16.2; 10.3 to not reached) compared to PD-L1 negative pts (10.7; 7.6 to not reached) but differences were not statistically significant due to the limited statistical power (HR = 0.99; 95% CI 0.35 to 2.12). No significant differences in OS were observed between pts receiving or not baseline DXM treatment. Treatment was well tolerated and no grade 5 toxicities were observed. **Conclusions:** In this updated analysis, treatment with atezolizumab plus carboplatin and pemetrexed yields a promising 2-year OS rate and intracranial response rate in patients with untreated BM from NSCLC, regardless of treatment with corticosteroids at baseline and PD-L1 expression. Clinical trial information: NCT03526900. Research Sponsor: ROCHE.

9011 **Clinical Science Symposium**

Randomized phase III study of nivolumab and ipilimumab versus carboplatin-based doublet in first-line treatment of PS 2 or elderly (≥ 70 years) patients with advanced non–small cell lung cancer (Energy-GFPC 06-2015 study). *First Author: Herve Lena, Centre Hospitalier Universitaire de Rennes, Rennes, France*

Background: Combination of anti-PD1 and CTLA4 have showed superiority to chemotherapy (CT) in advanced non–small cell lung cancer (NSCLC), but data for fit elderly or PS2 patients are scarce. **Methods:** eNErgy compared the combination of nivolumab ipilimumab (N-I) to a platinum doublet in elderly or PS2 patients with advanced NSCLC. Primary endpoint was overall survival (OS), secondary endpoints included progression-free survival (PFS), objective response rate (ORR), and safety. Main inclusion criteria were: stage IV histologically proven NSCLC, age ≥ 70 y, and PS 0/1/2 or age < 70 and PS2, EGFR ALK/ROS1 negative, judged fit enough to receive a platinum doublet. The main exclusion criteria were active cerebral metastasis or contraindication to N-I. Patients were randomly selected 1/1, stratified by age (≥ 70 vs. < 70 y), PS (0/1 vs. 2), and histology (squamous vs. no-squamous). Nivolumab (240 mg, 2w), ipilimumab, 1 mg/kg, 6w, was administrated until progression or unacceptable toxicity. CT was planned for 4 cycles, with carboplatin (AUC5) and pemetrexed (500 mg/m2, 3w) or paclitaxel (90 mg/m2, d1,d8, d15); 242 patients had to be randomized to detect a treatment effect hazard ratio (HR) on OS of 0.65, with a 85% power at a 2-sided alpha level of 5%. **Results:** A preplanned interim analysis carried out after observation of 33% of deaths, out of 174 randomized patients, showed a risk of futility especially for PS 2 patients, HR: 1.8 (95% CI, 0.99-3.3). This led to a halt in randomization but continued follow-up of the 204 patients randomized at the time of the decision. The current final analysis is carried out 18 months after the inclusion of the last patient: men, 71%, median age 74 (51-89, PS 0/1/2 in 30%, 37.5%, and 36.6% respectively), smokers or former smokers in 25.5 and 64.4%, with 62% adenocarcinoma. The median OS of N-I and chemo arms were 14.7 (95% CI, 8.0-19.7) and 9.9 (95% CI, 7.7-12.3) months, HR 0.85, 95% CI, 0.62-1.16. The subgroup analyses showed a significant benefit of the association N-I compared to CT for elderly PS 0/1 patients, with median OS of 22.6 (95% CI, 18.1-36) vs. 11.8 (95% CI, 8.9-20.5) months, p = 0.02. In PS2 patients, median OS of N-I and CT arms was 2.9 (1.4-4.8) vs. 6.1 (3.5-10.4) months (p = 0.22). Median PFS was significantly in favor of N-I arm in the entire population: 5.5 (2.8-8.7) vs. 4.6 (3.5-5.6); p = 0.015. Safety was similar with 31.4% of patients with grade ≥ 3 related SAES in N-I arm vs. 49.5% for CT. Treatment was discontinued for toxicity in 28.6% in N-I arm vs. 22.3% of patients in CT arm. **Conclusions:** Despite no statistically significant benefit in OS observed in the entire population, there was a clinical signal of efficacy of N-I combination over platinum doublet in elderly NSCLC patients PS 0-1 with a significant benefit of OS of 22.6 months vs. 11.8 for CT arm. Clinical trial information: NCT03351361. Research Sponsor: Bristol Myers Squibb, Groupe Français de PneumoCancerologie.

9012 **Clinical Science Symposium**

Checkpoint inhibitor accessibility in 15,000+ Indian patients. *First Author: Madala Ravikrishna, Tata Memorial Hospital, Mumbai, India*

Background: Access to newer therapies is an issue in low and low middle income countries. Hence we decided to audit our practice in the head and neck and thoracic medical oncology unit from 2015 to 2019 to study the accessibility of checkpoint inhibitors and factors influencing them. **Methods:** All patients who were registered in the head and neck and thoracic medical oncology unit between 2015-2019 were included in the study. The number of patients who received immunotherapy among them was identified from the prospective database of immunotherapy maintained in the department. We made a list of patients who were eligible for immunotherapy per year and identified how many of them received recommended immunotherapy. The indication for eligibility of immunotherapy was based on published pivotal data and its date of publication of the study online. For nominal and ordinal variable percentage with 95% CI was provided. Factors impacting the accessibility of immunotherapy were identified. **Results:** A total of 15,674 patients were identified who required immunotherapy; out of them only 444 (2.83%, 95% CI, 2.58-3.1) received it. The distribution of patients eligible as per cancer disease management group and time period is shown in the Table. Among head and neck cancer patients 4.5% (156 out of 3,435) received immunotherapy versus 2.35% (288 out of 12,239) among thoracic cancer patients ($p < 0.0001$). Among the general category (low socioeconomic), 0.29% (28 out of 9,405) versus 6.6% (416 out of 6,269) among the private category (high socioeconomic) received immunotherapy ($p < 0.0001$). While 3.7% (361 out of 9,737) among males versus 1.39% (83 out of 5,937) females received immunotherapy ($p < 0.0001$). There was also a temporal trend seen in the accessibility of immunotherapy ($p < 0.0001$, Table). **Conclusions:** The accessibility of immunotherapy is below 3% in India. Patients with head and neck cancers, those with private category and with male gender had higher access to this therapy. There was also a temporal trend observed suggesting increased accessibility over the years. Research Sponsor: None.

Disease Site	Years→	2015	2016	2017	2018	2019	p Value
Head and neck cancer	Number of patients with indication for immunotherapy	-	776	773	750	1136	< 0.0001
	Number of patients who received immunotherapy	-	2	27	43	84	
	Percentage of patients receiving immunotherapy	-	0.25	3.49	5.7	7.3	
	95% CI of the percentage of patients receiving immunotherapy	-	0.01-1	2.4-5.1	4.3-7.7	6-9.1	
Thoracic cancer	Number of patients with indication for immunotherapy	1,365	1,844	2,730	3,000	3,300	< 0.0001
	Number of patients who received immunotherapy	1	3	44	110	130	
	Percentage of patients receiving immunotherapy	0.07	0.16	1.6	3.6	3.9	
	95% CI of the percentage of patients receiving immunotherapy	0-0.4	0.03-0.5	1.2-2.1	3.1-4.4	3.3-4.7	

Both the cites significantly different increases in rates are observed.

9013 **Poster Discussion Session**

Phase 1/1b study of telisotuzumab vedotin (Teliso-V) + osimertinib (Osi), after failure on prior Osi, in patients with advanced, c-Met overexpressing, *EGFR*-mutated non-small cell lung cancer (NSCLC). *First Author: Jonathan W. Goldman, David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: Osi (third-generation tyrosine kinase inhibitor) is a standard frontline treatment (Tx) for advanced/metastatic *EGFR*-mutated NSCLC. However, tumors invariably progress after an initial response, with c-Met protein overexpression (OE) often associated with acquired resistance. Second- and third-line Tx options are limited to chemotherapy-based regimens with limited efficacy and significant toxicities. Teliso-V (ABBV-399), an anti–c-Met antibody-drug conjugate, delivers a cytotoxic payload (monomethyl auristatin E) into c-Met OE tumor cells. In a phase 1/1b study (NCT02099058) in patients (pts) with c-Met OE NSCLC, Teliso-V alone or in combination with erlotinib demonstrated an acceptable safety profile and antitumor activity. Interim safety and efficacy data from the Teliso-V + Osi cohort (arm E) of this trial are presented. **Methods:** Pts (≥18 yr) with metastatic *EGFR*-mutated, c-Met OE (by central immunohistochemistry) NSCLC who had progressed on a prior Osi regimen were eligible. Pts received Teliso-V (IV Q2W) + Osi (oral; 80 mg QD). Teliso-V was evaluated at 1.6 mg/kg and, after review of safety data, escalated to 1.9 mg/kg (safety evaluation). An expansion cohort was opened at 1.9 mg/kg for pts who had received ≤2 prior lines of systemic therapy. Pharmacokinetics (PK) were assessed throughout the study. Pts received study Tx until disease progression, unacceptable toxicity, or for up to 24 months. **Results:** As of 20 Dec 2021, 25 pts received Teliso-V (1.6 mg/kg, n = 7; 1.9 mg/kg, n = 18) + Osi. Median age was 60.0 yr; 14 (58%) pts were on prior Tx with Osi for > 12 mo. No dose-limiting toxicities (grade [Gr] ≥3 non-hematologic or Gr 4 hematologic Tx-related adverse events [AEs]) were reported during the safety lead-in or evaluation phases. All-Gr AEs considered possibly related to Teliso-V occurred in 22/25 (88%) pts: the most common (≥20%) were peripheral sensory neuropathy (36%), nausea, and peripheral edema (20% each); Gr ≥3 AEs (> 5%) were anemia (12%) and peripheral motor neuropathy (8%). No Gr 5 events related to Tx were reported. PK of Teliso-V + Osi was similar to single-agent Teliso-V. Efficacy data (19/25 pts) are in the table. The overall objective response rate (ORR) was 58% (67% at 1.9 mg/kg). **Conclusions:** Teliso-V + Osi is well tolerated with an ORR of 58% (67% at 1.9 mg/kg) in pts with c-Met OE NSCLC who progressed on prior Osi. Clinical trial information: NCT02099058. Research Sponsor: AbbVie.

9014 **Poster Discussion Session**

Osimertinib plus necitumumab in EGFR-mutant NSCLC: Final results from an ETCTN California Cancer Consortium phase I study. *First Author: Jonathan W. Riess, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Osimertinib (Osi) is standard of care in 1st line (1L) EGFR mut NSCLC and TKI resistant T790M^{pos} NSCLC but acquired resistance emerges; outcomes are less robust in T790M^{neg}, C797X^{pos} and EGFR exon 20 insertion (ex20ins) disease. We examined Osi with the EGFR monoclonal antibody Necitumumab (Neci) in select settings of EGFR TKI resistance. **Methods:** Pts were accrued to 5 expansion cohorts (ExC) at recommended phase 2 dose (RP2D) of Osi 80 mg daily and Neci 800 mg D1 + D8 of q21d cycle. ExC (18 pts/cohort): A) T790M^{neg} progressive disease (PD) on 1st/2nd gen TKI as last therapy, B) T790M^{neg} PD on 1st/2nd gen TKI and PD on 3rd gen TKI, C) T790M^{pos} PD on 1st/2nd gen TKI and PD on 3rd gen TKI, D) EGFR ex20ins PD on chemotherapy, E) PD on 1L osi. In ExC A-C, T790M was confirmed centrally (tissue) by ddPCR. Additional correlative studies include: tissue NGS (> 400 gene panel), EGFR FISH, plasma for PK and serial EGFR ctDNA by ddPCR. Adverse events were graded (Gr) by CTCAEv5; ORR, PFS by RECIST 1.1. Primary pre-specified efficacy endpoint ≥3/18 pts responding per cohort. **Results:** 101 patients accrued (100 evaluable). Efficacy is summarized in the Table. Drug related Gr 3 AEs were seen in 38% of pts, mainly rash (21%). ORR among all pts was 19% (95% CI 12-28%) that varied across cohorts (Table). In ExC A-C, 69% pts had detectable EGFR activating mutations in ctDNA, with decline in mutant allele frequency (AF) on treatment in 80% and ctDNA clearance in 33%. **Conclusions:** Osi/Neci is feasible and tolerable at the RP2D. EGFR ctDNA was detectable at baseline in the majority of pts with decrease in AF on treatment. Osi/Neci was active in select settings of EGFR-TKI resistance, meeting its prespecified efficacy endpoint in T790M^{neg} PD on 1st/2nd gen TKI as last therapy (ExC A), EGFR ex20ins post-chemo (ExC D) and PD on 1L osimertinib (ExC E). mPFS in the EGFR ex20ins cohort was within the range of current EGFR Exon 20 ins agents in development. EGFR monoclonal antibodies with osimertinib warrant further study in settings of de novo and acquired EGFR dependent resistance to EGFR-TKI. Clinical trial information: NCT02496663. Research Sponsor: U.S. National Institutes of Health.

Summary of Response and Progression-Free Survival.

Cohort	# Patients	Response	Median PFS in Months (90% confidence interval)*
Dose Escalation	10	5 PR (3 cPR)	9.7 (5.3, 13.7)
(A) T790M^{neg} PD on 1st/2nd gen TKI as last therapy	18	4 PR (3 cPR)**	3.9 (1.3, 5.7)
(B) T790M^{neg} PD on 1st/2nd gen TKI and PD on 3rd gen TKI	18	0	1.5 (1.2, 2.6)
(C) T790M^{pos} PD on 1st/2nd gen TKI and PD on 3rd gen TKI	18	2 PR (both cPR)	3.9 (2.4, 5.6)
(D) EGFR ex20ins PD on chemotherapy	18	4 PR (3 cPR)**	6.9 (4.1, 11.4)
(E) PD on 1L osimertinib	18	4 PR (3 cPR)**	2.3 (1.4, n/a)

*n/a means that the upper limit of the confidence interval was not reached at the time of the analysis;
** cohort met pre-specified efficacy endpoint
cPR = confirmed partial response.

9015 **Poster Discussion Session**

Antitumor activity of sunvozertinib in NSCLC patients with EGFR Exon20 insertion mutations after platinum and anti-PD(L)1 treatment failures. *First Author: Pasi A. Janne, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Platinum-based chemotherapy is the 1st line standard of care for NSCLC patients with EGFR exon 20 insertion mutations (Exon20ins), with anti-PD(L)1 frequently used as well. Here we present anti-tumor activity of sunvozertinib in these patients whose disease had progressed on these therapies from two ongoing phase 1/2 studies (WK-KONG1, NCT03974022 and WU-KONG2, CTR20192097). Based on these data, sunvozertinib was granted the Breakthrough Therapy Designation by both US FDA and China NMPA. **Methods:** The objective of this study is to characterize the safety and efficacy of sunvozertinib in platinum-pretreated advanced NSCLC patients harboring EGFR Exon20ins, with or without anti-PD(L1) treatment. In addition, the effect of prior treatment on sunvozertinib's safety and efficacy were explored. **Results:** As of July 30, 2021, a total of 52 locally advanced or metastatic NSCLC patients harboring EGFR Exon20ins post platinum treatment were enrolled into WU-KONG1 and WU-KONG2 studies, and included in the efficacy analysis set (dose range: 50 mg to 400 mg, once daily). Male/Female: 21/31; Median age 59; Asian/White: 44/8; Prior therapies: median 2.5 (range 1-10); 31% received prior anti-PD(L)1 treatment (all in £ 300 mg cohorts); 40% of the subjects with baseline brain metastasis. Partial response was observed at ≥ 100 mg. At the dose level of 100 mg, 200 mg, 300 mg and 400 mg, confirmed ORR was 50% (1/2), 55.6 % (5/9), 44.8% (13/29) and 22.2% (2/9), respectively. With a median follow-up time of 10.5 months, median DoR was not reached for 200 mg cohort; with a median follow-up of 7 months, median DoR of 300 mg group was 5.6 months. Progression free survival (PFS) rate at 6 months for 100 mg, 200 mg, 300 mg and 400 mg cohorts was 50%, 53.3%, 44.6% and 44.4%, respectively. In patients with/without prior anti-PD(L)1 treatment, comparable efficacy and safety profiles were observed. **Conclusions:** The data suggest sunvozertinib is active in platinum-pretreated patients with EGFR Exon20ins, irrespective of prior or after anti-PD(L)1 treatment. The updated data will be presented at the meeting. Sunvozertinib is currently in phase 2 pivotal clinical development (NCT03974022 and China CTR20211009). Clinical trial information: NCT03974022. Research Sponsor: None.

9016 **Poster Discussion Session**

Telisotuzumab vedotin (Teliso-V) monotherapy in patients (pts) with previously treated c-Met–overexpressing (OE) advanced non-small cell lung cancer (NSCLC). *First Author: D. Ross Camidge, University of Colorado Cancer Center, Aurora, CO*

Background: Teliso-V is an antibody-drug conjugate composed of a c-Met antibody (ABT-700) and a microtubule inhibitor (monomethyl auristatin E). The phase 2 M14-239 trial (LUMINOSITY, NCT03539536) aims to identify the c-Met OE NSCLC populations best suited to Teliso-V (Stage 1) and expand selected groups for further evaluation of efficacy (Stage 2). In Stage 1, pts were enrolled into cohorts defined by histopathology (non-squamous [NSQ] or squamous [SQ]) and *EGFR* mutation status (mutant or wild type [WT]); NSQ cohorts were further divided in groups on the basis of c-Met expression (high or intermediate). Updated data from the fourth interim analysis (IA4) are presented. **Methods:** Pts had locally advanced/metastatic NSCLC, ≤2 prior lines of systemic therapy, ≤1 line of chemotherapy, and tumors that were c-Met OE by central immunohistochemistry (IHC; Ventana; Tucson, AZ). c-Met OE was defined for the NSQ cohort as ≥25% 3+ by IHC (high, ≥50% 3+; intermediate, 25 to <50% 3+) and for the SQ cohort as ≥75% 1+ by IHC. The planned enrollment was up to approximately 150 pts in Stage 1 and 160 pts in Stage 2. Teliso-V was dosed at 1.9 mg/kg IV Q2W. The primary endpoint is objective response rate (ORR) by independent central review. Secondary endpoints include duration of response (DOR). **Results:** As of data cutoff (27 May 2021), 136 pts were treated with Teliso-V; 122 were evaluable for ORR. ORR was 36.5% in the NSQ *EGFR* WT cohort (52.2% in c-Met high group and 24.1% in c-Met intermediate group), but was modest in the NSQ *EGFR* mutant and SQ cohorts. Efficacy data in groups/cohorts are in the Table. The most common any-grade adverse events (AEs) were peripheral sensory neuropathy (25.0%), nausea (22.1%), and hypoalbuminemia (20.6%). Grade 5 AEs considered possibly related to Teliso-V occurred in 2 pts (sudden death and pneumonitis in 1 pt each in the SQ cohort). **Conclusions:** Teliso-V demonstrated a promising ORR in pts with previously treated c-Met OE NSQ *EGFR* WT NSCLC; this cohort is currently expanding in Stage 2. ORR was modest in the cohorts of pts with c-Met OE NSQ *EGFR* mutant NSCLC and with c-Met OE SQ NSCLC; both cohorts have now met the protocol-specified stopping criteria and are no longer enrolling. The safety profile observed was consistent with IA3. Clinical trial information: NCT03539536. Research Sponsor: AbbVie.

NSCLC Group	Confirmed Responses (n/N)	ORR,% (95% CI)	Events/Responders	Median DOR, mo (95% CI)
c-Met OE NSQ *EGFR* WT	19/52	36.5 (23.6, 51.0)	8/19	6.9 (4.1, –)
c-Met high	12/23	52.2 (30.6, 73.2)	5/12	6.9 (2.4, –)
c-Met intermediate	7/29	24.1 (10.3, 43.5)	3/7	– (4.1, –)
c-Met OE NSQ *EGFR* mutant	5/43	11.6 (3.9, 25.1)	2/5	– (3.0, –)
c-Met high	5/30	16.7 (5.6, 34.7)	2/5	– (3.0, –)
c-Met intermediate	0/13	0 (–, –)	0	Not applicable
c-Met OE SQ	3/27	11.1 (2.4, 29.2)	2/3	4.4 (3.0, –)

9017 **Poster Discussion Session**

Efficacy and safety of patritumab deruxtecan (HER3-DXd) in advanced/metastatic non-small cell lung cancer (NSCLC) without *EGFR*-activating mutations. *First Author: Conor Ernst Steuer, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Patients (pts) with advanced NSCLC without *EGFR*-activating mutations (*EGFR*m) have limited treatment options after failure of molecularly targeted therapies or platinum-based chemotherapy (PBC) with or without immunotherapy (IO). HER3-DXd is an antibody drug conjugate consisting of a fully human monoclonal antibody to HER3 attached to a topoisomerase I inhibitor payload via a tetrapeptide-based cleavable linker. We previously published efficacy and safety data from a study of HER3-DXd in *EGFR*m NSCLC after failure of EGFR tyrosine kinase inhibitor (TKI) therapy. Here we present results in pts without *EGFR*m who progressed after PBC ± IO treatment. **Methods:** This ongoing phase 1 dose expansion study included a cohort of pts with advanced NSCLC without *EGFR*m who received prior PBC ± IO (NCT03260491). Pts with stable brain metastases were eligible, as were pts with non-*EGFR* oncogenic alterations and prior targeted therapy. The primary endpoint was confirmed ORR by blinded independent central review (BICR) per RECIST v1.1; secondary endpoints included DOR, PFS, and safety. **Results:** At the Mar 26, 2021, data cutoff, 47 pts had been treated with HER3-DXd 5.6 mg/kg IV every 3 wk; 17 pts had an identified driver genomic alteration (4 *KRAS* and 1 *NRAS* mutations, 4 *EGFR* Ex20ins, 3 *ROS1* and 2 *ALK* fusions, and 3 other). Median age was 62 y (range, 29-79 y); 53% of pts were female; 17% had squamous NSCLC. Median follow-up was 9.5 mo (range, 3.7-19.1 mo). Median number of prior anticancer regimens in the advanced setting was 3 (range, 0-8). Median treatment duration on study was 4.1 mo (range, 0.7-13.6 mo); treatment was ongoing in 11 pts (23%) at data cutoff. Confirmed ORR by BICR was 28% (13/47 pts; 95% CI, 16%-43%; 13 PRs, 22 SD). Median DOR was 5.7 mo (95% CI, 3.7-10.7 mo) and median PFS was 5.4 mo (95% CI, 3.9-12.7 mo). Among pts with identified driver genomic alterations, 35% (6/17) had a confirmed response by BICR, including 3 of 5 pts with *KRAS/NRAS* mutations and 2 of 2 with *ALK* fusions. Among pts without identified driver genomic alterations, 23% (7/30) had a confirmed response by BICR. The most common grade ≥3 treatment-emergent adverse events (TEAEs) were neutropenia (26%), thrombocytopenia (15%), and fatigue (15%). Drug-related interstitial lung disease by central adjudication occurred in 4 pts (9%; 0 grade ≥3). Four pts (9%) had TEAEs associated with treatment discontinuation. No drug-related deaths occurred. **Conclusions:** These data show promising clinical activity in pts with NSCLC without *EGFR*m, including pts with other identified driver genomic alterations. Updated results from this study will be presented. The overall safety profile was similar to that previously reported in pts with *EGFR*m NSCLC. A phase 2 study of HER3-DXd in pts with *EGFR*m NSCLC after failure of EGFR TKI and PBC is ongoing (NCT04619004). Clinical trial information: NCT03260491. Research Sponsor: Daiichi Sankyo, Inc.

9018 **Poster Discussion Session**

Phase I trial of the RAF/MEK clamp VS-6766 in combination with everolimus using an intermittent schedule with expansion in NSCLC across multiple *KRAS* variants. *First Author: Anna Rachel Minchom, The Institute of Cancer Research and The Royal Marsden Hospital NHS Foundation Trust, London, United Kingdom*

Background: VS-6766 is a small molecule RAF/MEK clamp that results in the reduction of p-MEK and p-ERK. Preclinical data show synergy of VS-6766 with the mTOR inhibitor everolimus across a panel of *KRAS* mutated (mt) NSCLC cell lines. This clinical trial evaluated the safety and efficacy of a novel intermittent regimen of VS-6766 and everolimus with an expansion in *KRAS* mt NSCLC (NCT02407509). **Methods:** The trial used a 3+3 dose escalation design with an intermittent once a week schedule A, and if tolerated, twice a week schedule B (Mon-Thu or Tue-Fri) for both drugs on a 3 weeks on/1 week off, 28 day cycle. Patients with *RAS* or *RAF* mt cancers were eligible for the dose escalation cohort, and 20 patients with *KRAS* mt NSCLC will be treated in the dose expansion cohort. Toxicity was evaluated by NCI CTC V4 and efficacy was evaluated using RECIST 1.1. **Results:** A total of 28 patients have been treated; median age 60 yrs (range 36-78), and median lines of previous treatment 3 (range 0-7). Sixteen patients have been treated in the dose escalation (3 in schedule A and 13 in the schedule B). The doses of 4 mg of VS-6766 and 5 mg everolimus (once weekly) were tolerated with no dose limiting toxicities (DLTs) and the dose intensity escalated to schedule B (twice weekly). At 4 mg VS-6766 twice weekly, DLTs were observed in two out of six patients and included grade 4 CPK elevation and grade 3 rash. Thus, the dose in schedule B (twice weekly) was de-escalated to 3.2 mg VS-6766 and the dose of everolimus was kept at 5 mg. No DLTs were reported in 6 patients and thus this was declared as the recommended phase 2 dose (RP2D). At the RP2D, the grade 3-4 drug related AE were rash (18%) and pruritus (7%). In the dose escalation cohorts, 3 partial responses (PRs) were reported (2 *KRAS G12D* low grade serous ovarian cancer and 1 *NRAS Q61K* mt thyroid cancer). In the *KRAS* mt NSCLC expansion cohort, 10 patients are evaluable for efficacy and 2 confirmed responses were reported (*KRAS* mutations G12V and G13A) with an objective response rate (ORR) 20% to date. The disease control rate (PR + SD) at the first scheduled evaluation was 90%. The median progression free survival (PFS) in the *KRAS* mt NSCLC cohort is 6.35 months (95% CI 3.52 – not reached). Updated ORR and PFS data will be presented. **Conclusions:** A tolerable intermittent dosing schedule targeting both the MAPK and PI3K pathways has been established. The combination of VS-6766 with everolimus has shown activity in patients with a variety of *KRAS* mutation variants including responses in *KRAS* mt NSCLC. Research Sponsor: tbc.

9019 **Poster Discussion Session**

A phase II study of AK112 (PD-1/VEGF bispecific) in combination with chemotherapy in patients with advanced non-small cell lung cancer. *First Author: Yuangyuan Zhao, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Based on IMPOWER 150, atezolizumab in combination with bevacizumab and platinum-based chemotherapy has been the first-line treatment for advanced non-squamous NSCLC with negative driver genes. AK112 is a global first-in-class anti-PD-1/VEGF bi-specific antibody developed by Akesobio. Preclinical and clinical studies have indicated that AK112 possess potential anti-tumor efficacy in solid tumors. Therefore, we aimed to assess the efficacy and safety of AK112 in combination with chemotherapy for patients with advanced NSCLC. **Methods:** This was an open-label, multi-center phase II study evaluating the efficacy and safety of AK112 in combination with chemotherapy in pts with advanced NSCLC. Enrolled pts were divided into three cohorts: Previously untreated advanced NSCLC pts with wide-type EGFR/ALK (Cohort 1), pts with EGFR mutations who had failed prior EGFR-TKI therapies without T790M mutation or failed osimertinib treatment (Cohort 2), and pts who progressed after anti-PD-1/L1 and platinum-based chemotherapy (Cohort 3). Pts were treated with 10mg/kg or 20mg/kg AK112 once every 3 weeks in combination with carboplatin and pemetrexed or carboplatin and paclitaxel for Cohort 1/2, and docetaxel for Cohort 3. Primary endpoint was ORR as assessed by investigator per RECIST v1.1. **Results:** 133 pts were enrolled from Feb 03, 2021 to Dec 31, 2021 and received AK112 plus chemotherapy (44 received AK112 10 mg/kg and 89 received AK112 20 mg/kg). As of Dec 31, 2021, in cohort-1, among 26 evaluable pts with squamous cell carcinoma, 20 partial response and 6 stable disease were observed for a 76.9% ORR and a 100.0% DCR, median DOR and median PFS was not reached while 6-month PFS rate was 86.2%. In Cohort-2, among 19 evaluable pts, 13 partial response and 5 stable disease were observed for a 68.4% ORR and a 94.7% DCR while median DOR was 5.5 months, and median PFS was 8.3 months. In Cohort-3, among 20 evaluable pts, 8 partial response and 8 stable disease were observed for a 40.0% ORR and a 80.0% DCR, median DOR and median PFS was not reached while 6-month PFS rate was 71.1%. Treatment emergent adverse events (TEAE) occurred in 86.5% (115/133) of the pts, and grade ≥3 AEs occurred in 28.6% (38/133) of pts including two deaths. Most common AE (incidence ≥ 5%) included alanine/aspartate aminotransferase increased, epistaxis, anemia, vomiting, nausea, rash, leukopenia, thrombocytopenia, and neutropenia. Treatment discontinuation due to AE occurred in 3.0% (4/133) of the pts. **Conclusions:** AK112 plus chemotherapy has shown a promising anti-tumor efficacy in each cohort and warrants potentially superior safety in comparison to anti-PD-(L)1 and anti-VEGF combination therapies in advanced NSCLC. PFS and ORR were also significantly improved with AK112 plus chemotherapy. Therefore, phase III registration studies of AK112 plus chemotherapy in advanced NSCLC will be initiated in 2022. Clinical trial information: NCT04736823. Research Sponsor: Akeso Biopharma Co.,Ltd.

9020 **Poster Discussion Session**

Phase 1/2a trial of nadunolimab, a first-in-class fully humanized monoclonal antibody against IL1RAP, in combination with cisplatin and gemcitabine (CG) in patients with non-small cell lung cancer (NSCLC). *First Author: Astrid Paulus, CHU de Liège, Liège, Belgium*

Background: Interleukin-1 Receptor Accessory Protein (IL1RAP) is expressed by cancer and stromal cells of many solid tumors. The IL-1 pathway is active in tumors and upregulated in response to chemotherapy. IL1RAP interacts with IL-1R1 and modulates downstream factors (e.g. IL-6, IL-8) and CRP level. Nadunolimab (CAN04), a fully humanized ADCC-enhanced IgG1 antibody, targets IL1-RAP and blocks IL-1α and IL-1β signaling. Here, results are reported from the phase 1/2a clinical trial CANFOUR evaluating nadunolimab combined with CG in NSCLC. **Methods:** Patients (pts) with unresectable, locally advanced or metastatic NSCLC, progressed on pembrolizumab or in first line for advanced disease, were eligible. Pts received 1 (n =17), 2.5 (n = 3) or 5 mg/kg (= 13) nadunolimab given Q1W in Cycle 1 and Q2W from Cycle 2, combined with standard CG. Due to risk of infusion-related reactions, a priming dose of 0.5 mg/kg nadunolimab was given one week before CG. Primary objective was safety; secondary objectives included ORR, PFS and OS, and exploratory objectives included effects on serum and tumor tissue biomarkers. **Results:** Thirty-three pts were enrolled: median age 64 years (39-77), 30% female, 42% ECOG 0, 55% non-squamous histology, 82% stage IV, 45% received previous pembrolizumab monotherapy. Treatment-related adverse events of grade≥3 were observed in 73% of pts, including neutropenia (58%), febrile neutropenia (9%), thrombocytopenia (30%) and anemia (18%). Neutropenia could be managed by G-CSF. Thirty pts received combination therapy and were included in the efficacy analysis. Three pts did not receive chemotherapy due to clinical deterioration (n = 2) or consent withdrawal (n = 1). ORR was 53% (95% CI 34-72%), disease control rate 80% (61-92%) and median duration of response 5.5 months (3.7-7.0) with 23% of pts still on treatment. The lower limit of the 95% CI for the observed ORR excludes the pre-specified 30%. ORR in pts with squamous histology was 46% and non-squamous 56%. Median PFS was 6.7 months (5.5-7.3) and median OS 13.7 months. The neutrophil-lymphocyte ratio was reduced throughout the trial and was driven by the reduction in circulating neutrophil numbers. IL1RAP expression on both cancer and stromal cells was confirmed in tumor biopsies. **Conclusions:** Nadunolimab combined with CG shows manageable safety and promising efficacy with a response rate of 53% in NSCLC pts. Nadunolimab is currently evaluated in several clinical trials investigating chemotherapy or IO combinations, including carboplatin and pemetrexed in non-squamous NSCLC. Clinical trial information: NCT03267316. Research Sponsor: Cantargia AB.

Genomic correlates of acquired resistance to PD-(L)1 blockade in patients with advanced non-small cell lung cancer (NSCLC). *First Author: Biagio Ricciuti, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Despite improvements in survival with immune checkpoint inhibition (ICI), the majority of patients develop acquired resistance to ICI after an initial benefit. However, the mechanisms underlying acquired resistance to ICI in NSCLC are largely unknown. **Methods:** Patients with advanced NSCLC treated with ICI at the Dana-Farber Cancer Institute (DFCI), and whose tumors underwent genomic profiling before and after ICI, with no intervening therapies, were included. Mutations, tumor mutational burden (TMB), copy number variations (CNVs), and PD-L1 tumor proportion score (TPS) were compared between pre- and post-ICI samples. Acquired resistance was defined as the development of disease progression after an initial objective response, or stable disease ≥3 months with PD-(L)1 blockade. **Results:** Among 1763 patients with advanced NSCLC who received ICI, 45 had matched pre- and post-ICI tissue samples available for genomic profiling. Putative mechanisms of resistance were identified in 55% of cases (N = 25). Five patients (20%) acquired an *STK11* mutation, one patient (4%) acquired a *KEAP1* mutation, and another patient (4%) developed concurrent *KEAP1* and *SMARCA4* mutations. A patient (4%) with *KRAS* G12C-mutant NSCLC developed concurrent *STK11* and *KEAP1* mutations at resistance. In 3 cases (12%) with pre-existing *STK11* or *KEAP1* mutations prior to ICI administration, we identified acquired copy losses of *STK11* and *KEAP1*, respectively, resulting in bi-allelic inactivation of these genes. Acquired beta-2-microglobulin (*B2M*) mutations were detected in 3 patients (12%), one of whom developed concurrent *B2M* copy loss, indicating bi-allelic inactivation. Eight additional patients (32%) developed *B2M* gene deletions. Other acquired alterations that have been implicated in ICI resistance included *CDKN2A/B* loss (N = 10, 40%), including 5 with bi-allelic deletion, acquired *PTEN* deletions (N = 5, 20%), and *MDM2* amplification (N = 2, 8%). When we examined alterations in immune checkpoint genes, we identified acquired *CD274* (PD-L1) and *PDCD1LG2* (PD-L2) loss in 8% of cases (N = 2), and bi-allelic deletion in one case (4%). Intervening ICI did not affect TMB (median TMB: 8.7 [pre-ICI] vs 9.1 [post-ICI] mut/Mb, P = 0.6), PD-L1 expression (median PD-L1 TPS: 3% [pre-ICI] vs 5.0% [post-ICI] mut/Mb, P = 0.5), or aneuploidy levels (as fraction of genome altered [FGA]) (median FGA: 18.4% [pre-ICI] vs 21.1% [post-ICI], P = 0.2), indicating that acquired gene level CNVs were not a reflection of increased cancer aneuploidy. In a control cohort of 30 patients with pre- and post-chemotherapy matched samples which underwent genomic profiling, no acquired mutations in *STK11*, *KEAP1*, *SMARCA4*, or *B2M* were detected. **Conclusions:** Mechanisms of acquired resistance to PD-(L)1 blockade are heterogenous, and new therapeutic strategies are required to delay and overcome ICI resistance in patients with NSCLC. Research Sponsor: Society of Immunotherapy for Cancer.

Association of comprehensive molecular genotyping and overall survival in patients with advanced non-squamous non-small cell lung cancer. *First Author: Charu Aggarwal, University of Pennsylvania, Philadelphia, PA*

Background: Current guidelines recommend comprehensive molecular genotyping for newly diagnosed patients (pts) with metastatic non-squamous (non-Sq) NSCLC. We have previously demonstrated that concurrent plasma (P) and tissue (T) based next-generation sequencing (NGS) improves detection of clinically actionable mutations in pts with advanced NSCLC. We analyzed the impact of concurrent T+P NGS on comprehensiveness of molecular genotyping and on overall survival (OS). **Methods:** A retrospective cohort study of pts with newly diagnosed stage IV non-Sq NSCLC who received therapy at our institution between 01/2019 and 12/2020 was performed. Categories of NCCN guideline testing were defined, i) comprehensive: *EGFR, ALK, BRAF, ROS1, MET, RET,* and *NTRK* testing, ii) incomplete: 2-6 genes tested, and iii) no testing performed. The proportion of pts with comprehensive molecular testing performed, prior to 1st-line therapy and by detection modality (T NGS vs. T+P NGS), were compared using Fisher's exact test. Median OS was estimated using Kaplan-Meier methodology from diagnosis to death or censored at most recent follow-up. **Results:** 335 patients were included in this analysis, 98.5% (330/335) underwent molecular testing: either comprehensive: n = 291 (86.9%), incomplete testing: n = 39 (11.6%); or no testing n = 5 (1.5%). Testing with T NGS was completed in 32.7% (108/330); 67.2% (222/330) underwent concurrent T+P NGS. These groups were well balanced for baseline characteristics, with the exception of a higher number of never smokers in T+P vs. T NGS (30.2% vs. 14.8%, p < 0.0001). Proportion of pts with comprehensive molecular testing was higher among pts with T+P NGS: 99.5% (221/222) vs. T NGS: 64.8% (70/108), p < 0.0001. All pts with T+P NGS testing had results available prior to 1st line therapy; 100% (204/204) compared to 60.7% (51/84) for T NGS, p < 0.0001. With median follow up of 20.5 months (mos, range 0.3 - 33.1), median OS was 18.6 mos. Median OS for pts tested with T+P NGS vs T alone was numerically longer at 23.2 vs. 14.1 mos, but not statistically significant (p = 0.078). However, regardless of testing modality, patients with comprehensive molecular genotyping had superior OS compared to those with incomplete or no testing (22.1 mos vs. 11.6 mos, p = 0.017). The institution of oral targeted therapy had no bearing on this difference in OS (test for interaction, p = 0.6509). **Conclusions:** Performance of concurrent T+P NGS testing was associated with a higher likelihood of comprehensive molecular genotyping, as well as improved availability of results, including prior to first line therapy. Patients with comprehensive genotyping have improved OS compared to patients with incomplete or no testing. These results support implementation of a concurrent T+P NGS approach upon initial diagnosis of metastatic non-Sq NSCLC. Research Sponsor: National Comprehensive Cancer Network, Pharmaceutical/Biotech Company.

Efficacy/safety of entrectinib in patients (pts) with *ROS1*-positive *(ROS1+)* advanced/metastatic NSCLC from the Blood First Assay Screening Trial (BFAST). *First Author: Solange Peters, Lausanne University Hospital, Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, Switzerland*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

9024 **Poster Discussion Session**

Updated efficacy and safety of larotrectinib in patients with tropomyosin receptor kinase (TRK) fusion lung cancer. *First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Neurotrophic tyrosine receptor kinase (*NTRK*) gene fusions have been identified as oncogenic drivers in a variety of tumor types, including lung cancer. Larotrectinib is a highly selective, central nervous system (CNS)-active TRK inhibitor that demonstrated an objective response rate (ORR) of 73% across 15 investigator-assessed patients (pts) with lung cancer (Drilon et al, *JCO Precis Oncol* 2022). We report data on an expanded cohort of pts with TRK fusion lung cancer treated with larotrectinib. **Methods:** Pts with TRK fusion lung cancer enrolled in two larotrectinib clinical trials (NCT02576431 and NCT02122913) were included for this analysis. Larotrectinib was administered at 100 mg twice daily. Response was assessed by independent review committee (IRC) per RECIST v1.1. **Results:** As of July 20, 2021, a total of 26 pts with TRK fusion lung cancer (24 non-small cell lung cancer, 1 atypical carcinoid, 1 neuroendocrine) were enrolled, including 10 pts with CNS metastases at baseline. Median age was 51.5 years (range 25.0–76.0). The gene fusions involved *NTRK1* (n =21; 81%) or *NTRK3* (n =5; 19%). Pts received a median of 2 prior lines of systemic therapies with 19 (73%) receiving ≥2. Among 23 pts evaluable per IRC, the ORR was 83% (95% confidence interval [CI] 61–95): two complete responses, 17 partial responses (PR), and four stable disease (SD). The median time to response was 1.8 months. Among 10 evaluable pts with baseline CNS metastases, the ORR was 80% (95% CI 44–97): eight PR and two SD. Median duration of response (DoR) and progression-free survival (PFS) were not reached; median follow-up was 12.9 and 14.6 months, respectively. The 24-month rates for DoR and PFS were 72% and 67%, respectively. Median follow-up for overall survival (OS) was 12.9 months. The 24-month and 36-month rates for OS were both 72%. For the 10 evaluable pts with CNS metastases, the 12-month DoR, PFS, and OS rates were 26%, 22%, and 78%, respectively. Duration of treatment for all pts evaluable per IRC ranged from 2.1 to 52.7+ months. At data cut-off, six pts had progressed, with all six continuing treatment post-progression for ≥4 weeks. Treatment-related adverse events (TRAEs) were predominantly Grade 1–2. Grade 3–4 TRAEs were reported in five pts (increased alanine aminotransferase, increased aspartate aminotransferase, hypersensitivity, myalgia, and increased weight). There were no treatment discontinuations due to TRAEs. **Conclusions:** In this larger dataset, larotrectinib demonstrated rapid and durable responses, extended survival, and a favorable long-term safety profile in pts with advanced lung cancer harboring *NTRK* gene fusions, including in pts with CNS metastases. These results support testing for *NTRK* gene fusions in pts with lung cancer. Clinical trial information: NCT02576431, NCT02122913. Research Sponsor: Bayer HealthCare and Loxo Oncology.

A protocol pre-specified interim overall survival (OS) analysis of GEMSTONE-302: A phase 3 study of sugemalimab (suge) versus placebo plus platinum-based chemotherapy (chemo) as first-line (1L) treatment for patients (pts) with metastatic non–small cell lung cancer (NSCLC). *First Author: Caicun Zhou, Oncology Department, Shanghai Pulmonary Hospital, Shanghai, China*

Background: GEMSTONE-302, a randomized, double-blind, phase 3 study, previously met its primary endpoint and demonstrated statistically significant and clinically meaningful prolongation of progression-free survival (PFS) with suge+chemo vs placebo+chemo as a 1L treatment in pts with metastatic NSCLC. PFS benefit was observed in both squamous (sq) and non-squamous (nsq) NSCLC, regardless of PD-L1 expression levels. Here we report the data from a protocol pre-specified interim OS analysis. **Methods:** Pts with systemic treatment-naïve stage IV NSCLC, measurable disease per RECIST v1.1, ECOG PS 0-1, and no known EGFR, ALK, ROS1 and RET alterations were randomized 2:1 to receive suge (1200 mg, IV) or placebo plus chemo (sq-NSCLC: carboplatin+paclitaxel; nsq-NSCLC: carboplatin+pemetrexed) every 3 weeks for up to 4 cycles, followed by maintenance therapy (sq-NSCLC: suge/placebo; nsq-NSCLC: suge/placebo+pemetrexed) for up to 35 cycles. The primary endpoint was investigator assessed PFS (INV-PFS). Key secondary endpoints included OS, INV-PFS in pts with tumor PD-L1 expression ≥1%, and ORR. Pts in the placebo group could cross over to receive suge monotherapy upon disease progression. **Results:** As of 22 Nov 2021, among all 479 enrolled pts, 51 (15.9%) and 7 (4.4%), respectively, remained on treatment with suge+chemo or placebo+chemo. The median follow-up was 25.4 and 24.9 months, respectively. Following treatment discontinuation, 17.8% and 43.4% of the pts, respectively, received cross-over suge or other non-study anti-PD-(L)1-containing therapies. Median OS was 25.4 months in suge+chemo group vs 16.9 months in placebo+chemo group (HR = 0.65 [95%CI, 0.50-0.84], p = 0.0008), and 2-year OS rate was 51.7% vs 35.6%. OS benefits were observed across all subgroups including different tumor histologies (sq: HR = 0.56; nsq: HR = 0.72) and PD-L1 expression levels (≥1%: HR = 0.64; < 1%: HR = 0.66). In the intent-to-treat population, median PFS was 9.0 months with suge+chemo vs 4.9 months with placebo+chemo (HR = 0.49 [0.40-0.61]), and 2-year PFS rate was 20.8% vs 7.3%. In pts with PD-L1≥1%, the median PFS was 10.9 vs 4.9 months (HR = 0.48 [0.36-0.63], p < 0.0001). ORR was 63.4% vs 40.3% (p < 0.0001). Among pts with baseline brain metastases, suge+chemo improved their OS (HR = 0.45) and intracranial INV-PFS (post-hoc analysis, HR = 0.33) vs placebo+chemo. Safety profile was consistent with previously reported results. **Conclusions:** Suge plus chemo demonstrated statistically significant and clinically meaningful OS improvement compared with placebo plus chemo, irrespective of tumor histology or PD-L1 expression levels, in pts with newly diagnosed metastatic NSCLC, offering a new 1L treatment option for this group of pts. Clinical trial information: NCT03789604. Research Sponsor: CStone Pharmaceuticals.

Final progression-free survival, interim overall survival, and biomarker analyses of CHOICE-01: A phase 3 study of toripalimab versus placebo in combination with first-line chemotherapy for advanced NSCLC without EGFR/ALK mutations. *First Author: Jie Wang, State Key Laboratory of Molecular Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Toripalimab (anti-PD-1) in combination with chemotherapy showed significant improvement in progression-free survival (PFS) and overall survival (OS) in the first-line treatment of advanced NSCLC regardless of tumor PD-L1 expression. Whole exome sequencing (WES) was performed to identify correlative biomarkers for survival. **Methods:** Patients (n = 465) with treatment-naïve, advanced NSCLC without EGFR/ALK mutations were randomized 2:1 to receive toripalimab 240 mg (n = 309) or placebo (n = 156) in combination with chemotherapy for 4-6 cycles, followed by maintenance of toripalimab or placebo plus standard care until disease progression, intolerable toxicity, or completion of 2 years of treatment. Stratification factors included PD-L1 expression status, histology, and smoking status. The primary endpoint was PFS by investigator per RECIST v1.1. Secondary endpoints included PFS by a blinded independent review committee (BIRC), OS and safety. **Results:** At the prespecified final PFS analysis (cutoff date Oct 31, 2021), a significant improvement in PFS as assessed by investigator was observed for the toripalimab arm over the placebo arm: HR = 0.49 (95% CI: 0.39-0.61), two-sided $p < 0.0001$, median PFS 8.4 vs 5.6 months. The 1-year PFS rates were 36.7% vs 17.2%. PFS as assessed by BIRC was also significantly longer in the toripalimab arm. The improvements of PFS were observed across key subgroups, including histology and PD-L1 expression. At the interim OS analysis, the toripalimab arm had a significantly longer OS than the placebo arm: HR = 0.69 (95% CI: 0.52-0.92), two-sided p = 0.0099, median OS not reached vs 17.1 months. The incidence of Grade ≥3 adverse events (AEs) (78.6% vs 82.1%) was similar between the two arms. AEs leading to discontinuation of toripalimab/placebo (14.3% vs 3.2%) and fatal AEs (5.5% vs 2.6%) were more frequent in the toripalimab arm. WES results from 394 available patients revealed that patients with high tumor mutational burden (TMB) (≥10 mutations per million base pairs) were associated with significantly better PFS in the toripalimab arm over the placebo arm (median PFS 13.1 vs 5.5 months) (interaction P = 0.026). In addition, patients with mutations in the FAK-PI3K-Akt pathway or IL-7 signaling pathways achieved significantly better PFS and OS from the toripalimab chemotherapy combination (interaction P values ≤ 0.01). **Conclusions:** The addition of toripalimab to chemotherapy in patients with advanced NSCLC provided superior PFS and OS when compared to chemotherapy alone with a manageable safety profile. These results support the use of toripalimab with chemotherapy as 1st line therapy for advanced NSCLC patients without EGFR/ALK mutations. Clinical trial information: NCT03856411. Research Sponsor: Shanghai Junshi Biosciences.

9029 **Poster Session**

Association of progression-free survival and overall response rate with overall survival in first-line randomized trials of immune checkpoint inhibitor–based regimens for metastatic non–small cell lung cancer (NSCLC): An FDA pooled analysis. *First Author: Bernardo Haddock Lobo Goulart, U.S. Food & Drug Administration, Silver Spring, MD*

Background: Overall Survival (OS) has represented the endpoint of choice to support approvals of Immune Checkpoint Inhibitors (ICIs) in first-line metastatic NSCLC. Despite continued interest in the use of earlier clinical endpoints as true surrogates for OS in this setting, the correlation of Progression-Free Survival (PFS) and Overall Response Rate (ORR) with OS remain an area of active investigation. We conducted a patient-level and trial-level pooled analysis of first-line randomized trials of ICI-based regimens to assess correlations of early clinical endpoints of PFS and ORR with OS in first-line metastatic NSCLC. **Methods:** The analysis included randomized trials comparing ICI-based regimens (anti-PD-(L)1 with or without anti-CTLA4 antibodies, with or without platinum-based chemotherapy) to platinum-based chemotherapy alone for the first-line treatment of patients with metastatic NSCLC that were submitted to the U.S. Food and Drug Administration between July 2016 to March 2021 to support a marketing application. Patient-level associations were estimated using Spearman (rs) correlation coefficients for PFS and OS, and Cox Proportional Hazards models in RECIST response-based subgroups for ORR and OS. At the trial level, associations were estimated using R2 coefficients from weighted linear regression models, using the log of hazard-ratio (HRs) for PFS and OS and log-odds ratio for ORR. **Results:** The pooled analysis included 13 trials enrolling 9,285 patients total. Seven trials compared ICIs combined with chemotherapy vs chemotherapy; 6 trials compared ICIs alone vs chemotherapy. Among all patients, the distribution of PD-L1 expression was 31%, 66%, and 32% for PD-L1 <1%, ≥1%, and ≥50%, respectively. The table shows the correlation coefficients for PFS and OS, and ORR and OS at the patient and trial levels. At the patient level, the OS HR comparing ICI-based regimens to chemotherapy was 0.54 (95% CI: 0.48, 0.61) for RECIST responders and 0.96 (95% CI: 0.90, 1.02) for non-responders. **Conclusions:** This pooled analysis did not indicate a strong correlation between endpoints of PFS and ORR with OS at the patient and trial levels in first-line randomized trials of ICI-based regimens for metastatic NSCLC, potentially because of use of subsequent therapies, cross-over to ICIs, and continuation of ICIs beyond progression. Future research will explore the correlation of alternative endpoints with OS, such as time to treatment discontinuation. Our analysis supports the continued importance of OS as an endpoint for first-line NSCLC trials of ICI-based regimens. Research Sponsor: U.S. Food & Drug Administration.

Correlation of PFS and ORR with OS.

Endpoints	All Patients	PD-L1 ≥1%	PD-L1 ≥50%
Patient level			
PFS and OS (Spearman)	0.64	0.62	0.63
Trial level			
R2 (PFS and OS)	0.69	0.70	0.60
R2 (ORR and OS)	0.61	0.54	0.31

A randomized phase II/ III trial of nivolumab versus nivolumab plus docetaxel for previously treated advanced or recurrent non–small cell lung cancer: TORG1630. *First Author: Yosuke Kawashima, Department of Pulmonary Medicine, Sendai Kousei Hospital, Sendai, Japan*

Background: Immuno-checkpoint inhibitor (ICI) monotherapy is a standard second-line treatment for non-small-cell lung cancer (NSCLC). Addition of a cytotoxic agent to ICI may enhance the benefits. **Methods:** This multi-institutional open-label randomized phase II/III study compared the arm A consisting of nivolumab (NIV) monotherapy and arm B consisting of NIV + docetaxel (DTX) for patients with previously treated ICI-naïve NSCLC, prestratified by PS/histological types/sex/driver-mutations. The primary endpoint was superiority of arm B in OS in the phase III part. Assuming a HR of 0.75 for OS with the estimated mOS of arm A/B as 10.5/14.0 mo, a total 350 patients would be required to provide 80% power at a one-sided α of significance being 0.05. It was started at Nov. 2017, however, the patients' accrual was discontinued due to the approval of ICI in the first-line setting in late 2018. Eventually, a total of 131 patients were enrolled for analysis. **Results:** 128 patients (64 in each arm) were eligible and included in full analysis set (FAS), and the patients' demographics were well-balanced in each arm. The mOS was 14.7 mo (95%CI, 11.4-18.7) in arm A, and 23.1 mo (95%CI, 16.7-NR) in arm B. The HR of OS was 0.63 (90%CI, 0.42-0.95; p = 0.0310). The mPFS was 3.1 mo (95%CI, 2.0-3.9) and 6.7 mo (95%CI, 3.8-9.4) in arm A and B, respectively. The HR for PFS was 0.58 (95%CI, 0.39-0.88; p = 0.0095). The ORR was 14.0% (95%CI, 6.3-25.8) in arm A, and 41.8% (95%CI, 28.7-55.9) in arm B, with a statistical significance (p = 0.0014). Subgroup analyses for OS disclosed that the HRs favored arm B over arm A across all prespecified subgroups. The mOS of EGFR-mutant subgroup also showed better tendency in arm B than A (11.0 mo in arm A; 95%CI, 3.5-14.0; vs 20.6 mo in B; 95%CI, 5.8-NR; HR 0.45; 95%CI, 0.17-1.17). The hematological toxicity and gastrointestinal adverse events were more common in arm B than in A. Six (9.4%) in arm A and 25 patients (39.1%) in arm B discontinued protocol treatment due to adverse events. Overall, two treatment-related deaths were observed; one from pneumonitis in arm A, and one from myocarditis in arm B. **Conclusions:** Although the resulting statistical power was limited because of reduced sample size, the addition of DTX to NIV in the second-line NSCLC therapy significantly improved OS, PFS, and ORR, despite slightly elevated risk of toxicity. This is the first randomized clinical trial that confirmed significant survival benefit of ICI + chemotherapy over ICI alone in any cancer type. Clinical trial information: UMIN000021813. Research Sponsor: Ono Pharmaceutical Co. Ltd, Bristol-Myers Squib K.K.

Three days of CIV rh-Endostatin in combination with PD-1 antibody plus chemotherapy as first-line regimen for EGFR/ALK-negative, advanced or metastatic, non-squamous non–small cell lung cancer (NSCLC): A open label, multicenter, phase II and cohort study (ENPOWER). *First Author: Dong Wang, Third Military Medical University, Chongqing, China*

Background: rh-Endostatin, an antiangiogenic agent, in combination with chemotherapy is recommended by the CSCO guideline as the first-line treatment for EGFR/ALK-negative, advanced or metastatic, non-squamous non–small-cell lung cancer (NSCLC). However, evidence supporting the application of rh-Endostatin plus PD-1 antibody in clinical settings has been limited. The ENPOWER study is an open-label, multicenter, phase II and cohort study to evaluate the efficacy and safety of three days of continuous intravenous infusion (CIV) of rh-Endostatin in combination with PD-1 antibody plus chemotherapy as the first-line regimen for EGFR/ALK-negative, advanced or metastatic, non-squamous NSCLC. **Methods:** ENPOWER was an open label, multicenter, phase II and cohort study. Patients with EGFR/ALK-negative, advanced or metastatic, non-squamous NSCLC were enrolled and assigned into the following two cohorts. Patients in Cohort 1 (PD-1 combination) received rh-Endostatin plus PD-1 antibody plus standard chemotherapy (Carboplatin or Cisplatin plus Pemetrexed) during the induction period up to 4 - 6 cycles and rh-Endostatin plus PD-1 antibody during the maintenance period until disease progression or intolerable adverse events. Those in cohort 2 different from in cohort 1 was not subject to PD-1 antibody. **Results:** 43 subjects were evaluable for efficacy analysis, with 15 in Cohort 1 (PD-1 combination) and 28 in Cohort 2. ORR and DCR was 53% and 93% in Cohort 1 (CR, 0; PR, 8; SD, 6; PD,1) and 39% and 86% in Cohort 2 (CR 0; PR 11; SD, 13; PD, 4), respectively. 50 subjects were included in safety analysis. The overall incidence of AEs of any grade was 89%. 92% of the patients in the cohort 1 and 85% in the cohort 2. The majority of AEs was grade 1 or 2. Adverse events of any grade that occurred in at least 10% of patients were neutropenia（76%）, nausea/vomiting (61%), AST/ALT abnormal (33%), palpitate (28%), anemia (22%) and skin hypersensitivity (11%) in the cohort 1 and neutropenia（68%）, nausea/vomiting (59%), AST/ALT abnormal (21%), palpitate (16%), anemia (40%) in the cohort 2, respectively. Adverse events of grade 3 or higher found in the cohort 1 were neutropenia (23%) and those were neutropenia (19%), AST/ALT abnormal (3%) and anemia (3%) in the cohort 2. Seemingly, Adverse events that occurred more frequently in the cohort 1 than in the cohort 2 were AST/ALT abnormal, palpitate and skin hypersensitivity. **Conclusions:** Three days of CIV rh-Endostatin in combination with PD-1 antibody plus chemotherapy for the first line treatment of EGFR/ALK negative, advanced or metastatic, non-squamous NSCLC could obtain the better improvement in the efficacy and result in the higher frequent in some of AEs. Clinical trial information: NCT: 04063449. Research Sponsor: None.

Sintilimab versus pembrolizumab in monotherapy or combination with chemotherapy as first-line therapy for advanced non–small cell lung cancer: Results from phase 2, randomized clinical trial (CTONG1901). *First Author: Si-Yang Maggie Liu, Department of Hematology, First Affiliated Hospital, Institute of Hematology, School of Medicine, Key Laboratory for Regenerative Medicine of Ministry of Education, Jinan University; Chinese Thoracic Oncology Group (CTONG), Guangzhou, China*

Background: Immunotherapy has become standard therapy for untreated advanced NSCLC. However, no direct comparison between anti-PD-1 inhibitors has been reported. **Methods:** CTONG1901 is an open label, randomized, phase II clinical trial to compare sintilimab and pembrolizumab in monotherapy or combination with chemotherapy for advanced NSCLC at first-line setting. The primary endpoint was objective response rate (ORR). Patient without *EGFR* and *ALK* alteration were enrolled. Patients with PD-L1 tumor proportion score (TPS) ≥50% were randomly to receive sintilimab (A) or pembrolizumab (B) ; and with TPS<50% were randomly to receive sintilimab (C) or pembrolizumab (D) combined with chemotherapy. Sample size was calculated by Optimal Two-Stage Designs. 20 patients were enrolled in 1st stage. When ≥4 patients achieve partial response (PR) in sintilimab arms, the study will enter into 2nd stage and the sample size will be calculated based on the ORR results of the 1st stage. **Results:** The ORR was 57.1% in sintilimab and 33.3% in pembrolizumab arms at the 1st stage. The study successfully entered into the 2nd stage. 48 additional patients should be enrolled after calculation. When 15 PR in sintilimab arms achieved, the primary endpoint will be reached. From Mar. 2020 to Jan. 2022, 71 patients were screened and 68 patients were enrolled in two stages. Histologic subtypes and brain metastasis were well balanced between arms. As of Dec. 31st 2021, the median follow-up was 5.6 months. The confirmed ORR was 45.5% (15/33) in sintilimab vs. 28.6% (10/35) in pembrolizumab arms (A vs. B: 30.8% [4/13] vs. 28.6% [4/14]; C vs. D: 55.0% [11/20] vs. 28.6% [6/21]). Unconfirmed ORR was 57.6% vs. 42.9% and disease control rate (DCR) was 87.9% vs. 91.4% in sintilimab and pembrolizumab arms. The primary endpoint was reached. Survival data was immature. Any grade and 3-4 grade treatment-related adverse events (TRAEs) were comparable in sintilimab and pembrolizumab arms (Table). **Conclusions:** This is the first head-to-head phase II study to directly compare two anti-PD-1 antibodies as first-line treatment in advanced NSCLC. The result suggested comparable tumor response and similar safety profile between sintilimab and pembrolizumab. Clinical trial information: NCT04252365. Research Sponsor: CTONG1901.

Pathological and clinical efficacy of CTONG1901 in sintilimab and pembrolizumab arms.

PEOPLE (NTC03447678), a phase II trial of first-line, single-agent pembrolizumab in advanced NSCLC with low PD-L1: Clinical outcomes and association with circulating immune biomarkers. *First Author: Giuseppe Lo Russo, Thoracic Oncology Unit, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

Background: In advanced NSCLC (aNSCLC) with PD-L1 < 50% chemo-immunotherapy is the standard of care. Although the activity of single agent pembrolizumab was reported, no biomarkers have been identified able to select patients who mostly benefit. The trial aimed to identify immune biomarkers associated with PFS in aNSCLC patients with PD-L1 levels < 50% treated with first-line pembrolizumab. Here we reported for the first time the clinical outcomes of the trial and circulating immune profiling (CIP) biomarkers correlated to PFS. **Methods:** This phase II trial was conducted at Fondazione IRCCS Istituto Nazionale dei Tumori of Milan. Eligible patients were previously untreated stage IIIB-IV NSCLC, EGFR and ALK wild type with PD-L1 < 50%, PS 0-2. PD-L1 was assessed with 22-C3 antibody (Dako). Patients received pembrolizumab 200 mg every 3 weeks until 35 cycles, disease progression or unacceptable toxicity. The primary endpoint was the association of immune biomarkers with PFS. OS, ORR, DCR, DoR and safety were secondary endpoints. CIP was performed by determination of absolute cell counts for 36 innate and adaptive immunity subsets through multiparametric flow cytometry on freshly isolated whole blood samples at baseline. An orthoblique principal components-based clustering approach and multivariable Cox regression model adjusted for clinical variables were used to analyse CIP variables and their correlation with clinical endpoints. **Results:** From May 2018 to October 2020, of 87 screened, 65 patients were enrolled. The median age was 70.9 years, most patients were male (67.7%), smoker (87.7%), non-squamous (83.1%), PDL1 + (70.8%). 12 patients (18.5%) had PS 2. During a median follow-up of 26.4 months (mo), 51 radiological progressions, 46 deaths and 60 PFS events were observed. The median PFS was 2.9 mo (95%CI 1.8 - 5.6) and the median OS was 12.1 mo (95%CI 8.7 - 17.1). The ORR was 24.1% (2 complete and 12 partial responses), DCR was 53.4% and median DoR was 14.5 mo (95%CI 6.4 - 24.9). Drug related G3-G4 adverse events were: 2 hyponatremia, 2 lipase increased, 1 pneumonitis. Out of 7 CIP clusters identified, 2 were statistically significant at multivariable analysis on 57 patients. Higher baseline counts of 8 subsets within these two clusters were associated with better PFS (HR values range: 0.88-0.98; p values range: 0.001- 0.016). The significant subsets included lymphocytes (cells expressing CD3, or CD19 or CD56, but lacking granulocyte and monocyte markers) and main NK subsets (including CD56dim CD16+, CD56dim CD16- and HLA-DR+ NK cells). **Conclusions:** This trial confirmed that pembrolizumab as first-line single agent is safe and active also in a subgroup of aNSCLC patients with PD-L1 < 50%. CIP biomarkers can be useful to identify patients with a favourable outcome, thus avoiding the adding toxicity of chemotherapy. Clinical trial information: NTC03447678. Research Sponsor: Merck Sharp & Dohme.

Platinum-free chemotherapy in the new era of immunotherapy: A phase II study of camrelizumab combined with apatinib and albumin paclitaxel in advanced non-squamous NSCLC (CAPAP-lung). *First Author: Lin Wu, Department of Thoracic Medicine, Hunan Cancer Hospital, The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, China*

Background: Cytotoxic chemotherapy and anti-angiogenic therapy may enhance the therapeutic efficacy of immune checkpoint inhibitors (ICIs). Platinum-containing dual-agent chemotherapy combined with ICIs is the standard first-line treatment for non-small cell lung cancer (NSCLC), however, the optimal combination regimen remains unclear. The adverse effects of platinum-based chemotherapy are relatively serious, whether platinum chemotherapy can be eliminated in the first-line treatment of non-small cell lung cancer is a hotspot and difficulty in current research. Based on these results, we initiated CAPAP-lung study, which is a single-arm, multicenter Phase II trial to evaluate the efficacy and safety of Camrelizumab in combination with apatinib and albumin paclitaxel without platinum as the first-line therapy for non-squamous non-small cell lung cancer. **Methods:** Patients diagnosed with IIIB-IV non-squamous NSCLC without EGFR and ALK sensitive mutations received Camrelizumab (200mg/3w) in combination with Albumin Paclitacxel (135mg/m^2, d1, d8/3w, 4-6 cycles) and Apatinib (250mg Qd po for 5 days, resting for 2 days every week). From August 2020 to February 2022, 54 of the planned 63 patients have been enrolled. The primary endpoint is progression-free survival(PFS), and secondary endpoints were overall survival (OS), duration of Response (DOR), objective response rate (ORR), and disease control rate (DCR) assessed by RECIST v1.1. This study is registered with ClinicalTrials.gov, NCT04459078 (follow-up is ongoing). **Results:** The data for a total of 38 patients out of 54 enrolled patients were evaluable. Median PFS was 10.97 mo (95%CI 7.1-NR).The objective response rate (ORR) and disease control rate (DCR) were 71.1% (27/38, 95%CI 53.9-84.0) and 97.4% (37/38, 95%CI 84.6-99.9), respectively. The incidence of grade 3 and worse treatment-related adverse events was acceptable, with grade 3 events in 25(46.3%) patients and grade 4 events in 3(5.6%) patients. The most common grade 3 treatment-related adverse events were decreased neutrophil count (8 [14.8%]), liver function damage (9 [16.7%]), rash (3 [5.6%]), and decreased white blood cell count (3 [5.6%]). **Conclusions:** Camrelizumab combined with albumin paclitaxel and apatinib showed encouraging antitumor activity with an acceptable safety profile for the first-line treatment of advanced lung adenocarcinoma. Clinical trial information: NCT04459078. Research Sponsor: Suzhou Sheng Diya Biomedical Co., Ltd.

Durvalumab (D) +/- tremelimumab (T) + chemotherapy (CT) in first-line (1L) metastatic (m) NSCLC: AE management in POSEIDON. *First Author: Byoung Chul Cho, Yonsei Cancer Center, Seoul, South Korea*

Background: In the Phase 3 POSEIDON study in 1L mNSCLC, adding T to D+CT resulted in statistically significant improvements in PFS and OS vs CT. No new safety signals were identified and treatment discontinuations due to treatment-related AEs (TRAEs) were similar for the T+D+CT and D+CT arms (15.5% and 14.1%). Here we present details of AEs and their management. **Methods:** 1013 pts with *EGFR*/*ALK* wild-type mNSCLC were randomized 1:1:1 to 1L T+D+CT, D+CT or CT. Safety was assessed in all treated pts. **Results:** 330, 334 and 333 pts received T+D+CT, D+CT and CT; 78%, 82% and 74% received at least 4 cycles of platinum-based CT. The most common grade 3/4 TRAEs were hematologic (anemia in 17%, 15% and 20% of pts in the T+D+CT, D+CT and CT arms and neutropenia in 16%, 13% and 12%) and most were managed using standard approaches per local practice; 22%, 18% and 16% of pts received colony stimulating factors and 22%, 21% and 26% received blood transfusions. All grade immune-mediated AEs (imAEs) occurred in 34%, 19% and 5% of pts in the T+D+CT, D+CT and CT arms; a higher incidence of diarrhea/colitis, dermatitis/rash and endocrinopathies was seen with the addition of T to D+CT (Table). Grade 3/4 imAEs occurred in 10%, 7% and 2% of pts in the T+D+CT, D+CT and CT arms, and serious imAEs in 10%, 6% and 1%; imAEs led to discontinuation of any study treatment in 6%, 4% and 0.6%, and led to death in 0.6%, 0.3% and 0%. Most imAEs were low grade and manageable with systemic corticosteroids (received by 26%, 13% and 4% of pts in the T+D+CT, D+CT and CT arms) or endocrine therapy (12%, 8% and 1%). Median time from first dose to onset of imAEs (TTO) was generally > 60 days and the majority of non-endocrine imAEs resolved (Table). **Conclusions:** In POSEIDON, the safety profile of all regimens was manageable per standard guidelines and in line with the known profiles of D, T+D and CT; the most common grade 3/4 TRAEs were those typically associated with CT. As expected, more imAEs occurred with T+D+CT than D+CT, but the incidence of grade 3 or 4 imAEs, imAE-related deaths and treatment discontinuations due to imAEs was generally similar in the IO arms. T+D did not compromise the ability to administer planned CT. Clinical trial information: NCT03164616. Research Sponsor: AstraZeneca.

Association between immune-related adverse events and microbiome composition in patients with advanced non–small cell lung cancer treated with immunotherapy. *First Author: Marion Tonneau, Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), Montréal, QC, Canada*

Background: Despite immune-checkpoint inhibitors (ICI) achieving high response rates in patients (pts) with advanced non-small cell lung cancer (NSCLC), immune-related adverse events (irAE) remain an important therapeutic hurdle. The gut microbiome represents a novel prognostic marker of ICI response and early clinical evidence suggests that the microbiome may also regulate the development of irAE. We aimed to assess the association between irAE and the gut microbiome composition in advanced NSCLC pts amenable to ICI. **Methods:** In this study, we enrolled 464 pts from two independent cohorts (Montreal and Tokyo) with advanced NSCLC treated with ICI monotherapy or combination with chemotherapy. Fecal samples were collected prior to ICI initiation. Metagenomics microbiome profiling and 16S rRNA microbiome sequencing were performed for 81 pts and 133 pts respectively. The irAE were classified as CTCEA grade 0-1 (G0-1 irAE) and grade > 2 (G2-5 irAE). Microbiome composition of both groups was represented using alpha diversity, beta diversity indexes and LEfSe relative abundances. **Results:** Median follow-up was 28.3 months (mos) and the incidence of G2-5 irAE was 25.1% in the Montreal cohort. For the Tokyo cohort, the median follow-up was 19.6 mos and 30.8% pts developed G2-5 irAE. First, in both cohorts, overall survival (OS) and progression-free survival (PFS) were significantly improved for pts with G2-5 irAE compared to G0-1 irAE (OS: HR: 1.71, $p = 0.008$ and PFS: HR: 1.65, $p < 0.001$) and (OS: HR: 2.34, $p = 0.001$, and PFS: HR = 2.34, $p = 0.006$) respectively. Second, metagenomics analysis of 81 pts demonstrated a numerical decrease of the alpha diversity in terms of observed species in the G2-5 irAE. *Dorea sp CAG 31, Anaerosporobacter mobilis, Butyricicoccus,* and *Enterococcus faecium* were overrepresented in pts with G2-5 irAE. Conversely, *Gordonibacter* was increased in G0-1 irAE. Next, 16S rRNA profiling from the Tokyo cohort revealed an enrichment of *Dorea, Butyricicoccus,* and *Eubacterium ventriosum* in G2-5 irAE. Finally, we observed an enrichment in *Dorea* and *Butyricicoccus* in the pts with PFS > 6 months, as observed in the G2-5 irAE group. **Conclusions:** IrAE correlated with clinical outcome and microbiome composition in two independent cohorts of pts with advanced NSCLC. These results prompt further research on the potential mechanism underling the role of the microbiome in the development of irAE. Research Sponsor: None.

9037 **Poster Session**

First report of safety/tolerability and preliminary antitumor activity of CAN-2409 in inadequate responders to immune checkpoint inhibitors for stage III/IV NSCLC. *First Author: Charu Aggarwal, University of Pennsylvania, Philadelphia, PA*

Background: Immune checkpoint inhibitors (ICI) are standard of care for advanced NSCLC. Even among patients with initial response, a majority ultimately progress, and rational combination approaches are needed to improve outcomes. CAN-2409 is a replication-deficient adenoviral gene construct that delivers the thymidine kinase gene, resulting in local conversion of a prodrug (valacyclovir) into a toxic metabolite. This leads to tumor cell lysis and immunization against the injected tumor and uninjected metastases. We have previously shown that monotherapy intra-tumoral (IT) delivery of CAN-2409 followed by oral valacyclovir in NSCLC patients is safe and results in CD8+ T cell infiltration in the injected tumor and activation of this cell population in tissue and peripheral blood. **Methods:** This open-label Ph2 experimental medicine clinical trial evaluates safety and clinical activity of IT CAN-2409 combined with ICI (± chemo) for stage III/IV NSCLC. Three cohorts are defined based on response to ICI at enrollment: stable disease (SD; Cohort 1; C1), progressive disease (PD) after ≥18 weeks (w) of ICI (Cohort 2; C2), or ICI refractory disease (RD; Cohort 3; C3). Two doses of CAN-2409 ($5x10^{11}$ vp) are given 5-7w apart via bronchoscopic or percutaneous injection into a lung tumor, disease-positive lymph node or peripheral metastasis, followed by valacyclovir. Patients are assessed for safety, immunologic biomarkers (analysis in progress), and clinical response. **Results:** As of data cutoff (10Jan22), 28 patients received ≥1 dose of CAN-2409 (safety population). Median age was 70 years; 86% stage IV; 32% squamous; 11% PD-L1 >50%; 82% receiving pembrolizumab and 18% nivolumab. Study treatment and procedures were generally well tolerated. The most common TRAEs were Gr1/2, with fatigue, fever, and chills in 18-39% of patients; 1 patient had Gr3 fever. Twenty-two patients are alive and 6 patients died due to disease. Of the 14 RECIST evaluable patients who received 2 doses of CAN-2409, clinical response was seen in 4 patients (Table 1). Two PRs are ongoing (6w, 24w) and reduction in tumor size was observed in non-injected lesions. In C2, 6 of 7 patients achieving SD are ongoing with median duration of 13w (range 10-40w). **Conclusions:** The addition of CAN-2409 for patients with advanced NSCLC and inadequate response to front-line ICI (± chemo) appears to be well tolerated. Preliminary clinical data suggest that CAN-2409 induced a clinical response in 4/14 evaluable patients and produced disease stabilization in most patients entering the trial with PD, with evidence of abscopal effect in a subset of patients. Clinical trial information: NCT04495153. Research Sponsor: Candel Therapeutics, Inc, Partnership for Accelerating Cancer Therapies (PACT).

A phase 2 study of an off-the-shelf, multi-neoantigen vector (ADXS-503) in patients with metastatic non–small cell lung cancer either progressing on prior pembrolizumab or in the first-line setting. *First Author: Gregory James Gerstner, Illinois Cancer Care, Peoria, IL*

Background: ADXS-503 (A503) is an off-the-shelf, attenuated Listeria monocytogenes (Lm)-based immunotherapy bioengineered to elicit potent T-cell responses against 22 tumor antigens commonly found in non-small-cell lung cancer (NSCLC, i.e. 11 hotspot mutations and 11 tumor-associated antigens, TAAs). Pembrolizumab (pembro) is a programmed death receptor-1 (PD-1)-blocking antibody approved for the treatment of advanced lung cancer. A503 and pembro have complementary mechanisms of immune activation and reversal of immune tolerance. **Methods:** A phase 2 study of A503 ± pembro is being conducted in patients with metastatic squamous or non-squamous NSCLC. In Part B of the study, A503 was added-on to pembro within 12 weeks of the first scan showing disease progression following pembro (per RECIST criteria v1.1). In Part C of the study, A503 and pembro were administered to previously untreated patients. Both A503 ($1x10^8$ CFU) and pembro (200 mg) were infused by IV every 3 weeks until disease progression or limiting toxicity. **Results:** A total of 17 patients have been treated/evaluated from Part B (n = 14/13) and Part C (n = 3/3). Pembro + A503 was well tolerated in both parts of the study, with mostly grade 1–2, transient and reversible treatment-related adverse events, the most common being fever (47%), chills (35%), fatigue (29%) and nausea (21%). There have been no added immune-related toxicities associated with the combination. Of the 13 evaluable patients in Part B, 2 achieved partial response (PR) and 4 achieved stable disease (SD), yielding an objective response rate (ORR) of 15.4% and a disease control rate (DCR) of 46.2%. Two patients from Part C also achieved SD (DCR 67%). The 2 PRs in Part B have been durable (i.e. 710 and 189 days) as were 5 of the SDs: 3 in Part B (i.e. 448, 175, 117 days) and 2 in Part C (i.e. 322 and 175 days). Both patients with PR in Part B are still undergoing therapy in addition to the other patients who achieved SD. Patients who seem to achieve clinical benefit in both parts of the study include those with PD-L1 expression ≥ 50% and those who show proliferation and/or activation of NK and CD8+ T cells within the first weeks of therapy. In addition, patients with prior pembro exposure ≥ 6 months and DCR > 6 months seem to have clinical benefit when A503 is added to pembro (Part B). **Conclusions:** The addition of A503 to pembro after disease progression on pembro appears to be well tolerated and induced antigen-specific T-cell responses and durable disease control in 46% of patients in Part B and 67% of patients in Part C. Additional patients are currently being enrolled into both parts of the study to further explore the potential of A503 to restore or enhance sensitivity to checkpoint inhibitors. Clinical trial information: NCT03847519. Research Sponsor: Advaxis Inc.

Safety and efficacy of tusamitamab ravtansine (SAR408701) in long-term treated patients with nonsquamous non–small cell lung cancer (NSQ NSCLC) expressing carcinoembryonic antigen-related cell adhesion molecule 5 (CEACAM5). *First Author: Charles Ricordel, Service de Pneumologie, CHU Rennes, Rennes, France*

Background: Tusamitamab ravtansine (tusa) is a novel antibody-drug conjugate that selectively targets CEACAM5, a cell surface glycoprotein highly expressed in several tumor types. In previously reported results from an open-label Phase 1/2 study (NCT02187848), tusa showed promising antitumor activity in patients (pts) with heavily pretreated NSQ NSCLC and high CEACAM5 expression (Gazzah A et al. *J Clin Oncol.* 2020;38[15 suppl]:9505). Herein we report results for pts treated for ≥ 12 mo with NSQ NSCLC and high or moderate CEACAM5 expression. **Methods:** In the Phase 1/2 study, 92 pts with heavily pretreated NSQ NSCLC and high (n = 64) or moderate (n = 28) CEACAM5 expression (≥ 2+ intensity in ≥ 50% of tumor cells or in ≥ 1% to < 50% of tumor cells, respectively) were treated with tusa 100 mg/m^2 Q2W. As of Jan 2020, among CEACAM5 high expressors, 13 had confirmed partial response (PR) and 28 had stable disease (SD); among moderate expressors, 2 had PR and 15 had SD. We focus here on pts treated ≥ 12 mo as of Dec 2021. **Results:** A total of 24 pts were treated for ≥ 6 mo, 15 pts for ≥ 9 mo, 11 pts for ≥ 12 mo, 6 pts for ≥ 24 mo, and 2 pts for ≥ 42 mo. At the data cutoff, 5 pts remained on treatment, 1 for > 3.5 y. For pts treated ≥ 12 mo median (range) treatment duration was 26.6 (12.1–45.3) mo. Of 15 pts with PR in the prior analysis, as of Dec 2021 PR was still observed in 10 pts (67%) treated for ≥ 6 mo, 8 pts (53%) for ≥ 9 mo, and 7 pts (47%) for ≥ 12 mo. For the 11 pts treated ≥ 12 mo, 7 had PR and 4 had SD. Of the 11 pts treated ≥ 12 mo, 9 had high CEACAM5 expression and 2 had moderate CEACAM5 expression; most had prior treatment with an anti-PD1/PD-L1. Pts treated for ≥ 12 mo had better ECOG performance status and fewer prior treatments than the overall group. Of pts treated for ≥ 12 mo, PR occurred irrespective of CEACAM5 expression level. Only 1 pt treated for ≥ 12 mo discontinued due to a treatment emergent adverse event (TEAE) (breast cancer). Corneal events (keratitis/keratopathy) were the most frequent TEAEs, occurring in 8 pts (73%); 4 pts (36%) with Grade ≥ 3; 7 pts had subsequent treatment modification (delay or delay/reduced dose). No corneal TEAE was serious or led to treatment discontinuation. **Conclusions:** Almost half (47%) of pts who achieved a PR were treated for ≥ 1 y, suggesting that response to tusa in heavily pretreated pts was durable and frequently sustained. No patient discontinued long-term treatment because of drug-related toxicity. Corneal toxicity in these pts was manageable with dose modification (delay/reduction). The observed long-term clinical benefit and safety profile of tusa support its further clinical development; a Phase 3 study is ongoing to evaluate tusa monotherapy in previously treated pts with high CEACAM5 expressing NSQ NSCLC. Clinical trial information: NCT02187848. Research Sponsor: The study was funded by Sanofi. Editorial support was provided by Zeshan Mahmood, PharmD, and Elizabeth Strickland, PhD of inScience Communications (Philadelphia, PA, USA), funded by Sanofi.

A phase Ib/II study of AK112, a PD-1/VEGF bispecific antibody, as first- or second-line therapy for advanced non–small cell lung cancer (NSCLC). *First Author: Caicun Zhou, Shanghai Pulmonary Hospital, Shanghai, China*

Background: Besides the well-known antiangiogenic effects, anti-VEGF agents also modulate the tumor immune micro-environment, leading to synergic anti-tumor effects. AK112 is a humanized IgG1 bispecific antibody against PD-1 and VEGF. Here, we reported results of an ongoing phase Ib/II trial of AK112 in advanced NSCLC pts. **Methods:** Pts with stage IIIB/IIIC/IV NSCLC, ECOG PS 0-1 and negative oncogenic drivers were enrolled and given AK112 (10 mg/kg Q3W, 20 mg/kg Q2W, 20 mg/kg Q3W or 30 mg/kg Q3W) intravenously. The primary endpoints were ORR per RECIST v1.1 and safety. **Results:** At data cutoff (January 5, 2022), 94 pts were enrolled: median age 66.0 years (range: 48-75), PS 1 90.4%, male 85.1%, non-squamous 48.9%, PD-L1 positive (TPS ≥1%) 70.2% and treatment-naïve 84.0%. Of 83 pts evaluable for efficacy, ORR (unconfirmed, similarly hereinafter) and DCR were 22.2%/88.9%, 44.0%/92.0%, 37.9%/93.1% and 100%/100% at doses of 10 mg/kg Q3W, 20 mg/kg Q2W, 20 mg/kg Q3W and 30 mg/kg Q3W, respectively. When doses of AK112 > 10mg/kg Q3W, ORR and DCR were 42.9% (24/56) and 92.9% (52/56) in 56 evaluable pts, 56.3% (18/32) and 100% (32/32) in pts with TPS≥1% at 1st line setting, and 23.5% (4/17) and 76.5% (13/17) in pts with PD-L1 TPS < 1%, respectively. Grade≥3 treatment-related adverse events (TRAEs) occurred in 10.6% (10/94) pts, in which the most common event (occurring in > 1 pt) was pneumonia (2.1%, 2/94). No TRAEs led to permanent treatment discontinuation. Most frequent TRAEs (incidence ≥10%) were proteinuria (17.0%), hypertension (16.0%), lipase increase (12.8%), alanine aminotransferase increase (12.8%), blood urea increase (10.6%), apolipoprotein E increase (10.6%) and hyperglycaemia (10.6%). No significant difference in the incidences of TRAEs were observed between non-squamous and squamous pts. **Conclusions:** In advanced NSCLC, AK112 was well-tolerated and presented remarkable anti-tumor efficacy. Further phase III studies are planned to validate the findings of this study. Clinical trial information: NCT04900363. Research Sponsor: Akeso Biopharma, Inc.

Clinical efficacy and safety of the BAT1706 (proposed bevacizumab biosimilar) compared with reference bevacizumab in patients with advanced nonsquamous NSCLC: A randomized, double-blind, phase III study. *First Author: Likun Chen, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: A Randomized, Double-blind, Phase III Study was conducted to confirm clinical similarity between BAT1706, a proposed biosimilar to reference bevacizumab, and EU-bevacizumab in patients with advanced non-squamous non-small cell lung cancer (NSCLC). **Methods:** Patients were randomized 1:1 to BAT1706 plus paclitaxel and carboplatin (Arm A) or EU-bevacizumab plus paclitaxel and carboplatin (Arm B) given three weeks for 6 cycles, followed by maintenance therapy with BAT1706 or EU- bevacizumab. The primary endpoint was overall response rate at Week 18 (ORR_{18}). Secondary endpoints included ORR at Week 6 and 12, best ORR, duration of response (DoR), progression-free survival (PFS), and overall survival (OS). **Results:** A total of 651 patients were randomized: BAT1706 (n = 325) or EU- bevacizumab (n = 326). In total, 649 randomized patients (BAT1706 (n = 325) or EU- bevacizumab (n = 324)) received at least one cycle of combination treatment. The median duration of therapy was 29.1 weeks (ranging from 3.0 to 62.1 weeks) in the Arm A and 27.0 weeks (ranging from 3.0 to 53.9 weeks) in the Arm B. The extent of exposure to BAT1706 and EU- bevacizumab was similar between these two arms. Overall, the proportion of patients achieving an ORR by Week 18 was comparable across Arm A and B (48.0% and 44.5%). The ORR risk ratio of 1.08 with 90% CI (0.94, 1.24) and the ORR risk difference of 0.03, with 95% CI (-0.04, 0.11) were within pre-specified equivalence margin. In addition, the multivariate-adjusted risk ratio was 1.07, with a 90% CI (0.93, 1.22). The ORR_{18} risk difference between BAT1706 and EU- bevacizumab was 0.03, with the 2-sided 95% CI (-0.04, 0.11) that fell entirely within pre-specified equivalence margin. In addition, the multivariate-adjusted risk difference was 0.03, with a 95% CI (-0.04, 0.11). The hazard ratio stratified for time to PFS was 0.915 and the PFS rate at 12 months was 20.7% versus 21.8%. At the end of the study, there were no significant differences between both the treatments. The incidence of treatment-emergent adverse events (TEAEs) and study drug-related TEAEs was similar between these two arms. Overall, the safety profiles of BAT1706 were consistent with that of EU- bevacizumab, no new safety signals or noticeable trends were observed. The mean serum concentrations were comparable between BAT1706 and EU- bevacizumab over the entire sampling interval both in pre-dose and post-dose. The incidence of positive anti-drug antibodies results was low (≤5%) and decreased over time in both treatment arms. No patient was detected to have positive neutralizing anti-drug antibody result during the study. **Conclusions:** BAT1706 demonstrated clinical equivalence to reference EU-bevacizumab in terms of efficacy, safety, pharmacokinetics, and immunogenicity. Clinical trial information: NCT03329911. Research Sponsor: Bio-Thera Solution.

Immunogenicity and disease control induced by a multineoantigen vaccine (ADXS-503) in patients with metastatic non–small cell lung cancer who have progressed on pembrolizumab. *First Author: Aaron E. Lisberg, Department of Medicine, Division of Hematology/Oncology, UCLA, Los Angeles, CA*

Background: The administration of a lung cancer-specific immunotherapy with 22 tumor-associated antigens (ADXS-503, A503), has been evaluated as an add-on therapy for patients (pts) with metastatic non-small-cell lung cancer (NSCLC) who have progressed on pembrolizumab (pembro) as last therapy [Haigentz M et al. ASCO 2021]. The present study explores the immunogenicity and potential reversal of immune resistance with A503 when added-on to pembro at the time of progressive disease (PD). **Methods:** A phase 2 study of A503 + pembro is being conducted in pts with metastatic squamous or non-squamous NSCLC. In Part B of the study, A503 was added-on to pembro within 12 weeks after the first scan showing disease progression following pembro therapy (per RECIST criteria v1.1). Both A503 ($1x10^8$ CFU) and pembro (200 mg) were infused by IV every 3 weeks until disease progression or dose-limiting toxicity. Immunogenicity assays included serum cytokine and chemokine levels; flow cytometry; and in-vitro stimulation FluoroSpot assay with 4 different antigen-pools represented in A503 [i.e., hot spot mutations, heteroclitic/wild-type tumor-associated antigens and other antigens not included in the A503 construct (antigen spreading)]. **Results:** A total of 14 pts have been treated in Part B, of which 13 are clinically evaluable and up to 11 have immune assessments. Combination therapy was well tolerated with transient increased secretion of cytokines for several hours after infusion of A503 consistent with the expected immune activation and transient 'flu-like' syndrome. The objective response rate (16%) and disease control rate (46%) were encouraging with 2 partial responses (PR), 4 stable diseases (SD) and 7 pts with PD. Pts with disease control, in particular, generated CD8+ T cells reactive to neoantigens in 1 or more of the 4 antigen pools tested in FluoroSpot. Also, activation of NK cells and of cytotoxic- and memory-CD8+ T cells was mainly observed in pts with PR or SD, but not in those with PD, as shown in the table. **Conclusions:** Adding A503 to pembro after PD appears to induce innate and adaptive immune responses that may restore or enhance sensitivity to checkpoint inhibitors in pts with clinical benefit. Clinical trial information: NCT03847519. Research Sponsor: Advaxis Inc.

Three-year outcomes and correlative analyses in patients with non–small cell lung cancer (NSCLC) and a very high PD-L1 tumor proportion score (TPS) ≥ 90% treated with first-line pembrolizumab. *First Author: Biagio Ricciuti, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Although 1st-line PD-1 monotherapy has improved survival in advanced NSCLC with a PD-L1 TPS ≥50%, responses occur in ~45% of patients (pts). We previously showed that among pts treated with 1st-line pembrolizumab, clinical outcomes were significantly improved in those with a PD-L1 TPS of ≥90% compared to a TPS of 50-89%. Here, we report the 3-year survival analysis to 1st-line pembrolizumab in pts with a PD-L1 TPS ≥90% vs 50-89%, and characterize genomic and immunophenotypic differences between these PD-L1 expression groups. **Methods:** Pts with stage IV *EGFR/ALK* wild-type NSCLC and PD-L1 TPS ≥50% who received 1st-line pembrolizumab at the Dana-Farber Cancer Institute (DFCI) and Memorial Sloan Kettering Cancer Center (MSKCC), with a minimum follow-up of 3 years were included. Comprehensive tumor genomic profiling and multiplexed immunofluorescence (mIF) were performed to examine genomic and immunophenotypic correlates of very high PD-L1 expression on separate cohorts of NSCLC at the DFCI. **Results:** Among 396 pts, median age was 69, 53.3% were women, 90.1% had a history of tobacco use, 83.6% had a ECOG performance status of 0-1, and 28.8% had a *KRAS* mutation. At a median follow-up of 42.6 months, median progression-free (mPFS) and overall survival (mOS) in the entire cohort were 5.1 months, and 19.0 months, respectively. When compared to pts with a PD-L1 TPS of 50-89% (N = 252), those with PD-L1 TPS ≥90% (N = 144) had a significantly longer mPFS (6.0 vs 4.5 months, HR 0.67, p < 0.001), and longer mOS (30.2 vs 16.9 months, HR 0.66, p < 0.01). Kaplan-Meier estimates of the 3-year PFS and OS were 24.9% and 47.0% in the PD-L1 TPS ≥90% groups, and 9.4% and 27.7% in the PD-L1 TPS 50-89% group, respectively. A PD-L1 TPS ≥90% was confirmed to be an independent predictor of improved PFS (HR 0.68, p < 0.01) and OS (HR 0.67, p < 0.01) in multivariable analysis. Tumor genomic profiling from a separate cohort of 500 NSCLC samples revealed that mutations in *STK11*, *KEAP1*, *FBXW7*, and *CTNNB1* were significantly more frequent in tumors with a PD-L1 TPS of 50-89% compared to those with a PD-L1 TPS ≥90% (q < 0.05). mIF on 91 NSCLCs identified significantly higher CD8+PD1+ T cells and PD-L1+ immune cells in tumors with PD-L1 TPS ≥90% vs 50-89% (p < 0.05). **Conclusions:** Pembrolizumab monotherapy continues to demonstrate a meaningful long-term survival benefit in pts with advanced NSCLC and a PD-L1 TPS ≥90%. NSCLCs with very high PD-L1 TPS may have a more favorable genomic and immunophenotypic profile. These findings have implications for treatment selection and clinical trial interpretation and design. Dynamic changes in serum analyte levels associated with clinical outcome in squamous cell lung cancer trial SWOG Lung-MAP S1400I of nivolumab ± ipilimumab. *First Author: Edgar Gonzalez-Kozlova, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: *While* Immune checkpoint blockade (ICB) is standard treatment for lung cancer there are limited biomarkers that predict benefit, pharmacokinetic on-treatment activity or explain progression. S1400I was a randomized Phase III trial of nivolumab(N)+ipilimumab(I) versus N (NCT02154490, PMID 34264316) for ICB naïve, previously treated stage IV or recurrent squamous cell lung cancer. We performed circulating serum protein analysis of serial blood specimens from patients enrolled in S1400I to evaluate if serum proteins levels changed over time, changes differed by treatment arm, and if they were associated with overall survival. **Methods:** 561 serial blood specimens (baseline, weeks (wk) 3, 7, 9, and progression [PD]) from 160 of 252 eligible patients enrolled to S1400I were analyzed for 92 immuno-oncology analytes with the Olink proximity extension assay. Protein levels were normalized with use of internal controls and quantified as log2 protein expression (denoted as NPX). Linear mixed models evaluated change in expression from baseline at each time point (wks 3,7,9 and PD), and NPX differences at baseline, wk3, and PD depending on best objective response. A Cox model was used to evaluate the association between baseline NPX and survival. Overall survival and longitudinal cytokine expression were jointly modeled using a linear mixed model to estimate dynamic biomarker changes in NPX and a Cox model for survival. The joint models for time-varying NPX values included a random intercept and modeled time using a natural spline with three knots. Significance was defined as $P < 0.05$. **Results:** Serum proteins PCDC1, CXCL9, and CXCL10 were increased from baseline at wks 3,7,9 and at PD. CCL19 was increased at wks 3 and 7 but not at wk 9 and PD. IL10 and IFNγ were increased at wk 3 but subsequently returned to baseline. Change in CXCL13 from baseline to PD was larger for N+I versus N. Baseline CCL23, CSF-1, IL6, and MUC-16 were associated with shorter survival (HR > 1). Joint modeling of survival with cytokines showed an increased risk of death (HR > 1) with higher longitudinal serum levels of CXCL13, MMP12, CSF-1, and IL8. Patients achieving objective response had higher IL4 and LAMP3 and lower IL6 and IL8 at baseline and wk 3 compared to non-responders. **Conclusions:** Measurements of blood circulating soluble proteins represent easily accessible biomarkers that may be useful as indicators of outcome, and that will need to be prospectively confirmed. Clinical trial information: NCT02154490. Research Sponsor: U.S. National Institutes of Health.

CtDNA shed as a tool to select immune checkpoint inhibitors (ICPI) with or without chemotherapy for patients (pts) with advanced non–small cell lung cancer (aNSCLC). *First Author: Benjamin Besse, Cancer Medicine Department, Gustave Roussy, Villejuif, France*

Background: ICPI are compelling therapies for pts with aNSCLC given the potential for durable benefit and limited toxicity. Even in tumors with biomarkers associated with ICPI response, early progression (eP) can be seen, leading to chemotherapy combination approaches. We hypothesize that ctDNA tumor fraction (TF) may identify pts at risk of eP on ICPI, helping to select the optimal first-line regimen. **Methods:** This study used the nationwide (US-based) de-identified Flatiron Health-Foundation Medicine NSCLC clinico-genomic database (FH-FMI CGDB). The de-identified data originated from ~280 US cancer clinics (~800 sites of care). Real-world overall survival (rwOS) accounting for delayed entry and real-world progression free survival (rwPFS) were estimated with Kaplan-Meier analysis. Hazard ratios (HR) were calculated using multivariate Cox proportional hazard models adjusting for relevant covariates. TF was calculated using an aneuploidy-based measure plus variant-based estimate and was categorized as follows: ≥10%: elevated, 1-10%: intermediate, < 1%: low. eP was defined as rw progression within 8 weeks of starting therapy. **Results:** 426 pts with documented aNSCLC initiated 1st or 2nd line ICPI (128 ICPI, 298 ICPI+chemo) within 60 days of liquid biopsy. 88 (21%) pts had elevated TF, 193 (45%) had intermediate, and 145 (34%) had low. Pts with elevated TF had higher frequency of liver involvement (elevated: 27%; intermediate: 12%; low: 8%) and had worse performance status (ECOG 2+) near the start of therapy (elevated: 33%; intermediate 22%; low: 17%). PD-L1 was unknown for most pts (elevated: 44%; intermediate: 53%; low: 57%); elevated TF was associated with high PD-L1 positivity (elevated: 22%; intermediate: 17%; low: 12%). In pts with elevated TF, eP was more frequent (elevated: 26%, intermediate: 22%, low: 15%). Amongst all patients treated with either ICPI ± chemo, low TF was associated with better median rwPFS (low 6.7m [ref]; intermediate 5.1m, HR: 1.39 [1.11-1.74]; elevated 3.4m, HR: 1.74 [1.31-2.31]) and median rwOS: (low 14.2m [ref]; intermediate 8.4m, HR: 1.52 [1.10-2.09]; elevated 4.6m, HR: 2.17 [1.47-3.21]). In pts with elevated TF, the addition of chemo to ICPI was associated with favorable rwPFS and rwOS compared to pts who received ICPI alone (Table). **Conclusions:** ctDNA TF identifies pts with aNSCLC with an increased risk of eP on ICPI who may benefit from ICPI+chemo. In pts with low TF, outcomes on ICPI alone are favorable and similar to those receiving ICPI+chemo, suggesting low TF may be a non-invasive tool for identifying pts for single-agent ICPI. Research Sponsor: Foundation Medicine, Inc.

Multiomics profiling and association with molecular and immune features in association with benefits from immunotherapy for patients with previously treated stage IV or recurrent squamous cell lung cancer from the phase III SWOG LungMAP S1400I trial. *First Author: Edwin R. Parra, Department of Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Immune checkpoint blockade (ICB) has become a standard pillar of treatment for lung cancer. However, only ~20% of unselected patients can achieve durable clinical benefits. We performed immunogenomic profiling of tissue specimens from a randomized Phase III trial S1400I on metastatic lung squamous cell carcinoma (SCC) to evaluate if there were factors associated with better prognoses with ICB from single-agent versus combined targeting PD-1/CTLA-4 and evaluate if any differentiated between the treatments. **Methods:** We utilized FFPE tumor tissue submitted for Lung-MAP screening provided by the SWOG bank. SCC samples from 82 eligible patients treated with combined nivolumab+ipilimumab (N+I) or single agent nivolumab (N) were subjected to multiplex immunofluorescence (mIF, n = 82) and NanoString (ncounter Pan-Cancer Immune Profiling Panel, n = 32). Cell density phenotypes (cells/mm2) were defined using image analysis of staining for cytokeratin, CD3, CD8, granzyme B, CD45RO, FOXP3, PD1, PD-L1, and CD68. Immunogenomic features were associated with response, PFS, and OS derived from data provided by the LungMap team to the CIDC portal. For statistical analyses, non-parametric tests were utilized to assess associations of cell phenotypes versus continuous or categorical variables, and log-rank test analysis was performed to identify cell phenotypes or genes correlated with survival. **Results:** In both arms higher densities of total CD3+CD45RO+ T cells (P= 0.041), CD3+PD-1+ T cells (P= 0.024) and CD3+CD8+PD-1 T cells in stroma (P= 0.042) and CD3+CD8+GZMB+ T cells in the tumor compartment (P= 0.011) were positively associated with PFS. In the N+I arm but not in the N arm, higher densities of CD3+CD8+GZMB+ T cells in the tumor compartment were associated with better PFS (P= 0.015) and higher densities of stroma CD3+CD8-FOXP3+ T cells with worse OS. Spatial analysis showed that the presence of CD8+GZMB+ T cells close to malignant cells (median, ≤19.27 μm) was associated with better PFS (P= 0.037) in N+I arm and cluster analysis showed low clustering of cells in TMB-high vs. TMB-low tumors ($P < 0.01$). Gene expression profiling demonstrated that myeloid infiltration, immune recruitment, and inflammation genes were associated with a positive clinical outcome (P< 0.05). In both arms, *BLNK, CD163, FCGR2A* were associated with better OS (P< 0.01), *IRF1* and *BLNK* were associated with increased PFS (P< 0.01). In the N+I arm but not in the N arm, we observed significantly higher CD45 immune cell scores, including CD8 T cells and neutrophils, in responders versus non-responders. **Conclusions:** Our findings suggest a potential advantage in PFS and OS with an increased presence of cytotoxic immune cells and genes associated with the recruitment and proliferation of these cell types before therapy. 9047 **Poster Session**

Identifying prognostic and predictive value of mutations associated with clinical outcomes in first line (1L) patients with advanced or metastatic non–small cell lung cancer (aNSCLC). *First Author: Diego Perez Parente, Lung Cancer Squad, Roche Farma, Madrid, Spain*

Background: Whilst the impact of certain mutations on aNSCLC survival outcomes has been evaluated, real-world (rw) evidence on its predictive and prognostic value remains limited. We aimed to identify the predictive and prognostic value of non-driver mutations that are deemed to be clinically relevant in aNSCLC. **Methods:** This retrospective cohort study analysed de-identified electronic medical records from the Flatiron Clinico-Genomic (FCGD) and FoundationCORE™ databases of aNSCLC patients who have initiated 1L cancer immunotherapy (CIT, alone or in combination) or chemotherapy (chemo) under routine care between 2016 and 2021. Propensity-based multivariable models were used to determine associations between mutational status and progression-free survival (rwPFS), overall survival (rwOS) and overall response (rwR). **Results:** Of 10,795 patients identified, 2,999 met inclusion criteria (1,042 chemo, 1,957 CIT). Among these, 53% were men and 65% were ≥65 years old. Patients mostly had non-squamous histology (68%), a previous history of smoking (95%) and ECOG ≤1 (61%). 58% of patients were diagnosed as *de novo*. A total of 185 different mutations were identified in this population, and variants of the same mutation were grouped, identifying 58 mutation families. *STK11*, *KEAP1* and *CDKN2A/B* mutations were significantly associated with all effectiveness outcomes (Table), indicating lower response (rwR OR<1) and shorter survival (rwOS and rwPFS HR>1) in patients harbouring mutated vs. wild type genes. *APC* and *KRAS* mutations were only significantly associated with lower rwR, while *FGRF* and *HRAS* mutations were related to worse rwPFS and rwOS, respectively. In contrast, a significantly higher likelihood of response or PFS was associated with *ATM/R/RX* and *GATA3* mutations, respectively. Moreover, our results suggest that *KRAS* mutations potentially have predictive value for PFS in CIT-treated patients. Mutations with prognostic value on clinical outcomes (overall population). HR, hazard ratio; PFS, progression-free survival; OR, odds ratio; OS, overall survival; rw, real-world. **Conclusions:** *STK11*, *KEAP1* and *CDKN2A/B* mutations were significantly associated with poor prognosis in all effectiveness outcomes. In addition, *KRAS* mutations resulted in clinically significant differences in terms of PFS. Further analyses should be conducted to confirm this clinical significance and to evaluate the relevance of these mutations in future clinical trials design. Research Sponsor: Roche.

Clinical and genomic characteristics of pts with durable benefit from immune checkpoint inhibitors (ICI) in advanced non-small cell lung cancer (aNSCLC). *First Author: Jacob Sands, Dana-Farber Cancer Institute, Boston, MA*

Background: The 2-year mark has become a new milestone in pts with aNSCLC receiving immunotherapy. In pts who are progression free at that point, a subset experience ongoing disease control even after stopping active treatment. Some pts experience such impressive durability beyond 2 years, raising a question about potential cure. We queried a real-world (RW) clinico-genomic database (CGDB) to better understand these pts with durable benefit and their clinical and genomic features. **Methods:** Using the nationwide (~280 US cancer clinics) de-identified EHR-derived Flatiron Health-Foundation Medicine aNSCLC CGDB linked to genomic data, pts treated with ICI (+/- chemotherapy) from 01/2011-06/2021 were selected. RW progression (rwP) was obtained via technology-enabled abstraction of EHR data. Durable benefit was classified as absence of rwP, death or treatment failure (indicated by switch to a new line of therapy) within 24 mos of beginning ICI therapy. **Results:** In a cohort of 4,030 evaluable aNSCLC pts, 184 (4.6%) were free of rwP or treatment failure at 24 mos. Of these 184 pts with durable benefit, 84% received ICI monotherapy and 16% received ICI with chemotherapy; ICI treatment was more often first line (1L, 43%) or 2L (38%). 59% with durable benefit were still on ICI at the 2-year mark, whereas 41% had stopped a median of 11.4 mos after therapy start. Of 109 pts remaining on ICI for 2-years, median time on ICI was 36.3 mos from therapy start. Overall, pts with durable benefit had a median rwPFS of 37.1 mos and median rwOS of 58.8 mos from start of ICI. Compared to pts with rwP on ICI before 24 mos, those with durable benefit were more likely to have history of smoking (94% vs 86%) and absence of liver, brain or bone metastases (all $p < 0.001$). High tumor mutational burden (TMB ≥10) was more common (62% vs 35%, $p < 0.001$) and *STK11, CDKN2B, PIK3CA,* and *EGFR* alterations were less common in pts with durable-benefit vs those with rwP on ICI before 24 mos. In a multivariate cox model of rwPFS beyond 24 mos in pts with durable benefit, TMB ≥20 was significantly associated with longer rwPFS (HR 0.45 95% CI 0.24-0.83, $p = 0.01$) while TMB ≥10 was marginally significant (HR 0.65 95% CI 0.40-1.03, $p = 0.07$); treatment with ICI with chemotherapy was significantly associated with worse rwPFS (HR 1.84 95% 1.093.12, $p = 0.02$). High PD-L1 > 50% was noted in 728 (19%) of those without durable benefit and 38 (21%) of those with durable benefit, though many in the data set had unknown PD-L1 status. **Conclusions:** Pts with durable benefit > 2 years after starting ICI therapy for aNSCLC represent a unique population of immune survivors with a median OS of almost 5 years; 41% of pts stopped ICI before the 2-year mark. Elevated TMB was associated with durable benefit on ICI as well as prolonged rwPFS after the 2-year mark and deserves further investigation as a biomarker for prolonged benefit to ICI in aNSCLC. Clinical outcome and potential benefits of post-progression immunotherapy for patients with metastatic NSCLC with primary resistance to ipilumumab and nivolumab in the LONESTAR phase III study. *First Author: Mehmet Altan, MD Anderson Cancer Center, Houston, TX*

Background: Primary resistance to immune checkpoint inhibitor (ICI) therapy remains a major challenge in clinical oncology. Here, we describe the clinical outcome of patients who experienced radiologic progression within 12 weeks of therapy with nivolumab and ipilimumab (I+N) for metastatic non-small cell lung cancer (mNSCLC). **Methods:** The LONESTAR study is an ongoing phase III study (NCT03391869). Study enrolls patients with immunotherapy naïve mNSCLC (prior chemotherapy is allowed). All patients receive I+N for 12 weeks and are randomized to experimental therapy vs. control arm if they did not have disease progression. Patients who experience radiologic progression per RECIST v1.1 are not randomized and removed from the study. Treatment beyond progression is allowed if they clinically benefit from the systemic therapy. We prospectively collected clinicopathologic and radiologic outcome data from patients who experienced radiologic progression within 12 weeks of I+N therapy and have not randomized to investigational therapy. We described the primary progression pattern. We collected subsequent treatment, radiologic, and toxicity data and calculated clinical outcomes, including progression-free survival (PFS) and overall survival (OS). **Results:** Of the 194 patients who received at least one dose of I+N therapy, 72 patients had clinical and/or radiologic progression at ≤ 12 weeks. Thirty-five (35; 48%) patients did not receive subsequent treatment, 21 (29%) patients received subsequent 2nd line systemic therapy, and 16 (22%) patients were continued on I+N beyond radiologic progression due to ongoing clinical benefit. Among patients treated with 2nd line therapy, 13 patients were treated with platinum doublet +/- anti-PD-(L)1, seven (7) patients were treated with single-agent chemotherapy +/- VEGF inhibitor, and one (1) patient was treated with targeted therapy. The PFS for the 2nd line therapy was 6.5 months (95%CI: 4.8, 8.9), and OS was 10.4 months (95%CI: 6.6, 16.1). Among the 16 patients treated with I+N beyond progression, 13 had a mixed response to induction therapy, where primary progression was most frequently observed in mediastinal lymph nodes. LCT with radiotherapy was utilized with I+N in 10 patients. The median duration of post-progression treatment with I+N plus LCT was 8.7 months (95%CI: 5.9, 22.3) and 5.6 months (95%CI 4.4, 11.5) with I+N alone. The OS was 19.5 months (95% CI: 6.2,18.7). **Conclusions:** In this study cohort, primary resistance to I+N was observed in 37% of the patients, and in a subset of these patients treated with post-progression I+N, either alone or in combination with LCT, durable clinical benefit was observed. Further studies are warranted to identify which patients are most likely to benefit from post-progression I+N. Clinical trial information: NCT03391869. Research Sponsor: Bristol Myers Squibb.

Association between lung immune prognostic index, microbiome, and immunotherapy outcomes in non–small cell lung cancer. *First Author: Edouard Auclin, CRCHUM, Montreal, QC, Canada*

Background: Host-related inflammatory biomarkers and gut microbiome are two major prognostic factors for non-small cell lung cancer (NSCLC) patients (pts) treated with immune checkpoint inhibitors (ICI). In this study, we aimed to assess an association between the Lung Immune Prognostic Index (LIPI) and the microbiome composition on ICI outcomes in two independent cohorts of NSCLC pts. **Methods:** We included 205 patients with advanced NSCLC treated with ICI (monotherapy or in combination with chemotherapy) from two independent cohorts. Metagenomics microbiome profiling was performed on the Canadian discovery cohort of 72 pts while 16S rRNA microbiome sequencing was used in the Japanese validation cohort of 133 pts. The LIPI score was calculated using the dNLR (neutrophils/[leucocytes-neutrophils]) and lactate deshydrogenase (LDH). Pts were classified as Good (G: 0 high factor), Intermediate (I: 1 high factor) and Poor (P: 2 high factors). Median overall survival (OS) was estimated using the Kaplan-Meier method. Microbiome diversity indexes and bacterial relative abundances were compared according to LIPI groups. **Results:** Among the 72 pts included in the discovery cohort, the median follow-up of 20.6 months (mos). The LIPI was distributed as follows: G (n = 31, 43.1%), I (31, 43.1%), P (10, 13.8%) and baseline characteristics were well balanced between the 3 groups. When segregating pts according to LIPI, the OS was 25.6 mo, 19.8 mo, and 5.7 mo in the G, I (HR: 1.71, 95%CI: 0.80-3.65) and P (HR: 3.97, 95%CI: 1.60-9.82) groups, respectively ($p = 0.003$). The microbiome alpha diversity was lower in the P group compared with the G group ($p = 0.03$), and there was a trend towards different microbiome composition in beta diversity ($p = 0.055$) between both groups. Pts in the G group had a favorable microbiome (enriched in *Ruminococcus* and *Anaerostipes*), while pts from the P group had an unfavorable microbiome (enriched in *Enterobacteriaceae* and *Clostridium symbiosum and lavalense*). Next, in the validation cohort of 133 pts, LIPI was distributed as follows: G (n = 62, 46.6%), I (51, 38.3%), P (20, 15%). Pts with G LIPI had not reached their median OS compared to pts in the I [15.7 mo HR: 1.60 (0.88-2.94)] and P [8.8 mo groups, HR: 2.02 (0.98-4.19)], $p = 0.03$. Similar to the discovery cohort, at the genus level, G LIPI group had enrichment of *Ruminococcus* as well as *Anaerostipes* compared with pts in the P and I groups with an overrepresentation of *Hungatella*. **Conclusions:** Host-related inflammatory biomarkers, represented by the LIPI, seemed to be associated with microbiome and ICI outcomes in pts treated with NSCLC. This observation was validated in an external validation cohort. This link could be in relation to the presence of proinflammatory bacteria in pts with poor LIPI. PEOPLE (NTC03447678), a phase II trial to test pembrolizumab as first-line treatment in patients with advanced NSCLC with PD-L1 < 50%: A multiomics approach. *First Author: Marina Chiara Garassino, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: Chemo-immunotherapy is the standard of care for patients with advanced NSCLC and PD-L1 < 50%. Efficacy has been reported in this setting with single agent pembrolizumab, but no reliable biomarkers yet exist for selecting patients likely to respond to single agent immunotherapy. The aim of this trial was to identify potential new immune biomarkers associated with PFS in NSCLC patients with PD-L1 < 50% treated with first line pembrolizumab. **Methods:** Advanced EGFR and ALK wild type treatment-naïve NSCLC patients with PD-L1 < 50% were enrolled. Gene expression profile was performed using nCounter PanCancer IO 360 Panel (Nanostring) on baseline tissue. Circulating immune profiling was performed by determination of absolute cell counts with multiparametric flow cytometry on freshly isolated whole blood samples at baseline and at first radiological evaluation. Gut bacterial taxonomic abundance was obtained by shotgun metagenomic sequencing of stool sample at baseline. Pembrolizumab was administered at 200 mg flat dose every 3 weeks until 35 cycles, disease progression or unacceptable toxicity. Omics data was analyzed with sequential univariate Cox Proportional Hazards regression predicting PFS, with Benjamini-Hochberg multiple comparisons correction. Biological features significant with univariate analysis were analyzed with multivariate Least Absolute Shrinkage and Selection Operator (LASSO). **Results:** From May 2018 to October 2020 65 patients were enrolled. Main characteristics were: male 67.6%, smokers 87.7%, PD-L1 positive 70.8%. Median follow up and PFS were 26.4 and 2.9 months, respectively. Gene expression profile was performed in 48 patients, microbiome in 54 patients and circulating immune profiling in 56 patients at baseline and in 46 patients at first radiologic evaluation. LASSO multivariate analysis with optimal lambda of 0.28 showed high expression levels of IRF9 and COMP genes was associated with an unfavorable PFS (HR 3.03, 1.52 – 6.02, $p = 0.08$ and HR 1.22, 1.08 – 1.37, corrected $p = 0.06$, respectively). High expression levels of CD244 (HR 0.74, 0.62- 0.67, $p = 0.05$), PTPRC (HR 0.55, 0.38 – 0.81, $p = 0.098$), KLRB1 (HR 0.76, 0.66 – 0.89, $p = 0.05$) in tissue samples and NK cells/CD56dimCD16+ (HR 0.56, 0.41 – 0.76, $p = 0.006$) in peripheral blood at baseline and non classical CD14dim CD16+ monocytes (HR 0.52, 0.36 – 0.75, $p = 0.004$), eosinophils (CD 15+CD16-) (HR 0.62, 0.44 – 0.89, $p = 0.003$) lymphocytes (HR 0.28, 0.15 – 0.5, $p < 0.001$) in peripheral blood after first radiologic evaluation were associated to a favorable PFS. No microbiome features were selected by LASSO. **Conclusions:** To the best of our knowledge, this is the first prospective trial in NSCLC with PD-L1 < 50% performed with a multi-omic approach able to identify immune cell subsets and expression levels of genes associated to PFS under first line treatment with pembrolizumab. Clinical trial information: NTC03447678. Research Sponsor: Merck & Sharp Dohme.

Outcomes of single-agent PD-(L)-1 versus combination with chemotherapy in patients with PD-L1-high (≥ 50%) lung cancer. *First Author: Arielle Elkrief, Human Oncology & Pathogenesis Program, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Single agent PD-(L)-1 blockade (IO) and PD-(L)-1 blockade combined with chemotherapy (ChemoIO) are both standard first-line treatments for patients with PD-L1-high (≥ 50%) metastatic non-small cell lung cancer (NSCLC). These regimens have not been compared prospectively, so comparative effectiveness is unclear. It is also unknown if clinical and molecular tumor characteristics differentially associate with benefit to IO vs ChemoIO in patients with NSCLC with high PD-L1 tumor expression. **Methods:** All patients with metastatic NSCLC treated with IO or ChemoIO at two institutions (Memorial Sloan Kettering Cancer Center and Dana-Farber Cancer Institute) were reviewed. Patients with *EGFR* or *ALK* alterations, PD-L1 expression < 50%, treated with IO or ChemoIO in > 1st line setting were excluded. Overall survival (OS), progression-free survival (PFS), and objective response rate (ORR) were compared between the IO vs ChemoIO groups and association with clinical, pathologic, and molecular features was examined. To account for NGS panel differences, tumor mutational burden (TMB) values were harmonized using a z-score conversion as previously described (Vokes et al, 2019). **Results:** Of 639 patients with stage IV *EGFR*/*ALK* wild-type NSCLC and PD-L1 ≥50% treated in the 1st line setting, 504 received IO and 135 received ChemoIO. Baseline ECOG performance status (p = 0.3), median PD-L1 % (p > 0.9) and TMB (p = 0.2) were similar between the IO and ChemoIO groups. For patients receiving IO vs ChemoIO, there was no significant difference in OS (HR 0.8, 95% CI 0.6 to 1.08; p = 0.2). Median PFS was shorter (HR 0.7, 95% CI 0.6 to 0.9; p = 0.004) and ORR was lower (40% IO vs 55% ChemoIO, p = 0.002) in the IO group. Among patients with durable responses (> 6 months), never smokers were less common in the IO group (6% vs 18%, p < 0.001), but there was no difference in PD-L1 expression, TMB, or mutational (*KRAS*, *STK11*, or *KEAP1*) profile to suggest differential predictors of benefit to IO or ChemoIO. **Conclusions:** In patients with PD-L1 high NSCLC, there was no survival benefit associated with the addition of chemotherapy to IO. There were also no clear differences in PD-L1 expression or molecular features associated with durable response to IO vs ChemoIO. These findings have implications for treatment selection in this population. Impact of performance status on survival outcomes and health care utilization in patients with advanced non–small cell lung cancer treated with immune checkpoint inhibitors. *First Author: Daniel E. Meyers, Department of Medicine, University of Calgary, Calgary, AB, Canada*

Background: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment paradigm of non-small cell lung cancer (NSCLC). Despite the high prevalence of patients with poor Eastern Cooperative Oncology Group (ECOG) performance status (PS ≥2) in real-world practice, landmark studies have typically excluded this patient group from enrolment. The primary objective of this study was to evaluate the impact of ECOG PS on clinical outcomes and health care utilization in a large cohort of NSCLC patients treated with ICI in real-world practice. **Methods:** Using the Alberta Immunotherapy Database, we identified consecutive patients who received at least one dose of Pembrolizumab or Nivolumab for the treatment of advanced NSCLC between 1/1/2010 and 12/30/2019. The data cut-off date was 10/1/2020. Baseline clinical, pathological, and laboratory-based data were collected retrospectively. The primary outcome was median overall survival (mOS), as stratified by ECOG PS. The secondary outcomes were median time-to-treatment failure (mTTF) and metrics of health care utilization, including emergency department (ED) visits, hospitalizations, and death in hospital. Kaplan-Meier survival curves were used to determine survival outcomes, and compared with the log-rank test. The association between ECOG PS and healthcare utilization were represented with risk ratios and evaluated using chi-square tests. **Results:** A total of 790 patients were included. Median follow-up time was 20.6 months. 29.2% (n = 231) had PS ≥2 at the time of ICI initiation. As compared with the favorable PS group (PS < 2), patients with PS ≥2 had significantly lower mOS - 3.3 months (95% CI 2.5-4.0) versus 13.4 months (95% CI 11.7-16.0) (HR, 3.0; 95% CI 2.5-3.6, p < 0.0001), and mTTF – 1.4 months (95% CI 0.9-1.8) versus 4.9 months (95% CI 4.4-5.6) (HR, 2.2; 95% CI 1.9-2.6, p < 0.0001). 3- and 12-month survival rates were also significantly lower in the PS ≥2 group as compared with the PS < 2 group (52.8% versus 86.4% and 13.4% versus 41.0%, p < 0.0001 for both comparisons). Patients with PS ≥2 were also significantly more likely to present to the ED (RR 1.6; 95% CI, 1.3-2.0, p < 0.001) and be admitted to hospital (RR 2.3; 95% CI 1.7-3.0, p < 0.0001) within the first month after treatment initiation. These patients were also significantly more likely to die in hospital during their first admission (RR 2.7; 95% CI 1.8-4.1, p < 0.0001), as well as at any point during treatment (RR 2.2; 95% CI 1.60-3.0, p < 0.0001). **Conclusions:** NSCLC patients with poor ECOG PS at the time of ICI initiation had significantly worse survival outcomes and were significantly more likely to utilize health care services than those with favorable ECOG PS. The large proportion of patients with poor ECOG PS further justifies the urgent need for randomized trials evaluating the efficacy of ICI in this high-risk population. Research Sponsor: None.

9054 **Poster Session**

Immunophenotypic correlates and response to first-line pembrolizumab among elderly patients with PD-L1-high (≥ 50%) non–small cell lung cancer. *First Author: Adriana Paula de Castro Barrichello, Lowe Center For Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Older age is associated with increased levels of systemic inflammation and altered immunosurveillance in cancer. Whether aging correlates with a distinct immunophenotype or impacts clinical outcomes to first-line pembrolizumab in patients with advanced non-small-cell lung cancer (NSCLC) and a PD-L1 tumor proportion score (TPS) of ≥50% is unclear. **Methods:** We performed a retrospective analysis of patients with NSCLC. Multiplexed immunofluorescence (mIF) for CD8+, PD-1+, PD-1+CD8+ and FOXP3+ was performed to explore tumor immunophenotype. Clinical outcomes were analyzed on a separate cohort of patients with PD-L1-high (TPS of ≥50%) NSCLC (negative for sensitizing genomic alterations in *EGFR* and *ALK*) who received treatment with first-line pembrolizumab. Variables demonstrating a univariate signal of association of p < 0.1 were included in the multivariate model. The results were compared in patients < 80 vs ≥80 years old. **Results:** Among 541 patients with NSCLCs profiled by mIF, the median age was 67 (28-90). When comparing patients < 80y (n = 497) to ≥80y (n = 44), there was no difference in median CD8+ T cells/mm2 (171 vs 148; p = 0.69), PD-1+ immune cells/mm2 (81.1 vs 87.2; p = 0.95), or PD-1+CD8+ T cells/mm2 (18.0 vs 13.1; p = 0.56). NSCLCs from patients ≥80y had a higher median of intratumoral-associated FOXP3+ T cells/mm2 (63.6 vs 91.1; p = 0.03). In a cohort of 271 patients with PD-L1 ≥50% who received first-line pembrolizumab, baseline clinicopathological characteristics were balanced in the < 80y (n = 225) vs ≥80y (n = 46) groups in terms of sex, tobacco use, Eastern Cooperative Oncology Group-Performance Status (ECOG-PS), histology, presence of potentially targetable driver mutations (KRAS, MET, BRAF, HER2, RET), and PD-L1 TPS distribution (50-89% vs ≥90%). Compared to patients < 80y, patients ≥80y had no difference in objective response rate (ORR 39.1% vs 28.2%; p = 0.22) or median progression-free survival (mPFS 6.0 vs 3.0 months; p = 0.16). However, patients ≥80y had a shorter median overall survival (mOS 25.7 vs 7.6 months; p = 0.02), and this result remained significant after adjusting for ECOG-PS. Among those who experienced disease progression on pembrolizumab, patients ≥80y were significantly less likely to receive any second-line systemic therapy compared to patients < 80y (55.6% vs 30.8%; p = 0.008). **Conclusions:** In patients with NSCLC and PD-L1 ≥50%, the ORR and mPFS to first-line pembrolizumab were similar between patients < vs ≥80 years old. OS was shorter among patients ≥80y, potentially reflecting lower use of second-line therapy in elderly patients after progression on pembrolizumab. The immunophenotypic correlates of NSCLC in older patients need further investigation. Research Sponsor: None.

Real-world effectiveness of immune checkpoint inhibitors alone or in combination with chemotherapy in metastatic non–small cell lung cancer. *First Author: Lingzhi Hong, Department of Thoracic and Head and Neck Medical Oncology, Department of Imaging Physics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The benefit of combination immune checkpoint inhibitor (ICI) with chemotherapy over ICI monotherapy in non-small cell lung cancer (NSCLC) remains underexplored. **Methods:** This retrospective cohort included patients with metastatic NSCLC from a single-institution database treated with ICI monotherapy or with chemotherapy between 1/2014-2/2020. Clinical progression-free survival (PFS) and overall survival (OS) were the primary outcomes. Propensity score adjustment for clinical and sociodemographic characteristics was used for analysis of first-line treatment outcomes. **Results:** A total of 1,139 patients (54% male; median age, 64.9) were included. Adenocarcinoma histology, smoking history, higher PD-L1 expression, and lower metastatic stage associated with improved PFS. However, PD-L1 expression and smoking associated with PFS only in adenocarcinoma (LUAD); squamous (LUSC) patients had shorter PFS independent of PD-L1 and smoking history (PD-L1 > 50% vs 1-49%: LUAD $P < 0.001$; LUSC $P = 0.69$; Former vs never smoker: LUAD $P = 0.008$; LUSC $P = 0.89$). In first-line patients (n = 680), treatment with ICI plus chemotherapy (ICI-chemo) associated with higher progression-free rates at 3 and 6 months compared with ICI-monotherapy (ICI-chemo vs ICI-mono: 3-month PFS, 85.2% vs 68.8%, $P = 0.001$; 6-month PFS, 66.4% vs 52.6%, $P = 0.008$). However, there was no difference overall in PFS or OS in either the full or propensity-matched cohort. Treatment with ICI and chemotherapy concurrently vs sequentially was associated with similar PFS (log-rank $P = 0.12$). **Conclusions:** In this real-world cohort, the addition of chemotherapy to ICIs may protect against early progression but does not influence long-term outcomes. Treatment with sequential vs concurrent ICI and chemotherapy produced similar outcomes. These findings suggest that combination therapy may maximally benefit patients at risk of early progression. Differential prognostic effect of systemic inflammation in patients with NSCLC treated with immunotherapy or chemotherapy: A post hoc analysis of the phase III OAK trial. *First Author: Alessio Cortellini, Department of Surgery and Cancer, Imperial College London, London, United Kingdom*

Background: A pro-inflammatory diathesis as measured by the neutrophil-to-lymphocyte ratio (NLR) heralds an adverse disease course in non-small cell lung cancer (NSCLC). Whether the NLR identifies patients who derive a differential degree of benefit from immunotherapy versus chemotherapy is not known. **Methods:** This post hoc analysis used data from the phase III OAK trial, which randomized previously treated patients with NSCLC to receive atezolizumab or docetaxel. The main objective was to assess the differential impact of pre-treatment NLR on overall survival (OS) depending on the treatment modality. In addition, we assessed patients genomic characteristics according to inflammatory status using circulating free (cf)DNA NGS analysis. **Results:** A total of 600 and 575 patients with an available NLR were included in the atezolizumab and docetaxel cohort, with a median NLR of 4 (IQR: 2.6-6.7) for the pooled population. NLR $\geq$ 4 was associated with positive smoking status (88.6% vs 78.1%, $p < 0.01$), male sex (66.4% vs 57.6%, $p = 0.01$), worse performance status (71.3% vs 55.2%, $p < 0.01$), higher number of metastatic sites (63.2% vs 51.6%, $p = 0.01$), squamous histology (32.1% vs 21.4%, $p < 0.01$), and tissue KRAS mutation (30% vs 18.7%, $p = 0.02$), but not with PD-L1 expression, nor with tissue EGFR/ALK status. Pre-treatment NLR of $\geq$ 4 was more strongly associated with mortality following atezolizumab with an adjusted hazard ratio (HR) of 1.64 (95%CI:1.35-2.01) compared to docetaxel (HR 1.32, 95%CI: 1.08-1.60, multivariable (MVA) interaction $p = 0.08$. Exclusion of EGFR/ALK positive patients further increased the prognostic ability of baseline NLR in favor of atezolizumab (HR 1.67, 95%CI: 1.35-2.06), as compared with the docetaxel arm (HR 1.24, 95%CI: 1.02-1.52, MVA interaction $p = 0.02$). The HR for the risk of death for patients with NLR$\geq$ 4/PD-L1 negative tumours (compared to NLR < 4/PD-L1 positive) was significantly higher in the atezolizumab cohort (HR 2.28, 95%CI: 1.72-3.03) than in the docetaxel cohort (HR 1.42, 95%CI: 1.08-1.86, MVA interaction $p = 0.01$). NGS pretreatment cfDNA data showed that patients with a high blood tumor mutational burden (cut-off 16 Mut/Mb) had a higher median NLR (4.6 vs 3.7, $p = 0.01$). After adjusting for multiple comparisons, none among the selected variants of interest (EGFR, KRAS, TP53, KEAP1, STK11, SMARCA4, ARID1A and targeted DDR genes), were significantly associated with the NLR. **Conclusions:** In this post-hoc analysis, a baseline low NLR identifies patients with NSCLC who derive a greater survival benefit from atezolizumab as compared to those identified in the docetaxel cohort, irrespective of genomic features. Patients with a low NLR and PD-L1 positive tumors derive the greatest benefit with immunotherapy and the NLR could complement PD-L1 expression in tailoring treatment in this setting. Clinical trial information: NCT02008227. Research Sponsor: None.

Immunotherapy and chemo-immunotherapy for non–small cell lung cancer with novel actionable oncogenic driver alterations. *First Author: Laura Mazzeo, Medical Oncology Department, Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy*

Background: Immune checkpoint inhibitors (IO) single agent or in combination with platinum chemotherapy (CT-IO) are standard of care for Stage IV non-small cell lung cancer (NSCLC) according to PD-L1 expression. While the efficacy of IO among patients (pts) with common EGFR and ALK alterations appears to be limited, its activity in pts with novel oncogenic drivers alterations is not well characterized. Compared to non-oncogene-addicted NSCLC, the overall response rate (ORR) seems to be similar in BRAF and c-MET altered NSCLC, lower in RET altered NSCLC, while data are less consistent in HER2 and EGFR exon 20 (EGFRex20) altered NSCLCs. **Methods:** From January 2016 to January 2022, we retrospectively enrolled pts with Stage IV NSCLC that received IO or combination CT– IO in any line, ECOG PS 0 - 2 and detection of MET exon 14 skipping mutations (METex14), BRAF mutations (V600E or non-V600E), RET rearrangement, HER2 point mutations (HER2mut)/exon 20 insertions (HER2ex20) or uncommon EGFR mutations (uEGFRmut)/EGFRex20. A review of clinicopathologic and molecular features and an analysis of response to combination or single-agent IO were conducted. **Results:** Among sixty-four pts enrolled, 20 (31%) had METex14, 19 (30%) had EGFR alterations [12 (19%) EGFRex20, 7 (11%) uEGFRmut], 8 (12%) had BRAF mutation (3 V600E and 5 non-V600E), 13(20%) had HER2 alterations [7 (11%) HER2ex20, 6 (10%) HER2mut] and 4 (6%) were RET rearranged. 43 received IO single agent and 21 received CT-IO. With a median follow up of 22 months (m), median progression free survival (mPFS) was 5.40 m (0.95 CI 4.73-6.9) overall, 6.77m in CT-IO arm (0.95 CI 5.37-NA) and 5.10m in IO arm (0.95 CI 2.60-6.7), with a trend to better mPFS for CT-IO (p 0.054). Regarding specific mutations irrespectively from treatment arm, NSCLC harboring METex14 showed a mPFS of 5.33 m (0.95 CI, 2.30-13.9), BRAF 9.9 m (0.95 CI, 6.70-NA), EGFR 4.93 m (0.95 CI, 1.80-6.9), HER2 11.4 (0.95 CI, 4.2-NA), RET 5.28 (0.95 CI, 1.42-NA). Disease control rate (DCR) was better in the CT-IO arm vs IO one in the overall population (84.2% vs 50%, p 0.013). **Conclusions:** Novel driver alterations seem to show a benefit from IO treatments. CT-IO seems to have a better outcome in terms of DCR. Therefore, IO-based treatment should be evaluated also in tumors harboring novel driver alterations. Research Sponsor: None.

Driver alteration	n(%)	Gender n M/F	Treatment type IO n(%) - CT-IO n(%)	DCR n(%)	PFS m(95%CI)

Nivolumab timing as a major survival predictor in patients with stage IV non–small cell lung cancer. *First Author: Abdoulaye Karaboué, Medical Oncology Unit, GHT Grand Paris Est, Montfermeil Hospital, Montfermeil, France*

Background: Functional activity and trafficking of T(CD8) and other immune cells are regulated over the 24 hours by the circadian timing system. Nivolumab (NIV) binds to PD-1 receptors and targets T(CD8). These pharmacologic effects could be regulated by circadian clocks, hence suggesting possible daily changes in its efficacy, as substantiated for immune checkpoint inhibitors (ICIs) in two prior reports. **Methods:** Here we searched whether increasing the proportion of morning NIV infusions could critically improve efficacy in consecutive metastatic Non-Small Cell Lung Cancer (NSCLC) patients (pts). Pts received NIV (240 mg iv q 2 weeks) at a daily time that was 'randomly' allocated for each course by the day-hospital coordinators. The median time of actual NIV infusions was computed for each pt. The study population was split into three timing-groups: a 'morning' one, where the pts received at least 2/3 of NIV infusions before 12:54, i.e. the median time of all NIV infusions; an intermediate group, where the pts received at least 1/3 of NIV infusions before and 1/3 after 12:54; and an 'evening' group, where pts received at least 2/3 of NIV infusions after 12:54. CTCAE-toxicity rates, iRECIST-tumor responses, progression-free survival (PFS), and overall survival (OS) were computed according to NIV timing group. **Results:** 95 previously-treated stage IV NSCLC pts (M/F,79/16; PS 0-1, 96%; 41-83 years old) were retrospectively allocated to a 'morning' group (36 pts), an 'intermediate' group (24 pts), and an 'evening' group (35 pts). Pts received NIV as 2nd line (76%). Tumor PD-L1 status was positive for 39 of 72 pts (54%). Main metastatic sites were bone (52% of the pts), pleura (41%), liver (25%), brain (24%), and adrenal gland (20%). Pt characteristics were similar in the 3 groups, except for liver metastases (41.7%, 8.3% and 25.7% for 'morning', 'intermediate' and 'evening' groups respectively, $p = 0.010$). Grade 2-4 fatigue was least in the 'morning' group (28%) vs 62% ('intermediate') and 40% ('evening') ($p = 0.027$). Median PFS (months) was 11.1 for the 'morning' group, 5.9 for the 'intermediate' group, and 3.1 for the 'evening' group ($p = 0.002$). Median OS (months) [95% C.L.] was 34.2 [-] for the 'morning' group, 15.3 [8.0 – 22.7] for the 'intermediate' group, and 12.4 [4.0 – 20.7] for the 'evening' group ($p = 0.023$). Respective 2-years survival rates were was 52.6%, 26.2% for the and 15.0% ($p = 0.002$). Multivariable analysis confirmed that the administration of >2/3 NIV in the morning predicted for longer PFS (Hazard ratio, 0.26 [0.14-0.51], $p < 0.001$) and OS (0.22 [0.10-0.51], $p < 0.001$). **Conclusions:** NIV was largely more effective in the 'morning' as compared to the 'intermediate' or 'evening' groups, with no apparent bias. Randomized and translational circadian timing studies are needed to unravel the mechanisms at work in the chronopharmacology of ICI's, so as to minimize the risk of resistance and to maximize therapeutic benefits. Impact of *STK11* copy loss on clinical outcomes to PD-(L)1 blockade in non–small cell lung cancer. *First Author: Catherine Gutierrez, Harvard Medical School, Brookline, FL*

Background: *STK11* is among the most commonly altered genes in non-squamous lung cancers. While *STK11* mutation is associated with diminished efficacy of immune checkpoint inhibition (ICI), particularly in *KRAS* mutated tumors, it is not known whether *STK11* copy deletion influences outcomes to ICI. **Methods:** Patients with advanced non-squamous non-small cell lung cancer (NSCLC) treated with ICI whose tumors underwent genomic profiling were included. Clinical outcomes to ICI were analyzed according to *KRAS* mutation and *STK11* deletions. *STK11* copy number variations (CNVs) were determined using an internal informatic pipeline. Kaplan-Meier methodology was used to estimate event-time distributions. **Results:** Of 559 patients with non-squamous NSCLCs (Nsq-NSCLC), 40.4% (N = 226) had a *KRAS* mutation (*KRAS*^{mut}), 18.4% (N = 103) had an oncogenic *STK11* mutation (*STK11*^{mut}), and 22.5% had either single (N = 123), or bi-allelic (N = 3) deletion (*STK11*^{del}). Given that 32.5% of *STK11*^{del} cases had a concurrent oncogenic *STK11* mutation in our cohort, to isolate the impact of *STK11*^{del} on ICI outcomes we excluded samples with *STK11*^{mut} from this analysis. In all comers with NSCLC, *STK11*^{del} had no impact on objective response rate (22.2% versus 23.8%, P = 0.8), progression-free (PFS, HR 0.90, P = 0.30), and overall survival (OS, HR 0.96, P = 0.79) to ICI. When we examined the impact of *STK11*^{del} on clinical outcomes to PD-(L)1 blockade among *KRAS*^{mut} cases we found that *STK11*^{del} was associated with a numerically lower ORR (13.3% versus 30.0%, P = 0.12), and a significantly shorter PFS (HR 0.57, P = 0.018) compared to cases without *STK11*^{del}. No difference in OS were observed between these groups (HR 0.77, P = 0.39). Among *KRAS*^{wt} NSCLCs, *STK11*^{del} cases had a similar ORR (22.6% versus 22.9%, P = 0.99), PFS (HR 0.92, P = 0.63), and OS (HR 1.18, P = 0.32) to PD-(L)1 inhibition compared to cases without *STK11*^{del}. Among *KRAS*^{mut} but not *KRAS*^{wt} NSCLCs, cases with *STK11*^{del} had significantly lower PD-L1 expression compared to those without *STK11* deletions (27.5% versus 70%, P = 0.01). **Conclusions:** *STK11* deletion is associated with low response rate and short progression-free survival among *KRAS* mutant NSCLCs. Future analyses will incorporate additional cases to increase sample size and immunopathologic findings to assess impact of mono and bi-allelic deletion on protein expression. A phase II study of talazoparib plus avelumab in patients with stage IV or recurrent nonsquamous non–small cell lung cancer bearing pathogenic *STK11* genomic alterations (SWOG S1900C, LUNG-MAP sub-study, NCT04173507). *First Author: Ferdinandos Skoulidis, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Inactivating *STK11* genomic alterations are prevalent in non-squamous (nsq) NSCLC and define a patient (pt) subgroup with poor prognosis and inferior response to immune checkpoint inhibitors (CPIs). PARP inhibitors (PARPi) can potentiate response to CPIs in preclinical models. We conducted a single arm Phase II study within Lung-MAP to evaluate the efficacy and safety of talazoparib in combination with avelumab in patients (pts) with previously treated nsq NSCLC harboring pathogenic *STK11* genomic alterations. **Methods:** Eligibility: *STK11* pathogenic somatic mutation or bi-allelic loss on tumor identified via LUNGMAP screening; stage IV or recurrent nsq NSCLC, receipt of one prior line of anti-PD-1/anti-PD-L1 therapy and platinum-based chemotherapy for stage IV or recurrent disease (sequentially or in combination) and disease progression > 42 days following treatment initiation, a ECOG PS of 0-1, adequate organ function and no previous PARPi exposure. Pts received talazoparib (1000 mg PO daily) plus avelumab (800 mg IV Q2W). Co-primary objectives were to evaluate the best objective response rate (ORR) and disease control rate at 12 weeks (DCR12) after study registration, assessed by RECISTv1.1. Rejection of an ORR of 10% required ≥ 8 responses or rejection of a DCR12 of 30% required ≥18 w/ disease control at 12 weeks and ≥4 responses. **Results:** 47 pts enrolled from January 16 - November 16, 2020; 42 pts met eligibility (50% male, 50% female). 54% of pts had PD-L1 TPS < 1%. The median TMB was 8.83 Mut/Mb and 45% of pts had *KRAS* mutations. 52% of the pts had received ≥2 prior lines of treatment for stage IV disease. As of the November 24, 2021 data cutoff, 3 pts remain on treatment, the ORR was 2% (n = 1) and the DCR12 was 40% (n = 17). 26 pts (62%) had SD as best objective response. One responding pt remained on treatment for > 14 mo. The median progression-free survival (39 events) was 2.7 mo (95% CI, 1.6-3.9 mo) and the median overall survival (30 events) was 7.6 mo (95% CI, 6.3-12.2 mo). There were no reported grade 5 treatment toxicities and most grade 3-4 toxicities were hematologic. Additional biomarker analysis to assess effects of key co-mutations on clinical outcomes will be presented. **Conclusions:** Treatment with talazoparib and avelumab did not meet the pre-specified threshold for efficacy in previously treated *STK11*-mutant NSCLC in this biomarker-driven Phase II study, though durable disease stabilization was observed. Further studies are required to determine optimal therapeutic approaches for this challenging subset of NSCLC pts. Funding: NIH/NCI grants U10CA180888, U10CA180819. Talazoparib was provided by Pfizer. Avelumab was provided by Pfizer, as part of an alliance between Pfizer and the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100004755). Clinical trial information: NCT04173507. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Deep learning signature from chest CT and association with immunotherapy outcomes in EGFR/ALK-negative NSCLC. *First Author: Maliazurina B Saad, Department of Imaging Physics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Many clinicopathological and molecular features are associate with clinical benefit from immune checkpoint inhibitors (ICIs) for patients with non-small-cell lung cancer (NSCLC), yet none was exclusive underscoring the heterogeneity of lung cancers. As images may provide a holistic view of cancer, we attempted deep learning to chest CT scans to derive a predictor of response to ICIs and test its benefit relative to known clinicopathological factors. **Methods:** 928 stage IV, EGFR/ALK-negative NSCLC patients treated with ICIs alone or in combination (MD Anderson GEMINI Database) were divided into training (CT^{tr} = 572), validation (CT^{va} = 78), and testing (CT^{te} = 278) cohorts, balancing the distribution of clinicopathological and radiological factors. Progression-free (PFS) and overall survival (OS) were defined as outcomes. We analyzed whole lung, including tumor and normal parenchyma of chest CT images ≤ 3 months prior to ICI treatment. An ensemble learning model (CT-deep-learning) to clustering patients into high vs low risk groups of PFS or OS was developed by fusing risk scores from four independent deep learning networks (supervised, unsupervised, and hybrid). This CT-deep-learning model was further evaluated in different clinicopathological subgroups. Finally, a composite model (CT-Clinic-path) was built by combining image model with clinicopathological factors. Antolini's concordance index (C-index) was used to assess model performance. **Results:** Median PFS and OS were shorter in the high-risk vs low-risk group as defined by CT-deep-learning: PFS (CT^{tr}: 4.2 vs 9.6 mons; HR 1.96; 95% CI 1.62-2.38; P < 0.0001; CT^{va}: 3.7 vs 10.2 mons; HR 2.32; 95% CI 1.32-4.07; P = 0.0025; CT^{te}: 3.6 vs 9.1 mons; HR 1.89; 95% CI 1.39-2.56; P < 0.0001) and OS (CT^{tr}: 16.0 vs 31.4 mons; HR 2.19; 95% CI 1.72-2.79; P < 0.0001; CT^{va}: 12.7 vs 28.6 mons; HR 2.01; 95% CI 1.04-3.88; P = 0.035; CT^{te}: 14.8 vs 32.0 mons; HR 1.84; 95% CI 1.31-2.60; P = 0.0004). CT-deep-learning outperformed clinicopathologic features known to associate with ICI benefit, such as histology, smoking status, PD-L1 expression, and remained to be an independent (P < 0.001) prognostic factor on multivariate analysis. Furthermore, integrating CT-deep-learning to clinicopathological variables improved prediction performance with a net reclassification up to 7% (Clinic-path model, C-indices 0.60 – 0.62 vs CT-clinic-path model, 0.64 - 0.65 for PFS; Clinic-path model 0.64 – 0.67 vs CT-clinic-path model 0.69 – 0.71 for OS). **Conclusions:** We have developed and validated a deep learning signature associated with PFS and OS in ICI-treated NSCLC patients, which appears to be independent of and superior to known clinicopathological biomarkers. If validated, this signature may strengthen the predictive value of clinicopathological factors and facilitate selecting appropriate patients for ICI-based therapies. 18F-FDG PET–derived parameter total lesion glycolisis (TLG) as a tool to stratify patients (pts) with advanced non–small cell lung cancer (aNSCLC) treated with immunotherapy. *First Author: Filippo Gustavo Dall'Olio, Cancer Medicine Department, Institut Gustave Roussy, Villejuif, France, Villejuif, France*

Background: Upfront Immune Checkpoint Blockers (ICB) alone or in combination with chemotherapy (CT) have become the backbone treatment of non-oncogene addicted aNSCLC. PD-L1 remains the only predictive biomarker, but additional biomarkers are mandatory to better discriminate the population more suitable for the combination approach (CT-ICB). We hypothesized that TLG, a parameter that measure tumor burden and metabolic activity, may help to select the optimal first-line regimen. **Methods:** We performed a multicentric (n = 5) retrospective study including pts treated either with ICB alone, CT-ICB or CT alone. Overall survival (OS) and progression-free survival (PFS) were estimated with Kaplan-Meier analysis. Hazard ratios (HR) were calculated using multivariate Cox proportional Hazard models adjusting for relevant covariates (neutrophil/lymphocyte ratio, ECOG PS, liver, bone metastases). TLG was calculated on PET scans as the product of metabolic tumor volume (with a threshold of 42% of SUV max) and SUV mean. **Results:** 250 pts with aNSCLC initiated first-line treatment (94 ICB, 102 CT-ICB and an hystorical control group of 54 CT) within 42 days from PET. Median follow up was 22 months for ICB, 16 for CT-ICB and 47 for CT. 170 pts were male (68%), 210 had non-squamous histology (84%), 110 (44%)and 38 (15%) had bone and liver metastasis, respectively. On the 194 pts with PD-L1 status available: 20%, 29% and 50% had PD-L1 < 1%, 1-49% and > 50%, respectively. No correlation was seen between PD-L1 and TLG. Presence of liver metastases (13% vs 2%) and ECOG PS > 1 (16% vs 3%) were associated with elevated TLG. PFS correlated with TLG, with longer median PFS in the lower quartile (TLG < 380) either with ICB (12.4 vs 4.7 months, HR 1.9, 95% CI1.1 – 3.35, p 0.025) and CT-ICB (17.9 vs 7.3, HR 1.9, 95% CI1.1 – 3.7, p 0.032) but not with CT (4.2 vs 3.5, p 0.986), whereas OS was correlated with TLG < 380 in all 3 groups. The risk of progression under ICB was lower in tumors with TLG < 380 (15% vs.29%, p = 0.02), but no difference was seen in other 2 groups. In PD-L1 ≥50% pts with elevated TLG, treatment with CT-ICB (n = 20) increased the PFS respect with ICB (n = 55) (10.7 vs 3.9, HR 0.54, 95% CI 0.29 – 0.99, p = 0.048).The analysis was underpowered to find a difference in OS (HR 0.49, 95% CI 0.21 - 1.12, p = 0.092). **Conclusions:** TLG retains a prognostic validity in aNSCLC identifying pts with an increased rate of early progression on ICB, who may benefit from CT-ICB. Further analyses are required to compare CT-ICB and ICB in PD-L1 ≥50% according to TLG. Enrollement from other centers is ongoing, an update will be presented. Research Sponsor: None.

Association of early tumor growth rate and survival outcomes in first-line metastatic non–small cell lung cancer (mNSCLC). *First Author: Antonio Tito Fojo, Columbia University College of Physicians and Surgeons, New York, NY*

Background: Tumor growth rates (*g*) estimated using imaging measurements, have been associated with overall survival (OS) and progression-free survival (PFS) in patients with mNSCLC, including those treated with first-line immunotherapy (1L IO) or chemotherapy (chemo). Here, we evaluated whether early *g* estimates within 18 weeks of first treatment dose are associated with survival outcomes for 1L treatment in mNSCLC. **Methods:** This was a retrospective analysis of data from patients randomized to either nivolumab+ipilimumab (NIVO+IPI) or chemo in CheckMate 227 Part 1 (NCT02477826), or NIVO+IPI+chemo or chemo alone in CheckMate 9LA (NCT03215706). Tumor assessments were performed by blinded independent central review using RECIST v 1.1 at baseline, every 6 weeks for the first 48 weeks and then every 12 weeks until disease progression. The analysis included patients with at least 3 measurable timepoints, including baseline, week 6, week 12, and/or week 18. If a patient did not have a week 18 measurement, the first three measurements alone were used. To derive the median early *g*, sum of longest diameters (SLD), based on baseline, weeks 6, 12 and/or 18 assessments, and time relative to baseline were fitted to the model defined by sum of exponential growth (g) and decay (d): SLD (t) = exp (–d x t) + exp (g x t) – 1. OS and PFS were estimated using Kaplan-Meier methodology. **Results:** In the two studies, 865/1166 (75%) of randomized patients in CheckMate 227 Part 1 and 562/719 (78%) in CheckMate 9LA had evaluable tumor growth rate data (Table). The median early *g* at weeks 12 and 18 was numerically lower for the IO-containing arm vs chemo arm in both studies (Table). Patients with lower growth rate at week 12 or week 18 (*g* in first quartile [Q1]) had better OS relative to those with higher rate (*g* in fourth quartile [Q4]) across all treatment arms (Table). A similar trend was observed for PFS. **Conclusions:** Early *g* estimates based on 2 or 3 post-baseline tumor assessment timepoints were associated with longer-term survival outcomes for 1L treatment of mNSCLC and could discern efficacy outcomes. These findings provide the foundation for further research, which may incorporate volumetric segmentations of measurable lesions and radiomic feature changes to further explore indicators of patient outcomes that could inform future clinical trials and clinical practice. Research Sponsor: Bristol Myers Squibb.

Multimodal integration of radiology, pathology, and genomics for prediction of response to PD-1 blockade in patients with non–small cell lung cancer. *First Author: Jia Luo, Dana-Farber Cancer Institute, Boston, MA*

Background: Immunotherapy is now given to almost all patients with advanced non-small cell lung cancer (NSCLC). However, developing robust biomarkers to predict benefit remains challenging. We set out to evaluate the predictive capacity of integrating medical imaging, histopathologic, and genomic features to develop a multimodal biomarker for immunotherapy response. **Methods:** We used baseline data that is routinely obtained during diagnostic clinical workup at a single center in patients with NSCLC and known outcomes following immunotherapy. The multimodal dataset included DNA alterations from NGS, CT scan images, and digitized PD-L1 immunohistochemistry (IHC) slides. Guided by experts in each field, we developed a workflow to extract data for each patient and used an attention-gated machine learning approach to integrate the features into a risk prediction model. **Results:** Our cohort included 247 patients with advanced NSCLC who received immunotherapy and had complete radiology, pathology, genomic, and clinical data. The patient cohort was 54% female, had a median age of 68 years (range 38-93), and 88% patients had a smoking history. Responders (CR/PR) vs non-responders (SD/PD) showed a median PFS and OS of 2.7 months (95% CI 2.5-3.0) and 11.4 months (95% CI 10.3-12.8), respectively. Of all patients, 187 (76%) had segmentable disease on chest CT scans. We used a radiomics approach and aggregated the average individual lesion predictions to construct patient-level response predictions which resulted in an overall AUC = 0.65, 95% CI 0.57-0.73. We next studied digitized FFPE slides of pre-treatment PD-L1 IHC staining of tumor specimens. Overall, 52% of slides showed PD-L1 tumor proportion score (TPS) ≥ 1% and were used to extract IHC-texture, a novel spatial characterization of PD-L1 staining. Logistic regression modeling on IHC-texture resulted in prediction accuracy of AUC = 0.62 (95% CI 0.51-0.73) which was inferior to the pathologist-assessed PD-L1 TPS (AUC = 0.73, 95% CI 0.65-0.81). We next implemented a dynamic deep attention-based multiple instance learning model with masking to evaluate the impact of combining features from all modalities. Our multimodal model (AUC = 0.80, 95% CI 0.74-0.86) outperformed unimodal measures, including tumor mutational burden (AUC = 0.61, 95% CI 0.52-0.70) and PD-L1 TPS (AUC = 0.73, 95% CI 0.65-0.81). **Conclusions:** Our study is a proof of concept for using multimodal features to improve prediction of immunotherapy response over standard-of-care approaches in patients with NSCLC using expert-guided machine learning. Artificial intelligence in digital pathology approach identifies the predictive impact of tertiary lymphoid structures with immune-checkpoints therapy in NSCLC. *First Author: Mehrdad Rakaee, UiT The Arctic University of Norway, Tromsø, Norway*

Background: The presence of Tertiary Lymphoid Structures (TLS) in multiple cancer types has been recognized as a potential predictive biomarker for response to immune-checkpoint blockade. However, there is no standardized method to quantify their presence. In this context, Artificial Intelligence (AI)-based assessment of histology images may well contribute to improve reproducibility, accuracy and speed of TLS quantification. **Methods:** We developed an automated workflow for quantification of TLS on digitized H&E slides through A) pixel-level classification of tissue using supervised artificial neural networks model, B) object-level cell classification of candidate TLS regions, C) merging the two approaches for curation and validation of TLS *versus* non-TLS regions. 433 advanced stage non-small cell lung cancer (NSCLC) patients treated with first or subsequent line of anti-PD-(L)1 single agent at DFCI were included in this study. **Results:** TLS were detected in 37% (n = 161) of the patients H&E slides, with the highest score of 4.7 TLS per mm2 (interquartile range: Q1 = 0, Q2 = 0, Q3 = 0.03 TLS/mm2). TLS density (per mm2) was significantly higher in surgically resected (n = 246; TLS^{POS}= 49%) compared to bioptic samples (n = 187; TLS^{POS}= 21%). No association was observed between TLS and tumor mutational burden (TMB) or PD-L1 protein expression as continuous variables. Among clinically actionable mutations, EGFR (all subtypes) mutated patients (n = 38) had a significantly lower number of TLS compared to patients without EGFR mutations. Patients with ≥ 0.01 TLS/mm2 had a significantly higher objective response rate (32% *vs* 22%, p = 0.03), a significantly longer median progression-free survival (PFS, 4.8 *vs* 2.7 months, HR: 0.73, 95% CI: 0.59-0.90, p = 0.004), and a significantly improved median overall survival (OS, 16.5 *vs* 12.5 months, HR: 0.72, 95% CI: 0.57-0.92, p = 0.008). In multivariable analysis, after adjusting for PD-L1 (≥ *vs* < 50%), TMB (≥ *vs* < 10 mu/Mb), sex, age, ECOG score, smoking and line of treatment, TLS/mm2 (≥ *vs* < 0.01) levels were found to be an independent positive predictive factor for both PFS (HR:0.69, 95% CI: 0.54-0.88, p = 0.003) and OS (HR: 0.70, 95% CI: 0.52-0.93, p = 0.01). **Conclusions:** These findings suggest that TLS status is an independent predictor of immunotherapy effectiveness in NSCLC, with predictive value similar to that of PD-L1 expression and TMB. This novel AI system has potential for automated identification and quantification of the TLS on digital histopathological slides, and could be utilized in a standard pathology workflow with relative ease. These findings are currently being validated in other solid tumors and cohorts. Research Sponsor: None.

Digital quantification of lymphocytic infiltration on routine H&E images and immunotherapy response in non–small cell lung cancer. *First Author: Mehrdad Rakaee, Brigham and Women's Hospital, Harvard Medical School, Boston, MA*

Background: Current biomarker(s) for immuno-oncology (IO) therapy response prediction in lung cancer are limited. Additional predictive biomarkers are useful to help refine patient selection and guide precision therapy. **Methods:** Biopsy and surgical specimens stained with hematoxylin-eosin (H&E) were subjected to whole-slide scanning for 446 advanced stage non-small cell lung cancer (NSCLC) treated with single agent immune check point inhibitors (ICI). A machine learning model was trained on H&E images for classification of tumor infiltrating lymphocytes (TILs), tumor cells, and stromal cells in specific tissue types. **Results:** TIL levels were found to be highly variable, with a range of 12 to 4270 cells/mm2, and median of 319 (Q1 = 159, Q3 = 681). TIL levels were assessed on tissue samples from multiple organs which had shown primary or metastatic NSCLC, and were similar across all specimen sites except the liver, for which median TIL levels were significantly lower, at 90 cells/mm2. There was no correlation between tumor mutational burden (TMB) and TIL levels, while high TIL levels were correlated with high PD-L1 (≥ 50%) expression. Patients who experienced a partial/complete response to ICI therapy had a trend to higher median TILs compared to those who had progressive/stable disease (350 versus 310 cells/mm2, P = 0.09). In a multivariable analysis after controlling for covariates (incl. sex, age, cigarette smoking, ECOG, PD-L1, TMB & treatment line), a higher TIL level (≥ 250 cells/mm2) was an independent predictor of IO response for both progression-free survival (PFS; HR_{adj} 0.70; 95% CI, 0.55 - 0.89; P = 0.003) and overall survival (HR_{adj} 0.73; 95% CI, 0.56 - 0.95; P = 0.02). In a ROC analysis considering single biomarkers, PD-L1 had the highest AUC (0.68, P < 0.001), while TIL (AUC = 0.53, P = 0.08) and TMB (AUC = 0.55, P = 0.05) had similar AUC values for classifying responders from non-responders based on objective response rate. Using weighted linear regression approach to combine the biomarkers, paired PD-L1/TMB had the greatest AUC (0.70, P < 0.001) compared to PD-L1 single assay. In the PD-L1 negative (< 1%, N = 50) subgroup, TIL levels had superior predictive performance for classification of IO responders (AUC = 0.77, P = 0.02) compared to TMB (AUC = 0.57, P = 0.3), such that patients with a high TIL level (≥ 250 cells/mm2) had an improved PFS (median PFS: 2.7 vs 2.2 months; HR = 0.48; 95% CI, 0.26 - 0.87; P = 0.02). **Conclusions:** Digital TIL quantification with use of machine learning is feasible. TIL levels appear to be a robust and independent biomarker of likelihood of response to IO treatment in NSCLC, especially in the PD-L1 negative subgroup. The findings of this study are under validation in additional lung cancer cohorts. Research Sponsor: None.

Effect of bone metastasis on outcomes in the CCTG BR.34 phase II randomized trial of dual immune checkpoint inhibitor (ICI) treatment with or without chemotherapy in high-risk, stage IVA/B NSCLC. *First Author: Kim Leitzel, Penn State Hershey Medical Center, Hershey, PA*

Background: Bone metastasis (BM) occurs in about 40% of patients with metastatic lung cancer. Recently, BM was associated with decreased OS to nivolumab in previously-treated NSCLC (Landi L et al, P1.01.53, 19th WCLC, 2018). CCTG BR.34 (NCT03057106) was an open-label, randomized phase II clinical trial that randomized 301 patients with treatment-naïve, high-risk, stage IVA/B NSCLC without sensitizing EGFR or ALK alterations (1:1) to durvalumab plus tremelimumab with or without platinum doublet chemotherapy. First, 109 patients accrued with stage IVB, or selected IVA disease. Then 192 patients accrued with any stage IVA/B disease. In CCTG BR.34, median OS was not significantly different: 16.6 mo in the chemotherapy plus immunotherapy (C+IO) arm, vs 14.1 mo in the IO alone arm (HR 0.88, p = 0.46) (Leighl NB et al, J Thor Oncol, 2021). However, in BR.34 PFS was significantly longer in the C+IO arm (7.7 mo) compared to the IO alone arm (3.2 mo) (HR 0.67, 95% CI, 0.52 0.88). Here we analyzed the effect of BM on outcomes in BR.34. **Methods:** The 301 patients in the trial were characterized by the presence of BM at study entry (129-yes, 172-no). BM effect was evaluated on trial outcomes (OS, PFS, and ORR) using Cox/logistic regression analysis. Multivariable analysis was performed adjusting for the clinical and molecular covariates available. **Results:** In univariate analysis of the entire study population, median OS was significantly shorter for patients with BM vs those without BM (10. 9 vs 18.7 mos, HR 1.68, p = 0.001), as was median PFS (3.4 vs 7.2 mos, HR 1.82, p < 0.0001), and lower ORR (29.5% vs 45.9%, OR 0.52, p = 0.003), respectively. There was no evidence of differential association of BM with treatment arms for OS (p = 0.23), PFS (p = 0.84), and ORR (p = 0.25, Breslow-Day test). In multivariate analysis (MVA), BM remained significantly associated with worse OS (HR 1.44, p = 0.026), PFS (HR 1.69, p < 0.0001), and ORR (OR 0.52, p = 0.01). In MVA for OS: TMB, histology type, race, and ECOG were also significant; but age, smoking history, and PD-L1 IHC status were not significant. **Conclusions:** In CCTG BR.34 the presence of BM at trial entry was associated with significantly shorter OS, PFS, and lower ORR. BM is therefore a significant adverse prognostic factor in high-risk, stage IVA/B NSCLC treated with durvalumab and tremilimumab (with or without platinum doublet chemotherapy). If confirmed in a larger phase III trial, BM should be considered as an important new stratification factor in all clinical trials of immune checkpoint inhibitor (ICI) therapy. We and others have reported that molecules arising in the bone microenvironment (e.g: IL-8, PTHrP, TGF-b, sclerostin, and activin A) cause immunosuppression in cancer, and future trials should evaluate the addition of targeted therapies against these factors in combination with the ICIs in patients with BM. Research Sponsor: None.

Progression-free survival with subsequent anticancer therapies from a phase 3 trial of lorlatinib in treatment-naive patients (pts) with *ALK*+ advanced non–small cell lung cancer (NSCLC). *First Author: Benjamin J. Solomon, Department of Medical Oncology and Research Division, Peter MacCallum Cancer Centre & Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, VIC, Australia*

Background: Lorlatinib, a brain-penetrant, third generation ALK tyrosine kinase inhibitor (TKI), demonstrated statistically significant and clinically meaningful improvement in progression-free survival (PFS) vs crizotinib in a phase 3 study in pts with previously untreated *ALK*+ advanced NSCLC (CROWN; NCT03052608). This study investigated the efficacy of treatments following progression on lorlatinib or crizotinib from the CROWN trial. **Methods:** Pts were randomized 1:1 to receive oral lorlatinib 100 mg daily or crizotinib 250 mg twice daily. The primary endpoint was PFS assessed per blinded independent central review, and secondary endpoints included time from randomization to the date of progression of disease on first subsequent systemic anticancer therapy or death (PFS2). **Results:** As of September 20, 2021, 91 of 149 patients (61.1%) vs 12 of 147 patients (8.2%) were still receiving lorlatinib vs crizotinib, respectively. In the lorlatinib arm, 33 of 149 patients (22.1%) received ≥1 subsequent systemic anticancer therapy vs 103 of 147 patients (70.1%) in the crizotinib arm. Among the patients who received subsequent systemic anticancer therapy, most patients in both treatment arms received ALK TKIs as first subsequent treatment: 63.6% and 93.2% in the lorlatinib and crizotinib arms. Chemotherapy was administered as first subsequent therapy to 36.3% and 2.9% of the patients, respectively. Median duration of treatment on first subsequent anticancer therapy was 9.6 months (IQR, 2.9-18.1 months) for lorlatinib arm and 13.3 months (IQR, 4.8-21.2 months) for crizotinib arm. Median PFS2 was not reached (NR; 95% CI, NR-NR) in the lorlatinib arm and was 39.6 months (95% CI, 27.4-NR) in the crizotinib arm, with a hazard ratio for lorlatinib vs crizotinib of 0.45 (95% CI, 0.30-0.67). **Conclusions:** While subsequent anticancer therapies offered clinical benefit in both treatment arms, PFS2 results indicated that clinical benefit was prolonged with lorlatinib vs crizotinib. Clinical trial information: NCT03052608. Research Sponsor: Pfizer Inc.

9070 **Poster Session**

Phase 3 trial of lorlatinib in treatment-naive patients (Pts) with *ALK*-positive advanced non–small cell lung cancer (NSCLC): Comprehensive plasma and tumor genomic analyses. *First Author: Alessandra Bearz, CRO Centro di Riferimento Oncologico di Aviano, Aviano, Italy*

Background: Lorlatinib, a third-generation ALK tyrosine kinase inhibitor, has shown overall and intracranial activity in *ALK*+ advanced NSCLC. In the randomized, multicenter, phase 3 study in pts with previously untreated *ALK*+ advanced NSCLC (CROWN; NCT03052608), lorlatinib showed a statistically significant and clinically meaningful improvement in progression-free survival (PFS) vs crizotinib (Shaw AT, et al. *N Engl J Med.* 2020;383:2018-2029). Comprehensive molecular profiling of circulating tumor DNA (ctDNA) and tumor tissue was performed to identify molecular correlates of response. **Methods:** At baseline (BL), plasma samples were available from 134 and 129 pts in the lorlatinib and crizotinib arms, respectively. Analyses returned results for tumor tissue (archived or new biopsy) from 147 pts across both arms. Plasma and tumor DNA were analyzed by next-generation sequencing (NGS; Guardant360 and TissueNext, respectively, Guardant Health, Inc.). Objective response rate (ORR), duration of response, and PFS based on the September 20, 2021, cutoff, all assessed by blinded independent central review, were summarized according to mutation and tumor mutation burden (TMB) status. **Results:** At BL, 22% of pts had no detectable ctDNA. *ALK* missense mutations (n=19) or deletion (n=1) were detected in plasma of 12 pts (n=5 and 7 in the lorlatinib and crizotinib arms, respectively). Most pts harbored 1 mutation, but 3 pts harbored ≥3 mutations. In tumor samples, no somatic *ALK* mutation was detected. *ALK* fusions were detected in plasma of 48% of pts and in tumor of 80%. *EML4-ALK* variant (v) subtypes were highly concordant between ctDNA and tumor tissue. Based on ctDNA, ORRs were generally higher in the lorlatinib vs crizotinib arm, reaching 80% and 72% for *EML4-ALK* v1 and v3, respectively, in the lorlatinib arm, and 50% and 74% in the crizotinib arm. Median PFS was not reached for v1 in the lorlatinib arm and was 7.4 mo in the crizotinib arm; for v3, mPFS was 33.3 and 5.5 mo, respectively. *TP53* mutations were found in 42% of pts with detectable ctDNA, and their presence did not seem to influence lorlatinib activity. In the crizotinib arm, absence of *TP53* mutations led to longer PFS. These findings are being verified in tumor tissue. A pt treated with lorlatinib with an ongoing partial response in tumor lesions at the data cutoff date was found to have a *KRAS* G12V mutation and the presence of *ALK* fusion in tumor tissue but had no ctDNA detected at BL. **Conclusions:** Pts with untreated *ALK*+ advanced NSCLC had higher ORRs and potentially longer PFS across predefined biomarker subgroups when treated with lorlatinib compared with crizotinib in the phase 3 CROWN study. Based on pretreatment ctDNA and tumor tissue analyses, lorlatinib led to strong clinical benefit regardless of the type of *ALK* rearrangement or presence of potential driver co-mutation. Clinical trial information: NCT03052608. Research Sponsor: Pfizer.

9071 **Poster Session**

First-in-human phase I results of APG-2449, a novel FAK and third-generation ALK/ ROS1 tyrosine kinase inhibitor (TKI), in patients (pts) with second-generation TKI-resistant ALK/ROS1$^+$ non–small cell lung cancer (NSCLC) or mesothelioma. *First Author: Hongyun Zhao, State Key Laboratory of Oncology in South China Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Investigational agent APG-2449 is a novel, orally active FAK inhibitor and a third-generation ALK/ROS1 TKI that has shown potent activity against a range of ALK-resistant mutations, including *G1202R, L1196M*, *V1180L*, *E1210K*, *S1206F*, *G1269A*, *F1174L*, *I1171S,* and *C1156Y* in preclinical NSCLC, mesothelioma, and other solid tumor models. **Methods:** This dose escalation and dose expansion study evaluated APG-2449 in patients with second-generation TKI-resistant ALK/ROS1$^+$ NSCLC or mesothelioma. APG-2449 was administered orally once daily at the assigned doses on a 28-day cycle using a "3+3" dose escalation design under fasted/fed conditions. Study aims were to assess safety/tolerability, recommended phase 2 dose (RP2D), pharmacokinetics (PK), pharmacodynamics (PD), and efficacy. **Results:** As of the data cutoff date of December 30, 2021, 84 pts (median age 52 [range 21-78] years; 42% female) with NSCLC or mesothelioma enrolled were treated with APG-2449 at doses ranging from 150 to 1,500 mg. PK analyses indicated an approximately dose-proportional increase in plasma exposure under fed conditions across dose levels tested. Cerebrospinal fluid PK analyses showed that APG-2449 was brain-penetrant. Low-fat meals increased APG-2449 C_{max} and AUC by approximately 40% to 80% compared to fasting conditions. Based on PK, biomarker, efficacy, and safety results, the RP2D was determined to be 1,200 mg. Four partial responses (PRs) were observed in 14 ALK$^+$ pts resistant to second-generation TKIs treated at the RP2D. Another pt with the *G1202R* mutation following alectinib treatment had tumor shrinkage of 27.9%. Among 8 pts with brain metastases, 1 complete response and 3 PRs were observed intracranially. In 10 TKI-naïve pts, the overall response rate was 80% (ALK$^+$, 6/8; ROS1$^+$, 2/2) and the disease control rate (DCR) was 100%. Preliminary biomarker data showed decreased FAK phosphorylation in peripheral blood mononuclear cells and increased IFN-γ levels in serum after multiple doses of APG-2449. No dose-limiting toxicity was observed. A total of 66 (78.6%) pts experienced treatment-related adverse events (TRAEs). The most frequent TRAEs included elevated blood creatinine (33.3%), ALT (25.0%), and AST (19.0%) levels and gastrointestinal disorders: nausea (22.6%), vomiting (17.9%), and diarrhea (13.1%). Only 6 (7.1%) TRAEs were grade ≥ 3. **Conclusions:** APG-2449 has a favorable safety and PK profile and was well tolerated in 84 subjects. Preliminary efficacy was observed in pts whose disease was resistant to second-generation TKIs, especially among those with brain metastases, and in TKI-naïve pts. Biomarker data indicated potential target engagement on FAK and immunomodulatory effects of APG-2449. Clinical trial information: NCT03917043. Research Sponsor: Ascentage Pharma Group Corp Ltd (Hong Kong).

9072 **Poster Session**

Association of depth of target lesion response to brigatinib with outcomes in patients with ALK inhibitor-naive *ALK*+ NSCLC in ALTA-1L. *First Author: D. Ross Camidge, University of Colorado Cancer Center, Aurora, CO*

Background: In patients (pts) with crizotinib (CRZ)-refractory advanced *ALK+* NSCLC in the phase 2 ALTA trial (NCT02094573), the depth of target lesion response to brigatinib (BRG) correlated with PFS and OS. Here, we examine the association of maximum decrease in target lesions with PFS and OS in ALTA-1L (NCT02737501), a randomized phase 3 trial of BRG vs CRZ in pts with ALK inhibitor-naive advanced *ALK+* NSCLC. **Methods:** Pts were randomized 1:1 to receive BRG 180 mg qd (7-day lead-in at 90 mg; n=137) or CRZ 250 mg bid (n=138). Pts with target lesion assessment by blinded independent review committee (BIRC) were grouped based on greatest decrease from baseline per RECIST v1.1: none–50%, 51%–75%, and 76%–100% shrinkage. Outcomes in the ≤50% target lesion shrinkage group served as the comparator for outcomes in the 51%–75% and 76%–100% groups. **Results:** At study end (last pt contact: Jan 29, 2021), 124/137 pts in the BRG arm and 125/138 pts in the CRZ arm had ≥1 evaluable target lesion assessment; female (BRG/CRZ), 51%/59%; median age, 57.5/60.0 years. Median follow-up was 40.8/15.7 months. In BRG/CRZ arms, 76%-100% shrinkage was observed in 56%/34% of pts, 51%-75% shrinkage in 27%/30%, and ≤50% shrinkage in 16%/35%, respectively. BRG was associated with significantly more pts with target lesion shrinkage >75% vs CRZ (P=0.0005), and a Cochran-Armitage trend analysis demonstrated significantly deeper response across all shrinkage groups for BRG compared with CRZ (P<0.0001). A majority of pts in the BRG arm experienced 76%–100% target lesion shrinkage in all subgroups analyzed. Pts treated with BRG or CRZ with target lesion shrinkage >50% had lower risk of a PFS event (BRG HR [95% CI]: 51%–75% shrinkage, 0.58 [0.29–1.18]; 76%–100%, 0.23 [0.12–0.46]; CRZ: 51%–75% shrinkage, 0.68 [0.41–1.12]; 76%–100%, 0.26 [0.15–0.45]) or an OS event (BRG: 51%–75% shrinkage, 0.39 [0.17–0.89]; 76%–100%, 0.15 [0.07–0.35]; CRZ: 51%–75% shrinkage, 0.43 [0.21–0.85]; 76%–100%, 0.23 [0.10–0.50]) than pts with ≤50% shrinkage. Longer median time to PFS and OS and higher 4-year estimated OS rates were associated with depth of response in both arms (Table). **Conclusions:** In this exploratory post hoc analysis, BRG demonstrated significantly deeper target lesion response vs CRZ. Pts with >75% shrinkage had significantly reduced risk of a PFS or OS event vs pts with ≤50% target lesion shrinkage. Clinical trial information: NCT02737501. Research Sponsor: ARIAD Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited.

A phase II trial of ALK/ROS1 tyrosine kinase inhibitor WX-0593 (iruplinalkib) in *ALK*-positive and crizotinib-resistant advanced non–small cell lung cancer. *First Author: Yuankai Shi, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China*

Background: This single-arm, multicenter phase II trial aimed to evaluate the efficacy and safety of second generation ALK/ROS1 TKI WX-0593 (iruplinalkib) in advanced *ALK*/*ROS1*-positive non-small cell lung cancer (NSCLC). We reported the results from the crizotinib-resistant *ALK*-positive cohort. **Methods:** Patients aged ≥18 years, with histologically or cytologically confirmed *ALK*-positive NSCLC, progression on ≥12-week crizotinib treatment, ≥one measurable lesion according to RECIST v1.1, and ECOG PS of 0 to 2 were eligible. Patients received oral WX-0593 180 mg once daily (with a 7-day lead-in period at 60 mg once daily). The primary endpoint was confirmed overall response rate (ORR) by independent review committee (IRC) per RECIST v1.1. Secondary endpoints included confirmed disease control rate (DCR) by IRC, ORR, DCR, duration of response (DoR), progression-free survival (PFS), time to progression (TTP), intracranial ORR (iORR) per RANO-brain metastases criteria by investigator (INV), overall survival (OS), safety, and $C_{max,ss}$. **Results:** Between August 7, 2019 and October 30, 2020, totally 146 patients were enrolled. The data cutoff date was March 10, 2021. The median follow-up was 9.3 months (IQR 6.3-14.1). 90 (61.6%) patients had brain metastases, of which 41 (46%) had measurable intracranial lesions and 20 (22%) received prior radiotherapy to brain. 56 (38.4%) patients received prior chemotherapy. The IRC-assessed ORR was 67.8% (95% CI 59.6%-75.3%). Efficacy data were detailed in the Table. Additionally, subgroup analyses indicated IRC-assessed ORR were slightly higher in the patients without brain metastases (79% vs 61%) or prior radiotherapy to brain (66% vs 45%). Patients with prior chemotherapy or not had similar results (71% vs 66%). The iORR was 63% (95% CI 47%-78%) in pts with measurable intracranial lesions. OS data were immature. 134 (91.8%) of 146 experienced treatment-related adverse events (TRAEs). The most common TRAEs were AST increased (60 [41.1%]), ALT increased (52 [35.6%]), and blood creatine phosphokinase increased (49 [33.6%]). Dose reduction and discontinuation due to TRAE, and serious TRAEs occurred in 15 (10.3%), three (2.1%), and six (4.1%), respectively. No treatment-related death was reported. Drug concentration reaches steady state at Day 21 ($C_{max,ss}$ =255.4 ng/mL). **Conclusions:** WX-0593 showed promising activity against *ALK*-positive NSCLC after crizotinib resistance and favorable safety profile, demonstrating WX-0593 could be a new treatment option for this patient population. Clinical trial information: NCT04641754. Research Sponsor: Qilu Pharmaceutical Co., Ltd.

Endpoints	Results (n =146)
IRC ORR, % (95% CI)	67.8% (59.6%-75.3%)
IRC DCR, % (95% CI)	96.6% (92.2%-98.9%)
INV ORR, % (95% CI)	61.6% (53.2%-69.6%)
INV DCR, % (95% CI)	94.5% (89.5%-97.6%)
Median INV DoR, mo (95% CI)	13.1 (8.3-NE)
Median INV PFS/TTP, mo (95% CI)	14.4 (9.7-NE)
18-month OS rate, % (95% CI)	81.9% (69.8%-89.4%)

A phase II study of alectinib in combination with bevacizumab as first-line treatment in advanced NSCLC with confirmed ALK fusion: ALEK-B trial. *First Author: Oscar Gerardo Arrieta, Instituto Nacional De Cancerologia, Mexico DF, Mexico*

Background: Alectinib is one of the standard treatment options as an upfront therapy in advanced ALK-rearranged non-small-cell lung cancer. However, all patients will eventually progress to target therapy, developing resistance mechanisms. Preclinical data have demonstrated an enhanced activity combining an anti-vascular endothelial growth factor blockade to ALK tyrosine inhibitors. Hence, this study assesses the safety and efficacy of adding bevacizumab to alectinib. **Methods:** ALEK-B is an open-label phase II trial investigating the efficacy and safety of combined alectinib 600mg daily and bevacizumab 15mg/kg every three weeks in untreated patients with advanced ALK fusion-positive NSCLC. Every patient had confirmed molecular diagnosis by next-generation sequencing (Foundation One CDx) at baseline and progression. The primary endpoint was investigator progression-free survival (PFS). Secondary endpoints were investigator-assessed objective response rate (ORR), intracranial response (ICR), time to central nervous system (CNS) progression, and overall survival. Hence, we present the first interim analysis. **Results:** Between April 2020 and October 2021, 37 patients were recruited. At the data cut-off of January 31st, 2022, the median follow-up was 15.6 months (IQR 12.5), and an event of disease progression or death occurred in 1 of 36 patients (2.7%). The 12-month event-free survival rate was 97.1% (95% CI 91 to 99), and median PFS was not reached (95% IC 8.9 to NR). Of 36 evaluable patients, 35 had an objective response [ORR 97.2% (95% CI 91 to 99)], and 3 (8.3%) experienced a complete response. Five patients had brain metastases at baseline; among those with measurable disease (n = 4), the ICR was 100%, one complete response, and median duration of response of 11.4 months (IQR 13.1). The 12-month CNS event-free rate was 100%. Any grade adverse events occurred in 86.4% of patients; most common were AST/ALT increase (40.5%), diarrhea (32.4%), blood bilirubin increase (21.6%), anemia (18.9%), and peripheral edema (18.9%). Grade 1-2 hypertension and proteinuria occurred in five (13.5%) patients, and no > G3 occurred. Grade ≥3 treatment-related AEs (TRAEs) occurred in 32.4%; most frequent were AST/ALT increase (27%) and creatinine increase (5.4%). **Conclusions:** The combination of Alectinib and bevacizumab demonstrated to be a safe and highly effective treatment in terms of response in the first-line setting. Moreover, it seems promising for patients with brain metastases. These results warrant the design of larger confirmatory trials, ideally a randomized phase III study. Clinical trial information: NCT03779191. Research Sponsor: Roche.

Brigatinib in Japanese patients (pts) with *ALK*+ NSCLC: Final results from the phase 2 J-ALTA trial. *First Author: Pingkuan Zhang, Takeda Development Center Americas, Inc., Lexington, MA*

Background: In previous J-ALTA (NCT03410108) analyses, brigatinib demonstrated substantial efficacy and manageable safety in pts with TKI-refractory and TKI-naive *ALK*+ NSCLC. We report the final J-ALTA results. **Methods:** J-ALTA was a single arm, multicenter, open-label study that included ALK TKI-naive and -refractory NSCLC expansion parts. The main cohort within the refractory part was a group with alectinib-refractory NSCLC. Primary endpoints: IRC-assessed confirmed ORR in the alectinib-refractory cohort; IRC-assessed 12-month PFS in the TKI-naive cohort. Secondary endpoints included confirmed ORR (IRC-assessed in the total refractory cohort; investigator-assessed in all cohorts); DoR, PFS, DCR, and iPFS by IRC; and safety. Final analyses were performed following last pt last contact. **Results:** A total of 104 pts were enrolled; 72 had TKI-refractory (56% female; median age, 53.0 y) and 32 had TKI-naive (53% female; median age, 60.5 y) NSCLC. As of 28 July, 2021 (last pt last contact), median follow-up was 24.2 mo in the refractory cohort (alectinib-refractory subgroup [n = 47], 23.0 mo) and 22.1 mo in the TKI-naive cohort. Confirmed ORR was 34% (95% CI: 21–49) by IRC with 16 partial responses (PR) in the alectinib-refractory cohort and 32% (21–44; 22 PR) in the total refractory cohort. In the TKI-naive cohort, IRC-assessed 24-mo PFS was 73% (90% CI: 55–85); median PFS was not mature. Additional efficacy analyses are reported in Table. TEAEs were reported in all 104 pts (most common: increased CPK, 79%; hypertension, 48%; diarrhea, 47%). Grade ≥3 TEAEs were reported in 68% and 91% of pts in the TKI-refractory and -naive cohorts, respectively; most commonly (TKI-refractory/naive) elevated CPK, 24%/50%; elevated lipase, 15%/19%; hypertension, 11%/34%. Pneumonitis was mandated to be reported as an SAE regardless of severity and was the only SAE reported in > 5% of pts (refractory, n = 5 [7%; early onset, 1]; naive, n = 4 [13%; early onset, 0]). TEAEs led to dose interruption/reduction/discontinuation in 63%/31%/7% of pts in the TKI-refractory cohort and 94%/69%/0% in the TKI-naive cohort. **Conclusions:** Final efficacy and safety results in pts with TKI-refractory and -naive NSCLC were consistent with previous J-ALTA analyses. No new safety signals were observed in either cohort. Brigatinib demonstrated a favorable benefit-risk profile and is an important option for Japanese pts with *ALK*+ NSCLC regardless of TKI treatment history. Clinical trial information: NCT03410108. Research Sponsor: This study was funded by Takeda Pharmaceutical Company Limited.

SAF-189s in advanced, ALK-positive, non–small cell lung cancer: Results from a first-in-human phase 1/2, multicenter study. *First Author: Jin-Ji Yang, Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital and Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: SAF-189s is a potent, brain-penetrant, next-generation anaplastic lymphoma kinase (ALK) inhibitor with preclinical activity against most known resistance mutations of ALK. We investigated safety, population pharmacokinetics, efficacy, and antitumor activity of SAF-189s in advanced, ALK-positive (ALK+) non-small cell lung cancer (NSCLC). **Methods:** In this first-in-human phase 1/2 trial (NCT04237805), patients aged ≥18 years with histologically or cytologically confirmed, advanced, ALK+ NSCLC (with or without brain metastases) and an Eastern Cooperative Oncology Group performance status of 0–2 were recruited from 41 hospitals in China. Oral SAF-189s was given in escalating doses of 20–210 mg once daily in continuous, 21-day cycles until disease progression, unacceptable toxicity, consent withdrawal, or death. Phase 1 data were presented at ASCO 2020. Here, we report updated phase 1 results and preliminary phase 2 data. **Results:** At a clinical cutoff date of January 18, 2022, 45 patients with prior systemic therapy enrolled in phase 1 and 150 were enrolled in phase 2. SAF-189s was well tolerated, the most common grade 3–4 treatment-related adverse events were hyperglycemia (7%), hypertension (6%) and diarrhea (3%). No treatment-related death was reported. 160 mg was chosen as the recommended phase 2 dose. In phase 1, 11 (24%) patients were ALK inhibitor (ALKi)-naive and 34 (76%) were ALKi-pretreated. Median progression-free survival (PFS) was 33.1 and 22.1 months (95% CI 6.9–not reached: 13.8–26.6) in ALKi-naive and ALKi-pretreated patients, respectively. Disease control rates (DCRs) were 100% in both ALKi-naive and ALKi-pretreated patients. Most patients in phase 2 were ALKi-naive (n=104, 69%), 26 (17%) received prior crizotinib only and 20 (12%) were pretreated with ≥1 non-crizotinib ALKi. The median duration of follow-up was 11.7 months (range 10.3–16.8), ORRs were comparable between the full analysis set and the 71 patients with brain metastases at 78.7% (95% CI 71.2–84.9) and 74.6% (95% CI 62.9–84.2) respectively. ALKi-naive patients had ORR of 92.3% (95% CI 85.4–96.6), compared to 65.4% (95% CI 44.3–82.8) in the crizotinib-pretreated group. DCR was 98.1% in ALKi-naive and 88.5% in crizotinib-pretreated patients. PFS data are not mature. **Conclusions:** SAF-189s showed clinical antitumor activity and was well tolerated in patients with advanced, ALK+ NSCLC, including those with brain metastases and pretreated with crizotinib. SAF-189s represents a promising, next-generation, targeted therapy for patients with ALK+ NSCLC. Clinical trial information: NCT04237805. Research Sponsor: Wanbang Biopharmaceuticals.

Treatment patterns and outcomes in *ALK* or *ROS1* altered NSCLC: An ATOMIC Registry Study. *First Author: Melina Elpi Marmarelis, University of Pennsylvania, Philadelphia, PA*

Background: New tyrosine kinase inhibitors (TKIs) targeting *ALK* and *ROS1* alterations in non-small cell lung cancer (NSCLC) have emerged over the last decade. Given the rarity of these genetic changes in NSCLC, data on long term outcomes with sequential therapies are limited. **Methods:** We conducted a multicenter retrospective cohort study of patients with metastatic NSCLC and *ALK* or *ROS1* alterations across 12 Academic Thoracic Oncology Medical Investigators Consortium (ATOMIC) sites between 1/29/2007 and 3/31/2021. Data were abstracted from the electronic medical record. Median time to treatment discontinuation (TTD) of 1st TKI, overall survival (OS), and time to brain metastases were estimated using Kaplan-Meier methodology from start date of 1st TKI. **Results:** 566 patients with *ALK* (n = 464) or *ROS1* (n = 102) were included. The majority (ALK: 426/464, 92%; ROS1: 88/102, 86%) received a TKI at some point during therapy (1st line TKI n = 262 ALK, 48 ROS1). Crizotinib was the most common 1st TKI (ALK: 57%; ROS1: 88%). Following crizotinib, alectinib (64%) and lorlatinib (41%) were the most common subsequent TKIs for *ALK* and *ROS1*, respectively. Alectinib (38%) and entrectinib (10.2%) were the 2nd most common initial TKIs used in *ALK* and *ROS1*, respectively. Additional treatment patterns presented in table. With a median follow up time of 31.1 (ALK, 95% CI, 27.6-35.0) and 32.6 (ROS1, 95% CI, 25.7-39.6) months, median OS from start of 1st TKI was 53.3 (ALK, 95% CI, 40.0-68.9) and 42.0 (ROS1, 95% CI, 31.8-NA) months. Out of the 321 patients with brain imaging prior to 1st line therapy, 40% (105/262, ALK) and 39% (23/59, ROS1) had CNS disease. Median time to development of brain metastases from start of 1st TKI in those without previous CNS disease (ALK: 278; ROS1: 58) was 30.0 (ALK, 95% CI, 25.3-39.1) and 27.0 (ROS1, 95% CI, 18.2-NA) months. Median TTD of 1st TKI was 11.2 (ALK) and 10.8 (ROS1) months. **Conclusions:** This is the largest retrospective cohort of NSCLC patients with *ALK* or *ROS1* rearrangements treated in the real world setting. CNS metastases are common and subset analyses by agent and by year of diagnosis will be presented. Median time to CNS metastasis of > 2 years supports revision of the NCCN guidelines to include regular surveillance brain MRIs in this population. Research Sponsor: Takeda, Other Foundation.

ALK 1st TKI (n)	2nd TKI	% among those who switch to a 2nd TKI	ROS1 1st TKI (n)	2nd TKI	% among those who switch to a 2nd TKI
Crizotinib (243)	Alectinib	64% (121)	Crizotinib (77)	Lorlatinib	41% (15)

Crizotinib in *ROS1*-rearranged lung cancer (EUCROSS): Updated overall survival. *First Author: Sebastian Yves Friedrich Michels, University of Cologne, Department I of Internal Medicine, Faculty of Medicine and University Hospital Cologne Center for Integrated Oncology Aachen Bonn Cologne Düsseldorf, Lung Cancer Group, Cologne, Germany*

Background: *ROS1* rearrangements are found in approximately 1% of non-small cell lung cancer (NSCLC) patients. Prospective clinical trials showed high efficacy of crizotinib in this molecular subset. Lately, we reported an overall response rate (ORR) of 70% and a median progression-free survival (PFS) of 19.4 months for patients treated within the EUCROSS trial (Michels et al. Clin Oncol, 37(15_suppl):9066-9066, 2019). Here we present an updated analysis of the overall survival. **Methods:** EUCROSS is a European multi-centre, single arm phase 2 trial (Clinicaltrial.gov identifier: NCT02183870). Key eligibility criteria were ≥18 years of age, advanced/metastatic lung cancer, centrally confirmed *ROS1*-rearranged (fluorescence-in situ hybridisation) and no or stable brain metastases at baseline. Crizotinib was given at a dose of 250 mg twice daily. Primary endpoint of the trial was investigator-assessed ORR in the response-evaluable population (Response Evaluation Criteria in Solid Tumors, version 1.1), with secondary endpoints of PFS and overall survival (OS). **Results:** Of the 34 patients who received at least one dose of crizotinib (intention-to-treat population, ITT), 30 were included the primary efficacy analysis set (PAS). After a median follow-up of 55.9 months, 13 (43%) patients in the PAS and 15 (44%) in the ITT had died. Median OS was not reached in either group (95% CI, 17.1-NR and 20.3-NR, respectively). OS was negatively correlated with the presence of brain metastases (Log-rank p = 0.1805) and *TP53* mutations (Log-rank p = 0.015). Detailed listings of the survival rates are depicted in Table. No new safety signals were observed. Owing to the approval of crizotinib by the European Medicines Agency, all patients who were still on treatment by January 24th 2018 (n=8), were prescribed crizotinib outside the trial. **Conclusions:** Updated OS highlights the efficacy of crizotinib in patients with *ROS1*-rearranged lung cancer. Patients with co-occurring *TP53* mutations or brain metastases had worse outcomes and represent challenging populations. Clinical trial information: NCT02183870. Research Sponsor: Pfizer.

OS rates in the PAS.

Overall survival (OS)	
Median (months, 95% CI)	NR (17.1-NR)
Events censored	17/30 (56.6%)
OS rate at 24 months (%; 95% CI)	65.6 (45.5-79.8)
OS rate at 36 months (%; 95% CI)	58.7 (38.9-74.0)
OS rate at 48 months (%; 95% CI)	55.0 (35.4-70.9)

Use of RET inhibitors among patients with advanced NSCLC: A real-world evidence analysis. *First Author: Shaheenah S. Dawood, Mediclinic City Hospital, Dubai, United Arab Emirates*

Background: *RET* rearrangements are found in approximately 1% to 2% of patients with NSCLC. Two selective RET inhibitors have been FDA approved based on phase 1/2 data showing significant activity among patients with advanced NSCLC that have *RET*rearrangements. The objective of this retrospective analysis was to look at the prognostic outcome associated with the use of selective RET inhibitors (sRETi) and multikinase inhibitors (MKIs) that have been used to target RET fusions among pts with NSCLC in the real-world setting. **Methods:** We utilized a federated network of de-identified health data representing approximately 84 million pt lives available through the TriNetX Research Network. We identified 1,215 pts with metastatic NSCLC treated with selpercatinib, praseltinib, cabozantanib or vandetanib. Overall survival (OS) was evaluated with Kaplan Meier statistics and compared between patients treated with either sRETi (selpercatinib or pralsetinib) vs either MKI (cabozantanib or vandetanib). **Results:** Mean age among all anti-RET treated patients was 67.6 years. 518 pts (43%) were female and 697 (57%) were male. 531 (39.6%), 205 (15.3%) and 605 (45.1%) pts had received selpercatinib, pralsetinib, and either cabozantinib or vandetinib, respectively. 56.6% of pts receiving pralsetinib received prior selpercatinib. Among pts receiving sRETi, 39.7%, 6.4%, 11.2%, and 32.4% received sRETi in the 0-3, 3-6, 6-12, and 12+ months after metastatic diagnosis, respectively. Among pts receiving MKIs, 17.0%, 8.4%, 13.3%, and 44.9% received MKIs in the 0-3, 3-6, 6-12, and 12+ months after metastatic diagnosis. Median OS after treatment with MKIs and sRETi during any time frame was 16.3m and 25.0m, respectively (p < 0.01). Among pts treated with MKIs vs sRETi during the 0-3, 3-6, 6-12, and 12+ months after metastatic diagnosis, 1-year survival probability after treatment was 59.7% vs 55.9% (p = 0.39), 45.0% vs 83.1% (p < 0.01), 53.9% vs 82.2% (p < 0.01), and 57.7% vs 87.1% (p < 0.01), respectively. 30% of pts of all anti-RET treated patients had brain metastases, and median OS from index metastasis among pts with and without brain metastases was 31.4m and 63.1m respectively (p < 0.01). **Conclusions:** To our knowledge this is the first real world data set to show a > 8m improvement in OS with the use of sRETi compared to MKIs among pts with metastatic NSCLC. OS improvements may be more significant in pts treated in later lines of therapy with sRETi. Research Sponsor: None.

9080 **Poster Session**

Chylothorax and chylous ascites during RET tyrosine kinase inhibitor therapy. *First Author: Or Kalchiem-Dekel, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Spontaneous, atraumatic chylous effusions are rare. Investigators have observed a higher than anticipated incidence of chylothorax and chylous ascites in patients (pts) treated with RET tyrosine kinase inhibitors (TKIs). A systematic analysis of the occurrence of chylous effusions during RET TKI therapy and management strategies was thus performed. **Methods:** In this multicenter, retrospective study, the frequency of biochemically confirmed chylothorax or chylous ascites in pts treated with multikinase inhibitors (MKIs) with anti-RET activity or selective RET TKIs was determined. Clinicopathologic features and management of pts with chylous effusions were assessed. **Results:** A pan-cancer cohort of 7517 pts treated with at least 1 of 17 MKIs and selective RET TKIs and an independent cohort of 96 pts treated with the selective RET TKIs, selpercatinib or pralsetinib, were identified. Across cohorts, chylous effusions were identified in 22 pts and were most common with selpercatinib (7%; 15/217), followed by the MKIs agerafenib (4%; 1/24), cabozantinib (0.3%; 3/918), and lenvatinib (0.3%; 3/1185). Chylous effusions were not noted in 28 pts treated with pralsetinib. The distribution of malignancies included lung adenocarcinoma (54%) medullary thyroid carcinoma (23%), renal cell carcinoma (19%), and desmoplastic small round cell tumor (4%). Of the 22 pts, 12 had chylothorax, 5 had chylous ascites, and 5 had both. The cumulative incidence of chylous effusions from TKI initiation at 12 months was 3.09%. Median fluid triglyceride level was lower in chylothorax than in chylous ascites [397 mg/dL (IQR 282-4000) vs. 3786 mg/dL (IQR 676-6596), p = 0.035]. Median pleural fluid triglyceride level was higher with selpercatinib compared to MKIs [4,000 mg/dL (IQR 356-4425) vs. 287 mg/dL (IQR 216-395); p = 0.017]. Malignant cells were identified in the effusions from 12% (2/17) and 10% (1/10) of pts with chylothoraces and chylous ascites, respectively. Median time to disease progression from radiographic index and biochemical index across the full cohort was 1.5 years (IQR: 0.6-2.4) and 1.0 year (IQR: 0.1-1.2), respectively. Anatomic chyle leak was not identified in 6 pts who underwent lymphangiography. After initial drainage, additional drainage procedures were required in all cases with chylothorax and 50% of cases with chylous ascites. Chylous effusions prompted TKI dose reduction in 47% (7/15) of pts treated with selpercatinib and 14% (1/7) treated with MKI; none discontinued TKI due to chylous effusions. **Conclusions:** Chylous effusions can emerge on treatment with certain MKIs or selective RET TKIs. Recognition of this potential side effect is key to prevent misattribution of worsening effusions to progressive malignancy and to motivate a better understanding of its biology and management. Research Sponsor: U.S. National Institutes of Health.

Phase 1 dose escalation and expansion study of bemcentinib (BGB324), a first-in-class, selective AXL inhibitor, with docetaxel in patients with previously treated advanced NSCLC. *First Author: Sheena Bhalla, University of Texas Southwestern Medical Center, Dallas, TX*

Background: AXL, a transmembrane receptor tyrosine kinase, is overexpressed and associated with poor prognosis and treatment resistance in non-small cell lung cancer (NSCLC). Bemcentinib (BGB324) is a selective orally bioavailable small molecule inhibitor of AXL, currently in phase 2 clinical development, that has demonstrated synergistic activity with docetaxel in *in vivo* models of NSCLC. This phase I dose escalation and expansion trial assessed the safety, tolerability, and preliminary efficacy of bemcentinib in combination with docetaxel in previously treated advanced NSCLC. **Methods:** Dose escalation of daily bemcentinib in combination with docetaxel (60 or 75 mg/m^2 every 3 weeks) followed a standard 3+3 design. Bemcentinib monotherapy was administered for one week prior to docetaxel initiation to assess pharmacodynamic effects alone and in combination. Plasma protein biomarker levels were measured using the DiscoveryMap v3.3 panel (Myriad RBM) pre-dose (C1D-7), C1D1, and C2D1. **Results:** A total of 21 patients (pts) were enrolled with median age 62 (range 39-84) and 67% male. A median of 3 (range 1-13) cycles of therapy were administered. Principal treatment-related adverse events were neutropenia (86%, 76% ≥G3), diarrhea (57%, 0% ≥G3), fatigue (52%, 5% ≥G3), and nausea (52%, 0% ≥G3). Neutropenic fever ≥G3 occurred in 7 (33%) pts. The maximum tolerated dose was 60 mg/m^2 docetaxel plus 200 mg bemcentinib daily with prophylactic G-CSF support. Pharmacokinetics of bemcentinib alone and in combination with docetaxel were highly similar. Among 15 evaluable pts, 4 (27%) pts had partial response and 9 (60%) pts had stable disease as the best radiographic response. Bemcentinib treatment resulted in changes in plasma levels of proteins associated with regulation of sterol synthesis and AKT signaling. **Conclusions:** Bemcentinib in combination with docetaxel and prophylactic G-CSF support has a manageable safety profile, leads to decreases in systemic factors associated with tumor growth and metastasis, and demonstrates evidence of anti-tumor activity in previously treated, advanced NSCLC. Further studies to identify the patient population most likely to benefit from this regimen are warranted. Clinical trial information: NCT02922777. Research Sponsor: BerGenBio ASA, South Plains Oncology Consortium (SPOC).

Efficacy of dabrafenib-trametinib combination in *BRAF* V600E-mutated metastatic non–small cell lung cancer: Results of the IFCT-2004 BLaDE cohort. *First Author: Aurélie Swalduz, Department of Medical Oncology, Centre Léon Bérard, Lyon, France*

Background: *BRAF* V600E mutations occur up to 2% of advanced non-small cell lung (NSCLC). Dabrafenib-trametinib (D-T) combination was associated with improved OS rates in phase II study and was approved in the 1st-line setting and further. The IFCT-2004 BLaDE study reports the D-T combination efficacy in a large French real-world multicenter cohort of advanced *BRAF V600E*-mutated NSCLC. **Methods:** Patients (pts) with advanced NSCLC harboring *BRAF V600E* mutation diagnosed between 01.01.2016 and 31.12.2019 and treated with D-T combination (D 300 mg + T 2 mg daily) whatever the treatment line were included. Demographic, clinical, pathological data were collected as well as data of efficacy and reason of treatment discontinuation. The primary endpoint was 12 months-OS rate in pts receiving the D-T as 2nd-line or subsequent treatment (L2+). **Results:** 163 pts were included in 54 centers through 32 national testing labs: 50.3 % were female, 30.2% never-smokers, 95.1 % had adenocarcinoma and PDL1 was > 1% in 78.2%. Median age was 68.3 years. At D-T initiation, 80.8 % of pts were PS 0/1, 93.9 % were stage IIIB/C ineligible for surgery or local therapy and IV, 20.9% had brain metastases and 27% received D+T as 1st line treatment (L1). At the data cutoff (30.06.2021), median (m) follow-up was 27.4 months [95% CI 22.2-31.9] and 47 pts (28.8%) remained on study treatment. 12 months-OS rate in pts receiving D+T in L2+ (n = 119) was 67.4% [95% CI 57.8-75.3] with a median progression-free survival (mPFS) of 10.4 months [95% CI 7.3-13.1]. In the 44 pts receiving D+T in L1, 12 months-OS rate was also 67.4% [95% CI 51.2-79.3] with a mPFS of 18.2 months [95% CI 7.7-21.3]. Objective response rates were 73.8% [95% CI 65.5 - 82.2] and 82.9% [95% CI 71.4 - 94.4], disease progression was observed as best response in 3.7% [95% CI 0.1 - 7.3] and 0% in L2+ and L1, respectively. Other efficacy results are detailed in the table. D-T discontinuation for toxicity was reported in 10.3% of pts. 51.2% and 43.7% of pts received subsequent treatment in L2+ and L1 respectively. For L2+ pts, subsequent treatments were immunotherapy (IO)-based in 37.2 % and chemotherapy in 58.3%. For L1 pts, subsequent treatments were (IO)-based in 42.9% and chemotherapy in 42.7%. **Conclusions:** Our series confirms significant efficacy of D-T combination in *BRAF* V600E-mutated metastatic NSCLC. These results in real-world conditions are consistent with registration studies but also support its use in 1st line setting. Research Sponsor: NOVARTIS.

***BRAF* mutation classes and co-occurring mutations in NSCLC.** *First Author: Jiaxin Niu, Banner MD Anderson, Phoenix, AZ*

Background: Targeted therapy against unique molecular drivers has revolutionized non-small cell lung cancer (NSCLC) treatment. *BRAF* mutations, present in 2%-5%, have emerged as therapeutic targets, and can be divided into three classes: kinase-activating monomers (class I, V600) or dimers (class II), or kinase-inactivating dimers (class III). Most studies have focused on *BRAF* V600E NSCLC. Limited clinical data suggest classes II and III may not respond well to chemo- or targeted therapy and tend to have a poorer prognosis. Little is known about co-occurring mutations. This study examines *BRAF* classes and co-occurring mutations in NSCLC. **Methods:** Between October 2018 and October 2021, data from 3009 NSCLC Oncotype MAP test results were analyzed. This test utilizes tumor DNA to identify single nucleotide variants, indels, copy number alterations, and select structural variants/fusions by next generation sequencing with a 257 gene panel. Tumor mutational burden and microsatellite instability are also assessed. Pathogenic/likely pathogenic mutations were identified, *BRAF* mutations assigned to 3 different classes based on current understanding, and associations of other mutated genes with *BRAF* class examined. **Results:** Among samples, 133 (4.4%) had *BRAF* mutations: 30 class I (1%); 42 class II (1.4%); 36 class III (1.2%); and 25 unclassified (0.8%) (Table). Two genes showed associations with *BRAF* class: *STK11* was significantly overrepresented in class II and III, and *SETD2* in class I ($p<0.05$ for both). *BRAF* class II mutations were further divided into subclasses, IIa (n= 5) and IIb (n= 35); two could not be assigned. The lack of a positive association between *KRAS* (and *NF1*) and *BRAF* class III was unexpected since class III is RAS-dependent while class I and II are RAS-independent. The overrepresentation of *STK11* in classes II (with 11/12 events in IIb) and III might explain, at least in part, the poor prognosis relative to class I. By contrast, *SETD2* is overrepresented in class I, which might help explain its better response to immunotherapy. **Conclusions:** For the first time we report the incidence of *BRAF* mutation classes and associated co-mutations in NSCLC. These associations may help to explain therapeutic outcomes. The impact of coexisting STK11 mutations in class II subclasses warrants further investigation. Research Sponsor: Exact Sciences Corporation.

The most frequent co-occurring mutations in 133 mutant *BRAF* NSCLC samples.

Gene	n	Class I n=30	Class II (n=42)			Class III n=36	Unclassified n=25
			NA (n=2)	IIa (n=5)	IIb (n=35)		
TP53 (p53)	88	13 (43.3%)	2 (100.0%)	4 (80.0%)	22 (62.9%)	26 (72.2%)	21 (84.0%)
STK11*	22	1 (3.3%)	0	1 (20.0%)	11 (31.4%)	7 (19.4%)	2 (8.0%)
KRAS	21	1 (3.3%)	1 (50.0%)	1 (20.0%)	6 (17.1%)	8 (22.2%)	4 (16.0%)

Clinicopathologic and mutational landscape of *BRAF*^{V600E}-mutant non–small cell lung carcinoma. *First Author: Jane Sze Yin Sui, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *BRAF* mutations (mts) occur in 2-5% of non-small cell lung cancers (NSCLC) with approximately 50% being *BRAF*^{V600E}. Limited data is known regarding the mutational landscape (ML) and prognostic role of co-mutations in *BRAF*^{V600E} NSCLC. We performed this study to evaluate clinicopathological characteristics and the impact of ML in *BRAF*^{V600E} NSCLC. **Methods:** Patients (pts) with *BRAF*^{V600E}mutant NSCLC were identified using MSK-IMPACT at Memorial Sloan Kettering Cancer Center between January 2014 to October 2021. Baseline clinicopathological characteristics and treatment outcomes were annotated. Due to the enrichment of *SETD2* in *BRAF*^{V600E} NSCLC, we conducted further analyses using cbioportal to identify co-mutations of *SETD2* with other actionable mutations in NSCLC. Overall survival (OS) was assessed from the date of metastatic disease until death using the log-rank test. **Results:** *BRAF* mutations were detected in 5% of NSCLC samples (512/10220) with 22% (97/435 pts) being *BRAF*^{V600E}. Of the 97 pts with *BRAF*^{V600E} NSCLC identified: 57 pts (59%) were females, median age of 68 (range: 38-93 years), 58 pts (60%) were former smokers. All *BRAF*^{V600E} tumors were adenocarcinoma and the median tumor mutational burden was 5 mt/Mb (range: 0-40). 46 pts (48%) with *BRAF*^{V600E} NSCLC were diagnosed with de novo metastatic disease. Pts receiving targeted therapy at first, second, and subsequent lines of therapy numbered 17 (29%), 18 (31%), and 10 (17%) respectively. Co-alterations of *BRAF*^{V600E} with *TP53* and *SETD2* were found in 45% (44/97) and 42% (41/97), respectively. There is a much lower prevalence of concurrent inactivating *SETD2* mutations than with other actionable alterations in NSCLC: *ROS1* (9%), *ALK* (8%), *RET* (8%), *HER2* (6%), *MET* (5%), *KRAS* (5%), *EGFR* (2.9%) and *BRAF*$^{non\text{-}V600E}$ (2%). Median OS in *BRAF*$^{V600E+}$/*TP53*$^{+}$ vs *BRAF*$^{V600E+}$/*SETD2*$^{+}$ were 35 vs 36 mos (HR 0.88m 95% CI 0.45-1.75, *P*= 0.71) and *BRAF*$^{V600E+}$/*TP53*$^{+}$/*SETD2*$^{+}$ vs *BRAF*$^{V600E+}$/*TP53*$^{-}$/*SETD2*$^{-}$ were 19 vs 39 mos (HR 0.37, 95% CI 0.09-1.50, *P*= 0.06). **Conclusions:** Among the *BRAF*^{V600E} lung adenocarcinomas, concurrent *TP53* mutation and *SETD2* inactivation define a patient subset with significantly shorter overall survival. Further studies are warranted to investigate the role of *SETD2* mutations in the context of *BRAF*^{V600E} in NSCLC pts. Research Sponsor: None.

A first-in-human, phase 1 study of ASTX029, a dual-mechanism inhibitor of ERK1/2, in relapsed/refractory solid tumors. *First Author: Patricia LoRusso, Yale University, New Haven, CT*

Background: Aberrant activation of the RAS-RAF-MEK-ERK pathway is common in human cancers. This is an open-label Phase 1 study of ASTX029, a dual-mechanism extracellular signal-regulated kinase 1/2 (ERK1/2) inhibitor, in subjects with relapsed/refractory solid tumors (NCT03520075). **Methods:** The primary objective is to identify a recommended Phase 2 dose. Subjects with relapsed/refractory solid tumors were eligible for Phase 1A with any molecular feature and for Phase 1B if the tumor demonstrated RAS or BRAF mutations. ASTX029 was administered orally daily on a continuous basis in 21-day cycles. Phase 1A was a modified 3+3 dose-escalation design based on dose-limiting toxicity (DLT) events. Phase 1B subjects were treated at the recommended dose for expansion (RDE) based on emerging safety, pharmacokinetic (PK), and pharmacodynamic (PD) data. Disease response was evaluated by RECIST v1.1. **Results:** 76 subjects were treated with at least one dose of ASTX029 in Phase 1A (n = 56) and Phase 1B (n = 20). In Phase 1A, ASTX029 was evaluated from 10 mg to 280 mg daily. Two subjects experienced grade 2 central serous retinopathy (CSR) within a few days of dosing at the 280 mg daily dose level (one event was declared a DLT). Both subjects recovered to baseline within days of dose interruption. CSR is an expected AE based on the class of drugs. At the selected RDE dose level of 200 mg daily, the mean PK exposure was 109% of target exposure (13,022 ng*hr/ml), defined as the level expected to have biological activity based on mouse models. As of the data cut-off of February 7, 2022, the most frequent grade ≥2 AEs experienced by subjects (≥5%) assessed as related to ASTX029 included ocular AEs (n = 6: all Grade 2); nausea (n = 7: all Grade 2); diarrhea (n = 6: 5 Grade 2, 1 Grade 3); fatigue (n = 4: all Grade 2); rash (n = 4, 3 Grade 2, 1 Grade 3). There were 52 serious AEs, all unrelated to ASTX029 except for one subject with Grade 3 malaise. Four subjects had a partial response, including *KRAS*-G12A *BRAF*-D549N non-small cell lung cancer (NSCLC; Phase 1A: 120 mg treated 20.0 months); *KRAS*-G12D pancreatic cancer (Phase 1A: 200 mg treated 2.1 months); *KRAS*-G13D NSCLC (Phase 1B; treated 10.6 months); *KRAS*-G12S NSCLC (Phase 1B; treated 10.4 months and ongoing). In all, two partial responses were observed out of 3 NSCLC subjects enrolled in Phase 1B. Phospho-ERK and phospho-RSK were evaluated for PD effect on fresh tumor biopsies obtained at baseline and cycle 2. A PD effect and decreased cell proliferation (Ki-67) were observed in 6 of 9 and 3 of 8 evaluable Phase 1B samples, respectively. The most common reason for ASTX029 discontinuation was disease progression. **Conclusions:** This Phase 1 study of the ERK1/2 inhibitor ASTX029 has identified a dose level of 200 mg daily continuously for investigation in the Phase 2 study. PK and PD data suggest target exposures are achieved with preliminary clinical activity, especially in KRAS-mutated NSCLC. Clinical trial information: NCT03520075. Research Sponsor: Astex Pharmaceuticals, Inc.

Molecular characterization of NF1-mutated NSCLC and clinical outcomes. *First Author: Christopher Gates, West Virginia University Health Sciences Center, Morgantown, WV*

Background: *NF1* is a tumor suppressor gene that regulates the RAS-MAPK and mTOR pathways. Co-mutations previously observed with *NF1*-mutations (mt) include *TP53, KRAS, EGFR* and rarely *HER2, STK11,* and *PIK3CA* mutations. We report a comprehensive molecular characterization with clinical outcomes analyses for *NF1*-mt non-small cell lung cancer (NSCLC). **Methods:** Next-generation sequencing (NGS) of DNA (592-gene or whole exome) and RNA (whole transcriptome) was performed for NSCLC patient (pt) samples (n = 10,310) submitted to a CLIA-certified laboratory (Caris Life Sciences, Phoenix, AZ). . RAS-MAPK and PI3K-AKT-MTOR signaling were assessed by transcriptional signatures of pathway activation (MAPK pathway Activation Score [MPAS], Wagle, 2018; and GSEA Hallmarks collection, respectively)., PD-L1 by immunohistochemistry (IHC, positive: TPS ≥1%), high tumor mutational burden (TMB) defined as ≥10 mut/Mb, and deficient mismatch repair/high microsatellite instability (dMMR/MSI-High) was assessed by IHC/NGS. Overall survival (OS) was obtained from insurance claims. Statistical significance was determined using Chi-square & Wilcoxon rank sum tests. P-value adjust for multiple hypothesis testing (Benjamini-Hochberg). **Results:** *NF1*-mt were identified in 1,045 NSCLC samples (10.1%). Concurrent *KRAS, EGFR, ERBB2, BRAF* or *MET* alterations are noted in Table 1, with no *ROS1, RET or ALK* fusions identified. Compared to *NF1*-wt, *NF1*-mt NSCLC was associated with increased RAS-MAPK expression (3.0-fold, P < 0.0001), while PI3K-AKT-MTOR-signaling was not significantly increased (2.1-fold, P = 0.12). Rates of TMB-High (51.7% vs 32.5%, P < 0.0001), PD-L1+ (69.1% vs 58.8%, P = 0.06), and dMMR/MSI-High (1.7 vs 0.7%, P < 0.05) were higher in *NF1*-mt samples. OS and duration on treatment from the start of Pembrolizumab (HR: 1.0 and 1.0, respectively) or other IOs (HR: 0.9 and 1.0, respectively) were not significantly different between *NF1*-mt and *NF1*-wt patients, However, among *NF1-mt* samples, high TMB and *TP53*-wt were associated with better OS (HR 0.6, P < 0.05 each). **Conclusions:** *NF1*-mt patients rarely harbored actionable NSCLC driver co-alterations. *NF1*-mt cases showed increased activation of RAS-MAPK axis, which may represent a potential pathway to target with MEK inhibitors. *NF1-mt* are responsive to immunotherapy and better outcomes are seen with high TMB and absence of TP53 mutations. Further work is warranted to determine the influence of actionable drivers on targeted therapy outcomes in *NF1*-mt NSCLC. Research Sponsor: None.

A multicenter real-world study of tumor-derived DNA from cerebrospinal fluid in genomic profiling of NSCLC with central nervous system metastases. *First Author: Yongping Mu, Inner Mongolia Autonomous Region Cancer Hospital, Hohhot, China*

Background: Genomic profiling of cerebrospinal fluid (CSF) could be used to detect actionable mutations to guide the clinical treatment of NSCLC patients with central nervous system (CNS) metastases. Examining the performance of CSF samples in a real-world setting can further confirms the potential of CSF in genotyping for guiding therapy in clinical practice. **Methods:** A total of 1097 samples were collected from 773 treated NSCLC patients with CNS metastases in a real-world setting, including 117(10.67%) CSF samples, 287(26.16%) tissue samples and 693(63.17%) plasma samples. All samples were subjected to the targeted next-generation sequencing of 1021 cancer-relevant genes. **Results:** Of these 1097 treated samples, somatic alterations were identified in 112 (95.72%) of the CSF samples, comparing with 287 (100%) of tumor tissue samples and 592 (85.43%) of plasma**.** Among the tumor tissue samples, 242 were non-intracranial tissues, which could not reveal the unique genetic profiles of intracranial metastases. The median of maximal somatic allele frequency of CSF samples (72.35%) was significantly higher than those of plasma (1.30%) and tumor tissues (37.30%) (all p<0.001). In the thirty-two pairs CSF and plasma samples tested simultaneously, 442 alterations were detected, of which 377 were detected in CSFs and 92 in plasma. 27 alterations could be detected in both plasma and CSF, 65 were not detected in CSFs and 350 were not in plasma, the same alterations were 10.91% (27/442). For SNV or InDel, 220 mutations were detected, of which 155 were detected in CSFs and 89 in plasma, the same mutations were 10.91% (24/220)**.**For CNVs, 216 CNV alterations were detected, of which 216 were detected in CSFs and only one in plasma**.** We compared actionable mutation of these 1097 treated samples to further analyze the detection capability of actionable mutations of CSF samples in this real-world setting (Table). Compared with plasma, the detection rates of all actionable mutation and actionable *EGFR* in CSF were significantly higher than those in plasma samples (93.16% vs. 53.97% for all actionable mutation, 83.76% vs. 39.54% for *EGFR*, all p<0.001). **Conclusions:** This real-world large cohort study verified that CSF had higher sensitivity than plasma for identifying actionable mutations. In the process of multiple comparison, it can be seen that CSF is better than plasma in detecting alterations, especially in detecting CNV alteration. CSF can be used as a substitute in genomic profiling for NSCLC patients with CNS metastases when there is no intracranial tumor tissue. Research Sponsor: None.

Evaluation of weight gain and overall survival of patients with advanced non–small cell lung cancer (NSCLC) treated with first-line platinum-based chemotherapy. *First Author: Eric Roeland, Oregon Health and Sciences University Knight Cancer Institute, Portland, OR*

Background: Cachexia is a multifactorial syndrome frequently associated with cancer characterized by anorexia and unintentional weight loss, including skeletal muscle loss, fatigue, functional impairment, poor quality of life, and worse survival. The objective of this post-hoc analysis was to examine the relationship between weight gain and overall survival (OS) in patients with NSCLC treated with first-line platinum-based regimens. **Methods:** Data were pooled from three phase 3 clinical trials (NCT00254891, NCT00254904, and NCT00596830) conducted between Nov 2005 and Mar 2011 in patients with advanced NSCLC (stage IIIB or stage IV) treated with first-line standard-of-care (SOC) chemotherapy (control arm). Weight was recorded at baseline, prior to dosing on day 1 of each 3-week treatment cycle (up to 6 cycles), and post-treatment according to each study's schedule. Weight gain was categorized as > 0%, > 2.5%, and > 5% increase from baseline up to 4.5 months. Cox Proportional Hazards modeling of OS including time to weight gain and time to confirmed objective response (RECIST v1.0) and baseline covariates were used to estimate hazard ratios (HR) for each category. **Results:** The total 1,030 patients from the SOC control arms were predominantly male (70.5%) with Stage IV NSCLC (88.5%) and a mean age (SD) of 60.9 (9.4) years and BMI 24.6 (4.4) kg/m^2. Overall, 486 (47.2%), 299 (29.0%), and 164 (15.9%) patients experienced weight gain from baseline of > 0%, > 2.5%, and > 5%, respectively. Median time to > 0%, > 2.5%, and > 5% weight gain was 24, 43, and 64 days, respectively. After adjusting for statistically significant time-dependent confirmed objective response, the risk of death was significantly less for patients with weight gain. For patients with > 0% vs. ≤0% weight gain, HR was 0.70 (95%CI 0.61, 0.82) with median OS of 13.6 vs. 8.3 months. For patients with > 2.5% vs. ≤2.5% weight gain, HR was 0.70 (95%CI 0.59, 0.83) with median OS of 15.3 vs. 9.1 months. For patients with > 5% vs. ≤5% weight gain, HR was 0.76 (95%CI 0.61, 0.94) with a median OS of 14.4 vs. 9.8 months. **Conclusions:** In this pooled analysis, weight gain during treatment with first-line platinum-based chemotherapy was associated with a significantly reduced risk of death in patients with advanced NSCLC, independent of tumor response defined by RECIST criteria. The survival benefit was comparable for > 2.5% vs. > 5% weight gain. Weight gain of 2.5% may be an earlier predictor of survival outcomes and may have implications for the design of cancer cachexia trials. Clinical trial information: NCT00254891, NCT00254904, and NCT00596830. Research Sponsor: Pfizer.

Nedaplatin plus pemetrexed or cisplatin plus pemetrexed as first-line chemotherapy for EGFR/ALK-negative advanced lung adenocarcinoma (NACA): A multicenter, open-label, non-inferiority, randomized, phase III trial. *First Author: Xue Hou, Department of Medical Oncology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

Background: Platinum-based chemotherapy is the backbone of treatment for advanced non-small cell lung cancer. Cisplatin has well-known side effects such as gastrointestinal reaction and fatigue, and nedaplatin was developed to be an alternative platinum with less toxicity. We aimed to compare nedaplatin plus pemetrexed was non-inferior to cisplatin plus pemetrexed as first-line chemotherapy for advanced EGFR/ALK-negative lung adenocarcinoma. **Methods:** We did an open-label, randomized, phase III trial at 15 centers in China. Advanced lung adenocarcinoma patients with EGFR/ALK-negative status were randomly assigned to receive nedaplatin 90 mg/m^2 or cisplatin 75 mg/m^2 plus pemetrexed 500 mg/m^2 for 6 cycles as first-line treatment, and pemetrexed maintenance for those without progressive disease. The primary endpoint was progression-free survival (PFS), non-inferiority was shown if the upper limit of the 95% CI for the hazard ratio (HR) of PFS did not exceed 1.30. Secondary endpoints included objective response, overall survival and toxicity. This trial is registered with ClinicalTrials.gov, number NCT02607592. **Results:** Between Sep 2015 and May 2021, 218 patients were randomized to nedaplatin group (n = 111) or cisplatin group (n = 107). In the intention-to-treat population, median PFS time was 6.87 months (95%CI, 5.25 to 8.49) in the nedaplatin group and 5.53 months (95%CI, 4.57 to 6.50) in the cisplatin group, with a HR of 0.76 (95%CI, 0.56 to 1.03, p= 0.078). In the per-protocol population (nedaplatin group, n = 105; cisplatin group, n = 94), median PFS time was 6.87 months (95%CI, 5.36 to 8.37) and 5.20 months (95%CI, 4.03 to 6.37) respectively, with a HR of 0.76 (95%CI, 0.56 to 1.03, p= 0.082). Overall response rate was 41.9% in nedaplatin group and 26.6% in cisplatin group (p= 0.026). A significantly higher frequency of any grade nausea and vomiting (51[53.68%] of 95 in the cisplatin group *vs* 30[28.04%] of 107 in the nedaplatin group, p< 0.001), fatigue (37[38.95%] *vs* 27[25.23%], p= 0.037), and constipation (15[15.79%] *vs* 5[4.67%], p= 0.008) were reported in the cisplatin group compared with the nedaplatin group. Higher rate of grade 3/4 nausea and vomiting was observed in cisplatin group (10[10.53%] *vs* 0, p= 0.001). Patients in the nedaplatin group had higher frequency of thrombocytopenia but without statistical significance (any grade: 28[26.17%] of 107 in the nedaplatin group *vs*17[17.89%] of 95 in the cisplatin group, p= 0.158; grade 3/4: 8[7.48%] in the nedaplatin group *vs* 3[3.16%] in the cisplatin group, p= 0.177). **Conclusions:** Our findings show that nedaplatin plus pemetrexed is not inferior to cisplatin plus pemetrexed in progression-free survival, with less toxicities, which represents an alternative chemotherapy regimen for EGFR/ALK-negative advanced lung adenocarcinoma. Clinical trial information: NCT02607592. Research Sponsor: None.

9090 **Poster Session**

Subgroup analysis in patients (pts) with non-squamous (N-Sq), EGFR-wild type (wt), second/third-line NSCLC from the global phase (Ph) 3 trial DUBLIN-3 (BPI-2358-103) with the plinabulin/docetaxel (Plin/Doc) combination versus Doc alone. *First Author: Baohui Han, Department of Pulmonary Medicine, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China*

Background: With PD-1/PD-L1 inhibitors moving to first line in NSCLC, 2nd/3rd line NSCLC is a severe unmet medical need, dominated by docetaxel-based therapies with > 40% severe neutropenia and limited survival. Plin, a novel immune-enhancing small molecule, enhances dendritic cell maturation and T-Cell proliferation. In the ITT population, the Plin/Doc combination had superior Efficacy (mOS; HR = 0.82, p = 0.0399), Safety (lower Gr3/4 AE rate/pt/year (yr); p = 0.038) and better Quality of Life (QTWiST; p = 0.026) versus (vs) standard of care (SoC) Doc alone in advanced and metastatic NSCLC pts in DUBLIN-3 (Han, ESMO 2021) who failed platinum therapy. Here we report on the N-Sq pts subgroup. **Methods:** DUBLIN-3(NCT02504489) was a randomized, single-blind (pts only), active controlled Ph3 study in 2nd/3rd line stage IIIB/IV, EGFR wt NSCLC pts with a measurable lesion (RECIST 1.1) in the lung, and ECOG ≤ 2, conducted in US, Australia and China. Pts (n = 559) were randomized 1:1 to Plin/Doc or Doc/Placebo (21-day (D) cycle (C)). Doc (75 mg/m^2 on D1 and Plin 30 mg/m^2 on D1 and D8 were given by IV infusion. A post-hoc analysis of median Overall Survival (mOS) and restricted mean survival time (RMST) from K-M curves, OS rate at 24,36 and 48 month (Mo), and grade 4 neutropenia (Gr4N) rates was performed for the N-Sq patients (n = 153 for Plin/doc and n = 178 for Doc). **Results:** Baseline characteristics were balanced between both groups. Primary and key secondary objectives in the ITT population were met (Han, ESMO 2021). Plin/Doc was well tolerated. Estimated Adverse Event Rate per Year [95% CI] was 1.43 [1.13,1.81] for Plin/Doc versus 2.77 [2.33,3.28] for Doc alone (p < 0.001). The median OS benefit is 2.6 months (p = 0.023). The table below summarizes the results for the N-Sq subgroup. **Conclusions:** The addition of Plin to Doc was superior to SoC Doc alone for efficacy and safety in the clinically relevant subgroup of non-squamous EGFR-wild type, 2nd/3rd line NSCLC pts. Clinical trial information: NCT02504489. Research Sponsor: BeyondSpring Pharmaceuticals Inc.

DUBLIN-3 results on quality of life (QoL) in second/third-line EGFR-wild type NSCLC patients (pts) receiving docetaxel (Doc) with or without plinabulin (Plin) using the validated EORTC QLQ C30 and QLQ LC13 questionnaires. *First Author: Trevor Feinstein, Piedmont Cancer Institute, Fayetteville, GA*

Background: Plin, a novel immune-enhancing small molecule, enhances dendritic cell maturation and T-cell proliferation. In the ITT population, the Plin/Doc combination had superior Efficacy (mOS; p = 0.0399), Safety (Gr3/4 AE rate/pt/year; p = 0.038) and QTWiST (p = 0.026) vs standard of care (SoC) Doc alone in NSCLC pts in DUBLIN-3 (Han, ESMO 2021). Here we report DUBLIN-3 QoL results. **Methods:** DUBLIN-3(NCT02504489) was a randomized, single-blinded (pts only), active-controlled Ph3 study in 2nd/3rd line stage IIIB/IV, EGFR wt NSCLC pts with a measurable lesion (RECIST 1.1) in the lung, and ECOG ≤ 2, conducted in US, Australia, and China. Pts (n = 559) were randomized 1:1 to Plin/Doc or Doc/Placebo (21-day (D) cycle). Doc (75 mg/m^2 on D1 and Plin 30 mg/m^2 on D1 and D8 were given by IV infusion. QoL was evaluated by the validated questionnaires EORTC QLQ C30 and QLQ LC13 (which is specific for Lung Cancer), and patient-reported scores were collected at baseline and D1, D8 of each cycle (C). **Results:** Baseline characteristics and QLQ C30 and LC13 scores were comparable between both groups. Plin/Doc was well tolerated. Cumulative C30 sand LC13 scores were calculated for each patient. Mean (SEM) change from baseline in cumulative C30 and LC13 scores were comparable for Plin/Doc and Doc in the first 10 cycles, however separated after C10 in favor of Plin/Doc (table). LC13 items in favor of Plin/Doc vs Doc alone, were items 31 (Coughing; p < 0.05), 36 (Sore Mouth; p < 0.01), 37 (Dysphagia; p < 0.01). **Conclusions:** We previously reported an OS, Safety, and QTWiST benefit with Plin/Doc vs Doc alone (ESMO 2021) in EGFR wild type 2nd/3rd line NSCLC pts from DUBLIN-3. Here, we report statistically significant QoL benefits with Plin/Doc vs Doc alone, as assessed with EORTC QLQ C30 and LC13, which may be relevant to guide treatment decisions in this generally sick patient population. Clinical trial information: NCT02504489. Research Sponsor: BeyondSpring pharmaceuticals, Inc.

Effect of performance status (ECOG PS) on treatment outcome with second-line (2L) nintedanib (NIN) + docetaxel (DOC) for patients (pts) with lung adenocarcinoma after first-line (1L) immune checkpoint inhibitor (ICI) combination therapy. *First Author: Christian Grohé, Department of Respiratory Diseases, ELK Berlin, Berlin, Germany*

Background: ICIs with or without chemotherapy represent 1L standard of care for patients with advanced non-small cell lung cancer (NSCLC) without targetable driver mutations. Given the paucity of prospective randomized trials assessing second-line treatment options post-immunochemotherapy, non-interventional data may help support clinical decision making. Patients with ECOG PS > 1 are generally underrepresented in clinical trials relative to routine clinical practice. We therefore examined treatment outcomes with 2L NIN + DOC after 1L ICI combination therapy with respect to ECOG PS at baseline. **Methods:** In this analysis of Cohort C of the ongoing, non-interventional VARGADO study (NCT02392455), eligible pts had locally advanced, metastatic or locally recurrent adenocarcinoma NSCLC and received 2L NIN+DOC in routine clinical practice after failure on 1L ICI in combination with chemotherapy. The primary endpoint is 1-year survival rate (not yet mature). Tumor response was according to investigator review. **Results:** In 164 pts enrolled in Cohort C, median age was 63 years (range: 37 – 84), 100 pts (61.0%) were men, and 123 pts (75.0%) were ECOG PS 0–1. 146 pts (89.0%) had received prior 1L pembrolizumab-based combination therapy. Objective response rate (ORR) with 2L NIN+DOC was 35.4% (40/113 pts) in the overall population and 41.2%, 30.8% and 28.6% for pts with ECOG PS 0, 1 and > 1, respectively. Disease control rate (DCR) was 67.3% (76/113 pts) in the overall population and 76.5%, 65.4% and 50.0% for pts with ECOG PS 0, 1 and > 1, respectively. Median PFS was 4.7 months (95% CI: 3.4 – 5.3) in the overall population and 5.1 months (95% CI: 2.8 – 8.3), 3.7 months (95% CI: 2.5 – 5.3) and 2.1 months (95% CI: 1.3 – 6.5) for pts with ECOG PS 0, 1 and > 1, respectively. The median OS was 8.1 months (95% CI: 6.3 – 11.2) in the overall population and 9.1 months (95% CI: 5.4 – 14.5), 10.5 months (95% CI: 6.3 – 14.9) and 4.0 months (95% CI: 2.5 – 6.3) for pts with ECOG PS 0, 1 and > 1, respectively. **Conclusions:** Our results support 2L NIN+DOC as an effective treatment option in pts with advanced adenocarcinoma NSCLC following 1L ICI in combination with chemotherapy. ECOG PS > 1 was associated with lower ORR, DCR and shorter PFS and OS. These findings warrant further evaluation of the effect of ECOG PS on 2L treatment outcomes in patients after 1L ICI combination therapy. Clinical trial information: NCT02392455. 9093 **Poster Session**

Capecitabine in pretreated metastatic pulmonary lymphoepithelioma-like carcinoma: A retrospective study. *First Author: Gavin Tin Chun Cheung, Department of Clinical Oncology, Queen Elizabeth Hospital, Kowloon, Hong Kong*

Background: Pulmonary lymphoepithelioma-like carcinoma (LELC) is a rare disease, sharing common histological features with the undifferentiated subtype of nasopharyngeal carcinoma (NPC), and being under-represented in non-small cell lung cancer trials and clinical guidelines. While gemcitabine-based platinum doublet chemotherapy is more established in 1st line treatment of stage IV disease, there is limited evidence for subsequent treatment strategy. Oral capecitabine is one of the active agents in metastatic NPC, and was observed to have encouraging outcomes in pulmonary LELC. **Methods:** All consecutive patients with pulmonary LELC in 2010 – 2019 treated in a tertiary institution were reviewed. Patients with metastatic disease who progressed after gemcitabine-based platinum doublets and treated with capecitabine were included. Capecitabine was given at 1250 mg/m^2 twice daily for 14 days followed by 7 days of rest in each cycle. Treatment response was monitored by clinical history, physical examination and imaging. Treatment was continued till drug holiday, intolerance or disease progression. Progression-free survival (PFS) and overall survival (OS) were estimated by the Kaplan-Meier method. Clinical predictors for PFS and OS were analyzed using log-rank test and the Cox proportional hazard model. **Results:** Of the 140 LELC patients identified, 36 patients satisfied the above inclusion criteria (14 male, 22 female). Median age was 58.6 years old (range 41.5 – 75.6). All patients had an ECOG performance score of 0 or 1. 16 patients (44.4%) received 2 or more lines of prior systemic treatment. Median capecitabine cycles received was 5 (range 2 – 68). Objective response rate was 27.8% (complete response: 5.6%; partial response: 22.2%), disease control rate was 75.0%. With a median follow-up of 15.3 months (range 1.8 – 82.6), the median PFS and OS were 5.4 months (95% CI, 2.1 – 8.8) and 15.4 months (95% CI, 10.0 – 20.7) respectively. Capecitabine was generally well tolerated, with 22.2% grade 3 or above side effects, and 5.6% treatment termination due to intolerance. Bone and distant lymph node (LN) involvement were significant predictors of poorer PFS on multivariate analyses (bone: HR 3.24, 95% CI 1.44 – 7.29, p=0.004; distant LN: HR: 2.62, 95% CI 1.14 – 6.02, p=0.024). Age, sex, smoking history, number of treatment lines, and other sites of disease involvement were not significant predictors. **Conclusions:** This is to date the largest reported cohort of capecitabine in pre-treated metastatic pulmonary LELC. Capecitabine is effective and well tolerated, and should be considered as a treatment option after 1st line platinum-based chemotherapy. Future studies are warranted to delineate the optimal treatment pathway of this rare disease entity. Research Sponsor: None.

9094 **Poster Session**

Quality of life (QoL) of OSE2101 in patients with HLA-A2+ non–small cell lung cancer (NSCLC) after failure to immune checkpoint inhibitors (IO): Final data of phase 3 Atalante-1 randomized trial. *First Author: Benjamin Besse, Gustave Roussy Institute, Villejuif, France*

Background: OSE2101 (Tedopi) is an anticancer vaccine increasing overall survival (OS) versus Standard of Care (SoC docetaxel or pemetrexed) in HLA-A2+ NSCLC patients with secondary resistance after sequential Chemo (CT)-IO (ESMO 2021 #47LBA). Here we present the QoL analysis. **Methods:** EGFR and ALK negative NSCLC patients who failed prior IO, ECOG PS 0-1 were randomized 2:1 to receive either OSE2101 or SoC (docetaxel or pemetrexed). Primary endpoint was OS; secondary endpoints included time to ECOG PS deterioration and QoL by EORTC QLQ-C30/LC13 questionnaires at baseline and before each treatment administration until the end of treatment (EOT). Changes in QLQ-C30/LC13 scores from baseline to EoT were assessed using mixed-effects model for repeated measures (MMRM). Overall treatment effect and associated p value were estimated using MMRM. **Results:** 95 out of 118 (81%) patients with secondary resistance to IO completed baseline and ≥ one follow-up questionnaire. Median OS was 11.1 mo for OSE2101 vs 7.5 mo for SoC [HR 0.59; p = 0.02]. Median time to ECOG PS deterioration was 9.0 mo for OSE2101 vs 3.3 mo for SoC [HR: 0.43; p = 0.004]. Global Health Status remained stable with OSE2101 whereas it deteriorated from the 1st cycle with SoC (p = 0.045). Most pronounced effects were observed in the physical (ability to perform activities that require physical effort; p = 0.07) and the role (ability to work and carry out daily activities; p = 0.03) functioning scores (refer table below). Patients had less mouth soreness (p = 0.01), dysphagia (p = 0.01), peripheral neuropathy (p = 0.03), alopecia (p < 0.001) and fatigue (p = 0.06) with OSE2101 than with SoC. The change from baseline of dyspnea, coughing, hemoptysis, and pain were not significantly different between the 2 groups. **Conclusions:** In advanced HLA-A2+ NSCLC patients with secondary resistance to IO after sequential CT-IO, OSE2101 improves OS and maintains QoL vs. SoC, especially global health status, physical and role functioning scores. Patients presented fewer symptoms typically related to adverse effects of chemotherapy as compared to SoC. Clinical trial information: NCT02654587. Research Sponsor: OSE Immunotherapeutics.

Gefitinib plus chemotherapy versus gefitinib alone in untreated patients with *EGFR*-mutated non–small cell lung cancer and brain metastases (GAP Brain): An open-label, randomized, multicenter, phase 3 study. *First Author: Likun Chen, Department of Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Combination of tyrosine kinase inhibitor (TKI) and chemotherapy has shown improved clinical outcomes in advanced epidermal growth factor receptor (*EGFR*) mutated non-small cell lung cancer (NSCLC) patients. We conducted this phase 3, randomized, controlled trial to further investigate the clinical efficacy and safety of gefitinib combined with chemotherapy in *EGFR* mutated NSCLC patients with brain metastases. **Methods:** Treatment-naïve, confirmed brain metastases and *EGFR* sensitive mutated NSCLC patients were screened from six centers in China. The eligible patients were randomly assigned (1:1) to receive gefitinib alone or gefitinib plus pemetrexed-platinum chemotherapy until intracranial progressive diseases, unacceptable adverse, or any cause of death. Theprimary endpoint was intracranial progression-free survival (iPFS), secondary endpoints were PFS, overall survival, intracranial objective response rate, overall objective response rate, and safety. This study is registered at ClinicalTrials.gov, number NCT01951469. **Results:** From January 2017 to June 2021, 161 patients were randomly assigned to receive gefitinib (n = 81) or gefitinib plus pemetrexed-platinum chemotherapy (n = 80), the median follow-up time was 18.2 (IQR 11.8-29.7) months. The median intracranial PFS was 15.6 (14.3-16.9) months in gefitinib plus chemotherapy group versus 9.1 (8.0-10.2) months in gefitinib group (HR = 0.36, 95% CI, 0.25-0.53, P < 0.001). Similarly, the median PFS was also significantly longer in gefitinib plus chemotherapy than gefitinib alone (16.3 months vs 9.5 months, P < 0.001). In addition, gefitinib plus chemotherapy had better intracranial objective response rate (85.0% versus 63.0%, P = 0.002) and overall objective response rate (80.0% versus 64.2%, P = 0.035) than gefitinib alone. At the data cutoff, 50.3% of patients (35 patients in gefitinib plus chemotherapy group and 46 patients in gefitinib group) had died. The 3-year OS rate was significantly higher in gefitinib plus chemotherapy group (47.4%, 95% CI 36.3-58.7) than in gefitinib group (24.9%, 95% CI 15.1-34.3, P = 0.003). And median overall survival was 35.0 months (95% CI, 28.8-41.3 months) in gefitinib plus chemotherapy group versus 28.9 months (95% CI, 23.4-34.4 months) in gefitinib group (HR = 0.66, 95% CI, 0.42-1.03, P = 0.065). Grade 3 or worse adverse events were more common in gefitinib plus chemotherapy group (40.0% versus 21.0%, P = 0.010), but most of them were manageable. **Conclusions:** Inuntreated EGFR mutated NSCLC patients with brain metastases, gefitinib plus chemotherapy significantly improved intracranial PFS, PFS and a tendency of OS than gefitinib alone, and could be the optional first-line treatment. Clinical trial information: NCT01951469. Research Sponsor: None.

9096 **Poster Session**

Aumolertinib activity in patients with CNS metastases and EGFR-mutated NSCLC treated in the randomized double-blind phase III trial (AENEAS). *First Author: Shun Lu, Shanghai Chest Hospital, Jiao Tong University, Shanghai, China*

Background: We previously reported (Lu, ASCO 2021, abstract # 9013) that treatment with aumolertinib (Au), a 3rd generation EGFR TKI, led to robust improvement in progression free survival (PFS) (median PFS 19.3 to 9.9 months, HR = 0.46, p < 0.0001) when compared to gefitinib (G) with a predictable and encouraging safety profile. This benefit was maintained across all prespecified stratification factors including the subset of ~ 27% of patients (pts) with CNS metastases (HR = 0.38). Here we undertook this analysis to more fully characterize the activity and benefit of Au as compared to G in this clinically important subset of EGFR mutant NSCLC pts. **Methods:** Pts with previously untreated metastatic or locally advanced NSCLC with EGFR sensitizing mutations were enrolled and randomly assigned in a 1:1 ratio to receive either Au (110 mg QD) or G (250 mg QD). Predefined stratification factors were EGFR-mutated status (Ex19del vs L858R) and CNS metastases (yes vs no). Patients with stable, asymptomatic CNS metastases were eligible for enrollment. All pts had baseline brain imaging by magnetic resonance imaging or computed tomography. The primary endpoint was PFS assessed by investigator per RECIST v1.1 in full analysis set (systemic analysis). Independent CNS efficacy was performed both in pts with baseline CNS metastases (CNS full analysis set, cFAS) and in pts with baseline CNS target lesions (CNS evaluable-for-response set, cEFS) by blinded independent central neuroradiology review (BICR) per RECIST v1.1. **Results:** Of 429 pts, 106 pts (Au, n = 51; G, n = 55) were found to have CNS metastases (cFAS) and 61 pts (Au, n = 29; G, n = 32) had CNS target lesions as defined by RECIST 1.1 (cEFS) at baseline by BICR. At the cutoff date (Aug 6, 2021), based on cEFS, CNS PFS events were observed in 11 pts (38%) treated with Au versus 20 pts (63%) who were randomized to receive G. Treatment with Au significantly prolonged CNS median PFS compared with G (29.0 vs 8.3 months; HR = 0.300; 95% CI, 0.137-0.657; *P* = 0.0015). Estimated CNS PFS rate at 12 and 18 months were 71% and 62% in Au arm compared with 23% and 0% in G arm. The confirmed CNS ORR were 82.8% and 75.0% in pts treated with Au and G, respectively (odds ratio = 1.600; 95% CI, 0.457-5.597; *P* = 0.4621). Au also achieved longer CNS median PFS over G in cFAS (29.0 vs 8.3 months; HR = 0.323; 95% CI, 0.181-0.576; *P* < 0.0001). No new safety findings were observed. **Conclusions:** Au demonstrated superior clinical efficacy against CNS metastases over G as first-line therapy in EGFR-mutated advanced NSCLC, and the safety profile was consistent with that reported previously. Additional randomized studies of Au in pts with CNS metastases are ongoing (NCT04870190). Clinical trial information: NCT03849768. Research Sponsor: Hansoh Pharmaceutical Group Co. Ltd.

9097 **Poster Session**

A phase II study of osimertinib in combination with platinum plus pemetrexed in patients with EGFR-mutated, advanced non–small cell lung cancer: The OPAL study (NEJ032C/LOGIK1801). *First Author: Atsushi Nakamura, Department of Pulmonary Medicine, Sendai Kousei Hospital, Sendai, Japan*

Background: Osimertinib (OSI), a third-generation EGFR-tyrosine kinase inhibitor (EGFR-TKI), is now a standard treatment for previously untreated EGFR-mutated (EGFRm) advanced non-small cell lung cancer (NSCLC). In the two randomized phase 3 studies, progression-free survival (PFS) and overall survival were statistically significant and clinically longer with gefitinib and platinum-based chemotherapy compared with gefitinib monotherapy. Based on these data, we have planned this phase 2 study to evaluate the safety and efficacy of OSI combined with platinum-based chemotherapy. **Patients and Methods:** This multicenter phase 2 study enrolled patients (pts) with clinical stage IIIB, IIIC, IVA, IVB or postoperative recurrent, previously untreated EGFRm NSCLC. Pts received oral OSI 80mg once daily (QD), with either cisplatin 75mg/m2 (arm A) or carboplatin [area under the curve (AUC) = 5, arm B], plus pemetrexed (PEM) 500 mg/ m2 every 3 weeks (Q3W) for four cycles. In both arms, maintenance was OSI 80mg QD with PEM 500 mg/ m2 Q3W until disease progression or discontinuation. The co-primary endpoints were the safety and the objective response rate (ORR), and the secondary endpoints included the complete response rate (CRR), disease control rate (DCR), and PFS. **Results:** From July 2019 to February 2020, 67 pts (34 pts in Arm A; 33 pts in arm B) were enrolled: median (range) age 67 (26-75) years; 43 (64.2%) female; 46 (68.7%) ECOG PS 0; 66 (98.5%) adenocarcinoma; 31 (46.3%) EGFR exon19 deletion, 35 (52.2) L858R, and 1 (1.5%) both. One pt did not comply with the eligibility criteria and was excluded from the efficacy analysis. At data cut off (August 31, 2021), 27 (40.3%) pts [15 (44.1%) in arm A and 12 (36.4%) in arm B] had discontinued the protocol treatment, including 9 (13.4%) pts [5 (14.7%) in arm A and 4 (12.1%) in arm B] due to the adverse event (AE). The rate of grade (G) ≥ 3 AEs were 91.0% (88.2% in arm A and 93.9% in arm B). For the safety, neutropenia, anemia and thromobocytopenia were numerically higher in arm B and the rates of G ≥ 3 were 29.4%/60.6%, 14.7%/27.3% and 0.0%/42.4% in arm A/B, respectively. G ≥ 3 QTc interval prolonged and G ≥ 2 anorexia were observed in 14.7%/21.2% and 26.5%/24.2%, respectively. For the efficacy, the ORR was 90.9% [95% confidence interval (CI); 84.0-97.8%]. The CRR/DCR were 3.0%/97.0% (95% CI; 0.0-7.2%/92.8%-100.0%), respectively. At a median follow-up time of 21.4 months (range, 18.2-25.7), median PFS was not reached in both A and B, with an estimated 12-/24-months PFS rate of 90.4%/70.0%. **Conclusions:** OSI combined with platinum-based chemotherapy for previously untreated EGFRm advanced NSCLC showed the excellent efficacy with tolerable toxicity. This combination treatment is highly promising and should be validated in the phase 3 study. Clinical trial information: jRCTs031180226. Research Sponsor: Astrazeneca.

9098 **Poster Session**

Efficacy and safety of rezivertinib (BPI-7711) in patients with locally advanced or metastatic/recurrent EGFR T790M-mutated NSCLC: A phase IIb, multicenter, single-arm, open-label study. *First Author: Shiman Wu, The First Hospital of Shanxi Medical University, Taiyuan, China*

Background: Rezivertinib (BPI-7711) is a third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) targeting both EGFR-sensitizing mutations and EGFR T790M mutation. This study aimed to evaluate the efficacy and safety of Rezivertinib in patients with locally advanced or metastatic/recurrent EGFR T790M mutated non-small cell lung cancer (NSCLC). **Methods:** Locally advanced or metastatic/recurrent NSCLC patients with histologic or cytologic or plasmatic confirmation of EGFR T790M mutations who progressed after first/second generation EGFR-TKIs therapy or primary EGFR T790M mutations were enrolled. Patients received Rezivertinib at 180mg orally once daily until disease progression, unacceptable toxicity, or withdrawal of consent. The primary endpoint was objective response rate (ORR) assessed by blinded independent central review (BICR) per RECIST1.1. The efficacy for patients with central nervous system (CNS) metastases was measured by BICR according to the Response Assessment in Neuro-Oncology Brain Metastases. Secondary endpoints included disease control rate (DCR), duration of response (DoR), progression-free survival (PFS), overall survival (OS) and safety. Safety was assessed as per CTCAE 4.03. **Results:** A total of 226 patients were enrolled from Jul 5, 2019, to Jan 22, 2020. 91 (40.3%) patients had brain metastases. The tissue sample and plasma sample were positive for *EGFR* T790M in 120 (53.1%) and 116 (51.3%) patients, respectively. By the data cut-off date on Dec 23, 2021, the ORR by BICR was 64.6% (95%CI:58.0-70.8) and DCR was 89.8% (95%CI:85.1-93.4). The median DoR was 12.5 (95%CI:10.0-13.9) months and median PFS was 12.2 (95%CI:9.6-13.9) months. The median OS was 23.9 (95%CI:20.0-NC) months. Subgroup ORR: exon 19 deletion 72.4% (95%CI:64.4-79.5), L858R 51.9% (95%CI:40.4-63.3), tissue T790M positive 70% (95%CI:61.0-78.0), plasma T790M positive 56.9% (95%CI:47.4-66.1). Subgroup PFS: exon 19 deletion 12.4 (95%CI:8.8-15.1) months, L858R 10.3 (95%CI:8.3-13.9) months, tissue T790M positive 13.9 (95%CI:11.3-17.9) months, plasma T790M positive 9.6 (95%CI:7.0-11.0) months. Among 91 patients with CNS metastases, 29 patients had at least one brain target lesion whose CNS-ORR and CNS-DCR were 69.0% (95%CI:49.2-84.7) and 100% (95%CI:88.1-100), respectively. Time to progression of CNS was 16.5 (95%CI:9.7-NC) months. 188 of 226 (83.2%) patients had at least one adverse drug reaction, with the most common being white blood cell count decreased (27.9%), platelet count decreased (23.0%), anemia (22.6%). No interstitial lung disease was reported. **Conclusions:** Rezivertinib demonstrated promising efficacy and favorable safety for locally advanced or metastatic/recurrent NSCLC patients with EGFR T790M mutation. Clinical trial information: NCT003812809. Research Sponsor: Beta Pharma (Shanghai) Co., Ltd.

9099 **Poster Session**

Mobocertinib (TAK-788) in *EGFR* exon 20 insertion (ex20ins)+ metastatic non–small cell lung cancer (mNSCLC): Treatment (tx) beyond progressive disease (PD) in platinum-pretreated patients (pts) with and without intracranial PD. *First Author: Pasi A. Janne, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Mobocertinib is a potent, irreversible, oral tyrosine kinase inhibitor selectively targeting *EGFR* ex20ins in NSCLC. Mobocertinib demonstrated clinical efficacy in 114 platinum-pretreated pts (PPP) with *EGFR* ex20ins+ mNSCLC in a phase 1/2 study. **Methods:** In this study (NCT02716116), pts with ECOG status 0–1 and ≥1 prior therapy line for locally advanced/metastatic *EGFR* ex20ins+ NSCLC received mobocertinib 160 mg QD. Pts were allowed to continue tx beyond PD at the discretion of the investigator (INV) if evidence of clinical benefit existed. We present data on continuation of mobocertinib tx beyond PD in the PPP cohort by site of first PD (brain vs extracranial). **Results:** At the November 1, 2020, data cutoff, among PPP (n=114; median age 60 y, 66% female, 60% Asian), 59% had ≥2 prior systemic anticancer lines; 35% had baseline brain metastases (Zhou C, et al. *JAMA Oncol.* 2021;7(12):e214761. doi:10.1001/jamaoncol.2021). Confirmed objective response rate (cORR) per independent review committee (IRC) was 28%; median duration of response was 17.5 mo. IRC-assessed cORR was 34% among PPP with no baseline brain metastases versus 18% among PPP with baseline brain metastases (Zhou C, et al. *JAMA Oncol.* 2021;7(12):e214761. doi:10.1001/jamaoncol.2021); median progression-free survival was 9.2 and 3.7 mo, respectively. Per INV assessment, 64 pts had PD. Duration of mobocertinib tx beyond PD is summarized in the Table. Among pts with first site of PD in brain per INV (n=21), 17 (81%) pts remained on mobocertinib tx beyond PD; 7 (33%) received radiotherapy to brain and remained on mobocertinib tx, of whom 3 pts remained on mobocertinib tx for ≥6 mo and 1 pt for ≥12 mo. Among pts with first site of PD outside the brain per INV (n=43), 28 (65%) pts continued tx beyond PD and 4 (9%) pts remained on mobocertinib tx for ≥6 mo. **Conclusions:** These results suggest that mobocertinib may have limited intracranial activity given the high frequency of first PD in brain (25%) and numerically lower IRC-assessed cORR in pts with baseline brain metastases. Per INV assessment, pts may derive ongoing systemic benefit from mobocertinib. Duration of time to next progression based on local therapy continues to be investigated. Clinical trial information: NCT02716116. Research Sponsor: Sponsored by Takeda Development Center Americas, Inc.

INV Assessment	First Site of PD in Brain (n=21)	Extracranial First Site of PD (n=43)
Pts remaining on tx after PD per INV, n (%)	17 (81)	28 (65)
Median time on tx after PD, mo (range)	2.8 (0.2, 15.4)	1.0 (0.1, 18.4)
≥3 mo, n (%)	8 (38)	7 (16)
≥6 mo, n (%)	4 (19)	4 (9)

INV, investigator; PD, progressive disease.

Identification of pretreatment genomic biomarkers and mechanisms of acquired resistance to first-line osimertinib in advanced *EGFR*-mutant lung cancers. *First Author: Noura J. Choudhury, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Despite its widespread use, few series explore genomic biomarkers that impact progression-free survival (PFS) for first line osimertinib use and how mechanisms of acquired resistance impact post-osimertinib progression survival. **Methods:** All pts treated with first line osimertinib at Memorial Sloan Kettering Cancer Center were identified; available pre-osimertinib and post-progression tumor samples underwent next-generation sequencing (NGS) using MSK-IMPACT. Real-world (rw)PFS was estimated with Kaplan-Meier methods from start of osimertinib to progression, defined using interpretation of imaging reports. Post-baseline factors were evaluated using time-dependent covariate Cox model. **Results:** We identified 331 pts, of which 67 had paired tumor samples and 28 had post-progression tumor samples that underwent MSK-IMPACT. Most pts with biopsies were women (68%), never smokers (83%) and did not have baseline brain metastases (56%). With median follow-up of 24 months (mo), median rwPFS was 14 mo (95% confidence interval (CI) 13 -17 mo, n = 331). *EGFR* driver alterations (n = 40 atypical, n = 108 L858R, n = 182 exon 19 deletion) were associated with distinct rwPFS (median 8 (95% CI 6-12), 14 (12-18) and 16 mo (13-21), respectively, $p < 0.001$ logrank test). Pts with concurrent pre-treatment *TP53* (14 mo,12-17) or *TP53/RB1* (12 mo, 9-15) alterations had shorter median rwPFS compared to pts without these alterations (20 mo,16-24, $p < 0.001$, logrank test). Fifty patients (53%) had an identified mechanism of resistance. Off target mechanisms (n = 9 *MET* amplification (amp), n = 3 *HER2* amp, n = 3 *PIK3CA* mutations, n = 3 acquired fusions, n = 2 *RB1* loss and n = 1 *CCND1* amp, *MYC* amp, *CDK4* amp, *KRAS* G12A, respectively) and histological transformation (n = 7 small cell, n = 5 squamous and n = 2 large cell neuroendocrine) were detected. On target acquired mechanisms were *EGFR* amplification (n = 7), and G724S (n = 2) and C797S (n = 3) mutations. Pts with an identified mechanism of resistance did not have improved post-progression survival (12 mo HR 1.6, p = 0.09), but receiving next line of therapy based on post-progression tumor biopsy results (including platinum-etoposide for transformation) did improve post-progression survival (12 mo HR 0.4, p = 0.01). **Conclusions:** Pts with atypical *EGFR* drivers or concurrent *TP53+/-RB1* alterations have significantly shorter rwPFS on first line osimertinib, highlighting need for additional interventions for these patients. Given the high frequency of transformation and improvement in post-progression survival by tailoring next line of therapy to the identified mechanism, pts with *EGFR*-mutant lung cancer on first line osimertinib may benefit from tissue biopsies at progression. For pts without an identified resistance mechanism by NGS, additional methods of interrogating tumors at progression are needed. Central nervous system efficacy of furmonertinib versus gefitinib in patients with non–small cell lung cancer with epidermal growth factor receptor mutations: Results from FURLONG study. *First Author: Gongyan Chen, Department of Respiration, Harbin Medical University Cancer Hospital, Harbin, China*

Background: Furmonertinib (AST2818) is a third-generation epidermal growth factor receptor (*EGFR*) tyrosine kinase inhibitor (TKI) with central nervous system (CNS) penetration. Here we report the CNS response to furmonertinib versus gefitinib as first-line therapy in *EGFR*-mutated non-small cell lung cancer (NSCLC) patients in the FURLONG study. **Methods:** FURLONG was a randomized, double-blind, multi-center phase III study. Patients were randomized 1:1 to receive first-line furmonertinib 80mg/d or gefitinib 250mg/d. Brain scan was mandatory at screening. Patients with asymptomatic CNS metastases who did not require steroid treatment for 28 days or more were enrolled. A pre-planned CNS efficacy analysis was done using RECIST v1.1 in patients with measurable or non-measurable CNS lesions (cFAS) and patients with only measurable CNS lesions (cEFR). **Results:** Of 358 enrolled patients in the FURLONG study, 133 (37%) patients were defined as cFAS and 60 (17%) were defined as cEFR according to baseline brain scan judged by a blinded independent review committee (IRC). At the cut-off date of Sep 15, 2021, CNS progression-free survival (PFS) assessed by IRC in the cFAS population was significantly longer in the furmonertinib group than in the gefitinib group (20.8 vs 9.8 months, HR 0.40 [95% 0.23-0.71]; p = 0.0011). CNS PFS rate at 6, 12, 18 months were 91%, 77%, 63% in the furmonertinib group, and 76%, 46%, 34% in the gefitinib group. In the cEFR set, confirmed CNS objective response rate was 91% in patients with furmonertinib and 65% in patients with gefitinib (p = 0.0277), and CNS disease control rate were 100% vs 84% (p = 0.9420), respectively. The mean best percentage change in the sum of target CNS lesion size from baseline in cEFR was -61.8% in the furmonertinib group versus -38.7% in the gefitinib group (p = 0.0011). **Conclusions:** Furmonertinib showed CNS efficacy as first-line therapy in EGFR-mutated NSCLC patients with CNS lesions. Patients treated with furmonertinib had a reduced risk of CNS progression or death, a higher CNS ORR and a deeper CNS response compared with gefitinib. Clinical trial information: NCT03787992. Research Sponsor: Shanghai Allist Pharmaceuticals Co., Ltd, China National Major Project for New Drug Innovation (2017ZX09304015).

Mefatinib as first-line treatment of patients with advanced non–small cell lung cancer harboring rare EGFR mutations. *First Author: Pingli Wang, Department of Respiratory Medicine, The Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China*

Background: Mefatinib is a novel, second-generation, irreversible epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI). A Phase Ib/II study has showed promising efficacy in patients with advanced EGFR (19del/L858R) mutant non-small cell lung cancer (NSCLC). This study is aimed to assess the efficacy and safety of mefatinib as first-line therapy for advanced rare EGFR mutations (G719X/S768I/L861Q) NSCLC. **Methods:** In this phase II study, we enrolled patients with stage IIIB-IV lung adenocarcinoma with at least one mutation in G719X, L861Q, and S768I who hadn¡t received front-line anticancer therapy. Other concurrent EGFR mutations were allowed with the exception of Ex19del, L858R, and exon 20 insertions. Eligible patients were treated with mefatinib 80 mg orally once daily. The primary endpoint was objective response rate (ORR) according to RECIST 1.1 criteria. **Results:** A total of 21 patients (median age 57.6, 47.62% male) have been enrolled, 80.95% with G719X, 33.3% S768I, and 19.05% L861Q. Six (28.57%) patients had concurrent mutations of G719X and S768I, and one (4.76%) patient had co-mutations of G719X and L861Q. As of data cut-off (Jan, 6, 2022), median follow-up was 25.1 months. Among the 21 efficacy evaluable patients, ORR was 85.71% (95% CI, 63.66-96.95) with a duration of response (DOR) of 22.2 months (95% CI, 8.4-NA). Disease control rate (DCR) was 100% (95% CI, 83.89-100.00). Median progression-free survival (mPFS) was 20.6 months (95% CI, 8.3-NA). Median overall survival (OS) was not reached.. The most common treatment-related adverse events (TRAEs) were rash (20, 95.24%), diarrhea (19, 90.48%), stomatitis (15, 71.43%), and pandactilitis (9, 42.86%). Grade 3 TRAEs were reported in 47.63% patients. Common Grade 3 TRAEs (¡Ý5%) included diarrhea (8, 38.10%) and rash (5, 23.81%). No ¡ÝGrade 4 TRAE or treatment-related SAE reported. 33.33% (n=7) of patients experienced dose reduction due to AEs (mainly diarrhea and rash). All TRAEs were reversible and remained stable or recovered without sequelae after dose reduction. None of the patients discontinued treatment or died due to TRAE. **Conclusions:** Mefatinib has shown promising anti-tumor activity and a favorable safety profile in patients with advanced NSCLC harboring rare EGFR mutations. Clinical trial information: CTR20190110. Research Sponsor: HangZhou ZhongMei HuaDong Pharmaceutical Company.

Co-occurring gene alterations associated with efficacy of osimertinib in EGFR-mutated lung cancer: Based on a large-scale genomic screening project (LC-SCRUM-Asia). *First Author: Yuji Shibata, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Osimertinib is a standard drug for first-line treatment of patients with advanced non–small cell lung cancer (NSCLC) harboring EGFR mutations (mt). While tumor mutational burden (TMB)-high and co-occurring genetic alterations (alt) have been reported to be negatively associated with the efficacy of other EGFR-TKIs, the impact of co-occurring genetic alt with EGFR major mt on the efficacy of osimertinib remains unclear. **Methods:** In a multi-institutional genomic screening project (LC-SCRUM-Asia), we have analyzed lung cancer patients for genomic alt by a targeted next-generation sequencing (NGS) system, Oncomine Comprehensive Assay and Genexus/OPA. We retrospectively evaluated the association between the genomic profile and efficacy of first-line osimertinib for EGFR-mutated NSCLC based on the LC-SCRUM-Asia database. **Results:** Between March 2015 and January 2022, 12,705 NSCLC patients were enrolled in the LC-SCRUM-Asia database, and EGFR mt was detected in 2,232 patients. Of these, 324 patients, including 171 with ex19del (53%) and 153 with L858R (47%), received first-line treatment with osimertinib. The patient characteristics were as follows: median age, 69 years (range 31-97); females, 64%; never-smokers, 57%; adenocarcinoma, 97%; and performance status 0-1, 99%. The frequency of compound EGFR mt and TMB were higher in the L858R (LR) group than in the ex19del (Ex19) group (compound mt (%), 12 vs. 4; mean TMB (mt/Mb), 3.4 vs. 2.5). There were no differences in the frequencies of other co-occurring genetic alt between the two groups. Higher TMB, alt of genes encoding receptor tyrosine kinase (RTK), including FGFR1, RET, MET etc., and amp of cell-cycle related genes were significantly associated with shorter progression-free survival (PFS) in the entire group (median PFS: TMB > 3 vs. ≤3 mt/Mb = 11.4 vs. 17.1 months; p = 0.023; RTK gene alt+ vs. alt- = 9.7 vs. 15.2 months; p = 0.014; cell-cycle gene amp+ vs. amp- = 10.6 vs. 15.6 months, p = 0.001). EGFR subgroup analysis showed that a higher TMB was significantly associated with a shorter PFS in the LR group (> 3 vs. ≤3 mt/Mb = 10.0 vs. 17.1 months, p < 0.001), but not in the Ex19 group. On the other hand, alt of genes encoding RTK and amp of cell-cycle related genes were significantly associated with a shorter PFS in the Ex19 group (RTK gene alt+ vs. alt- = 8.4 vs. 17.8 months, p = 0.008; cell-cycle gene amp+ vs. amp- = 10.6 vs. 17.5 months, p = 0.003), but not in the LR group. Multivariate analysis identified RTK gene alt in the Ex19 group and higher TMB in the LR group as being independently associated with a shorter PFS. **Conclusions:** First-line osimertinib treatment was less effective in NSCLC patients harboring Ex19 with other RTK gene alt or LR with a higher TMB, indicating that co-occurring genetic alt affecting the efficacy of osimertinib differ between NSCLC patients harboring Ex19 and LR. Research Sponsor: Japan Agency for Medical Research and Development.

Results of a phase 1b study of osimertinib plus sapanisertib or alisertib for osimertinib-resistant, EGFR-mutant non–small cell lung cancer (NSCLC). *First Author: Yasir Y Elamin, Department of Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The aurora kinase and mTOR pathways are implicated in resistance to EGFR inhibitor osimertinib. Here, we investigated the safety and efficacy of the aurora kinase inhibitor alisertib and the mTOR inhibitor sapanisertib in combination with osimertinib. **Methods:** This is a phase 1b study with dose finding and expansion portions (NCT04479306). The dose finding portion used a Bayesian optimal interval (BOIN) design to assess two arms: osimertinib 80 mg daily in combination with alisertib 20 mg, 30 mg, and 40 mg daily day 1-21 of 28-day cycle (osi-ali arm) and osimertinib 80 mg daily in combination with sapanisertib 2 mg and 3 mg daily (osi-sapa arm). Dose limiting toxicities (DLTs) were predefined in the protocol. Patients with EGFR (L858R/exon 19 deletion) mutant NSCLC whose disease have progressed on osi and up to one additional line of systemic therapy were assigned, at investigator discretion, to either study arm. Tumor biopsy was mandatory at study entry and optional upon progression. **Results:** As of February 1, 2022, 40 patients are enrolled (20 in each arm). One DLT was observed in each arm: grade 3 nausea in ali-osi arm and grade 3 AST elevation in osi-sapa arm. Grade 3 treatment emergent adverse events (TEAEs) occurred in 10% of each arm, and no grade 4 TEAEs were observed. The most common TEAEs in osi-ali arm was leucopenia (45%) and anemia (35%) while in osi-sapa arm, hyperglycemia (45%) and stomatitis (40%). In osi-ali arm (n = 20), median progression free survival (mPFS) was 1.9 months while objective response rate (ORR) and disease control rate (DCR) were 5% (95% CI: 0.1 ~ 24.9%) and 40% (95% CI: 19.1 ~ 63.9%), respectively. In osi-sapa arm (n = 16, evaluated for response to date), mPFS was 4.6 months while ORR and DCR were 12.5% (95% CI: 1.6 ~ 38.3%) and 68.7% (95% CI: 35.7 ~ 82.7%), respectively. **Conclusions:** Osimertinib with alisertib or sapanisertib is well tolerated in osimertinib-resistant, EGFR mutant NSCLC. The sapanisertib combination, but not the alisertib combination, demonstrates antitumor activity suggesting that mTOR inhibition warrants further exploration in this population. Biomarker analysis is ongoing to identify the molecular determinants of response and resistance to sapasertib. Clinical trial information: NCT04479306. Research Sponsor: Takeda.

Efficacy and safety of ASK120067 (limertinib) in patients with locally advanced or metastatic EGFR T790M-mutated non–small cell lung cancer: A multicenter, single-arm, phase IIb study. *First Author: Baolan Li, Beijing Chest Hospital, Beijing, China*

Background: ASK120067 (Limertinib) is a newly developed third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) targeting both sensitizing *EGFR* and *EGFR* T790M mutations. This study aimed to evaluate the efficacy and safety of ASK120067 in patients with locally advanced or metastatic *EGFR* T790M mutated non-small cell lung cancer (NSCLC). **Methods:** This study was a single-arm, open-label, phase 2b study conducted at 62 hospitals across China. Patients with locally advanced or metastatic NSCLC with centrally confirmed *EGFR* T790M mutations in tumor tissue or blood plasma who progressed after first or second generation EGFR TKIs or with primary *EGFR* T790M mutations were enrolled. Patients received ASK120067 160mg orally twice daily, until disease progression, or unacceptable toxicity. The primary endpoint was objective response rate (ORR) assessed by Independent Review Committee (IRC) per RECIST1.1. Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), duration of response (DOR), overall survival (OS), and safety. Safety was assessed according to CTCAE 4.03. **Results:** Between June 24th, 2019 and Feb 25th, 2021 301 patients were enrolled and received ASK120067 treatment. All patients entered the full analysis set (FAS) and safety set (SS). A total of 99 (32.9%) patients had central nervous system (CNS) metastases at baseline. By the data cutoff date on Sep 9th, 2021, 76 (25.2%) remained on treatment. The median follow-up time was10.4 (range 0.3-26.3) months. Based on FAS, the IRC-assessed ORR was 68.8% (95%CI 63.2%-74.0%) and DCR was 92.4% (95%CI 88.8%-95.1%). The median PFS was 11.0 (95%CI 9.7-12.4) months, median DOR was 11.1 (95%CI 9.6-13.8) months, and median OS was not reached (NR) (95%CI 19.7 months-NR). Objective responses were achieved across all pre-specified subgroups. For 99 patients with CNS metastases, the ORR was 64.6% (95%CI 54.4%-74.0%), median PFS was 9.7 (95%CI 5.9-11.6) months, and median DOR was 9.6 (95%CI 8.1-15.2) months. For 41 patients who had evaluable CNS lesion, the confirmed CNS-ORR was 56.1% (95%CI, 39.7%-71.5%) and median CNS-PFS was 10.6 (95%CI 5.6-NE) months. In SS, 289 (96.0%) patients experienced at least one adverse drug reaction (ADR), with the most common being diarrhea (81.7%), anemia (32.6%), rash (29.9%) and appetite decrease (28.2%). Grade ≥3 ADRs occurred in 104 (34.6%) patients, and the most common included diarrhea (13.0%), hypokalemia (4.3%), anemia (4.0%) and rash (3.3%). ADRs leading to dose interruption and dose discontinuation occurred 24.6% and 2% of patients, respectively. No ADR leading to death occurred. **Conclusions:** ASK120067 demonstrated promising efficacy and an acceptable safety profile for the treatment of patients with locally advanced or metastatic *EGFR* T790M mutated NSCLC. Clinical trial information: NCT03502850. Research Sponsor: Jiangsu Aosaikang Pharmaceutical Co. Ltd.

9107 **Poster Session**

A randomized phase II study comparing erlotinib with or without bevacizumab in patients with advanced non–small cell lung cancer (NSCLC) with *EGFR* mutation. *First Author: Youngjoo Lee, National Cancer Center, Goyang, South Korea*

Background: Synergistic anti-tumor effect of double blocking EGFR and VEGF pathways is proven by preclinical and clinical data. This study evaluated whether an addition of bevacizumab to erlotinib improves clinical outcomes in patients (pts) with untreated advanced *EGFR*-mutated NSCLC. **Methods:** This is an open-label, multi-center, randomized phase II study conducted in South Korea. Key eligibility was age ≥ 19 years old, untreated stage IIIB/IV NSCLC, *EGFR* exon 19 deletion or exon 21 L858R mutation, and ECOG performance status of 0 or 1. Asymptomatic brain metastasis (BM) was permitted without local treatment. Pts were randomly assigned to receive either oral erlotinib (E) 150 mg/day alone or erlotinib plus bevacizumab (E+B) at 15 mg/kg intravenously every 3 weeks. Primary endpoint was progression-free survival (PFS) with secondary endpoints including response rate (RR), overall survival (OS), and toxicity. **Results:** Between Dec 16, 2016, and Mar 8, 2019, a total of 127 pts were randomly assigned to receive E (n=63) or E+B (n=64). Median follow-up duration was 38.9 months. Fifty-nine (46.5%) pts had baseline BM. While the prevalence of baseline BM was similar between both arms (45.3% vs. 47.6%), more pts of the E arm received radiotherapy for BM before the study enrollment, compared to the E+B arm (40.0% vs. 10.3%). A trend toward improved PFS was observed with the E+B arm compared to the E arm (median PFS, 17.5 months vs 12.4 months; hazard ratio [HR] = 0.74 [95% confidence interval (CI), 0.51–1.08], *P*= 0.119). The RR was similar between both arms (85.9% vs. 83.9%; *P*= 0.746). The most significant PFS benefit from the E+B was found in the subgroup with baseline BM (median PFS, 18.6 months vs 10.3 months; HR = 0.54 [95% CI, 0.31–0.95], *P*= 0.032). The 12-month and 24-month cumulative central nervous system (CNS) progression rate was 4.4% and 6.8% in the E+B arm compared to 15.1% and 32.5% in the E arm. Thus, the E+B arm significantly reduced the risk for CNS progression than the E arm (HR = 0.33 [95% CI, 0.11–0.93], *P*= 0.035). Grade 3 or worse adverse events occurred in 56.6% of the E+B arm while 20.6% of the E arm. The E+B arm tended to increase the incidence or severity of some erlotinib-related adverse effects: grade 3 skin rash (17.2% vs. 4.8%) and any grade paronychia (60.9% vs. 46.0%), and oral mucositis (51.6% vs. 33.3). At the time of disease progression, more pts in the E arm showed *EGFR* T790M positivity (82% vs. 64%) and received 3rd generation EGFR tyrosine kinase inhibitor as the 2nd line therapy (58% vs. 22%) compared to the E+B arm. OS data are immature (events: 34%, HR = 1.24 [95% CI, 0.68–2.26]). **Conclusions:** A trend to improvement in PFS was observed with the combination of erlotinib and bevacizumab vs. erlotinib alone in advanced *EGFR*-mutated NSCLC. Especially, the PFS benefit from this combination was most significant in the pts with BM. Clinical trial information: NCT03126799. Research Sponsor: Roche Korea Inc.

9108 **Poster Session**

Molecular analysis of circulating tumor DNA (ctDNA) in patients (pts) with *EGFR* exon 20 insertion-positive (ex20ins+) advanced NSCLC treated with mobocertinib. *First Author: Sylvie Vincent, Takeda Development Center Americas, Inc., Lexington, MA*

Background: ctDNA is an important tool to diagnose and monitor mutations in pts with non–small cell lung cancer (NSCLC). We evaluated epidermal growth factor receptor gene (*EGFR)* ex20ins mutations in tumor vs plasma samples, assessed changes in *EGFR* ex20ins variant allele frequency (VAF) with mobocertinib treatment and correlation with response, and identified potential emerging variants of acquired resistance. **Methods:** Tumor tissue samples were collected at baseline (BL) from pts with *EGFR* ex20ins+ advanced NSCLC receiving mobocertinib 160 mg QD in a phase 1/2 study (NCT02716116); plasma samples were collected at BL, after 2 treatment cycles (Cycle 3, Day 1 [C3D1]) and at disease progression/end of treatment (DP/EOT). ctDNA samples were analyzed by next-generation sequencing for *EGFR* ex20ins to determine concordance rate detection between tissue and plasma ctDNA at BL. Changes in VAF for *EGFR* ex20ins from BL were analyzed at C3D1 and DP/EOT by confirmed response (RECIST v1.1) to mobocertinib per independent review committee. Emerging variants at DP/EOT were evaluated by elimination of germline variants seen in healthy populations (gnomAD databases and 1000 Genomes) and nonharmful variants predicted by PolyPhen and SIFT tools or annotated as benign in ClinVar database. **Results:** BL *EGFR* ex20ins mutations were detected by ctDNA sequencing in 29 of 38 pts (76%) with tissue-confirmed *EGFR* ex20ins+ NSCLC. VAFs for *EGFR* ex20ins significantly decreased at C3D1 in mobocertinib-treated pts with confirmed partial response (PR; *P*=0.0057) or stable disease (SD; *P*=0.0016), but not in pts with progressive disease (PD; *P*=0.14) (Table). ctDNA at EOT/DP analysis identified numerous genetic variants; *EGFR*, *TP53,* and *DNMT3A* were the most common genes with emerging variants. Twelve emerging missense mutations were identified in *EGFR* in 9 pts, including mutations located in the exon 20 loop following the C-helix (6), T790M (5), and D379E (1). **Conclusions:** Concordance between tissue and plasma ctDNA for *EGFR* ex20ins mutations at BL was 76%. *EGFR* ex20ins VAF decreased significantly after 2 treatment cycles in mobocertinib-treated patients with PR and SD. Plasma ctDNA longitudinal monitoring may be useful to assess mutation status and disease progression in pts with NSCLC treated with mobocertinib. Clinical trial information: NCT02716116. Research Sponsor: Takeda Development Center Americas, Inc., Lexington, MA, USA.

VAF by response to mobocertinib over time.

	Median VAF (%; IQR)		
Response	**BL**	**C3D1**	**DP/EOT**
PR (n=11)	2.75 (0.37–26.51)	0.01 (0.01–0.16)[a]	17.70 (12.73–30.61)
SD (n=35)	2.40 (1.08–17.33)	0.08 (0.01–2.17)[a]	3.47 (0.79–25.77)
PD (n=10)	3.86 (1.73–19.43)	0.30 (0.20–1.19)	1.32 (1.02–20.49)

IQR, interquartile range; PD, progressive disease. [a]*P*≤0.05 vs BL (Wilcoxon rank sum).

Uncommon EGFR mutations on osimertinib, real-life data (UNICORN study): Updated results, brain efficacy, and resistance mechanisms. *First Author: Jair Bar, Institute of Oncology, Sheba Medical Center, Ramat Gan, Israel*

Background: About 10% of EGFR mutations (EGFRm) are 'uncommon mutations' (ucEGFRm). osimertinib is a 3rd generation EGFRi, active against common EGFRm. We aimed to collect real-world data about systemic and brain response and resistance mechanisms to osimertinib for ucEGFRm patients. **Methods:** This is a multi-center, retrospective study of ucEGFRm mNSCLC treated with osimertinib as first EGFRi. RECIST and RANO-BM response was evaluated by investigators. Progression free survival (PFS), overall survival (OS) and duration of response (DOR) were calculated from initiation of osimertinib. Mutations found at resistance were collected. **Results:** 62 patients (pts) were identified in 22 centers from 9 countries. Median age was 64 (35-91) years, 74% females, 84% Caucasian, never/former/current smokers were 48%/39%/11% respectively, ECOG PS was 0-1/2/3-4 in 84%/10%/5%. Histology was adenocarcinoma in 97%. The largest subgroups were G719X, de novo T790M and L861Q (Table). Compound EGFR mutations were found in 27 pts (44%), TP53 mutations in 21 pts (34%). In 17 cases (27%), compound mutations included the common L858R/deletion19 and/or de novo T790M. Most frequent metastatic sites were lung/bone/brain in 45%/44%/39%. Most frequent toxicities were gastrointestinal (32 pts, 52%) and skin (24 pts, 39%); 8 pts had grade 3-4 AEs. No grade 5 AE occurred. 3 pts had AEs leading to discontinuation. RECIST response (RR) was available for 53 pts, CR - 4 (8%), PR - 27 (51%), SD - 17 (32%), and PD - 5 (9%). Median DOR (mDOR) was 17.4 months (95% CI 9.1-NA). mPFS was 9.5 months (95% CI 8.5–17.4). mOS was 24.5 months (95% CI 17.4-35.1). See Table for efficacy in the major subgroups. 24 pts (39%) had brain metastasis at presentation, for 12 pts a brain response by RANO-BM was available with 25%/25%/33%/17% CR/PR/SD/PD. For 14 pts, rebiopsy mutation analysis at progression on osimertinib was available: 3 pts with an additional EGFR mutation (C797S,D585Y, E709K), 3 pts with a new TP53 mutation, 1 with c-Met amplification and 1 pt with transformation to neuroendocrine carcinoma. **Conclusions:** Osimertinib demonstrated activity in ucEGFRm with 91% disease control rate and encouraging PFS and DOR. Brain response was seen in 50% of cases. Several resistance mechanisms were identified. This report comprises, to the best of our knowledge, the largest dataset of osimertinib as the first EGFRi for ucEGFRm presented so far. Research Sponsor: AstraZeneca.

NEJ043: A phase 2 study of atezolizumab (atezo) plus bevacizumab (bev) plus carboplatin (carbo) plus paclitaxel (pac; ABCP) for previously treated patients with NSCLC harboring *EGFR* mutations (EGFRm). *First Author: Naoki Furuya, Division of Respiratory Medicine, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, OH, Japan*

Background: Previous studies have demonstrated poor clinical outcomes of patients (pts) with EGFRm NSCLC treated with PD-1/PD-L1 inhibitors. However, a recent subgroup analysis of the IMpower150 trial suggested the effectiveness of ABCP in NSCLC with EGFRm. The aim of this study is to further evaluate efficacy and safety of ABCP in patients with EGFRm NSCLC. **Methods:** This single-arm multicenter phase 2 study included pts with nonsquamous NSCLC harboring sensitizing EGFRm with prior EGFR-TKI therapy. Pts received the combination dose of atezo 1200 mg, bev 15 mg/kg, carbo AUC 6 mg/mL/min and pac 175 mg/m^2 every 3 weeks up to 4 cycles followed by atezo plus bev until loss of clinical benefit. The primary endpoint was PFS by extramural review (ER). The key secondary endpoints included OS, ORR, DoR, relative dose intensity of pac, and safety. **Results:** 60 pts were enrolled (median age 68 y [40–74 y], 67% were female, 55% were Ex19del and 40% were L858R). At data cutoff (November 30, 2021), median follow-up was 12.8 months in the ITT population. Median cycles of induction and maintenance therapy were 4 and 9, respectively. Median PFS was 7.4 month (95% CI, 5.7-8.2) and median OS was 18.9 month (95% CI, 13-not reached). Confirmed ORR by ER was 56% (95% CI, 43-69) and median DoR was 7.1 months (95% CI, 4.9-9.8). T790M was associated with a favorable PFS and response to the combination therapy (PFS 8.1 vs 6.8, ORR 71% vs 50%). Relative dose intensity of pac was 84%. Grade ≥3 adverse events (AEs) were reported in 92% of pts and the most common grade ≥3 AE was neutropenia (63%). Interstitial lung disease occurred in one patient (2%). AEs leading to treatment discontinuation occurred in 12% of pts. **Conclusions:** NEJ043 study showed that the median PFS of ABCP was 7.4 months with good tolerability. We will continue to investigate the tail plateau phenomenon of PFS and OS to conclude the clinical efficacy. Clinical trial information: 031190066. Research Sponsor: Chugai Pharmaceutical.

Final progression-free survival analysis of phase II study with the combination therapy of DFP-14323, protease inhibitor, and low-dose afatinib as first-line therapy for common *EGFR* mutation–positive NSCLC. *First Author: Hiroshige Yoshioka, Department of Thoracic Oncology, Kansai Medical University Hospital, Osaka, Japan*

Background: DFP-14323(INN: ubenimex) was developed as a biological response modifier and has been approved for maintenance therapy of AML in Japan. Ubenimex is an inhibitor of aminopeptidase N (APN), originated from *Streptomyces olivoreticuli*. APN is well known as one of the prognostic factors for several cancer types, including non-small-cell lung cancer (NSCLC). Meanwhile, afatinib is one of the standard treatments in NSCLC with *EGFR* mutation, but the toxicities often require dose reduction. Recently, it is suggested that reducing afatinib doses can decrease treatment-related adverse events without affecting efficacy. We aimed to examine efficacy of DFP-14323 with low-dose afatinib by conducting phase II study in patients with metastatic NSCLC harboring *EGFR* mutation. **Methods:** The study was a multi-center, single-arm, open-label phase II trial. Stage III/IV and treatment-naïve patients with common *EGFR* mutation-positive (L858R/19del) NSCLC were treated with DFP-14323 at a fixed dose of 10mg/day and afatinib at a starting dose of 20 mg/day until disease progression or intolerable toxicity. The primary endpoint was disease control rate (DCR), defined by sum the CR, PR and SD. The secondary endpoints were progression-free survival(PFS), overall response rate(ORR), N/L ratio, and safety. A sample size of 26 patients was determined, assuming a threshold DCR 70% and an expected DCR 90% with a two sided α error of 0.05 and a β error of 0.20, based on the Simon's two stage design. **Results:** From July 2018 to March 2020, 26 patients were enrolled. A median age was 72 years (range, 53-82), 21(81%) were female, and 16 (62%) were never-smokers. Half of patients had Del-19 and other half had L858R. An efficacy analysis provided a DCR of 100% (previously reported) with 18 responders (ORR : 69%). Independent imaging evaluation at 72 weeks provided a median PFS was confirmed to be 16.6mts (95% CI 10.2, 22.9, median follow-up time for censored cases: 16.3mts). According to updated exploratory follow-up by physicians, as of the data cut-off of Dec 2021, median PFS was calculated 20.6 mts (95% CI, 12.6, 28.5, median follow-up time for censored case: 20.9mts). Seven Grade 3 adverse events were observed in 6patient(23%), and paronychias in 3 patients and diarrhea, stomatitis, dermatitis, and lymphocytopenia in 1 patient each. One paronychia was considered to be related to DFP-14323 and the other events to afatinib. No grade 4 or 5 adverse events were observed. One Grade 1 ILD was observed but recovered soon without treatment. **Conclusions:** Combination of DFP-14323 and low-dose afatinib has shown comparable potential as a first-line treatment for *EGFR* mutation positive NSCLC with feasible efficacy and good safety profile. We are planning a phase III study to evaluate this combination therapy as compared with other EGFR-TKIs. Clinical trial information: UMIN000033062. Research Sponsor: Delta-Fly Pharma Inc.

Afatinib (Afa) + bevacizumab (Bev) versus afatinib alone as first-line treatment of patients with EGFR-mutated advanced non-squamous NSCLC: Primary analysis of the multicenter, randomized, phase II study—AfaBev-CS study. *First Author: Nobuhisa Ishikawa, Department of Respiratory Medicine, Hiroshima Prefectural Hospital, Hiroshima, Japan*

Background: Adding Bev to erlotinib prolonged PFS in NEJ026 and CTONG1509 trials, but limited data are available adding Bev to a second-generation EGFR-tyrosine kinase inhibitor. AfaBev-CS is a Japanese no-profit, randomized, open-label, multicenter phase II trial of Afa plus Bev vs Afa alone as first-line treatment for EGFR-mutated advanced NSCLC. **Methods:** This study enrolled untreated pts of advanced non-squamous NSCLC harboring EGFR sensitizing mutation (Del19 or L858R) and without symptomatic brain metastases. 100 eligible pts were randomized in a 1:1 ratio to receive either Afa (30 mg, daily) plus Bev (15 mg/kg, every 3 weeks) (AfaBev arm) or Afa (40 mg, daily) monotherapy (Afa arm), and stratified according to stage, EGFR mutation status and institution. The primary endpoint was PFS and the secondary endpoints were OS, tumor response and time to treatment failure. The sample size was set in terms of feasibility. The power is greater than 50% under the assumptions of a median PFS of 12 months for the Afa arm and HR of 0.6 for the AfaBev arm, with an accrual of 2.5 years and a minimum planned follow-up period of 2 years with the type 1 error of 0.05 (two-sided). **Results:** Between August 2017 and September 2019, 100 pts were enrolled (each arm, 50 pts). At a median follow-up of 31.3 months for all randomized pts, total 69 events occurred. Median PFS was 16.3 months for AfaBev arm and 16.1 months for Afa arm, with a hazard ratio (HR) of 0.865 (95%CI, 0.539 – 1.388; loglank p = 0.5476). In subgroup analysis, pts < 70 years old (HR 0.347) and pts with brain metastasis (HR 0.353) showed better trend of PFS in AfaBev arm. On the other hand, pts ≥ 70 years old (HR 1.738) and pts without brain metastasis (HR 1.196) did not show better trend in AfaBev arm. In terms of OS, result was immature because number of events was still small. Objective response rate was 77.6% in AfaBev arm and 72.0% in Afa arm. Severe adverse events were observed in 11 pts for each arm. Grade 3 or more diarrhea, hypertension, rash acneiform, paronychia and stomatitis were frequently observed in AfaBev arm. Pneumonitis was not observed for AfaBev arm and observed in 3 (6.0%) for Afa arm, and grade 3 in one patient. **Conclusions:** This study failed to show the efficacy of AfaBev arm for improving PFS in untreated pts with EGFR mutated non-squamous NSCLC. In pts < 70 years old, Afa plus Bev might be promising. Clinical trial information: jRCTs061180006. Research Sponsor: Boehringer Ingelheim.

Acquired EGFR-resistant mutations in non–small cell lung cancer (NSCLC). *First Author: Luis E. Raez, Thoracic Oncology Program, Memorial Cancer Institute/Florida Atlantic University, Miami, FL*

Background: EGFR mutations are present in more than 10% of patients (pts) with NSCLC in the US. While EGFR with tyrosine kinase inhibitors (TKIs) are effective, acquired resistance is expected. Known mechanisms include acquired EGFR mutations (e.g. 718V, c797x, 724s, 721s or T790M); copy number amplifications in MET, ERBB2, and PIK3CA; gene fusion events; and histological transformation. We herein present the prevalence of resistance mutations in the largest reported cohort of EGFR mutant NSCLC. **Methods:** Non-small cell lung cancer (NSCLC) tumor samples were submitted to Caris Life Sciences (Phoenix, AZ) for NextGen Sequencing (NextSeq, 592 Genes) and whole exome sequencing (NovaSeq, WES). PD-L1 expression was tested by IHC using 22c3 (Dako) and TPS scores were reported (cutoff >1). TMB was measured by totaling somatic mutations (TMB-high cut-off > 10 mutations per MB), genomic loss of heterozygosity (gLOH) was determined by WES. Patient treatment information was obtained from insurance claims data. **Results:** A total of 27,848 NSCLC tumors were evaluated and 3,223 (12%) had a EGFR sensitizing mutations. We found 60 tumors with common missense resistance mutations: 790 (n = 30, 0.9%), 797 (n = 38, 1.2 %), 718 (n = 11, 0.3%), 724 (n = 7, 0.2%) and 721 (n = 4, 0.1). Table 1 describes the frequencies, PD-L1 expression and the most common co-mutations. TMB-H (> = 10) was found in 12.5% of the tumors and dMMR/MSI-H in 1.8%. The most prevalent co-alterations were TP53 54%), gLOH (28%), CTNNB1 (19%), NFKB1A (13%), APC (10%), PIK3CA (11%), SMAD4 (9%) and other 15 co-mutations in less than 7% were seen. In the 30 T790M mutants, in addition to TP53 mutations, other prevalent co-mutations were PIK3CA (14%) and CTNNB1 (17%). In 797-mutant tumors, in addition to T790M, the most prevalent co-mutations were TP53 (53%), CTNNB1 (22%), APC (16%) and PIK3CA (11%). L718 mutations co-occurred with either L858R (8/11), exon 19 (3/11) or T790M mutations (3/11). G724 mutations were found in 7 patients (0.02%) and G721 mutations in 4 patients (0.01%). **Conclusions:** Acquired resistance in EGFR mutant NSCLC is very heterogeneous and their frequency is still low most likely due to lack of enough sequencing of EGFR resistant tumors. While T790M and C797S mutations are well described, this report also notes a significant number of L718V mutations, primarily in osimertinib-treated pts with an original L858R. These data support the NGS evaluation of patients with resistant EGFR mutant lung cancers. Research Sponsor: None.

EGFR MT	N	%	T790M co-mt	PD-L1	TP53	LOH
797	38	1.2	26/38 (68%)	11/36 (30%)	20/38 (53%)	4/14 (28%)
718	11	0.3	3/11 (27%)	4/9 (44%)	7/10 (70%)	0/1 (0%)
724	7	0.2	1/7 (14%)	5/7 (71%)	3/7 (43%)	0/1 (0%)

Improved survival from early combined radiotherapy: A phase II clinical study and underlying mechanisms of delaying EGFR-TKI acquired resistance in patients with advanced lung cancer. *First Author: Li Zhang, Tongji Hospital Tongji Medical College Huazhong University of Science and Technology, Wuhan, China*

Background: Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) have a significant therapeutic effect in the treatment of advanced non-small-cell lung cancer (NSCLC). However, patients treated with EGFR-TKIs had a median progression-free survival (PFS) of only 8 to 18 months. The occurrence of acquired resistance greatly limits the survival benefit of TKI for NSCLC patients. Extensive efforts have been paid to find a well-tolerated drug or treatment that works before acquired resistance to EGFR-TKI with low toxicity. Focusing on clinical trials of targeted combination radiotherapy, we observed some encouraging results. **Methods:** Stage IV NSCLC patients with EGFR sensitive mutation (19DEL or 21L858R) have received first-line EGFR TKIs treatment and achieved stable disease or partial response have been enrolled in this prospective, multicenter, randomized controlled, phaseIIstudy. Recruited from 4 hospitals in China, patients were divided into two groups: Stereotactic Body Radiation Therapy (SBRT) combined with TKIs group as the experimental and TKIs treatment group as an active comparator. The primary endpoint is PFS, and the secondary endpoint aims to overall survival (OS) and safety. To further confirmed these clinical observations in patients, xenograft experiments in nude mice were conducted. To examine the specific mechanism, transcriptome sequencing analysis was performed. **Results:** Between Mar 2015 and Mar 2018, A total of 61 patients who met the inclusion criteria were randomized to the TKI group and SBRT combined group. The median PFS of the TKI group and SBRT combined group were 9.0 vs 17.6 months (p = 0.016). Meanwhile, the median OS were 23.2 vs 33.6 months (p = 0.026). The total number of patients with T790m was 30(49.1%), and the incidence of T790M did not differ between the two groups. Toxicity data and subgroup analyses including different radiation sites will be presented at the conference. As for the xenograft experiments, data on tumor regression and time of drug resistance of early radiotherapy group was clearly superior to others. Transcriptome sequencing analysis found expression of c-Fos was the key point that led to the phenomena. **Conclusions:** The addition of SBRT significantly delayed the onset of EGFR TKIs acquired resistance and prolonged the PFS and OS of patients. Radiotherapy for the primary site alone might be superior to metastatic sites. Treatment-related adverse events were generally safe and controllable. The oncogenic role of c-Fos in the effect of radiotherapy on gefitinib resistance and promoting the proliferation of NSCLC cells is confirmed. Clinical trial information: NCT03595644. Research Sponsor: National Science Foundation of China (No. 82172825).

Matching-adjusted indirect comparison (MAIC) of mobocertinib versus amivantamab in patients with non–small cell lung cancer (NSCLC) with *EGFR* exon 20 insertions (ex20ins). *First Author: Sai-Hong Ignatius Ou, Chao Family Comprehensive Cancer Center, University of California Irvine, Orange, CA*

Background: Mobocertinib (mobo) and amivantamab (ami) are FDA-approved treatments for patients (pts) with locally advanced or metastatic NSCLC with *EGFR* ex20ins whose disease progressed on or after platinum-based chemotherapy. An unanchored MAIC was used to compare confirmed overall response rate (cORR), duration of response (DoR), progression-free survival (PFS) and overall survival (OS) between mobo and ami. **Methods:** Clinical outcomes were compared in platinum-pretreated pts with *EGFR* ex20ins+ NSCLC treated with mobo 160 mg QD in a phase I/II single-arm study (NCT02716116, cut-off 1 Nov 2020, n=114) or with ami 1,050 mg (1,400 mg, ≥80 kg) in a phase I single-arm study (NCT02609776, cut-off 8 June 2020, n=81). Differences in baseline characteristics reported in both studies, including age, race, sex, smoking status, Eastern Cooperative Oncology Group, histology, sites of metastasis (brain, bone and liver), time from advanced diagnosis, number of prior lines of therapy, prior immunooncology therapy, prior EGFR tyrosine kinase inhibitor treatment and prior *EGFR* ex20ins targeted therapy, were adjusted with MAIC. **Results:** After MAIC weighting all reported baseline characteristics were balanced between mobo and ami. OS and cORR per investigator assessment (INV) were similar between mobo and ami (Table). cORR per independent review committee (IRC) was numerically higher for ami (odds ratio [OR]=0.64, p value=0.230). For PFS per IRC, the adjusted hazard ratio (HR) was numerically favorable for mobo (HR=0.82, p value=0.417). Among the responders, DoR was longer for mobo (DoR per INV: HR=0.44, p value=0.049; DoR per IRC: HR=0.56, p value=0.149). **Conclusions:** Mobo and ami appear to have overall similar efficacy. As each has a different mechanism of action and route of administration, they provide multiple options in the treatment of *EGFR* ex20ins+ NSCLC. Clinical trial information: NCT02716116. Research Sponsor: Takeda Development Center Americas, Inc.

Updated study results of pelcitoclax (APG-1252) in combination with osimertinib in patients (pts) with *EGFR*-mutant non–small cell lung cancer (NSCLC). *First Author: Li Zhang, State Key Laboratory of Oncology in South China Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Investigational agent pelcitoclax is a dual BCL-2/BCL-xL inhibitor, which enhanced antitumor effects of osimertinib in preclinical models. A report presented at International Association for the Study of Lung Cancer 2021 World Conference on Lung Cancer demonstrated that the combination of pelcitoclax and osimertinib at the recommended phase 2 dose (RP2D) was safe, and preliminary efficacy was observed in some patients whose disease failed prior osimertinib or other third-generation EGFR-TKI treatments. Here, we further provide safety and efficacy results of this combination therapy. **Methods:** After RP2D was determined to be pelcitoclax 160 mg per week plus osimertinib 80 mg QD, pts were enrolled into 3 expansion cohorts of 20 pts each: Cohort 1 (EC-1) included those with disease resistant to third-generation EGFR-TKIs; Cohort 2 (EC-2) included those with osimertinib-naïve, *EGFR*-sensitive or *T790M*-positive mutations; and Cohort 3 (EC-3) included those with the *EGFR* exon 20 insertion mutation. **Results:** At the data cutoff date of January 6, 2022, 61 pts (median age, 56 years [69% female]) had been treated with pelcitoclax plus osimertinib. Among them, 13 were in dose escalation cohorts, 20 in EC-1, 20 in EC-2, and 8 in EC-3. Sixteen pts in EC-2 were EGFR-TKI naïve, and 4 were T790M positive with prior TKI treatment. All pts in EC-2 experienced treatment-related adverse events (TRAEs) but only 4 (20%) had grade ≥ 3. Common TRAEs included increased aspartate aminotransferase (90%) and alanine aminotransferase (85%) levels, reduced platelets (40%), diarrhea (40%), and increased lipase (35%). Among 20 evaluable pts, 17 PRs (85%) were observed and 16 (80%) confirmed. The median (range) time to response was 1.4 (1.2-7.0) months, and the median duration of response (DOR) was not reached. The DOR rate at 9 months after first response was 71.4% (95% CI 25.8-92.0). Seven pts had brain metastases at baseline in EC-2; 2 CRs and 3 PRs were observed intracranially. **Conclusions:** Osimertinib in combination with targeted therapies has been of clinical interest to improve the outcomes of patients with *EGFR*-mutant NSCLC. Pelcitoclax plus osimertinib was well tolerated and showed comparable efficacy in TKI-naïve pts. Further randomized control trials are warranted to elucidate the role of pelcitoclax when combined with osimertinib. Clinical trial information: NCT04001777. Research Sponsor: Ascentage Pharma Group Corp. Ltd (Hong Kong).

Afatinib (AFA) plus bevacizumab (BEV) combination after osimertinib (OSI) resistance in advanced EGFR-mutant NSCLC: A phase II study (ABCD-study). *First Author: Akito Hata, Department of Thoracic Oncology, Kobe Minimally Invasive Cancer Center, Kobe, Japan*

Background: After OSI failure, various resistant mechanisms such as C797S and uncommon EGFR mutations, or MET amplification have been reported. AFA is an irreversible EGFR-TKI with a potency as pan-HER inhibitor, including high sensitivity to uncommon EGFR mutations. Many clinical studies have also shown a synergy of EGFR-TKIs and VEGF inhibitors. **Methods:** ECOG PS 0-1 patients (pt) with EGFR-mutant NSCLC were enrolled after OSI resistance. AFA was prescribed at 30-40 mg QD, and BEV was administered at 15 mg/kg tri-weekly until progression. Plasma/histologic rebiopsied samples taken after OSI failure but before enrollment were analyzed to examine resistant mechanisms including gene alterations/copy-number gain using cancer personalized profiling by deep sequencing. **Results:** Between January 2018 and October 2020, 28 pts were enrolled. Mutation subtypes were: 9 (32%) Del-19; 5 (18%) Del-19+T790M; 5 (18%) L858R; 7 (25%) L858R+T790M; 1 (4%) Del-19+L858R+T790M; and 1 (4%) G719S. Median line of prior OSI was 2 (range, 1-9). CR/PR was obtained by prior OSI in 24 (86%) pts. Regarding AFA+BEV efficacy, one (4%) CR, 4 (14%) PR, and 17 (61%) SD were confirmed, resulting in response rate of 17.9% and disease control rate of 78.6%. Median DoR was 9.0 (range, 4.2-22.3) months. Median PFS and OS were 2.7 (95% CI, 2.0-4.6) months and not reached, respectively. Twenty-eight (100%) plasma and/or 21 (75%) histologic rebiopsies identified: 17 (61%) TP53; 15 (54%) T790M; 9 (32%) uncommon EGFR; 9 (32%) MET; 6 (21%) C797S; 3 (11%) BRAF; 2 (7%) HER2; 2 (7%) KRAS; and 2 (7%) PI3K mutations; or 14 (50%) EGFR; 6 (21%) MET; and 2 (7%) HER2 amplifications. One (4%) small cell transformation was found. Among 6 C797S pts, 1 CR, 4 SD, and 1 PD were confirmed. Three (33%) of 9 uncommon EGFR and 1 (50%) of 2 HER2 mutation positive pts achieved radiographic response. All 15 T790M-positive pts showed no response, but 5 (38%) of 13 T790M-negative pts responded to AFA+BEV. None (0%) of six pts with EGFR downstream signaling mutations such as BRAF, KRAS, or PI3K responded. Five (50%) of 10 pts without T790M/BRAF/KRAS/PIK3 mutations exhibited confirmed response. FAT1 mutation was found in two (40%) of 5 responded pts. Dose reduction/interruption of AFA was performed in 15 (54%) pts. Median number of BEV administrations was 4 (range, 1-32). There were neither TRD nor ILD. Adverse events ≥grade 3: hypertension (29%); proteinuria (7%); diarrhea (7%); and rash (4%) were observed. One (4%) grade 4 duodenal perforation was reported. **Conclusions:** AFA+BEV after OSI resistance demonstrated moderate efficacy and favorable safety. A small portion of C797S pts exhibited the sensitivity. Higher potency was suggested in T790M/BRAF/KRAS/PIK3 mutation-negative and uncommon EGFR/HER2 mutation-positive pts. Selected population could obtain clinical benefit from AFA+BEV, based on rebiopsy results after OSI resistance. Clinical trial information: UMIN000030545. Research Sponsor: Boehringer Ingelheim.

9118 **Poster Session**

Efficacy and safety of capmatinib plus pembrolizumab in treatment (tx)-naïve patients with advanced non–small cell lung cancer (NSCLC) with high tumor PD-L1 expression: Results of a randomized, open-label, multicenter, phase 2 study. *First Author: Tony S. K. Mok, Chinese University of Hong Kong, Hong Kong, China*

Background: Capmatinib is a selective MET inhibitor approved for patients (pts) with metastatic NSCLC harboring *MET* exon 14 skipping mutation. Pembrolizumab (pembro) is a programmed death protein-1 (PD-1) inhibitor approved as monotherapy for pts with advanced NSCLC expressing PD-ligand 1 (PD-L1). Preclinical studies have shown that capmatinib enhances T cell mediated antitumor response in mice treated with PD-1 inhibitors. Combining capmatinib with pembro may be beneficial in pts with advanced NSCLC expressing high tumor PD-L1. **Methods:** Herein we evaluated the efficacy and safety of capmatinib plus pembro (combo) versus pembro alone in tx-naïve pts with advanced MET-unselected NSCLC expressing PD-L1 with tumor proportion score (TPS) ≥50%, and no *ALK* or *EGFR* tumor aberrations. Pts received pembro 200 mg IV q3w in the pembro alone arm or with capmatinib 400 mg orally BID in the combo arm. The primary endpoint was investigator-assessed progression-free survival (PFS) using RECIST v1.1. Secondary endpoints included overall response rate (ORR), disease control rate (DCR), pharmacokinetics and safety. **Results:** As of the data cut off (DCO) of 28 Feb 2021, 76 pts were randomized 2:1 to the combo arm (n = 51) or pembro alone arm (n = 25). Baseline demographics and disease status were mostly comparable across study arms. At this interim analysis, PFS data were not mature. Median PFS (95% CI) was 6.3 (3.2, not evaluable [NE]) months in the combo arm and 4.3 (2.3, NE) months in the pembro alone arm. The ORR (95% CI) was 15.7% (7.0%, 28.6%) and 28.0% (12.1%, 49.4%) in the combo and pembro alone arms, respectively. The DCR (95% CI) was comparable across study arms; combo: 56.9% (42.2%, 70.7%) and pembro alone: 56.0% (34.9%, 75.6%). In the combo arm, capmatinib exposure (C_{max}: 3580 ng/mL [n = 7] and AUC_{tau}: 19700 hr*ng/mL [n = 2]) was consistent with data from previous studies. Tx-related grade (GR) ≥3 adverse events (AEs) were more common in the combo (37.3%) vs pembro alone arm (16%). Tx-related AEs occurring in ≥10% of pts are shown in the Table. Tx discontinuation and dose adjustment/interruptions were more common in the combo (27.5% and 52.9%) vs pembro alone arm (16% and 16%). Capmatinib was stopped prematurely in the combo arm, and at DCO, 32 (62.7%) pts in the combo arm and 18 (72%) pts in the pembro alone arm were receiving pembro monotherapy. **Conclusions:** Combination tx with capmatinib and pembro was not well tolerated and did not improve antitumor activity in tx-naïve pts with advanced NSCLC with PD-L1 TPS ≥50%. Clinical trial information: NCT04139317. Research Sponsor: Novartis.

Analysis of *MET* exon 14 skipping mutations in non–small cell lung cancer (NSCLC) by histology and specific mutation. *First Author: Jennifer Aline Marks, Emory University School of Medicine, Atlanta, GA*

Background: MET exon 14 skipping mutations (METex14) join a growing list of viable therapeutic targets in advanced NSCLC. Several unique features distinguish METex14 from other established targets. METex14 has been characterized as a tumor-agnostic genomic alteration, though most frequently reported in lung adenocarcinoma. However, METex14 represents a family of mutations (mt), not a single alteration, and there is notable heterogeneity in histology. The degree and significance of heterogeneity within METex14 have not been well characterized. **Methods:** NSCLC tissue samples were analyzed with DNA-based next-generation sequencing (NGS; 592 genes, NextSeq) or whole-exome sequencing (NovaSeq), RNA-based whole transcriptome sequencing (WTS, NovaSeq), and immunohistochemistry (IHC) at Caris Life Sciences (Phoenix, AZ). PD-L1 expression utilized the 22C3 clone (Dako); TMB-high was defined as ≥ 10 mt/Mb. Wilcoxon or Fisher's exact were used to determine statistical significance (p without and q with multi comparison correction). Immune cell fraction (QuanTiseq) and pathway analysis (ssGSEA) were informed by WTS analysis. **Results:** A total of 440 METex14 cases were identified: 49 (11.1%) with squamous histology, 381 (86.6%) with non-squamous histology, and 10 (0.2%) with adenosquamous histology. A total of 147 distinct METex14 mutations were detected. The most common METex14 mutations were D1028H (8.4%), D1028N (7.0%), c.3082+2T > C (5.7%), D1028Y (5.2%), and c.3082+1G > A (4.5%). Co-mutations in TP53 were common (43.9%) but varied by specific METex14 mutation; TP53 co-mutations were observed in 53.9% of c.3082+3A > T but only 21.1% of c.3082+1G > T. Among all METex14 cases, 8.6% were TMB-high, but this varied by specific mutation with a median TMB of 2 mt/Mb in MET c.3082+2T > A and a median of 7 mt/Mb in MET c.3082+1G > C ($q < 0.05$). PD-L1 expression ≥ 1% was present in 82.2% of METex14 samples but also varied by specific METex14 mutation with a median PD-L1 tumor proportion score (TPS) of 97.5% in MET c.3082+1G > C and a median TPS of 0% in MET c.3082+3A > G ($q < 0.05$). Co-mutations varied by histology: in squamous METex14, 90.4% had TP53 mt ($p < 0.001$), 17.9% had KMT2D mt ($p < 0.05$), and 10.7% had PIK3CA mt ($p < 0.05$), while in non-squamous METex14, 60.7% had TP53 mt, 2.7% had KMT2D mt, and 4.3% had PIK3CA mt. Survival was numerically shorter in squamous METex14 NSCLC compared to non-squamous (HR 1.22, p = 0.47, mOS 336 vs.1106 days). **Conclusions:** There is significant heterogeneity within METex14 NSCLC with differences in co-mutations, TMB, and PD-L1 expression noted among different METex14 mutations. While METex14 is detected in both squamous and non-squamous NSCLC, there are differences in enrichment of oncogenic pathways. The clinical impact of these differences warrants further investigation. Research Sponsor: None.

Tepotinib in Asian patients with advanced NSCLC with *MET* exon 14 (*MET*ex14) skipping. *First Author: Terufumi Kato, Department of Thoracic Oncology, Kanagawa Cancer Center, Yokohama, Japan*

Background: Tepotinib is a highly selective, potent MET inhibitor approved in several Asian countries for the treatment of advanced *MET*ex14 skipping NSCLC. In VISION (n=275; data cut-off: Feb 1, 2021), tepotinib had an objective response rate (ORR) of 49.1% (95% CI: 43.0, 55.2) by independent review (IRC), with a median (m) DOR of 13.8 months (9.9, 19.4) across treatment lines. Here, we report outcomes in Asian pts. **Methods:** Pts with advanced *METex*14 skipping NSCLC, detected by liquid (L+) or tissue (T+) biopsy, received tepotinib 500 mg (450 mg active moiety) QD. Primary endpoint was objective response by IRC. Efficacy was assessed in 79 Asian pts with ≥3 months' follow-up, and safety was assessed in 88 Asian pts who received tepotinib by data cut-off (Feb 1, 2021). Only pts enrolled in Asia were assessed for HRQoL. **Results:** In 79 Asian pts assessed for efficacy (38% female, 42% smoking history, 34% treatment-naïve [1L] and 82% adenocarcinoma), ORR was 54.4% (42.8, 65.7), mDOR was 18.5 months (8.3, ne), mPFS was 12.1 months (6.9, ne) and mOS was 20.4 months (19.1, ne). ORR was 66.7% (46.0, 83.5) in 1L pts (n=27), and 48.1% (34.0, 62.4) in previously treated pts (n=52). Meaningful activity was observed irrespective of *MET*ex14 skipping detection method (Table). In pts analyzed for HRQoL (n=73), mean change from baseline for EORTC QLQ-C30 GHS (3.94), EQ-5D-5L VAS (0.83), and EORTC QLQ-LC13 for cough (-6.59), dyspnea (-1.26), and chest pain (-6.14) symptom scores, demonstrated stability in QoL. In 88 Asian pts analyzed for safety, the most common adverse events (AEs) were peripheral edema, increased blood creatinine, and diarrhea. 29.5% of pts had Grade ≥3 treatment-related (TR) AEs. TRAEs led to dose reductions in 29.5%, temporary interruption in 43.2%, and permanent discontinuation in 14.8% of pts. **Conclusions:** In VISION, tepotinib showed robust and durable clinical activity in Asian pts with *METex*14 skipping NSCLC. TRAEs were manageable, with few leading to treatment discontinuation. Currently, VISION has enrolled 106 Asian pts with *METex*14 skipping NSCLC; analysis in this population is ongoing. Clinical trial information: NCT02864992. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany.

Clinical response to tepotinib according to circulating tumor (ct) DNA biomarkers in patients with advanced NSCLC with high-level *MET* amplification (*MET*amp) detected by liquid biopsy (LBx). *First Author: Xiuning Le, Department of Thoracic Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Tepotinib, a potent, highly selective, oral, MET inhibitor, showed meaningful activity in patients (pts) with NSCLC with high-level *MET*amp by LBx in VISION. Exploratory biomarker analyses are presented herein. **Methods:** Pts had 0–2 prior therapy lines, high-level *MET*amp by LBx (Guardant360; *MET* copy number ≥2.5), and no *MET* exon 14 skipping or *EGFR*/*ALK* alterations. Pts received tepotinib 500 mg once daily (450 mg active moiety). Primary endpoint was objective response by independent review; data cut-off: Aug 20, 2021. Exploratory biomarker analysis included LBx at baseline (BL), on treatment, and end of treatment (EOT). Early molecular response (eMR) was defined as undetectable *MET*amp 6–8 weeks on treatment. **Results:** 24 pts were enrolled (median age: 63.4 years [yrs]; smokers: 88%; ECOG PS 1: 88%; adenocarcinoma: 67%). Treatment duration was ≥1 yr in five pts and ≥2 yrs in two pts (both ongoing). Overall, objective response rate (ORR) was 41.7% (95% CI: 22.1, 63.4). Treatment-naïve pts (n=7) had an ORR of 71.4% (29.0, 96.3), median (m) DOR was 14.3 months (2.8, not estimable [ne]), and mPFS was 15.6 months (1.4, ne). BL biomarker analyses according to clinical benefit (CR/PR/SD [n=11] vs PD/NE [n=13]) showed association with better outcomes in pts with focal *MET*amp, or without *MYC*amp or *RB1* mutation (Table). *MYC*amp/*RB1* mutation was detected in 4/7 pts with neuroendocrine/not otherwise specified histology; *MYC*amp in 2/3 pts with neuroendocrine histology. Low BL ctDNA mutant allele frequency (MAF) was associated with better outcomes. 14 pts had eMRs (ORR 71.4%); persistent *MET*amp (n=4) was associated with lack of clinical response. 2/9 pts with EOT biomarker profiles had emerging resistance mechanisms (MET kinase domain mutations Y1230 and D1228); both had *MET*amp re-emergence. Treatment-related adverse events included edema (composite term; any grade: 46%; Grade 3: 13%) and constipation (any grade: 17%; Grade ≥3: 0%). **Conclusions:** Tepotinib showed meaningful activity, especially in first line, in the first trial of a MET inhibitor in *EGFR* WT NSCLC with high-level *MET*amp to enroll based on a convenient LBx assay. BL biomarker analyses indicated focal *MET*amp, *MYC/RB1* WT, and low ctDNA MAF were associated with improved outcomes. Serial LBx could monitor molecular response and evaluate resistance. Clinical trial information: NCT02864992. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany.

Characterization of *MET* exon 14 skipping alterations (*MET*ex14) in non–small cell lung cancer (NSCLC) using whole transcriptome sequencing (WTS). *First Author: So Yeon Kim, Montefiore Medical Center, Bronx, NY*

Background: Multiple DNA alterations in exon 14 splice sites have been identified in NSCLC and result in skipping of the juxtamembrane domain Cbl-E3 ubiquitin ligase binding region, leading to increased MET stability and oncogenesis. The effects of these alterations on transcriptome-level have not been fully characterized. We present the largest cohort study of *MET*ex14 using WTS and identify key cellular pathways associated with invasion and metastases in *MET*ex14. **Methods:** 17,666 NSCLC tumor samples underwent genomic profiling at Caris Life Sciences. Analyses included next generation sequencing of DNA (592 Gene Panel, NextSeq, whole exome sequencing, NovaSeq) and RNA (NovaSeq, WTS). *MET*ex14 was captured via WTS. ssGSEA analysis was used to evaluate pathway enrichment. Wilcoxon, Fisher's exact were used for statistical significance (p without and q values with multiple comparison correction). **Results:** 440 patients (2.5%) with *MET*ex14 were identified. *MET*ex14 patients were of older age, female gender, and enriched in sarcomatoid histology (Table 1). The most common alterations were point mutations (51.5%) and deletions (17.3%) at donor splice sites. Splice site alterations except point mutations at splice acceptor site translated to increased mRNA expression compared to wild-type *MET* (WT). *MET* amplification translated to higher mRNA expression compared to *MET*ex14 and WT with synergistic expression when co-altered with *MET*ex14 (q<0.05). The most common co-alterations were amplifications of *MDM2* (18.5% vs. 1.8% WT), *HMGA2* (13.7% vs 0.9% WT), and *CDK4* (10.4% vs 1.4% WT) (q < 0.05). *MET*ex14 were mutually exclusive to mutations in *KRAS* and *EGFR*. High PD-L1 (22c3) > 50% (53% vs. 27.6% WT, q<0.001) and lower TMB (4 mut/Mb vs. 7 mut/Mb WT, p<0.001) were observed with *MET*ex14 and pathways associated with skipping variants included IFNγ signaling, angiogenesis, and apical junction pathways on univariate analysis (q<0.05). **Conclusions:** We present the largest WTS analysis of *MET*ex14. Splicing alterations and *MET* co-amplification translated to higher and synergistic MET expression at transcriptome level, respectively. Association with upregulated angiogenic and apical junction pathways support preclinical observation of vascular and cytoskeletal remodeling as potential mechanisms of invasion and metastases in *MET* ex14 NSCLC. Research Sponsor: None.

Real-world (rw) analysis of quantitative *MET* copy number (CN) as a biomarker in NSCLC. *First Author: David Chun Cheong Tsui, University of Colorado Cancer Center, Aurora, CO*

Background: *MET* amplification (amp) can be a de novo driver or mechanism of resistance to targeted therapy. We explored the genomic landscape of *MET* amp NSCLC, including co-driver alterations and amplicon size, and its association with outcomes to MET tyrosine kinase inhibitors (TKIs) using rw data. **Methods:** Comprehensive genomic profiling (CGP) results from 64,521 tissue and 5,177 liquid NSCLC samples were queried for *MET* amp (focal amplicons ≥4 copies above specimen ploidy). Sub analysis comparing focal (≤20Mbp) and non-focal (> 20Mbp) amp was performed. Using the nationwide (~280 US cancer clinics) de-identified EHR-derived Flatiron Health-Foundation Medicine aNSCLC clinicogenomic database (CGDB) linked to tissue CGP (8/2014-9/2021), we assessed co-driver presence (*EGFR*, *ALK*, *RET*, *ROS1*, *NTRK*, *BRAF*, *KRAS*) prior to therapy exposure and outcomes to MET TKIs. **Results:** *MET* amp was detected in 2,102 (3.3%) NSCLC tissue samples (median CN of 11, range 6-168). Evaluating full gene focal amplicons as well as non-focal *MET* amps (n = 398, median CN 7), smaller amplicon size significantly correlated with higher CN (p < 0.001). In 5,177 liquid samples, *MET* amp was detected in 40 (0.77%) cases; frequency increased to 3.2% (33/1,033) in those with a tumor fraction above 10%. In the CGDB, 261 (3.2%) pts had NSCLC with *MET* amp (median CN 11). Among 241 pts with *MET* amp detected prior to receipt of any targeted therapy, *MET* amp co-occurred with another driver in 32 (13%) cases (81% *KRAS*, 16% *EGFR*, 3.1% *BRAF*) and with a *MET* exon 14 skipping alteration (*MET*ex14) in 25 (10%). *MET* CN negatively correlated with the presence of a co-driver (median 11 with *MET* amp alone vs 9 with a non-*MET*ex14 co-driver, p < 0.001); however, *MET* CN was similar in *MET* amp cases with and without *MET*ex14 (median 11 for both, p = 0.60). Co-occurring non-*MET*ex14 drivers were detected in 26% of *MET* amp cases with CN < 8 and 19% with CN 8-9, but in only 9.1% with CN 10-20 and 2.6% with CN > 20. Tumor mutational burden was not significantly correlated with *MET* CN. In 14 cases with an *EGFR* or *ALK* co-driver and *MET* amp detected post-treatment with an EGFR or ALK TKI, median *MET* CN was 13. Of 241 targeted therapy naïve *MET* amp pts, 39 received a MET TKI after CGP (30 crizotinib, 9 capmatinib) and 26 had rw response assessment available. Excluding 5 pts with co-*MET*ex14, 12/21 (57%) pts had a partial response and median rwPFS was 3.6 months. This rw cohort analysis was underpowered to assess the relationship between CN and outcome. **Conclusions:** *MET* amp was detected in 3.3% of NSCLC tissue samples and 3.2% of high tumor fraction blood samples. In TKI-naïve pts, *MET* CN negatively correlated with the presence of a concurrent NSCLC driver. *MET* amp was associated with response to MET TKIs. Further studies evaluating *MET* CN, amplicon size and presence of other potential drivers in both blood and tissue, as predictive biomarkers for MET TKIs and potential combination strategies for targeting *MET* amp, are warranted. Activating MET kinase domain mutations define a novel molecular subtype of non–small cell lung cancer that is clinically targetable with the MET inhibitor elzovantinib (TPX-0022). *First Author: Federica Pecci, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: In non-small cell lung cancer (NSCLC), *MET* exon 14 skipping (METex14) mutations and *MET* amplification can be targeted with MET inhibitors. Here, we describe a novel, actionable molecular subtype of NSCLC characterized by activating MET-tyrosine kinase domain (MET-TKD) mutations in the absence of METex14 mutations. **Methods:** Clinicopathologic and genomic data were abstracted from NSCLC cases included in a multi-institutional cohort of tumors that underwent genomic profiling in the GENIE v10, China PanCancer, and the International Cancer Genome Consortium/ The Cancer Genome Atlas (ICGC/TCGA) datasets. External validation of the prevalence of MET-TKD mutations was performed on an independent cohort of NSCLC tissue and liquid samples from the Foundation Medicine genomic database. **Results:** Among 14,099 NSCLC samples in the multi-institutional cohort, 71 (0.5%) harbored MET-TKD mutations without concurrent METex14 mutations: 55 of these had uncertain pathogenic significance and 16 had known oncogenic potential, including MET H1094Y/R, D1228H/N/V, N1100S, H1106D, V1188I, and M1250T, in order of decreasing prevalence. In a separate cohort of 91,515 NSCLC samples from the Foundation Medicine database, MET-TKD mutations lacking concurrent METex14 mutations were identified in 799 (0.9%) samples, including H1094Y, L1195V, D1228H/N, M1250T and others. Among 60 NSCLC samples harboring MET-TKD mutations without concurrent METex14 mutations with complete genomic data in the multi-institutional cohort, 36 (60%) had concurrent driver alterations in KRAS, EGFR, ROS1, BRAF, HER2, or RET, while 24 (40%) had no concurrent oncogenic drivers. Among patients with available demographic data in the multi-institutional cohort, those with MET-TKD-mutant NSCLC (N = 70) were significantly younger than patients with METex14-mutant NSCLC (N = 353) (median age 63 [range 30-86] vs 73 [range 44-88], p < 0.0001), and there was no significant difference in sex or self-reported race. Confirmed partial responses to the MET tyrosine kinase inhibitor elzovantinib (TPX-0022) were observed in two patients with MET-TKD-mutant NSCLC and no other detectable driver mutations: a 64-year-old man with MET H1094Y-mutant NSCLC, and an 80-year-old man with MET F1200I-mutant NSCLC. **Conclusions:** Potentially actionable MET-TKD mutations lacking concurrent METex14 mutations represent a novel genomic subtype in 0.5-0.9% of NSCLC, and occur in the absence of other known drivers in a subset of cases. Ancestry-based differences in gene alterations in non–small cell lung cancer: Real-world data using genetic ancestry analysis. *First Author: Keita Miura, Department of Respiratory Medicine, Juntendo University Graduate School of Medicine, Tokyo, Japan*

Background: Racial differences in morbidity and mortality of non-small cell lung cancer (NSCLC) have been demonstrated and some genomic alterations (e.g. *EGFR*) in NSCLC are known to differ according to race. However, studies have been limited in sample size and hence, limited in their capacity to detect discrepancies in less frequently altered genes. Here, we investigated alteration prevalence in a large real-world NSCLC cohort, stratified by genetic ancestry. **Methods:** 75,362 NSCLC patients from the United States, were profiled with comprehensive genomic profiling (CGP) of tissue biopsy, as part of routine clinical care (Foundation Medicine Inc., FMI; Frampton GM, et al. Nat Biotechnol 2013). 296 genes targeted across all assays were examined for known/likely pathogenic alterations of all classes. Predominant genetic ancestry was inferred using a SNP-based approach (Newberg J, et al. AACR 2019), and patients were categorized into European (EUR), African (AFR), East Asian (EAS), Admixed American (AMR), and South Asian (SAS) ancestry groups. Patients were additionally stratified by histological type, age (≥40/ < 40), and sex. The prevalence of high tumor mutational burden (TMB-High), defined as ≥ 10 mutations/mb (Chalmers ZR, et al. Genome Med 2017), and microsatellite instability status (Trabucco, et al. J Mol Diagn 2019) was also calculated. **Results:** In this NSCLC cohort, ancestry was split 82.2% for EUR, 10.0% for AFR, 4.4% for EAS, 2.7% for AMR, and 0.8% for SAS. 50.4% were female (n = 37,972) and 49.6% male (n = 37,360). The most prevalent alterations in the overall cohort included *TP53* (67.5%), *KRAS* (30.6%), *CDKN2A* (29.2%), *CDKN2B* (17.2%), *STK11* (16.1%), and *EGFR* (15.3%). The prevalence of TMB-High status in the overall cohort was 34.6%. Stratified by ancestry, the prevalence of *EGFR* alterations was significantly enriched in EAS vs. other ancestry groups ($p < 0.001$). *KRAS* and *STK11* were enriched in EUR and AFR vs. other groups ($p < 0.001$). TMB-High status was significantly enriched in AFR vs. all other groups ($p < 0.001$). In EAS and SAS, TMB-High was typically reduced vs. other ancestry groups (TMB-High AFR 41.6%, AMR 20.1%, EAS 14.1%, EUR 35.5%, SAS 11.7%). A similar analysis based on sex revealed differences in prevalence of 80 gene alterations and TMB-High with sex-specific enrichments (e.g., *EGFR* 19.0% female vs. 11.5% male; *KRAS* 34.6% vs. 26.6%). With respect to age, the prevalence of 41 gene alterations and TMB-High were significantly different between samples from patients age < 40 and age ≥ 40 (e.g., *ALK* 21.1% age < 40 vs. 2.7% age ≥ 40; *KRAS* 13.0% vs. 30.8%; TMB-High 14.4% vs. 34.8%). **Conclusions:** Comprehensive analysis of this real-world dataset, which includes the largest NSCLC patient cohort, revealed ancestry-associated differences in genomic alterations in NSCLC. Age and sex were also associated with differences in genomic alteration and TMB-High prevalence. Research Sponsor: None.

Clinical and economic outcomes associated with upfront comprehensive genomic profiling in newly diagnosed advanced lung cancer in the United States from 2018-2020: Evidence from the SEQUENCE study. *First Author: Gboyega Adeboyeje, Merck & Co., Kenilworth, NJ*

Background: As the number of approved molecularly-targeted therapies for the treatment of lung cancer increases, the debate continues as to whether a clinical strategy leveraging next-generation sequencing (NGS) comprehensive genomic profiling (CGP) to match patients to targeted treatments is advantageous versus a narrow/single-gene (N/S) panel testing. We examined clinical and economic outcomes of patients with advanced lung cancer (aLC) in the United States (US). **Methods:** In this retrospective study, newly diagnosed aLC patients aged 65-89 years were identified from a US Medicare Advantage plan from 2018-2020. Patients receiving genomic testing within 90 days of diagnosis and an FDA-approved pharmacotherapy cancer treatment after diagnosis were categorized by initial sequencing with NGS CGP (51+ genes) vs N/S (≤50 genes) panel testing using administrative claims based on previously validated algorithms. We assessed the proportion of patients with an inpatient or emergency department (INP/ED) visit for select outcomes (e.g., neutropenia) within 6 months of start of treatment, all-cause mortality, and PPPM (per patient per month) total healthcare costs through all available follow-up. Genomic testing costs within 90 days of cancer diagnosis were estimated using the Medicare fee schedule. Among patients with treatment within 30 days of testing, we assessed the proportion who did not switch treatment and were alive within 6 months. Descriptive analyses were conducted, and average effects were estimated using inverse probability weighted regression models. **Results:** We identified 3,532 patients who received genomic testing and pharmacotherapy cancer treatment (NGS CGP, n = 968; N/S, n = 2,564). Characteristics were similar between testing groups. The proportion of patients with INP/ED for outcomes of interest was similar following NGS CGP vs. N/S panels (15.0% vs. 17.8%; IRR [95% CI]: 0.76 [0.57 – 1.02]; p = 0.066), as were mortality (56.2% vs. 59.2%; HR: 1.05 [0.95 - 1.16]; p = 0.323) and PPPM costs (PPPM median cost difference -$575; ratio from regression 0.99, 0.94-1.04; p = 0.228). Among a subgroup of patients treated within 30 days of testing, a higher proportion receiving NGS CGP did not switch treatment and were alive after 6 months (47.6%) vs those receiving N/S panels (39.8%) (OR [95% CI]: 1.33 [1.12 - 1.59]; p = 0.001). Median genomic testing costs were $3,049 for NGS CGP vs. $218 for N/S testing. **Conclusions:** Outcomes were similar between patients receiving NGS CGP and N/S panel testing. Among patients with treatment within 30 days of testing, upfront NGS CGP was associated with fewer patients switching treatment and 6-month survival. Upfront testing with NGS CGP may represent a beneficial genomic profiling strategy as part of the initial management of patients with aLC. Research Sponsor: Merck.

Associations between biomarker testing and characteristics of patients with metastatic non–small cell lung cancer (mNSCLC): An analysis of CancerLinQ Discovery (CLQD) data. *First Author: Kathryn Finch Mileham, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: Guidelines have evolved from 2011-2019; there are now 23 approved therapies targeting various predictive biomarkers in mNSCLC. 2021 NCCN Guidelines advocate for a minimum of ALK, EGFR, BRAF, METex14, NTRK1/2/3, RET, KRAS, and ROS1 testing before determining a treatment regimen. The study objective was to estimate the association between the presence of biomarker testing and smoking status, age, sex, race, ethnicity, histology, and diagnosis year in patients with mNSCLC. **Methods:** CLQD is a real-world data source that provides de-identified electronic health record (EHR) data from more than 60 U.S. oncology practices utilizing 10 different EHRs. This retrospective analysis included patients initially diagnosed with mNSCLC from January 1, 2011, to December 31, 2019. Standard logistic regression models were fit separately by practice to estimate practice-specific odds ratios to assess variability across practices in associations between covariates (smoking status, age, race, etc.) and the primary outcome of biomarker testing, defined as documented testing for EGFR, ALK, ROS1, BRAF, KRAS, MET, RET, ERBB2, and/or PD-L1 within -60 to +365 days of mNSCLC diagnosis. Random effects logistic regression was then used to estimate associations with random intercepts, accounting for clustering by practices. Results are reported as odds ratios (OR) with 95% confidence intervals (CI). **Results:** 8704 patients from 31 practices were eligible. Testing rates increased from 31.5% in 2011 to a peak of 62.3% in 2017. Patients with a smoking history were half as likely to receive testing than patients without a smoking history (OR = 0.50, 95% CI: 0.41, 0.60); patients with unknown smoking history were 0.66 times as likely (95% CI: 0.52, 0.84). Females were more likely to be tested than males (OR = 1.19, 95% CI: 1.07, 1.32). After adjusting for other covariates, Asian patients were 1.51 times more likely to be tested than patients of other races (95% CI: 1.05, 2.17); Hispanic patients were 1.33 times more likely to be tested than patients without Hispanic ethnicity (95% CI: 0.99, 1.78). The odds of receiving biomarker testing were 6x greater for patients with non-squamous mNSCLC versus squamous mNSCLC (95% CI: 5.45, 7.20). Patients > 70 years old were less likely to be tested (OR = 0.83, 95% CI: 0.75, 0.93) than younger patients. **Conclusions:** Our data demonstrate annual increases in testing rates, reflecting guideline changes. However, in this cohort of patients with mNSCLC, biomarker testing was more likely for non-squamous mNSCLC patients, females, Asians, Hispanics, or those who did not have a history of smoking. Patient characteristics should no longer factor into obtaining biomarker testing. Non-discriminant, broad panel-based reflex molecular testing in mNSCLC can reduce treatment choice ambiguity and enhance patient opportunities. Research Sponsor: None.

Molecular testing and patterns of treatment in patients with NSCLC: An IASLC analysis of ASCO CancerLinQ Discovery Data. *First Author: Madhusmita Behera, Winship Cancer Institute of Emory University, Atlanta, GA*

Background: Precision medicine has resulted in improved outcomes for non-small cell lung cancer (NSCLC); while molecular testing is considered critical for guiding treatment decisions for advanced stage NSCLC, adoption of testing in routine practice is variable. We analyzed the factors contributing to molecular testing and treatment patterns in patients with lung cancer. **Methods:** The ASCO CancerLinQ Discovery dataset was queried to identify patients diagnosed with lung cancer between the years 2010-2018. Data on demographics, tumor stage, histology and treatments were extracted, and receipt of molecular testing was investigated as the primary outcome. Univariate association of each clinicopathological variable with molecular testing outcome was performed using chi-square test for categorical variables and ANOVA test for numerical variables. A multivariable logistic regression analysis with backward selection at an alpha of 0.05 was reported. All analyses were conducted using SAS 9.4. **Results:** A total of 37,925 NSCLC patients with stage IV disease were analyzed. Patient characteristics: median age 65 years, 51% male, 68% white, 33.5% adenocarcinoma. Approximately 22% of all NSCLC patients had molecular testing results. In adenocarcinoma patients, 49% had molecular testing results available. In the stage IV group, 47% were treated with chemotherapy, 16% with immunotherapy and 3% with targeted therapy. On multivariable analysis, females were more likely to have molecular testing compared to males [(OR: 1.29 (1.22-1.37); p < 0.001]. Compared to White patients, Black patients were less likely to have molecular testing [OR: 0.89 (0.81-0.97); p = 0.009] and Asians were more likely to undergo testing [OR: 2.22 (1.79-2.75); p < 0.001]. Hispanic patients were more likely to undergo molecular testing compared to non-Hispanics [OR:1.24 (1.02-1.52); p = 0.03]. Additionally, treatment with immunotherapy [OR: 1.86 (1.72-2.01); p < 0.001] and targeted therapy [OR: 2.29 (2.00-2.64); p < 0.001] were associated with significantly higher likelihood of having molecular testing. These results were also confirmed on a subgroup analysis of adenocarcinoma patients. **Conclusions:** In this analysis of a US-based real-world dataset of stage IV NSCLC patients, White race and female sex are associated with higher likelihood of having molecular test performed. The percentage of patients undergoing testing remains sub-optimal. Research Sponsor: IASLC.

Increased adherence to molecular profiling recommendations in non–small cell lung cancer through use of prior authorization and peer review. *First Author: Stephen A. Hamilton, eviCore healthcare, Bluffton, SC*

Background: National oncology guidelines advocate for broad molecular profiling to detect potentially actionable driver mutations prior to initiation of first-line therapy for patients with advanced non-small cell lung cancer (NSCLC). Results of genomic tests can confirm the presence of specific cancer tumor mutations that are best treated with more targeted therapies. Recent studies have shown that up to 30% of lung cancer patients may not receive the most effective treatment due to a lack of guideline-concordant genomic testing. We analyzed data from our prior authorization medical oncology program to determine adherence to national guidelines recommendations, and then developed a program to improve adherence to broad molecular profiling utilizing our proprietary prior authorization algorithms and our proactive peer consultation model. **Methods:** eviCore healthcare uses the NCCN Clinical Practice Guidelines in Oncology (NCCN Guidelines) to support its proprietary program for medical oncology drug management, and requires attestation on the results of NCCN recommended genomic/molecular test results in advanced NSCLC during prior authorization of systemic therapy. In November 2019, we implemented a next-generation sequencing (NGS) testing results requirement for metastatic non-squamous NSCLC patients prior to first-line therapy approval. If testing had not been completed, a peer to peer consultation was performed to advocate for testing prior to initiation of chemoimmunotherapy regimens. The rate of appropriate tumor testing is defined by provider attestation of test results prior to initiation of therapy. We define the control period (pre- implementation) as October 2018 through September 2019 (*n = 667*). The measurement period (post-implementation) is January 2020 through December 2020 (*n = 390*). **Results:** From pre to post there was a 35% increase in testing adherence (p < 0.001). After the testing requirement was implemented, the appropriate tumor testing rate increased to 99% by the second half of 2020, compared to the control period (62%). Additionally, after the testing requirement began, pembrolizumab utilization for advanced stage NSCLC decreased by a net 4.2% per month. This decrease in pembrolizumab utilization likely reflected patients being matched to more appropriate targeted therapy based on genomic testing results. **Conclusions:** We demonstrate that by combining medical oncology prior authorization with focused peer consultation, adherence to national society recommendations for broad molecular profiling prior to initiating first line therapy in advanced NSCLC can be significantly improved. By improving testing adherence, the most effective and appropriate therapy can be matched to the patient. Research Sponsor: None.

Predictors of biomarker testing among patients (pts) with metastatic non–small cell lung cancer (mNSCLC). *First Author: Nicholas J. Robert, Ontada, Irving, TX*

Background: The MYLUNG (Molecularly Informed Lung Cancer Treatment in a Community Cancer Network) Consortium pragmatic study assessed real-world biomarker testing rates for mNSCLC within The US Oncology Network of over 1,000 providers. We previously reported that 90% of pts had at least one test performed for ALK, BRAF, EGFR, ROS1, or PD-L1, but only 46% had testing for all 5. We examined patient factors associated with rates of biomarker testing. **Methods:** Retrospective observational chart review study of pts with mNSCLC initiating first-line systemic therapy between 04/01/2018 and 03/31/2020. Patient characteristics including age, sex, race, geographic location, BMI, laboratory values, histology, performance status, stage at diagnosis, and comorbidities were obtained from iKnowMed electronic health records. Predictors of biomarker testing were identified using multivariable logistic regression. **Results:** Of the 3474 adults included in the study, median age was 69 years (range 23-90), 51% female, 65% White, 8% Black or African American, and 46% treated in the South US census region. Histology was adenocarcinoma in 74% and squamous cell carcinoma in 19%. Modeling for any biomarker testing resulted in histology and geographic region as significantly associated with increased likelihood of testing: adenocarcinoma vs squamous cell, odds ratio (OR) 1.76 (CI 1.33-3.23, p<0.0001) and Midwest vs South, OR 2.04 (CI 1.24-3.34, p=0.005). For comprehensive testing of all 5 biomarkers, increased albumin, adenocarcinoma or not otherwise specified histology, Midwest, Northeast or West geographic regions, and larger practice size were all significantly associated with increased likelihood of testing, while Black or African American race was associated with significantly decreased likelihood of testing (Table). **Conclusions:** Black or African American race, smaller practice size, Southern practice, and squamous cell histology were significantly associated with lower comprehensive biomarker testing rates. Understanding clinical and social determinants of health will be important when evaluating interventions to improve testing rates in the prospective phases of the MYLUNG study. Research Sponsor: Amgen, AstraZeneca, Eli Lilly, Genentech, Mirati Therapeutics.

Impact of cancer susceptibility gene (CSG) mutations in advanced NSCLC (aNSCLC). *First Author: Danielle Klingberg, St. George Hospital, Kogarah, NSW, Australia*

Background: Next generation sequencing (NGS) is used widely to identify somatic oncogenic driver mutations in aNSCLC to guide treatment. Comprehensive profiling has led to identification of multiple gene mutations of unclear significance, including germline genes associated with cancer risk, termed CSG. Using data from two randomized trials comparing atezolizumab to docetaxel, we investigated the prognostic and predictive values of CSG in aNSCLC. **Methods:** We used publicly available data from the OAK (NCT02008227) and POPLAR (NCT01903993) trials. At baseline, plasma was analyzed for cfDNA using FoundationOne CDx NGS assay. We defined CSGs as pathogenic variants of APC, BAP1, BRCA1/2, BRIP1, CDH1, CDKN2A, CHEK2, FH, FLCN, MEN1, MET, MSH2/6, MLH1, PMS2, PALB2, PTCH1, PTEN, RAD51, RB1, SDHB, SMARCA4, STK11, TSC1/2 and VHL. Cox models with treatment covariate, CSG status (mutant [mt] vs wild-type [wt]) and their interaction was used to assess the predictive value by treatment of CSG mt for overall survival (OS) and progression free survival (PFS) using univariate and multivariate models. Similar analysis was performed for objective response rate (ORR). **Results:** Of 1137 patients, 853 with sufficient tumor content formed the analysis population. In total, 295 (35%) had a known/likely pathogenic CSG mt. The variant allele frequencies (vAF) of CSG mt ≥30%, 10-30%, and <10% were 8% (N=23), 25% (N=73), and 67% (N=199) respectively. Patients with CSG mt were more likely to be smokers (89% vs 81%, P=0.005), had squamous tumors (37% vs 26%, P=0.001) with higher blood-based tumor mutation burden (mean 13.8 vs 10.2 per megabase, P<0.001). CSG mt was not predictive of greater OS benefit with atezolizumab over docetaxel (Table). CSG mt was associated with 35% increase risk of death in univariable analysis (HR 1.35, 95% CI 1.15-1.59). CSG mt was associated with inferior OS in multivariable analysis adjusting for performance status, smoking status, tumor histology, age, sex and number of organ sites of metastasis (HR 1.26, 95% CI 1.07-1.48). **Conclusions:** Plasma CSG mt is an independent poor prognostic factor in two large aNSCLC clinical trial datasets. Majority of vAF of CSG were low, suggesting that very few were potentially germline in origin, but dedicated sequencing for confirmation will be required. If confirmed, CSG status could be used as a stratification factor in future aNSCLC trials. Research Sponsor: None.

Demographic and socioeconomic factors associated with stage at diagnosis in non–small cell lung cancer: An NCDB analysis. *First Author: Kiana Verplancke, Creighton University School of Medicine, Omaha, NE*

Background: There were 2.21 million new diagnoses of lung cancer worldwide in 2020, accounting for approximately 25% of all cancer related deaths. A factor that impacts the overall mortality of lung cancer is the stage at initial presentation for diagnosis. Current 5-year survival estimates of non-small cell (NSC) lung cancer range from 73% in early-stage disease to 13% in advanced disease. The stark differences in survival rate in early and late disease, highlight the importance of determining if socioeconomic and demographic factors impact the stage of cancer at diagnosis. This study sought to determine if certain socioeconomic and demographic factors are associated with receiving an early (Stage 0-I) or delayed (Stage IV) diagnosis of NSC lung cancer. **Methods:** Using the National Cancer Database, 1,149,539 patients were identified as having a NCDB Analytic Stage Group diagnosis of Stage 0-I (early) vs Stage IV (delayed/advanced) NSC lung cancer between 2004 and 2018. Using SPSS statistics 27, patients with early and delayed diagnoses were compared to each other based on certain characteristics including sex, race, ethnicity, and level of education. Results were analyzed using multivariate and chi square analyses, as well as one-way ANOVA. **Results:** We identified significant differences ($p < .005$) between stage at presentation and certain socioeconomic factors. Females were 70% less likely to be diagnosed with advanced disease in comparison to males ($p < .001$, 95% CI = .697-.708). African Americans and Native Americans were more likely to present with advanced disease in comparison to white patients ($p < .001$, 95% CI = 1.407-1.449 and 1.046 – 1.235, respectively). Hispanic patients were 49.3% more likely to present with advanced disease than non-Hispanic patients ($p < .001$, 95% CI = 1.389 – 1.605). Patients with at least one comorbidity (CCI score ≥ 1) were less likely to present with advanced disease ($p < .001$). Those who lived in a zip code where 21% or more of the residents lacked a high school degree were more likely to present with stage IV disease, in comparison to patients who lived in a zip code where less than 20.9% of its residents did not graduate from high school ($p < .001$). **Conclusions:** Demographic and socioeconomic factors associated with a delayed diagnosis of NSC lung cancer include male sex, non-white race, being Hispanic, having no comorbidities, and living in a zip code where 21% or more residents have no high school degree. Research Sponsor: None.

The 10-year journey of non–small cell lung cancer: A real-world experience. *First Author: Hyun Ae Jung, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: Over the past 10 years, the treatment of non-small cell lung cancer (NSCLC) has been continuously revolutionized. This study evaluated how this revolution improved outcomes in the real-world. **Methods:** We collected clinical, pathological, and molecular data of patient with NSCLC using an in house real-time updated cohort (ROOT-HEALTH). The primary objective was the 3-year survival (OS3) rate by clinical stage, histology, and driver mutations including *EGFR*, *ALK*, *ROS1*, *RET*, *MET exon 14 skipping*, *BRAF V600E*, *KRAS G12C*, and *NTRK* between two time periods (Period I: 2010-2015 vs. Period II: 2016-2021). **Results:** We included data on 22,060 patients who received any anti-cancer treatment between January 2010 and December 2020. Adenocarcinoma (AD) was the predominant histology (70.2% in Period I vs. 74.2% in Period II) (Standardized mean difference [SMD] = 0.09, $P < 0.001$). In Period I, 36.8%, 10.4%, 15.9%, and 34.6% patients were in stage I, II, III, and IV respectively. In Period II, 44.8%, 9.6%, 15.1%, 29.9% were in each stage, respectively (SMD = 0.15, $P < 0.001$). Patients during Period II were more likely to perform molecular tests for *EGFR*, *ALK*, and/or others than those during Period I in both of AD (79.1% in Period I vs. 95.1% in Period II) and non-AD (53.5% in Period I and 85.0% in Period II). In patients with AD, 49.4% in Period I and 56.4% in Period II had any druggable mutations. Among non-AD patients, 4.9% and 6.2% of patients had any druggable mutations in Period I and II, respectively. In patients with AD, in Period I, the OS3 rates were 92.9 %, 72.6%, 56.6%, and 29.0% for each stage (I, II, III, and IV), respectively. In Period II, the OS3 rates of AD were 96.4 %, 86.8%, 70.2%, and 52.1% for each stage, respectively ($P < 0.001$). In stage IV AD with *EGFR* mutation, the OS3 rates were 42.5% and 65.4% in Period I and II, respectively ($P < 0.001$). In stage IV AD with *ALK* rearrangement, the OS3 rates were 53.2% and 73.6% in Period I and II, respectively ($P < 0.001$). In patients with non-AD, the OS3 rates were 71.6%, 60.2%, 38.8%, and 10.2% for each stage in Period I. In Period II, the OS3 rates of non-AD were 83.1%, 73.7%, 58.2%, and 29.6% for each stage ($P < 0.001$). In stage IV non-AD with any druggable mutations, the OS3 rates were 27.1% and 46.0% in Period I and II, respectively ($P = 0.05$). **Conclusions:** Our study is meaningful as a large-scale study that reflects changes of survival outcome in a timely manner.Through our real-world experience of over 10 years, the proportions of early stage and were found to be increased. The implementation of molecular testing has also been expanded. Of note, the survival outcomes were remarkably improved across all stages, especially in patients with stage III-IV. Further improvement of outcomes through effect of emerging driver mutations in the next five years is expected. Effectiveness of nationwide insurance coverage for next-generation sequencing in advanced non–small cell lung cancer: A real-world data study. *First Author: Dong-Won Kang, Sungkyunkwan University, Suwon, South Korea*

Background: Next-generation sequencing (NGS) has been covered by Korean national health insurance since March 2017 for patients with advanced non-small cell lung cancer (NSCLC). We explored the clinical and socioeconomic impact of NGS compared with that of a single gene test (SGT) alone. **Methods:** From the nationwide database, we identified patients who 1) are diagnosed with advanced NSCLC classified as a distant disease using Summary Stage between March 1, 2017, and December 31, 2018; 2) had NGS or SGT within 2 months after diagnosis of advanced NSCLC. Patients with squamous cell carcinoma were excluded. We conducted multivariate logistic regression to identify factors (e.g., age, sex, Charlson comorbidity index, insurance type, year of diagnosis, and region and type of hospital with the initial diagnosis) affecting the performance of NGS. Further, we divided the cohort into subgroups based on whether patients received treatment targeting epidermal growth factor receptor (EGFR) and anaplastic lymphoma kinase (ALK) mutations (group A) or not (group B). We conducted 1:5 propensity score matching for each group to minimize the impact of confounding factors. The median overall survival and the adjusted hazard ratio (aHR) for death were estimated using the Kaplan-Meier method and the Cox proportional hazard model, respectively. We calculated the total medical cost, and per patient per year (PPPY) cost adjusted for the survival period. **Results:** Among 10,247 patients with advanced NSCLC, 768 patients were identified as group A and 1,596 as group B after matching. Old age, low household income, and rural region were factors negatively impacting on having NGS tests. In Group A, we did not find a significant difference in survival outcome between the NGS cohort and the SGT cohort (median survival 31.6 vs. 27.5 months, $P = .331$; aHR 0.80, $P = .204$). In contrast, significantly favorable survival was observed for the NGS group in Group B (median survival 14.1 vs. 9.5 months, $P = .023$; aHR 0.80, $P = .009$). Although the total medical cost was higher in the NGS group ($39,145) than the SGT group ($36,207) for Group B, the PPPY cost was lower in the NGS group ($57,502 and $63,293, respectively). **Conclusions:** Socioeconomic factors hampering the implementation of NGS were identified. Lowering the barrier by covering the NGS cost publicly in a specific clinical setting may have survival and cost-benefit in patients with advanced NSCLC. Multifocal bronchial neuroendocrine tumor (bNET): A new clinical entity. *First Author: Nirosha D. Perera, Department of Internal Medicine, Mayo Clinic, Rochester, MN*

Background: Bronchial carcinoid (BC) is often categorized into multifocal (MBC) or solitary (SBC). MBC, excluding tumorlet and diffuse idiopathic pulmonary neuroendocrine cell hyperplasia, is considered a relatively uncommon subgroup of BC, with much of the MBC literature stemming from case reports/small series. Our study analyzes MBC among a large cohort of 569 patients with BC and argues for change to the current clinical understanding of MBC. We suggest using the term bronchial neuroendocrine tumor (bNET) to more accurately represent its cells of origin and move away from "carcinoid" (historically meaning "carcinoma-like") and the outdated associated connotation that carcinoids all have a similar, benign clinical and biological behavior. **Methods:** Using the Mayo Clinic Epidemiology and Genetics of Lung Cancer Database with Institutional Review Board approval, we retrospectively reviewed 569 patients with bNET (204 males, 365 females) presenting to Mayo Clinic Rochester between 1/1997-12/2012. We used univariate and multivariate Cox regression analyses to evaluate factors affecting overall survival. **Results:** 80 patients (of 569, 14.1%) were diagnosed with multifocal (MbNET) and 489 with solitary (SbNET). Two-sided Fisher's exact tests found that older age, female gender, never having smoked cigarettes, and tumorlets were associated with MbNET diagnosis. Family lung cancer history, histopathologic grading (pathology: typical vs. atypical), Ki67, and presence of syndromes (carcinoid, Cushing, and MEN1 syndromes) were similar between MbNET and SbNET groups. Most MbNET cases were stage III-IV at the time of diagnosis, while the majority of SbNET cases were stage I. 5-year OS (83%) and 5-year PFS (75%) of MbNET patients were higher than those of their SbNET counterparts (74% and 68%, respectively). Metastasis status was an independent prognostic factor of poor OS in SbNET (P<0.001) but not in MbNET (P=0.71)(Table). **Conclusions:** Clinical, radiologic, and histopathologic characteristics and prognostic factors differed between SbNET and MbNET. MbNET arose as a new entity often with advanced stage disease, but good prognosis, which does not follow the NSCLC TNM staging system as in the 2009 NCCN guidelines (used during this study) or the updated 2021 NCCN guidelines which continue to stage lung carcinoid similarly to NSCLC. It may be beneficial to consider multifocal lung carcinoid instead as multifocal bNET, a new clinical entity, warranting a novel staging approach that more accurately reflects prognosis. Research Sponsor: None.

Patient-derived organoids to predict the drug response in locally advanced or metastatic lung cancer: A real-world study. *First Author: Chan-Yuan Zhang, Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong Provincial People's Hospital & Guangdon, Guangzhou, China*

Background: Lung cancer organoids (LCOs) were expected to be the potential precision medicine approach for clinical response prediction. However, the clinical applications of both tissue and malignant serous effusions (MSE) derived LCOs were rarely reported. Our previous work demonstrated that MSE-derived LCOs maintain the genomic signature of the original tumor. In this study, we aimed to create LCOs using tissue or MSE, then validate the reliability of the model by comparing LCOs and their origin from the pathological and molecular levels. Furthermore, drug sensitivity tests of LCOs were also performed to evaluate the feasibility of LCO drug test as an approach for personalized medicine. **Methods:** Primary or metastatic tumor tissues were obtained from advanced lung cancer patients through core biopsy or surgically resected biopsy at the Guangdong Provincial People's Hospital. MSEs were also collected. LCOs were generated from the obtained tissue and MSE, and the pathological features and genomic profiles were verified by analyzing the consistency with their origin. Then, the drug sensitivity scheme was formulated to follow the principles of clinical medication. In addition, proteomics analysis by 4D LC-MS/MS was also performed to analysis the molecular details of combinational therapy. **Results:** In our study, we generated 213 LCOs from 106 patients, mainly from MSE. The success rate to generate LCOs derived from MSE was 81.4% (131/161). The concordance rate of pathological phenotypes of LCOs samples verified by immunohistochemistry with clinical samples was 75% (63/84). In our cohort, LCO based drug sensitivity tests (LCO-DST) of targeted therapies were performed to predict the tumor response, and the AUC value of ROC analysis of osimertinib in *EGFR*-mutant adenocarcinoma reached 0.94(LCOs samples = 15, $p = 0.0047$). There were 2 patients with advanced lung adenocarcinoma, one with *de novo EGFR* mutation*/MET* amplification and the other with *EGFR* mutation combined with acquired *RET* fusion. The results of LCO based drug tests of 2 patients showed that combined targeted therapy (osimertinib plus savolitinib/cabozantinib) showed high tumor inhibition rate validated in clinical treatment and made differences. Then, 4D label-free high through-put proteomic analysis was performed in the patient with *EGFR* mutation and acquired *RET* fusion, demonstrating caspase 3 increased dramatically in combination of osimertinib and BLU-667 and the downstream proteins of EGFR and RET were down-regulated. **Conclusions:** LCOs derived from MSE faithfully reflected the pathological and genomic features of their original patients. The LCOs based drug test results are remarkably consistent with the tumor response. These results suggested the important prospects of LCO as an in vitro model for lung cancer precision medicine. TPS9137 **Poster Session**

Open-label, randomized, multicenter, phase 3 study evaluating trastuzumab deruxtecan (T-DXd) as first-line treatment in patients with unresectable, locally advanced, or metastatic non–small cell lung cancer (NSCLC) harboring HER2 exon 19 or 20 mutations (DESTINY-Lung04). *First Author: Bob T. Li, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The standard of care (SOC) for patients with oncogene driver subsets of metastatic NSCLC is guided by specific molecular characterization and includes immunotherapy, chemoimmunotherapy, and matched targeted therapies. Although targeting HER2 has transformed the care of patients with breast and gastric cancers, there is currently no approved HER2-targeted therapy for NSCLC. T-DXd is an antibody-drug conjugate consisting of an anti-HER2 antibody, a cleavable tetrapeptide-based linker, and a topoisomerase I inhibitor payload. In a cohort of pretreated patients (median, 2 prior lines) with unresectable or metastatic HER2-mutant NSCLC, T-DXd demonstrated durable and robust anticancer activity, with a confirmed objective response rate (ORR) of 55% and median duration of response (DOR), progression-free survival (PFS), and overall survival (OS) of 9.3, 8.2, and 17.8 months, respectively (Li et al. *N Engl J Med.* 2022). Given the efficacy observed in later-line settings and the unmet need for targeted therapies in patients with HER2-mutant NSCLC, evaluating the efficacy of T-DXd in the first-line setting vs SOC is important to determine the optimal treatment. Here we describe the phase 3 DESTINY-Lung04 trial (NCT05048797) evaluating T-DXd as a first-line treatment in patients with NSCLC harboring HER2 mutations. **Methods:** DESTINY-Lung04 is an open-label, randomized, multicenter, phase 3 study evaluating the efficacy and safety of first-line T-DXd vs SOC in patients with unresectable, locally advanced (not amenable to curative therapy), or metastatic nonsquamous NSCLC with HER2 exon 19 or 20 mutations (detected in tissue or circulating tumor DNA). Patients must be naive to systemic therapy with palliative intent in the locally advanced or metastatic disease setting and must not have tumors with *EGFR* or other targetable oncogenic alterations. Patients with brain metastases must have previously completed local therapy. Patients will be randomized to receive T-DXd or SOC (platinum [investigator's choice of cisplatin or carboplatin], pemetrexed, and pembrolizumab). The primary endpoint is PFS defined by RECIST version 1.1 per blinded independent central review (BICR). Secondary endpoints include OS, ORR, and DOR (by RECIST 1.1 per BICR and investigator), investigator-assessed PFS (by RECIST 1.1) and time to second progression or death (per local standard clinical practice), central nervous system PFS (by RECIST 1.1 per BICR), landmark PFS at 12 months (by RECIST 1.1 per BICR and investigator), and landmark OS at 24 months. Safety and tolerability, pharmacokinetics, immunogenicity, and patient-reported outcomes, including pulmonary symptoms and tolerability, will be assessed. Clinical trial information: NCT05048797. Research Sponsor: This study is funded by AstraZeneca Pharmaceuticals. In March 2019, AstraZeneca entered into a global development and commercialization collaboration agreement with Daiichi Sankyo for trastuzumab deruxtecan (T-DXd; DS-8201).

TPS9138 **Poster Session**

A phase I/II multisite study of rucaparib and pembrolizumab maintenance therapy in stage IV non-squamous non–small cell lung cancer after initial therapy with carboplatin, pemetrexed, and pembrolizumab. *First Author: Angel Qin, University of Michigan, Rogel Cancer Center, Ann Arbor, MI*

Background: Carboplatin, pemetrexed, and pembrolizumab (CPP) followed by pemetrexed and pembrolizumab maintenance is a standard of care (SOC) for non-squamous metastatic non-small cell lung cancer (NSCLC), based on results of the KEYNOTE-189 study. The progression free survival (PFS) on this study was 8.8 months. There is increasing data to support that certain sporadic tumors harbor somatic mutations in genes of the homologous recombinant repair (HRR) pathway resulting in a "BRCAness" phenotype rendering sensitivity to PARP inhibitors (PARPi). TCGA data suggest up to 38% of NSCLC have mutations in HRR pathway genes. Furthermore, treatment with PARPi is shown to upregulate PD-L1 expression, which is associated with pembrolizumab response in NSCLC. We therefore hypothesized that maintenance therapy with a PARPi and pembrolizumab will improve PFS compared to SOC pemetrexed and pembrolizumab. **Methods:** This is a single arm, multi-site, investigator-initiated phase I/II study that is enrolling treatment-naïve patients with stage IV nonsquamous metastatic NSCLC without any targetable driver mutations eligible for CPP. Patients without progression after 4 cycles of CPP then proceed to maintenance with rucaparib 600mg PO BID and pembrolizumab 200mg IV every 21 days. The primary objective is efficacy assessed by PFS and second objectives include overall survival, safety, tolerability, and objective response rate (ORR). Correlatives in this study include PD-L1 expression, tumor mutational burden (TMB), and measurements of HRR deficiency as assessed by homologous repair deficiency (HRD) and loss of heterozygosity (LOH) using established methods. Key exclusion criteria include untreated brain metastases and prior exposure to a PARPi or PD-1/PD-L1 inhibitor. The phase I cohort which consisted of 6 patients treated with the approved full doses of rucaparib and pembrolizumab was completed without dose limiting toxicity (DLT). Using a Bayesian decision-theoretic two-stage design, the first stage will enroll 38 patients. If predefined PFS parameters are met, an additional 17 patients, for a total of 55 patients, will be enrolled. To date, 21 patients have been enrolled. Clinical trial information: NCT03559049. Research Sponsor: Merck and Clovis.

TPS9139 **Poster Session**

A phase 1b/2 trial of dupilumab given in conjunction with PD-(L)1 blockade in the treatment of relapsed/refractory metastatic NSCLC. *First Author: Bailey Gleason Fitzgerald, The Tisch Cancer Institute at Mount Sinai Health System, New York, NY*

Background: Although tumor microenvironments may contain chronic inflammatory cells, this milieu can lead to immune evasion and may contribute to resistance to immunotherapy. Dendritic cells are one of the most potent cross presenters of tumor antigen, and their function is crucial to tumor-directed adaptive immune responses. In the KP mouse model of lung adenocarcinoma (KrasG12D; Tp53-/-), we recently identified interleukin-4 (IL-4)-driven suppression of tumor-antigen charged dendritic cells, which was similarly seen in human lung cancer lesions (Maier, B., et al., *A conserved dendritic-cell regulatory program limits antitumour immunity.* Nature, 2020.580(7802):257-262). In the mouse model IL-4 blockade resulted in an increase in IL-12, IFNg and TNF in CD8+ T cells and decreased tumor burden, and further antitumor activity was seen when combined with PD-L1 blockade. Dupilumab is a fully human monoclonal antibody that blocks the IL-4 receptor alpha subunit which disrupts signaling through receptors for both IL-4 and IL-13; it is FDA approved for patients with multiple atopic conditions, in whom series adverse effects are rare. Based on this pre-clinical data, we hypothesize that the addition of dupilumab to anti PD-(L)1 therapy will be well tolerated, and will rescue the anti-tumor effect of immune checkpoint blockade. **Methods:** This is a phase Ib/II trial. Patients with relapsed/refractory NSCLC who have received prior anti PD-(L)1 treatment are eligible for enrollment. In a phase Ib safety run-in, six patients will be enrolled in a modified set-dose 3+3 design. If no more than 1 DLT is observed during this phase, the trial will proceed to phase II. Phase II will enroll a further 15 patients in a minimax design with early stopping for futility to a maximum total of 21 patients. Patients will undergo pre-treatment biopsies and peripheral blood sampling prior to receiving 3 doses of dupilumab, administered every three weeks, in conjunction with continuing standard-of-care anti-PD-(L)1 therapy. Patients will undergo repeat biopsies 4 weeks after starting therapy. After completion of dupilumab (at 9 weeks) patients will undergo repeat staging. The primary endpoint of phase 1b is safety as measured by frequency and severity of adverse effects. The primary endpoint of phase II is overall response rate as assessed using RECIST 1.1 criteria at the time of post-dupilumab imaging. Exploratory endpoints include analysis of peripheral blood by CyTOF and O-link, and tissue biopsies will be analyzed by multiplex-IHC and bulk-RNA-sequencing. T cell receptor sequencing will be performed on tumor and matched peripheral blood samples, and circulating tumor DNA will be assessed at multiple time points. Phase 1b is currently enrolling as planned. Clinical trial information: NCT05013450. Research Sponsor: The Center of Excellence for Thoracic Oncology at Mount Sinai's The Tisch Cancer Institute.

TPS9140 **Poster Session**

Combi-TED: A multicenter, phase II, open-label, randomized trial evaluating efficacy of OSE2021 plus docetaxel or OSE2021 plus nivolumab as second-line therapy in metastatic NSCLC progressing after first-line chemo-immunotherapy. *First Author: Federico Cappuzzo, Istituto Nazionale Tumori Regina Elena, Roma, Italy*

Background: First line combination of chemotherapy and immune checkpoint inhibitors (ICIs) improves overall survival (OS) compared with chemotherapy alone in non-small cell lung cancer (NSCLC) patients. However, only few options are available at chemoimmunotherapy failure, with docetaxel representing the standard of care. Tedopi is a cancer vaccine which stimulates killer T cells, currently under development for the therapy of HLA-A2+ lung cancer. In the ATALANTE-1 Phase III trial (EudraCT no. 2015-003183-36), Tedopi provided clinical benefits in patients with advanced NSCLC who failed to respond to checkpoint inhibitors. Given the need for new therapeutic options in patients failing first-line chemo-immunotherapy and the encouraging preliminary data with Tedopi, there is a strong rationale for investigating the activity of Tedopi plus nivolumab or Tedopi plus docetaxel in patients with metastatic NSCLC failing standard first-line therapy. **Methods:** This is a phase II, non-comparative, randomized multicenter study assessing the combination of Tedopi with docetaxel or nivolumab in NSCLC patients failing after first-line chemoimmunotherapy (EudraCT no. 2020-005170-10). All NSCLC patient candidates for second-line therapy are considered eligible for the study if they are HLA-A2+, with no evidence of EGFR mutations or ALK/ROS1 rearrangement and if they progressed after at least 4 cycles of previous first-line chemo-immunotherapy. Patients are randomly assigned to Tedopi plus docetaxel, Tedopi plus nivolumab (treatment arms) or docetaxel monotherapy (standard arm). The primary endpoint is 1-year OS rate. Secondary endpoints include OS, 2-year OS rate, progression-free survival (PFS), objective response rate (ORR), and safety. An explorative analysis of the correlation of efficacy with several tumor or blood biomarkers (PD-L1 expression, tumor mutational burden, Tedopi neoantigen expression, T cell infiltration), is also performed. Sample size was calculated assuming a 1-year OS rate in the standard arm of 20%. According to the single-stage design, in both treatment arms a 1-year OS rate of 20% would imply that treatment does not warrant further investigation and a 1-year OS rate of 40%, would imply that treatment has a sufficient activity. With a one-sided significance level of 5% and a power of 80%, a total number of 105 patients (35 per treatment arm) need to be enrolled. At the drafting of this abstract, 7 patients have already been enrolled. Total follow-up will be 24 months from last enrolment, for an approximate duration of 48 months. Clinical trial information: NCT04884282. Research Sponsor: OSE Immunotherapeutics.

TPS9141 **Poster Session**

A randomized phase 3 study of entrectinib versus crizotinib in patients (pts) with locally advanced/metastatic *ROS1* fusion-positive (fp) NSCLC with or without baseline CNS metastases (mets). *First Author: Anne-Marie C. Dingemans, Department of Pulmonology, Erasmus University Medical Center, Rotterdam, Netherlands*

Background: ROS proto-oncogene 1 (*ROS1*) fusions are found in 1–2% of NSCLC cases. As CNS mets are common in pts with *ROS1*-fp NSCLC and associated with poor prognosis, CNS-active treatments are needed for these pts. Entrectinib and crizotinib are tyrosine kinase inhibitors (TKIs) of ROS1, recommended as first-line treatments for *ROS1*-fp NSCLC. Both drugs have shown robust systemic efficacy and good tolerability in pts with *ROS1*-fp NSCLC. While crizotinib may have suboptimal CNS activity, entrectinib has shown intracranial efficacy in pts with baseline CNS mets by blinded independent central review (BICR, PMIDs 30215676; 33646820). We hypothesized that entrectinib may have greater CNS activity than crizotinib, potentially addressing the unmet need for pts with *ROS1*-fp NSCLC with CNS mets. **Methods:** This randomized, open-label, multicenter, phase 3 trial (NCT04603807) aims to compare the efficacy and safety of entrectinib vs crizotinib in adult pts with TKI-naïve advanced/metastatic *ROS1*-fp NSCLC, with or without CNS mets. Key eligibility criteria: advanced/recurrent/metastatic NSCLC with *ROS1* fusion determined locally by certified clinical laboratory testing; measurable systemic disease (RECIST 1.1); age ≥18 years; ECOG PS ≤2; no prior ROS1 TKI or systemic treatment for advanced/metastatic disease; adequate hematologic, renal and hepatic functions; prior radiotherapy ≥14 days before randomization and neurologically stable CNS mets per RECIST 1.1 are permitted. Pts will be randomized 1:1 to receive 600 mg entrectinib once a day or 250 mg crizotinib twice a day. Stratification factors are baseline CNS mets (none/measurable/non-measurable) and prior brain radiotherapy ≤2 months (yes/no); to allow sufficient power, ≥30% of randomized pts will have baseline CNS mets. Study treatment will continue until progressive disease, unacceptable toxicity, death or withdrawal from the study. Pts with radiographic disease progression or isolated asymptomatic CNS progression may continue treatment at the investigator's discretion. Tumor assessments (brain MRI and chest, abdomen and pelvis CT/MRI) will occur at screening, Wk 4, Wk 8 and every 8 wks thereafter. Blood samples will be collected at every visit. Primary endpoint: progression-free survival (PFS) by BICR in pts with baseline CNS mets (CNS population, target HR = 0.57). Secondary endpoints: CNS-PFS by BICR and ORR, duration of response (DoR) and PFS (by BICR and investigator) in the intent-to-treat (ITT) population; overall survival in the CNS and ITT populations; CNS-ORR and CNS-DoR by BICR in the CNS population. Impact on quality of life, functioning and lung cancer-specific symptoms will be evaluated via questionnaires in the ITT population. Safety endpoints and biomarkers will also be evaluated. As of 12 Jan 2022, 8 pts are enrolled (first pt enrolled in Oct 2021). Clinical trial information: NCT04603807. Research Sponsor: F. Hoffmann-La Roche Ltd.

TPS9142 **Poster Session**

A phase 1/2 study of the highly selective EGFR inhibitor, BLU-701, in patients with *EGFR*-mutant non–small cell lung cancer (NSCLC). *First Author: Alexander I. Spira, NEXT Oncology Virginia and Virginia Cancer Specialists Research Institute, Fairfax, VA*

Background: Although 3rd-generation tyrosine kinase inhibitors (TKIs), such as osimertinib, are highly effective in front-line metastatic *EGFR*-mutated (*EGFR*m) NSCLC, treatment resistance ultimately occurs, including the emergence of the on-target C797X mutation for which there are no approved TKIs. BLU-701 is an investigational, reversible, brain-penetrant, wildtype-sparing oral TKI with nanomolar potency on common activating (exon 19 deletion and L858R) and C797X resistance mutations (Tavera L et al. AACR 2022). BLU-701 has shown promising preclinical data, including antitumor central nervous system (CNS) activity that may improve patient outcomes. Additionally, combining BLU-701 with standard of care therapies may provide enhanced disease control across multiple lines of treatment, including against heterogenous tumors, in patients with *EGFR*m NSCLC. **Methods:** HARMONY (NCT05153408) is an ongoing, global phase 1/2, open-label, first-in-human study designed to evaluate the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and antitumor activity of BLU-701 as a monotherapy or in combination with osimertinib or platinum-based chemotherapy in patients with *EGFR*m NSCLC. Key inclusion criteria include patients ≥18 years of age with metastatic *EGFR*m NSCLC; Eastern Cooperative Oncology Group performance status 0–1; and previous treatment with ≥1 EGFR-targeted TKI. Patients in the phase 2 monotherapy part must harbor an *EGFR* C797X resistance mutation (locally assessed). Key exclusion criteria are tumors harboring *EGFR* T790M mutations, *EGFR* exon 20 insertions, or other known driver alterations, including *KRAS*, *BRAF* V600E, *NTRK1/2/3*, *HER2*, *ALK*, *ROS1*, *MET*, or *RET*. Phase 1 primary endpoints are maximum tolerated dose, recommended phase 2 dose (RP2D), and safety. The phase 2 primary endpoint is overall response rate (ORR) by RECIST 1.1. Secondary endpoints include ORR (phase 1), duration of response, and PK/PD (phase 1 and phase 2); disease control rate, progression-free survival, overall survival, antitumor CNS activity, and safety (phase 2). The phase 1 dose escalation will adopt a Bayesian optimal interval design. Patients will be enrolled into 3 treatment cohorts: part 1A (n≈40–80; BLU-701), part 1B (n≈35; BLU-701 + osimertinib), and part 1C (n≈18; BLU-701 + carboplatin and pemetrexed). Patients in the phase 2 dose expansion (n≈24) will be treated at the RP2D of BLU-701 as monotherapy. Patients may receive treatment until disease progression, unacceptable toxicity, or other discontinuation criteria are met. Enrollment in this study has started, and sites will be open across North America, Europe, and Asia. Clinical trial information: NCT05153408. Research Sponsor: Blueprint Medicines Corporation.

TPS9143 **Poster Session**

A phase I, open-label, dose escalation, confirmation, and expansion trial of BI 1810631 as monotherapy in patients with advanced/metastatic solid tumors with HER2 aberrations. *First Author: John Heymach, Department of Thoracic/Head and Neck Medical Oncology, Division of Cancer Medicine, MD Anderson Cancer Center, University of Texas, Houston, TX*

Background: *HER2* mutations are present in 2–4% of NSCLC tumors; of these ~50% are exon 20 insertion (ex20ins) mutations. There is an unmet need for effective targeted therapy against *HER2* mutations in solid tumors, particularly in NSCLC. Historically, ex20ins mutations have responded poorly to TKIs. Moreover, TKIs that inhibit both mutant EGFR and HER2 are typically limited by toxicities associated with inhibition of wild-type EGFR. Despite the promise of trastuzumab deruxtecan and other agents in this setting, the development of orally available selective TKIs is important given the heterogeneity of HER2 aberrations, potential for combination regimens, and the risk of ILD with ADCs. BI 1810631 is a HER2 selective TKI that covalently binds to both wild-type and mutated HER2 receptors, including ex20ins, whilst sparing EGFR signaling; preclinical data suggest good tolerability and efficacy. This Phase Ia/Ib, open-label, non-randomized study aims to determine the safety, MTD, PK, pharmacodynamics, and preliminary efficacy of BI 1810631 in pts with *HER2+* solid tumors (NCT04886804). **Methods:** ~96 pts from 5–7 sites in the US, Netherlands, Japan, and China will be recruited. Phase Ia: consecutive cohorts of pts will receive BI 1810631 QD or BID at escalating doses. Starting dose level: 15 mg BID (~36 pts); QD schedule will begin after one dose level above estimated therapeutic dose of BI 1810631 is determined safe by the Dose Escalation Committee (expected starting dose: 60 mg [~30 pts]). BI 1810631 dose escalation will continue until MTD/RP2D for each schedule is determined, as well as a preferred Phase Ib schedule. Phase Ib: an initial 30 pts with *HER2* ex20ins mutation-positive, pre-treated NSCLC will be enrolled, with possible inclusion of additional cohorts in the future. Overall pt inclusion criteria (Phase Ia): ≥18 years of age; histologically/cytologically confirmed *HER2+* (defined as overexpression, gene amplification, non-synonymous somatic mutation, or gene rearrangement involving *HER2* or *NRG1)* advanced/unresectable/metastatic solid tumor refractory/not suitable for standard therapy; exhausted treatment options; measurable/evaluable lesions (per RECIST v1.1); ECOG PS ≤1. Phase Ib criteria: *HER2* ex20ins mutation-positive NSCLC; received ≥1 line of platinum-based combination chemotherapy in the advanced/metastatic setting. Primary endpoints: MTD based on number of DLTs/number of pts with DLTs (Phase Ia); objective response (Phase Ib). Secondary endpoints: number of pts with DLTs throughout entire treatment period and PK parameters (Phase Ia/Ib); duration of response, disease control, duration of disease control, and PFS (Phase Ib). The trial is actively recruiting with 6 pts enrolled to date. More patients may be recruited depending on whether 2 dose levels have been completed and the MTD/RP2D determined. Clinical trial information: NCT04886804. Research Sponsor: Boehringer Ingelheim, Behbood Sadrolhefazi.

TPS9144 **Poster Session**

A phase II randomized, open-labelled, multicenter study of safety and efficacy of combination brigatinib and carboplatin-pemetrexed therapy or brigatinib monotherapy as first-line treatment in patients with advanced ALK-positive non–small cell lung cancer (IFCT-2101 MASTERPROTOCOL ALK). *First Author: Michael Duruisseaux, URCOT, Hôpital Louis Pradel, Hospices Civils de Lyon Cancer Institute, Bron, France*

Background: Second generation ALK tyrosine kinase inhibitors (ALK-TKI), including brigatinib, provide substantial therapeutic benefit in first-line treatment of ALK-positive NSCLC patients (pts) but relapse eventually occurs in all pts due to development of drug resistance, possibly caused by emergence of drug-tolerant cells (DTC). Combining chemotherapy to TKI may prevent DTC emergence in preclinical studies, and results in prolonged progression-free survival (PFS) and overall survival in *EGFR*-mutant NSCLC. We hypothesize that combination of second generation ALK-TKI with chemotherapy will improve clinical outcomes in advanced *ALK*-positive NSCLC patients. The IFCT-2101 MASTERPROTOCOL ALK trial will evaluate the efficacy and safety of brigatinib and carboplatin-pemetrexed combination in treatment-naïve metastatic *ALK*-positive NSCLC. **Methods:** The IFCT-2101 MASTERPROTOCOL ALK randomized, open-label phase II trial will enrol 110 pts in 30 French centers over 24 months. Eligible pts will have metastatic NSCLC with *ALK*-fusion according to local testing, be untreated for advanced disease, and have an ECOG Performance Status (PS) of 0-1 and at least one measurable lesion per RECIST 1.1. Pts with asymptomatic and stable brain metastases (BM) will be eligible. Exclusion criteria include leptomeningeal metastases. Patients will be randomized 1:1 to receive brigatinib monotherapy (Arm A) or combination brigatinib and carboplatin-pemetrexed therapy (Arm B), with PS (0 *vs* 1) and BM (presence *vs* absence) as stratification factors. Brigatinib will be administered at a dose of 90 mg QD for a 7-day lead-in period followed by 180 mg QD continuously, in 28-day cycles. In Arm B, 4 cycles of carboplatin (AUC 5) and pemetrexed (500 mg/m^2) therapy every 3 weeks will be added at Day 8 of brigatinib treatment. Treatment will continue until progression, intolerable toxicity or discontinuation. The first 26 pts enrolled in Arm B will represent the population of a safety phase, during which adverse events (AE) will be closely monitored by an independent data monitoring committee. The primary endpoint is investigator-assessed 12-month PFS rate. Secondary endpoints include independently-reviewed 12-month PFS rate, overall response rate (ORR), 12-month intracranial PFS and ORR, incidence, nature and severity of AEs, and impact of *ALK*-fusion detection, co-mutations and clearance of circulating tumor (ct) DNA (Guardant360) on outcome. Exploratory objectives include the evaluation of early blood ctDNA decrease on patient outcome. The study is enrolling and primary completion date is March 2025. Clinical trial information: NCT05200481. Research Sponsor: Takeda France, IFCT.

TPS9145 **Poster Session**

FoRT 05-BEAT: A phase II randomized trial comparing atezolizumab versus atezolizumab + bevacizumab as first-line treatment in patients with PD-L1 high advanced/metastatic NSCLC. *First Author: Rita Migliorino, Pulmonary Oncology Unit, San Camillo-Forlanini Hospital, Rome, Italy*

Background: Several ongoing phase III studies are evaluating the efficacy of first-line atezolizumab in combination with chemotherapy in patients with non small-cell lung cancer (NSCLC). Among angiogenesis inhibitors, bevacizumab is approved as first-line therapy in combination with chemotherapy or in combination with erlotinib in patients with NSCLC harboring activating EGFR mutations. Recent evidence (Wallin 2016) suggests that the combination of atezolizumab and bevacizumab increases intra-tumoral CD8+T cells, suggesting that dual VEGF and PD-L1 inhibition improves antigen-specific T-cell migration. In addition, preliminary clinical data suggested a strong synergistic effects of bevacizumab with immune checkpoint inhibitors. There is therefore a strong rationale for investigating the combination of atezolizumab and bevacizumab in patients with advanced/metastatic NSCLC. The FoRT 05-BEAT is a multicenter, Italian, phase II, randomized study comparing atezolizumab monotherapy versus the combination of atezolizumab and bevacizumab in patients with chemo-naive metastatic NSCLC and high levels of PD-L1 expression. **Methods:** The trial was conducted in 35 Italian centers: chemotherapy naive metastatic NSCLC patients, with high levels of PD-L1 expression (PD-L1 TPS ≥50% or TC/IC 3 scoring) were randomly assigned to atezolizumab monotherapy (1200 mg every 3 weeks) or to the combination of atezolizumab (1200 mg every 3 weeks) and bevacizumab (15 mg/kg every 3 weeks).The primary endpoint is overall survival (OS) rate at 18 months. Secondary endpoints include response rate (RR), PFS, OS according to presence of bone and/or hepatic metastases. Safety considerations will be considered. Exploratory analysis of predictive biomarker on tumor tissue and blood samples has been planned. Sample size has been calculated assuming a 18 months OS of 50% in the atezolizumab arm. Therefore, a total of 186 patients is needed to detect an absolute improvement of 20%, thus obtaining a 18mOS of 70% in the combination arm, with a power of 80% at a significance level of 5%. Taking into account the percentage of patients lost-to-follow-up, the sample size has been increased by 10% (N = 206 patients, 103 per arm). At the drafting of this abstract, 57 patients have already been enrolled (47 randomized). Clinical trial information: NCT03896074. Research Sponsor: Roche.

TPS9146 **Poster Session**

EVOKE-02: A phase 2 study of sacituzumab govitecan (SG) plus pembrolizumab (pembro) with or without platinum chemotherapy in first-line metastatic non–small cell lung cancer (NSCLC). *First Author: Edward B. Garon, Ronald Reagan UCLA Medical Center, Santa Monica, CA*

Background: Most patients (pts) with advanced NSCLC do not harbor genomic alterations associated with approved first-line targeted therapies. The standard of care for these pts is a programmed death (ligand)-1 (PD-[L]1) inhibitor alone, if the tumor highly expresses PD-L1, or in combination with platinum doublet chemotherapy, independent of PD-L1 expression. However, most pts do not respond to these therapies or achieve only a transient response, highlighting an unmet need. SG is an antibody-drug conjugate composed of an anti–Trop-2 antibody coupled to the cytotoxic SN-38 payload via a proprietary, hydrolyzable linker. In the phase 1/2 IMMU-132-01 basket study (NCT01631552), SG demonstrated an objective response rate (ORR) of 17% and median overall survival (OS) of 9.5 mo, with a manageable safety profile in 54 pts with metastatic NSCLC after multiple prior therapies (Heist RS, et al. *J Clin Oncol. 2017*). We hypothesize that combining SG with pembro or with pembro + platinum chemotherapy will improve outcomes for pts with advanced NSCLC. **Methods:** EVOKE-02 (NCT05186974) is an open-label, multicenter, multicohort, global phase 2 study evaluating SG plus pembro with or without carboplatin (carbo) or cisplatin (cis) in advanced NSCLC. Key eligibility criteria include age ≥18 y, stage IV NSCLC at enrollment, measurable disease by RECIST v1.1, ECOG performance status of 0 or 1, and adequate organ function. Pts must not have actionable genomic alterations and must not have received prior systemic therapy for metastatic NSCLC. Up to 164 pts will be enrolled. SG plus pembro will be assessed in squamous/nonsquamous NSCLC with Tumor Proportion Score (TPS) ≥50% (cohort A, ~30 pts) and TPS < 50% (cohort B, ~30 pts), and SG plus pembro with carbo/cis in nonsquamous (cohort C, ~40 pts) and squamous (cohort D, ~40 pts) NSCLC regardless of PD-L1 expression. Pts are randomly assigned if cohorts enrolling concurrently have overlapping eligibility. SG will be administered intravenously (IV) at 10 mg/kg on d 1 and 8 until disease progression or unacceptable toxicity, pembro 200 mg IV on d 1 for up to 35 cycles, carbo AUC 5 or cis 75 mg/m^2 on d 1 for up to 4 cycles in 21-d cycles. A safety run-in will be conducted for cohorts C and D (up to 24 pts each) to determine the optimal SG dose by dose de-escalation. Choice of platinum will be based on preliminary efficacy in safety run-in. The primary endpoints are ORR assessed by independent review per RECIST v1.1 and the incidence of dose-limiting toxicities per dose for the first 21 d of the safety run-in to determine the recommended phase 2 dose of SG in combination with pembro and a platinum. Key secondary endpoints include progression-free survival by independent review, OS, duration of response, disease control rate, and safety. This study is open for recruitment and is enrolling globally. Clinical trial information: NCT05186974. Research Sponsor: Gilead Sciences, Inc.

TPS9147 **Poster Session**

A phase 2 study of VS-6766 (RAF/MEK clamp) RAMP 202, as a single agent and in combination with defactinib (FAK inhibitor) in recurrent KRAS mutant (mt) and BRAF mt non–small cell lung cancer (NSCLC). *First Author: D. Ross Camidge, University of Colorado Cancer Center, Aurora, CO*

Background: KRAS is mutated (mt) in 25% of NSCLC adenocarcinoma, with KRAS G12V and G12C mt occurring in ~7% and ~13% of patients (pts), respectively. Whereas G12C inhibitors have demonstrated promising activity in pts with KRAS G12C NSCLC, KRAS G12V NSCLC remains an unmet need. BRAF mt occurs in ~4% of NSCLC with roughly equal split between BRAF V600E and non-V600E. VS-6766 is a small molecule RAF/MEK clamp that inhibits BRAF, CRAF and MEK, enabling VS-6766 to block MEK signaling without compensatory activation of MEK observed with MEK-only inhibitors. VS-6766 potently inhibits proliferation of KRAS and BRAF mt cell lines. Focal adhesion kinase (FAK) activation is a putative resistance mechanism to RAF and MEK inhibition, and defactinib, a small molecule FAKi, has shown synergistic anti-tumor activity with VS-6766 in KRAS mt NSCLC models. In a KRAS G12V mt NSCLC mouse model, which was shown to be especially dependent on CRAF, VS-6766 induced strong tumor regressions both as monotherapy and in combination with FAKi (Coma AACR 2021). Clinically, VS-6766 monotherapy has shown responses in KRAS mt NSCLC including pts with KRAS G12V and in pts with BRAF V600E solid tumors (Guo 2020; Martinez-Garcia 2012). The combination of VS-6766 + defactinib is currently being evaluated in the Investigator Sponsored FRAME study. In an updated analysis of response in 20 pts with KRAS mt NSCLC, there were 2 confirmed PRs, 1 unconfirmed PR and 10 SDs (ORR = 15%; DCR = 65%) with 7/20 pts remaining on treatment for ≥24 weeks. The 2 pts with KRAS G12V NSCLC both had confirmed PRs (ORR = 100%). This combination regimen exhibited a manageable safety profile with no NSCLC pts discontinuing for adverse events (Krebs AACR 2021). **Methods:** This is an international phase 2, adaptive, multicenter, randomized, open label study designed to evaluate the efficacy and safety of VS-6766 vs. VS-6766 + defactinib in pts with recurrent KRAS or BRAF mt NSCLC (NCT04620330). Part A will determine the optimal regimen, either VS-6766 monotherapy or VS-6766 + defactinib based on pts with KRAS G12V. Part A will consist of 5 NSCLC arms: Arm 1 VS-6766 monotherapy in KRAS G12V, Arm 2 VS-6766 + defactinib in KRAS G12V, Arm 3 the combination in KRAS non-G12V, Arm 4 the combination in BRAF V600E and Arm 5 the combination in BRAF non-V600E. Part B will determine the efficacy of the optimal regimen identified in Part A. Pts must have histologic or cytologic evidence of NSCLC, measurable disease according to RECIST V1.1, known KRAS or BRAF mt and at least 1 prior systemic therapy (appropriate therapy for activating mutation and/or platinum-based therapy). Part A will enroll 102 pts Arms 1 and 2 (KRAS G12V), and Arms 4 and 5 (BRAF V600E and non-V600E) are currently open. Arm 3 (KRAS non-G12V) enrollment is completed. The total number of pts in Part B will be determined by results from Part A. Clinical trial information: NCT04620330. Research Sponsor: Verastem.

TPS9148 **Poster Session**

A phase 1/2 study of VS-6766 (RAF/MEK clamp) in combination with sotorasib (G12C inhibitor) in patients with KRAS G12C mutant non–small cell lung cancer (NSCLC) (RAMP 203). *First Author: Ramaswamy Govindan, Washington University School of Medicine, St. Louis, MO*

Background: KRAS is mutated (mt) in 25% of non-small cell lung cancer (NSCLC) adenocarcinoma, with KRAS G12C mt occurring in ~13% of patients. The G12C inhibitor (G12Ci) sotorasib has recently received FDA approval for patients with KRAS G12C NSCLC. Several studies have shown that simultaneous targeting of multiple nodes in the RAS pathway may be optimal for durable pathway inhibition and response. Furthermore, acquired mutations and amplifications in the RAS pathway occur clinically upon progression on sotorasib or adagrasib. Accordingly, combination of G12Ci with a downstream blocker of the RAS pathway may be needed for more durable response. VS-6766 is a unique small molecule RAF/MEK clamp that inhibits BRAF, CRAF and MEK, enabling VS-6766 to block MEK signaling more consistently without the compensatory activation of MEK that reduces the efficacy of MEK-only inhibitors. In vitro 3D proliferation and in vivo tumor models were used to assess anti-tumor efficacy of VS-6766 ± G12Ci. In KRAS G12C mt NSCLC cell lines, VS-6766 was synergistic with both sotorasib and adagrasib in reducing tumor cell viability which correlated with deeper inhibition of RAS pathway signaling. In vivo, combination of VS-6766 with sotorasib induced strong tumor regressions in contrast to sotorasib monotherapy or sotorasib plus trametinib. Initial clinical activity of VS-6766 in KRAS G12C mt NSCLC is supported by the FRAME study [NCT03875820] results, in which 4/6 patients with KRAS G12C mt NSCLC showed tumor reduction including 1 PR. These results support the clinical evaluation of VS-6766 in combination with a G12Ci for treatment of KRAS G12C mt NSCLC. **Methods:** This is a Phase 1/2, multicenter, open label, dose evaluation/dose expansion study designed to evaluate the efficacy and safety of VS-6766 in combination with sotorasib in patients with KRAS G12C mt NSCLC who have not previously been treated with a KRAS G12Ci or have experienced disease progression while undergoing therapy with a KRAS G12Ci [NCT05074810]. The study will be conducted in two parts: Part A (dose evaluation) and Part B (dose expansion). Up to 3 dose levels will be evaluated in Part A to determine the Recommended Phase 2 Dose (RP2D) for Part B. Part B will assess the efficacy of the RP2D and will be conducted in 2 cohorts: patients who are G12Ci treatment naïve (cohort 1) and patients who have experienced disease progress during G12Ci therapy (Cohort 2). Patients enrolled must have histologic or cytologic evidence of NSCLC, measurable disease according to RECIST V1.1 and known KRAS G12C mutation. The study will enroll up to 121 patients with a minimum of 6 and a maximum of 12 patients in Part A and an additional 109 patients in Part B (minimum of 41 patients at RP2D stage 1 for cohort 1 and 2 or RP2D stages 1 and 2 in both cohorts). Clinical trial information: NCT05074810. Research Sponsor: Verastem.

TPS9149 **Poster Session**

EVOKE-01: A phase 3 study of sacituzumab govitecan (SG) versus docetaxel in patients with non–small cell lung cancer (NSCLC) progressing on or after platinum-based chemotherapy and checkpoint inhibitors. *First Author: Marina Chiara Garassino, University of Chicago, Department of Medicine, Chicago, IL*

Background: Single-agent chemotherapy, such as docetaxel, is the standard of care in patients with metastatic NSCLC who progressed on platinum-based therapy and checkpoint inhibitors. However, docetaxel is associated with poor survival (median overall survival [OS] of < 1 year); thus, novel agents are needed to further improve outcomes in this setting. SG is an antibody-drug conjugate composed of an anti–Trop-2 antibody coupled to the cytotoxic SN-38 payload via a proprietary, hydrolyzable linker. In a single-arm expansion of the phase 1/2 IMMU-132-01 basket study of advanced epithelial cancers (NCT01631552), SG demonstrated an objective response rate (ORR) of 17% and median OS of 9.5 months, with a manageable safety profile in 54 patients with metastatic NSCLC who had multiple prior therapies (Heist RS, et al. *J Clin Oncol.* 2017). EVOKE-01 randomized phase 3 study was designed to further evaluate SG in patients with metastatic NSCLC. **Methods:** EVOKE-01 (NCT05089734) is an open-label, global, multicenter, randomized, phase 3 study comparing the efficacy and safety of SG vs docetaxel in patients with metastatic NSCLC. Key eligibility criteria include age ≥18 years, pathologically documented stage IV NSCLC at time of study entry, and progression after platinum-based chemotherapy and anti-PD(L)1 therapy given either in combination or sequentially. Patients with EGFR, ALK, or other known actionable genomic alterations must have also received treatment with ≥1 approved appropriate TKI. Other inclusion criteria are ECOG performance status 0-1 and adequate hematologic, hepatic, and renal function. Patients with prior treatment with topoisomerase inhibitors are excluded. Patients are randomized 1:1 to receive intravenous SG (10 mg/kg on day 1 and 8) or docetaxel (75 mg/m^2 on day 1) in 21-day cycles until progressive disease or unacceptable toxicity. Stratification is based on predominant histology (squamous vs nonsquamous), best response to prior immune therapy (PD/SD vs CR/PR), and prior therapy for actionable genomic alteration (yes vs no). The primary endpoint is OS. Key secondary endpoints include progression-free survival, ORR, duration of response, and disease control rate, as assessed by investigator RECIST v1.1, mean change from baseline in NSCLC-SAQ total score and shortness of breath, and safety. This study plans to enroll ~520 patients globally and is open for recruitment. Clinical trial information: NCT05089734. Research Sponsor: Gilead Sciences, Inc.

TPS9150 **Poster Session**

Trial in progress: A phase 2 study of sotorasib as first-line treatment in patients with stage IV non–small cell lung cancer (NSCLC) whose tumors harbor a *KRAS p.G12C* mutation (CodeBreaK 201). *First Author: Kathryn Cecilia Arbour, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Chemo-immunotherapy regimens represent a standard of care for the first-line treatment of metastatic NSCLC, yet clinical outcomes in patients bearing tumors that lack PD-L1 expression [PD-L1 Tumor Proportion Score (TPS) < 1%)] or harbor a serine/threonine kinase 11 (*STK11*) mutation remain poor. Sotorasib is a selective, irreversible small molecule $KRAS^{G12C}$ inhibitor that is approved for the treatment of patients with locally advanced or metastatic *KRAS* p.G12C-mutated NSCLC following failure of at least one prior line of systemic therapy and has previously demonstrated robust antitumor activity in subgroups of *KRAS* p.G12C mutant NSCLC with PD-L1 TPS <1% and/or *STK11* co-mutations. We hypothesized that sotorasib may represent an effective first-line therapy for subgroups of NSCLC patients who may have suboptimal chemo-immunotherapy outcomes and a high unmet clinical need. **Methods:** This phase 2, open-label, global study is designed to evaluate the efficacy and safety of sotorasib (960 mg or 240 mg daily) as first-line treatment in approximately 170 patients with *KRAS* p.G12C-mutated, metastatic NSCLC with PD-L1 TPS <1% as determined by immunohistochemical assay and/or presence of *STK11* mutation as determined by next-generation sequencing (NGS). Key eligibility criteria include patients with untreated metastatic NSCLC without active brain metastases. Patients will be stratified by known presence of *STK11* mutation. The primary endpoint is objective response assessed by Response Evaluation Criteria in Solid Tumors (RECIST) 1.1. Secondary endpoints include disease control, duration of response, time to response, progression-free survival per RECIST 1.1, overall survival, safety and tolerability, and pharmacokinetic profile. Enrollment began in January 2022 and is ongoing. Contact Amgen Medical Information for more information. Clinical trial information: NCT04933695. Research Sponsor: Amgen Inc.

TPS9151 **Poster Session**

Aumolertinib plus apatinib versus aumolertinib as first-line treatment in patients with EGFR mutation–positive locally advanced or metastatic non–small cell lung cancer (NSCLC). *First Author: Fan Zhang, Department of Oncology, Chinese PLA General Hospital, Beijing, China*

Background: Currently, EGFR-TKIs are widely accepted as the standard treatment for EGFR-mutant advanced NSCLC; however, acquired resistance is inevitable. Preclinical and clinical evidence has demonstrated that dual blockade of the EGFR and VEGF pathways is a viable strategy in the EGFR-mutant advanced NSCLC population to overcome the resistance to EGFR-TKIs. Aumolertinib (HS-10296) is a novel, third-generation EGFR-TKI approved in China to treat EGFR mutation positive non-small cell lung cancer. Apatinib is a small-molecule tyrosine kinase inhibitor that has promising anti-angiogenesis and antitumor activity for NSCLC. Here, we aimed to evaluate the safety and anticancer activity of aumolertinib alone/with apatinib for advanced/metastatic NSCLC patients with EGFR mutation. **Methods:** The phase III, multicenter, randomized, open-label, controlled study is evaluating the efficacy and safety of aumolertinib plus apatinib versus aumolertinib alone as first line therapy in adult patients with EGFR+ NSCLC. Adult patients with histologically confirmed stage IIIB/IV NSCLC harboring EGFR mutations without prior EGFR TKI treatment are eligible for this study. The performance status (Eastern Cooperative Oncology Group) is 0 or 1. This trial prepared to enroll approximately 300 patients, which will be randomized (1:1) to receive oral aumolertinib once daily 110 mg or adding apatinib 250 mg a day until assessed progressive disease(PD)，stratified by EGFR mutation (Ex19del /L858R/others) and distant metastases sites (brain/liver/others). The primary endpoint is progression free survival assessed by investigators using Response Evaluation Criteria in Solid Tumors 1.1. Secondary endpoints are disease control rate, duration of response, overall survival and safety. Adverse effects were graded per CTCAE v.4.03. This trial is registered as ChiCTR2100047453. Results: Recruiting. Conclusions: Recruiting. Clinical trial information: ChiCTR2100047453. Research Sponsor: Hansoh Pharma.

TPS9152 **Poster Session**

GALLANT-1: Galectin-3 (Gal-3) inhibitor GB1211 plus atezolizumab (atezo) in patients with non–small cell lung cancer (NSCLC)—A randomized, double-blind trial. *First Author: François Ghiringhelli, University of Burgundy, Genetic and Immunotherapy Medical Institute, Centre Georges Francois Leclerc, Dijon, France*

Background: Gal-3 is a protein that binds specifically to N-acetylglucosamine-expressing carbohydrates, which are upregulated on key tumorigenic cell surface proteins. Gal-3 is widely overexpressed in the tumor microenvironment and is generally linked to poor outcomes. Gal-3 regulates immune cell function of T cells and macrophages, and promotes neovascularization and fibrosis [Peng Cancer Res 2008; Markowska J Biol Chem 2011; Kouo Cancer Immunol Res 2015]. Gal-3 sequesters interferon gamma, reduces T-cell influx, and contributes to tumor cell evasion of the immune system via LAG-3 activation [Chen PNAS 2009; Gordon-Alonso Nat Commun 2017]. Gal-3 has been identified as a marker of resistance to checkpoint inhibitors (CPIs); patients with stage IV NSCLC with high Gal-3 levels (> 70% Gal-3 immunohistochemical staining) have been shown to be resistant to the CPI pembrolizumab [Capalbo Int J Mol Sci 2019]. Animal data indicate synergy between CPI therapy and Gal-3 inhibition [Vuong Cancer Res 2019; Zhang FEBS Open Bio 2021]. Thus, inhibiting Gal-3 together with CPI-based immunotherapy may enhance tumor-specific immune responses, and overcome CPI resistance. **Methods:** GALLANT-1 (NCT05240131) is a 3-part, placebo-controlled phase Ib/IIa trial that will investigate safety and efficacy of GB1211 (a Gal-3 inhibitor) + atezo vs placebo + atezo in patients with advanced NSCLC. Part A will include 8–12 patients and study safety and tolerability of 200 mg and 400 mg GB1211 twice-daily + atezo (open-label). Primary endpoint is number of adverse events (AEs) after 12 weeks' treatment and will determine the dosage for Part B. Part B will include 75–94 patients, and is a randomized, double-blind study of GB1211 + atezo or placebo + atezo. Primary endpoints are safety (number of AEs) and efficacy (percentage change from baseline in the sum of longest diameter of target lesions after 12 weeks' treatment). Part C is an expansion study including patients from Parts A and B, with safety and efficacy assessments. Eligibility criteria: advanced or metastatic stage IIIB or IV NSCLC adenocarcinoma; measurable disease per RECIST v1.1; expression of programmed death ligand-1 on ≥50% of tumor cells; eligible for 1200 mg atezo every 3 weeks. Exclusion criteria: symptomatic, untreated, or actively progressing central nervous system metastases; prior systemic chemotherapy for treatment of recurrent advanced or metastatic disease, except if part of neoadjuvant/adjuvant therapy; prior treatment with immune CPIs and/or GB1211; presence of *EGFR* mutation and *ALK*, *ROS1*, and *RET* alterations; treatment with antineoplastic or systemic immunotherapeutic agents prior to first GB1211 dose; severe infectious disease < 4 weeks prior to first GB1211 dose; active hepatitis B or C, HIV, or COVID-19. The study is being initiated; updated enrollment status will be presented at the meeting. Clinical trial information: NCT05240131. Research Sponsor: NCT05240131 (GALLANT-1) is sponsored by Galecto, Inc. Atezolizumab is manufactured by Roche Registration GmbH, Germany. Third-party medical writing assistance was provided by Lynda McEvoy, PhD, of Ashfield Health, funded by Galecto, Inc.

TPS9153 **Poster Session**

Capmatinib plus osimertinib versus platinum-pemetrexed doublet chemotherapy as second-line therapy in patients with stage IIIb/IIIc or IV *EGFR*-mutant, T790M-negative NSCLC harboring *MET* amplification. *First Author: Yi-Long Wu, Department of Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital and Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: *MET* amplification can arise as a bypass resistance mechanism to EGFR tyrosine kinase inhibitors (TKIs) and occurs in ~5-26% of EGFR TKI resistant *EGFR*-mutant non-small cell lung cancer (NSCLC). These patients (pts) have limited treatment options, particularly in the *EGFR* T790M negative (T790M–) setting. Capmatinib, a MET inhibitor, is approved in about ten countries for the treatment of metastatic *MET* exon 14 skipping NSCLC. In preliminary studies, capmatinib plus EGFR TKIs showed antitumor activity in the post-EGFR TKI, *EGFR*-mutant NSCLC setting. GEOMETRY-E (NCT04816214) is a randomized, controlled, open-label, multicenter, phase 3 study evaluating the efficacy and safety of capmatinib + osimertinib vs platinum-pemetrexed doublet chemotherapy as second line treatment for advanced NSCLC. **Methods:** This ongoing study began enrollment in September 2021 and is recruiting adult pts with stage IIIB/IIIC or IV *EGFR*-mutant, T790M–, *MET*-amplified NSCLC who had progressed on either $1^{st}/2^{nd}$ generation EGFR TKIs, osimertinib or other 3^{rd} generation EGFR TKIs. Pts with neurologically unstable, symptomatic CNS metastases or those requiring increasing doses of steroids ≤2 weeks prior to study entry to manage CNS symptoms are ineligible. This is a 2-part study where Part 1 (initial run-in,~10 pts) will confirm the recommended dose for the randomized Part 2 and evaluate the safety and tolerability of capmatinib + osimertinib. In Part 1, pts will receive oral capmatinib 400 mg twice daily + osimertinib 80 mg once daily in 21-day cycles. Part 2 will evaluate the efficacy and safety of capmatinib + osimertinib vs platinum (cisplatin/carboplatin)-pemetrexed. Part 2 will enroll ~225 pts, in 2:1 randomization, stratified by the presence of brain metastases (yes/no) and prior treatment with 3^{rd} generation EGFR TKIs (yes/no). In Part 1, the primary endpoint is the incidence of dose limiting toxicities during the first 21 days of treatment. Secondary endpoints include safety; tolerability; pharmacokinetics (PK); investigator-assessed overall response rate (ORR), duration of response (DOR), time to response (TTR), disease control rate (DCR) and progression-free survival (PFS) per the Response Evaluation Criteria in Solid Tumors version 1.1 (RECIST 1.1). In Part 2, the primary endpoint is blinded independent review committee (BIRC)-assessed PFS per RECIST 1.1. The key secondary endpoints are ORR by BIRC per RECIST 1.1 and overall intracranial response rate (OiRR) by BIRC per Response Assessment in Neuro-Oncology Brain Metastases (RANO-BM). Other secondary endpoints include DOR, TTR and DCR by BIRC; investigator-assessed PFS after next line of treatment; PK; safety; overall survival; patient-reported outcomes; intracranial DCR, duration of and time to intracranial response by BIRC per RANO-BM. Clinical trial information: NCT04816214. Research Sponsor: Novartis Pharmaceuticals.

TPS9154 **Poster Session**

Phase I trial of in situ vaccination with autologous CCL21-modified dendritic cells (CCL21-DC) combined with pembrolizumab for advanced NSCLC. *First Author: Aaron E. Lisberg, University of California-Los Angeles, Los Angeles, CA*

Background: Effective immunotherapy options are lacking for patients with advanced non-small cell lung cancer (NSCLC) who progress on a programmed cell death-(ligand)1 [PD-(L)1] inhibitor and for those that are epidermal growth factor receptor (EGFR) mutation or anaplastic lymphoma kinase (ALK) rearrangement positive after progression on tyrosine kinase inhibitor (TKI) therapy. One potential approach to improve immune checkpoint efficacy in these patient populations is to promote cytolytic T cell infiltration into tumors. This can be accomplished via *in situ* vaccination with functional antigen presenting cells (APCs) which can take advantage of the full repertoire of tumor antigens and convert the tumor into a lymph node-like environment promoting both local and systemic T cell activation. The chemokine CCL21 promotes co-localization of naive T cells and antigen-experienced dendritic cells (DCs) to facilitate T cell activation. Our preclinical studies and phase I trial of intratumoral (IT) administration of DC genetically modified to overexpress CCL21 (CCL21-DC) revealed augmentation of tumor antigen presentation *in situ*, resulting in systemic antitumor immunity. However, increased PD-L1 expression was observed in some patient tumors, suggesting that tumor-mediated impairment of T cell function may be forestalling a more robust CCL21-DC mediated antitumor response. Similarly, improved PD-(L)1 inhibitor efficacy may be possible with enhanced T cell infiltration and augmented APC function following IT CCL21-DC. Therefore, we are conducting a phase I trial, combining IT CCL21-DC with pembrolizumab in patients with advanced NSCLC that are either (1) EGFR/ALK wild-type after progression on a PD-(L)1 inhibitor or (2) EGFR/ALK mutant after progression on TKI therapy. **Methods:** Phase I, dose-escalating, multi-cohort trial followed by dose expansion. Maximum of 24 patients (9-12 escalation + 12 expansion) with stage IV NSCLC will be evaluated who have tumors accessible for IT injection and are either (1) EGFR/ALK wild-type after progression on a PD-(L)1 inhibitor or (2) EGFR/ALK mutant after progression on TKI therapy. Three IT injections of autologous CCL21-DC (days 0, 21, 42) will be concurrently administered with pembrolizumab, followed by q3wk pembrolizumab up to 1 year. Primary objective of dose escalation is safety and determination of maximum tolerated dose (MTD) of IT CCL21-DC ($5x10^6$, $1x10^7$, or $3x10^7$) when combined with pembrolizumab. Primary objective of dose expansion is objective response rate at MTD. Secondary objectives include adverse event profiling and determination of drug target activity by immune monitoring studies. This trial is currently open for enrollment. Clinical trial information: NCT03546361. Research Sponsor: CIRM, NIH.

TPS9155 **Poster Session**

Phase 1/2 study of BLU-451, a central nervous system (CNS) penetrant, small molecule inhibitor of EGFR, in incurable advanced cancers with *EGFR* exon 20 insertion (ex20ins) mutations. *First Author: Alexander I. Spira, Next Oncology Virginia and Virginia Cancer Specialists Research Institute, Fairfax, VA*

Background: Oncogenic *EGFR* ex20ins mutations, found in ~2% of non-small cell lung cancers (NSCLC) and a small percentage of other cancers, are generally not responsive to EGFR-targeted agents that have been approved for treatment of NSCLC with a common *EGFR* mutation, including L858R and exon 19 deletion. Similar to these more common types of *EGFR*-mutated NSCLC, CNS metastases are a challenge with *EGFR* ex20ins NSCLC and are associated with poor outcomes. While two EGFR ex20ins-targeting drugs were recently approved by the FDA (amivantamab and mobocertinib), neither have established CNS activity. BLU-451 is a CNS penetrant, wild type-sparing, covalent small molecule inhibitor of EGFR ex20ins as well as atypical (G719C, G719S, L861Q) and common EGFR mutants. Preclinical data have shown BLU-451 to have potent antitumor activity, including in an intracranial xenograft model, which has led to its clinical development in *EGFR*-mutant NSCLC. **Methods:** BLU-451-1101 (NCT05241873) is a phase 1/2, global, open-label study designed to evaluate single-agent BLU-451 in patients with NSCLC harboring *EGFR* ex20ins that has progressed following prior treatment for incurable recurrent or metastatic disease. Patients with Eastern Cooperative Oncology Group performance status 0–1 and EGFR ex20ins, exon 18 G719X or exon 21 L861Q mutant NSCLC (phases 1 and 2) or other cancers except primary CNS tumors (phase 1 only) are eligible. Patients with known ROS, RAF, ALK, or *EGFR* C797S mutations will be excluded. Stable, asymptomatic brain metastases are permitted, and active asymptomatic brain metastases are permitted in specific cohorts. Primary endpoints are determination of maximum tolerated dose (MTD), recommended phase 2 dose (RP2D), safety and tolerability (phase 1), in addition to evaluation of antitumor activity at the RP2D by RECIST v1.1 (phase 2). Secondary endpoints are evaluation of pharmacokinetics (PK) and antitumor activity by RECIST v1.1.(phase 1) and PK, safety, tolerability, and CNS antitumor activity (phase 2). Dose escalation will utilize a 3+3 design with up to 6 patients per cohort in phase 1 dose escalation and up to 12 per cohort in phase 1 dose expansion. Phase 2 will enroll patients in 3 cohorts (n = 18 each): patients with prior platinum-based chemotherapy and an EGFR ex20ins-targeted agent; patients with prior platinum but no EGFR ex20ins-targeted agent; and patients with active asymptomatic brain metastases with prior platinum with or without an EGFR ex20ins-targeted agent. The study is planned for approximately 40 centers in North America, the Asia-Pacific region, and/or Europe. Clinical trial information: NCT05241873. Research Sponsor: Blueprint Medicines Corporation.

TPS9156 **Poster Session**

A phase 1/2 study of BLU-945 in patients with common activating *EGFR*-mutant non–small cell lung cancer (NSCLC): SYMPHONY trial in progress. *First Author: Elaine Shum, Perlmutter Cancer Center, New York University Langone Health, New York, NY*

Background: Although EGFR-targeted therapies have improved outcomes in patients with *EGFR*-mutant (*EGFR*m) NSCLC, such as *EGFR* ex19del and L858R, resistance to these drugs is inevitable. BLU-945 is an investigational next-generation EGFR tyrosine kinase inhibitor (TKI) designed to suppress common activating and on-target resistance EGFR mutations, such as C797S and T790M. Preclinically it has shown activity as monotherapy in osimertinib-resistant patient-derived xenograft (PDX) models. In addition, BLU-945 has > 450-fold selectivity for C797S and T790M mutants over wildtype, advantageous for combinations with complementary EGFR-targeting agents, such as osimertinib. These combinations have shown enhanced activity in PDX models. The SYMPHONY trial (BLU-945-1101; NCT04862780) is an international, open-label, first-in-human, phase 1/2 study designed to evaluate safety, tolerability, and antitumor activity of BLU-945 as monotherapy and in combination with osimertinib in patients with *EGFR*m NSCLC. **Methods:** Key eligibility criteria include adults with pathologically confirmed metastatic NSCLC with an activating *EGFR* mutation, Eastern Cooperative Oncology Group performance status 0–1, and previous treatment with ≥1 EGFR-targeted TKI. Patients with asymptomatic brain metastases who are on stable doses of corticosteroids are eligible. Tumors with additional known driver alterations, including *EGFR* exon 20 insertions and other kinase drivers, are excluded. Primary endpoints are maximum tolerated dose, recommended phase 2 dose (RP2D) and safety (phase 1); and overall response rate (ORR) by RECIST 1.1 (phase 2). Key secondary endpoints include ORR, duration of response (DOR), pharmacokinetics (PK), and pharmacodynamics (PD; phase 1); and DOR, progression-free survival, overall survival, CNS efficacy, PK, and safety (phase 2). Phase 1 dose escalation will be done using Bayesian optimal interval design; ~85 patients will receive BLU-945 monotherapy and ~18 will receive combination BLU-945 and osimertinib. In the phase 2 dose expansion, patients will receive BLU-945 at the RP2D of the monotherapy in 3 groups based on *EGFR* mutational profile: T790M and C797S (n≈37), T790M, but not C797S (n≈12), and C797S, but not T790M (n≈12). In a combination group, BLU-945 plus osimertinib will be administered at RP2D of the combination to n≈24 patients, ≥12 with both T790M and C797S mutations. Patients may receive treatment until disease progression or unacceptable toxicity. Recruitment has started and approximately 30 sites will be open for enrollment across North America, Europe, and Asia. Clinical trial information: NCT04862780. Research Sponsor: Blueprint Medicines Corporation.

TPS9157 **Poster Session**

Additional chemotherapy for EGFRm patients with the continued presence of plasma ctDNA EGFRm at week 3 after start of osimertinib first-line treatment (PACE). *First Author: Jan Alexander Stratmann, University Hospital Frankfurt, Frankfurt, Germany*

Background: *Epidermal growth factor receptor* (EGFR) – mutated non-small cell lung cancer (NSCLC) is susceptible to *EGFR* targeting tyrosine kinase inhibitors (TKI), such as the third generation TKI osimertinib. However, response rate and duration vary between patients. Among others, the specific subtype of EGFR-mutation, its co-occurrence with other genetic alterations, and the detection of phosphorylated EGFR (pEGFR) in the plasma, and its clearance upon treatment were previously identified as markers that predict therapy response. A high proportion of patients with early (3-6 weeks after start) pEGFR clearance from plasma show impressive survival upon single-agent TKI. However, failure to achieve early clearance upon Osimertinib is associated with unfavorable outcome. For these patients, treatment concepts are lacking. Here, we report about the initiation of a clinical trial that evaluates the combination of EGFR-directed TKI and platinum-based chemotherapy as an early treatment escalation strategy for this high-risk patient population. **Methods:** PACE is a prospective multicenter single-arm investigator-initiated phase II trial. Patients with NSCLC harboring *L858R or del19 EGFR* mutation, who are treated with first-line Osimertinib are subjected to liquid biopsy-based early response assessment three weeks after start of therapy. Failure to clear pEGFR from plasma at this time point triggers treatment escalation with the addition of platinum-based doublet chemotherapy to the Osimertinib treatment. The primary outcome measure of the trial is progression-free survival (PFS), with the objective to assess the efficacy of biomarker-driven escalation of osimertinib therapy with a combination platinum-based regimen. Secondary outcome measures are the overall response rate (ORR), overall survival (OS), and the Quality of life (QLQ-C30, CTCAE-PROs) of the treated patients. In exploratory analyses, we will assess whether specific patterns of co-mutations are associated with early treatment failure (upon TKI) and pEGFR persistence. Fig. 1 illustrates the trial concept. A sample of 46 subjects achieves 80% power at a 0.05 significance level to detect a PFS of 14.4 months in the experimental treatment group when the PFS of the historic control group is 9.1 months; a total of 400 patients need to be screened within the national Network Genomic Medicine. Enrollment started in 12/2021. The clinical trial is supported by AstraZeneca and Guardant. EudraCT registration number: 2019-004757-88.

TPS9158 **Poster Session**

Randomized phase 2 study evaluating efficacy and safety of inupadenant in combination with chemotherapy in adults with metastatic non–small cell lung cancer (mNSCLC) who progressed on immunotherapy. *First Author: Mary E.R. O'Brien, The Institute of Cancer Research and the Royal Marsden NHS Foundation Trust, Surrey, United Kingdom*

Background: In cancer, the accumulation of adenosine in the tumor microenvironment (TME) mediates immune suppression mainly via the high affinity A2A receptor (A2AR), causing dysregulation of innate and adaptative immune cell subsets and dampening the antitumor immune response. This results in increased tumor cell survival and immune escape (Blay 1997; Merighi 2003; Muller-Haegele 2014). Therefore, inhibiting A2AR could reverse immunosuppression and re-establish immune surveillance in the tumor microenvironment. Inupadenant is an antagonist of the A2AR with potent inhibition of A2AR even at the high concentrations of adenosine present in the tumor microenvironment. Ongoing clinical studies have established inupadenant as a molecule with a favorable safety profile with preliminary evidence of clinical activity in multiple tumor types, including durable PRs in patients who have exhausted standard treatment options (Buisseret 2021). The standard treatment for patients without a driving mutation who progress on first-line IO is a platinum-based doublet chemotherapy regimen. Carboplatin plus Pemetrexed (C+P) is the preferred chemotherapy in nonsquamous mNSCLC. Study A2A-005 will evaluate the efficacy of inupadenant in combination with C+P as a second-line therapy in adult patients with nonsquamous mNSCLC (post-IO). A successful outcome from study A2A-005 will help address a high unmet need for this patient population and could lead to new therapeutic options. **Methods:** This is a 2-part study. The first part is an open label dose-finding part to determine the safety and recommended Phase 2 dose (RP2D) of inupadenant in combination with C+P (N = 40). In Part 2, 150 patients will be randomized 1:1 to inupadenant or placebo, both in combination with C+P. Tumor response will be determined according to RECIST 1.1 criteria and safety findings will be reviewed by the Safety Review Committee (for Part 1) and the Data Monitoring Committee (for Part 2). Key eligibility criteria include 1) mNSCLC of nonsquamous pathology, 2) have received only 1 line of anti-PD-(L)1 therapy in the metastatic setting, without concomitant chemotherapy, and have progressed (IO/IO combination therapy is allowed), 3) have measurable disease as defined by RECIST v1.1 criteria and 4) Eastern Cooperative Oncology Group status ≤1. Primary endpoints are RP2D (for Part 1) and PFS (for Part 2). Secondary endpoints include change in tumor size, ORR, OS, and adverse events. Correlative aims include assessing blood and tissue biomarkers for association with clinical benefit. The study will be conducted in approximately 11 countries in North America and Europe. Clinical trial information: EudraCT 2021-005487-22. Research Sponsor: Iteos Therapeutics, Gosselies, Belgium.

TPS9159 **Poster Session**

AcceleRET Lung: A phase 3 study of first-line pralsetinib in patients with *RET* fusion–positive advanced/metastatic NSCLC. *First Author: Sanjay Popat, Lung Cancer Unit, Department of Medicine, The Royal Marsden Hospital, London, United Kingdom*

Background: *RET* gene fusions have been identified as oncogenic drivers in multiple tumor types, including 1–2% of non-small cell lung cancer (NSCLC). Pralsetinib is a potent, selective RET inhibitor, approved in the US and EU for the treatment of metastatic *RET* fusion–positive NSCLC based on the phase 1/2 ARROW study (NCT03037385). In the ARROW study (data cutoff: Nov 6, 2020), patients who initiated 400 mg once daily (QD) of pralsetinib after platinum-based chemotherapy achieved an overall response rate (ORR) of 62%, per independent central review. In the treatment-naïve group, the ORR was 79%. Most treatment-related adverse events were grade 1–2 across the entire safety population treated at 400 mg QD (n=471). AcceleRET Lung, an international, open-label, randomized, phase 3 study (NCT04222972), will evaluate the efficacy and safety of pralsetinib versus standard of care (SOC) for first-line treatment of advanced/metastatic *RET* fusion–positive NSCLC. Abstracts for this study were previously submitted to the European Lung Cancer Congress 2020, the American Society of Clinical Oncology 2020 annual meeting, and 2020 World Conference on Lung Cancer. **Methods:** Approximately 226 patients with metastatic *RET* fusion–positive NSCLC will be randomized 1:1 to oral pralsetinib (400 mg QD) or SOC (non-squamous histology: platinum/pemetrexed ± pembrolizumab followed by maintenance pemetrexed ± pembrolizumab [at investigator's discretion]; squamous histology: platinum/gemcitabine or platinum + pembrolizumab + paclitaxel/nab-paclitaxel followed by maintenance pembrolizumab). Stratification factors include intended use of pembrolizumab, history of brain metastases, and Eastern Cooperative Oncology Group Performance Status. Key eligibility criteria include no prior systemic treatment for advanced/metastatic NSCLC; *RET* fusion–positive tumor by local or central assessment; no additional actionable oncogenic drivers; no prior selective RET inhibitor; measurable disease per Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. Patients with central nervous system metastases were permitted if asymptomatic and on a stable dose of corticosteroids. Cross-over to receive pralsetinib upon disease progression will be permitted for patients randomized to SOC. The primary endpoint is progression-free survival (blinded independent central review; RECIST v1.1). Secondary endpoints include ORR, overall survival, duration of response, disease control rate, clinical benefit rate, time to intracranial progression, intracranial ORR, safety/tolerability and quality of life evaluations. Identification of potential biomarkers of antineoplastic activity and resistance was an exploratory endpoint. Recruitment has begun with sites (active or planned) in North America, Central America, Europe and Asia. Clinical trial information: NCT04222972. Research Sponsor: F. Hoffmann-La Roche, Ltd.

TPS9160 **Poster Session**

A randomized, double-blind, phase 3 trial of MK-7684A plus chemotherapy versus pembrolizumab plus chemotherapy as first-line therapy for metastatic non–small cell lung cancer (NSCLC): KeyVibe-007. *First Author: Marina Chiara Garassino, University of Chicago Medicine & Biological Sciences, Knapp Center for Biomedical Discovery (KCBD), Chicago, IL*

Background: Pembrolizumab (pembro) plus chemotherapy is a standard first-line treatment for patients with metastatic NSCLC without *EGFR* or *ALK* genomic alterations regardless of PD-L1 expression. The combination of pembro and vibostolimab, a humanized monoclonal antibody that blocks the interaction between the T-cell immunoreceptor with immunoglobulin and ITIM domains (TIGIT) and its ligands CD112 and CD155, showed antitumor activity and manageable safety in patients with advanced or metastatic NSCLC in the phase 1 MK-7684-001 study. The phase 3 KeyVibe-007 (NCT05226598) study is evaluating the efficacy and safety of pembro and vibostolimab, coformulated as MK-7684A, in combination with chemotherapy versus pembro plus chemotherapy as first-line therapy for metastatic NSCLC. **Methods:** his randomized, double-blind study is enrolling adults with histologically or cytologically confirmed, previously untreated, stage IV squamous or nonsquamous NSCLC without *EGFR* mutations or *ALK/ROS1* gene rearrangements. Patients must have measurable disease per RECIST v1.1, ECOG PS of 0 or 1, and a tumor tissue sample for PD-L1 assessment. Patients are randomized 1:1 to receive MK-7684A (MK-7684 200 mg + pembro 200 mg) IV or pembro 200 mg IV plus chemotherapy (squamous: carboplatin area under the curve [AUC] 6 mg/mL/min plus paclitaxel 200 mg/m^2 or nab-paclitaxel 100 mg/m^2 [days 1, 8, 15]; nonsquamous: pemetrexed 500 mg/m^2 plus cisplatin 75 mg/m^2 or carboplatin AUC 5 mg/mL/min) Q3W for 4 cycles followed by MK-7684A or pembro Q3W, per randomized therapy, for up to 31 additional cycles (plus continued pemetrexed maintenance, nonsquamous only) or until PD, unacceptable AEs, investigator decision, or patient withdrawal. Patients with PD after completing first-course treatment may be eligible for up to 17 additional cycles of their randomized therapy (MK-7684A or pembro). Randomization is stratified by ECOG PS (0 vs 1), tumor histology (squamous vs nonsquamous), PD-L1 expression (TPS < 50% vs ≥50%), and region (East Asia vs North America/Western Europe vs rest of world). Dual primary endpoints are PFS per RECIST v1.1 by blinded independent central review (BICR) and OS. Secondary endpoints are ORR and duration of response per RECIST v1.1 by BICR, change from baseline and time to true deterioration in patient-reported outcomes (PROs), and safety. Imaging assessments occur at weeks 6, 12, and 18, then Q9W through week 63 and Q12W thereafter until disease progression, start of new anticancer treatment, withdrawal of consent, or death. PROs are assessed using validated instruments including the EORTC Quality of Life Questionnaire Lung Cancer13 and NSCLC Symptom Assessment Questionnaire. AEs are graded according to National Cancer Institute Common Terminology Criteria for Adverse Events v5.0. Enrollment is ongoing. Clinical trial information: NCT05226598. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Distant metastasis-free survival with pembrolizumab versus placebo as adjuvant therapy in stage IIB or IIC melanoma: The phase 3 KEYNOTE-716 study. *First Author: Georgina V. Long, Melanoma Institute Australia, The University of Sydney, Royal North Shore and Mater Hospitals, Sydney, Australia*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

9501 **Oral Abstract Session**

Survival data of PRADO: A phase 2 study of personalized response-driven surgery and adjuvant therapy after neoadjuvant ipilimumab (IPI) and nivolumab (NIVO) in resectable stage III melanoma. *First Author: Christian U. Blank, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: In the OpACIN-neo study, 2 cycles neoadjuvant (neoadj) IPI 1mg/kg + NIVO 3mg/kg (I1N3) have been identified as most favorable dosing scheme with a pathologic response rate (pRR) of 77% and 20% grade 3-4 irAEs. After 24.6 months median follow-up (FU), the 2-year (2y) RFS was 96.9% for patients (pts) with pathologic response versus 35.5% for non-responders (>50% viable tumor; pNR). These data raised the question whether therapeutic lymph node dissection (TLND) could be safely omitted in pts achieving a major pathologic response (MPR; ≤10% viable tumor) in their index node (ILN; largest LN metastasis at baseline), and if additional adjuvant (adj) therapy could improve the outcome of pNR pts. **Methods:** PRADO is an extension cohort of the phase 2 OpACIN-neo study aiming to confirm the pRR and safety of neoadj I1N3 and to test response-driven subsequent therapy. Pts with stage III melanoma were included to receive 2 cycles neoadj I1N3 after marker placement in the ILN. ILN resection was planned at week 6. Pts that achieved MPR in the ILN did not undergo TLND; pts with partial response (pPR; >10 – ≤50% viable tumor) underwent TLND; and pts with pNR underwent TLND and received adj NIVO or dabrafenib plus trametinib (D+T) for 52 weeks ±radiotherapy (RT). Primary endpoints were pRR in the ILN and RFS at 2y. The 2y RFS rates were calculated using a Kaplan Meier based method. **Results:** Between Nov 2018 and Jan 2020, 99 patients were enrolled and treated with at least 1 cycle of neoadj I1N3. We previously showed a pRR of 72% (95% CI 62 - 80), including 60 (61%) pts with MPR and 11 (11%) pts with pPR. TLND omission in MPR pts resulted in significant reduced surgical morbidity and improved quality of life. There were 27 non-responders of whom 6 developed distant metastasis before ILN resection. Of the other 21 pNR pts, 7 received adj NIVO, 10 adj D+T, 3 no adj therapy, and 1 was lost to FU. After a median FU of 27.9 months (data cutoff Jan 31, 2022), the estimated 2y RFS rate for MPR pts was 93.3% (95% CI 87.2 – 99.9), with 4/60 pts developing a regional relapse. Distant metastasis-free survival (DMFS) was 100%. Of the 11 pPR pts, 4 developed a relapse (all distant), resulting in a 2y RFS and DMFS rate of 63.6% (95% CI 40.7 – 99.5). The 2y RFS rate of the pNR pts was 71.4% (95% CI 54.5 – 93.6), and DMFS 76.2%. At data cutoff, relapse occurred in 2/7 pNR pts with adj NIVO and 3/10 with adj D+T. Final data cutoff is planned mid Feb, 2022. **Conclusions:** MPR pts in whom TLND was omitted showed a 2y RFS rate of 93.3% and DMFS of 100%, indicating that the ILN procedure and omitting adj therapy could become a safe approach in these pts. Adj systemic therapy in pNR pts seems to improve RFS as compared to historic control (OpACIN-neo), thus should be considered in this unfavorable pNR group. The DMFS rate of 63.6% observed in the pPR group advocates the consideration of adj therapy also for this subgroup in the future. Clinical trial information: NCT02977052. Research Sponsor: BMS.

9502 **Oral Abstract Session**

Neoadjuvant PD-1 blockade in patients with resectable desmoplastic melanoma (SWOG 1512). *First Author: Kari Lynn Kendra, The Ohio State University Comprehensive Cancer Center, Department of Internal Medicine, Columbus, OH*

Background: Desmoplastic melanoma (DM) is a rare cancer defined by a dense fibrous collagen matrix. It is associated with high UV exposure leading to a high mutational load. When locally advanced, the standard of care is wide excision and radiation therapy due to its propensity for local relapses. Metastatic DM has a high response rate (RR) to PD-1 blockade therapy (Eroglu et al. Nature 2018). We hypothesized that neoadjuvant treatment with anti-PD-1 monotherapy may induce pathologically confirmed regressions in a high percentage of cases, potentially allowing for less extensive local treatment. **Methods:** Patients > 18 years old with histologically confirmed resectable (primary, recurrent, or regional lymph node metastasis) DM with clinical evidence of residual disease received pembrolizumab 200 mg q3 weeks (wk) 3 followed by excision. No adjuvant therapy was administered. Primary endpoint: pathological complete response (pCR), with the assumption that pCR of 25% would be considered a positive result worthy of future study. To test this hypothesis, a single arm trial with 25 eligible patients would have a 3.4% probability of a positive result with a true pCR of 5%, and a power of 90% of a positive result if the true pCR is 25%. Secondary endpoints: clinical RR by imaging and clinical exam, median overall survival (OS), and evaluation of safety/tolerability of neoadjuvant pembrolizumab. Adverse events were assessed q3 wk. Disease assessments occurred at baseline and q9 wk. NCT02775851. **Results:** We enrolled-29 eligible patients with resectable DM. One patient refused treatment and was omitted from further analysis. Median age was 75, 79% were male, primary sites of disease were 72% H&N, 10% torso, 14% extremities, 3% unknown. No patients received prior systemic therapy. Mean time from C1D1 treatment to surgery was 84.2 (range: 52-135) days, mean number of cycles received 3.3 (range: 2-4). 26/27 (93%) of patients underwent wide excision of the resectable disease, of which 14 (54%) underwent sentinel lymph node biopsy. One patient underwent resection of a nodal recurrence thus did not require wide excision. pCR was noted in 15/27 (56%) of patients (95% CI: 35%-75%). One patient without a pCR had a major pathologic response with 0.2 mm residual melanoma. In addition, one patient with a clinical CR did not undergo resection by choice. None became inoperable. Clinical RR was 52% (95% CI: 32%-71%). Median OS has not been reached, with two nontreatment related deaths (acute hypoxic respiratory failure; unknown). No > grade 2 related adverse events were observed. **Conclusions:** Neoadjuvant pembrolizumab in resectable DM results in a high pCR rate with excellent tolerance, which supports consideration of PD-1 blockade therapy prior to surgery. Funding: U10CA180888 and U10CA180819; and in part by Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA. Clinical trial information: NCT02775851. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

9503 **Oral Abstract Session**

NeoTrio: Randomized trial of neoadjuvant (NAT) pembrolizumab (Pembro) alone, in sequence (SEQ) with, or concurrent (CON) with dabrafenib plus trametinib (D+T) in resectable BRAF-mutant stage III melanoma to determine optimal combination of therapy. *First Author: Georgina V. Long, Melanoma Institute Australia, The University of Sydney, Royal North Shore and Mater Hospitals, Sydney, NSW, Australia*

Background: Combination anti-PD(L)1 and BRAF/MEK-targeted therapy (TT) improves PFS in stage IV melanoma vs TT. In stage IV melanoma recent data suggest immunotherapy 1st until progression, rather than BRAF-TT, improves OS, and induction TT upfront adds little benefit. NeoTrio explored the optimal combination of BRAF-TT and anti-PD1 using the NAT platform in pts with stage III melanoma (NCT02858921). **Methods:** 60 pts with resectable, RECIST measurable stage III (no in-transit) $BRAF^{V600}$-mutant melanoma were randomized 1:1:1 to 3 arms of 6 wks of NAT followed by complete lymph node dissection (CLND): A) Pembro ALONE (200mg Q3W x 2); B) SEQ - D+T (150mg bd + 2mg od) for 1 wk followed by pembro (200mg x 2); C) CON – D+T+pembro (doses as SEQ). Pts had 46 wks pembro post-CLND. Primary endpoint was the pathological response rate (pRR) and pathological complete response (pCR) at wk 6. Secondary endpoints; RECIST RR at wk 6, event-free survival (EFS), RFS, OS, adverse events (AE) and translational endpoints. **Results:** At data cutoff 2 Jan 2022, 20 pts per arm had similar baseline characteristics; overall 42% female, med age 53 yrs, 82% BRAF V600E, 62% clinical N1b. Med f/u was 20 months (95% CI 17-31). The pCR rate and pRR were highest in CON arm, and similar in ALONE and SEQ arms (Table). Events (progression before surgery, recurrence after surgery or death) were highest in ALONE arm at this 1st analysis (Table). Assessment of the durability of path response subtypes in each arm is ongoing. Most common Rx related AE were fatigue (65%, 70%, 70%, ALONE, SEQ and CON respectively), pyrexia (0%, 25%, 85%) and rash (50%, 35%, 35%). Gd 3/4 AE occurred in 30%, 25% and 55%, respectively; pyrexia and hepatitis were common in CON during NAT. Rx interruptions during NAT occurred in 0, 3 and 19 pts, respectively; 1, 0 and 8 pts permanently discontinued. Post NAT surgical operability was the same or improved in 81%. Longitudinal analysis of melanoma tissue, microenvironment and microbiome is ongoing. **Conclusions:** CON D+T+pembro achieved the highest pRR, pCR rate, but with greater toxicity. Recurrences were seen in those with pCR/near pCR in BRAF-TT containing arms, but not in pembro ALONE, in keeping with previous data of NAT with checkpoint inhibitors vs BRAF-TT. Short course of D+T prior to PD1 did not improve path response, despite previous translational data showing increased tumour infiltrating T-cells early-during treatment with D+T. Follow up is ongoing. Clinical trial information: NCT02858921. Research Sponsor: Melanoma Institute Australia and MSD.

Nivolumab (NIVO) + relatlimab (RELA) versus NIVO in previously untreated metastatic or unresectable melanoma: OS and ORR by key subgroups from RELATIVITY-047. *First Author: Hussein A. Tawbi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In the phase 2/3 RELATIVITY-047 trial, NIVO + RELA as a fixed-dose combination (FDC) significantly improved the primary endpoint of progression-free survival (PFS) versus NIVO in patients (pts) with previously untreated metastatic or unresectable melanoma. Secondary endpoints showed a clinically meaningful improvement in overall survival (OS), although not statistically significant, and a higher objective response rate (ORR). As previously reported, PFS and OS favored NIVO + RELA over NIVO across prespecified stratification factors (LAG-3 expression, PD-L1 expression, *BRAF* V600 mutation status, and metastasis stage). Here we report the first disclosure of ORR analyzed by prespecified stratification factors and OS and ORR in additional subgroups. **Methods:** Pts were randomized 1:1 to receive NIVO 480 mg + RELA 160 mg FDC or NIVO 480 mg intravenously Q4W. The primary endpoint was PFS per RECIST v1.1 assessed by blinded independent central review (BICR). Secondary endpoints were OS and ORR by BICR, tested in hierarchy. Exploratory analyses were performed for PFS, OS, and ORR by prespecified subgroups. **Results:** PFS continued to favor NIVO + RELA over NIVO across key subgroups. OS and ORR also favored NIVO + RELA over NIVO across key subgroups including those associated with poor prognosis (Table). ORR favored NIVO + RELA over NIVO for pts with LAG-3 expression ≥ 1% (47% vs 35%) and < 1% (31% vs 24%), PD-L1 expression ≥ 1% (53% vs 45%) and < 1% (36% vs 24%), and *BRAF* wild-type (43% vs 34%) and mutant (43% vs 31%) melanoma, respectively. Additional key prespecified subgroups will be presented. In all treated pts, NIVO + RELA maintained a manageable safety profile with no new or unexpected safety signals. **Conclusions:** NIVO + RELA was favored over NIVO across key subgroups for PFS, OS, and ORR, and findings appeared consistent with outcomes in the overall population. NIVO + RELA had a favorable benefit-risk profile. Clinical trial information: NCT03470922. Research Sponsor: Bristol Myers Squibb.

9506 **Oral Abstract Session**

Navtemadlin (KRT-232) activity after failure of anti-PD-1/L1 therapy in patients (pts) with *TP53^{WT}* Merkel cell carcinoma (MCC). *First Author: Michael K.K. Wong, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MCC is a rare, aggressive, neuroendocrine skin cancer with a high risk of recurrence and metastases. A median survival of about 4 mo for pts with metastatic MCC who failed anti-PD-1/L1 therapy highlights an urgent need for novel therapies. In *TP53^{WT}* MCC, oncoproteins from the Merkel cell polyomavirus (MCPyV) inhibit p53 tumor suppressor functions by activating murine double minute 2 (MDM2). Navtemadlin is a potent, selective, orally available MDM2 inhibitor that overcomes MDM2 dysregulation by restoring p53 activity and inducing apoptosis of *TP53^{WT}* tumors. **Methods:** The dose-finding, phase 1b/2 KRT-232-103 study (NCT03787602) evaluated navtemadlin in adult *TP53^{WT}* MCC pts who failed anti-PD-1/L1 therapy. Pts were randomly assigned to oral navtemadlin once daily in 21- or 28-day cycles: 240 mg 7 days (D) on/14D off or 5D on/23D off, 180 mg 5D on/23 D off or 7D on/21D off, or 120 mg 7D on/14D off, until disease progression or unacceptable toxicity. The primary endpoint was Recommended Phase 2 Dose (RP2D); objective response rate (ORR) was assessed per RECIST v1.1. **Results:** As of Nov 30, 2021, 31 pts were enrolled with median age 66 y (range, 25-82); 52% had visceral disease and 71% had received ≥2 lines of prior therapy. Baseline tumor profiling of available samples showed low tumor mutation burden, MCPyV-positivity, and nonamplified *MDM2* gene in 100%, 92%, and 100% of pts, respectively. Treatment-emergent adverse events (TEAEs) were observed in 100% (68% grade 3/4) of pts. The most common Grade 3/4 TEAEs were hematologic: 32% anemia, 32% lymphopenia, and 19% thrombocytopenia. Navtemadlin doses ≤180 mg were well tolerated with fewer dose reductions and longer treatment durations; subsequently the 240 mg arms were closed to further enrollment. Evaluable pts receiving 180 mg 5D on/23D off showed a 25% confirmed ORR, a 38% unconfirmed + confirmed ORR, and a 63% disease control rate (Table); median duration of response was not reached (range, 6-16.2+ mo) and median time to treatment response was 4.1 mo (range, 1.2-7). Notably, one responder, following a prolonged partial response, achieved complete metabolic remission by PET/CT after 2 y on treatment. The 120 mg arm was closed due to a low response rate. The 180 mg dose has been selected for further evaluation. **Conclusions:** Navtemadlin is the first targeted agent to show promising single-agent activity in heavily pretreated MCC pts who failed anti-PD-1/L1 therapy. This study demonstrates that upregulation of the p53 pathway is a viable therapeutic strategy in MCC. Clinical trial information: NCT03787602. Research Sponsor: Kartos Therapeutics, Inc.

9507 **Oral Abstract Session**

Nivolumab (NIVO) + tacrolimus (TACRO) + prednisone (PRED) +/- ipilimumab (IPI) for kidney transplant recipients (KTR) with advanced cutaneous cancers. *First Author: Kara M. Schenk, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: Cancer is a leading cause of death among KTR, but these patients (pts) have been excluded from trials of immune checkpoint inhibitors due to immunosuppression and risk of allograft loss. We report findings from the first prospective clinical trial of NIVO + TACRO + PRED +/- IPI in KTR with selected advanced cutaneous cancers. **Methods:** The primary composite endpoint was lack of tumor progression per RECIST v1.1 without allograft loss at 16 weeks (W) on NIVO. Adult KTR with advanced melanoma, basal, cutaneous squamous, or Merkel cell carcinoma (MEL, BCC, CSCC, MCC), for whom non-immune therapies were insufficient were eligible. Immunosuppression was standardized to low-dose TACRO (goal trough 2-5 ng/mL) + PRED 5mg daily; pts then received NIVO 480mg IV q4W. Pts with progressive disease (PD) could receive NIVO 3mg/kg + IPI 1mg/kg IV q3W x 4 followed by NIVO 480mg IV q4W. Donor-derived cell-free DNA (dd-cfDNA) levels were measured q2W as a potential predictor of allograft rejection. **Results:** From 11/2019 - 4/2021, of 12 pts enrolled, 8 pts with CSCC, MCC or MEL were evaluable for response (Table). All pts experienced PD on NIVO; treatment-related allograft loss (TRAL) occurred in 1 pt. 6 pts then received IPI + NIVO. Responses: 2 (33%) with marked tumor regression at 6W and eventual complete response (CR; 1 with TRAL), and 4 (67%) with PD (1 with TRAL). 7/8 pre-NIVO tumor biopsies contained a paucity of infiltrating immune cells. Only 2/5 on-NIVO biopsies demonstrated moderate immune infiltrates; both of these pts later developed a CR to IPI + NIVO. Rejecting allografts contained dense immune responses (plasma cells, CD4+ & CD8+ lymphocytes, PD-1+ lymphocytes, macrophages, PD-L1+ glomerular endothelium, and focal PD-1 & PD-L1 positivity in renal tubules). In 2/3 pts with TRAL, elevations in dd-cfDNA levels occurred 10 and 15 days earlier than increases in weekly serum creatinine levels. TRAL #3 occurred after discontinuation of study therapy (including TACRO) and dd-cfDNA monitoring. **Conclusions:** In KTR receiving low-dose TACRO + PRED, NIVO augments tumor immune cell infiltration in some pts but is insufficient to mediate tumor regression. Adding IPI can enhance anti-tumor immunity and mediate tumor regression. TACRO + PRED was insufficient to prevent allograft rejection after PD-1 +/- CTLA-4 blockade in 2/8 pts. In pts with TRAL, increased dd-cfDNA levels preceded increased serum creatinine. Based on these findings, we are modifying the trial therapy regimen to augment anti-tumor immunity and preserve allograft function. Clinical trial information: NCT03816332. Research Sponsor: U.S. National Institutes of Health, The Marilyn and Michael Glosserman Fund for Basal Cell Carcinoma and Melanoma Research, and The Bloomberg~Kimmel Institute for Cancer Immunotherapy.

9508 **Oral Abstract Session**

A phase II clinical trial of camrelizumab (CAM, an IgG4 antibody against PD-1) combined with apatinib (APA, a VEGFR-2 tyrosine kinase inhibitor) and temozolomide (TMZ) as the first-line treatment for patients (pts) with advanced acral melanoma (AM). *First Author: Lu Si, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/ Beijing), Department of Melanoma and Sarcoma, Peking University Cancer Hospital and Institute, Beijing, China*

Background: PD-1 monotherapy as the first line stand treatment for advanced melanoma yields an objective response rate (ORR) of < 20% in AM. Although multiple clinical trials are ongoing testing TMZ/APA, TMZ/PD-1 and APA/PD-1 combo therapies in AM, the reported ORR (range 17-23.8%) are far from satisfactory. We therefore conducted a phase II study of CAM/APA/TMZ combo in this subtype aiming for improved efficacy. **Methods:** We performed a single center, single arm phase II study (NCT04397770) testing the efficacy and safety of CAM/APA/TMZ combo as first-line therapy in pts with advanced AM. The primary endpoint was ORR per RECIST1.1, secondary endpoints included progression free survival (PFS), disease control rate (DCR), overall survival (OS), and safety. All pts received iv CAM (200mg q2w), iv TMZ (200mg/m2 d1-5, q4w) and po APA (250mg qd) until disease progression or intolerable toxicity. **Results:** By Jan 2022, fifty pts were enrolled (48 evaluable), the median follow-up was 12.1 mo (IQR 8.4-14.5). Thirty-one pts achieved CR/PR as the best response (including 1 CR and 30 PR), the ORR was 64.6% (95% CI 49.4-77.4%). The DCR was 95.8% (95%CI, 84.6-99.3%). Both the median PFS and OS was not reached (NR); 6-mo and 12-mo PFS rate was 81.7% (95%CI 71.6-93.3%) and 62.9% (95%CI 48.4-81.7%), respectively; 12-mo OS rate was 82.3% (95%CI 68.2-99.2%). The incidence of treatment-related adverse events (TRAEs) was 94% (47/50). Of 50 patients, the most common grade ≥3 TRAEs included γ-glutamyl transferase elevation (24.0%), direct bilirubin elevation (22.0%), aspartase transaminase elevation (20.0%), alanine transaminase elevation (16.0%), and hypertriglyceridemia (14.0%). No treatment-related deaths occurred. **Conclusions:** The CAM/APA/TMZ combination demonstrated promising efficacy as the first-line treatment for pts with advanced AM, and was generally well tolerated. Phase III randomized control trial is warranted. Clinical trial information: NCT04397770. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

LBA9509 **Poster Discussion Session**

Isolated hepatic perfusion as a treatment for uveal melanoma liver metastases, first results from a phase III randomized controlled multicenter trial (the SCANDIUM trial). *First Author: Roger Olofsson Bagge, Wallenberg Centre for Molecular and Translational Medicine, University of Gothenburg, Gothenburg, Sweden*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

9510 **Poster Discussion Session**

FOCUS phase 3 trial results: Percutaneous hepatic perfusion (PHP) with melphalan for patients with ocular melanoma liver metastases (PHP-OCM-301/301A). *First Author: Jonathan S. Zager, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Ocular melanoma, the most common intraocular malignancy, frequently metastasizes to the liver but to date there is no established standard of care for hepatic-dominant ocular melanoma patients. The FOCUS trial began as a randomized, Ph 3 trial (301) comparing PHP with best alternative care (BAC). The trial was subsequently amended (301A) to halt the BAC arm due to enrollment concerns. **Methods:** Eligible patients with hepatic-dominant ocular melanoma were randomized 1:1 to receive PHP or BAC (investigator's choice of TACE, pembrolizumab, ipilimumab, or dacarbazine) on the 301 trial. All eligible patients received PHP on the 301A trial. PHP patients could receive up to 6 PHP treatments, repeated every 6-8 weeks with melphalan dosed at 3.0mg/kg ideal body weight (IBW). Patients with progressive disease (PD) were discontinued from study treatment and all patients are followed until death. Patientswere imaged every 12 (±2) weeks until PD. The primary endpoint, ORR (per RECIST 1.1) as assessed by Independent Review Committee, was characterized by the point estimate and 95% CI for each group (PHP and BAC). **Results:** 144 patients were enrolled overall; 102 were assigned to PHP (301: n = 43; 301A: n = 59) and 42 were assigned to BAC. 91 PHP patients received treatment (301: n = 40; 301A: n = 51) and 32 BAC patients received treatment. ORR among PHP patients was 35.2% (32/91; 95% CI: 25.44-45.88%). ORR among BAC patients was 12.5% (4/32; 95% CI: 3.51-28.99%; p= 0.0154). The median DOR was 14 months for PHP patients and not calculable for BAC patients. The DCR among PHP patients was 73.6% (67/91; 95% CI: 63.35-82.31%) and among BAC patients was 37.5% (12/32; 95% CI: 21.10-56.31%; p= 0.0002). The median PFS was 9.03 months (95% CI: 6.34-11.56) among PHP patients and was 3.12 months (95% CI: 2.89-5.65) among BAC patients (p= 0.0007). The median OS was 20.53 months (95% CI: 16.59-24.35) among PHP patients and was 14.06 months (95% CI: 9.99-19.78) among BAC patients. With the last treatment occurring in May 2021, the OS, DOR, and PFS data continues to mature as patients are still being followed for survival. Among the 94 patients assessed for safety after treatment with PHP, 42.6% of patients experienced a serious treatment-emergent adverse event, the majority of which were hematological, transient in nature, and resolved without sequelae. There were no treatment related deaths in the trial. **Conclusions:** In this analysis of data from the FOCUS trial, PHP demonstrates superior ORR, DOR, DCR, PFS, and OS in comparison with BAC in the treatment of hepatic metastases from ocular melanoma. This therapy offers a potential option for patients with this rare indication that is associated with a poor prognosis and few treatment options. Clinical trial information: NCT02678572. Research Sponsor: Delcath Systems, Inc.

9511 **Poster Discussion Session**

First interim analysis of the SirTac trial: A randomized phase II study of SIRT and DSM-TACE in patients with liver metastases from uveal melanoma. *First Author: Caroline-Anna Anna Peuker, Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Hematology, Oncology and Cancer Immunology, Berlin, Germany*

Background: The liver is the most common site of metastases in patients (pts) with uveal melanoma (UM). Here, we present results from the prespecified first interim analysis of the SirTac trial, a prospective, single-center, randomized, investigator-initiated, open-label phase 2 study of Selective Internal Radiation Therapy with Yttrium-90-bearing resin microspheres; SIR-Spheres (SIRT) vs Transarterial Chemoembolization with Cisplatin and degradable starch microspheres; EmboCept S (DSM-TACE) in pts with liver-dominant metastatic UM. **Methods:** Pts with histologically confirmed, liver-dominant metastatic UM and ECOG PS 0-2 were enrolled and randomized 1:1 to SIRT or DSM-TACE. Randomization was stratified by lactate dehydrogenase (<2x vs ≥2x upper limit of normal) and pre-treatment with antiangiogenic agents. Extrahepatic metastases were allowed, if asymptomatic. Primary endpoint was progression-free survival (PFS). A total of 108 pts (54 per arm) were planned to be enrolled. Pts received TACE every 4-6 weeks until tumor devascularization or disease progression or intolerable toxicity was observed, and SIRT either as one whole-liver application or in two sequential sessions for each liver lobe. The primary objective of this prespecified analysis was to assess response by RECIST criteria v1.1 in the per-protocol (PP) population of the first 40 pts (20 pts in each arm). **Results:** Two patients had been treated with previous liver surgery, whereas all other patients had not received previous treatment for metastatic disease. There were no clinicopathological differences between the groups, except for a difference in age (median age SIRT arm 64 y vs 75 y in the TACE arm, p=0.018). All but 1 pt received treatment as randomized. This pt was excluded and replaced by the next TACE pt for this PP interim analysis. There were no differences in best overall response rates between the groups (no complete response, 1 partial response in both arms, stable disease in 19 (95%) and 17 (85%) pts in the SIRT and TACE arm, respectively, and 2 pts with progressive disease in the TACE arm). At a median follow-up of 13.9 mo from treatment start, median PFS in the PP population was 4.9 mo in the SIRT arm vs 2.2 mo in the TACE arm (p=0.037), with a higher median liver-PFS in the SIRT vs TACE arm (8.3 vs 2.2, p=0.026). **Conclusions:** In this planned interim analysis treatment in both arms was feasible with no differences in response. The explorativePFS analysis allows no conclusions on the final outcome after completion of the trial. The study continues recruitment. Clinical trial information: NCT02936388. Research Sponsor: Sirtex Medical, PharmaCept GmbH, Other Foundation.

Toripalimab plus axitinib versus toripalimab or axitinib alone in patients with treatment-naive unresectable or metastatic mucosal melanoma: Interim results from a randomized, controlled, phase II trial. *First Author: Chuanliang Cui, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: A phase IB trial had showen promising antitumor activity with toripalimab (T, a PD-1 antibody) plus axitinib (A, a VEGF receptor inhibitor) in treatment-naive unresectable or metastatic mucosal melanoma. Now we conducted a phase II trial to compare the combined treatment with monotherapy. **Methods:** In this randomized, controlled, phase II trial, patients with pathologically confirmed treatment-naive unresectable or metastatic mucosal melanoma were stratified by PD-L1 expression and randomized 1:1:1 into three groups to receive treatment of T+A (toripalimab 240 mg i.v. every 3 weeks, axitinib 5 mg orally twice a day) , T (toripalimab 240 mg i.v. every 3 weeks) or A (axitinib 5 mg orally twice a day). Subjects in T or A who meet the criteria after disease progression may cross over to receive T+A. The primary endpoint was progression-free survival (PFS). Secondary endpoints included Objective response rate (ORR), Duration of response (DOR), overall survival (OS), and safety. The protocol was registered at ClinicalTrials.gov (NCT03941795). This is the interim analysis for efficacy and safety. **Results:** Between Nov 2019 and Jan 2022, 51 patients were randomized (18 to T+A, 20 to T, and 13 to A due to preliminary efficacy analysis). Anatomic site of head and neck, gastrointestinal, gynecological were 49.0%, 29.4%, 21.6%, respectively. Stage II or III unresectable, M1a, M1b, M1c were 3.9%, 23.5%, 17.6%, 51.0%, respectively. PD-L1 positivity was defined as ≥1% of tumor cells and/or infiltrating immune cells and were identified in 55.6%, 45.0%, 53.8% patients in T+A, T, A group, respectively. 17, 17 and 12 patients could be evaluated in T+A, T and A group, respectively. 24 patients from T or A crossover to T+A group. At a median follow-up of 6.60 months, patients receiving T+A had a higher median PFS (5.83 vs 2.80 vs 1.40 months; HR = 0.538; 95% CI, 0.237 to 1.221; HR = 0.444; 95% CI, 0.182 to 1.081; P = 0.170), ORR (35.3% (29.7% if including crossover patients) vs 17.6% vs 8.3%), DOR (82.4% (70.3% if including crossover patients) vs 52.9% vs 58.3%) versus T or A group. The median OS was not reached. 80.4% patients experienced treatment-related adverse events (TRAEs). The most common TRAEs were mild (grade 1 or 2) and included diarrhea, proteinuria, hand and foot syndrome, fatigue, elevated transaminase, elevated bilirubin, hypertension, hypo- or hyperthyroidism, and rash. Grade 3 or greater TRAEs occurred in 33.3%, 30.0%, 30.8% of patients in T+A, T, A groups. **Conclusions:** Toripalimab plus axitinib showed promising antitumor activity versus toripalimab or axitinib alone in patients with treatment-naive unresectable or metastatic mucosal melanoma. Clinical trial information: NCT03941795. Research Sponsor: None.

9513 **Poster Discussion Session**

AMBER parts 1c and 1e: A phase 1 study of cobolimab plus dostarlimab in patients (pts) with advanced/metastatic melanoma. *First Author: Antoni Ribas, University of California Los Angeles, Los Angeles, CA*

Background: TIM-3 and PD-1 are markers of T-cell suppression that are upregulated in melanoma. AMBER (NCT02817633) is evaluating cobolimab (TSR-022/GSK4069889), an anti-TIM-3 therapy, monotherapy or with PD-1 inhibitors, including dostarlimab, in pts with solid tumors. **Methods:** This multicenter, open-label study was conducted in 2 parts: dose escalation (Parts 1 A–D and F–H) and cohort expansion (Parts 2 A–D). Part 1C and exploratory cohort 1E (reported here) included pts with advanced/metastatic melanoma; prior therapies, except for immunotherapies, were permitted. Pts received cobolimab (100 [1C only], 300, or 900 mg IV) with dostarlimab (500 mg IV) Q3W. Part 1C primary endpoints were safety, tolerability, and recommended Phase 2 dose. Objective response rate (ORR; complete [CR] or partial [PR] response per RECIST v1.1) was a secondary endpoint in 1C and the primary endpoint in 1E (ad hoc efficacy analysis reported). An integrated safety analysis for all pts (Parts 1 and 2) receiving cobolimab with dostarlimab, regardless of tumor type or cobolimab dose, is reported here. **Results:** 28 pts were enrolled in 1C (n=10) and 1E (n=18). Most pts (n=23; 82.1%) had cutaneous disease of the skin. One pt had anorectal mucosal disease and 3 pts in the 900-mg cohort had uveal melanoma. Most pts (67.9%) had an ECOG PS=0. At data cut-off (May 19, 2021), treatment was ongoing in 5 pts. In the integrated safety analysis of pts who received cobolimab 100 mg (n=41), 300 mg (n=167), or 900 mg (n=69) with dostarlimab, treatment-related treatment-emergent AEs (TR-TEAEs) occurred in 53.7%, 57.5%, and 59.4%, respectively. The most common TR-TEAEs (any grade, ≥10% in 100 mg, 300 mg, or 900 mg groups, respectively) were fatigue (22.0%, 13.2%, 24.6%), rash (9.8%, 5.4%, 11.6%), diarrhea (4.9%, 6.0%, 10.1%), and dyspnea (2.4%, 0%, 10.1%). Grade ≥3 TR-TEAEs occurred in 12.2% (100 mg), 10.8% (300 mg), and 20.3% (900 mg); serious TR-TEAEs occurred in 7.3%, 7.8%, and 11.6%, respectively. No pts died due to TR-TEAEs; 2.4% (100 mg), 4.2% (300 mg), and 7.2% (900 mg) discontinued due to TR-TEAEs. ORR and disease control rate (DCR: stable disease [SD] ≥16 weeks, PR, or CR) are shown in the Table. Twelve pts achieved a PR and an immune-related (ir)PR (1 in 100 mg; 8 in 300 mg; 3 in 900 mg groups). Three pts achieved SD (2 in 300 mg; 1 in 900 mg groups); 8 pts had irSD (1 in 100 mg; 4 in 300 mg; 3 in 900 mg groups). **Conclusions:** Cobolimab with dostarlimab showed preliminary clinical responses in pts with advanced/metastatic melanoma and an acceptable safety profile across advanced cancers. Funding: GSK (213348). Clinical trial information: NCT02817633. Research Sponsor: GlaxoSmithKline.

9514 **Poster Discussion Session**

Phase II study of nivolumab (nivo) with relatlimab (rela) in patients (pts) with first-line advanced melanoma: Early on-treatment major pathologic response on biopsy. *First Author: Lilit Karapetyan, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: A phase II study of nivo and rela was designed to evaluate the antitumor activity and mechanism of this combination and components for first-line treatment of pts with advanced melanoma. Pts received lead-in treatment with 1 cycle of nivo (480mg IV q4wk), rela (160mg IV q4wk), or nivo-rela followed by combination therapy. We assessed the effect of each lead-in treatment on immune-related pathological response (irPR) at 4-wk biopsy to develop early biomarkers of antitumor response. **Methods:** Core biopsy of an index lesion was performed at baseline and after 4 wk on-treatment. Immune characteristics of pathological response were assessed on H&E sections, including presence of tumor-infiltrating lymphocytes (TIL), neovascularization, proliferative fibrosis, plasma cells, and lymphoid aggregates. irPR score was calculated as described by Stein JE et al Ann Oncol 2019, from 0 (no irPR features) to 3 (major pathologic response on biopsy [MPRbx], ≤10% residual viable tumor). We assessed the association between irPR and radiological response (RECIST v1.1) at 4-wk evaluations. **Results:** The current cohort includes 22 pts, median age = 67, male = 13. Pts were randomized to nivo = 7, rela = 7, and nivo-rela = 8 lead-in groups. Two pts had no irPR evaluation due to early progression and unscorable tumor. Among 20 evaluable pts, proliferative fibrosis, neovascularization, plasma cells, brisk TIL, and lymphoid aggregates were identified in 50%, 35%, 26.3%, 25%, and 5% of cases, respectively. Lead-in nivo (n = 2/6), rela (n = 0/6), and nivo-rela (n = 3/8) resulted in irPR = 3 in 25% of pts. Radiological response was identified as partial response (PR) = 1/22 (4.5%), stable disease (SD) = 12/22 (54.5%), and progressive disease (PD) = 9/22 (41%). Among pts with PD, 44% received rela-, 33% nivo-, and 22% nivo-rela- lead-in. Pts with irPR score = 3 had radiological PR = 1, SD = 3, and PD = 1 at 4wks. No association was found between MPRbx and radiological response at 4 wks. **Conclusions:** Four-wk MPRbx may serve as an early biomarker of treatment response in advanced melanoma. Lead-in treatment resulted in MPRbx of 25% and was greatest with nivo-rela lead-in. Correlations between 4 wk MPRbx and later radiological responses, survival and other endpoints will be made at completion of trial accrual. Clinical trial information: NCT03743766. Research Sponsor: Bristol Myers Squibb, Melanoma and Skin Cancer SPORE Program.

9515 **Oral Abstract Session**

Atezolizumab (A), cobimetinib (C), and vemurafenib (V) in patients (pts) with *BRAF*^{V600} mutation–positive melanoma with central nervous system (CNS) metastases (mets): Primary results from phase 2 Tricotel study. *First Author: Reinhard Dummer, Skin Cancer Center, University Hospital of Zurich, Zurich, Switzerland*

Background: Despite recent advances in the treatment of melanoma, there remains an urgent need to improve outcomes in pts with CNS mets. To date, studies evaluating intracranial activity of immunotherapies and targeted therapies have included limited numbers of pts with symptomatic CNS mets. Cohort 2 of the phase 2 Tricotel study evaluated the safety and efficacy of A + C + V in *BRAF*^{V600}-mutated melanoma with CNS mets, including symptomatic pts receiving corticosteroids. **Methods:** Eligible pts were aged ≥18 y and had melanoma, MRI-confirmed CNS mets ≥5 mm in ≥1 dimension, and no prior systemic treatment for metastatic disease. Pts received A (840 mg on days 1 and 15 of each 28-d cycle) + C (60 mg once daily for 21 d on, 7 d off) + V (720 mg twice daily) except in cycle 1, during which A was withheld. Primary outcome was intracranial objective response rate (ORR; confirmed by assessments ≥4 wk apart per independent review committee [IRC]). Secondary end points were investigator-assessed intracranial ORR, extracranial ORR, overall ORR, duration of response (DOR), disease control rate, progression-free survival (PFS), overall survival (OS), and safety. Prespecified subgroup analyses were performed in pts receiving corticosteroids (>2 mg/d dexamethasone) and/or with CNS-related symptoms at baseline vs asymptomatic pts. **Results:** This study enrolled 65 pts (median age, 55 y; 63% male). At baseline, 37% were on corticosteroids and/or were symptomatic; 49% had elevated lactate dehydrogenase. Median follow-up was 9.7 mo for all pts, 10.0 mo for pts on corticosteroids and/or symptomatic at baseline (n = 24), and 9.7 mo for asymptomatic pts (n = 41). Intracranial ORR was 42% by IRC and 51% by investigator (BOR concordance: 68%). Intracranial DOR and PFS are listed in the Table. In pts on corticosteroids and/or symptomatic at baseline, ORR was 58%, DOR was 10.2 mo, and PFS was 7.2 mo by investigator; in asymptomatic pts, ORR was 46%, DOR was 5.7 mo, and PFS was 5.5 mo. Additional secondary efficacy end points will be presented. In 60 pts who received A + C + V, grade 3/4 adverse events (AEs) occurred in 70% of pts; most commonly lipase increased (27%) and blood CPK increased (17%). Serious AEs occurred in 30% of pts. AEs led to discontinuation of any study treatment in 27% of pts. **Conclusions:** Addition of A to C + V provides promising intracranial activity in pts with *BRAF*^{V600}-mutated melanoma with CNS mets, particularly in those receiving corticosteroids and/or in symptomatic pts. The safety profile of A + C + V is consistent with that observed in the IMspire150 study. Clinical trial information: NCT03625141. Research Sponsor: Roche.

9516 **Poster Discussion Session**

Pembrolizumab (pembro) plus dabrafenib (dab) and trametinib (tram) in *BRAF*$^{V600E/K}$-mutant melanoma: Long-term follow-up of KEYNOTE-022 parts 1, 2, and 3. *First Author: Antoni Ribas, UCLA, Los Angeles, CA*

Background: KEYNOTE-022 (NCT02130466) was a phase 1/2 study of pembro + dab + tram or pembro + tram in patients (pts) with unresectable stage III/IV melanoma (parts 1-3) or solid tumors (parts 4 and 5). In previous analyses of pts with *BRAF*$^{V600E/K}$-mutant melanoma, pembro + dab + tram was shown to have manageable safety in parts 1-3, albeit with a higher incidence of TRAEs in part 3, and substantially improved PFS, DOR, and OS vs placebo + dab + tram in part 3, although the primary end point of a statistically significant improvement in PFS was not met. Long-term follow-up of pts with *BRAF*$^{V600E/K}$-mutant melanoma in parts 1-3 are presented. **Methods:** Eligible pts were ≥18 y with unresectable stage III/IV *BRAF*$^{V600E/K}$-mutant melanoma, ≥1 measurable lesion per RECIST v1.1, ECOG PS 0/1, and no prior systemic therapy for advanced disease. In parts 1 and 2, which involved dose finding and confirmation, pts received pembro 2 mg/kg IV Q3W + dab 150 mg PO BID + tram 2 mg PO QD (MTD). In part 3, pts were randomized 1:1 to pembro + dab + tram at MTD or placebo + dab + tram. Primary end points were safety, tolerability, and MTD (parts 1 and 2); ORR per RECIST v1.1 by investigator review (part 2); and PFS per RECIST v1.1 by investigator review (part 3). Data cutoff was July 14, 2021. **Results:** Median (range) study follow-up was 72.9 mo (68.4-84.5) in parts 1 and 2 (n = 15) and 61.2 mo (50.7-67.5) for all pts (n = 120; 60 each arm) in part 3. Safety of pembro + dab + tram in parts 1 and 2 was consistent with prior reports; grade 3/4 TRAEs occurred in 11 pts (73%), and no additional DLTs occurred. ORR in parts 1 and 2 was 67% (95% CI, 38-88), which was similar to that reported at an earlier data cut (73% [95% CI, 45-92]); median DOR was 19.4 mo (95% CI, 2.8-NR), median OS was NR (95% CI, 10.3-NR), 48-mo OS rate was 60%, median PFS was 15.2 mo (95% CI, 4.2-NR), and 48-mo PFS rate was 28% (Ribas A et al. *Nat Med.* 2019;25:936-940). In part 3, median PFS was 17.0 mo (95% CI, 11.3-NR) for pembro + dab + tram vs 9.9 mo (95% CI, 6.7-15.6) for placebo + dab + tram (HR, 0.46; 95% CI, 0.29-0.74) and 24-mo PFS rate was 47% vs 16%, and median OS was 46.3 mo (95% CI, 23.9-NR) vs 26.3 mo (95% CI, 18.2-38.6); and 24-mo OS rate was 63% vs 52%, respectively. ORR was 65% (95% CI, 52-77) for pembro + dab + tram vs 72% (95% CI, 59-83) for placebo + dab + tram; median DOR was 30.2 mo (95% CI, 14.1-NR) vs 12.1 mo (95% CI, 6.0-15.7). Safety in part 3 was similar to prior reports; grade 3-5 TRAEs occurred in 42 pts (70%) in the pembro + dab + tram arm vs 27 pts (45%) in the placebo + dab + tram arm (Ferrucci PF et al. *J Immunother Cancer.* 2020;8:e001806). No additional grade 5 TRAEs occurred (1 grade 5 pneumonitis had occurred at prior analysis). **Conclusions:** At long-term follow-up, first-line pembro + dab + tram continued to show improved PFS, DOR, and OS compared with placebo + dab + tram in pts with *BRAF*$^{V600E/K}$-mutant melanoma. TRAEs were more common with pembro + dab + tram but no new safety signals were identified. Clinical trial information: NCT02130466. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

9517 **Poster Discussion Session**

Newly updated activity results of alrizomadlin (APG-115), a novel MDM2/p53 inhibitor, plus pembrolizumab: Phase 2 study in adults and children with various solid tumors. *First Author: Meredith McKean, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: Alrizomadlin restores *TP53* function, activating p53-mediated apoptosis in tumor cells with wild-type *TP53* and/or *MDM2* amplification. Alrizomadlin also functions as a host immunomodulator and may restore antitumor activity in pts with cancers that progressed on PD-1/PD-L1 inhibitors. **Methods:** This US/Australian multicenter trial evaluated alrizomadlin, an investigational MDM2-selective, small-molecule inhibitor, combined with pembrolizumab, in pts with unresectable/metastatic melanoma that progressed on I-O drugs; pts with malignant peripheral nerve sheath tumor (MPNST), well-differentiated/dedifferentiated liposarcoma, non-small cell lung cancer (NSCLC), or solid tumors with *ATM* mutations that progressed on available standard therapy; or pts for whom therapy was unavailable. Eligible pts had ECOG performance status of 0-2 and, if present, stable brain metastases. Alrizomadlin 150 mg PO was administered QOD for 2 consecutive weeks, with 1 week off, and pembrolizumab 200 mg IV over 30 minutes on Day 1 of a 21-day cycle. **Results:** As of November 3, 2021, preliminary and interim results are reported for 130 pts in 6 cohorts: melanoma (n = 44), NSCLC (n = 26), *ATM* mutation (n = 18), liposarcoma (n = 17), urothelial (n = 13), and MPNST (n = 12). In the melanoma cohort, confirmed ORR by RECIST, (PR + CR) was 13% (2 CRs + 3 PRs/38 efficacy evaluable [EE] pts). In cutaneous and uveal melanoma subcohorts, confirmed ORR was 24% (2 CRs + 2 PRs/17 EE pts) and 9% (1 PR/11 EE pts), respectively. In the MPNST cohort, the clinical benefit rate, defined by confirmed ORR + SD of > 4 cycles, was 40% (4 SDs/10 EE pts). Additional confirmed PRs were reported in NSCLC, urothelial, and liposarcoma cohorts (1 each). Common treatment (alrizomadlin or pembrolizumab)-related adverse events (TRAEs; ≥ 10%) were nausea (62%), thrombocytopenia (39%), vomiting (38%), fatigue (38%), decreased appetite (29%), diarrhea (25%), neutropenia (15%), and anemia (12%). Grade 3^{+} TRAEs (≥ 5%) included thrombocytopenia (23%), neutropenia (10%), and anemia (7%). A total of 16 pts discontinued treatment due to AEs; 6 were treatment related, including grade 4 thrombocytopenia (n = 3), grade 2 vomiting (n = 1), grade 2 fatigue (n = 1), and grade 2 posterior reversible encephalopathy syndrome (PRES; n = 1). A total of 10 pts reported treatment-related SAEs: 1 each of abdominal pain, asthenia, colitis, febrile neutropenia, hypophysitis, peripheral edema, overdose, PRES, pulmonary embolism, pyrexia, and thrombocytopenia**. Conclusions:** Alrizomadlin, combined with pembrolizumab, is well tolerated and demonstrates preliminary antitumor activity in multiple tumor types and may restore antitumor effects in pts with cancer resistant or intolerant to I-O drugs. Internal study identifiers: APG-115-US-002; Keynote MK-3475-B66. Clinical trial information: NCT03611868. Research Sponsor: Ascentage Pharma Group Corp. Ltd (Hong Kong).

9518 **Poster Discussion Session**

Primary analysis of a phase 2, open-label, multicenter trial of talimogene laherparepvec (T-VEC) plus pembrolizumab (pembro) for the treatment (Tx) of patients (pts) with advanced melanoma (MEL) who progressed on prior anti–PD-1 therapy: MASTERKEY-115. *First Author: Brian Gastman, Cleveland Clinic Lerner College of Medicine, Cleveland, OH*

Background: Despite advances in anti–PD-1–based Tx for MEL, an unmet need remains for immunotherapy failure in advanced metastatic or unresectable MEL. Also, there is a growing population of pts who received adjuvant anti–PD-1 and recurred; yet trials to address this population are lacking. Combination Tx with T-VEC, an oncolytic viral intratumoral Tx designed to produce GM-CSF, and pembro, an anti–PD-1 agent, may overcome immunotherapy failure. We report the MASTERKEY-115 primary analysis on the efficacy and safety of T-VEC + pembro in pts with advanced MEL who had progressive disease (PD) on prior anti–PD-1. **Methods:** This open-label, single-arm, multicenter, phase 2 study (NCT04068181) enrolled pts at 26 international sites (Jan 2020–Feb 2021). Cohorts 1 and 2, primary and acquired resistance, respectively, received anti–PD-1 in a locally recurrent or metastatic setting and had PD within 12 wks of the last anti–PD-1 dose. Cohorts 3 and 4 included only pts who received adjuvant anti–PD-1 and were disease-free for < 6 mos (Cohort 3) or ≥ 6 mos (Cohort 4) before confirmed PD. Eligible pts had histologically confirmed unresectable or metastatic stage IIIB–IVM1d MEL, measurable and injectable disease, ECOG PS 0/1, and progressed on anti–PD-1 directly before enrollment. T-VEC at standard dosage and pembro 200 mg were given Q3W. The primary endpoint was objective response rate (ORR). Key secondary endpoints were complete response (CR) rate, progression-free survival (PFS), and safety. Tx decisions were per modified immune-related response criteria (irRECIST). **Results:** 72 pts (median age, 65 y) were enrolled. Of the 71 evaluable pts, 37 (52.1%) had stage IVM1b–d disease, 30 (42.3%) had confirmed PD-L1–positive tumor (CPS ≥ 1%), 20 (28.2%) had a $BRAF^{V600}$ mutation, and 21 (29.6%) had LDH > 1ULN. At data cutoff (Aug 2021), 47 (65.3%) pts remained on study. ORR was 0%, 6.7%, 40%, and 46.7% in cohorts 1–4, respectively (table). Any-grade Tx-related adverse events (TRAEs) were reported in 54 (76.1%) pts; the most common were pyrexia (29.6%), fatigue, and influenza-like illness (15.5% each). Grade ≥ 3 TRAEs occurred in 9 (12.7%) pts. **Conclusions:** T-VEC + pembro showed manageable safety in pts with advanced MEL after anti–PD-1 failure; the promising ORR observed in pts who progressed on prior adjuvant anti–PD-1 warrants further analysis. Clinical trial information: NCT04068181. Research Sponsor: Amgen Inc; Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Long-term outcomes of a phase II trial of neoadjuvant immunotherapy for advanced, resectable cutaneous squamous cell carcinoma of the head and neck (CSCC-HN). *First Author: Neil D. Gross, The University of Texas MD Anderson Cancer Center, Department of Head and Neck Surgery, Houston, TX*

Background: In a pilot phase II trial, we investigated the use of neoadjuvant immunotherapy to induce a pathologic response in patients with stage III/IV (M0) cutaneous squamous cell carcinoma of the head and neck (CSCC-HN). Here, we report the long-term outcomes according to pathologic response. **Methods:** Patients with newly diagnosed or recurrent stage III/IV (M0) (AJCC 8th Ed) CSCC-HN were treated with 2 doses of cemiplimab 350 mg intravenously every 3 weeks prior to surgery. The primary endpoint was overall response rate (ORR) per RECIST v1.1. Secondary endpoints included safety, pathologic response, disease-free and overall survival. **Results:** Of 20 patients enrolled, 7 (35%) had recurrent disease and 12 (60%) were stage IV on presentation. Neoadjuvant immunotherapy was generally well-tolerated and there were no surgical delays. Adverse events (AEs) were observed in 7 (35%) patients; 1 (5%) grade 3 diarrhea, 6 (30%) ≤ grade 2 AEs. ORR by RECIST was 30%. However, 85% (17/20) achieved a pathologic response (≤50% viable tumor), with pathologic complete response (pCR) in 11 (55%), major pathologic response (MPR, ≤10% viable tumor) in 4 (20%) and pathologic partial response (pPR, >10% and ≤50% viable tumor) in 2 (10%). Patients with a pCR did not receive planned radiotherapy after surgery. Patients who did not have a pathologic response (> 50% viable tumor) either progressed and died (1, 5%) or developed recurrence (2, 10%) despite surgery and adjuvant radiation or chemoradiation. At a median follow up of 34.5 months (range: 7.7-42.7), none of the patients who achieved a pathologic response have recurred. **Conclusions:** Consistent with other cancer types, pathologic response to neoadjuvant immunotherapy is durable in patients with advanced, resectable CSCC-HN. Adjuvant radiation therapy may be spared in patients who achieve a pCR and warrants further investigation. Clinical trial information: NCT03565783. Research Sponsor: Regeneron.

9520 **Poster Discussion Session**

Immunotherapy followed by cetuximab in locally advanced/metastatic (LA/M) cutaneous squamous cell carcinomas (cSCC): The I-TACKLE trial. *First Author: Paolo Bossi, Medical Oncology Unit, Department of Medical & Surgical Specialties, Radiological Sciences & Public Health, University of Brescia, ASST Spedali Civili, Brescia, Italy*

Background: In LA/M cSCC patients (pts), immunotherapy with pembrolizumab (P) and cemiplimab showed an overall response rate (ORR) of 34-49%, with durable antitumor activity. However, primary and acquired resistance represents a therapeutic challenge. In cSCC, monotherapy with cetuximab (C) showed promising signs of activity (ORR 28%), but with limited duration of response. This study aims at reverting P resistance by adding C, leveraging on its mechanism of action in reducing immune escape process. **Methods:** I-TACKLE is an open-label, nonrandomized, phase II trial in pts with LA/M cSCC conducted in 3 Italian centers. Eligible pts had LA/M cSCC not manageable with surgery or radiation and with ECOG PS= 0 or 1. They received intravenous P 200 mg every 3 weeks. In case of partial (PR) or complete response (CR), pts continued to receive P alone. In case of stable disease (SD) or progression (PD), pts received C (400 mg/sm loading dose, then weekly 250 mg/sm) in addition to P until progression. The primary endpoint was cumulative ORR by single agent or by combination strategy; safety, PFS (since start of P and P+C), OS and duration of response (DOR) were secondary endpoints. **Results:** Between May 2019 and April 2021, 43 pts were enrolled and treated with P. Table 1 depicts population baseline features. The median follow up was 24 (range 7-30) months. Twenty-three pts underwent the combination treatment (17/23 due to PD and 6/23 due to SD); 21 of them due to primary resistance and 2 because of acquired resistance. Median treatment exposure was 3 and 4 months to P and combination therapy, respectively. Cumulative ORR was 63% [95% confidence interval 48-77], including 19/43 (44%) pts with response to P and 8/21 (38%) with response to combination strategy after primary resistance to P. Both pts experiencing an acquired resistance to P obtained PR when C was introduced. Overall, 10/23 pts (44%) obtained a response to combination therapy. Median DOR and OS were not reached both with P alone and with P+ C. One-year PFS was 51% with P alone and 42% with P+C. Overall, grade 3-4 treatment-related adverse events occurred in 7/43 (16%) pts during treatment with P and 8/23 (35%) pts during P+C, mostly dermatitis 7/23 (30%). Three out of 43 (7%) pts discontinued treatment because of toxicity, one pancreatitis, one impaired renal function and one for worsening of clinical condition, all during treatment with P. Four patients died during treatment, due to PD. **Conclusions:** In LA/M cSCC, the addition of C to P reverts primary and acquired resistance, with manageable toxicities. The sequential approach deserves to be studied in future clinical trials. Clinical trial information: NCT03666325. Research Sponsor: Merck Sharp & Dohme MISP (Merck Investigator Studies Program).

A retrospective study of ipilimumab plus nivolumab in anti–PD-L1/PD-1-refractory merkel cell carcinoma. *First Author: Sophia Z. Shalhout, Division of Hematology/Oncology, Department of Medicine, Massachusetts General Hospital, Harvard Medical School, Boston, MA*

Background: Merkel cell carcinoma (MCC) is a rare cutaneous neuroendocrine carcinoma with a high recurrence and mortality rate. Immune checkpoint inhibitors (ICIs) targeting the PD-L1/PD-1 axis have shown significant clinical benefit with durable responses in patients with advanced MCC leading to regulatory approvals by the U.S. Food and Drug Administration for two agents: avelumab (anti-PD-L1) and pembrolizumab (anti-PD-1). However, many patients (~50%) with advanced MCC treated with ICI do not experience tumor regression. Studies regarding systemic therapy options following progression due to primary or acquired resistance to immunotherapy are limited and management remains a clinical challenge. In this retrospective study, we evaluated objective clinical response to combination ipilimumab and nivolumab (ipi-nivo) salvage therapy in advanced MCC refractory to anti-PD-L1/PD-1 treatment. **Methods:** We reviewed the electronic medical record at Mass General Brigham associated institutions to identify patients with advanced MCC that progressed on upfront immunotherapy (e.g., pembrolizumab, avelumab or nivolumab) and were re-challenged with combination ipi-nivo between 2016 to 2021. Patients treated with prior surgery, radiation, or cytotoxic chemotherapy after progressing on immunotherapy were not excluded. Responses to ipi-nivo were evaluated for every patient at each re-staging/interval assessment following baseline analysis utilizing Response Evaluation Criteria in Solid Tumors (RECISTv1.1) as well as immune-related Response Evaluation Criteria in Solid Tumors (irRECIST) to ensure conventional RECIST did not underestimate the benefit of ipi-nivo. **Results:** Four patients (31%) experienced grade III/IV immune-related adverse events. No patients (0/13) in this case series achieved an objective response via RECISTv1.1/irRECIST. Stable disease was seen in 23% (3/13) and the median progression-free survival was 1.3 months (90% CI, 1.1-1.5). The median overall survival from the initiation of ipi-nivo was 4.7 months (95% CI, 3-17). **Conclusions:** This study suggests limited, if any, clinical benefit of ipi-nivo in patients with advanced anti-PD-L1/anti-PD-1-refractory MCC. New strategies for second-line treatment of MCC are needed and referral to innovative clinical trials should be a priority for patients with refractory metastatic MCC. Long-term survival in advanced melanoma for patients treated with nivolumab plus ipilimumab in CheckMate 067. *First Author: F. Stephen Hodi, Dana-Farber Cancer Institute, Boston, MA*

Background: Durable clinical benefit has been achieved with nivolumab (NIVO) + ipilimumab (IPI), including an overall survival (OS) of 49% and a melanoma-specific survival (MSS) of 56%, with median MSS not reached (NR) at 6.5-y minimum follow-up. Here we report sustained efficacy outcomes at 7.5 y. **Methods:** Patients (pts) with previously untreated, unresectable stage III/IV melanoma were randomly assigned 1:1:1 and stratified by PD-L1 status, *BRAF* mutation status, and metastasis stage to receive NIVO 1 mg/kg + IPI 3 mg/kg for 4 doses Q3W, followed by NIVO 3 mg/kg Q2W (n = 314); NIVO 3 mg/kg Q2W + placebo (n = 316); or IPI 3 mg/kg Q3W for 4 doses + placebo (n = 315) until progression or unacceptable toxicity. Co-primary endpoints were progression-free survival (PFS) and OS with NIVO + IPI or NIVO alone versus IPI. **Results:** With a minimum follow-up of 7.5 y, median OS remained stable at 72.1 mo (NIVO + IPI), 36.9 mo (NIVO), and 19.9 mo (IPI); median MSS was NR, 49.4 mo, and 21.9 mo, respectively (Table). While the objective response rate remained stable at 58% (NIVO + IPI), 45% (NIVO), and 19% (IPI), median duration of response had now been reached for NIVO at 90.8 mo and remains NR and 19.2 mo for NIVO + IPI and IPI, respectively. Subsequent systemic therapy was received by 36%, 49%, and 66% of NIVO + IPI-, NIVO-, and IPI-treated patients, respectively, and median time to that therapy was NR (95% CI, 45.9–NR), 24.7 mo (16.0–38.7), and 8.0 mo (6.5–8.7). Of patients alive at 7.5 y, 106/138 (77%, NIVO + IPI), 80/115 (70%, NIVO), and 27/60 (45%, IPI) were off treatment and had never received subsequent systemic therapy. No change to the safety summary was observed with additional follow-up; updated health-related quality of life data will be reported. Of the 10 new deaths since the 6.5-y follow-up (ie, 5 NIVO + IPI; 3 NIVO; 2 IPI), none were treatment-related; 4 were due to melanoma progression; 1 was due to an unknown cause; and 5 were due to other causes, but not associated with a COVID diagnosis. **Conclusions:** The 7.5-y follow-up continues to demonstrate the durability of responses with NIVO + IPI and an ongoing survival plateau. A substantial difference in median OS and MSS between patients treated with NIVO + IPI or NIVO was observed in descriptive analyses. Clinical trial information: NCT04540705. Research Sponsor: Bristol Myers Squibb, Pharmaceutical/Biotech Company, Grant P30CA008748 to J. D. W. from the National Cancer Institute, and a grant to J. L. from the National Institute for Health Research Royal Marsden–Institute of Cancer Research Biomedical Research Centre.

	NIVO + IPI(n = 314)	NIVO (n = 316)	IPI (n = 315)

Androgen receptor blockade promotes response to BRAF/MEK-targeted therapy. *First Author: Michael White, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Treatment with BRAF+/-MEK inhibition (BRAF+/-MEKi) has revolutionized treatment in melanoma and other cancers, but resistance is common and innovative treatment strategies are needed. Sexual dimorphism in response to BRAF+/-MEKi have been noted, but mechanisms behind this are poorly understood and hormonal modulation has not been well-studied in this setting. **Methods:** We examined outcomes by sex in five clinical cohorts of patients (pts) (total n = 792, 362 female, 430 male) with *BRAF*-mutated melanoma who were treated with BRAF/MEKi in either the neoadjuvant or metastatic setting. Rates of major pathologic response (MPR), clinical benefit (CB), progression free survival (PFS) relapse-free survival (RFS) and overall survival (OS) were assessed. Translational research studies were performed on available pre- and on-treatment tumor samples (n = 27 pts) including RNA sequencing and profiling androgen receptor (AR) expression. Parallel studies were performed in preclinical models to assess the effect of sex and AR modulation on response to BRAF+/-MEKi. **Results:** In this study, improved rates of MPR, CB, PFS and OS were observed in female vs male pts. Specifically, female patients treated with neoadjuvant BRAF+MEKi showed significantly higher rates of MPR (66% v. 14%, p = 0.001), and improved RFS (64% versus 32% at 2 years, p = 0.021) vs male pts in the neoadjuvant setting (n = 51). These findings were not observed in a 2nd smaller trial of pts (n = 35), but were validated in a cohort of pts with unresectable metastatic melanoma treated with BRAF+MEKi (n = 69), with significantly higher rates of CB (80% v. 68%, p = 0.022) and PFS (12 v. 7 months, p = 0.003) in female vs male pts. Data from several published trials was analyzed (COMBI-D and METRIC trials), demonstrating improved PFS/OS at 2 years in female vs male pts treated with combined BRAF/MEKi (n = 211; p = 0.03 and, p = 0.04) and in female vs male pts treated with MEKi monotherapy (n = 206; p = 0.04 and p = 0.002), but not in female vs male pts treated with BRAFi monotherapy (n = 211; p = 0.21 and 0.095). Significantly higher expression AR expression was observed in available on- vs pre-treatment samples from male pts (p = 0.01), suggesting that treatment with BRAF/MEKi may induce AR expression in tumors. Findings were recapitulated in several preclinical models, and treatment with pharmacologic inhibitors of AR signaling (enzalutamide) in combination with BRAF/MEKi was associated with significantly enhanced anti-tumor activity in both male and female mice (p = 0.003 and p < 0.0001). Conversely, systemic treatment with testosterone was associated with significantly impaired tumor control in male and female mice (p = 0.021 and < 0.001). **Conclusions:** These data suggest that AR blockade may promote BRAF/MEKi response in melanoma, warranting further investigation in clinical trials. The impact of AR signaling, and modulation should be studied in MAPK-targeted therapy across other cancer types. Research Sponsor: U.S. National Institutes of Health.

Tumor mutational burden (TMB) in immune checkpoint inhibitor (ICI)-naïve and -experienced patients with metastatic melanoma treated with lifileucel, a tumor-infiltrating lymphocyte (TIL) cell therapy. *First Author: Harriet M. Kluger, Yale University School of Medicine, Smilow Cancer Center, New Haven Hospital, New Haven, CT*

Background: Cutaneous melanoma is characterized by high TMB, which is associated with increased tumor-specific neoantigen expression (Schumacher Science 2015) and an increased response rate to ICI (Yarchoan NEJM 2019). The TMB in tumors that recur/progress after ICI is not well defined. Lifileucel is a one-time, autologous TIL cell therapy under investigation for treatment of patients (pts) with advanced melanoma. We conducted a matched case-control study of prospectively enrolled pts with advanced melanoma treated with lifileucel in the ICI-naïve (IOV-COM-202 trial, Cohort 1A [C1A]) and post-ICI (C-144-01 trial, Cohort 2 [C2]) setting to investigate the potential association between prior ICI therapy, TMB, and response to lifileucel. **Methods:** All pts had unresectable or metastatic melanoma. Available cases from C1A (ICI-naïve pts receiving lifileucel + pembrolizumab [pembro]) were matched to controls from C2 (pts receiving lifileucel alone after progression on antiPD-1/PD-L1 therapy); 3 controls per case were matched at least for BRAF status and disease stage at study entry, and if possible, for anatomic site of tumor harvest. Lifileucel regimen was similar in C1A and C2. In C1A, 1 dose of pembro was given after tumor harvest and before nonmyeloablative lymphodepletion and resumed after lifileucel per standard treatment, for up to 2 y. Objective response rate (ORR) was assessed by investigators per RECIST v1.1. TMB of the resected tumor was measured using the ImmunoID NeXT (C1A) or PGDx elio (C2) platform; a validated conversion factor was used to compare TMB between platforms (Vega Ann Oncol 2021). High TMB was defined as ≥10 mut/MB. **Results:** Seven pts in C1A and 21 in C2 were included in the case-control study and had ORR of 71.4% and 38.1%, respectively. The percentage of pts with high TMB was 57.1% in C1A and 19.0% in C2 (P = 0.1). ORR in the low and high TMB groups was 66.7% and 75.0%, respectively, in C1A and 41.1% and 25.0% in C2; 60% of responders in C1A and 12.5% in C2 had high TMB. In logistic regression analysis adjusted for cohort, TMB was not associated with response to lifileucel (odds ratio, 1.0; 95% CI, 0.91.1; P = 0.8). Data on tumor mutations and neoantigens, T-cell receptor repertoire, and tumor microenvironment profile will be presented. **Conclusions:** Our preliminary data indicate that the efficacy (ORR) of lifileucel may be independent of TMB, regardless of treatment setting, consistent with its proposed immune checkpoint pathway-independent mechanism of action. The percentage of patients with high TMB tended to be lower in tumors with prior ICI exposure than in those that were ICI-naïve. Clinical trial information: NCT03645928; NCT02360579. Research Sponsor: Iovance Biotherapeutics.

Atezolizumab plus bevacizumab in patients with unresectable or metastatic mucosal melanoma: A multicenter, open-label, single-arm phase 2 study. *First Author: Lili Mao, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Melanoma and Sarcoma, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Anti-programed cell death-1 (PD-1) monotherapy is a part of the standard therapy for cutaneous melanoma but has demonstrated low efficacy in mucosal melanoma. This study evaluated the efficacy and safety of atezolizumab plus bevacizumab as a first-line therapy in patients with advanced mucosal melanoma. **Methods:** This multicenter, open-label, single-arm, phase 2 study utilized a Simon's two-stage design. Atezolizumab (fixed-dose, 1200 mg) and bevacizumab (7.5 mg/kg) were administered by intravenous infusion every 3 weeks. The primary endpoint was objective response rate (ORR), determined by the investigator per RECIST v1.1. Secondary endpoints included progression-free survival (PFS), overall survival (OS), duration of response (DOR), disease control rate (DCR), and safety with adverse events summarized using NCI-CTCAE v5.0. **Results:** In total, 43 patients were enrolled, including 20 (46.5%) with unresectable and 23 (53.5%) with metastatic mucosal melanoma. Median follow-up was 13.4 months at data cut-off (July 30, 2021). Forty patients were evaluable for response: In stage I analysis set (n=22), the best confirmed ORR according to RECIST v1.1 was 40.9% (9/22; 95% CI 20.7-63.7), including one CR and eight PRs. The ORR in the FAS population was 45.0% (95% CI, 29.3-61.5) (1 CR, 17 PRs) and the DCR was 65.0% (95% CI, 48.3-79.4). The median PFS was 8.2 months (95% CI, 2.7-9.6), the 6- and 12-month PFS rates were 53.4% (95% CI, 36.6-67.6) and 28.1% (95% CI, 14.2-43.9), respectively. The median OS was not reached (NR) (95% CI, 14.4-NR). The 6- and 12-month OS rates were 92.5% (95% CI, 78.5-97.5) and 76.0% (95% CI, 57.1-87.5), respectively. The median DOR was 12.5 months (95% CI, 5.5-NR). Overall, 90.7% (39/43) of patients experienced treatment-related adverse events, and 25.6% (11/43) experienced grade ≥ 3 events. **Conclusions:** Atezolizumab in combination with bevacizumab showed promising efficacy and a manageable safety profile in patients with advanced mucosal melanoma. Encorafenib plus binimetinib in patients with locally advanced, unresectable, or metastatic BRAF^{V600}-mutant melanoma: Updated data from the multicenter, multinational, prospective, non-interventional longitudinal study BERING^{MELANOMA}. *First Author: Erika Richtig, Department of Dermatology, Medical University of Graz, Graz, Austria*

Background: For the treatment of advanced BRAF^{V600}-mutated melanoma, targeted BRAF/MEK-inhibition is a standard of care. Encorafenib + binimetinib (EB) were approved 2018 in the EU and 2019 in Switzerland, based on positive results from COLUMBUS (NCT01909453), median progression-free survival (PFS) 14.9 mo (5-yr PFS: 23%), overall survival (OS) 33.6 mo (5-yr OS: 35%). As data from controlled trials are based on selected populations, BERING^{MELANOMA} investigates EB-use under real-world conditions in a broader population. **Methods:** BERING^{MELANOMA} (NCT04045691) is an ongoing, multi-national, prospective, longitudinal, non-interventional study. It analyzes the effectiveness (prim. endpoint: 1-yr PFS-rate), QoL and safety of EB-therapy in the unresectable advanced or metastatic setting under real-world conditions, focusing on the first- (1L) and second-line setting including an evaluation of the impact of prognostic factors. The project aims to enroll up to 750 patients (pts) in a total of 80 German, Austrian and Swiss sites (study duration: 8 yrs). So far (10/2019-01/2022), 280 pts have been included. Pts with prior BRAF-/MEK-inhibition (except adjuvant use completed > 6 mo) and > 1 prior therapy line with CPI in the palliative setting were excluded (adjuvant CPI allowed). **Results:** Here we present the 2nd planned interim snapshot based on the initial 200 enrolled pts (186 treated / 182 evaluable; median FU: 14.2 mo). This analysis set shows a median age of 60.5 yrs (range 20.0-89.0), 45% of pts were female. 87% presented with distant metastases (brain: 30%), with an involvement of ≥3 organ systems in 51% and elevated LDH in 43%. 54% of pts underwent any prior systemic therapy (adjuvant: 30%; 1L CPI palliative: 24%, mainly with ipilimumab + nivolumab). EB was mainly administered in the 1L-setting (60%). Main reasons for EB-selection were: efficacy (44%), physician's preference (34%), QoL (17%). Median estimated EB treatment duration was 11.6 mo (95%CI 8.8-18.6), median relative dose intensity for both drugs: 100%, main reasons EB-discontinuation: PD (55%), toxicity (16%). Treatment adaptations were required in 40% of pts (interruption E 26%, B 29%), toxicity as main reason (E 26%, B 29%). Adverse events were reported in 86% of pts (grade 3/4: 34%), mainly (≥10%, all grades): diarrhea, nausea, fatigue (each 17%), CK increase (16%), GGT increase (11%). No fatal toxicities were observed. **Conclusions:** This 2nd interim snapshot shows an investigation of EB in a real-world population with advanced disease. Despite the poorer prognosis configuration as compared to the pivotal study, the observed tolerability profile is largely consistent with data derived from COLUMBUS without any new safety signals. The 3rd interim snapshot will be performed after enrollment of 300 pts. Research Sponsor: Pierre Fabre Pharma.

9527 **Poster Session**

Dabrafenib (D) and trametinib (T) plus spartalizumab (S) in patients (pts) with previously untreated *BRAF* V600–mutant unresectable or metastatic melanoma: Three-year overall survival (OS) data from the randomized part 3 of the phase III COMBI-i trial. *First Author: Reinhard Dummer, Universitäts Spital Zürich, Zurich, Switzerland*

Background: Combination of immune checkpoint inhibitors and targeted therapy may produce durable and deep response in a higher proportion of pts with *BRAF* V600–mutant unresectable or metastatic melanoma. A recent report from the randomized, double-blind, placebo (PBO)-controlled Part 3 of the Phase 3 COMBI-i trial (NCT02967692) failed to show a statistically significant progression-free survival (PFS) benefit (hazard ratio (HR) of 0.82 (95% CI, 0.66–1.03, *p*= .042)). Here, we report 3-year OS data from COMBI-i part 3. **Methods:** Eligible pts were randomized 1:1 to receive either S+D+T (n = 267; S 400 mg IV Q4W + D 150 mg orally BID + T 2 mg orally QD) or PBO+D+T (n = 265), until progression or unacceptable toxicity. Although the primary endpoint of PFS was not met, exploratory OS and safety analyses were performed. OS was summarized descriptively using Kaplan–Meier methods and HR was estimated using a stratified cox regression model. **Results:** As of October 19, 2021 (median follow-up, 42.8 months), the median OS was not reached in S+D+T arm and was 40.4 months with PBO+D+T (HR 0.796; 95% CI, 0.615–1.029). There were 113 (42.3%) deaths in the S+D+T and 126 (47.5%) in the PBO+D+T. Estimated 2-year and 3-year OS rates were 67.7% (95% CI 61.6–73.1) and 60.1% (95% CI 53.8–65.8) with S+D+T vs 61.9% (95% CI 55.6–67.5) and 52.9% (95% CI 46.6–58.9) with PBO+D+T, respectively. An OS benefit was observed with S+D+T in these prespecified subgroups – Eastern Cooperative Oncology Group Performance Status (ECOG PS) 1 (HR 0.50; 95% CI, 0.32–0.8), age ≥65 years (HR 0.58; 95% CI, 0.36–0.94), PD-L1 negative (< 1%) (HR 0.62; 95% CI, 0.42–0.91), sum of lesion diameters ≥ 66 mm at baseline (HR 0.63; 95% CI, 0.43–0.91) and metastatic sites ≥ 3 (HR 0.66; 95% CI, 0.47–0.94). Adverse events (AEs) irrespective of study treatment relationship were observed in 99.3% of pts in S+D+T vs 97.3% in PBO+D+T. The most common AEs (in > 30%; all grades) were pyrexia, diarrhea, and nausea. Grade ≥3 treatment-related AEs (TRAEs) occurred in 56.9% vs 35.2% of pts treated with S+D+T vs PBO+D+T, respectively. Dose reductions of D and T due to AEs were more frequent in the S+D+T arm than PBO+D+T arm (47.2% vs 25.4% and 45.7% vs 25.4%, respectively), contributing to a lower relative dose intensity; the TRAEs leading to discontinuation of all 3 study drugs occurred in 13.5% vs 8% of pts, respectively. **Conclusions:** Results from this landmark 3-year OS analysis from COMBI-i- part 3 was consistent with the primary analysis, while the PBO+D+T showed a higher OS rate than previously observed for D+T alone in COMBI D/V studies, with a longer median follow-up. Subgroup analyses showed that ECOG PS 1, age ≥65 years, negative PD-L1 status and high tumor burden were associated with better OS in S+D+T in terms of HR. Clinical trial information: NCT02967692. Research Sponsor: Novartis.

9528 **Poster Session**

Efficacy and safety of nivolumab for locally advanced or metastatic cutaneous cell carcinoma (NIVOSQUACS trial). *First Author: Roland Lang, Department of Dermatology and Allergology, Paracelsus Medical University Salzburg, Salzburg, Austria*

Background: Cutaneous squamous cell carcinoma (cSCC) is the second most frequent skin cancer and considered as a tumor with strong immunogenicity. Consistently, immune checkpoint-inhibition with programmed death (PD)-1 antibodies has become the novel standard of care in the treatment of advanced cSCC. In this study, we evaluated efficacy and safety of the PD-1 antibody nivolumab in patients with locally advanced or metastatic cSCC, including individuals with concomitant hematological malignancies (CHM) – a highly vulnerable subgroup of cSCC patients typically excluded from clinical trials. **Methods:** This phase II, open-label, single-arm multicentre study included patients aged ≥ 18 years with histologically confirmed locally advanced and/or metastatic cSCC and at least one measurable lesion according to RECIST v1.1. Enrolled patients received nivolumab 240 mg intravenously over 30 min every 2 weeks for up to 2 years. A sample size of 31 patients was needed to provide 90% power to detect an objective response rate (ORR) of at least 12.6% after 24 weeks with a type I error of 5% assuming a dropout-rate of 15%. The primary endpoint was investigator assessed ORR as per RECIST v1.1. Secondary endpoints included disease control rate (DCR), progression-free survival (PFS) and overall survival (OS). **Results:** Between July 2017 and October 2020, 31 patients with advanced cSCC, including 11 patients with CHM, were enrolled and received at least one dose of nivolumab. The median age was 80 years (range 66-92) and the majority of patients was male (71%). Upon enrollment, 19.4% of patients had locally advanced, 51.6% loco-regional metastatic and 25.8% distant metastasic disease. Seven patients (22.6%) had received one prior systemic therapy for cSCC. At data-cut-off (March 2021; week-24 RECIST assessment completed in all available patients), five patients (16.1%) were still on treatment, one patient completed treatment per protocol, whereas 25 patients had discontinued therapy. Of 29 patients who were evaluable for response assessment, 12 patients achieved a partial and 7 a complete response, resulting in a best ORR of 65.2% (95% CI: 45.7% - 82.1%), a DCR of 68.9% (95% CI: 50.8%-82.7%) and a median PFS of 11.1 months (95% CI: 3.7 - 12.9). Treatment related adverse events occurred in 18 patients (58.1%) and led to nivolumab discontinuation in two patients (6.5%). Subgroup analysis of patients with CHM revealed a best ORR of 55.6% (95% CI: 21.2% - 86.3%), a DCR of 66.7% (95% CI: 35.4% -87.9%) and a median PFS of 10.9 months (95% CI: 0.6 - 21.4). Median OS in this subgroup was 20.7 months (95% CI: 6.5 - 35.0), whereas overall median OS was not reached. **Conclusions:** Nivolumab showed a robust antitumor-activity similar to other anti-PD-1 agents in advanced cSCC. Although ORR and OS were slightly reduced in patients with CHM, nivolumab proved effectiveness also in this subgroup while no new safety signals occurred. Clinical trial information: NCT04204837. Research Sponsor: Bristol-Myers Squibb.

Efficacy of immune checkpoint inhibitor (ICI) rechallenge in advanced melanoma patients responders to a first course of ICI: A multicenter, national, retrospective study of the French group of skin cancers (GCC). *First Author: Charlee Nardin, Université de Franche-Comté, Inserm 1098 RIGHT, Besançon, France*

Background: The efficacy of ICI rechallenge for progressive/recurrent disease of advanced melanoma patients (pts) after a first course of ICI interrupted for disease control has not been systematically described. **Methods:** A retrospective observational multicenter national real-life study evaluated the efficacy and tolerance of ICI rechallenge (anti-PD1, anti-CTLA-4, or combination therapy) in melanoma pts who progressed after disease control with an ICI subsequently interrupted. Primary objective was to evaluate tumor response using RECIST version 1.1. Secondary objectives were the factors associated with tumor response, progression-free survival (PFS), overall survival (OS) and the tolerance of the rechallenge. **Results:** 85 pts from 12 French different centers rechallenged with an ICI between July 2014 and June 2021 were included. Median (IQR) age of pts was 72.00 (30–89) years. Most pts were male (n = 47, 55%) with an AJCC stage IV melanoma (n = 75, 88%). BRAFV600-mutant melanoma and elevated LDH were reported in 19 pts (22%). Pts were rechallenged with anti-PD1 (Pembrolizumab (n = 44, 52%), Nivolumab (n = 35, 41%)), anti-CTLA-4 (Ipilimumab (n = 2, 2%)) or the combination therapy (Ipilimumab + Nivolumab (n = 4, 5%)). Median follow-up after rechallenge was 13 months (1.1-76.2). All pts included had had disease control with the first course of ICI including complete response (CR) in 47 pts (55%), partial response (PR) in 28 pts (33%) and stable disease (SD) in 10 pts (12%). Adverse events (AEs) of the first course of ICI had occurred in 51% pts including grade 3-4 AEs (22%). Median time between ICI interruption and ICI rechallenge was 9,3 months (1.2-63,9). The response rates of ICI rechallenge (2nd course of ICI) were CR in 30 pts (35%), PR in 17 pts (20%) and SD in 17 pts (20%). Progression occurred in 21 pts (25%). The use of steroids for brain metastases was the only factor associated with a higher recurrence rate in multivariate analysis (p = 0,002) and tends to be associated with lower outcomes. There was no correlation between best overall response to the first course of ICI and response to ICI rechallenge. Median duration of response, PFS and OS after ICI rechallenge were not reached. At last follow-up, 23 pts have died. 28 AEs of ICI rechallenge occurred in 23 pts (27%) with a median time of 3 (0.4-36.2) months, including grade 1-2 and grade 3-4 AEs in 13 (15%) and 9 (11%) pts respectively. **Conclusions:** ICI rechallenge for progressive/recurrent disease was associated with high objective response rate (CR+PR = 55%) and disease control rate (CR+PR+SD = 75%) in melanoma pts with a previous disease control induced by ICI. Thus, ICI rechallenge should be considered as an attractive therapeutic option for melanoma pts with progressive/recurrent disease after ICI interruption. Research Sponsor: None.

Characterization of patients with metastatic melanoma that relapses following complete metabolic response from anti–PD-1 therapy. *First Author: Vincent T Ma, University of Wisconsin, Madison, WI*

Background: Treatment with PD-1 inhibitor-based therapy has significantly improved survival in patients with metastatic melanoma over the past decade. Many of these patients achieve complete metabolic response (CMR) by FDG-PET/CT and electively stop treatment. However, the outcomes of patients who relapse after CMR remain uncertain. In this study, we attempt to further characterize metastatic melanoma patients who relapsed following elective discontinuation of anti-PD-1 based therapy due to CMR. **Methods:** We performed a single-center, retrospective analysis on a cohort of patients with metastatic or unresectable melanoma from 2012 to 2021 who were treated with anti-PD-1 monotherapy (pembrolizumab or nivolumab) or combination ipilimumab/nivolumab (I/N), with or without local therapies (surgery or radiation therapy). Patients who achieved a CMR from treatment were identified. CMR was defined as no evidence of metabolically active disease on full-body ^{18}F-FDG-PET/CT and no evidence of new intracranial metastasis on MRI brain. Multiple clinical variables and survival outcomes were assessed. **Results:** Among 386 advanced stage melanoma patients analyzed, 87 achieved a CMR followed by elective treatment cessation with a median anti-PD-1 therapy duration of 10.4 months. 19/87 patients had brain metastasis at baseline. 17/87 patients had disease relapse with a median time to relapse from CMR of 12.1 months. Of those 17 patients, 8 received I/N, 9 received anti-PD-1 monotherapy, and 2 required local therapies to obtain CMR. 7/17 patients were able to achieve CMR again following resumption of anti-PD-1 monotherapy (n = 6) and BRAF/MEK targeted therapy (n = 1). 10/17 patients relapsed in the brain with 7 of those patients having no history of brain metastasis at baseline. Median overall survival after relapse from CMR was 34.1 months. The most common cause of death following relapse from CMR was brain metastasis progression (n = 5). **Conclusions:** A small proportion of metastatic melanoma patients who achieve complete metabolic (CMR) following treatment with anti-PD-1 therapy develop disease relapse. We found that relapse in the brain is common, regardless of baseline involvement at time of therapy, and is a common cause of mortality suggesting the importance of intracranial surveillance following treatment cessation. Ongoing studies are warranted to identify clinicopathologic factors that predict relapse to better inform patients and providers who elect to stop anti-PD-1 therapy. Research Sponsor: None.

Progression and mortality post-immunotherapy discontinuation among patients with BRAFV600-mutant (BRAF+) metastatic melanoma. *First Author: Sunandana Chandra, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Immunotherapy (IO) is commonly used to treat BRAF+ metastatic melanoma (MM) patients in the first line (1L) setting and has demonstrated durable outcomes in clinical trials. However, most patients discontinue IO therapy for toxicity, disease progression, or other reasons. To date, no multi-center or nationwide US-based study has examined treatment patterns and outcomes for patients with BRAF+ MM post discontinuation of 1L IO. The aim of this study is to describe real-world treatment patterns and outcomes among patients who discontinued 1L IO. **Methods:** This retrospective cohort study used the Novartis BRAF+ meLanoma patients ObsErvational (NOBLE) database, the harmonized customized data from Flatiron and ConcertAI. Patients were ≥18 years old, had a diagnosis of BRAF+ MM, were treated with pembrolizumab, nivolumab, or ipilimumab + nivolumab on or after 9/1/2014, and then discontinued 1L therapy. Reason for discontinuation was extracted from medical records. Descriptive statistics were used to describe baseline characteristics and treatment patterns. Kaplan–Meier curves were used to analyze time to progression or death (TTPD) and time to death (TTD). **Results:** Of the 898 included patients (mean age: 61 years; male: 65%); 46% initiated ipilimumab + nivolumab, 24% nivolumab, and 30% pembrolizumab. The most common reasons for 1L discontinuation were toxicity (26%) and progression (25%). Medical records noted 5.3% completed therapy on discontinuation and 34.5% provided no reason of discontinuation with median duration of therapy (MDOT) of 379 and 138 days respectively. At 6 months, 34 % (n = 303) remain on IL IO. MDOT for patients who discontinued IO due to toxicity and those who discontinued due to progression were 54 and 63.5 days respectively. Patients who discontinued due to toxicity had a median time of 142 days to next treatment. TTPD was best for patients who discontinued therapy due to completion or toxicity (6-month progression rate: 13% and 20%). Patients who discontinued due to progression did especially poorly (6-month progression rate: 59%). About 33% of patients (n = 296) needed second line (2L) therapy, and the majority (80.7%) received combination BRAF+ targeted therapy. Overall, 38% and 50% of patients died post IO discontinuation for any reason at 1 and 2 years, respectively. 31% of patients had brain metastases and a greater proportion (56%) died within a 2-year period compared with those without brain metastases (56% vs 49%, p = 0.0036). **Conclusions:** IO, although effective, is not curative for all patients. A significant number of patients discontinue therapy due to progression. Patients with BRAF+ MM who progress early on 1L IO therapy have a high risk of death and should be considered for other therapy options, including targeted therapy. Research Sponsor: Novartis Pharmaceuticals Corporation.

Real-world evaluation of the association between baseline metastatic patterns and clinical outcomes among patients with BRAF-positive metastatic melanoma. *First Author: Zeynep Eroglu, Moffitt Cancer Center, Tampa, FL*

Background: While immunotherapy (IO) and BRAF-targeted therapy (TT) have benefit in BRAFV600 mutant (BRAF+) metastatic melanoma (MM), there is a paucity of real-world data on the impact of systemic therapy choice on outcomes based on key characteristics such as site and number of baseline metastases. Patients with >1 baseline site and certain sites of metastases are also underrepresented or excluded in clinical trials. The aim of this study was to evaluate the association between these characteristics and survival among BRAF+ MM patients. **Methods:** This was a retrospective cohort study using the Novartis BRAF+ meLanoma patients ObsErvational (NOBLE) dataset – harmonized customized data from Flatiron and ConcertAI. It included patients ≥18 years, who received treatment with a first-line (1L) IO (anti-PD-1 mono or combination therapy ipilimumab + nivolumab) or TT (any BRAF/MEK-inhibitors) after 1/1/2014. Progression free survival (PFS) and overall survival (OS) for IO and TT were analyzed according to number (1, 2, 3+ sites) and location (brain, lung, liver, bone) of baseline metastasis. Treatment sequence from 1L to 2L (i.e. IO/TT vs TT/IO) were also compared for PFS and OS outcomes. **Results:** A total of 1,961 patients were included, with 620 patients (32%) on IO monotherapy, 501 patients (26%) on IO combo therapy, and 840 patients (43%) on TT in the 1L. When adjusted for sex, age, ECOG, and Charlson Comorbidity Index, there was no difference in PFS or OS between 1L IO mono, IO combo and TT therapies in patients who had 1, 2, or 3+ baseline metastases. For patients who had either baseline brain, liver, lung, or bone metastasis, there was no difference in PFS and OS between IO mono, IO combo, and TT combo therapies. Of the 521 patients included in the sequencing analysis (only patients who received 2L therapy), 239 patients (46%) had 1L IO/2L TT. There was no difference in PFS or OS between treatment sequences for patients with any number or location of baseline metastasis. **Conclusions:** In this real-world retrospective cohort study, there is no difference in survival between 1L TT and IO for BRAF+ MM patients. Outcomes are comparable regardless of number and location of metastases, including brain metastasis. Whether switching from 1L TT to IO before progression may account for differences compared to trial data will be explored further. Research Sponsor: Novartis Pharmaceuticals Corporation.

Outcomes stratified by number of metastases and metastatic site among patients who received sequencing therapy 1L TT/2L IO.

Reference group: 1L IO/2L TT		PFS		OS	
Number of metastases	N	HR	95% CI	HR	95% CI
1	165	0.96	0.57 - 1.61	1.51	0.53 – 4.34
2	132	0.56	0.29 - 1.07	0.95	0.22 – 4.03

Fecal microbiota transplantation followed by anti–PD-1 treatment in patients with advanced melanoma. *First Author: Wilson H. Miller, Segal Cancer Centre at the Jewish General Hospital, McGill University, Montreal, QC, Canada*

Background: The gut microbiome has been shown to be a biomarker of response in patients (pts) with melanoma. Strategies to modify the microbiome are currently being investigated. We report the effects of Fecal Microbiota Transplantation (FMT) on safety and anti-PD-1 response in pts with melanoma from a phase I trial (NCT03772899). **Methods:** 20 pts with advanced melanoma with RECIST-evaluable disease, without prior anti-PD-1 treatment for advanced disease, were recruited from 3 Canadian academic centers. Pts with ECOG > 2, autoimmune diseases, immunosuppression or unstable brain metastases were excluded. Pts received 80-100 g of healthy donor stool via oral capsules and were treated with anti-PD-1 one week later. The primary objective was safety of combining FMT with anti-PD-1 therapy. Objective response rate (ORR) by RECIST 1.1 and correlative studies were secondary objectives. Flow cytometry and multiplex ELISA were performed on pts blood samples. Avatar mice were transplanted with stool samples obtained from participants on the trial before and after FMT. Mice were subsequently implanted with B-16 or MCA-205 tumors and received anti-PD-1 antibodies. **Results:** Median age was 75.5 years, 12 (60%) were male, 18 (90%) had stage 4 disease, and 5 (25%) pts harbored a BRAF mutation. Median follow-up was 11.2 months. FMT-related adverse events included grade 2 diarrhea (2 pts) and hypophosphatemia (1 pt), and 13 pts (65%) experienced grade 1 gastrointestinal toxicities. Grade 3 immune-related adverse events (irAE) were one each of myocarditis, nephritis, and fatigue. Anti-PD-1 therapy was discontinued for toxicity in 2 (10%) pts. No unexpected irAE or death on treatment occurred. ORR was 65% (13/20), of which 3 were CR. Clinical benefit rate (includes SD lasting > 6 months) was 75% (15/20). Median PFS was not reached, and one pt died from their disease. Translational analyses demonstrated upregulation of IL-17 post-FMT in responders, which correlated with upregulation of the frequency of Th17 cells in peripheral blood. In parallel, murine experiments showed that feces from pts pre-FMT did not sensitize tumors to anti-PD-1. In both tumor models, only feces obtained post-FMT from responders restored anti-PD-1 efficacy in mice, providing strong support that FMT contributed to the anti-tumor response observed in pts. **Conclusions:** FMT followed by anti-PD-1 treatment in melanoma pts undergoing therapy is safe and may lead to improved anti-tumor responses that can be reproduced in tumor mouse models. The gut microbiome plays an important role in responses to anti-PD-1 in patients with advanced melanoma, paving the way for future microbiome-based interventions. Clinical trial information: NCT03772899. Research Sponsor: Canadian Cancer Society, Lotte & John Hecht Memorial Foundation and the Division of Medical Oncology at London Regional Cancer Program.

Outcomes of combined ipilimumab/nivolumab in metastatic uveal melanoma: A prevalence meta-analysis. *First Author: Ceren Durer, SUNY Upstate Medical University, Syracuse, NY*

Background: Uveal melanoma is the most common primary intraocular malignant tumor in adults and, approximately 40-50% of the patients eventually develop metastatic disease. Metastatic uveal melanoma has a dismal prognosis with an overall survival of < 50% at 1-year. Single-agent check point inhibitors revealed minimal benefit and novel approaches are underway to improve the outcomes with the recent approval of Tebentafusp in uveal melanoma. The purpose of this metanalysis was to assess the safety and efficacy of combined immunotherapy with ipilimumab (3 mg/kg x q3w for 4 cycles) and nivolumab (1 mg/kg x q3w for 4 cycles) in metastatic uveal melanoma. **Methods:** A comprehensive literature search on PubMed, Embase, Cochrane and Web of Science was conducted. Two independent reviewers screened the literature and extracted data. Our search strategy included MeSH terms and key words for metastatic uveal melanoma; ipilimumab and nivolumab. OpenMeta[Analyst] software was used for the analysis. The endpoints included the prevalence of overall response rate (ORR), complete response (CR), ≥grade-III diarrhea/colitis, and ≥grade-III hepatic toxicity. Additional endpoint included the median overall survival (OS) was reported as a range. Random-effects model (DerSimonian-Laird method) was applied. **Results:** Overall, eight studies (n = 379) were included for the analysis. Five studies were phase II, three studies were retrospective. 52% of the patients were male with good performance status. Median follow-up ranged from 9.2 mo-28 mo. 40% of the patients (n = 142) had elevated LDH at the time of treatment . GNAQ and GNA11 mutations were reported in three studies, BRAF mutation was reported in two studies. The pooled prevalence for ORR was 13.7% (95% CI: 9.2–18.2%, N = 6 studies, n = 33/226) with CR of 2.1% (95% CI: 0.3–3.9%, N = 6 studies, n = 8/226). The median OS ranged from 12.7 to 19.1 months (N = 7 studies). Majority of the patients experienced treatment-related adverse events. Most common side effects included diarrhea, colitis, hepatic toxicities, skin disorders, hypothyroidism. The pooled prevalence for ≥grade III hepatic toxicity was 26.2% (95% CI: 13.9–0.385%, N = 5 studies, n = 60/219). **Conclusions:** Combined checkpoint blockade with ipilimumab and nivolumab showed an ORR of 13.7% which appears to show better clinical activity than single-agent checkpoint inhibitor. Most common treatment side effect was hepatic toxicity. Research Sponsor: None.

Phase II study SECOMBIT (sequential combo immuno and target therapy study): A subgroup analysis with a longer follow-up. *First Author: Paolo Antonio Ascierto, Melanoma, Cancer Immunotherapy and Development Therapeutics Unit, Istituto Nazionale Tumori IRCCS "Fondazione G. Pascale", Naples, Italy*

Background: To investigate the best sequential strategy, we started the SECOMBIT study, a randomized three parallel arms phase 2 study (NCT02631447). We used the combination of encorafenib/binimetinib (E+B) as targeted therapy (T-T) and the combination of ipilimumab/nivolumab (I+N) as immunotherapy (I-O). We explored the two different sequences and the "sandwich" strategy with a short course of target therapy, switched by combo immunotherapy at the best response, and not at progression of disease. In our previous report we have observed a trend in favor of the arms where I-O was given as first, confirmed by the first report of the DreamSeq study, a phase III study which compared the two different sequences with T-T and I-O. Here we updated the study data with a subgroup analysis. **Methods:** From Nov 2016 to May 2019, 37 centers in 9 countries enrolled 251 patients with untreated, metastatic *BRAFV600* melanoma. Patients were randomized to Arm A [E+B until PD, followed by I+N], or Arm B (I+N until PD, followed by E+B) or Arm C (E+B for 8 weeks, followed by I+N until PD, followed by E+B). The overall survival (OS) is the primary endpoint of the study. Secondary endpoints included total progression-free survival (tPFS), 2- and 3-years survival rate, best overall response rate, duration of response, biomarkers evaluation. **Results:** The study primary endpoint was met in each arm with at least 30 patients alive at 24 months. The median follow-up estimated with the reverse Kaplan-Meier method was 37.1 months (IQR: 32.8-46.4). The OS at 2 and 3 years was calculated in the three arms for all patients, and in the subgroups normal or elevate LDH level and < 3 or ≥ 3 metastatic sites. OS and tPFS rates at 2 and 3 years are shown in the table. **Conclusions:** With a 37.1 months median follow-up, 2 and 3-years OS as well as tPFS rates are higher in Arm B and C. In line with recent findings, the SECOMBIT results confirm a better trend in favor of Arm B and C treatment sequence. The analysis of the secondary endpoints is ongoing. Clinical trial information: NCT02631447. Research Sponsor: BMS and Array Biopharma/Pfizer.

	2-year tPFS	3-year tPFS	2-year OS	3-year OS	2-year OS < 3ms	3-year OS < 3ms	2-year OS ≥ 3ms	3-year OS ≥ 3ms	2-year OS nLDH	3-year OS nLDH	2-year OS eLDH	3-year OS eLDH
Arm A	44%	34%	62%	53%	70%	62%	50%	36%	73%	67%	50%	42%
Arm B	65%	56%	73%	63%	74%	63%	72%	61%	76%	69%	67%	50%
Arm C	57%	54%	69%	60%	79%	64%	54%	54%	70%	56%	65%	65%

tPFS = time from randomization to second progression; OS = overall survival; ms = no. of metastatic sites; nLDH = normal LDH levels; eLDH = elevated LDH levels.

Autoantibodies as potential biomarkers of immune-related adverse events in patients with advanced cutaneous melanoma treated with immune checkpoint inhibitors. *First Author: Aesha Gandhi, Edith Cowan University, Perth, Australia*

Background: The majority of patients treated with immune checkpoint inhibitors (ICIs) develop immune-related adverse events (irAE). It is currently not possible to predict the development of irAEs using biomarkers. Here we evaluated the IgG autoantibodies (AAbs) profile in pre-treatment sera of cutaneous metastatic melanoma patients treated with ICIs to identify AAbs that are associated with irAEs. **Methods:** Clinical data of patients with metastatic melanoma treated with pembrolizumab or nivolumab monotherapy (n = 48) or combination ipilimumab and nivolumab (n = 37) was retrospectively evaluated. irAEs were graded using CTCAE v5.0. Sera from the 85 patients were evaluated for IgG AAbs using the HuProt™ microarray v4.0 covering 23,059 proteins (> 81% of the human proteome). AAb profiles were compared between groups (any irAEs vs no irAEs), using the no irAEs group as control group. Results were inputted into the Advaita Bio's iPathwayGuide software to find significantly differentially expressed AAbs using $p < 0.05$ and Log2FC > 0.6, and identify relevant biological pathways. **Results:** Out of 85 patients, 60 experienced any grade irAEs, 29 of 48 (60.4%) in the PD-1 group and 31 of 37 (83.8%) in the combination group. We found 758 proteins were differentially elevated, 102 in the in the PD-1 group and 666 in the combination treatment group. A comparison of these groups identified 10 AAbs that were elevated in patients experiencing irAEs independent of ICI regimen. These targeted proteins are highly expressed in tissues that are commonly affected by irAEs. Previous studies have shown their links to autoimmune and inflammatory conditions such as dermatitis and thyroiditis. Pathway analysis shows the RIG like receptor signalling pathway, which has been associated with autoinflammatory conditions, was significantly affected in the PD-1 group ($p = 0.011$), but not in the combination group ($p = 0.442$). Other pathways involved included the NOD-like receptor, purine and D-amino acid metabolism which play a role in innate immune system and assembly of inflammasomes and maturation, pro-inflammatory cytokines and mediators that contribute to inflammatory response. **Conclusions:** Further analyses are being conducted to identify the correlation of irAE type and severity to specific autoantibodies which will be presented. Prospective studies are required for validation of these AAbs specificities. This approach could be used to identify patients at high risk of irAEs, for treatment monitoring to maintain an effective stimulation of the patient's anti-cancer immune response, to determine if treatment cessation is required and prevent hospitalisation or lengthy immunosuppression to treat irAEs. Efficacy and safety of cosibelimab, an anti–PD-L1 antibody, in patients with metastatic cutaneous squamous cell carcinoma. *First Author: Philip R. Clingan, Southern Medical Day Care Centre, Wollongong, Australia*

Background: Programmed death receptor-1 (PD-1)–blocking antibodies are approved as monotherapy treatment for patients (pts) with metastatic or locally advanced cutaneous squamous cell carcinoma (CSCC) who are not candidates for curative surgery or radiation. Cosibelimab is a high-affinity, fully human programmed death ligand-1 (PD-L1)–blocking antibody with a functional Fc domain capable of inducing antibody-dependent cellular cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC) against tumor cells. Study CK-301-101 (NCT03212404) is a global, multicenter, multicohort, pivotal trial that enrolled pts with select advanced cancers for treatment with cosibelimab. Here we present the primary analysis of the registration-enabling expansion cohort in pts with metastatic CSCC. **Methods:** Adult pts with Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1 who had metastatic (nodal and/or distant) CSCC not amenable to local therapy were eligible to participate. Cosibelimab was administered as a fixed dose of 800 mg every 2 weeks (Q2W) intravenously. The primary endpoint was confirmed objective response rate (ORR; complete response [CR] + partial response [PR]) assessed by independent central review according to Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1 and the key secondary endpoint was duration of response. **Results:** Seventy-eight pts with metastatic CSCC were treated with cosibelimab and comprise the efficacy and safety populations (59M/19F; median age: 71 years). The confirmed ORR was 47.4% (95% CI: 36.0, 59.1; 6 CRs and 31 PRs) and the median duration of response was not reached at the time of data cutoff (median duration of follow-up: 15.2 months), with 76% of responses ongoing (range: 1.4-31.8+ months). The Kaplan–Meier estimated probability of maintaining a response at 6 and 24 months was 88.1% and 72.5%, respectively. Treatment-related adverse events (TRAEs) were reported in 54 pts (69.2%); 7 pts (9.0%) experienced at least 1 grade 3 TRAE (no grade 4 or grade 5 TRAEs were reported) with the most common being increased serum lipase in 2 pts. **Conclusions:** Treatment with cosibelimab monotherapy resulted in a robust ORR with durable responses and demonstrated a predictable and manageable safety profile in pts with metastatic CSCC, supporting its use in the treatment of this cancer. Clinical trial information: NCT03212404. Research Sponsor: Checkpoint Therapeutics.

Anti-LAG-3 antibody LBL-007 in combination with toripalimab in patients with unresectable or metastatic melanoma: A phase I, open-label, multicenter, dose escalation/expansion study. *First Author: Xue Bai, Key laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Melanoma and Sarcoma, Peking University Cancer Hospital and Institute, Beijing, China*

Background: LBL007 is a novel, fully human IgG4 monoclonal antibody targeting human Lymphocyte-activation gene3 (LAG-3). Dual inhibition of anti-programmed cell death protein 1 (PD-1) and LAG-3 is anticipated to synergistically increase immune response against tumor growth. Here we report the preliminary safety and efficacy of LBL-007 in combination with Toripalimab (an anti-PD-1 antibody has approved for treatment of melanoma in China) in patients (pts) with unresectable or metastatic melanoma. **Methods:** Pts with unresectable or metastatic melanoma with or without prior anti-PD-(L)1 therapy were enrolled. This trial comprised 2 parts, namely part 1 (dose escalation), pts received LBL-007 (0.25/1/3/6 mg/kg) /Toripalimab (3 mg/kg) both i.v., Q2W; and part 2 (expansion), pts received LBL-007 (3/6 mg/kg)/Toripalimab (3 mg/kg) both i.v., Q2W. The primary objective was safety, the second objectives included pharmacokinetics, pharmacodynamics and efficacy (per RECIST 1.1). **Results:** By Jan 2022, 37 pts (15 [40.5%] male, median age 59 [range 31-74] years, 9 pts [24.3%] with baseline LDH elevation, 18 [48.6%] with acral, 12 [32.4%] mucosal, 5 [13.5%] nonacral cutaneous, 2 [5.4%] primary site unknown) were enrolled, with 17 in part 1 and 20 in part 2. No dose-limiting toxicity was observed in part 1, and the MTD was not reached. Of all 37 pts, the most common treatment-emergent adverse events (TEAEs) included anemia (24.3%), creatine phosphokinase elevation (24.3%), hypothyroidism (21.6%), and aspartate aminotransferase elevation (21.6%). For 32 radiologically evaluable pts, ORR was 12.5%, DCR was 53.1%. In a preplanned subtype-specific analysis in anti-PD-(L)1 treatment-naïve pts, ORR was 27.3 % vs. 0%, and DCR was 81.8% vs. 50.0% in acral and mucosal melanoma subtypes, respectively. For anti-PD-(L)1-resistant pts (n = 11), DCR was 18.2%. **Conclusions:** LBL007/Toripalimab combination is well tolerated and promising efficacy in pts with unresectable or metastatic melanoma, especially in the acral type without prior anti-PD-(L)1 therapy. Clinical trial information: NCT04640545. Research Sponsor: Nanjing Leads Biolabs Co.,Ltd.

The interferon-gamma (IFN-γ) signature from baseline tumor material predicts pathologic response after neoadjuvant ipilimumab (IPI) + nivolumab (NIVO) in stage III melanoma. *First Author: Irene L.M. Reijers, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Neoadjuvant IPI + NIVO induces high pathologic response rates (pRR) of 74-78% in macroscopic stage III melanoma. Pathologic response (< 50% viable tumor) is strongly associated with improved relapse-free survival (RFS); the previous OpACIN-neo study demonstrated a 2-year RFS of 96.9% in patients (pts) with pathologic response, whereas the 2-year RFS in non-responders was 35.5%. These data highlight the need for baseline biomarkers predictive for response and survival. Here, we present the predictive value of the 10-gene IFN-γ expression signature algorithm (based on Ayers et al.) for pathologic response and relapse in a cohort of melanoma pts treated with neoadjuvant IPI + NIVO. **Methods:** Baseline tumor biopsies from lymph node metastases of stage III melanoma pts were used for IFN-γ signature assessment. Pts were treated with a maximum of two cycles of neoadjuvant IPI 1mg/kg + NIVO 3mg/kg in the OpACIN-neo (arm B) and PRADO studies. RNA expression analysis was conducted using the nCounter® PanCancer Immune Profiling panel on the NanoString Flex machine (NanoString Technologies), which is clinically applicable due to its fast turn-around-time (two days). An IFN-γ signature gene expression score (IFN-γ score) was calculated using a NKI-developed algorithm. Association between IFN-γ score and pathologic response or event-free survival (EFS) was examined by logistic regression and Cox analyses. The optimal cutoff between a high and low IFN-γ score was defined based on a summary receiver operating characteristic (sROC) curve. **Results:** In total, 103 pts treated in the OpACIN-neo and PRADO studies had baseline tumor material available. Median age was 56 years, 62% was male, and 52% had a high baseline IFN-γ score. The pRR of the total cohort was 70% (72/103 pts), including 56% (58/103) major pathologic response (MPR, 0-≤10% viable tumor) and 14% (14/103) partial responses (pPR, 10-≤50% viable tumor). 30% (31/103 pts) had no pathologic response. After a median follow-up of 25.2 months, 26 pts (25.2%) developed a melanoma relapse. The IFN-γ score was significantly associated with response (OR 1.061, p < 0.001) and relapse (OR 0. 974, p = 0.029). The pRR was 89% (48/54) in pts with a high IFN-γ score versus 49% (24/49) in those with a low IFN-γ score (p < 0.001). Pts with a high IFN-γ score were also less likely to develop a relapse (11% [6/54] versus 41% [20/49], p = 0.001). **Conclusions:** Pts with a high IFN-γ score in pre-treatment biopsies are more likely to respond to neoadjuvant IPI + NIVO with favorable EFS. A rapid gene expression analysis enables the IFN-γ score to be used in daily clinical practice to identify pts who might qualify for treatment escalation or de-escalation. The DONIMI study [NCT04133948] currently investigates different neoadjuvant treatment combinations in stage III melanoma pts based on their intratumoral IFN-γ score. Research Sponsor: None.

EMRseq: Registry-based outcome analysis on 1,000 patients with BRAF V600–mutated metastatic melanoma in Europe treated with either immune checkpoint or BRAF-/MEK inhibition. *First Author: Michael Weichenthal, University Department of Dermatology, Kiel, Germany*

Background: In BRAF mutated metastatic melanoma, potential outcome differences for different choices of 1st line treatments including immunotherapy or BRAF-/MEK inhibition are not completely understood. We therefore analyzed the treatment patterns and outcome of systemic therapies for patients BRAF mutated metastatic melanoma. **Methods:** From the EUMelaReg treatment registry, patients fulfilling the following inclusion criteria were consecutively included until a number of 1,000 evaluable cases was reached. 1) Patients with metastatic melanoma and BRAF V600 mutation 2) First line treatment with either combined BRAF-/MEK or immune checkpoint inhibition (ICI) with PD-1 single agent or combined PD-1/CTLA-4 antibodies. Multivariable cox regression analysis as well as propensity score based weighting were used to control for bias from baseline imbalances. Primary outcomes of interest were overall survival (OS) and 2nd line PFS (PFS-2), stratified for upfront treatment decision of ICI versus targeted therapy. PFS-2 was defined as the interval from start of first line treatment to a progression after a 2nd line treatment or death of any cause. Further endpoints were evaluated including time on treatment (ToT), time to next treatment and 2nd line treatments. **Results:** In total 529 (52.9 %) patients received BRAF/MEK-i, and 471 (47.1%) ICI. For various co-variates there were significant imbalances between strata, including number of metastatic sites, AJCC substage, serum LDH, and ECOG performance status, with more favorable prognostic variables for patients receiving immunotherapy. The ORR for BRAF/MEK-i was significantly higher than for ICI (53.3% vs. 42.0%; p=0.0004), but for OS and PFS2 the adjusted hazard ratios were significantly in favor for ICI (HR 0.62 and 0.66, respectively; p <0.0001). In 2nd line, patients switching from ICI to BRAF/MEK-i had again markedly higher ORR than patients switching vice versa (57.7% vs. 19.9%; P<0.0001), and also significantly longer unadjusted PFS (8.1 vs. 3.1 months; p <0.0001) and OS (15.7 vs. 10.6 mths; p=0.01) after start of 2nd line treatment. **Conclusions:** The two cohorts had imbalances on key prognosis variables. After adjustment for these imbalances, upfront ICI still resulted in significantly longer OS as compared to BRAF/MEK-i. Due to the nature of real-world observational data causing inherent imbalances in the treatments cohorts and being unable to account for potential unknown confounders, outcome may still be biased despite adjustment efforts. Research Sponsor: None.

	1st line Therapy		
	BRAFi+MEKi (N = 529)	ICI (N = 471)	P value
Objective Remissions	282 (53.3%)	198 (42.0%)	0.0004
Median PFS2 [m] (95% CI)*	12.3 (11.3-14.8)	21.9 (17.6-33.0)	< 0.0001
Median OS [m] (95% CI)*	16.9 (15.2-22.3)	45.0 (30.2-NA)	< 0.0001

Meta-analysis of randomized phase II-III trials evaluating triplet combinations of immunotherapy and targeted therapy for BRAF V600-mutant unresectable or metastatic melanoma. *First Author: Pier Francesco Ferrucci, European Institute of Oncology, Milan, Italy*

Background: Immune-checkpoint inhibitors (ICI) and targeted-therapies (TT) have become standard options for BRAF -V600 metastatic melanoma (B-mut MM) patients. However, still more than 50% of those patients do not respond or relapse to these current strategies. Preclinical and translational data suggest that ICI plus TT may improve treatment outcomes in patients with B-mut MM, but with conflicting results in the clinical setting. **Methods:** We performed a systematic review and meta-analysis of randomized phase II-III studies published until January 2022 comparing first-line ICI+TT vs TT alone in B-mut MM. We obtained summary estimates through random-effects models. Overall survival (OS) and progression-free survival (PFS) were the main outcomes retrieved but we look also at difference in responses and adverse events. **Results:** We summarized data from 3 independent trials and we showed a significant advantage in terms of PFS and OS for the experimental arms in B-mut MM patients treated with ICI+TT rather than TT alone. The summary estimate indicates a significant 23% decrease in risk of progression (SHR = 0.77, 95%CI: 0.66-0.89, with no between-study heterogeneity I^2= 0%) and a significant 21% reduction in risk of death (SHR = 0.79, 95%CI: 0.66-0.96, with no heterogeneity I^2= 0%). However, no difference was shown (p-value = 0.56) between arms in terms of summary Objective Response Rate (ORR) estimates (Summary ORR doublet = 65.4% [61.5%; 69.2%] and Summary ORR triplet = 67% [63%; 70.9%], respectively). From the subgroup analysis on PFS risk estimates, no significant differences were observed in summary HRs by age (< 65 vs ≥65 years, p-value = 0.11), sex (female vs male, p-value = 0.58), ECOG PS (0 vs 1, p-value = 0.36), LDH levels (lower vs upper, p-value = 0.59) and PDL1 status (positive vs negative, p-value = 0.89). Significant differences were found in frequencies of grade 3 or more adverse events with higher number of events occurring in B-mut MM vs TT alone (Summary Odd Ratio = 2.01, 95%CI: 1.16-3.47, I^2= 74%), whereas no significant differences were found in terms of any adverse event between arms (SOR = 1.83, 95%CI: 0.70-4.78, I^2= 0%). **Conclusions:** This study supports and extend the discussion on first-line available combinations to be offered to B-mut MM patients. Combining ICI with TT demonstrated an effective advantage on both PFS and OS, although augmenting toxicities. Further biomarker-driven investigation may identify patient subpopulations who could benefit from ICI+TT combinations in order to expand their window of therapeutic opportunities. The prognostic impact of immune-related adverse events in real-world patients with metastatic melanoma treated with single-agent and combination immune checkpoint blockade. *First Author: Alexander Watson, Tom Baker Cancer Centre, University of Calgary, Calgary, AB, Canada*

Background: Immune checkpoint blockade (ICB) has revolutionized the treatment of metastatic melanoma (MM). Immune-related Adverse Events (irAEs) associated with ICB have been shown to correlate positively with survival outcomes across solid tumours. In MM, conclusions on the impact of irAE severity have been conflicting, and combination ICB therapy experience is limited to smaller cohorts. We sought to clarify these relationships using the Alberta Immunotherapy Database (AID). **Methods:** The AID provides a multi-centre, province-wide observational cohort comprising consecutive patients treated with ICB. We included adult patients with MM, treated with ICB (single agent nivolumab or pembrolizumab, or combination ipilimumab and nivolumab) at any line of therapy, agnostic to site of origin, from August 2013 to May 2020, with analysis in December 2021. The primary endpoint of interest was the identification of a relationship between development of irAEs and subsequent overall survival (OS, defined from time of ICB initiation). To minimize immortal time bias from poor prognosis patients who may have died prior to the development of irAEs, patients who died before 12 weeks were excluded from OS and time-to-next-treatment (TTNT) analysis. Adjusted Cox regression analyses were performed to determine the association of variables with OS. **Results:** Of 492 MM patients receiving ICB, 124 received combination ICB, 198 developed an irAE and 67 required hospitalization for an irAE. irAEs were more common in patients < 50 years old (p = 0.02), with ECOG 0 (p < 0.001) and normal albumin (p = 0.002). Median time to irAE development (2.6 months) and frequency of individual irAEs were consistent with the published literature. In the overall population, patients who experienced an irAE had longer median OS (56.3 vs 18.5mo, p < 0.0001), and TTNT (49.6 vs 12.9mo, p < 0.0001). This remained consistent in combination ICB-treated patients (median OS 56.3 vs 19mo, p < 0.0001). Patients hospitalized for an irAE had improved OS and TTNT over patients requiring only outpatient treatment (median OS NR vs 27.9mo, p = 0.0039), while ICB re-challenge after an irAE also improved OS (56.3 vs 31.5mo, p = 0.0093). Development of an irAE retained independent association with OS after adjusted multivariable regression (HR 0.376, p < 0.001). **Conclusions:** These data support the association of irAEs and improved survival outcomes in MM, including those patients treated with combination ICB. Among patients with irAE, hospitalization for irAE, and ICB re-challenge post-irAE, were further associated with improved outcomes. Research Sponsor: None.

Metabolic complete responses (mCR) in patients with metastatic uveal melanoma (mUM) treated with image-guided injection (IGI) of PV-10. *First Author: Krysta McVay, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Traditional CT imaging can underestimate the degree of anti-cancer treatment effect due to reliance on morphological changes of visualized tumors. In contrast, PET imaging offers information on metabolic activity using a positron emitting radiolabeled agent (e.g. FDG) but is less sensitive to changes in tumor size. FDG-PET images acquired, co-registered, and superimposed on CT images (PET-CT) allow spatial detection of anti-cancer activity. Moreoever, FDG-PET-CT can provide information regarding anti-tumor immune responses in patients receiving immunotherapy. Rose bengal (PV-10) is a small molecule autolytic immunotherapy in development for metastatic disease. When administered by intralesional injection, PV-10 can produce immunogenic cell death and a T-cell mediated immune response against treatment-refractory and immunologically-cold tumors. Herein, we report the FDG-PET-CT imaging responses of 7 metastatic uveal melanoma (mUM) patients who received percutaneous image-guided injection (IGI) of PV-10 into hepatic tumors. **Methods:** The Phase 1 study is evaluating safety, tolerability, and efficacy of intralesional PV-10 in hepatic tumors. PV-10 is administered percutaneously via IGI into designated tumors ≤4.9 cm in diameter. Response is assessed at Day 28, then every 3 months, using CT/MRI or PET-CT. Patients with multiple tumors may receive further IGI of PV-10 after Day 28. **Results:** To date, 25 mUM patients with liver metastases have been treated; 16 patients received standard of care immune checkpoint inhibitor (ICI) during or post PV-10 treatment. Seven subjects had FDG-PET-CT imaging during the study (baseline 1, follow-up 6). Two follow-up FDG-PET-CTs were performed 1 and 3 years after PV-10 injection with intervening ICI, and another was 1.5 years after PV-10, without any follow-on treatment. Four patients experienced mCR in all metastatic sites, including extrahepatic metastasis. **Conclusions:** FDG-PET-CT shows that PV-10 is capable of inducing mCR in injected (adscopal) and non-injected (abscopal) lesions. This pattern of response is suggestive of immunogenic cell death in mUM patients with liver metastases. Clinical trial information: NCT00986661. Research Sponsor: Provectus Biopharmaceuticals.

Better (a little) late than never: The impact of steroidal treatment initiation timing on the outcome of patients with melanoma treated with immunotherapy. *First Author: Nethanel Asher, The Ella Lemelbaum Institute for Immuno-Oncology at Sheba Medical Center, Ramat Gan, Israel*

Background: The immune-system manipulation by immune-checkpoint inhibitors (ICI) has led to unprecedented clinical advances in melanoma. The management of the consequent immune-related adverse events (irAEs) is based mostly on steroids and other immune-modulators. **Methods:** A real world single-site cohort of metastatic melanoma patients who were treated with immunotherapy as first line between 2014 and 2020. This study explores the effect of dose, timing, and duration of steroid exposure on treatment efficacy. **Results:** Four hundred and forty patients were treated with either anti PD-1 (n = 285, 65%) or combination of anti PD-1 and ipilimumab ICI (n = 112, 25%), or ipilimumab alone (n = 43, 10%). The median age was 68 years [12-99y], and 57% were male. Any-grade irAEs were seen in 71% of the patients, and 49% were exposed to steroids. The median steroid dose was 0.75mg/kg prednisolone equivalent [0.03- 80mg/kg], the median duration of steroidal treatment was 11.2 weeks [0.1-316w] and the median time to onset of steroids was 7.6 weeks [0-193w]. Both experiencing irAEs, and the associated steroid exposure were associated with a significant progression free survival (PFS) benefit [HR 0.47, p < 0.001; 95%CI 0.39-0.6 and HR 0.77, p = 0.026; 95%CI 0.60-0.97, respectively], regardless of dose and duration. Notably, within those who were exposed to steroids, an earlier onset of < 4 weeks from immunotherapy initiation was significantly associated with a shorter PFS [HR = 3.5, p < 0.001 (95%CI 2.32-5.45)]. This observation resulted significant also on multivariable analysis including other prognostic variables – ECOG PS, M-stage, LDH and protocol. **Conclusions:** Steroidal treatment during the immunotherapy priming phase (first 4 weeks) might have a deleterious effect on its' efficacy and should be explored in larger prospective cohorts. Research Sponsor: None.

Glycoproteomics as a powerful liquid biopsy-based predictor of checkpoint inhibitor treatment benefit in metastatic malignant melanoma. *First Author: Klaus Lindpaintner, InterVenn, South San Francisco, CA*

Background: Protein glycosylation is the most abundant and complex form of post-translational protein modification. Glycosylation profoundly affects protein structure, conformation, and function. The elucidation of the potential role of differential protein glycosylation as biomarkers has so far been limited by the technical complexity of generating and interpreting this information. We have recently established a novel, powerful platform that combines liquid chromatography/mass spectrometry with a proprietary artificial-intelligence-based data processing engine that allows, for the first time highly scalable interrogation of the glycoproteome. **Methods:** Using this platform, we interrogated 526 glycopeptide (GP) signatures derived from 75 serum proteins in pretreatment blood samples from a cohort of 205 individuals (66 females, 139 males, age range 24 to 97 years) with metastatic malignant melanoma treated either with nivolumab plus ipilimumab (95 patients) or pembrolizumab (110 patients) immune-checkpoint inhibitor (ICI) therapy. **Results:** In an optimized assay containing 27 glycopeptides and 20 non-glycosylated peptides, we identified 14 GPs with abundance differences at FDR q≤0.05 with regard to PFS. Using 40% of the cohort as a training set and selecting 12 glycopeptide and non-glycosylated peptide biomarker features of the 47 total by LASSO shrinkage, we created a multivariable-model-based classifier for PFS that yielded a hazard ratio (HR) for prediction of likely ICI benefit of 7.5 at $p < 0.0001$. This classifier was validated in the test set comprised of the held-out 60% of patients, yielding a HR of 4.7 at a similar p-value for separating patients likely benefiting from ICI therapy and those likely not benefiting from ICI therapy (50% PFS of 18 months vs. 3 months based on classifier score above/below cutoff). This classifier has a sensitivity of > 99% to predict likely ICI benefit, while still performing at a specificity of 26%, thus helping to safely reduce ultimately unnecessary and non-beneficial exposure to these agents of one in four who otherwise would unnecessarily be exposed to them. **Conclusions:** Our results indicate that glycoproteomics holds a strong promise as a predictor for checkpoint inhibitor treatment benefit that appears to significantly outperform other currently pursued biomarker approaches in this context. Research Sponsor: None.

Management of checkpoint inhibitor toxicity and survival in patients with advanced melanoma. *First Author: Olivier Jules van Not, University Medical Center Utrecht, Leiden, Netherlands*

Background: Management of checkpoint-inhibitor-induced immune-related adverse events (irAEs) is primarily based on expert opinion. Recent studies have suggested detrimental effects of immunosuppressive treatment with anti-TNF on checkpoint-inhibitor efficacy. **Methods:** Advanced melanoma patients experiencing grade ≥3 irAEs after treatment with first-line ipilimumab-nivolumab between 2015 and 2021 were included from the Dutch Melanoma Treatment Registry. Progression-free survival (PFS), overall survival (OS) and melanoma-specific survival (MSS) were analyzed according to toxicity management regimen. A cox proportional hazards model was used to account for the confounders age, sex, performance status, lactate dehydrogenase, site of metastases and type of irAE. **Results:** Out of 771 ipilimumab-nivolumab treated patients, 350 were treated with immunosuppression for severe irAEs. Of these patients, 235 received steroids only and 115 received steroids with second-line immunosuppressants consisting of anti-TNF, mycophenolic acid, tacrolimus and other immunosuppressants. Median PFS was significantly longer for patients treated with steroids (11.3 months) than for patients treated with steroids and second-line immunosuppressants (5.4 months; HR 1.43; 95%CI 1.07-1.90; p = 0.01). Median OS was also significantly longer for the steroids group (46.1 months) than for the steroids and second-line immunosuppressants group (22.5 months; HR 1.64; 95%CI 1.16-2.32; p = 0.005). Results for MSS were similar (not reached versus 28.8 months; HR 1.70; 95%CI 1.16-2.49; p = 0.006). Median PFS, OS and MSS are shown in Table 1. After adjustment for potential confounders, patients treated with steroids + second-line immunosuppressants showed a non-significant trend towards a higher risk of progression (HR_{adj} 1.40; 95%CI 1.00-1.97; p = 0.05), a higher risk of death (HR_{adj} 1.54; 95%CI 1.03-2.30; p = 0.04) and of melanoma-specific death (HR_{adj} 1.62; 95%CI 1.04-2.51; p = 0.032) compared to the steroids group. **Conclusions:** Second-line immunosuppression for irAEs is associated with impaired PFS, OS, and MSS in advanced melanoma patients treated with first-line ipilimumab-nivolumab, irrespective of being anti-TNF or other second-line immunosuppressants. These findings stress the importance of assessing the effects of differential irAE management strategies, not only in melanoma but also in other tumor types. Research Sponsor: The Netherlands Organization for Health Research and Development (ZonMW, project number 836002002).

Overall survival (OS) with first-line atezolizumab (A) or placebo (P) in combination with vemurafenib (V) and cobimetinib (C) in *BRAF*^{V600} mutation-positive advanced melanoma: Second interim OS analysis of the phase 3 IMspire150 study. *First Author: Grant A. McArthur, Melanoma and Skin Service and Cancer Biology and Therapeutics Program, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Primary analysis of the phase 3 IMspire150 study (NCT02908672) demonstrated improved investigator-assessed progression-free survival (PFS) with first-line A + V + C vs P + V + C in patients (pts) with *BRAF*^{V600} mutation–positive advanced melanoma (hazard ratio [HR] 0.78; 95% CI, 0.63-0.97; *P*= 0.025). With median follow-up of 18.9 months at primary analysis, OS data were immature; interim analysis of OS at the time of the primary analysis demonstrated a trend in favor of A + V + C over P + V + C (estimated 2-year OS rate, 60.4% vs 53.1%) (Gutzmer et al. *Lancet* 2020;395:1835-1844). Herein, we present results from the second interim OS analysis of the IMspire150 study. **Methods:** IMspire150 enrolled previously untreated pts with stage IV or unresectable stage IIIc *BRAF*^{V600} mutation-positive melanoma (n = 514). Pts were randomized 1:1 to receive 28-day cycles of A + V + C (n = 256) or P + V + C (n = 258). Pts received V + C in cycle 1; A or P was added on days 1 and 15 from cycle 2 onwards. The second interim OS analysis was planned after ~270 OS events were recorded, and was projected to have a minimally detectable difference of HR of 0.74 with a *P* value boundary of 0.0140. OS was estimated using the Kaplan-Meier method. **Results:** At data cutoff (Sept 8, 2021), 273 OS events had occurred. Median follow-up was 29.1 months (range, 1-54) for A + V + C and 22.8 months (range, 0-54) for P + V + C. A continued trend toward OS benefit in favor of A + V + C over P + V + C was observed with median OS of 39.0 vs 25.8 months, but the difference did not reach statistical significance (HR, 0.84; 95% CI, 0.66-1.06; *P*= 0.1432). A delayed treatment effect was observed, with landmark OS rates for A + V + C vs P + V + C of 76.1% vs 76.5% at 12 months and 61.5% vs 53.3% at 24 months. With additional follow-up, A + V + C continued to show PFS benefit over P + V + C (HR, 0.79; 95% CI, 0.64-0.97; *P*= 0.0224); overall response rates (66.7% vs 65.0%) and median duration of response (21.0 vs 12.6 months) remained consistent with those reported at primary analysis. No new safety signals were observed with additional follow-up. **Conclusions:** With further follow-up, A + V + C demonstrated a consistent, but not statistically significant, improvement in OS and continued benefit in duration of response versus P + V + C in previously untreated pts with *BRAF*^{V600} mutation–positive advanced melanoma. Clinical trial information: NCT02908672. Research Sponsor: This study and medical writing and editorial support for this abstract was funded by F. Hoffmann-La Roche Ltd.

Efficacy and safety of sequencing with vemurafenib (V) plus cobimetinib (C) followed by atezolizumab (Atezo) in patients (pts) with advanced *BRAF*^{V600}-positive melanoma: Interim analysis of the ImmunoCobiVem study. *First Author: Dirk Schadendorf, Department of Dermatology, University Hospital Essen, Essen, Germany*

Background: Immunotherapies (ICI) and targeted therapies (TT) have improved PFS and OS in *BRAF*^{V600}-mutated advanced melanoma pts, but evidence regarding their optimal sequence is limited. The randomized phase 2 ImmunoCobiVem study evaluated efficacy and safety of an early switch to Atezo after initial treatment with V + C. Interim results are reported. **Methods:** Pts with previously untreated *BRAF*^{V600}-mutated advanced melanoma received a 3-mo run-in with V (960 mg twice daily) + C (60 mg once daily for 21/28 days). Pts without PD/treatment interruption due to AEs during run-in were then randomized 1:1 to continue V + C (Arm A) or switch to Atezo (1200 mg every 3 wks; Arm B) until first documented PD (PD1), followed by crossover to the alternate treatment until second documented PD (PD2). End points were PFS1 (time from start of run-in until PD1 or death from any cause), PFS2 (time from start of run-in until PD2 or death from any cause), PFS3 (time from PD1 until PD2 or death from any cause), DCR, ORR, OS, and safety. **Results:** 185 pts were enrolled between Nov 2016 and Dec 2019 (63% male; median age 58 y); 135 pts completed run-in and were randomized to Arm A (n=69) or Arm B (n=66). At data cutoff, median follow-up for all pts was 19.0 mo. In Arm A, 36/69 pts (52%) discontinued V + C due to PD and 21/36 (58%) crossed over to Atezo; in Arm B, 49/66 pts (74%) discontinued Atezo due to PD and 35/49 (71%) crossed over to V + C. Median PFS1 was significantly longer in Arm A vs Arm B (HR 0.55; 95% CI 0.37–0.84; *P*=0.001), while median PFS3 was significantly shorter in Arm A vs Arm B (HR 2.24; 95% CI 1.17–4.30; *P*=0.013); median PFS2 was not significantly different between arms (HR 1.57; 95% CI 0.83–2.96; *P*=0.163) (Table). During the randomized phase, ORR and DCR were higher in Arm A before crossover and in Arm B after crossover (Table). OS was similar between arms (HR 1.22; 95% CI 0.69–2.16; *P*=0.389). Median (range) treatment duration across treatment phases was 11.2 mo (2.3–56.1) for Arm A and 10.7 mo (2.8–56.7) for Arm B. Grade 3/4 AEs occurred in 55% of pts in Arm A and 64% in Arm B; AEs led to discontinuation in 10% and 12%, respectively. **Conclusions:** Early switch from V + C to Atezo is feasible and safe, but tumor control achieved in run-in is maintained in only a subset of pts on subsequent ICI monotherapy. Crossover to ICI monotherapy at PD results in low response, while response to TT re-exposure is frequent. Clinical trial information: NCT02902029. Research Sponsor: This study and medical writing and editorial support for this abstract was funded by F. Hoffmann-La Roche Ltd.

Merkel polyoma virus specific T-cell receptor transgenic T-cell therapy in PD-1 inhibitor refractory Merkel cell carcinoma. *First Author: Joshua Veatch, Hutchinson Cancer Rsrch Ctr, Seattle, WA*

Background: Merkel cell carcinoma is an aggressive neuroendocrine tumor of skin origin with most cases caused by the Merkel polyoma virus (MCPyV). While many patients benefit from PD-1/PD-L1 axis blockade, most patients do not respond or develop resistance. We sought to ask whether adoptive transfer of autologous T cells transduced with MCPyV specific T cells could lead to clinical responses in PD-1 inhibitor refractory patients. **Methods:** Five MCPyV positive, HLA-A02 patients with PD-1 inhibitor refractory metastatic Merkel cell carcinoma were treated with adoptive transfer of CD62L+ CD8+ and CD4+ autologous T cells transduced with a T cell receptor (TCR) targeting an HLA-A0201 restricted MCPyV epitope. Two different strategies were used to facilitate T cell expansion: In 3 patients, single fraction radiation was administered to a subset of lesions prior to T cell transfer. In 2 patients, lymphodepleting chemotherapy with cyclophosphamide and fludarabine was administered prior to T cell transfer. Anti PD-1/PD-L1 therapy was given 14 days after T cell infusion. Transgenic T cells were visualized in tumor biopsies by multiplex immunohistochemistry. **Results:** 5 patients were treated, with 4 patients receiving 100 million tetramer positive CD8+ T cells and one patient receiving 500 million cells. 3 patients received second infusions with between 300 million and 900 million tetramer positive cells. No dose limiting toxicities or cytokine release syndrome were observed. T cell persistence was lower in the 2 patients treated with lymphodepleting chemotherapy relative to the 3 patients treated with single fraction radiation. Transgenic T cells persisted at tumor sites greater than 1 month following transfer. 4 patients experienced progressive disease, and a single patient had a mixed response and greater than 1 year disease free interval following local therapy of an isolated site of progression. The responding patient was the only patient with class I MHC staining on tumor cells prior to treatment, and the site of local progression in that patient showed the presence of TCR transgenic T cells but loss of class I MHC expression. **Conclusions:** MCPyV specific transgenic T cells are safe, traffic to tumor sites, and can result in a clinical response, but their clinical activity may be limited by down-regulation of class I MHC expression on tumors. A future trial will address strategies to increase class I MHC expression on Merkel tumors. Clinical trial information: NCT03747484. Research Sponsor: Bluebird, Other Government Agency.

Camrelizumab plus apatinib for patients with advanced mucosal melanoma: A prospective single-arm study. *First Author: Zhengyun Zou, Nanjing Drum Tower Hospital, Nanjing, China*

Background: Mucosal melanoma is a rare subtype in white populations, but the second most common subtype in Asian populations. This subtype is a more aggressive malignancy, with high risk of metastasis and death. Immune checkpoint inhibitor combined with anti-angiogenic agent has been investigated in many solid tumors, including some preliminary evidence (NCT03086174 and NCT04091217) in Chinese patients with advanced mucosal melanoma. This study investigated the efficacy and safety of camrelizumab plus apatinib in patients with advanced mucosal melanoma. **Methods:** In this prospective, single-arm study (ChiCTR1900023277), patients with inoperable stage III-IV or recurrent/metastatic mucosal melanoma and Eastern Cooperative Oncology Group performance status of 0-1 were enrolled. Patients received camrelizumab 200 mg once every 2 weeks and apatinib 500 mg once daily until disease progression or intolerable toxicity. The primary endpoint was objective response rate (ORR) according to the Response Evaluation Criteria In Solid Tumors, version 1.1. **Results:** Between April 2019 and January 2022, a total of 30 patients were enrolled (Table). As of January 2022, 21 patients had at least one efficacy assessment, and the median follow-up duration was 8.1 months. The ORR was 42.9%, including one (4.8%) patient with confirmed complete response, six (28.6%) with confirmed partial response (PR), and two (9.5%) with unconfirmed PR. The disease control rate (DCR) was 81.0%. The median progression-free survival was 7.2 months (95%CI, 5.8-not reached [NR]) in 21 patients, 7.7 months (95%CI, 5.8-NR) in 19 patients with first-line camrelizumab plus apatinib treatment, and 9.8 months (95%CI, 4.2-NR) in 11 patients without prior chemotherapy. The most common treatment-related adverse events in 27 patients with available safety data were fatigue (17 [63.0%]), hypertension (15 [55.6%]), and elevated transaminase (14 [51.9%]). No treatment-related deaths occurred. Exploratory analysis found a tendency that patients with high T cell receptor diversity had better prognosis. Higher frequencies of Vβ-Jβ (including Vβ5-8Jβ2-7, Vβ28J2-4 and Vβ12-5Jβ1-1) indicate better survival, and Vβ12-5Jβ1-1 is an independent factor after multivariate adjustment. **Conclusions:** Camrelizumab plus apatinib showed favorable ORR and DCR in patients with advanced mucosal melanoma, with an acceptable safety profile. Follow-up for survival outcomes is ongoing. Clinical trial information: ChiCTR1900023277. Research Sponsor: National Natural Science Foundation of China (No. 81872484 and 82073365), Other Foundation.

Characteristics	Patients (n = 30)
Age (years), median (range)	62 (35-77)
Sex (male/female)	13/17
Current therapy line (1/≥2)	27/3
Prior chemotherapy (perioperative therapy/for advanced disease/no)	12/3/15
Primary site (head and neck/esophagus/vagina and cervix/rectum)	16/2/7/5
Metastatic site (liver/lung/lymph node)	7/11/12
Lactate dehydrogenase level (≤upper limit of normal/ > upper limit of normal)	20/10

Analysis of overall survival (OS) and relapse-free-survival (RFS) in the phase 1b clinical trial of anti–PD-1 ab (toripalimab) plus intralesional injection of OrienX010 in stage IV **melanoma with liver metastases.** *First Author: Chuanliang Cui, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Advanced melanoma with liver metastasis has reduced response to anti-PD-1 monotherapy with ORR of 4.3% in a pooled analysis, and initial results of the phase 1b trial, systemic toripalimab combined with intrahepatic OrienX010 injection - a HSV-1-derived oncolytic virotherapy with expression of GM-CSF had shown its efficacy. Here we report the RFS and OS outcomes. **Methods:** Eligible pts included those over 18 with injectable liver metastasis confirmed by biopsy with or without extra-hepatic metastasis; the ocular melanoma and brain metastasis were excluded. Pts received intravenous toripalimab Q2W combined with ultrasound guided intratumoral injection of OrienX010 Q2W (8×10^7 pfu/ml, 10ml per injection) until intolerance or disease progression per iRECIST criteria. Liver biopsy would be performed at baseline and first tumor evaluation (8-12weeks). The primary endpoint was toxicity; secondary endpoints included ORR, DCR and PFS. **Results:** From Jul 2019 to Jan 2022, 23 pts were eligible and enrolled. Baseline characteristics: median age 69 yrs; primary: mucosal 60.9%, cutaneous 13.0%, unknown primary 13.0%, acral 13.0%; gene mutation status: Braf 17.4%, Nras 4.3%; 69.6% got extra-hepatic metastasis: regional or distant lymph node 56.3%, lung 37.5%, bone 31.3%; LDH > ULN 26.1%; median size of injected lesions: 35mm(10-94mm); median number of liver metastasis: 7(1-10); median number of injection: 10 (3-36). Among these pts, 20 pts could be evaluated for efficacy. The median PFS was 7.0 months (95%CI: 4.3-9.7 months) and the median OS was 18.6 months (95%CI: 13.4-23.7 months) with a median follow-up time of 19.8 months (range, 0.9-29.7). The global ORR by investigator was 15% (3/20), DCR 50% (10/20); the response rate was 35%(7/20) for injected lesions, 27.8%(5/18) for non-injected lesions in liver, and 26.7% (4/15) for extra-hepatic metastases. Biopsies of 15 pts for injected lesions at 8 to 12 weeks after first injection were examined to determine the situation of TIL infiltration. Among them, the median PFS of the pts (7/15) with impressive TIL infiltration (Brisk n = 4 and Nonbrisk n = 3 according to the definition of AJCC 8th edition) was 7.8 months (95%CI: 2.8-12.8 months) versus 4.1 months (95%CI: 0-9.1 months) of the pts without impressive TIL infiltration. For pts (21.7%(2 PR and 3 SD)) with no melanoma cells residual by immunohistochemistry in biopsies the median PFS was 13.8 months (95%CI: 4.0-23.6 months), and it was much longer than that of other pts which was 5.6 months (95%CI: 2.4-8.8 months). The median OS of the pts with no melanoma cells was 19.7 months (95%CI: 7.5-31.9 months). **Conclusions:** Systemic toripalimab combined with intrahepatic OrienX010 injection has shown remarkable long PFS and OS in melanoma pts with liver metastases. Clinical trial information: NCT04206358. Research Sponsor: None.

IMPemBra, a phase 2 study comparing pembrolizumab with intermittent/short-term dual MAPK pathway inhibition plus pembrolizumab in patients with melanoma harboring the BRAFV600 mutation: Three-year survival data and translational analyses. *First Author: Elisa A. Rozeman, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Continuous combination of MAPK pathway inhibition (MAPKi) and anti-PD-(L)1 showed high response rates, but also high frequency of treatment-related adverse events (TRAE) in BRAFV600-mutated melanoma patients (pts). Short-time MAPKi already induces T cell infiltration in pts and was synergistic with anti-PD-1 in a pre-clinical model. This phase 2b trial aimed to identify the optimal duration of MAPKi with dabrafenib + trametinib (D+T) in combination with pembrolizumab (PEM). We have previously shown that no SUSARs were observed, toxicity was related to duration of D+T, and response rates increased after addition of D+T. Here we present 3-year PFS and OS data and results of translational analyses. **Methods:** In IMPemBra, pts with treatment-naïve BRAFV600E/K mutant advanced melanoma started with PEM 200mg Q3W. After 2 cycles, pts were randomized to continue PEM only (cohort 1) or to receive in addition intermittent dabrafenib 150 mg BID + trametinib 2mg QD for 2 x 1 week (cohort 2), 2 x 2 weeks (cohort 3) or continuous for 6 weeks (cohort 4). All cohorts continued PEM for up to 2 years. Primary endpoints were safety, treatment adherence and immune-activating capacity of the different regimens. Secondary endpoints were objective response rate (ORR) and PFS, OS was an exploratory endpoint. For survival analyses, pts that received D+T (cohort 2-4) were pooled. **Results:** Thirty-two pts were randomized, 56% were male, 53% had M1c disease and 88% had a LDH level < ULN. No new grade 3-4 TRAE were observed; frequencies were 12%, 12%, 50% and 62% for pts in cohort 1, 2, 3 and 4, respectively. ORRs were 75% in cohort 1 and 2, and 88% in cohort 3 and 4. The frequency of $PD1^+CD8^+$ T cells in peripheral blood decreased slightly during treatment and there were no differences between cohorts. In cohort 1 and 2, an increase in IFNγ signature in tumor biopsies was already observed after 6 weeks of PEM, in cohort 3-4 an increase in IFNγ signature was observed in week 9, after addition of D+T. The same pattern was observed for $CD8^+$ T cell infiltration and PD-L1 expression. After a median follow-up of 43.5 months, the median PFS of pts treated with PEM monotherapy was 10.6 months versus 32.3 months for pts treated with PEM plus D+T ($p = 0.19$). The 3-year PFS rates were 25.0% and 50.0% respectively. Median OS was 40.5 months in the PEM pts and not reached for pts treated with PEM plus D+T ($p = 0.32$); 3-year OS rates were 62.5% and 70.8% respectively. **Conclusions:** IMPemBra demonstrated that short-term addition of intermittent D+T to PEM seems a more feasible, tolerable and an effective alternative for the continuous triple combination. In addition, it gives the opportunity to treat with second line targeted therapy after disease progression. Therefore, this regimen should be considered for further investigation in a larger cohort. Clinical trial information: NCT02625337. Research Sponsor: MSD.

Updated results from the skin cancer cohorts from an ongoing phase 1/2 multicohort study of RP1, an enhanced potency oncolytic HSV, combined with nivolumab (IGNYTE). *First Author: Mohammed M. Milhem, University of Iowa, Iowa City, IA*

Background: RP1 is an enhanced potency oncolytic version of HSV1 that expresses human GM-CSF and the fusogenic protein GALV-GP R-. IGNYTE is a multicohort phase 1/2 study that evaluates the safety and efficacy of RP1 in combination with nivo (NCT03767348) in a range of tumor types. Preliminary data demonstrated a durable anti-tumor activity and tolerability for RP1+nivo. Here, we present updated results from the initial and melanoma (mel) and anti-PD1 naïve non-melanoma skin cancer (NMSC) cohorts with RP1+nivo. **Methods:** RP1 is administered via intratumoral injection Q2W, up to 10 mL/visit, first alone at a dose of 10^6 PFU/mL and then starting with the 2nd dose at 10^7 PFU/mL in combination with nivo (240 mg IV Q2W for 4 months (mos) then 480 mg IV Q4W up to 2 yrs) for up to 8 doses, with the option to re-initiate RP-1. Eligible patients (pts) must have at least one measurable & injectable tumor of ≥ 1 cm, ECOG 0-1, and no prior oncolytic therapy. For mel, both anti-PD1 naïve and failed pts were eligible, for NMSC pts who were anti-PD1 naïve. **Results:** As of data extraction on January 31, 2022, 13/36 pts with mel (36.1%) and 19/31 pts with NMSC (61.3%) had a best response of PR or CR. For mel this was 5/8 (62.5%), 6/16 (37.5%), 0/6 and 2/6 (33.3%) for pts with anti-PD1 naïve cutaneous, anti-PD1/anti-PD1+anti-CTLA-4 failed cutaneous, uveal and mucosal mel respectively. For the anti-PD1 naïve NMSC this included 11/17 (64.7%), 1/4 (25%), 3/4 (75%) and 4/6 (66.6%) patients with CSCC, BCC, MCC and angiosarcoma respectively, including 8/17 (47.1%) being CR for CSCC. Current immature median DOR was 13.27 mos (current range 3.67-16.93 mos) for mel, and 7.32 mos (current range 1.88-23.11mos) for anti-PD1 naïve NMSC. Any grade TEAE (> 25%) in all cohorts combined were fatigue, nausea, pyrexia, chills, diarrhoea, pruritus, and influenza-like illness. TEAE ≥grade 3 (> 5%) were disease progression and fatigue. No deaths related to RP1 was observed, with one death related to nivo (myocarditis). Biomarker data from paired biopsies indicated robust T cell infiltration and an increase in tumor inflammation gene signature post-treatment. Clinical responses observed were independent of baseline tumor PD-L1 expression status. **Conclusions:** RP1 in combination with nivo provides a durable anti-tumor activity in pts with skin cancers, including anti-PD1 failed and anti-PD1/anti-CTLA-4 failed mel. The combination continued to be generally well tolerated with no new safety signals identified. Based on this data, enrollment into both a registration-directed cohort of pts who have anti-PD1 failed cutaneous mel (n = 125) and a cohort of pts with anti-PD1 failed NMSC (n = 30) is ongoing. Up-to-date data from this ongoing trial will be reported at the conference. A randomized Ph2 trial of RP1+cemiplimab vs. cemiplimab alone in anti-PD1 naïve NMSC is also underway (NCT04050436). Clinical trial information: NCT03767348. Research Sponsor: Replimune Group Inc.

9554 **Poster Session**

A phase II study to evaluate the safety and efficacy of IMM-101 in combination with checkpoint inhibitors in patients with advanced melanoma: Final results of the IMM-101-015 trial. *First Author: Alberto Fusi, St. George's University Hospitals NHS Foundation Trust, St. George's University of London, London, United Kingdom*

Background: IMM-101 is a suspension of heat-killed whole cell *Mycobacterium obuense* (NCTC 13365), which enhances the innate immune response and dendritic cell maturation. In animal models, it increases antigen specific responses and number of CD8+ CTL and CD4 + Th1 cells. The clinical studies with IMM-101 have shown promising efficacy signals in pancreatic cancer when combined with gemcitabine and in melanoma as adjunctive or single agent. **Methods:** IMM-101-015 is an open-label Phase 2a study to investigate the safety and efficacy of IMM-101 in combination with checkpoint inhibitors (CPIs) in patients (pts) with advanced melanoma who were either treatment-naive (cohort A), or whose disease had progressed during PD-1 blockade (cohort B). Pts with evaluable lesions, adequate performance status and organ function were eligible. Pts received 1.0 mg of IMM-101 every 2 weeks for the first 3 doses followed by a rest period of 4 weeks, then every 2 weeks for the next 3 doses, and thereafter every 4 weeks. Nivolumab was given every 2 or 4 weeks (dependent on Investigator choice). Pts in cohort B had the option to change to ipilimumab and IMM-101 if their disease continued to progress. Biopsies and blood samples were obtained at baseline and during treatment for assessment of tumor biomarkers and immune correlatives. The primary objectives of the study were to evaluate the overall response rate (ORR) after a maximum of 18 months of treatment by RECIST 1.1 and to assess the safety and tolerability of the combination of IMM-101 + CPIs. **Results:** Sixteen pts (11 Cohort A and 5 Cohort B) were treated between October 2018 and May 2021. The median age was 68.5 yrs (range 36-92) and 11 (69%) were male. The ECOG ps was 0 in 9 (56%) and 1 in 7 (44%) pts. Four (25%) had unresectable stage III melanoma and 12 (75%) stage IV. In Cohort A (3 stage III, 5 stage IV M1b and 3 M1c) 3 pts (27%) had an elevated baseline LDH, 6 (55%) a positive PD-L1 status and 3 (27%) a BRAF mutation. Pts in cohort A were on study for a median time of 8.5 months (range 1.5 - 19.1) and those in cohort B for 3.0 months (range 1.5 - 7.4). All pts were evaluated for response. The ORR was 73% (95% CI 39.03, 93.98) in cohort A whereas all pts in cohort B reported progressive disease. With respect to cohort A, 2 (18%) pts had CR, 6 (55%) PR and 1 (9%) SD. The median progression-free survival time was 10.2 months (95% CI 2.50, NE) with 41% of the pts progression-free at 18 months. The most frequent treatment emergent adverse events (TEAEs) were injection site reaction (63%), pruritus (44%), fatigue (38%), skin rash (25%), hypothyroidism (25%) and diarrhoea (19%). There were no grade 4 TEAEs. Grade 3 TEAEs occured in 10 patients (63%), mostly skin toxicity (19%) and lab abnormalities (13%). **Conclusions:** IMM-101 in combination with nivolumab is safe and shows encouraging antitumor activity in treatment-naive patients with advanced melanoma. Clinical trial information: NCT03711188. Research Sponsor: Immodulon Therapeutics Ltd.

Clinical predictors of longer survival in patients with BRAF^{V600}-mutated metastatic melanoma receiving immunotherapy prior to BRAF/MEK inhibition in the metastatic setting. *First Author: Adriana Matutino Kahn, Yale School of Medicine, New Haven, CT*

Background: Patients with advanced BRAF^{V600}-mutated melanoma are typically treated with immunotherapy in the first-line setting, followed by BRAF/MEKi upon disease progression based on an absolute 20% improvement in 2-year overall survival over initial treatment with BRAF/MEKi in the DREAMseq trial. Our goal was to identify clinical predictors of longer survival for patients treated in our institution with this approach. **Methods:** We identified 40 patients with BRAF^{V600}-mutated metastatic melanoma treated at our institution from 2011 to 2020 with immunotherapy followed by BRAF/MEKi upon progression. Clinical data were collected and analyzed by Cox regression and Kaplan-Meier methods. Favorable outcome was defined as survival > 2 years (y) after starting BRAF/MEKis. **Results:** Median follow up was 33 months (m, 3 – 172 m). Median age was 54 y (20 - 83). Most patients were female (n = 24, %). Most patients were initially treated with ipilimumab plus nivolumab (n = 34, 85%), with 13 of these patients (38%) tolerating all 4 cycles of initial ipilimumab. Adverse events of any grade were seen in 28 (70%) patients after first-line immunotherapy, with the most common being hepatitis, colitis, hypothyroidism, rash, and fatigue. Median duration of first-line immunotherapy was 3.5 m (.75 - 42.5 m). Most common sites of progression on immunotherapy were lymph nodes (n = 14, 35%), liver (n = 12, 30%), bone (n = 10, 25%) and brain (n = 10, 25%). Prior to BRAF/MEKis, median ECOG-PS was 1 (0-4) and median LDH was 268 mg/dL (151 - 11,300). Most common BRAF/MEKi regimen was dabrafenib plus trametinib (n = 34, 85%). Adverse events of any grade were seen in 30 (75%) patients, with the most common being fever, fatigue, nausea, and vomiting. Best response to BRAF/MEKi was CR (n = 4, 10%), PR (n = 26, 65%), SD (n = 4, 10%) and PD (n = 6, 15%), and at the data cutoff, 35 (87.5%) patients progressed on BRAF/MEKi. Median duration of BRAF/MEK inhibition was 7 m (0.5 – 106 m). Median survival since starting BRAF/MEKi was 19.2 m (1.7 – 106 m). On multivariable analyses assessing predictors of survival, presence of bone metastases after disease progression on first-line immunotherapy was associated with worse 2-year survival after initiation of BRAF/MEKi (OR 2.5, 95% CI, 0.51-5.6, p = 0.0121). Other factors, such as ECOG-PS 0-2, normal LDH prior to BRAF/MEKi, and age at metastatic diagnosis < 60 years were not significantly associated with longer survival after initiation of BRAF/MEKi. **Conclusions:** We showed that the presence of bone metastases upon progression on first-line immunotherapy was associated with worse 2-y survival on salvage BRAF/MEKi for patients with BRAF^{V600}-mutated metastatic melanoma. Predictive and prognostic biomarkers for long-term response to both immunotherapy and BRAF/MEKi are needed to optimize treatment strategies and patient outcomes. Research Sponsor: None.

Efficacy and tolerance of systemic therapies in metastatic melanoma of unknown primary versus known cutaneous: A multicenter retrospective study from the MelBase French Cohort. *First Author: Perrine Rousset, CHU de Nice, Nice, France*

Background: Melanoma of unknown primary (MUP) account for 3% of all melanomas. Clinical outcome of advanced MUP in the era of novel therapies including immunotherapies (ICI) and targeted therapies (TT) have been only scarcely studied, whereas a possibly different biologic background might introduce changes in its management. Recent retrospective studies suggested that patients with advanced MUP could benefit at least as much from novel therapies as patients with known primary cutaneous melanoma (cMKP). **Methods:** Based on the nationwide MelBase prospective database (NCT02828202) this retrospective study included patients with advanced melanoma treated with first-line ICI, TT or CT. MUP was defined by upfront occurrence of (sub)cutaneous, nodal and/or visceral metastasis without any known prior or concomitant primary tumor. Patients with primary mucosal or ocular melanoma were excluded. Both progression-free survival (PFS) and overall survival (OS) were analyzed as co-primary variables in MUP vs cMKP, stratified by treatment subset (ICI vs TT vs CT vs whole cohort). Secondary variable was treatment-related toxicity. Multivariate analyses and propensity score analysis were performed. Objective: To investigate the efficacy and safety of systemic treatments (ICI, TT and chemotherapy (CT)) in patients with advanced MUP comparatively to stage-matched cMKP. **Results:** A total of 1882 patients were analyzed, including 265 (14.1%) MUP. Most patients were treated with first-line ICI. Median follow-up was 16 months. Patients in the MUP cohort more often displayed unfavorable initial prognostic factors (Table). PFS and OS did not significantly differ in MUP compared to MKP patients (p=0.73 and p=0.93 respectively). Stratification of cohorts by treatment type and application of propensity score did not lead to data modification. Treatment-related toxicity rate and severity did not differ between MUP and MKP, regardless of treatment type. **Conclusions:** Our results suggest that advanced MUP should be managed with similar strategies as advanced MKP. In our cohort, MUP patients benefited from novel therapies as much as MKP patients despite less favorable baseline prognostic factors. Exploratory studies investigating mutational burden and host immunity are needed to identify the underlying mechanisms. Research Sponsor: None.

Prophylactic lymphaticovenous bypass performed during complete lymphadenectomy is oncologically safe. *First Author: Cagri Cakmakoglu, Cleveland Clinic Lerner College of Medicine, Cleveland, OH*

Background: Lymphaticovenous anastomosis (LVA) is a physiologic surgery indicated for secondary lymphedema of the extremities, particularly for disease refractory to conservative management. Immediate lymphatic reconstruction (ILR) is prophylactic LVA concurrently performed with CLND. After the transected lymphatics are mapped through a dye injection, they are anastomosed to a nearby venous outflow tract. Though prophylactic LVA is increasingly being performed, its risk on cancer recurrence and distant metastasis is currently unknown. The purpose of this study was to compare the distant-metastasis free survival (DMFS) and relapse-free survival (RFS) times in melanoma patients who underwent prophylactic LVA during CLND versus those who underwent conventional CLND for grossly metastatic disease. Our study is the first prospective evaluation of the impact of prophylactic LVA on DMFS in patients undergoing CLND. **Methods:** This was a prospective study of patients with cutaneous melanoma who underwent CLND with concurrent LVA (LVA group) or CLND alone (comparison group) between 2012 and 2021. Patients were excluded if they had non-melanoma skin cancers, stage IV cancers before CLND, microscopic lymphatic disease only or follow-up time of less than 12 months who did not die from melanoma-related causes. The comparison group consisted of all consecutive patients that underwent CLND alone and met inclusion criteria. To reduce surgical technique variability, all cases were performed by a single, high-volume surgeon at a tertiary care center. **Results:** A total of 46 melanoma patients underwent prophylactic LVA during this time period. Twenty-three of these patients met all inclusion criteria and were included in the LVA group. Twenty-two consecutive patients that underwent CLND alone were included in the comparison group. All patients underwent either axillary or inguinal CLND. Average number of lymph nodes removed during CLND were 18.20 ± 9.61 and 17.04 ± 9.97 for the LVA and comparison groups, respectively (p = 0.69). Size of largest metastatic tumor in lymph nodes was 45.91 ± 35.03 mm and 44.54 ± 23.32 mm, respectively (p = 0.99). Average time to first recurrence diagnoses was 6.75 ± 3.54 months vs 8.28 ± 5.66 months. For distant metastases only, the average time to first recurrence diagnoses was 6.16 ± 3.79 months and 9.39 ± 6.19 months, respectively (p = 0.25). There was no significant difference in recurrence type between the two groups (p = 0.66). There were no differences in DMFS and RFS times between the LVA and comparison groups. **Conclusions:** Prophylactic LVA performed for grossly metastatic melanoma does not negatively impact DMFS nor RFS. Considering the extremely aggressive nature of melanoma, our finding is potentially applicable to other cancers that are amenable to CLND and LVA. Research Sponsor: None.

Preferences for adjuvant immunotherapy in patients with resected stage III melanoma: A discrete choice experiment. *First Author: Ann Livingstone, University of Sydney, Sydney, Australia*

Background: Adjuvant immunotherapy has revolutionized the management of resectable melanoma, substantially reducing the risk of recurrence but at the risk of immune-related adverse events (AE). This study aimed to quantify patients' preferences for adjuvant immunotherapy, the influence of varying levels of key attributes, and baseline characteristics associated with preferences. **Methods:** We performed a discrete choice experiment (DCE), including patients with resected stage III melanoma considering or having received adjuvant immunotherapy. Patients chose between twelve randomly presented choice tasks of two alternative options (adjuvant immunotherapy versus observation without adjuvant immunotherapy). The two options varied across two-three levels of six attributes: chance of 3-year melanoma recurrence, mild, permanent, or fatal AE, drug regimen, and out-of-pocket costs. We calculated the marginal rate of substitution (MRS, how much an individual was willing to trade one attribute for preferred levels of another) and willingness-to-pay (WTP, maximum price to trade their preferred attributes) per year. **Results:** One hundred and sixteen patients completed the DCE. Patients chose adjuvant immunotherapy over observation without adjuvant immunotherapy in 70% of choice tasks. Patients preferred adjuvant immunotherapy with reduced probabilities of recurrence (OR 0.76, 95% CI 0.70-0.83, p<0.001), fatal AE (OR 0.60, 95% CI 0.44-0.80, p=0.006), permanent AE (OR 0.94, 95% CI 0.89-0.99, p=0.046), and lowered out-of-pocket costs, for those with lower incomes (OR 0.63, 95% CI 0.47-0.85, p=0.003) and higher incomes (OR 0.84, 95% CI 0.15-4.86, p=0.064). Patients accepted an increase in their chance of mild AE from 1% to 37% (OR 2.06, 95% CI 1.13-3.78, p=0.019) in return for adjuvant immunotherapy. Willingness-to-pay was lower for patients with incomes that were lower rather than higher: US$595 (95% CI US-$555 to 1,305) and US$1,638 (95% CI US$ -1,235 to 3,419) per year for adjuvant immunotherapy with an absolute reduction of 1% in the 3-year risk of recurrence. **Conclusions:** Almost three-quarters of patients preferred adjuvant immunotherapy over observation without adjuvant immunotherapy. Patients were more likely to select immunotherapy if the risk of melanoma recurrence and the chance of fatal AE were reduced. Understanding patient preferences and acceptable trade-offs for adjuvant immunotherapy may allow better-informed decisions for individuals and assist policymakers in decisions about access and subsidization of effective and expensive treatments. Early quality of life (QOL) and symptom analysis from the DREAMseq phase III randomized control trial of combination immunotherapy versus targeted therapy in patients (pts) with *BRAF*-mutant metastatic melanoma (MM) (ECOG-ACRIN EA6134). *First Author: Roxanne E. Jensen, National Cancer Institute, Bethesda, MD*

Background: Combinations of either immune checkpoint inhibitors (anti-PD-1/anti-CTLA-4) or BRAF/MEK-targeted therapies have shown significant clinical benefit in pts with BRAFV600 mutant MM. Until recently, little prospective data existed to guide the choice of initial therapy or sequence. Results of the DREAMseq Trial showed that the treatment sequence beginning with nivolumab/ipilimumab (Nivo/Ipi) immunotherapy produced a clinically meaningful 20% improvement in 2-year overall survival (OS) compared to the sequence beginning with dabrafenib/trametinib (Dab/Tram) targeted therapy. The OS and progression-free survival (PFS) curves were biphasic crossing at 10 and 6 months, respectively. Our aim is to characterize QOL trends within and between the initial therapies through 24 weeks (wks). **Methods:** 265 pts were randomly assigned to Nivo/Ipi for up to 12 wks then Nivo alone (Arm A) or Dab/Tram continuously (Arm B) and at disease progression (PD) received the alternate therapy. QOL was assessed by the PROMIS Profile 29 at baseline, wk 12 (end of cycle (C) 2), and wk 24 (end of C4). Wilcoxon Signed Rank test was used to examine changes over time within treatment arms. OS was estimated by Kaplan-Meier method to compare between pts who stopped treatment for toxicity on Arm A by C2 and who continued on Arm A therapy to C4. A complete case analysis compared QOL domain means for (C2) vs. (C4). Pt-reported adverse events were also collected. **Results:** Baseline completion rates for the PROMIS-29 for Arm A (n = 108, 81.2%) and Arm B (n = 117, 88.6%) and decreased to 28.6% and 53.8%, respectively at C4. Through C4, the principal reasons for drop-out were toxicity (35.2% for Arm A and 11.9% for Arm B) and PD (26.1% for Arm A and 18.6% for Arm B). From Baseline to C2: Arm B reported statistically significant improvements in Pain Interference (-3.45, P = 0.007), Sleep (-2.11, P = 0.014), and Anxiety (-3.74, P < 0.001). By C4, these early differences had dissipated (mean diff. = 0.73 – 1.73, all p = NS). For pts remaining on treatment to C4 (n = 157), a complete case analysis indicates no significant QOL differences between C2 vs C4. Pts stopping for toxicity on Arm A after C2 had similar 2-yr OS to pts who continued on Arm A to C4. QOL at C2 (Arm A: stopping for toxicity vs. on treatment) were meaningful, but underpowered (Physical Health (PH) mean difference = -3.5, p = 0.18). **Conclusions:** Over the first 12 wks, Dab/Tram is associated with significant improvement in overall function and less disturbance in in sleep, pain, physical function, and PH than Nivo/Ipi as expected by PFS curves and toxicity profiles. These differences dissipate by 24 wks when Arm A therapy has switched to Nivo alone and PFS curves cross. Early QOL and treatment cessation due to Nivo/Ipi toxicity was not associated with differences in 2-yr OS. Clinical trial information: NCT02224781. Research Sponsor: U.S. National Institutes of Health.

Safety and efficacy of combined melphalan percutaneous hepatic perfusion (M-PHP) and ipilimumab plus nivolumab (IPI+NIVO) in metastasized uveal melanoma (mUM): First results of the phase Ib part of the CHOPIN trial. *First Author: Thaï s M.L. Tong, Leiden University Medical Center, Department of Medical Oncology/Radiology, Leiden, Netherlands*

Background: Uveal melanoma (UM) is the most frequent intraocular malignant tumor in adults. Approximately 50% of all patients (pts) will develop metastatic disease in the liver. Until now, there is no systemic therapy that has been shown to improve overall survival (OS), apart from tebentafusp. M-PHP is frequently applied for liver-only UM. However, the majority of pts eventually develops extrahepatic disease after M-PHP. IPI+NIVO has been shown to induce up to 20% response rates in mUM. Our observations that checkpoint inhibition was most effective on extrahepatic UM disease has led to the CHOPIN trial testing the combination of M-PHP and IPI+NIVO. Here we present the safety and efficacy data of the phase 1b part of CHOPIN. **Methods:** Adult pts with confirmed measurable hepatic mUM and WHO PS 0-1 were included. Two courses of 6 weekly M-PHPs (melphalan 3mg/kg, max 220mg) were combined with four courses IPI+NIVO three-weekly escalating the dosing from 1mg/kg each IPI+NIVO (cohort 1) to IPI 1mg/kg + NIVO 3mg/kg (cohort 2). Primary endpoint was safety of IPI+NIVO plus M-PHP. Secondary endpoints were best overall response (BOR) according to RECIST 1.1, progression-free survival (PFS), and OS. **Results:** 7 pts were included (4 male, median age 63.6 years (range 50-74)). Both cohorts were tolerated with no dose-limiting toxicities or deaths. Grade III/IV adverse events (AE) were observed in 2/3 pts in cohort 1 and in 3/4 pts in cohort 2 consisting of SIRS, febrile neutropenia, cholecystitis, neutropenia, thrombopenia, leukopenia, increased transaminases and fever. Grade I/II immune-related AEs occurred in all pts (myositis, hypothyroidism, hepatitis and dermatitis). BOR was 1 complete response, 5 partial responses and 1 stable disease accounting for an objective response rate (ORR) of 85.7%. At a median FU time of 20.2 months, 4 pts have an ongoing response. Currently the median PFS is 22.4 months, and all pts are still alive. **Conclusions:** Combining M-PHP with IPI+NIVO is safe at a dosing of IPI 1 mg/kg and NIVO 3 mg/kg and very promising ORR, PFS and OS have been observed. The randomized phase II part comparing M-PHP versus M-PHP+IPI+NIVO is currently recruiting. Clinical trial information: NCT04283890. Research Sponsor: Bristol Myers Squibb and Delcath Systems Inc.

9561 **Poster Session**

A phase 1b/2a study of safety and efficacy of NT-I7 in combination with anti-PD-L1 (atezolizumab) in patients with anti-PD-1/PD-L1 naïve or relapsed/refractory (R/R) high-risk skin cancers: The phase 1b report. *First Author: Brian Gastman, Cleveland Clinic Lerner College of Medicine, Cleveland, OH*

Background: Novel immunotherapy approaches have changed the treatment landscape of patients (pts) with high-risk cancers like melanoma, Merkel cell carcinoma (MCC) and cutaneous squamous cell carcinoma (cSCC). However, despite the widespread use of checkpoint inhibitors (CPI) in these indications, most pts either fail to respond or eventually have progressed. NT-I7 (efineptakin alfa) is a long-acting human IL-7 that can increase the number and functionality of T-cells in peripheral blood and within the tumors. NT-I7 in combination with atezolizumab (atezo), may augment the efficacy in high-risk skin cancers. **Methods:** This is a phase 1b/2a study to evaluate the safety and efficacy of NT-I7 in combination with atezo in pts with CPI- naïve or relapsed/refractory (R/R) high-risk skin cancers. Phase 1b dose escalation followed a 3+3 design, in which pts who received NT-I7 IM every 3 weeks (Q3W) at 3 dose levels (DL1-3): 120, 360, and 840 μg/kg or Q6W at DL4 1200 μg/kg, and atezo IV 1200 mg Q3W. The objectives of the phase 1b were to evaluate dose-limiting toxicity (DLT), determine the MTD and the recommended phase 2 dose (RP2D), pharmacokinetics (PK), pharmacodynamics and preliminary antitumor activity. **Results:** As of January 14, 2022, 16 pts were enrolled in phase 1b: DL1 (n = 3), DL2 (n = 3), DL3 (n = 7), and DL4 (n = 3). The median age was 66 years [46-86], with ECOG PS 0 in 6 (37%), 1 in 7 (44%) and 2 in 3 (19%), and median number of prior therapies 1 [1-2]. One pt had a DLT at DL3 [Grade (G)3 confusion and G3 increased AST] but no DLTs were reported at DL4 and MTD was not reached. The RP2D was 1200 μg/kg Q6W of NT-I7 plus atezo 1200 mg Q3W. All pts had drug related AEs. Most AEs were G 1- 2 in 11(69%) pts; 5 (31%) in G3. There were no related G4/G5 AEs. Eleven pts had stable disease and the disease control rate was 69% (11/16). Preliminary PK analysis of DL1- 3 showed dose dependent C_{max}, with T_{max} at ~24hr and $T^1/_2$ ranging ~75hr to 125hr. NT-I7 dose-dependent expansion of the absolute lymphocyte count, $CD3^+$, $CD4^+$ and $CD8^+$ T-cells peaked after one dose and the increase was maintained by repeat dosing until the end of treatment. Immunophenotyping of memory T-cell subsets showed a 5-fold expansion in most T-cell subsets and a 30-fold expansion of the stem cell memory CD8+ T-cell subset (Tscm) at DL4. **Conclusions:** This trial is the first time an IL-7 cytokine-based therapy and CPI has been assessed in UV induced high-risk skin cancers including in IO refractory pts. The combination of NT-I7 and atezo showed favorable safety and anticancer activity. NT-I7 significantly increased total lymphocyte and the T-cell compartment, with a greatest expansion of the CD8+ Tscm, a vital population for eliciting antitumor activity. Additional safety and efficacy updates will be provided by the ongoing phase 2a trial in CPI-naïve cSCC and MCC and CPI R/R MCC, cSCC and melanoma. Clinical trial information: NCT03901573. Research Sponsor: Neoimmunetech, Inc.

Distinct mutational landscapes characterize melanomas metastatic to different anatomical sites. *First Author: Mahesh Y. Iddawela, Alfred Health, Central Clinical School,Monash University, Melbourne, VIC, Australia*

Background: Despite revolutionary advances in systemic therapies for melanoma, many patients with metastatic disease have limited treatment options and some sites of disease remain particularly challenging to control, such as brain and liver metastases. We sought to define anatomical site-specific mutational profiles of melanoma metastases from which potentially novel personalized therapeutic opportunities may be developed. **Methods:** Targeted exome genomic profiling was performed via the FoundationOneCDx platform and known or likely pathogenic variants retained for analysis. PD-L1 immunohistochemistry was performed with the Dako 22C3 assay with PD-L1+ defined as tumor proportion score ≥1. Tumor mutational burden (TMB)-high was defined as TMB ≥10mut/Mb. UV signature was calculated using established algorithms. Aberrations in 23 genes potentially actionable in melanoma (*BARD1*, *BRAF*, *BRCA1/2*, *CDKN2A*, *DDX3X*, *FANCC*, *HRAS*, *IDH1*, *KIT*, *KRAS*, *MAP2K1*, *NF1*, *NRAS*, *PALB2*, *PIK3CA*, *PPP6C*, *PTEN*, *RAC1*, *RAD51C/D*, *RB1*, *TP53*) were compared across metastatic sites including skin, lymph node, lung, liver, and brain. **Results:** A total of 4918 cutaneous-type melanoma tumors was evaluated, including 2854 skin lesions (primary/metastasis) and metastases from lymph nodes (n = 858), liver (n = 194), lung (n = 342), and brain (n = 200). The commonly mutated genes were *CDKN2A* (2220/4918, 45.1%), *BRAF* (2148/4918, 43.7%), *NRAS*(1347/4918, 27.4%), *NF1* (1038/4918, 21.1%), *TP53* (1234/4918, 25.1%) and *PTEN* (1038/4918, 13.5%). Compared with skin lesions, metastases to the lung were enriched for variants affecting *NF1* (OR 2.57, p = 8.99e-13), *TP53* (OR 1.65, p = 3.04e-04) and depleted in *NRAS* (OR 0.49, p = 9.00e-06) and *BRAF* (OR 0.70, p = 1.13e-02). Lung metastases were associated with higher prevalence of UV signatures, PD-L1 positivity and high TMB. *PTEN* variants were enriched in both brain (OR 3.00, p = 2.38e-08) and small intestine (OR3.46, p = 6.63e-3) metastases. Brain metastases were also enriched for *CDKN2A* variants (OR 1.56, p = 4.50e-02). Lymph node metastases had lower rates of UV signatures, *NF1* variants, or high TMB, but were associated with PD-L1 positivity. Positional analysis of variants revealed that several, including *NRAS*, *MAP2K1*, *KRAS*,*HRAS*, *IDH1*, *RAC1*, *GNA11* and *GNAQ* were highly restricted to hotspot loci, without definite variation by metastatic site. Conversely, variants affecting *CDKN2A*, *PTEN*, *TP53* and *NF1* were distributed widely across the gene, with high levels of non-hotspot mutations observed in skin lesions, suggesting that such non-hotspot subclones contribute less to distant metastatic potential and are lost during disease evolution. **Conclusions:** We observed distinct and organ site-specific mutational patterns in patients with metastatic melanoma. These data raise the possibility of metastatic phenotype-directed therapy to improve the personalization and outcomes of treatment for this disease. Research Sponsor: None.

Adjuvant dabrafenib plus trametinib (D + T) versus placebo in patients with resected stage III *BRAF*^{V600}-mutant melanoma: Updated 5-year distant metastases-free survival (DMFS) analysis of COMBI-AD. *First Author: Dirk Schadendorf, University Hospital Essen, Essen and German Cancer Consortium, Heidelberg, Germany*

Background: DMFS is an important endpoint for patients with stage III cutaneous melanoma, as delaying or preventing systemic disease is associated with improved clinical and patient-reported outcomes. Prior results from the phase 3 COMBI-AD trial (NCT01682083) showed 5-year DMFS rates of 65% with adjuvant D + T vs 54% with placebo (PBO; hazard ratio [HR] = 0.55; 95% CI: 0.44-0.70). An analysis of DMFS by AJCC-7 stages IIIA-C suggested a similar benefit of D + T vs PBO regardless of stage (Dummer R et al. *N Engl J Med*. 2020). Here, we report 5-year DMFS rates by AJCC-8 stages IIIA-D, other prognostic subgroups, and results of a regression tree analysis with DMFS. **Methods:** Patients with resected AJCC-7 stage III *BRAF*$^{V600E/K}$-mutant melanoma were randomized to either D (150 mg twice daily) + T (2 mg once daily) or 2 matched PBOs for 12 months. Primary endpoint was relapse-free survival (RFS); DMFS was a secondary endpoint. Kaplan-Meier survival analyses were performed to assess the long-term benefits for DMFS rates with D + T vs PBO. The regression tree analysis (data cutoff: 5 years) for all patients (N = 870) evaluated potential prognostic/predictive factors of long-term DMFS including baseline age, sex, region, *BRAF* mutation type, body mass index, lactate dehydrogenase levels, ECOG, T and N categories, histology, primary tumor ulceration, treatment type, number of lymph nodes with metastases, tumor mutational burden, and interferon-gamma gene expression signature (IFN-γ GES). **Results:** At 5 years, DMFS rates were higher for patients with AJCC-8 stages IIIB-D disease receiving adjuvant D + T vs PBO (table). Five-year DMFS rates also favored D + T vs PBO in subgroups of patients with microscopic or macroscopic lymph node involvement (table) and those with or without primary tumor ulceration and/or in-transit metastases. A regression tree revealed T and N stage, treatment type, and IFN-γ GES as important variables defining 5-year DMFS subgroups. **Conclusions:** In this retrospective analysis, adjuvant D + T provided long-term DMFS benefit vs PBO in stage IIIB-D patients with resected *BRAF*$^{V600E/K}$-mutant melanoma. Key clinical and patient factors impacting DMFS were similar to prior RFS findings (ESMO 2021; Robert C et al. *Ann Oncol*. 2021) and included T and N stage, treatment type, and IFN-γ GES. These results further validate the robust long-term clinical benefit of adjuvant D + T for patients with melanoma. Clinical trial information: NCT01682083. Research Sponsor: Novartis Pharmaceuticals Corporation.

Prognostic significance of the CP-GEP assay combining clinicopathologic factors and gene expression profiling in patients (pts) with AJCC v8 stage I/II cutaneous melanoma (CM). *First Author: Teresa Maria Santos Amaral, Center for Dermatooncology, Department of Dermatology, Eberhard Karls University of Tuebingen, Tuebingen, Germany*

Background: AJCC v8 includes Breslow thickness and ulceration to subdivide stage I and II CM pts into risk groups. In light of the results from adjuvant therapy in stage II CM, it has been discussed that pts' follow-up and eventually treatment should consider additional markers, namely CP-GEP, to further refine the risk classification provided by the AJCC v8. The aim of this single center study was to clinically validate a prognostic CP-GEP-based risk score for stage I/II CMs combining Breslow, age and the expression of 8 genes *SERPINE2*, *GDF15*, *ITGB3*, *CXCL8*, *LOXL4*, *TGFBR1*, *PLAT* and *MLANA*. **Methods:** All obtainable formalin-fixed paraffin-embedded primaries of stage I/II CMs with negative sentinel lymph node (SLN) from the Central Malignant Melanoma Registry of Germany diagnosed between 2000-2017 and archived in Tuebingen were included. Study hypothesis and protocol were prospectively formulated. Tumors were analyzed blinded to clinical outcome. Quantitative reverse transcription polymerase chain reaction of the 8 genes was performed and combined with age and tumor thickness to define CP-GEP low- vs. high-score groups. Relapse-free survival (RFS), distant metastasis free survival (DMFS) and overall survival (OS) were evaluated using Kaplan-Meier curves. CP-GEP score performance was tested using multivariate Cox regression adjusted for tumor thickness, ulceration and age. **Results:** We included 543 pts with Stage IA (n=78); IB (n=223); IIA (n= 123); IIB (n=73); IIC (n=46). 43% were females, median Breslow was 1.7mm and 25% of tumors had ulceration. The median follow-up was 78 months (IQR 47-116). 311 (57%) patients had a high-risk CP-GEP score. The 5-y RFS rate was 71% and 92% (HR 4.2; p<0.001), the 5-y DMFS rate was 86% and 96% (HR 4.35; p<0.001) and the 5-y OS was 85% and 95% (HR 3.2; p=0.001), respectively for high and low-risk CP-GEP score. In multivariate Cox regression analysis for RFS including Breslow thickness, ulceration and age, contribution of CP-GEP score remained independently significant (HR 2.75; p=0.0008) compared to age (HR 1.03; p<0.0007), Breslow (HR 1.21; p<0.0001) and ulceration (HR 1.37; p=0.1694). **Conclusions:** CP-GEP risk score is a non-invasive and independent prognostic model for risk of relapse in stage I/II melanoma validated in this study. It identifies SLN negative pts at high risk of relapse and should be considered for complementing AJCC classification and for inclusion in future clinical trials. Research Sponsor: SkylineDX.

Immune profiling of metastatic uveal melanoma and response to immune checkpoint inhibitors. *First Author: Yusra F. Shao, Barbara Ann Karmanos Cancer Institute, Wayne State University, Detroit, MI*

Background: Response to immune checkpoint inhibitors (ICI) in uveal melanoma (UM) is low. We aimed to elucidate tumor markers correlated with improved survival in ICI treated UM patients. **Methods:** Tumor samples of UM patients were tested at Caris Life Sciences (Phoenix, AZ) with NextGen Sequencing on DNA (592 genes assay or whole exome sequencing) and RNA (whole transcriptome sequencing). Somatic mutations were totaled to calculate tumor mutational burden (TMB) and cutoff for high vs low was 10 mt/MB. PDL1 was tested with immunohistochemistry for tumor staining and cutoff was ≥2+, 5% for high vs low. *NCOA2* gene amplification was considered a surrogate for gain of chromosome 8q (cutoff ≥6). Median RNA expression level for LAG3 was calculated for each cohort and used as cutoff for high vs low. All ICI treated patients were considered to have metastatic disease. Real-world overall survival (rwOS) was obtained from insurance claims data and calculated from tissue collection to last contact. Time on treatment (TOT) was calculated from start to finish of ICI treatment and was considered as surrogate for progression-free survival (PFS). Comparison of survival was performed by Kaplan-Meier analysis. **Results:** A total of 450 UM samples were analyzed. Of these, 108 were from ICI treated patients and were obtained from primary (10/108) or metastatic (98/108) sites. Most tumors were PDL1 low in the entire UM (86%, 240/279) and ICI treated (62%, 55/89) cohorts. There was no difference in TOT between PDL1 high vs low in ICI treated cohort (HR 1.46, 95% CI 0.82-2.6, median TOT 3.1 months vs 2.3 months). Similarly, 98% (257/263) of all UM samples had low TMB. ICI treated patients with high LAG3 expression had similar TOT compared to low (HR 1.3, 95% CI 0.59-2.9, median TOT 6 months vs 2 months). In the entire UM cohort, most tumors were *NF1*-wildtype (95%, 56/59). *NF1*-wildtype status was associated with a longer rwOS compared to *NF1*-mutated (HR 0.18, 95% CI 0.051-0.64, median rwOS of 20.8 months vs 7 months). *NCOA2* amplification was associated with a worse rwOS as compared to patients without *NCOA2* amplification in the entire UM (HR 0.68, 95% CI 0.50-0.91) but not in ICI treated cohort (HR 0.84, 95% CI 0.52-1.4). There was no difference in TOT in ICI treated patients by *BAP1* and *SF3B1* mutational status. **Conclusions:** UM lacks traditional markers of response to ICI. Short TOT seen in our study is consistent with PFS of 3 to 5.5 months seen in clinical trials. High LAG3 expression was associated with a clinically significant improvement in TOT. Traditional markers of poor prognosis were not implicated in survival differences in ICI treated patients. This likely represents a poor prognosis in all mUM patients regardless of traditional prognostic markers. *NF1* mutation is uncommon in UM and its significance as a prognostic marker should be validated in a larger cohort. Ongoing research is needed to understand the biology of UM and approach to treatment. Research Sponsor: None.

The relationship between circulating tumor DNA with Merkel cell carcinoma tumor burden and detection of recurrence. *First Author: Tomoko Akaike, University of Washington, Seattle, WA*

Background: Merkel cell carcinoma (MCC) is an aggressive skin cancer with a recurrence rate of 40%. Early detection of recurrence can improve outcomes, and effective surveillance is crucial for management of patients with MCC. While Merkel cell polyomavirus (MCPyV) oncoprotein serology is useful in surveillance for MCPyV-positive MCC tumors, patients with MCPyV-negative tumors have no available blood biomarkers and require frequent imaging. This prospective, multicenter study assessed whether circulating tumor DNA (ctDNA) can assess disease burden and detect recurrence regardless of virus status. **Methods:** A total of 328 blood samples were collected from 125 patients at various time points with a median follow-up of 6 months (range: 0-21 months) between April 2020 to January 2022. Whole-exome sequencing was performed on tumor tissue and matched normal blood to identify a set of somatic, clonal single nucleotide variants, which were tracked in subsequent blood (plasma) samples using a personalized and multiplex PCR-NGS based ctDNA assay (Signatera). Clinically evident disease was defined as MCC noted either by physical exam or by imaging, and molecular evidence of disease was defined as a positive ctDNA test. Surveillance phase began once there was no clinically evident or molecular evidence of disease. **Results:** Among 125 patients, 47 (38%) had clinically evident MCC and all were found to be ctDNA-positive at the first time point (sensitivity: 100%; 95% CI: 91-100%). Of the 47, 24 were newly diagnosed with MCC and had a median primary tumor size of 2.2 cm (range 0.5-8.5 cm) and a median ctDNA value of 26 mean tumor molecules (MTM)/mL (range: 0.08-1470 MTM/mL). Primary tumor diameter and ctDNA value were strongly correlated (Spearman's $r = 0.81$, $p < 0.001$). Of the 125 patients, 73 (58%) patients were assessed in the surveillance setting and had a total of 152 plasma samples available for longitudinal ctDNA testing. Over this period, 7 ctDNA tests were positive while 145 were negative. After a positive test, 5/7 developed a clinically evident recurrence (4 within 60 days). Of the remaining 2 without clinical recurrence, one had < 60 days of follow-up at time of data analysis. The estimated risk of recurrence, accounting for incomplete follow-up, was 57% within 60 days of a positive ctDNA test (n = 7 tests). In contrast, after a negative ctDNA test (n = 145 tests), the risk of recurrence was 0% within 60 days and 3% between 60-90 days. **Conclusions:** To our knowledge, this is the largest study to explore ctDNA testing in MCC patients. This study demonstrates that ctDNA testing can detect MCC recurrence early and is a promising clinical surveillance tool regardless of tumor viral status. Plasma methylated DNA markers of cutaneous melanoma: Association with PET/CT-positive disease. *First Author: Alexander Meves, Mayo Clinic, Rochester, MN*

Background: Cutaneous melanoma surveillance is important to identify low-volume systemic disease, but imaging is costly and poorly accessible to patients; frequent skin checks lack sensitivity and specificity. We aimed to establish clinical feasibility of a liquid biopsy blood test, which quantifies validated, melanoma-specific, methylated DNA markers (MDMs), previously discovered, and reported by our team, using tissue extracted DNA. **Methods:** We prospectively collected blood from adult patients with histologically confirmed melanoma metastases and no other internal malignancies (within 5-years) who underwent surveillance by FDG-PET/CT (N = 88). Blood from age- and sex balanced cancer-free controls (N = 100) were compared. From PET/CT, we extracted the number of organs involved, SUV-max, and largest tumor diameter. Unequivocal metastasis was defined as SUV ≥ 4 and largest diameter > 5 mm. Because PET/CT is inadequate for the screening of brain metastases, we excluded the brain from the analysis. MDMs (*chr11.149, HOXA9, chr20.210, FLJ22536, CLIC5, SIX4, chr7.155, chr17.730, chr1.110*) were assayed using target enrichment long-probe quantitative-amplified signal assays, normalized to *B3GALT6*, in blinded fashion. Using a logistic regression approach and nine candidate MDMs, we calculated the sensitivity for detecting patients with metastasis on PET/CT at 100% specificity. **Results:** 52/88 (59%) of melanoma patients showed evidence of metastasis on PET/CT at the time of blood draw. At 100% specificity, a panel of 4 MDMs (*HOXA9, chr20.210, chr17.730, chr1.110*) yielded a sensitivity of 86.5% (45/52 cases) vs. 100 cancer-free controls. When applying this model to the 36 PET/CT-negative patients, specificity was as high as 97.2% (35/36 cases) while maintaining a sensitivity of 86.5% (one patient with a positive test result had a complete metabolic response to binimetinib / encorafenib prior to negative PET/CT). For patients with ≥ 2 organs involved by metastasis, sensitivity was 100% (29/29 cases). False-negative cases had metastasis in single organs and were characterized by minimal tumor burden and oral corticosteroid use. One false-negative patient had localized stage III disease without known primary melanoma. **Conclusions:** Plasma MDM levels appear highly concordant with FDG-PET/CT in patients with metastatic cutaneous melanoma. A liquid biopsy approach has potential to lower cost and improve patient access to surveillance. Additional prospective studies in larger intended use cohorts are needed to validate our results. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

9568 **Poster Session**

The effect of the microbiome on immune checkpoint inhibitor toxicity in patients with melanoma. *First Author: Nyelia Williams, The Ohio State University, Columbus, OH*

Background: Immune-checkpoint inhibitor (ICI) immunotherapy has increased survival in patients with melanoma. However, only half of the patients respond, and many experience immune-related adverse events (irAEs). Recent evidence suggests that modification of the gut microbiome may increase response to ICIs and decrease toxicity. Here we describe the first results of a clinical trial to determine if the microbiome can predict the response or toxicity during the first 16 weeks of ICI treatment. **Methods:** We enrolled patients aged 18 or older in a prospective observational cohort study at The Ohio State University Comprehensive Cancer Center Skin Cancer Clinic (OSUCCC-SCC) who were to receive treatment with pembrolizumab or nivolumab alone or in combination with other treatments (e.g. nivolumab and ipilimumab) for melanoma. Patients receiving systemic or oral corticosteroids at the start of ICI cycle 1 were excluded but were eligible if receiving adrenal physiologic replacement. Patients collected stool samples at baseline, within 2 days of an adverse event (if applicable), and at 12 weeks. The response to ICIs was evaluated by Response Evaluation Criteria in Solid Tumors (RECIST v1.1) at a 12-week computed tomography scan. Metagenomic whole-genome shotgun sequencing was performed on an Illumina NovaSeq 6000 and then classified using HUMAnN3. The effect of microbe relative abundances on potential irAEs was modeled by logistic regression with the R package glmm. **Results:** In total, 88 patients consented to the trial. Pre-treatment microbiome samples were collected from 49 patients. Potential irAEs were observed in 16 out of the 49 patients for whom pre-treatment microbiome samples were collected. There was no significant difference in the ages ($p = 0.150$, genders ($p = 0.2$), stages ($p = 0.2$) or treatments ($p = 0.07$) of those who developed potential irAEs . Pretreatment abundance of the family *Ruminococcaceae* was most strongly associated with the development of a potential irAE ($p = 0.03$), followed by a taxon in an unclassified order within the phylum *Firmicutes* ($p = 0.05$). The family *Bacteroidaceae* was most strongly associated with no potential irAE ($p = 0.05$). **Conclusions:** Longitudinal and event-driven biospecimen collection in the context of treatment with immunotherapies was feasible in the OSUCCC-SCC. The abundance of the two high-taxonomic rank microbe groups was significantly associated with potential irAEs. The association with *Ruminococcaceae* is consistent with previous studies where it was associated with response to ICIs and, in separate studies, development of an irAE was associated with a better response. The unclassified taxon is potentially a new biomarker for the prediction of toxicity and a therapeutic target to reduce treatment side effects. Future analyses will associate microbes with treatment response and test for consistent microbiome changes at the time of irAE development. Clinical trial information: NCT05102773. Research Sponsor: Pelotonia Junior Investigator Award.

The efficacy of immune checkpoint blockade for melanoma in-transit with or without nodal metastases: A multicenter cohort study. *First Author: Roger Olofsson Bagge, Sahlgrenska Center for Cancer Research, Department of Surgery, Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

Background: Guidelines addressing melanoma in-transit metastasis (ITM) recommend immune checkpoint inhibitors (ICI) as a first-line treatment option, despite the fact that there are no efficacy data available from prospective trials for exclusively ITM disease. The aim of this study was to analyze the outcome of patients with ITM treated with ICI based on data from a large cohort of patients treated at international high-volume melanoma centers. **Methods:** A multicenter retrospective cohort study of patients treated between January 2015 and December 2020 from Australia, Europe, and USA, evaluating treatment with ICI for ITM with or without nodal involvement (AJCC8 N1c, N2c and N3c) and without distant disease (M0). Patients were treated with PD-1 inhibitor (nivolumab or pembrolizumab) and/or CTLA-4 inhibitor (ipilimumab). We assessed response rates, progression-free survival (PFS), melanoma-specific survival (MSS) and overall survival (OS). **Results:** A total of 287 patients from 21 institutions in 8 countries were included. Immunotherapy was first-line treatment in 64 (22%) patients. Monotherapy with a PD-1 or CTLA-4 inhibitor was given in 233 (81%) and 23 (8%) patients respectively, while 31 (11%) received both in combination. Overall response rate was 56%, complete response (CR) rate 36% and progressive disease (PD) rate 32%. Median PFS was 10 months (95% CI 7.4-12.6 months) with a 1-, 2- and 5-year PFS rate of 48%, 33% and 18% respectively. Median MSS was not reached, and the 1-, 2- and 5-year MSS rates were 95%, 83% and 71% respectively. **Conclusions:** Systemic immunotherapy is an effective treatment for melanoma ITM. Future studies should evaluate the optimal role for systemic immunotherapy in the context of multimodality therapy including locoregional treatments such as surgery, intralesional therapy, and regional therapies. Research Sponsor: Institutional support from Knut and Alice Wallenberg Foundation.

9570 **Poster Session**

Multicenter real-world data of adjuvant treatment and disease outcome of patients with melanoma with high-risk of recurrence. *First Author: Elisabeth Livingstone, Department of Dermatology, University Hospital Essen, Essen, Germany*

Background: Clinical trials demonstrated a significantly improved recurrence-free survival (RFS) of melanoma patients treated adjuvantly with immune checkpoint inhibition (ICI) and targeted therapy (TT). As data from controlled trials are based on selected populations, we investigated melanoma patients with high risk of recurrence who opted for ICI, TT, or no adjuvant treatment (NoTx) under real-world conditions. **Methods:** In a prior analysis of this multicenter, retrospective cohort study, patients with resected melanoma stage III-IV between 06/2018 and 09/2019 were analyzed for adjuvant therapy choice (Lodde et al., Cancers 2021). In this follow-up study, the treatment course of ICI- and TT-treated patients as well as recurrence characteristics, subsequent management and outcomes also including NoTx patients were examined. **Results:** 814 patients were included (72 stage IIIA, 266 IIIB, 383 IIIC, 24 IIID, 69 IV; 309 BRAF mut); 533 patients received ICI (66%), 114 TT (14%, 36.9% of all BRAF mutated patients), 167 patients had opted for NoTx (21%). Median treatment duration was 10.2 and 11.7 months for ICI and TT, respectively. ICI was discontinued prematurely in 51% (273/533) and TT in 44% (50/114) of patients. The main reason for discontinuation was progressive disease (PD) in ICI patients (58%, 158/273) and adverse events in TT patients (60%, 33/50). At a median follow-up (FU) of 24.6 months for ICI, 25.3 months for TT, and 21.8 months for NoTx, 48% of ICI (255/533), 35% of TT (40/114), and 45% of NoTx (75/167) patients had developed a recurrence mostly at distant sites (ICI 62%, TT 63%, NoTx 64%). In patients with recurrence, median time from start of adjuvant treatment to 1st recurrence was 6.1 months in ICI and 17.6 months in TT. Median RFS was 32.0 months for ICI (95% CI 25.7-38.3), not reached for TT, and 22.3 months for NoTx (95% CI 15.2-29.4). Among BRAF mut patients with stage III, risk of recurrence was higher for ICI than TT (hazard ratio adjusted for age, sex and tumor stage, 2.31; 95% CI 1.56-3.43). Subsequent systemic treatment for the 1st recurrence was given in 76% (192/253) of ICI, 83% (33/40) of TT, and 53% (40/75) of NoTx patients. Among patients who received the 1st subsequent systemic treatment for metastatic disease, PD was the best response in 67% (82/123) for ICI, 55% (11/20) for TT, and 50% (16/32) for NoTX. **Conclusions:** After 2 years of FU, recurrences were mostly at distant sites in all groups. ICI had higher discontinuation rates and more and earlier recurrences than TT. BRAF mut melanoma patients treated with ICI had a significantly higher risk of relapse than TT-treated patients. Response to subsequent systemic treatment was low for both ICI and TT. Research Sponsor: None.

Use of Merlin Assay to identify patients with a low-risk for SN metastasis in a prospective multicenter Dutch study of a primary melanoma gene-signature (CP-GEP model) to predict sentinel node status during COVID-19. *First Author: Robert Stassen, Erasmus MC Kankerinstituut, Rotterdam, Netherlands*

Background: Approximately 70%-85% of patients who undergo sentinel lymph node biopsy (SLNb) show no nodal metastasis in the sentinel node (SN). The clinicopathological and gene expression profile (CP-GEP) model (*Merlin Assay*) was developed and validated to identify patients that may forgo the SLNb surgery due to their low risk for for nodal metastasis This study was initiated during the first wave of Covid-19 pandemic to allow for surgical triage on SLNb and evaluate the implementation of the Merlin assay in clinical practice. **Methods:** This study was conducted in four designated melanoma centers in the Netherlands. Patients (age > 18y) with newly diagnosed melanoma of the skin, eligible to undergo SLNb were screened for study inclusion. Main exclusion criteria was prior history of primary melanoma (> T1b) in the past 5 years. After enrollment, tissue sections of the primary melanoma were centrally reviewed at the Erasmus MC Cancer Institute to determine Breslow thickness at primary diagnosis. FFPE tumor tissue was dispatched for molecular analysis of eight target genes known to play a role in cancer development. In combination with age, Breslow thickness, and GEP outcome, risk of having nodal metastasis was calculated. Results were binary presented as 'CP-GEP low risk' and 'CP-GEP high risk'. SLNb status was used as gold standard for comparison. **Results:** A total of 177 patients were analyzed using the CP-GEP model. Median age was 64 years (IQR 52-73) Median Breslow thickness was 1.4mm (IQR 1.0-2.4). Of all patients 28.2% was diagnosed with T1, 40.7% with T2 and 20.9% with T3 melanoma. Corresponding positivity rate was 7%, 14% and 29% respectively. A total of 24 out of 177 patients had a positive SLNb. Median turn-around time from inclusion to CP-GEP result was 15 days. Overall 37.1.% of patients had a CP-GEP low risk profile. The CP-GEP model had a NPV of 94.6%. **Conclusions:** This is the first prospective multicenter implementation study for the Merlin assay. Results are in line with previous validation studies. The CP-GEP model could accurately identify patients at low risk for SN metastasis. Implementation in clinical practice is feasible based on current turn-around time. In the future, using the Merlin assay to deselect patients for SLNB may allow for a reduction of surgery in patients with melanoma. Research Sponsor: None.

Survival update of neoadjuvant ipilimumab + nivolumab in macroscopic stage III melanoma: The OpACIN and OpACIN-neo trials. *First Author: Judith M. Versluis, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: OpACIN was the first trial testing neoadjuvant ipilimumab (IPI) + nivolumab (NIVO) versus the same combination given adjuvant. An unexpected high pathologic responses of 78% was observed in the neoadjuvant arm with a 2-year relapse-free survival (RFS) rate of 80%. The subsequent OpACIN-neo trial tested 3 different dosing schedules of neoadjuvant IPI + NIVO and identified 2 cycles IPI 1 mg/kg + NIVO 3 mg/kg q3w as most favorable schedule with a pathologic response rate of 77% and 20% grade 3-4 immune-related adverse events. Long-term data on the durability of the pathologic (path) responses upon neoadjuvant checkpoint inhibition are lacking so far. Therefore, we present here the updated RFS and overall survival (OS) data of both trials. **Methods:** In OpACIN 20 macroscopic stage III melanoma pts were randomized to receive either IPI 3 mg/kg + NIVO 1 mg/kg q3w 4 cycles adjuvant after lymph node dissection or split 2 cycles neoadjuvant and 2 adjuvant. In OpACIN-neo 86 macroscopic stage III melanoma pts were randomized to arm A (2x IPI 3 mg/kg + NIVO 1 mg/kg q3w, n=30), arm B (2x IPI 1 mg/kg + NIVO 3 mg/kg q3w, n=30), or arm C (2x IPI 3 mg/kg q3w followed by 2x NIVO 3 mg/kg q2w, n=26) followed by lymph node dissection in week 6. RFS and OS were estimated using Kaplan Meier method. All comparative efficacy endpoints are descriptive for OpACIN, since the trial was not powered for comparison of the arms. **Results:** After a median follow-up (FU) of 68.6 months for OpACIN (minimum FU of 59.8 months), median RFS and OS were not reached. Only 1/7 patients (pts) with a pathologic response on neoadjuvant therapy has relapsed. Estimated 5-year RFS and OS rates for the neoadjuvant arm were 70.0% (95%CI: 46.7-100.0) and 90.0% (95%CI: 73.2-100.0) versus 60.0% (95%CI 36.2-99.5) and 70.0% (95%CI: 46.7-100.0) for the adjuvant arm. After a median FU of 46.8 months for OpACIN-neo (minimum FU of 38.2 months), median RFS and OS were not reached. Of pts with path response on neoadjuvant therapy, 3/64 (4.7%) had an event (2 pts relapsed, 1 pt died due to toxicity), versus 14/21 (66.7%) without path response. This resulted in a 3-year RFS rate of 95.3% (95%CI: 90.3-100.0) for responding versus 36.8% (95%CI: 20.4-66.4) for non-responding pts (p<0.001). Of the pts who relapsed after response, 1 had major path response (<10% vital tumor) and 1 a partial response (10-15% vital tumor). Estimated 3-year RFS and OS rates are presented in the Table. **Conclusions:** Updated data from OpACIN and OpACIN-neo trials confirm the durability of responses upon neoadjuvant combination checkpoint inhibition in high risk stage III melanoma. Pathologic response remains a reliable surrogate marker for RFS and OS. Clinical trial information: NCT02437279, NCT02977052. Research Sponsor: BMS, with NKI as sponsor.

	3-year RFS (95%CI)	3-year OS (95%CI)
OpACIN	80.0% (58.7-100.0)	90.0% (73.2-100.0)
OpACIN-neo	81.9% (74.1-90.6)	91.9% (86.3-97.8)
Arm A	86.7% (75.3-99.7)	90.0% (79.9-100.0)
Arm B	79.3% (65.9-95.5)	93.3% (84.8-100.0)
Arm C	79.2% (64.5-97.2)	92.3% (82.6-100.0)

9573 **Poster Session**

SALVO: Single-arm trial of ipilimumab and nivolumab as adjuvant therapy for resected mucosal melanoma. *First Author: Lisa A. Kottschade, Mayo Clinic, Rochester, MN*

Background: Mucosal melanoma is a rare, highly aggressive form of melanoma with extremely high recurrence rates, despite definitive surgical resection. Median RFS has been reported to be 5.4m, with RFS rates at 1 and 2 years of 10%, and 0%, respectively (Lian B, Si L, Cui C, et al. Phase II Randomized Trial Comparing High-Dose IFN-α2b with Temozolomide Plus Cisplatin as Systemic Adjuvant Therapy for Resected Mucosal Melanoma. *Clinical Cancer Research* 2013, **19**(16):4488-4498). Currently there is no consensus on recommendations for adjuvant therapy. Data on the use of immune checkpoint inhibitors (ICI) adjuvantly is lacking. **Methods:** We performed a single arm, multicenter clinical trial using "flip dose" ipilimumab (1mg/kg q3w x4 cycles),and nivolumab (3 mg.kg q3w x4 cycles), then Nivolumab 480 mg q4w x 11 cycles to complete a year of adjuvant therapy. The primary endpoint was recurrence-free survival (RFS), and the study had 85% power to detect an improvement in RFS between 5.5 and 9.5 months using a one-sided log rank test. Participants must have had R0/R1 resection <90 days prior to registration, and no prior systemic therapy (adjuvant radiation allowed), ECOG 0/1, no uncontrolled significant autoimmune disease or other invasive cancer. Patients were recruited through the Midwest Melanoma Partnership/Hoosier Oncology Network. **Results:** From 9/17 to 8/21, 44 patients were approached at 6 centers. Of these 9 were ineligible, and 35 were enrolled. Of these, 29 (83%) had R0 resections, and 7 (20%) had adjuvant radiation prior to enrollment. As of Dec 2021, 31 patients have completed the treatment phase. Of the 35 patients treated on study, 20 patients have recurred (7 local, 5 distant, 3 regional, 5 sites unconfirmed), 6 stopped therapy due to adverse effects, and 8 have died. The mean age of patients was 65.8 years and 21 (60.0%) were female. The primary site of disease was vulvovaginal N=12 (32.4%) patients, sinonasal N= 11 (29.7%), anorectal N= 9 (24.3%) and other site N= 5 (13.5%). Adjuvant radiation had been given in 7 pts. Driver mutations were rare, with only 3 (8.6%) patients having a KIT mutation, and one patient (2.9%) each having a NRAS or BRAF mutation. RFS rates at 1 and 2 years were 50% (95% CI 31-66%) and 37% (95% CI 19-55%), with OS rates at 1 and 2 years of 87% (95% CI 68-95%) and 68% (95% CI 46-83%). Median RFS was 10.3 m (95% CI5.7-25.8). Most common grade 3 adverse events were diarrhea (14%), hypertension (14%), hyponatremia (11%), with no grade 4/5 toxicities. **Conclusions:** Flip dose ipilimumab and nivolumab after resection is associated with outcomes improved over previously reported outcomes in the absence of therapy. Long term follow up is ongoing as are subgroup analyses and correlative studies. Clinical trial information: NCT03241186. Research Sponsor: Bristol Myers Squibb.

9574 **Poster Session**

Primary ipilimumab/nivolumab followed by adjuvant nivolumab in patients with locally advanced or oligometastatic melanoma: Update on outcome. *First Author: Emilia Cocorocchio, Istituto Europeo di Oncologia, IRCCS, Milano, Italy*

Background: The aim of neo-adjuvant therapy in locally advanced or oligometastatic melanoma is to facilitate radical resection, improve outcomes and undertake research to identify biomarkers of response and resistance. The optimal schedule to balance efficacy vs toxicity in dual PD1/CTLA4 blockade regimens remains a matter of debate. We initiated an open- label, single arm study to investigate the Nivo 3/ Ipi 1 schedule as primary treatment of locally advanced or oligometastatic melanoma patients (pts). **Methods:** Treatment schedule consists in 4 neoadjuvant cycles of Ipilimumab 1 mg/kg and Nivolumab 3 mg/kg every 3 weeks, followed by surgery and adjuvant Nivolumab 480 mg every 4 weeks for 6 cycles. Primary objective is pathological complete remission (pCR) rate, according to Neoadjuvant Melanoma Consortium criteria. Secondary objectives are: safety, feasibility and efficacy; QoL; identification of molecular and immunological biomarkers of response and resistance (somatic genetic drivers, tumor mutational burden, mutational signatures, predicted neoantigens, germline HLA typing, somatic HLA mutations and liquid biopsy); degree of immune activation; evaluation of microbioma **Results:** From March 2019 to April 2021, 35 pts were included within the trial. All pts completed the treatment program. 6 pts (17%) developed immune-related (IR) G3-4 adverse events (AE): 3 transaminitis, 1 pneumonitis, 1 myocarditis and 1 CPK increase; all of them but one underwent surgery after toxicity resolution. 4 pts (11%) experienced G3-4 non-IR AE. 31 pts underwent surgery after neoadjuvant phase: pCR, near pCR, pathological partial remission (pPR) and pathological no response (pNR) were achieved in 18 (58%), 2 (7%), 4 (13%) and 7 (22%) cases, respectively. 2 pts progressed before surgery and 8 pts progressed during/after adjuvant phase (6/8 in NR at surgery). 4 pts died, 3 after disease progression and 1 for ischemic stroke 5 months after the end of therapy. At 18 months, progression free survival (PFS) and overall survival (OS) were 80 and 85%, respectively (median follow-up: 23 months); non responders (pNR) have a higher risk of relapse or death vs responders (pCR+near pCR+pPR) [HR= 4.11, 95%CI (0.96 -17) adjusted for age, p=0.06]. **Conclusions:** Our study lends further support to the adoption of the Nivo 3/ Ipi 1 schedule as primary treatment for locally advanced/oligometastatic melanoma, as this regimen achieved a pCR/near pCR rate of 65% with a rate of severe IR-AEs (17%) lower than previously reported in CheckMate 511 trial (34%) using Nivo3/ Ipi1 schedule. Available translational data on potential genomic biomarkers of response, gut microbiome and systemic inflammatory landscape evaluated longitudinally during therapy on each patient will be presented. Clinical trial information: 2018-002172-40. Research Sponsor: BMS.

Efficacy and safety of "second adjuvant" therapy with BRAF/MEK inhibitors after resection of recurrent melanoma following adjuvant PD-1–based immunotherapy. *First Author: Amelia M. Taylor, Melanoma Institute Australia, Sydney, Australia*

Background: Both anti-PD-1 antibodies and BRAK/MEK inhibitors (BRAF/MEKi) reduce the risk of recurrence for patients with resected stage III melanoma. For patients with V600 BRAF-mutated melanoma who recur with resectable disease on or after adjuvant, many may be suitable for 'second adjuvant' treatment after surgery. We sought to examine the efficacy and safety of 'second adjuvant' BRAF/MEKi in patients who recurred despite adjuvant PD-1 based immunotherapy. **Methods:** Patients with V600 BRAF-mutated melanoma treated with adjuvant PD-1 based immunotherapy for resected stage III/IV disease who recurred, underwent resection of recurrence and were then treated with adjuvant BRAF/MEKi were identified retrospectively from 13 centres. Demographics, disease characteristics, treatment details, and outcome data were examined. **Results:** 55 patients were included; median age at commencement of PD-1 was 53y, most were V600E (91%) and had IIIB (42%) or IIIC (44%) melanoma. PD-1 based adjuvant therapy included nivolumab (71%), nivolumab plus ipilimumab (14%), pembrolizumab (13%) and pembrolizumab plus mRNA-4157 vaccine (2%). Patients had initial recurrence after mean 8.4 months (95% CI 7.4-10.6), mainly while on treatment (65%), in regional nodes (42%), in-transit metastases (ITMs; 38%), both regional nodes and ITMs (7%) and distant metastases (13%). Surgical management included CLND (36%), selected nodal resection (11%), ITM resection (33%) and resection of distant metastasis (13%). A minority had adjuvant radiotherapy (17%). Stage at start of second adjuvant BRAF/MEKi included IIIB (29%), IIIC (53%) IIID (4%) and IV (15%). Patients received dabrafenib and trametinib (95%, N = 52) and encorafenib and binimetinib (5%, N = 3). After a median follow up of 21.4 months (19.7-25.4), 17 (31%) patients have recurred again. Mean duration of treatment was 9 months (95% CI 7.4-10.6); 20% ceased for toxicity, 7% for recurrence and 35% were on treatment at last follow up. The most common toxicity was pyrexia (43%) and 21% patients experienced a severe (G3-4) adverse event. Median RFS was 33.4 months (14.3.7-NR) and median DMFS was not reached. At 12 months, 72% (59-88) of patients were recurrence free and 90% (81-100) were free of distant recurrence. For those whose disease recurred again, most recurred after cessation of second adjuvant BRAF/MEKi (13/17, 76%). 7 (41%) recurred locally and 8 (47%) recurred with new metastatic disease but none had brain metastases. **Conclusions:** This is the first study examining outcomes of patients receiving second adjuvant targeted therapy for melanoma, after failure of adjuvant PD-1 based immunotherapy. While RFS appears shorter compared to first line trials, second adjuvant treatment with BRAF/MEKi appears safe and active in preventing further recurrence. Further data on sequencing adjuvant therapies are needed. Research Sponsor: None.

A single-center experience of 98 patients (pts) with regionally metastatic Merkel cell carcinoma (MCC) of known (MCCKP) and unknown (MCCUP) primary at presentation. *First Author: Brandon Cope, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: MCC is a rare skin cancer historically associated with poor survival rates and which is increasing in incidence. A small number of retrospective series suggest that MCCUP may be associated with better prognosis than MCCKP while others report worse outcomes. Recent advances in immunotherapy have changed the multimodal treatment landscape and outcomes of advanced MCC pts. We describe our experience with the management and outcomes of pts presenting with regional MCC metastasis of known and unknown primary origin. **Methods:** A retrospective review of pts with clinical regional disease at MCC diagnosis treated at our institution from 3/2003-3/2021 was performed. Clinicopathologic variables and outcomes were assessed. Overall survival (OS), recurrence-free survival (RFS) and progression-free survival (PFS) were estimated by the Kaplan Meier method. **Results:** Of 98 pts with regional disease on exam at presentation, 56 (57%) had MCCUP and 42 (43%) had MCCKP. Median follow-up from diagnosis to last follow-up or death was 33 months. Pts were generally older (MCCUP vs MCCKP: 68.7 vs 73.1 years), male (MCCUP vs MCCKP: 82% vs 74%) and Caucasian (MCCUP vs MCCKP: 84% vs 83%). Over half the pts had a history of another malignancy (MCCUP vs MCCKP: 52% vs 60%) with 9% and 14% being immunocompromised at diagnosis, respectively. After completion of staging workup, MCCUP pts had earlier stage disease at presentation compared with MCCKP pts (stage IIIA: 80% vs 55%, IIIB: 5% vs 31%, IV: 15% vs 14%, respectively). The cervical nodal basin was most commonly involved in MCCUP pts while regional disease was more varied in MCCKP pts (MCCUP vs MCCKP: cervical 54% vs 28%, axillary 15% vs 33%, inguinal 33% vs 3%, inguinal and pelvic 0% vs 11%, in transit 0% vs 14%). Formal lymphadenectomy (LND) was performed in 27 (48%) and 18 (43%) of MCCUP and MCCKP pts, respectively. Of these pts, 33% and 50% received neoadjuvant systemic therapy, most commonly immunotherapy; 70% and 55% received adjuvant radiotherapy. MCCUP pts had better outcomes compared to MCCKP pts (Table), with longer RFS in pts who underwent LND (not reached [NR] vs 13.1 months) as well as longer PFS in pts who did not undergo LND (17 vs 9 months) with longer OS in both subgroups (LND: NR vs 102.7 months; no LND: 74.4 vs 48.7 months). **Conclusions:** MCCUP patients with regional disease on exam at presentation have improved survival compared to MCCKP. Current stage III survival estimates may underestimate survival in patients with resectable disease. Research Sponsor: None.

Last known status of MCCUP and MCCKP patients presenting with regional disease on exam.

All pts	MCCUP (n=56)	MCCKP (n=42)
Alive, no evidence of disease (NED)	28 (50%)	12 (28.6%)
Alive with disease (AWD)	11 (19.6%)	10 (23.8%)
Deceased	17 (30.4%)	20 (47.6%)
Pts who underwent LND	**MCCUP (n=27)**	**MCCKP (n=18)**
NED	19 (70.4%)	4 (23.5%)
AWD	4 (14.8%)	5 (29.4%)
Deceased	4 (14.8%)	8 (47.1%)

9577 **Poster Session**

Adjuvant treatment of in-transit melanoma: Addressing the knowledge gap left by clinical trials. *First Author: Melissa Melanie de Meza, Leiden University Medical Center, Leiden, Netherlands*

Background: Few clinical trials address the efficacy of adjuvant systemic treatment in patients with ITM. This study describes the efficacy of adjuvant systemic therapy of ITM patients beyond the clinical trial setting. **Methods:** All stage III adjuvant-treated melanoma patients registered in the nationwide Dutch Melanoma Treatment Registry between 01-07-2018 and 31-12-2020 were included. Patients were divided into three groups: patients with ITM only, with ITM and nodal disease, and patients with nodal disease only. Differences in recurrence patterns were analysed. An exploratory analysis was performed for stage III patients who underwent surgical resection without adjuvant treatment. Recurrence-free survival (RFS) and overall survival (OS) at 12-months were assessed. **Results:** A total of 1037 stage III melanoma patients received adjuvant anti-PD-1 therapy, and 260 underwent surgical resection only. Of the adjuvant-treated patients, 16.9% had ITM only, 15.5% had ITM with nodal disease, and 66.8% had nodal disease only. Of the surgical resection only patients 20.4% had ITM only, 12.3% had ITM with nodal disease and 67.3% had nodal disease only. In the adjuvant-treated patients, 12-months RFS was comparable between patients with ITM only and patients with nodal disease only (71.1% vs. 72.2% respectively, p = 0.95), but significantly lower for patients with ITM and nodal disease (57.1%; ITM with nodal disease vs. ITM-only p = 0.01, and ITM with nodal disease vs. nodal disease only p < 0.01). Locoregional metastases occurred as first recurrence site in 72.7% of ITM-only patients, 42.9% of ITM and nodal disease patients and 38.9% of patients with nodal disease only, while distant recurrences occurred in 18.2% of patients with ITM only, in 36.7% of patients with ITM and nodal disease, and in 42.3% of patients with nodal disease only (p = 0.01). OS at 12-months was significantly higher for ITM-only patients compared to patients with ITM and nodal disease (97.7% vs. 90.6%, p < 0.01), and was better compared to patients with nodal disease only (97.7% vs. 94.4%, p = 0.05). OS at 12-months was comparable for patients with ITM and nodal disease and patients with nodal disease only (p = 0.19). In general, surgery-only ITM patients were older and had a worse performance score. 12-months RFS appeared worse compared to adjuvant-treated ITM patients (36.6% vs. 68.3%). In this group of surgery-only ITM patients OS at 12-months also appeared worse compared to adjuvant-treated ITM patients (89.7% vs. 95.5%). **Conclusions:** RFS rates in ITM-only patients are similar to non-ITM patients, while RFS in patients with ITM and nodal disease is shorter. Adjuvant-treated patients with ITM without nodal disease less often experience distant recurrences and have a superior OS compared to other adjuvant stage III patients. Our results suggest that other treatment strategies for ITM patients with nodal disease should be considered. Research Sponsor: None.

Adjuvant temozolomide plus cisplatin versus high-dose interferon alpha-2b in resected mucosal melanoma: A randomized, multicenter, controlled, phase III trial. *First Author: Bin Lian, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: Mucosal melanoma (MuM) is a rare cancer with an extremely poor prognosis and no established standard adjuvant therapy. A phase II trial showed promising outcomes with adjuvant temozolomide plus cisplatin (Chemo) versus high-dose interferon alpha-2b (HDI) in resected mucosal melanoma. We conducted the phase III trial to definitively compare these two treatments. **Methods:** In this multicenter, randomized, controlled, phase III trial, patients with pathologically confirmed stage I-III mucosal melanoma who had undergone complete resection were stratified by primary site (head and neck vs. non-head and neck) and disease stage (I/II vs. III) and randomized 1:1 to receive Chemo (temozolomide 200 mg/m^2/day orally on days 1 to 5 plus cisplatin 75 mg/m^2 i.v. on days 1-3, repeated every 3 weeks for six cycles) or HDI (15×10^6 U/m^2/day i.v on days 1 to 5 each week for 4 weeks followed by 9×10^6 U three times per week for 48 weeks). Postoperative radiotherapy was recommended for head and neck MuM patients, with a total dose of 65-70 Gy/30-35 fx to GTV and 60 Gy/30 Fx to CTV. The primary endpoint was relapse-free survival (RFS). Secondary endpoints included distant metastasis-free survival (DMFS), overall survival (OS), and safety. The protocol was registered at ClinicalTrials.gov (NCT03435302). **Results:** Between Feb 2014 and Jun 2016, 204 patients were randomized to treatment (Chemo group: n = 103, HDI group: n = 101). Baseline characteristics were generally well balanced between the two groups. Anatomic site of head and neck, gastrointestinal, gynecological were 38.8% vs 49.5%, 35.9% vs 22.8%, 25.2% vs 27.7% in Chemo and HDI group, respectively. Stage of I/II, III were 68.9% vs 73.3%, 31.1% vs 26.7% in Chemo and HDI group, respectively. CKIT, BRAF, NRAS Mutation were 7.0% vs 8.2%, 5.0% vs 8.2%, 13.4% vs 15.8% in Chemo and HDI group, respectively. In the ITT population, At a median follow-up of 64.8 months, patients receiving Chemo had a higher median RFS (15.5 vs. 9.9 months; HR = 0.622; 95% CI, 0.463 to 0.836; P = 0.001), DMFS (19.5 vs. 12.7 months; HR = 0.705; 95% CI, 0.518 to 0.959; P = 0.025) and OS (38.2 vs. 33.5 months; HR = 0.832; 95% CI, 0.598 to 1.155; P = 0.270) versus the HDI group. A subgroup analysis revealed consistent improvements in RFS, DMFS and OS with Chemo versus HDI across multiple subgroups. Toxicities were generally mild to moderate in both groups. The most common adverse events were fatigue, anorexia, nausea/vomiting, leukopenia, Neutropenia, hepatotoxicity, fever and anemia, 23 patients (22.3%) in Chemo group and 57 patients (56.4%) in HDI group had a grade 3 or 4 adverse events. **Conclusions:** Adjuvant temozolomide plus cisplatin led to a significantly lower risk of relapse and distant metastasis in patients with resected mucosal melanoma versus high-dose IFN-a2b and was generally well tolerated. Clinical trial information: NCT03435302. Research Sponsor: National Natural Science Foundation of China, Beijing Municipal Administration of Hospitals' Youth Programme.

Leveraging personalized circulating tumor DNA (ctDNA) for detection and monitoring of molecular residual disease in high-risk melanoma. *First Author: Sofia Genta, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: High-risk melanoma has variable prognosis. Adjuvant immuno- (IO) and targeted therapy (TT) are approved for stage III-IV resected disease. However, a significant proportion of patients (pts) are cured by local treatment alone or relapse despite adjuvant therapy. Liquid biopsy with ctDNA assays have been used to predict response to treatment and identify pts at higher risk of progression/death. Personalized ctDNA assays are a highly sensitive approach that may enhance upfront risk stratification and early detection of relapse. **Methods:** Serial ctDNA Monitoring as a predictive Biomarker in advanced neoplAsms (SAMBA) is a Princess Margaret prospective ctDNA kinetics study (NCT03702309) in high-risk melanoma pts. Plasma is collected pre-op (pre-local treatment, if feasible), post-op (after surgery), and every 3-6 months (m) until radiological progressive disease (rPD). Personalized amplicon based NGS assays by Inivata (RaDaR) were used to detect somatic variants in ctDNA identified through whole-exome sequencing of matched tumor tissue. Progression free survival (PFS) and overall survival (OS) from the time of surgery were estimated with the Kaplan Meier and compared with the log-rank test. **Results:** As of December 2021, 82 of 100 planned pts have been enrolled. A total of 191 samples from 47 pts have been analyzed. Median age was 66 years (27-87), 33 were male (70%). Seven (15%), 30 (64%) and 10 (21%) were stage II/III/IV respectively. All pts had surgery and 8 (17%) adjuvant radiation. No systemic therapy was given to 11 pts (23%); 30 (64%) had IO and 6 (13%) TT. rPD occurred in 13 pts (28%). Median follow up was 24 months. A median of 48 variants were included in the personalized ctDNA panel design (35-52). ctDNA was detected (ctDNA+) at any time point in 12/47 pts (26%), of which 5/12 (42%) were *BRAF* and *NRAS* wt on tissue. Median PFS was 4.9 months (m) for ctDNA+ pts and not reached (NR) for ctDNA- pts at post-op (HR = 2.71 CI 0.60-12.31, p = 0.179). Median OS was 23.1 m vs NR in ctDNA+ vs ctDNA- pts (HR = 8.9, CI 1.45-54.77, p = 0.004). Two ctDNA+ pts had neoadjuvant IO and became ctDNA- before surgery. One, free of disease after 12 m, had ctDNA- in 4 follow up samples. The other pt was ctDNA+ in the post-op sample and relapsed within 3 m. Four of 45 (9%) pts had ctDNA+ at post-op. Two of them, including a pt who had neoadjuvant IO, did not receive adjuvant therapy and had rPD within 3 m. The other 2 pts received adjuvant IO; ctDNA cleared and pts remain free of disease at 12 and 34 m. Three pts with rising ctDNA over time experienced rPD after a median of 4 m (2-7). **Conclusions:** Personalized ctDNA analysis with RaDaR may improve risk of death stratification and selection of pts who could benefit from adjuvant treatment. Detection of ctDNA may precede rPD. Follow-up will continue in pts with rising ctDNA who have not yet had rPD. Pts accrual and sample collection are ongoing, and additional data will be presented. Clinical trial information: NCT03702309. Research Sponsor: Princess Margaret Cancer Center institutional founding, Princess Margaret Cancer Foundation.

Neoadjuvant dabrafenib and trametinib (D+T) for stage III melanoma: Long-term results from the NeoCombi trial. *First Author: Alexander M. Menzies, Melanoma Institute Australia, The University of Sydney, and Royal North Shore and Mater Hospitals, Sydney, NSW, Australia*

Background: Neoadjuvant D+T has a high pathologic response rate and impressive short-term survival. The NeoCombi trial (NCT01972347) enrolled 35 patients with resectable stage III melanoma, with last patient commencing treatment April 19th 2017. We report 5-year outcomes from this trial. **Methods:** Pts received 12 wks neoadjuvant standard dose D+T, then 40 wks adjuvant D+T. Eligible pts were ≥ 18 yrs, ECOG PS ≤ 1 with clinical stage III BRAF V600E/K melanoma. CT and PET scans were performed at baseline and prior to surgery. Pathologic response was determined as per International Neoadjuvant Melanoma Consortium (INMC) criteria and defined as complete (pCR), near complete, partial (pPR) or no response (pNR). CT monitoring was continued 12 wkly thereafter to 2 yrs, then 6 monthly to 3 yrs, then as standard care. The primary endpoints were the complete pathological response (pCR) and RECIST response rate (rRR) at wk 12. Secondary endpoints included relapse free survival (RFS), OS, and toxicity. **Results:** 35 pts were enrolled, 6 with IIIB, 29 IIIC (7 ITM only) disease (clinical AJCCv7). At data cut August 17th 2021, median F/U was 60 mo (95% CI 56-72). No patients progressed in the neoadjuvant phase, and (49%) had a pCR, 1 near pCR, 6 pPR, 11 pNR. 5-year RFS, DMFS and OS data are shown in the Table. The majority of recurrences occurred within the first 2 years, with no recurrences beyond 3y. 21 patients recurred; 12 (57%) had first recurrence locoregional (6/12 subsequent distant recurrence) and 9 (43%) had first recurrence in distant sites (3/9 in brain). Locoregional recurrence was managed with surgery alone in 4/12, systemic therapy alone in 2/12, or both surgery and systemic therapy in 5/12 (4/5 had adjuvant systemic therapy), 1 pt was observed until distant recurrence. Subsequent systemic therapy in the 15 patients with a distant recurrence included PD-1 based immunotherapy (N=14) and BRAF targeted therapy (N=10). **Conclusions:** Neoadjuvant D+T in clinical stage III melanoma has impressive early activity, however patients remain at high risk of recurrence. Pathologic response can identify patients at the highest risk of recurrence, offering a chance of alternative adjuvant therapy in non-responders. Clinical trial information: NCT01972347. Research Sponsor: GlaxoSmithKline, Novartis, National Health and Medical Research Council, Australia; and Melanoma Institute Australia.

	5y RFS	5y DMFS	5y OS
All (N=35)	40%	57%	80%

Health-related quality of life (HRQoL) with pembrolizumab (pembro) in resected high-risk stage II melanoma in the phase 3 KEYNOTE-716 study. *First Author: Muhammad Adnan Khattak, Fiona Stanley Hospital and Edith Cowan University, Perth, Western Australia, Australia*

Background: Adjuvant pembro improved RFS vs placebo (HR, 0.61; 95% CI, 0.45-0.82) and had manageable safety in patients (pts) with resected high-risk stage II melanoma at second interim analysis of KEYNOTE-716 (NCT03553836). HRQoL results are presented. **Methods:** Pts aged ≥12 y with resected stage IIB/C melanoma were randomized 1:1 to adjuvant pembro 200 mg (2 mg/kg for pts ≥12 and < 18 y) Q3W or placebo for ≤17 cycles. Change from baseline in HRQoL was an exploratory end point. EORTC QLQ-C30 and EQ-5D-5L were administered at baseline; cycles 5, 9, 13, and 17 in y 1; every 12 wk in y 2; and every 6 mo in y 3. The HRQoL population included all pts who received ≥1 dose of study treatment and had ≥1 HRQoL assessment available. Least-squares mean (LSM) change from baseline to wk 48 in EORTC QLQ-C30 global health status (GHS)/quality of life (QoL) and physical functioning (PF) and EQ-5D-5L visual analog scale (VAS) were calculated using a constrained longitudinal data analysis model; HRQoL score was the response variable with treatment by time interaction and T stage at baseline as covariates. Empirical mean change from baseline in QLQ-C30 GHS/QoL and PF scores over time was evaluated. A ≥10-point improvement or decline in QLQ-C30 scores was considered clinically meaningful. Data cutoff was June 21, 2021. **Results:** Of 976 pts enrolled, 969 were included in the HRQoL population (483 pembro; 486 placebo). Median follow-up in the ITT population was 20.5 mo (range, 4.6-32.7). At wk 48, compliance (adherence) for EORTC QLQ-C30 was 83.4% for pembro and 89.3% for placebo and completion was 70.6% and 75.7%, respectively. At wk 48, compliance for EQ-5D-5L was 84.1% for pembro and 90.0% for placebo and completion was 71.2% and 76.3%, respectively. QLQ-C30 GHS/QoL and PF and EQ-5D-5L VAS scores were similar between arms at baseline. LSM change from baseline to wk 48 in QLQ-C30 GHS/QoL score was –4.49 (95% CI, –6.19 to –2.79) for pembro and –0.82 (95% CI, –2.47 to 0.83) for placebo (LSM difference: –3.67; 95% CI, –5.91 to –1.44). LSM change from baseline to wk 48 in QLQ-C30 PF score was –3.27 (95% CI, –4.61 to –1.92) for pembro and –1.77 (95% CI, –3.07 to –0.46) for placebo (LSM difference: –1.50; 95% CI, –3.33 to 0.32). LSM change from baseline to wk 48 in EQ-5D-5L VAS score was –2.19 (95% CI, –3.52 to –0.85) for pembro and –0.25 (95% CI, –1.54 to 1.04) for placebo (LSM difference: –1.94; 95% CI, –3.72 to –0.16). LSM change from baseline to wk 48 in other QLQ-C30 functioning and symptom scales was similar in both arms. Empirical mean change from baseline in QLQ-C30 GHS/QoL and PF was similar over 96 wk in both arms. **Conclusions:** No clinically meaningful decreases in EORTC QLQ-C30 or EQ-5D-5L VAS scores were observed for adjuvant pembro or placebo. These results, along with improved RFS and manageable safety, support the use of adjuvant pembro in resected high-risk stage II melanoma. Clinical trial information: NCT03553836. Successful management of Australian patients with extensive skin field cancerization (ESFC) with widefield volumetric arc radiation therapy (VMAT): Report with 12-month follow-up. *First Author: Walter J Curran, GenesisCare, Atlanta, GA*

Background: Non-melanomatous skin cancer (NMSC) diagnoses are associated with a high risk of developing new skin cancers in adjacent areas. Patients with extensive skin field cancerization (ESFC) have large areas (generally ≥50cm^2) of compromised skin characterized by pre-cancerous actinic keratoses often requiring repeated interventions. Lesion-directed therapies have excellent cure rates, but therapies targeting a wider region have limited durability, including topical agents such as 5-flurouracil. The development of volumetric modulated arc radiation therapy (VMAT) to precisely target large, curved skin surfaces has generated interest in its application to ESFC. This is a report on the efficacy, safety, and cosmetic outcomes of VMAT in the management of patients with ESFC at facilities across five Australian states. **Methods:** Sixty-three ESFC zones on 60 patients were prescribed widefield VMAT and prospectively enrolled in the National (Australian) Dermatology Radiation Oncology Registry (NDROR). Over 80% of patients had received up to 4 prior non-radiotherapy interventions. Fields included lower and upper limb, face, scalp, or trunk regions. Total widefield VMAT RT doses ranged from 45-50 Gy delivered in 25-30 daily fractions across 5-7 weeks. 3-, 6-, and 12-month follow-up assessments rated the percentage of disease clearance, cosmesis using the Lovett's scale, and toxicity based on CTCAE. **Results:** At 12-month follow-up, 97% of treated zones had achieved and maintained clinical success, defined as > 90% field clearance. Five percent of patients exhibited recurrence of original disease, whereas 10% of patients developed a new actinic keratosis or NMSC. Cosmesis was rated as excellent or good in 98% of patients. Most patients exhibited grade 1-2 radiation-induced dermatitis during therapy, which resolved by 3-month follow-up. Grade 3 dermatitis at end of treatment was exhibited in 7% of the patients, which also resolved. Eight percent of patients discontinued treatment due to acute toxicities. The most common persistent toxicity at 12-month follow-up was localized grade 1 xerosis (dryness) at 43% and/or alopecia at 33%. **Conclusions:** Widefield VMAT achieved very promising clinical success in patients with ESFC for whom other therapies had failed. VMAT yielded favorable cosmetic outcomes, and treatment-related toxicity was manageable and transient in most patients. While additional follow up is necessary, these results demonstrate that widefield VMAT may be an excellent option for some patients with increasingly unmanageable presentations of ESFC. Research Sponsor: GenesisCare.

Sentinel lymph node biopsy in Merkel cell carcinoma: A multi-institutional study from the Pan-Canadian Merkel Cell Collaborative. *First Author: Megan Delisle, University of Ottawa, Ottawa, ON, Canada*

Background: There is controversy regarding sentinel lymph node biopsy (SLNB) in clinically node-negative Merkel Cell Carcinoma (MCC). We compared MCC recurrence and survival between patients who did versus did not undergo a SLNB. **Methods:** Patients with MCC across 13 Canadian centers were reviewed, from 2000-2018. Of a total cohort of 750 patients, 485 had clinically node-negative disease at presentation. A propensity score was created. The association between SLNB and local, regional and distant recurrence, and cancer-specific and overall survival were evaluated using competing risks and Cox proportional hazards regression. **Results:** 195 patients (40.2%) underwent a SLNB. SLNB was performed more commonly in younger, healthier patients with MCC located in the extremities or torso (Table). The results of 177 SLNBs were available; 60 (33.9%) were positive. SLNB-positive patients underwent completion dissection (n=15, 25%), completion dissection and nodal radiation (n=22, 36.7%), nodal radiation alone (n=18, 30%) or observation (n=5, 8.3%). Patients who did not undergo a SLNB underwent nodal radiation alone (n=40, 13.8%) or observation (n=250, 86.2%). The median follow-up was 2.7 years (range 0.2-14.4). The regional recurrence rate was 14.5% (n=17) among SLNB-negative versus 15% (n=9) among SLNB-positive patients. Among patients who did not undergo a SLNB, the regional recurrence rate was 25.2% (n=63) among those who underwent observation and 15% (n=6) among those who received nodal radiation alone. After propensity score matching, SLNB patients had a lower risk of regional recurrence (sHR 0.54 95% CI 0.34-0.86 p=0.01) and improved overall survival (HR 0.32 95% CI 0.23-0.45 p<0.01), but there was no difference in local recurrence (sHR 0.92 95% CI 0.50-1.69 p=0.79), distant recurrence (sHR 0.88 95% CI 0.52-1.49 p=0.63), or cancer-specific survival (HR 0.67 95% CI 0.31-1.45 p=0.31). **Conclusions:** SLNB is associated with a reduced risk of regional recurrence and improved overall survival. The role of SLNB in selecting patients for emerging therapies, such as immunotherapy, needs to be evaluated. Research Sponsor: None.

Analysis of the effect of systemic corticosteroids on survival from tebentafusp in a phase 3 trial of metastatic uveal melanoma. *First Author: Alexandra Ikeguchi, University of Oklahoma, Oklahoma City, OK*

Background: All immune therapies that rapidly activate T cells, including T cell engagers, can induce cytokine release syndrome (CRS). Tebentafusp (tebe), a T cell receptor bispecific (gp100 x CD3) can also induce skin adverse events (AEs), due to gp100+ cutaneous melanocytes. CRS and skin AEs may require management with short term corticosteroids, which may also be used as premedication for subsequent tebe doses. Here we report the first analysis of systemic corticosteroid use and correlation with efficacy from a Phase (Ph) 3 trial for any T cell engager. **Methods:** Post hoc analyses were performed on the tebe arm of the Ph3 [NCT03070392] study in previously untreated HLA-A*02:01+ metastatic uveal melanoma (mUM) (N = 245). Due to the low rate of severe AEs in Ph1 trials, prophylactic corticosteroids were not mandated. The association between overall survival (OS) and corticosteroid use (new start within 30 days of first tebe dose) was investigated using landmark analyses in the safety population. Multivariate analyses were adjusted for key patient characteristics and AEs of special interest: CRS, rash, and liver function test (LFT) elevation. Steroid type (hydrocortisone vs. others) and treatment duration (1 vs. > 1 day) were also investigated. **Results:** In the Ph3 trial, 64/245 (26%) patients received new systemic corticosteroid within 30 days after the first dose of tebe, mostly for treatment of AEs (56/64, 88%) or pre-medication due to previous AE (14/64, 22%). 25 of the 64 patients received corticosteroids only for a single day. The most frequent AEs (≥15%) were rash (18/64, 28%), CRS (15/64, 23%), and hypotension (12/64, 19%). In a logistic regression model, elevated baseline LDH, the dominant prognostic marker, was most strongly associated with use of corticosteroids (p = 0.01). In the multivariate analysis, corticosteroids were not associated with any significant OS difference (HR 1.41, 95% CI 0.83-2.4, p = 0.2) and this effect did not differ in patients with or without CRS, rash or LFT elevation (all interaction tests p > 0.2). There was no difference in OS according to corticosteroid type or whether administered for 1 vs > 1 day. **Conclusions:** This is the first analysis from a phase 3 trial of the impact of systemic corticosteroids on survival for a T cell engaging cancer therapy. The vast majority of tebe-treated patients (84%) either did not require corticosteroids (74%) or only received them on a single day (10%). The most frequent reason for corticosteroid use was an emergent AE, including CRS and rash. Corticosteroid use following the pre-specified AE guidelines was not associated with any significant impact on OS. Clinical trial information: NCT03070392. Research Sponsor: Immunocore.

Treatment with tebentafusp beyond radiographic progressive disease (PD) in metastatic uveal melanoma (mUM). *First Author: Ryan J. Sullivan, Massachusetts General Hospital, Boston, MA*

Background: Tebentafusp (tebe) is the first T cell receptor therapeutic to demonstrate overall survival (OS) benefit in a randomized Phase 3 study vs investigator's choice (IC) [NCT03070392]. OS benefit was also observed in patients (pts) with best objective response (BOR) PD (HR 0.43), and in pts who had tumor growth ≥20% as best change in tumor size (HR 0.41), suggesting tebe-treated pts may exhibit atypical radiological responses and could benefit from treatment beyond radiographic progression (TBP), a well-established concept in immuno-oncology. Here we analyzed tumor kinetics and clinical benefit in pts treated with tebe beyond initial radiographic progression (TBP). **Methods:** 378 mUM pts were randomized 2:1 to tebe vs. IC. BOR was assessed by investigators using RECIST v1.1. TBP was permitted until: 1) additional ≥20% increase in tumor burden with absolute increase of ≥5 mm, or 2) unequivocal PD of non-target lesions; or 3) new non-measurable lesions. A Cox model adjusted for baseline covariates and for covariates at time of progression for TBP-eligible pts was used to compare survival post progression between those who did (TBP) and did not receive TBP (non-TBP). Stepwise selection of covariates (using $p < 0.1$ as the entry and staying criterion) was applied. Analysis performed on data cut-off 13Oct2020. **Results:** 183 tebe pts were eligible for TBP per protocol; 60% (109/183) received TBP with median duration of 8 wks. 21% of all tebe doses were administered as TBP. The proportion of pts with new lesions at initial progression (44% vs 57%) and median time to initial progression (2.9 mo vs 2.9 mo) were similar between TBP and non-TBP pts. Pts receiving TBP were more likely to have favorable key prognostic factors at baseline or at time of progression. After adjusting for these differences, a numerical benefit in post-progression OS favoring TBP was observed (HR 0.67, 95% CI [0.38,1.19]). Serial review of radiographic time points identified initial progression of sum of target lesions followed by stabilization for > 3 months after initial progression in some TBP pts. Safety profile during TBP was consistent with that expected for pts established on tebe and no pts experienced an AE leading to treatment discontinuation. **Conclusions:** An OS benefit observed for tebentafusp among mUM patients who have initial radiographic progression demonstrates that RECIST assessment underestimates benefit. In a post-hoc analysis of OS following initial radiographic progression, continued treatment with tebentafusp was associated with numerically longer OS after adjusting for key prognostic variables. Tebentafusp treatment beyond progression was tolerated without new safety signals and, in some patients, was associated with radiological stabilization of sum of target lesions for > 3 months following the initial progression. Clinical trial information: NCT03070392. Research Sponsor: Immunocore.

9586 **Poster Session**

Randomized phase II study of adjuvant sunitinib or valproic acid in high-risk patients with uveal melanoma: The final analysis of cohort 1. *First Author: Rino S. Seedor, Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA*

Background: Despite successful treatment of primary uveal melanoma (UM), tumors with monosomy 3 and 8q amplification (M3 + 8q amp) or DecisionDx-UM Class 2 have high metastatic death rates. We report the final analysis of Cohort 1 in the randomized phase II clinical trial of 6 months of adjuvant sunitinib or valproic acid (VPA) in high-risk UM patients. **Methods:** High risk for systemic metastasis was defined as the following: A) M3 + 8q amp; B) Class 2. Patients within 6 months of initial treatment of primary UM were randomized 1:1 to receive either sunitinib 25 mg daily or VPA 750 mg daily for 6 consecutive months. The primary endpoint was to evaluate the improvement of 2-year overall survival (OS) rate from 70% (historical references) to 85% in each arm. Secondary endpoints included 1) systemic relapse-free survival (RFS) rate at 18 months, 2) ability to complete adjuvant treatment and, 3) toxicity assessment. **Results:** Eighty-eight patients were included in the final analysis. There were no differences in tumor size or T stage between the two treatment arms. Nine of 45 patients in the sunitinib arm and 4 of 43 patients in the VPA arm could not complete the 6-month treatment due to toxicity (sunitinib n = 6, VPA n = 2) or systemic progression (sunitinib n = 3, VPA n = 2). All but 9 patients (death due to metastasis, sunitinib n =4, VPA n = 5) were followed for at least 2 years. With a median follow-up of 52.6 months, both drugs met the primary end point with 2-year OS rates of 95.6% (sunitinib, 90% CI 86.5-98.6%) and 90.7% (VPA, 90% CI 80.1-95.8%). The 18-month RFS rates were 75.6% (sunitinib, 90% CI 63.1-84.3%) and 62.8% (VPA, 90% CI 49.4-73.5%). Although not statistically significant, there was a trend of superior RFS with sunitinib over VPA in primary UM with T-stage 3-4 (p=0.131) or >12mm (p=0.129). There was no significant difference in median RFS in HLA-A*02:01 positive or negative status (24.6 vs. 24.8 months). It is of note that the potential survival benefit of sunitinib over VPA diminished after 3 years, indicating longer duration of sunitinib administration might be required. In the multivariable Cox analysis, the RFS was not significantly different in the two treatment arms, but increase of tumor diameter was associated with increase hazard of progression (HR=1.23, 95% CI: 1.13, 1.33; p<0.001). **Conclusions:** Six months of adjuvant sunitinib or VPA resulted in 2-year OS of 95.6% and 90.7%, respectively, meeting the primary endpoint of the study. Sunitinib showed a tendency for a better outcome until 3 years after randomization, thus Cohort 2 was created to investigate the safety and prolonged improvement of RFS and OS with 12 months of sunitinib. Additionally, Cohort 3 with adjuvant sunitinib in combination with VPA for 12 months is currently ongoing. The size of primary tumor influenced the survival and should be adjusted for future adjuvant studies. Clinical trial information: NCT02068586. Research Sponsor: Pfizer Inc., Institutional funds at Thomas Jefferson University.

The association between mediators of the receptor for advanced glycation end product (RAGE) axis and immune checkpoint inhibitor (ICI)–induced colitis in patients with melanoma. *First Author: Morgan Simons, NYU Grossman School of Medicine, New York, NY*

Background: Colitis and other gastrointestinal (GI) toxicity are a frequent and occasionally severe form of immune-related adverse events (irAEs) in patients treated with ICIs. To date, no definitive mechanism has been identified, and this area remains an active field of investigation. We hypothesized that activation of the RAGE axis, known to be implicated in inflammatory bowel disease through stimulation of signal transduction targeted by pro-inflammatory RAGE ligands, members of the S100 family and High Mobility Group Box 1 (HMGB1), might be associated with irAE- colitis. **Methods:** We examined sera from 111 advanced melanoma patients prospectively accrued and followed up at NYULH (treated with anti-PD-L1, n = 44; antiCTL4, n = 23; and combination, n = 44). 24 (22%) developed GI toxicity grade >2. Serum biomarkers of the ligand-RAGE pathways, soluble (s)RAGE, endogenous secretory (es)RAGE, S100B, and HMGB1, were measured in the patients' sera during ICI treatment. Multivariable ordinal logistic regression analyses with all grades of GI toxicity as the primary outcome for all the recorded covariates (including serum biomarkers, clinical covariates) were performed. We then used ordinal multivariable logistic regression with stepwise variable selection. Similar analyses with GI toxicity as a binary outcome ((≥grade 1 vs no toxicity) were also conducted. Only those variables that jointly contributed to the odds of developing toxicity were included in the final stepwise model. No adjustments for multiplicity were included. As sRAGE and esRAGE are highly correlated (r = 0.86), esRAGE concentrations were not used in the joint models. **Results:** A significant association between GI toxicity and concentrations of sRAGE and S100B was identified. The final stepwise multivariable logistic model includes only sRAGE and S100B. The odds of having a one level increase in GI toxicity grade increase 1.100 times (95% CI: 1.008, 1.199; p = 0.029) for each unit decrease of sRAGE (= sRAGE/100). The odds of a one level increase in GI toxicity increase 1.059 times (95% CI: 1.004, 1.116; p = 0.035) for each unit increase of S100B (= s100B/100). All other analyses yielded comparable results. In contrast, concentrations of HMGB1 and other clinical covariates, including response and treatment category, were not associated with GI toxicity. **Conclusions:** Mediators of the RAGE axis, specifically sRAGE and S100B, might have a role in GI toxicity in patients receiving ICIs. The ligand-RAGE axis may be a novel target for irAE therapies for patients receiving ICIs to mitigate the severity of GI toxicity. Research Sponsor: None.

9588 **Poster Session**

A qualitative exploration of melanoma awareness and prevention among Latinx and non-Latinx White populations in urban and rural California. *First Author: Susan M. Swetter, Stanford University Medical Center and Cancer Institute, Stanford, CA*

Background: Melanoma mortality rates remain high among individuals of lower socioeconomic (SES) status, and racial/ethnic minorities, despite rates declining in non-Latinx whites (NLW). To improve understanding about the factors contributing to inequities in melanoma prevention and care, a qualitative exploratory study was conducted in Northern and Southern California regarding awareness, prevention, and early detection of melanoma in lower SES NLW and Latinx populations living in urban and semi-rural areas. **Methods:** Nineteen focus group (n = 176 individuals: 77% female, 59% self-identified Latinx/Hispanic, and 40% Medi-Cal/state insurance recipients) were conducted with adult participants, stratified by race/ethnicity (Latinx, low-income NLW), geography (semi-rural, urban), and language (English and Spanish). The interview topics included: 1) awareness and views of melanoma risk, prevention, and early detection screening practices; 2) acceptability of primary and secondary prevention strategies in their respective community; and 3) barriers and facilitators of engagement in melanoma prevention and care. Using a hybrid inductive and deductive approach, thematic analysis was used for data analysis. Findings were organized within a socioecological model (individual, interpersonal, community and health system/policy level). **Results:** Individual level findings revealed that many participants were not familiar about melanoma yet were willing to learn through trusted sources. Brown or darker skin tones were perceived as having less risk for skin cancer. Interpersonally, social relationships were important influences for individuals practicing skin cancer prevention. However, for several Latinx and semi-rural participants, conversations about melanoma prevention did not occur with family and peers. At the community level, semi-rural participants reported distance or lack of transportation to a clinic as challenges for dermatology care access. Healthcare systems barriers included burdens of additional medical care costs and obtaining dermatology referral. Many participants were in support of health regulations and education that reduce skin cancer risks for outdoor workers and children. **Conclusions:** Varying and intersecting factors influence melanoma awareness, and behaviors associated with knowledge, prevention, and early detection of melanoma in low-income NLW and Latinx individuals and in those living in semi-rural areas. Our findings promote understanding of how barriers across the socioecological spectrum may affect melanoma prevention and early detection particularly among men, individuals of lower socioeconomic status, and Latinx individuals. The study results have implications for health education interventions, which can involve health navigation strategies for individuals and families. Research Sponsor: Mary E. Brenneisen Fund at Stanford Medicine, U.S. National Institutes of Health.

TPS9589 **Poster Session**

Randomized phase 3 trial of IO102-IO103 plus pembrolizumab versus pembrolizumab alone in patients with previously untreated, unresectable, or metastatic melanoma. *First Author: Inge Marie Svane, National Center for Cancer Immune Therapy, CCIT-DK, Copenhagen University Hospital, Herlev, Denmark*

Background: The treatment of melanoma has improved markedly with the emergence of new immune therapies, and both anti-PD-1 monotherapy and the combination of the anti-PD-1 antibody nivolumab and anti-CTLA-4 therapy ipilimumab are now considered standard-of-care in the unresectable or metastatic (advanced) melanoma setting. However, many patients have primary or acquired resistance to these therapies, thereby underpinning the need for more effective approaches. IO102-IO103 is a potentially first-in-class, dual-antigen, immune-modulatory therapy targeting the key cancer immune resistance pathways mediated by IDO and PD-L1. The ability of IO102 and IO103 to respectively activate the specific T cells that recognize these checkpoint molecules and directly modulate immune regulation has previously been demonstrated both preclinically and in human clinical trials. A synergistic anti-tumor response upon treatment against both IDO and PD-L1 has also previously been demonstrated in a preclinical model where IDO and PD-L1 were expressed by different cells in the tumor microenvironment. Due to the distinctive mechanisms of action of IO102-IO103 and anti-PD-1 antibodies, there may be a further synergistic effect when treatment is combined. A previous Phase 1/2 trial investigating the use of IO102-IO103 plus nivolumab in patients with anti-PD-1-naïve metastatic melanoma has demonstrated promising anti-tumor activity with an overall response rate (ORR) of 80%, median progression-free survival (PFS) of 26 months and a manageable safety profile (NCT03047928; Kjeldsen et al, Nat Med 2021). **Methods:** This is a Phase 3, multicenter, open-label, randomized, 2-arm trial investigating the efficacy and safety of IO102-IO103 plus pembrolizumab versus pembrolizumab alone (EudraCT: 2021-004594-32; ClinicalTrials.gov No: NCT05155254). Inclusion criteria include: adult patients with untreated, unresectable (Stage III), or metastatic (Stage IV) melanoma; > 6 months since last dose of (neo)adjuvant treatment with targeted or immune therapy (in those previously treated); and ≥1 measurable lesion by RECIST v1.1. Primary endpoint is PFS by blinded independent central review. Secondary endpoints include ORR, durable response rate, complete response rate, duration of response, time to response, disease control rate, overall survival, and safety/tolerability. Target enrollment is 300 patients at > 100 sites in 20 countries. Patients are randomized 1:1 to receive either pembrolizumab 200 mg intravenously (IV) every 3 weeks up to 2 years or pembrolizumab 200 mg IV every 3 weeks up to 2 years with dual-antigen IO103-IO102 85-85 μg and Montanide adjuvant subcutaneously on Day 1 and 8 of cycle 1 and 2 and on Day 1 of each cycle thereafter. Enrolment for the study is ongoing. Clinical trial information: EudraCT: 2021-004594-32; ClinicalTrials.gov No: NCT05155254. Research Sponsor: IO Biotech ApS & Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS9590 **Poster Session**

First-in-human clinical trial of an oncolytic adenovirus armed with TNFa and IL-2 in patients with advanced melanoma receiving adoptive cell transfer of tumor-infiltrating lymphocytes. *First Author: Inge Marie Svane, National Center for Cancer Immune Therapy, CCIT-DK, Copenhagen University Hospital, Herlev, Denmark*

Background: The long-term complete remission experienced by some cancer patients after receiving immunotherapies, such as adoptively transferred tumor-infiltrating lymphocytes (ACT-TIL), represent the ideal outcome to pursue for the development of therapies for oncology. At the same time, those responses are limited to a minority of treated patients, and adverse events resulting from preconditioning chemotherapy and postconditioning IL2 are a rather common scenario. TILT-123 is an oncolytic adenovirus (Ad5/3-E2F-D24-TNFa-IRES-IL2) designed to enable T-cell therapies and checkpoint inhibition against cancer. Ultimately, the aim of this approach is to expand the proportion of patients benefiting from immunotherapies. Extensive preclinical studies with this technology showed that the virus repolarizes the tumor's immune microenvironment in a way that favors T-cell presence and their activity against tumor cells. When TILT-123 was used together with TILs in preclinical in vivo models, animals had a higher chance to display curative results while showing reduced toxicity as the use of TILT-123 replaces the pre and post conditioning (Havunen R. et al Mol Ther Oncolytics 2016, Santos J.M. Mol Ther 2018). A Phase I clinical trial (NCT04217473) is ongoing to evaluate safety of the approach in advanced melanoma patients. Extensive biological assays of patient aim to characterize viral transduction of tumors through the intravenous and intratumoral routes, and the recruitment of activated lymphocytes to tumors in order to elucidate the immunological impact of the drug. **Methods:** The primary aim of NCT04217473 is to evaluate safety of TILT-123 in advanced melanoma patients. Refractory or recurrent stage III/IV patients, which cannot be treated with curative intent with available therapies, and are eligible for ACT-TIL therapy, can potentially participate in the study. TILT-123 administration begins while the manufacturing of ACT-TILs takes place and continues after the TIL-therapy is administered to the patient. In contrast with standard ACT-TIL therapy, patients are not conditioned with lymphodepletion or IL-2 in this approach. Patients must present at least one biopsiable/operable tumor for the generation of TILs and another injectable lesion for intratumoral administration of TILT-123. The open label, dose escalation trial has the main endpoint of establishing TILT-123 safety by day 36 (prior to TIL administration), which is based on the incidence of adverse events, severe adverse events, vital signs, ECG, and safety laboratory results. Secondary endpoints include safety and tolerability after TIL therapy has been administered, evaluation of antitumor responses and studies of tumor immune repolarization. Cohorts 1-3 have been completed without DLTs. Enrollment in cohort 4 was initiated in December 2021. Clinical trial information: NCT04217473. Research Sponsor: TILT Biotherapeutics Ltd.

TPS9591 **Poster Session**

A phase II study of biomarker-driven early discontinuation of anti–PD-1 therapy in patients with advanced melanoma (PET-Stop): ECOG-ACRIN EA6192. *First Author: Geoffrey Thomas Gibney, Georgetown-Lombardi Comprehensive Cancer Center, Washington, DC*

Background: In patients (pts) with advanced, metastatic melanoma (aMM) anti-PD-1 monotherapy and anti-PD-1/anti-CTLA-4 combination regimens yield durable responses, yet the optimal therapy duration remains unclear. Most prospective studies have treated responding pts for at least 2 years unless there has been a prohibitive treatment related adverse event (TRAE). Durable treatment-free survival has been observed in pts where anti-PD-1 therapy is discontinued after short courses due to TRAEs. Biomarkers are needed to define which pts may safely discontinue anti-PD-1 therapy in order to reduce financial toxicity and risk of late TRAEs, and to improve quality of life. ^{18}FDG-PET/CT scan and tumor biopsy may better assess for active residual disease and identify pts who can safely discontinue treatment. A retrospective study at G-LCCC demonstrated responding pts with aMM who elected to discontinue their anti-PD-1 therapy (median treatment duration 12 months) after a negative PET/CT scan and/or tumor biopsy had event free survival (EFS) of 95% at 3 years (Gibney et al JITC 2021). We hypothesize that pts with disease control by CT scan after 12 months on anti-PD-1 therapy can be safely discontinued from treatment if no hypermetabolic activity on PET/CT scan or negative biopsy for active disease. **Methods:** EA6192 is a multicenter phase II study to evaluate the EFS after discontinuation of anti-PD-1-based therapy in aMM pts with PET/CT scan and/or biopsy that is negative for active disease. Pts with unresectable stage IIIB-IV aMM treated with nivolumab/ipilimumab (nivo/ipi), nivo, pembrolizumab (pembro), or pembro/ipi are eligible. Pts with uveal melanoma are excluded. Pts must receive 52 weeks of therapy, have disease control (CR, PR or SD by imRECIST) and no prohibitive TRAEs. Eligible pts undergo screening including ^{18}FDG-PET/CT scan at 52 weeks (+/- 2 weeks) from start of anti-PD-1 therapy. Pts with hypermetabolic tumor site(s) undergo biopsy. Pts with non-hypermetabolic PET/CT scan or negative biopsy are assigned to Arm A and are monitored off active treatment. Pts with hypermetabolic PET/CT scan and positive or non-feasible biopsy are assigned to Arm B and remain on active treatment for another 48 weeks. Restaging scans are performed every 12 weeks. Arm B pts with disease control undergo a second PET/CT scan and biopsy, and then are monitored off active treatment. 150 patients are planned for accrual. The primary objective is to accurately define the 12-month EFS rate of Arm A, distinguishing between the null and alternative hypotheses of 12-month EFS rate of 88% and 95% with 92% power and one-sided type 1 error rate of 0.072. Secondary and exploratory objectives include assessment of pathologic response, EFS for Arm B, overall survival, incidence of late TRAEs, and correlative biomarker studies. This study is actively enrolling pts. Clinical trial information: NCT04462406. Research Sponsor: U.S. National Institutes of Health.

TPS9592 **Poster Session**

C-POST protocol update: A phase 3, randomized, double-blind study of adjuvant cemiplimab versus placebo post-surgery and radiation therapy (RT) in patients (pts) with high-risk cutaneous squamous cell carcinoma (CSCC). *First Author: Danny Rischin, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia*

Background: CSCC is the second most common skin cancer with an estimated incidence of 1 million cases per year in the US. While the surgical cure rate for CSCC is > 95%, some pts have high risk of recurrence as assessed by immune status, primary disease stage, extent of nodal involvement, presence of extracapsular extension (ECE), and prior treatment. Postoperative RT is recommended for these pts but relapse with locoregional recurrence or distant metastases may still occur. C-POST is evaluating the efficacy of cemiplimab as adjuvant therapy for pts with high-risk CSCC. Here, we provide summary of the most recent study protocol amendment. **Methods:** C-POST is a randomized, placebo-controlled, double-blind, multicenter Phase 3 study to evaluate cemiplimab as adjuvant treatment for pts with high-risk CSCC, based on surgical and clinicopathologic findings, who completed surgery and postoperative RT (minimum total dose 50Gy, within 10 weeks before randomization) (NCT03969004). Pts with at least one of the following high-risk features are eligible: (1) nodal disease with (a) ECE and at least one node ≥20 mm or (b) at least three lymph nodes positive on surgical pathology report, regardless of ECE; (2) in-transit metastases; (3) T4 lesion; (4) perineural invasion; and (5) recurrent CSCC with at least one other risk factor. Pts with CSCC involvement in at least three lymph nodes (feature 1b) were added to the eligibility criteria, as this group was found to be at similar risk of CSCC recurrence as the initially planned study population. Protocol amendment now allows patients with chronic lymphocytic leukemia (CLL) who are not on active treatment to be enrolled. The study has two parts. In Part 1 (blinded), pts are randomly assigned 1:1 to receive cemiplimab 350 mg or placebo intravenously every 3 weeks for 12 weeks, followed by cemiplimab 700 mg or placebo every 6 weeks for 36 weeks. In optional Part 2 (unblinded), pts in the placebo arm who experience disease recurrence and pts in the cemiplimab arm who experience disease recurrence ≥3 months after completion of 48-week treatment in Part 1 are eligible to receive open-label cemiplimab for up to 96 weeks. The trial is expected to enrol 412 pts from about 100 sites in North and South America, Europe, and Asia-Pacific regions. Key primary objective is to compare disease-free survival; secondary objectives include evaluating overall survival, freedom from locoregional relapse, and distant relapse with adjuvant cemiplimab versus placebo in patients with high-risk CSCC. This study is once again open for enrolment following interruptions owing to the COVID-19 pandemic. Clinical trial information: NCT03969004. Research Sponsor: Regeneron Pharmaceuticals, Inc., and Sanofi.

TPS9593 **Poster Session**

A randomized, controlled, open-label, phase 2 study of cemiplimab ± RP1 in patients with advanced cutaneous squamous cell carcinoma (CERPASS). *First Author: Andrew Mark Haydon, The Alfred Hospital, Melbourne, VIC, Australia*

Background: RP1 is an oncolytic virus (HSV-1) that expresses a fusogenic glycoprotein (GALV-GP R-) and granulocyte macrophage colony stimulating factor (GM-CSF). In preclinical studies, RP1 induced immunogenic tumor cell death and provided potent systemic anti-tumor activity, which is further improved by combining anti-PD-1 therapy. The prognosis for advanced and metastatic cutaneous squamous cell carcinoma (CSCC) remains poor for many patients despite the adoption of cemiplimab and pembrolizumab as a standard treatment. Preliminary results from IGNYTE, a phase I/II clinical study of RP1 in combination with nivolumab showed a high rate of deep and durable responses in patients (pts) with CSCC. This study is evaluating the efficacy and safety of cemiplimab ± RP1 versus cemiplimab alone in advanced CSCC. **Methods:** This global, multicenter, randomized phase 2 study is enrolling pts with metastatic or unresectable, locally advanced CSCC who are not candidates for/refuse surgery and/or radiation therapy. Key eligibility criteria include no prior treatment with anti-PD1/PD-L1 antibodies or oncolytic viruses. The clinical trial is enrolling approximately 180 pts from centers in the EU, Australia, Canada, and USA. Pts are randomized in a 2:1 ratio to receive combination therapy or monotherapy respectively. Pts receive 350 mg of cemiplimab intravenously (IV) Q3W for up to 108 weeks. In the RP1 + cemiplimab arm, RP1 is injected intratumorally at a starting RP1 dose of 1×10^6 plaque-forming units (PFU)/mL alone, followed by up to 7 doses of RP1 at 1×10^7 PFU/mL Q3W together with the same dose of cemiplimab. Pts in the combination arm may receive up to 8 additional RP1 doses if protocol specific criteria are met. No crossover is allowed. Pts are stratified by disease status (nodal or distant metastatic or locally advanced CSCC) and prior systemic therapy. Tumor assessments are performed every 9 weeks. The dual independent primary endpoints are overall response rate and complete response rate, both by a blinded independent review. Secondary endpoints include safety, progression-free survival, duration of response, and overall survival. Exploratory endpoints include quality of life, and immune biomarker analyses. This trial is currently enrolling pts. Clinical trial information: NCT04050436. Research Sponsor: Replimune Group Inc.

TPS9594 **Poster Session**

DELTA-1: A global, multicenter, phase 2 study of ITIL-168, an unrestricted autologous tumor-infiltrating lymphocyte (TIL) cell therapy, in adult patients with advanced cutaneous melanoma. *First Author: Brian Gastman, Cleveland Clinic Lerner College of Medicine, Cleveland, OH*

Background: Patients (pts) with advanced (unresectable or metastatic) cutaneous melanoma and persistent disease after checkpoint inhibitor therapy have poor outcomes and limited treatment options, highlighting a significant unmet medical need (Schadendorf D et al. *Lancet.* 2018;392:971-984). Investigational autologous TIL cell therapies have shown promise in this population, partly attributable to their intrinsic and patient-specific antitumor activity (Borch TH et al. *J Immunother Cancer.* 2020;8:e000668). Made from each patient's digested and cryopreserved tumor, ITIL-168 is an autologous TIL cell therapy manufactured to offer an unrestricted T-cell receptor repertoire. A single-center, compassionate use clinical series demonstrated the feasibility and clinical utility of an earlier version of ITIL-168, with a high overall response rate among pts previously treated with PD-1 inhibitor (PD-1i) therapy (58%, n = 12; Pillai M et al. *Ann Oncol.* 2021;32[suppl 5]:S882). DELTA-1 (NCT05050006) is a global, multicenter phase 2 study to evaluate efficacy and safety of ITIL-168 in pts with cutaneous melanoma relapsed or refractory to a PD-1i, pts intolerant to a PD-1i, and pts whose current best response to a PD-1i is stable disease. **Methods:** Pts aged ≥18 years with histologically confirmed advanced cutaneous melanoma, ECOG performance status 0-1, and adequate organ function will be enrolled in 1 of 3 cohorts. Cohort 1 (n≈80) will include pts who relapsed after or were refractory to ≥1 prior line of systemic therapy, including a PD-1i and, if *BRAF*-mutated, a BRAFi ± MEKi. Cohorts 2 and 3 (n≈25 each) will include pts intolerant to PD-1i and those with stable disease after ≥4 doses of PD-1i, respectively. After tumor resection for TIL harvest, pts must have ≥1 remaining measurable lesion per RECIST 1.1. Pts with uveal, acral, or mucosal melanoma, prior allogeneic transplant or cell therapy, and with central nervous system (CNS) disorder or symptomatic and/or untreated CNS metastases are ineligible. Pts will receive 5 days of lymphodepleting chemotherapy (cyclophosphamide ×2 days overlapping with fludarabine ×5 days) followed by a single ITIL-168 infusion ($\geq 5 \times 10^9$ cells) and supportive short-course, high-dose IL-2. The primary endpoint is objective response rate (ORR) per central review. Secondary endpoints include duration of response, progression-free survival, overall survival, disease control rate, TIL persistence, and safety. Hypothesis testing of ORR will be performed for cohort 1. The primary analysis will occur when all pts in the cohort 1 modified intent-to-treat population have been followed for ≥6 months after the first posttreatment disease assessment. DELTA-1 opened for enrollment in September 2021. Updated site information will be given at the time of presentation. Clinical trial information: NCT05050006. Research Sponsor: Instil Bio, Inc.

TPS9595 **Poster Session**

Optimization of Voyager V1 (VV1) oncolytic virus systemic delivery in combination with cemiplimab and ipilimumab in patients with melanoma and non–small cell lung cancer (NSCLC). *First Author: Jose Lutzky, University of Miami Sylvester Comprehensive Cancer Center, Miami, FL*

Background: There is a need for novel immunotherapies to address the patient population that never or no longer responds to immune checkpoint inhibitors (CPI). VV1 is an oncolytic vesicular stomatitis virus engineered to express human interferon beta (IFNβ) to enhance cellular anti-tumor immune responses and tumor selectivity. Phase 1 studies demonstrated VV1 anti-tumor activity in several malignancies with or without a CPI. We are exploring ways to optimize VV1 efficacy in combination with cemiplimab, an anti-PD1 antibody approved for lung, basal and squamous cell skin cancers. Recent clinical data support a 5-fold higher dose of VV1 than was previously explored, and pre-clinical data show synergy between the oncolytic and an anti-CTLA4 antibody, in addition to cemiplimab, supporting exploration of a triplet. What was originally a five-arm study of intravenous (IV) VV1 in combination with IV cemiplimab has been amended to focus on 2 means of optimizing efficacy: use of a higher dose of VV1 and triplet combination in proof-of-concept populations. **Methods:** We are now enrolling pts with advanced melanoma (after progression on anti-PD1) and plan to include 1st-line NSCLC pts with PD-L1 expression ≥50%. The study is first exploring the preliminary anti-tumor activity, safety, and immunogenic activity of the combination of IV VV1 at a dose of 1.0×10^{11} $TCID_{50}$ once on D1 followed by IV cemiplimab Q3W starting on D8, or the same regimen with an additional intratumoral injection of VV1 1.0×10^9 $TCID_{50}$ once on D1 for pts with accessible lesions. Pts receive IV cemiplimab Q3W until confirmed disease progression or intolerable toxicity. Once at least 6 pts have been treated with acceptable safety across the 2 melanoma doublet cohorts using this higher dose of VV1, a 3rd melanoma cohort will open to add a single dose of ipilimumab 50 mg on D1 (all IV triplet). Once 6 melanoma pts have received the triplet safely, the 1st-line NSCLC cohort will open. All cohort decisions are guided by a Data Review Committee. Cohorts will be expanded based on a Simon 2-stage design using a type I error rate of 0.05 and power of 85%. Null ORR is 10% with a target of 35% for 2nd line melanoma and null ORR is 40% in 1st line NSCLC with a target of 70%. Each melanoma cohort will require a response in ≥2 of 10 pts in the 1st stage to add 11 more in the 2nd stage, while NSCLC will first need 5/9 evaluable pts to respond, then an additional 13 to complete the design. Response is assessed at week 7 then Q9W per RECIST v1.1. The study includes serial biopsies in ≥3/10 pts in Stage 1 of each of the IV melanoma cohorts (doublet and triplet therapy), all pts in Stage 2 of these IV melanoma cohorts, and all pts in both Stage 1 and Stage 2 of the IV/IT melanoma cohort, to permit a thorough investigation of the impact of the 3 immunotherapies under investigation. The study is currently ongoing in the USA. Clinical trial information: NCT04291105. Research Sponsor: Vyriad and Regeneron.

TPS9596 **Poster Session**

ATTAC-MCC: Phase I/II study of autologous CD8+ and CD4+ transgenic T cells expressing a high affinity MCPyV-specific TCR combined with checkpoint inhibitors and class I MHC-upregulation in patients with metastatic MCC refractory to PD-1 axis blockade. *First Author: Joshua Veatch, Hutchinson Cancer Rsrch Ctr, Seattle, WA*

Background: Merkel cell carcinoma (MCC) is a highly aggressive skin cancer, with an incidence that has doubled in the last 20 years to approximately 3000 cases/year in the US. Over one-third of patients will develop widespread disease, and survival in these patients has been historically poor with a 5-year survival rate of < 10%. MCC is highly immune-sensitive due to the antigenicity of the cancer-causing Merkel cell polyomavirus (MCPyV) expressed in most MCC tumors. Although immune checkpoint inhibitors (ICIs) targeting the PD-(L)1 axis show promising efficacy, most MCC patients will eventually relapse. There is no standard of care for patients that become refractory to ICIs. We hypothesize that cellular immune therapies targeting MCPyV may provide additional clinical benefit to these patients. To test this, we have engineered high-affinity TCR T cells against MCPyV and initiated a clinical trial. **Methods:** NCT03747484 is an ongoing phase I/II, open label, investigator-initiated trial (IIT) of FH-MCVA2TCR in combination with an anti-PD-(L)1 checkpoint inhibitor and an agent to upregulate MHC-I expression on tumor cells. The trial is conducted in patients aged 18 years or older with metastatic or unresectable, histologically confirmed virus-positive MCC whose disease has progressed on or after treatment with a PD-(L)1 axis checkpoint inhibitor. Patients undergo leukapheresis to collect white blood cells (WBCs) for TCR T cell product manufacturing. The cell product is administered on day 0. Patients receive an agent to upregulate MHC-I on tumor cells and continue on an anti-PD-(L)1 checkpoint inhibitor for up to one year. In phase I, three patients receive up to two infusions of dose level 1 of the T cell product. The primary objectives of phase I are to determine safety and tolerability based on dose-limiting toxicities (DLT) during an observation period of 28 days after the first infusion. Phase II enrolls patients at dose level 2. The total sample size of phase II is 12 patients. The first three patients are enrolled in a staggered manner and observed for DLTs. If no DLTs occur, the remaining sample size is accrued in open enrollment. The main objectives of phase II are safety based on number of adverse events and preliminary efficacy based on tumor response according to RECISTv1.1 and iRECIST. Secondary/exploratory objectives include cellular kinetics of TCR T cells, T cell phenotype, tumor infiltration kinetics, and MHC-I expression dynamics over time. After the first 12 months, patients transition to a long-term follow-up (LTFU) study for up to 15 years as per FDA guidelines. Clinical trial information: NCT03747484. Research Sponsor: Affini-T Therapeutics, Inc.

TPS9597 **Poster Session**

An open-label, multicenter, phase 1b/2 study of RP1, a first-in-class, enhanced potency oncolytic virus in solid organ transplant recipients with advanced cutaneous malignancies (ARTACUS). *First Author: Michael Robert Migden, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: RP1 is an oncolytic virus (HSV-1) that expresses a fusogenic glycoprotein (GALV-GP R-) and granulocyte macrophage colony stimulating factor (GM-CSF). In preclinical studies, RP1 induced immunogenic tumor cell death and provided potent systemic anti-tumor activity. Clinical data in combination with nivolumab has demonstrated a high rate of deep and durable response in patients with advanced skin cancer. Solid organ transplantation (SOT) is an important lifesaving procedure for patients with a wide range of end-organ diseases, but requires patients (pts) to undergo lifelong immunosuppression to prevent allograft rejection, and skin cancers (SCs) – including cutaneous squamous cell carcinoma (CSCC) – are common post-transplant malignancies. SC in SOT pts is generally managed with surgical resection, radiation therapy, and chemotherapy or targeted therapy. The use of immune checkpoint inhibitors in SOT recipients has improved outcomes but is associated with a high risk of allograft rejection. Thus, there is a high unmet need for a safe and effective treatment that also protects pts from allograft rejection. The objective of this study is to assess the safety and efficacy of single-agent RP1 in SOT patients with SCs, with a focus on CSCC. **Methods:** This study will enroll up to 65 evaluable SOT pts with locally advanced or metastatic SCs. The study has two parts. In Part A, pts will receive an initial dose of 1 x 10^6 plaque-forming units (PFU) of RP1. Two weeks later they will receive 1 x 10^7 PFU of RP1 and continue every two weeks until pre-specified study endpoints are met. In Part B, after determining the safety and tolerability in the initial cohort with kidney and liver transplants, the study may also enroll heart and lung transplant recipients. RP1 will be administered by intra-tumoral injection, utilizing image guidance as clinically appropriate. Key inclusion criteria are pts with confirmed recurrent, locally advanced or metastatic CSCC and up to 10 pts with non-CSCC SC, stable allograft function and ECOG performance status of ≤1. Pts with prior systemic anti-cancer treatment are allowed. Key exclusion criteria are prior treatment with an oncolytic therapy, active herpetic infections or prior complications of HSV-1 infection and a history of organ graft rejection within 12 months. The primary objective of the trial is to assess efficacy determined by objective response rate and safety of single agent RP1. Additional secondary endpoints include duration of response, complete response rate, disease control rate, progression-free survival and overall survival. Clinical trial information: NCT04349436. Research Sponsor: Replimune Group Inc.

TPS9598 **Poster Session**

Early together: A randomized phase III study of early palliative care in metastatic uveal melanoma (MUM). *First Author: Sophie Piperno-Neumann, Medical Oncology Department, Institut Curie, Paris, France*

Background: Uveal melanoma is a rare cancer. Up to 50% of patients (pts) develop metastasis, mainly hepatic. Overall survival in metastatic pts is 12 months (mo), contrasting with a good overall condition until death. To evaluate the impact of integrating early palliative care on patient needs and self-efficacy, we designed a comparative randomized trial in MUM pts. **Methods:** 162 pts will be randomized (1:2) between the control and the experimental groups in two French centres (Institut Curie-Paris and Centre Antoine Lacassagne-Nice). In the control group, palliative care is introduced according to international guidelines. In the experimental group, it is added earlier, concomitant to the announcement of metastases by the medical oncologist. The main objective is to assess if early supportive care impacts on patient psychological needs at 6 mo, versus standard of care, based on the SCNS-SF34 questionnaire. Secondary objectives include patient's other needs at 6 and 12 mo, quality of life (QLQ-C30), progression-free and overall survival, and partners' needs (SCNS-P&C). MUM pts, suitable for a treatment with no curative intent, ECOG PS 0-1, with no physical or biological sign of disease, and capable of filling questionnaires are eligible. Questionnaires are completed by all pts at each oncological visit (baseline, 3, 6, 9 and 12 mo). Supportive care visits take place every 6 weeks if needed and address patient's information needs, disease and treatment understanding, social and psychological status, symptoms, and partners' involvement. Prognostic uncertainty and disease seriousness in the absence of symptom is addressed depending on pts' expressed needs. Medical oncologists and supportive care physicians from both centres attend communication skill training provided by an expert during the study. Analyses: SCNS-SF34 psychological needs scale scores at 6-mo will be compared with a Student's t-test, in an ITT analysis. For 10 points mean score difference expected between groups (within standard deviation of 20 points) and a two-sided type 1 error of 5%, inclusion of 54 pts (control group) and 108 pts (experimental group) provides the study 85% of power. The planned inclusion period is 3 years, pts will be followed for one year, for a total study duration of 4 years. From July 2020 to January 2022, 63 pts have been enrolled in the trial; 2 pts declined. Five pts were removed early from the study: one for consent retrieval, 4 for early death due to metastasis. COVID-19 delayed enrollment for 5 months. We plan to complete the study Q4 2023 and to analyze the data Q4 2024. Clinical trial information: NCT04728113. Research Sponsor: Cancéropôle Ile-de-France and INCa SHS-E-P 2019 French national grants, Patients donations.

Questionnaires.	
1	Supportive Care Needs Survey (SCNS-SF34)
2	European Organization for Research and Treatment (EORTC) QLQ-C30
3	Hospital Anxiety and Depression Scale (HADS)

A biomarker-guided Bayesian response-adaptive phase II trial for metastatic melanoma: The Personalized Immunotherapy Platform (PIP) trial design. *First Author: Serigne N. Lo, Melanoma Institute Australia, Faculty of Medicine and Health, The University of Sydney, Sydney, Australia*

Background: Anti-PD1-based immunotherapies have been approved for many cancer types and are now a standard therapy for advanced melanoma. Despite this, ~50% of advanced melanoma patients (pts) fail to respond or eventually progress after response. It is therefore critical to identify pts with a low likelihood of response to anti-PD1-based therapy and efficiently assess activity of rationally-selected alternative novel immunotherapies. **Methods:** We designed this investigator-initiated phase II PIP-Trial to evaluate two consecutive biomarker testing platforms, followed by the activity of rationally selected 5 novel agents in pts with advanced melanoma. Two separate pt populations are included: Part-A) treatment-naïve pts predicted to be resistant to either anti-PD-1 alone or combined with ipilimumab using Biomarker Test-1); and Part-B) pts who had progressed on 1 prior line of PD1-based therapy. Part-A) is a Bayesian adaptive multi-arm multi-stage design using response adaptive randomisation after a burn-in period where pts are randomised to the existing arms with equal probability. From then on, regular interim analyses will be carried out with the objective to either drop poorly performing arms or continue. Part-B) is an open platform without control that combined a selection and an expansion phase to identify best novel agent(s) as second-line therapy. Expansion phase decisions will be based on enrichment for biomarker Test-2. Dropping an arm occurs when the posterior probability of observing a clinically significant effect on the primary outcome (i.e. 6-month RECIST objective response rate (ORR)) is low. The operational characteristics of the design were investigated through simulations considering 4 plausible scenarios with 40% ORR in the control arm (anti-PD1 + Anti-CTLA4). Simulations were based on the upcoming R package BATS. Part-A has at least 85% power to detect a 30% absolute improvement in ORR with respect to the control arm (with a max N = 216 – Table below). Part-B will be able to select two promising treatments in the expansion phase and formally test their efficacy against a minimum ORR of 25% at 80% power (max N = 150). Research Sponsor: The Melanoma Institute Australia, Cancer Institute of New South Wales.

Scenario	Probability of declaring a treatment effective					Average N per arm						Maximum N
	Arm A	Arm B	Arm C	Arm D	Arm E	Control	Arm A	Arm B	Arm C	Arm D	Arm E	
1	0.05	0.04	0.05	0.04	0.04	46	29	28	29	29	29	190

Tocilizumab in combination with ipilimumab and nivolumab in solid tumors. *First Author: Noha Abdel-Wahab, Assiut University Hospital, Faculty of Medicine, Assiut, Egypt*

Background: Immune checkpoint inhibitors (ICIs) are approved for multiple malignancies, however, durable remission rates with ICI monotherapy remains low. Combined treatment with anti-CTLA-4 and anti-PD1 has shown higher response rates in several cancers but is associated with up to 60% grade 3/4 immune-related adverse events (irAEs) leading to frequent treatment discontinuation. The need for corticosteroids to control irAEs may further diminish anti-tumor activity. A multi-disciplinary approach using clinical, preclinical, and translational analyses implicated the IL-6/Th17 axis in both ICI-related autoimmunity and resistance. Further, preliminary data showed that targeting interleukin 6 (IL-6) could be an effective approach to reduce irAEs while maintaining and possibly boosting the antitumor immune response. **Methods:** We are conducting a phase II, open-label, single center study to evaluate the use of combination treatment with tocilizumab (toci; anti-IL6), ipilimumab (ipi; anti-CTLA4) and nivolumab (nivo; anti-PD1) as a front-line therapy for patients (pts) with treatment-naïve advanced cutaneous melanoma (cohort 1), urothelial carcinoma (cohort 2), and EGFR mutant non-small cell lung cancer after tyrosine kinase inhibitors failure (cohort 3) (NCT04940299). Ten pts per disease site will be enrolled, plus an additional 25 melanoma pts in an expansion cohort. Key inclusion criteria are age ≥18 years (yrs) and histologically confirmed locally advanced or metastatic disease, with specific eligibility criteria defined for each cohort. Patients with interstitial lung diseases, autoimmune diseases, infection, or conditions requiring immunosuppressive therapies are not eligible, but stable asymptomatic brain mets are allowed. Ipi/Nivo dosing is as per approved disease indications: in cohort 1 &2, ipi 3 mg/kg + nivo 1 mg/kg is administered intravenously (IV) every 3 weeks (wks) for 4 doses then nivo 480 mg/4 wks up to 2 yrs. In cohort 3, IV ipi 1 mg/kg/6 wks + nivo 3 mg/kg/2 wks is administered up to 2 yrs. In all 3 cohorts, subcutaneous (SQ) toci 162 mg/2wks is administered up to 12 wks. Imaging is every 12 wks up to 2 yrs or until dose-limiting toxicities or progression. The primary outcome is safety/tolerability of the triple therapy. The secondary outcomes are antitumor efficacy and overall survival. Additionally, tumor and blood samples are being collected for longitudinal immune analysis, including gene expression and multiplex histochemistry to identify predictive biomarkers of response, resistance, and toxicity. The trial opened in October 2021 and has enrolled 14 patients to date. Clinical trial information: NCT04940299. Research Sponsor: The University of Texas MD Anderson Cancer Center Prioritizing Research Innovation and Mentoring Excellence Award, Other Foundation.

TPS9601 **Poster Session**

Design and rationale of a first-in-human (FIH) phase 1/1b study evaluating KIN-3248, a next-generation, irreversible (irrev), pan-FGFR inhibitor (FGFRi), in adult patients with solid tumors harboring FGFR2 and/or FGFR3 gene alterations (NCT05242822). *First Author: Lipika Goyal, Mass General Cancer Center, Harvard Medical School, Boston, MA*

Background: FGFR1-4 gene alterations are observed in approximately 7% of all human cancers. There are currently 3 FDA-approved, reversible FGFRi for treatment of patients w/previously treated, locally advanced or metastatic (met) cholangiocarcinoma (CCA) harboring FGFR2 gene fusions/rearrangements (pemigatinib and infigratinib) or met urothelial carcinoma (UC) w/susceptible FGFR2 or FGFR3 genetic alterations (erdafitinib). A major limitation of approved and clinical-stage FGFRi is emergence of secondary, on-target resistance mutations (mutn) that reduce duration of response. Up to 67% of CCA patients treated with either reversible or irrev FGFRi exhibit secondary FGFR2 kinase domain resistance mutn at the time of relapse. KIN-3248 is a next-generation, selective, irrev, small molecule pan-FGFRi, structurally designed to inhibit primary FGFR oncogenic alterations as well as secondary kinase domain mutn associated w/disease progression. Preclinically, KIN-3248 has favorable pharmaceutical properties, is well-tolerated with continuous, daily oral administration in 28d GLP toxicology studies in rats and beagle dogs and is efficacious against primary FGFR2 and FGFR3 oncogenic driver alterations as well as secondary FGFR2 resistance mutn (e.g., gatekeeper and molecular brake) in human cancer cell and PDX models *in vitro* and *in vivo*. **Methods:** This is a FIH, multicenter, non-randomized Ph1 study of KIN-3248 in adult pts with advanced & metastatic solid tumors (AMST) harboring FGFR2 and/or FGFR3 gene alterations. KIN-3248 is given po qd continuously in 28-day cycles until drug intolerance or disease progression. Planned sample size is approx. 120 pts: Part A is a dose-escalation to MTD for pts w/AMST having either FGFR2 and/or FGFR3 alterations. Part A assesses single agent KIN-3248; Part B will evaluate a selected dose of KIN-3248 in 3 cohorts of pts (ICC, UC, or other AMST), each driven by specified FGFR alterations. Standard Ph1 enrollment criteria are required (ECOG PS 0-1, normal organ function, prior receipt of standard treatment or medical judgment that such is not appropriate). Pts may have measurable or evaluable disease. Key exclusion criteria include known active brain metastases and active/uncontrolled HBV/HCV. FGFRi-naïve & -pretreated patients are both eligible. Primary endpoints are safety/tolerability (Part A), and preliminary antitumor activity: objective response rate, disease control rate, duration of response, & duration of stable disease (Part B). Secondary objectives include pharmacokinetic and pharmacodynamic assessments including measures of FGFR pathway modulation. Enrollment is expected to commence in April 2022. Clinical trial information: NCT05242822. Research Sponsor: Kinnate Biopharma.

TPS9602 **Poster Session**

Evaluating the impact of perioperative antibiotic prophylaxis on the microbiome in patients with cutaneous malignancy. *First Author: Samuel Cass, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Preoperative antibiotic prophylaxis is commonly used to reduce surgical site infections (SSIs). However, the rate of SSIs following surgical procedures classified as clean is only 2-3%. Overuse of antibiotics is associated with several potential adverse effects, including dysregulation of the gut microbiome. Disruption of the composition and function of the native gut microbiota, referred to as dysbiosis, has been implicated in a number of inflammatory and autoimmune disorders, as well as gastrointestinal (GI) and non-GI cancers. Recent studies have demonstrated that antibiotics have a profound and persistent effect on the gut microbiota, as evidenced by diminished overall abundance and diversity, as well as alteration of community composition that includes a decreased relative abundance of bacteria in the Ruminococcaceae family. In melanoma, diversity of gut microbiota and relative abundance of Ruminococcaceae have been linked to improved survival and enhanced response following immune checkpoint blockade. In this study, we seek to determine the impact of preoperative prophylactic antibiotic use on the gut microbiome in patients following surgery for stage I or II melanoma. **Methods:** In this non-comparative randomized pilot trial, the impact of prophylactic antibiotic use at the time of surgical intervention on gut microbiome diversity and composition will be studied. Patients diagnosed with clinical stage I or II melanoma undergoing wide excision with or without lymphatic mapping and sentinel lymph node biopsy are randomized 1:1 to either receive preoperative cefazolin or no preoperative antibiotics. Stool samples and peripheral blood are collected before surgery, the day of surgery (optional), on post-operative day 3 (optional), and 2 weeks and 3 months following surgery. The primary endpoint for the study is change in microbiome alpha diversity at 2 weeks following surgery. Secondary endpoints are change in relative abundance of microbes at 2 weeks and 3 months after surgery and SSI rates according to whether or not prophylactic antibiotics were administered at time of surgery. Exclusion criteria include recent antibiotic use (within 3 months), allergy to beta-lactam or cephalosporin antibiotics, increased risk of infection due to medical comorbidity or use of immunosuppressive medication. Enrollment began in October 2021. As of January 2022, 22 of 30 patients have been accrued to ensure complete sample collection for 20 patients. Study findings may inform a larger trial evaluating interventions to mitigate antibiotic impact. Clinical trial information: NCT04875728. Research Sponsor: None.

TPS9603 **Poster Session**

DETECTION phase II/III trial: Circulating tumor DNA–guided therapy for stage IIB/C melanoma after surgical resection. *First Author: Rebecca Lee, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: Circulating tumor DNA (ctDNA; the tumor derived fraction of circulating free DNA in the blood) is a well recognized, minimally-invasive biomarker of tumor burden/progression in many cancers. We have previously shown in retrospective and prospective cohorts of patients with melanoma that ctDNA analysis of serial blood samples following curative intent surgery can identify minimal residual disease (MRD) or molecular relapse. The majority of patients with resected stage II melanoma do not recur, therefore better strategies to identify high risk patients are required. Furthermore, a consistent finding in studies of immune therapy in stage IV melanoma is that patients with small volume disease have the best outcome. We aim to test whether early relapse can be identified by ctDNA analysis and acted upon in a clinically relevant timeframe, and if early treatment of molecular recurrence with immune therapy improves outcomes for patients with resected stage IIB/C melanoma. **Methods:** We designed a phase II/III multicenter study across 21 UK and 4 Australian sites with a tumor informed approach employed for ctDNA detection. Droplet digital assays for *BRAF/NRAS/TERT* promoter mutations were validated for sensitive ctDNA detection across two accredited clinical testing laboratories. Patients with stage IIB/C melanoma, *BRAF/NRAS/TERT* promoter mutant cutaneous melanoma, ECOG 0/1, adequate organ function, with complete resection (including sentinel lymph node biopsy) performed within 12 weeks and radiological/clinical disease-free status confirmed within 4 weeks prior to registration, no prior immune/targeted therapy will be followed up with blinded ctDNA sampling in addition to clinical follow-up. Patients with ctDNA detected will be randomised 1:1 in a double blind fashion to continue routine follow-up with investigators choice treatment if they develop disease recurrence, or unblinded and treated with nivolumab 480mg IV Q4-weekly. Primary objectives include i) whether MRD/molecular relapse following curative intent surgery can be identified earlier than clinical relapse, ii) whether early treatment of molecular recurrence with nivolumab improves overall survival. 1050 patients are planned to be enrolled. The study opened in the UK in November 2021 and will open in Australia in Spring 2022. Clinical trial information: NCT04901988. Research Sponsor: Cancer Research UK, Other Government Agency.

TPS9604 **Poster Session**

Confirmatory trial of narrower side margin excision for head and neck basal cell carcinoma in the Japanese (East Asian) population: JCOG2005 (J-BASE-MARGIN). *First Author: Yasuhiro Nakamura, Department of Skin Oncology/Dermatology, Saitama Medical University International Medical Center, Saitama, Japan*

Background: Basal cell carcinomas (BCCs), the most common type of skin cancer, frequently occur on the head and neck. Because distant metastases are extremely rare, complete excision with clear margins is the standard treatment for BCCs. In the NCCN Guidelines, the recommended surgical treatment strategies include standard excision with wider margins (> 4 mm) or Mohs surgery or other forms of peripheral and deep en face margin assessment (PDEMA) for head and neck BCCs. However, these strategies are based on studies in the Caucasian population, with BCCs mostly arising as non-pigmented lesions and/or with poorly defined clinical borders. Conversely, in East Asians, most BCCs tend to present as pigmented lesions with well-defined clinical tumor borders. Recent retrospective studies from East Asia have reported positive side margin proportions and local recurrence proportions in BCCs excised with narrower margins that are lower than guidelines-recommended margins. Our previous study investigating 1000 East Asian BCCs also indicated that the estimated positive side margin proportions with 2- and 3-mm surgical margin excision in East Asian BCCs were 3.8% and 1.4%, respectively. Those findings may lead to very limited need for Mohs micrographic surgery or PDEMA in East Asian head and neck BCCs; however, there have been no clinical trials regarding fixed narrower margin excision for those cohorts. **Methods:** This is an investigator-initiated, prospective, multicenter, non-randomized phase III confirmatory trial evaluating the efficacy and safety of narrower surgical margins for the treatment of East Asian patients with head and neck, solitary, primary BCCs with sizes ranging from 3 mm to 20 mm. Eligible patients are aged ≥20 years (≤85 years in men or ≤90 years in women). Narrower margin excisions of 2 mm and 3 mm are applied to BCCs with well-defined clinical borders (cohort A) and poorly defined borders (cohort B), respectively. The primary endpoint is the 5-year local recurrence proportion, and the secondary endpoints are positive side margin proportion and incidence of adverse events. We anticipated an expected 5-year local recurrence proportion of 0.8% in both cohorts and a threshold of 3.3% in cohort A and 4.1% in cohort B. The planned sample size is 410 patients (cohort A, 250; cohort B, 160) to provide a power of 80% with one-sided alpha of 5%, assuming a 5% competing risk of death from other diseases. The planned accrual period is 5 years, and the follow-up period is 10 years; primary analysis will be performed at the completion of 5-year follow-up for all registered patients. The trial began in March 2021, and 225 patients (cohort A, 170; cohort B, 55) have already been enrolled as of January 2022. Clinical trial information: UMIN000043511. Research Sponsor: Japan Agency for Medical Research and Development, Other Foundation.

TPS9605 **Poster Session**

The NADINA trial: A multicenter, randomised, phase 3 trial comparing the efficacy of neoadjuvant ipilimumab plus nivolumab with standard adjuvant nivolumab in macroscopic resectable stage III melanoma. *First Author: Minke W. Lucas, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Adjuvant treatment with anti-PD1 therapy improves the recurrence free survival (RFS) in resectable stage III melanoma. The Checkmate-238 and KEYNOTE-054 trials respectively reported a 4-year RFS of 52.5% for adjuvant nivolumab and a 3-year RFS of 63.7% for adjuvant pembrolizumab. Despite these improved outcomes, a considerable proportion of patients have a relapse in the years after therapeutic lymph node dissection (TLND). The OpACIN trial showed that neoadjuvant treatment with nivolumab (NIVO) plus ipilimumab (IPI) is feasible and induces a stronger and broader T-cell response. The subsequent OpACIN-neo trial identified 2 cycles of NIVO 3mg/kg + IPI 1mg/kg as a neoadjuvant dosing scheme with decreased toxicity and preserved high pathologic response rates (77%), which was confirmed in the PRADO trial. A favorable 2-year RFS (83,6%) was achieved in the overall OpACIN-neo population, although patients with a pathological partial or non-response have a worse prognosis and may therefore benefit from additional adjuvant therapy. The efficacy of neoadjuvant checkpoint inhibition versus the current standard of adjuvant therapy needs to be confirmed in a phase III trial, before neoadjuvant therapy can be considered as a standard option for this patient population. **Methods:** This international, randomized phase 3 trial aims to compare the efficacy of neoadjuvant IPI + NIVO with adjuvant NIVO in macroscopic stage III melanoma. In total 420 patients diagnosed with recurrent or de novo melanoma, with at least one pathologically proven, clinically detectable lymph node (up to 3 in-transit metastases (ITMs) allowed), will be randomized to neoadjuvant or adjuvant treatment. The population will be stratified by BRAF mutation, continent and the presence of ITMs. Patients in arm A will receive 2 cycles of IPI 80mg + NIVO 240mg and will undergo TLND at week 6. In the case of pathological partial response or non-response, surgery will be followed by adjuvant NIVO (11 cycles) or adjuvant dabrafenib + trametinib (46 weeks) if BRAFV600-mutation is present. Patients in arm B will undergo upfront TLND followed by 12 cycles of NIVO 480mg. The primary endpoint will be the event free survival (EFS) defined as the time from randomization until progression to unresectable stage III or stage IV melanoma, recurrent melanoma, a new primary melanoma or death due to melanoma or treatment. Final analysis will be performed after 132 events have been observed, or at latest 2 years after the last patient is included. Baseline biopsies and blood samples (screening, week 0, 3, 6, 9 and 12) will be collected for translational research. Quality of Life questionnaires and electronic Patient Reported Outcomes will be collected using the Kaiku application. The first patient was enrolled on the 23rd of July 2021. Clinical trial information: NCT04949113. Research Sponsor: Bristol Myers Squibb, Other Government Agency.

TPS9606 **Poster Session**

MERLIN_001: A prospective registry study of a primary melanoma gene-signature to predict sentinel node (SN) status and determine its prognostic value for more accurate staging of patients with SN-negative melanoma. *First Author: Tina J. Hieken, Mayo Clinic, Rochester, MN*

Background: For patients with cutaneous melanoma, sentinel lymph node biopsy (SLNB) provides important staging and prognostic information that guides surveillance and adjuvant systemic therapy decisions. At most centers, SLNB is indicated for patients with cutaneous melanoma with at least a 5% risk of having nodal metastases, typically melanomas ≥ 0.8 mm in thickness or thinner lesions with high-risk features such as elevated mitotic rate and/or ulceration. SLNB, generally involving a separate incision, does carry a small but measurable risk of complications including seroma, infection and rarely lymphedema, and most patients have negative sentinel lymph nodes. Currently, there is an unmet clinical need to identify patients who may safely forgo SLNB due to a low (<5%) risk of nodal metastasis, who otherwise meet established criteria for SLNB. Previously, a model consisting of gene expression profile (GEP) of the primary tumor combined with clinicopathological features (CP) has been developed to identify melanoma patients with a low risk of having a positive SLNB. The model has also been validated in multiple retrospective studies. The aim of the MERLIN_001 registry study is to prospectively validate the CP-GEP model in an independent multicenter cohort of primary cutaneous melanoma patients who undergo SLNB for standard indications. **Methods:** In the next two years, a total of 10 centers across the US will enroll 2,340 patients with clinically node-negative cutaneous melanoma undergoing SLNB using current guideline indications and will follow these patients for 5 years (ClinicalTrials.gov identifier: NCT04759781). Enrollment of patients started in September 2021 and 242 patients have been enrolled as of February 1, 2022. FFPE material from the initial melanoma biopsy will be used to assess the GEP of the primary melanoma. The CP-GEP probability scores will be expressed as a binary classification (Low Risk or High Risk for nodal metastasis) and will be compared to SLN pathology. Performance metrics for CP-GEP will be evaluated and will include: Negative Predictive Value, Positive Predictive Value, Sensitivity and Specificity, and the corresponding 95% confidence intervals. Risk for nodal metastasis will be calculated for Low Risk and High Risk CP-GEP patients. Finally, the performance of CP-GEP to stratify patients according to risk of recurrence (local, regional, distant, death) will also be studied, since data will be collected for up to 5 yrs. Clinical trial information: NCT04759781. Research Sponsor: SkylineDx B.V.

TPS9607 **Poster Session**

Neo-adjuvant T-VEC plus nivolumab combination therapy for resectable early-stage or metastatic (IIIB-IVM1a) melanoma with injectable disease: The NIVEC trial. *First Author: Maartje W. Rohaan, Division of Medical Oncology, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: The prognosis of patients with melanoma is significantly correlated with disease stage and has greatly improved with the introduction of the currently approved therapies. Trials investigating neo-adjuvant treatment with immune checkpoint inhibitors (ICI) have shown high pathologic response rates up to 25-80%, however, still a large group of patients derive no (durable) clinical benefit. Treatment with talimogene laherparepvec (T-VEC), a modified herpes simplex virus type-1, is approved for patients with unresectable stage IIIB-IVM1a melanoma, with high and durable response rates and a mild toxicity profile. Earlier trials have suggested that T-VEC has the capacity to heighten the immune response and to elicit an abscopal effect in melanoma when given in combination with ICI. Combination ICI and intralesional T-VEC has already been investigated in patients with unresectable stage IIIB-IV disease, however, no data is available yet on the potential benefit of this combination therapy in neo-adjuvant setting. This is the first trial investigating the efficacy and safety of neo-adjuvant treatment of T-VEC in combination with nivolumab (anti-PD-1 antibody), followed by surgical resection in patients with resectable stage IIIB-IVM1a melanoma, with the potential of high pathologic response rates and acceptable toxicity. **Methods:** In this single center, single arm, phase II study, a total of 24 patients ≥18 years of age and a good clinical performance score with treatment naïve, stage IIIB-IVM1a melanoma (AJCC 8th edition) with injectable disease and resectable (sub)cutaneous satellite or in-transit metastases and/or tumor positive lymph nodes, will be included. Patients will receive four courses of T-VEC up to 4mL (first dose as seroconversion dose) and three doses of nivolumab (240mg flatdose) every two weeks, followed by surgical resection in week nine. The primary endpoint of this trial is pathologic response rate, with the aim to show a high major pathologic (near-complete or complete) response rate up to 45%. Secondary endpoints are safety according to CTCAE v5.0, the rate of delay of surgery and event free survival. Additionally, prognostic and predictive biomarker research and health-related quality of life evaluation will be performed. Enrollment started in June 2020 in the Netherlands Cancer Institute, with currently 13 of the 24 planned patients treated. Clinical trial information: NCT04330430. Research Sponsor: Amgen Inc.

TPS9608 **Poster Session**

A first-in-human, phase 1b study to evaluate the safety, tolerability, pharmacokinetics, and anti-tumor activity of neoadjuvant use of ph-762 administered intratumorally in subjects with advanced melanoma. *First Author: Caroline Robert, Gustave Roussy and Paris-Saclay University, Villejuif-Paris, France*

Background: Antibodies targeting immune checkpoints such as PD-1 and CTLA-4 has shown significant benefit in late-stage melanoma. But further improvements in therapeutic options are still required. Two approaches for improving the outcome of immunotherapy with checkpoint inhibitors are neoadjuvant treatment and local intratumoral (IT) injection. IT immunotherapy uses the tumor as its own vaccine to activate the immune system, priming an anti-tumor immune response and generating systemic tumor responses, whilst minimizing systemic exposure and off-target toxicities. Neoadjuvant therapy provides the opportunity for preoperative disease shrinkage with the potential to improve surgical morbidity. There is currently no neoadjuvant standard of care for resectable, advanced melanoma patients. PH-762 is a potent RNAi molecule targeting PD-1 with structural and chemical modifications conferring properties suitable for IT administration, including an optimized cell and tissue uptake profile. Pharmacology studies show potent *in vitro* silencing of PD-1 associated with T cell activation, and robust, dose-dependent *in vivo* inhibition of tumor growth in syngeneic tumor models. **Methods:** The purpose of this study is to evaluate the safety of neoadjuvant use of PH-762 administered by IT injection in subjects with resectable stage IIIB/IIIC/IIID or IV melanoma, to determine the recommended Phase 2 dose, PK after IT injection, and potential immunologic and pathologic tumor responses. Study treatment constitutes of once weekly injections with PH-762 into one designated tumor lesion for 4 weeks prior to surgical excision at 5-6 weeks after the initial injection, with up to 5 dose levels tested in a serial fashion in cohorts of 3 or more subjects. Eligible subjects will have at least one resectable melanoma deposit that is large enough to allow IT injection, and that can undergo repeated biopsy. Subjects with active brain metastases, leptomeningeal disease, uveal melanoma, and auto-immune disease are excluded. The dose of PH-762 will be normalized to tumor volume to ensure an equivalent local dose (tumor tissue concentration). Post tumor excision, subjects will be followed-up for 6 weeks. Primary endpoint is to determine a safe dose of PH-762 assessed by incidence of Dose Limiting Toxicities (DLT) prior to tumor resection. Bayesian optimal interval (BOIN) design will be employed to evaluate escalating doses of PH-762 to determine the Maximum Tolerated Dose based on occurrence of DLT. Tumor changes will be evaluated per RECIST criteria (version 1.1 and iRECIST version adapted for use with IT therapy) and pathological response. Immunological response in tumor tissue and blood samples will be assessed as secondary endpoints. Enrollment commenced in February 2022. Clinical trial information: 2021-002859-10. Research Sponsor: Phio Pharmaceutical.

TPS9609 **Poster Session**

ARTISTRY-6: Nemvaleukin alfa monotherapy in patients with advanced mucosal and cutaneous melanoma. *First Author: Jeffrey S. Weber, Laura and Isaac Perlmutter Cancer Center, NYU Langone Health, New York, NY*

Background: Despite improved outcomes for melanoma patients with the introduction of checkpoint inhibitors (CPIs), ~50% of patients do not respond. A subset of responders ultimately progress and have limited treatment options, underscoring a high unmet need for novel treatments with durable benefit. Patients with mucosal melanoma exhibit response rates and progression-free survival times ~2 times lower than those with cutaneous melanoma. Nemvaleukin alfa (nemvaleukin, ALKS 4230) is a novel, engineered cytokine that selectively binds the intermediate-affinity interleukin-2 receptor complex to preferentially activate $CD8^+$ T and NK cells with minimal expansion of regulatory T cells. Nemvaleukin has been granted Orphan Drug designation for the treatment of mucosal melanoma by the FDA. In ARTISTRY-1, the intravenous (IV) recommended phase 2 dose (RP2D) of 6 μg/kg nemvaleukin monotherapy demonstrated durable antitumor activity in patients with advanced melanoma, including mucosal melanoma, previously treated with a CPI. In ARTISTRY-2, the subcutaneous (SC) RP2D of 3 mg q7d was identified demonstrating pharmacodynamic effects consistent with IV delivery. Data support further evaluation of nemvaleukin monotherapy among patients with advanced mucosal and cutaneous melanoma. **Methods:** ARTISTRY-6 is a phase 2, global, multicenter, open-label study. Eligible patients have had prior treatment with an anti–PD-(L)1 therapy with or without anti–CTLA-4 therapy and have an ECOG performance status of 0 or 1 and adequate hematologic reserve and hepatic and renal function. Patients with advanced cutaneous (Cohort 1) and mucosal (Cohort 2) melanoma will receive nemvaleukin at the SC and IV RP2D, respectively. Patients will receive nemvaleukin until progression or intolerable toxicity. The primary objective is to evaluate the antitumor activity of nemvaleukin monotherapy defined by overall response rate. Additional objectives include the evaluation of safety, health-related quality of life, predictive biomarkers, pharmacokinetics, immunogenicity, and pharmacodynamic effects. Clinical trial information: NCT04830124. Research Sponsor: Alkermes, Inc.

TPS9610 **Poster Session**

Capturing uveal melanoma (UM) global practice patterns and clinical outcomes in the collaborative ocular melanoma natural history (OMNi) study (NCT04588662). *First Author: Joseph J. Sacco, Clatterbridge Cancer Centre, Wirral, United Kingdom*

Background: Geographical differences in the management of primary UM, surveillance for recurrence, and care of metastatic disease have emerged based upon local expertise, treatment availability and insurance coverage. We have initiated accrual to OMNi (NCT04588662), an ambispective database developed to provide contemporary real-world data of UM, capturing its natural history and serving as a virtual biospecimen repository. The overall objectives of OMNi are to characterize regional/international UM management practice patterns and associated clinical outcomes in an effort to inform best practice recommendations. **Methods:** OMNi utilizes the Pulse Infoframe Healthie platform, a globally compliant platform which enables the structured collection of data mapped to Observational Medical Outcomes Partnership. The data fields created permit longitudinal capture of data including baseline patient and tumor characteristics, treatment of primary lesion and outcomes, surveillance patterns, time to disease recurrence, treatment of recurrent disease with outcomes, and survival. Inclusion criteria include a diagnosis of uveal melanoma and the ability to provide written informed consent for participation in the prospective registry or an institutional waiver by the IRB/ethics committee for retrospective data collection without written informed consent. We have initiated data collection at 3 US and 3 Australian centers, with 184 patients enrolled to date. Based upon feasibility assessment, we anticipate retrospective data entry for ~2,000 patients and annual recruitment of ~700 patients once all centers are active. Data collected in this OMNi collaboration, which will include additional US, UK and Australian sites, will facilitate new insights, hypothesis testing, as well as clinical trial development and conduct, and through a governance structure, will be made accessible for research. The OMNi dataset can serve and aid in interpretation of clinical trial outcomes in the real-world, facilitate cutting-edge research, and accelerate the development of diagnostics and therapeutics. Clinical trial information: NCT04588662. Research Sponsor: Immunocore and BMS.

10000 **Oral Abstract Session**

Updated safety and efficacy data from an open-label, phase 1/2 study of frontline brentuximab vedotin plus doxorubicin, vinblastine, and dacarbazine (A+AVD) in pediatric patients with advanced-stage classical Hodgkin lymphoma (cHL). *First Author: Anna Rachel Keating Franklin, University of Colorado School of Medicine, Aurora, CO*

Background: A+AVD is approved for treatment of adult patients with previously untreated Stage III or IV cHL. Here we present updated results from a phase 1/2 open-label study of frontline A+AVD in treatment-naïve pediatric patients with advanced stage cHL. **Methods:** Patients aged 5 to < 18 years with CD30+, stage III or IV, newly diagnosed cHL received A+AVD on days 1 and 15 of each 28-day cycle for up to 6 cycles. In phase 1, eight patients were treated with 48 mg/m^2 of brentuximab vedotin combined with doxorubicin, vinblastine, and dacarbazine (AVD). Dose-limiting toxicity (DLT) was evaluated from day 1 of cycle 1 to day 56. In phase 2, a further 51 patients were treated with the same regimen. Results presented here refer to phases 1 and 2 combined. Progression-free survival (PFS) was defined as the time from first dose to disease progression; event-free survival (EFS) was defined as the time from first dose to treatment failure, events included disease progression, treatment withdrawal or death. Data cutoff was September 24 2021, when all patients had been on study for at least 2 years. **Results:** In phase 1, no DLT occurred in the 6 DLT-evaluable patients. The maximum tolerated dose of brentuximab vedotin was not reached and 48 mg/m^2 was determined to be the recommended dose. All 59 patients in phase 1 and 2 completed 6 cycles of A+AVD and all experienced ≥1 treatment-emergent adverse event (TEAE). The most common any-grade TEAEs were vomiting (85%), nausea (75%), and neutropenia (58%). In total, 14/59 patients (24%) developed treatment-emergent peripheral neuropathy (PN); 10 patients had PN resolved by end of treatment (EOT); by last contact, 13 patients had resolved PN and one patient had grade 1 paraesthesia. No patients died on study. The PET-negative rate (Deauville 1, 2, or 3) after cycle 2 was 90%. Objective response rate ([ORR], defined as complete response [CR] + partial response [PR] per independent review facility [IRF] at EOT) was 88%, and 76% of patients achieved a CR. Median duration of response and duration of CR were not estimable. Median PFS and EFS had not been reached, suggesting encouraging efficacy of the combination in this pediatric patient population. Additional PFS, EFS and overall survival data will be presented during the meeting. **Conclusions:** Brentuximab vedotin given at 48 mg/m^2 every two weeks in combination with AVD had an acceptable safety profile and was associated with an efficacy benefit in CD30+, treatment-naïve pediatric patients with advanced cHL, supporting A+AVD as a frontline treatment option for this patient population. Clinical trial information: NCT02979522. Research Sponsor: Takeda Development Center Americas, Inc.

10001 **Oral Abstract Session**

Efficacy and safety of daratumumab (DARA) in pediatric and young adult patients (pts) with relapsed/refractory T-cell acute lymphoblastic leukemia (ALL) or lymphoblastic lymphoma (LL): Results from the phase 2 DELPHINUS study. *First Author: Laura E. Hogan, Department of Pediatrics, Stony Brook Children's, Stony Brook, NY*

Background: Approximately 15-20% of pediatric pts with ALL or LL will be refractory to/relapse after frontline treatment; relapsed disease is associated with poor outcomes. In a phase 2 study, 2 of 7 (28.6%) pts with T-cell ALL in first relapse achieved a complete response (CR) using the vincristine, prednisone, PEG-asparaginase, and doxorubicin (VPLD) reinduction backbone. DARA, a human IgGκ monoclonal antibody targeting CD38 approved for treating multiple myeloma, has shown preclinical efficacy in ALL models. We report the initial results of DARA plus VPLD in pediatric and young adult pts with relapsed/refractory T-cell ALL or LL enrolled in the phase 2, open-label DELPHINUS study. **Methods:** Eligible pts were aged 1-30 y, had T-cell ALL or LL in first relapse or refractory to 1 prior induction/consolidation regimen, and had a performance status ≥70. DARA (16 mg/kg IV QW) was given with VPLD in Cycle 1 and with methotrexate, cyclophosphamide, cytarabine, and 6-mercaptopurine in Cycle 2. Pts received age/risk-adjusted intrathecal therapy. Response was measured at the end of each cycle by local bone marrow morphology. The primary endpoint for ALL pts was CR rate in pediatric pts at the end of Cycle 1. Pts achieving CR after Cycles 1 or 2 could proceed to allogeneic HSCT off study. Overall response rate (ORR) was defined as CR or CR with incomplete hematological recovery (CRi) at any time before start of subsequent therapy or HSCT. Minimal residual disease (MRD) negativity (< 0.01%) at any time before disease progression, start of subsequent therapy, or HSCT was centrally reviewed by flow cytometry. **Results:** Twenty-four pediatric (age 1-17 y) and 5 young adult (age 18-30 y) ALL pts and 10 LL pts (age 1-30 y) received ≥1 DARA dose. Median (range) age was 10.0 (2-25) y (ALL) and 14.5 (5-22) y (LL); median (range) time from initial diagnosis to first study treatment was 2.0 (0.1-6.1) y (ALL) and 0.8 (0.5-6.0) y (LL). Pediatric ALL pts received a median (range) of 2 (1-3) treatment cycles; young adult ALL pts and LL pts each received 2 (1-2). Among pediatric ALL pts, 10 (41.7%) pts (90% CI, 24.6-60.3) achieved CR at the end of Cycle 1. ORR was 83.3% (CR, 13 [54.2%] pts; CRi, 7 [29.2%] pts) in pediatric and 60.0% (all CR) in young adult ALL pts and 40.0% (all CR) in LL pts. Ten (41.7%) pediatric ALL pts achieved MRD negativity. All pediatric ALL pts had a grade 3/4 TEAE. No pediatric ALL pt discontinued DARA primarily due to AEs and 1 (4.2%) died due to TEAEs (brain edema and hepatic failure) attributed to study treatment but unrelated to DARA. **Conclusions:** The addition of DARA to VPLD in pediatric and young adult pts with relapsed/refractory T-cell ALL or LL showed initial activity, generating improved response rates compared to those achieved with backbone therapy alone, with a manageable safety profile. Clinical trial information: NCT03384654. Research Sponsor: Janssen Research & Development, LLC.

10002 **Oral Abstract Session**

BEACON-Immuno: Results of the dinutuximab beta (dB) randomization of the BEACON-Neuroblastoma phase 2 trial—A European Innovative Therapies for Children with Cancer (ITCC–International Society of Paediatric Oncology Europe Neuroblastoma Group (SIOPEN) trial. *First Author: Juliet Gray, University of Southamtpon, Southampton, United Kingdom*

Background: The BEACON phase II trial (NCT02308527) addressed a number of questions in children with relapsed/refractory high-risk neuroblastoma (RR-HRNB). Here we report the chemo-immunotherapy randomisation, assessing if anti-GD2 (dB) demonstrates activity when added to chemotherapy. **Methods:** Patients aged 1-21 years with RR-HRNB with adequate organ function and performance status were randomised in a 1:2 ratio to receive chemotherapy alone or with dB, given concurrently as a 7 day continuous infusion (10 mg/m^2/24hr). As the trial had a factorial design, some patients were also randomised between chemotherapy regimens (temozolomide (T) versus Temozolomide-Topotecan (TTo); this randomisation closed soon after the dB randomisation opened and all patients subsequently received TTo chemotherapy. Cross-over to dB with topotecan and cyclophosphamide was allowed for patients randomised to chemotherapy alone who experienced disease progression. The primary outcome measure was best response (complete or partial) at any point during the first 6 courses of treatment, by RECIST or International Neuroblastoma Response Criteria for patients with measurable and evaluable disease respectively. Progression free and overall survival (PFS & OS) and safety were secondary outcomes. The success criterion for proceeding to a Phase 3 trial was a one-sided p-value (1p) less than 0.23 for Objective Response Rate (ORR). **Results:** From Aug 2019 to Feb 2021, 65 patients were randomised to chemotherapy alone (3 T, 19 TTo) or with dB (6 dBT, 37 dBTTo). Median age was 4 years; 48 and 17 had measurable and evaluable disease respectively; 29 and 36 had refractory and relapsed disease respectively; 19 had MYCN amplification. Baseline characteristics were balanced between arms. Response was assessable in all patients. The ORR was 18% with chemotherapy alone and 35% for patients receiving chemotherapy with dB (risk ratio 1.66, 80% confidence interval (CI) 0.9 to 3.06, 1p = 0.19). 1-year PFS was 27% for chemotherapy alone, and 57% for those receiving chemotherapy +dB (HR 0.63, 95% CI 0.32 to 1.25, p = 0.19). Twelve patients in the chemotherapy only arm crossed over to receive dB at progression. OS did not differ between the arms: HR = 0.99, 95% CI 0.42 to 2.36, p = 0.99. Nine (41%) patients receiving chemotherapy alone and 13 (30%) receiving chemotherapy plus dB had grade ≥3 toxicities (CTCAE v4.0). Neurotoxicities were more common in patients receiving dB compared to chemotherapy alone (Grade 1-2: 67.4% vs 13.6%, Grade 3: 9.3 vs 0%). Other toxicities were similar with and without dB. **Conclusions:** The Phase 2 success criterion for ORR was met and PFS is also encouraging. The addition of dB to temozolomide-based chemotherapy shows promising activity in patients with RR-HR-NB. Clinical trial information: NCT02308527. Research Sponsor: Solving Kids Cancer, Imagine for Margo, Cancer Research UK.

10003 **Oral Abstract Session**

A pilot induction regimen incorporating dinutuximab and sargramostim for the treatment of newly diagnosed high-risk neuroblastoma: A report from the Children's Oncology Group. *First Author: Sara Michele Federico, St. Jude Children's Research Hospital, Memphis, TN*

Background: The addition of dinutuximab (DIN) in the post-consolidation setting led to improved event-free survival rates for patients with high-risk neuroblastoma. Chemoimmunotherapy including irinotecan, temozolomide, DIN and sargramostim (GM-CSF) in patients with recurrent or refractory neuroblastoma results in robust objective clinical responses. Evaluation of chemoimmunotherapy in the induction setting for patients with newly-diagnosed high-risk neuroblastoma (HR-NBL) warrants investigation. **Methods:** Children's Oncology Group (COG) ANBL17P1 is a prospective, single arm, limited institution pilot study to assess the tolerability and feasibility of administering DIN (17.5mg/m^2/dose, IV Days 2-5) and GM-CSF (250mcg/m^2/dose, subcutaneous Days 6-count recovery) with COG Induction chemotherapy Cycles 3-5 for patients with newly-diagnosed high-risk neuroblastoma. The primary endpoint of tolerability included the number of toxic deaths and number of patients experiencing predefined unacceptable toxicities during Induction Cycles 3-5. Unacceptable toxicities included: hypotension requiring pressors > 24 hours, respiratory toxicity requiring ventilatory support > 24 hours, Grade 4 neuropathy that did not resolve prior to the next cycle, and failure to recover the ANC to > 750 mm^3 by day 35. Feasibility was assessed as being able to receive > 75% of planned DIN doses administered during Induction Cycles 3-5. Revised International Neuroblastoma Response Criteria (INRC) were used to assess end of Induction (EOI) response. **Results:** Forty-two eligible and evaluable patients with newly-diagnosed high-risk neuroblastoma enrolled at 8 sites (22 [52.4%] males; median age 3.3 years at diagnosis) from January 14, 2019 to June 4, 2020. The most common DIN related Grade >3 toxicities observed during Induction Cycles 3-5 included fever (31.0%) and pain (9.5%). None of the patients experienced a toxic death or unacceptable toxicity during Induction Cycles 3-5. Thus, the regimen was deemed tolerable. Patients received 97.4% - 101.8% of the total DIN dose expected to be administered during Induction Cycles 3-5. Therefore, the regimen was deemed feasible. Thirty-eight of 42 patients completed the EOI evaluations, including 11 with complete response, 22 with partial response, 0 with minor response, 3 with stable disease and 2 with progressive disease. The overall EOI objective response rate (CR+PR+MR) was 86.8%. **Conclusions:** The administration of DIN and GM-CSF to COG Induction Cycles 3-5 for patients with newly-diagnosed high-risk neuroblastoma was tolerable and feasible. The objective response rate at EOI appears encouraging. This therapeutic regimen will be studied in a randomized phase 3 trial to further evaluate the efficacy of Induction phase chemoimmunotherapy for high-risk neuroblastoma. Clinical trial information: NCT03786783. Research Sponsor: NCTN Operations Center Grant U10CA180886, Other Foundation, Other Government Agency, Pharmaceutical/Biotech Company.

10004 **Oral Abstract Session**

Poverty, race, ethnicity, and survival among U.S. children with non-metastatic osteosarcoma treated on EURAMOS-1: A report from the Children's Oncology Group. *First Author: Lenka Ilcisin, Boston Children's Hospital Department of Surgery, Boston, MA*

Background: Children living in poverty and those who identify as a race/ethnicity other than non-Hispanic White experience higher rates of relapse and lower overall survival across many pediatric cancers. Racial, ethnic and socioeconomic disparities have not been comprehensively investigated in osteosarcoma. We leveraged data from US-enrolled patients on the recent international EURAMOS-1 trial to investigate disparities in survival outcomes. Aim: Identify if race/ethnicity, household or neighborhood poverty exposure are associated with event-free survival (EFS) or overall survival (OS) in patients with non-metastatic osteosarcoma enrolled at a US-center on EURAMOS-1. **Methods:** Retrospective cohort study of US patients aged 5-21 years enrolled on EURAMOS-1 with a diagnosis of non-metastatic, primary osteosarcoma. Poverty was the primary exposure defined at the household- (sole coverage with Medicaid or CHIP public insurance versus other) and neighborhood- (Census-defined high-poverty ZIP code with >20% of residents living at <100% Federal Poverty Level vs other) levels. Race and ethnicity were categorized to reflect structural inequities and historically marginalized populations, as Hispanic, non-Hispanic Black (NHB), non-Hispanic Other (NHO), and non-Hispanic White (NHW). OS and EFS as a function of time from trial enrollment were estimated using the Kaplan-Meier method. Hypotheses of associations between risks for EFS-event, death and post-relapse death with poverty-exposures and race/ethnicity were assessed using log-rank tests. Statistical comparisons were performed excluding patients with missing values for the exposures considered. P-values <=0.05 were considered significant. **Results:** Among 758 patients, 27% were household poverty-exposed and 29% were neighborhood-poverty exposed. Twenty-one percent of children identified as Hispanic, 17% NHB, 5% NHO and 57% NHW. Neither household- or neighborhood-poverty, nor race/ethnicity were significantly associated with risks for EFS-event or death. Post-relapse risk for death differed significantly across race/ethnicity with NHB at greatest risk compared to others (4-Year post-relapse survival 35.7% Hispanic vs. 13.0% NHB vs. 43.8% NHO vs 38.9% NHW; p=0.0046). **Conclusions:** Neither poverty-exposures nor race/ethnicity were associated with EFS or OS in this COG trial-enrolled cohort, suggesting equitable outcomes following standardized therapy. Despite this, non-Hispanic Black children experienced significantly inferior post-relapse survival. Investigation of mechanisms driving these post-relapse disparities, including inequities in health care delivery and access to post-relapse trial-enrollment, are paramount to ensure equity in outcomes for all children with cancer. Research Sponsor: None.

Racial, ethnic, and socioeconomic survival disparities among children with high-risk neuroblastoma treated on upfront Children's Oncology Group clinical trials. *First Author: Puja J Umaretiya, Dana-Farber and Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: Racial and socioeconomic disparities have not been comprehensively investigated in high-risk neuroblastoma (HR NBL). Prior Children's Oncology Group (COG) investigations have demonstrated population-based disparities in late relapse rates among Black children, and trial-based disparities in relapse and survival among children living in poverty receiving post-consolidation immunotherapy. It is unknown whether these disparities persist in upfront trials for newly diagnosed patients. We leveraged COG data to investigate race, ethnicity, and socioeconomic disparities in a cohort of children with HR NBL treated on upfront clinical trials from 2007-2016. **Methods:** Retrospective cohort study of children enrolled on upfront COG HR NBL trials ANBL0532, ANBL09P1, and ANBL12P1. Race and ethnicity were the primary exposures categorized as: Black Non-Hispanic (BNH); Hispanic; Other Non-Hispanic (ONH); or White Non-Hispanic (WNH). Poverty was the secondary exposure, defined as household (public insurance only vs others), area (census-defined high-poverty ZIP code with >20% of population living below 100% Federal Poverty Level (FPL) vs <20% below 100% FPL), and rural (Census-defined rurality measures linked to ZIP code). Overall (OS) and event-free (EFS) survival from time of trial enrollment were plotted by Kaplan-Meier methods; associations with race/ethnicity and poverty were evaluated by log-rank tests. **Results:** Among 696 children, 16% were BNH, 11% Hispanic, 4% ONH, and 69% WNH. One-third (33%) of children were household poverty-exposed, 26% area poverty-exposed, and 15% rural-exposed. Tumor stage and biology did not differ by race/ethnicity or poverty measures. Five-year OS differed significantly by race/ethnicity (47% Hispanic vs. 50% ONH vs. 61% WNH vs. 62% BNH; p=0.047). Five-year OS was inferior among children exposed to household-poverty (53% vs. 63%; p=0.036) and neighborhood-poverty (54% vs. 62%; p=0.050) compared to unexposed children. There was no difference in OS by rurality. Similar directionality in 5-year EFS outcomes by race/ethnicity and poverty were observed without statistical significance. **Conclusions:** Race/ethnicity and poverty-exposure are associated with inferior OS outcomes among children with HR NBL despite uniform planned treatment on upfront COG trials. Investigation of mechanisms driving these disparities, including disparate early phase trial enrollment are ongoing to inform targeted health equity interventions to improve outcomes. Research Sponsor: None.

Securing access to innovative anticancer therapies for children, adolescents, and young adults outside clinical trials: The SACHA study of the French Society of Pediatric Oncology (SFCE). *First Author: Pablo Berlanga, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Access to innovative anticancer therapies for children, adolescents and young adults within clinical trials in France is steadily increasing in the last years. However, current clinical trials portfolios are still inadequate and thus pediatric hemato-oncologists regularly prescribe innovative medicines outside their marketing authorization, and/or experimental drugs through compassionate use. **Methods:** The Secured Access to innovative medicines for CHildren with cAncer (SACHA) is a French prospective observational study developed by the French Society of Pediatric Oncology (SFCE) with Gustave Roussy as the legal sponsor to prospectively collect real-world safety and activity data of innovative therapies administered to patients ≤ 25 years-old with pediatric malignancies (solid tumor or leukemia) or other related conditions, either on compassionate use of experimental drugs or off-label use of anti-cancer medicines that have been first approved in adults after 2007. Prior to SACHA inclusion, multicenter tumor board discussion defining best available therapeutic options for each patient with a relapsed malignancy is mandatory. **Results:** The SACHA study opened in March 2020 and by February 2022, 283 patients have been included from 29/31 SFCE recruiting centers; median age: 11.0 years (range: 0.3-24.4). Main cancer types were central nervous system (CNS) tumors (47%), followed by non-CNS tumors (40%) and leukemias (13%). Innovative therapies prescribed in > 10 patients with reported objective response rate (ORR) and related CTCAE v.5 grade ≥2 clinical and/or grade ≥3 biological adverse drug reactions (ADRs) are described in Table. **Conclusions:** SACHA confirms the feasibility of this type of prospective real word registry, with a high participation of French centers. Based on this French experience, the Innovative Therapies for Children with Cancer (ITCC) consortium is currently developing a "SACHA International Project" to be opened in ITCC and collaborating countries. Research Sponsor: Imagine for Margo, Association Hubert Gouin, Fondation du LEEM and the SFCE.

Innovative drug	N	Reported ORR / evaluable patients*	Patients with at least 1 reported ADR / evaluable patients*	Serious ADR*
Trametinib	64	9/40	30/64	3
Trametinib/Dabrafenib	36	11/20	2/33	2

Regorafenib	15	0/9	7/15	0
Tazemetostat	14	1/14	4/14	1

ORR: objective response rate; ADR: adverse drug reaction. *Data cut-off: 4th February 2022.

10007 **Oral Abstract Session**

Late mortality and morbidity among adult survivors of childhood glioma treated over three decades: A report from the Childhood Cancer Survivor Study. *First Author: Peter de Blank, University of Cincinnati, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Therapy for pediatric low-grade glioma has evolved to delay or eliminate the need for cranial radiation. The impact of this change in approach on long-term outcomes remains unknown. **Methods:** Cumulative incidence of late mortality (death ≥5 years from diagnosis), subsequent neoplasms (SNs), and chronic health conditions (CHCs, graded using CTCAE criteria) were evaluated in the Childhood Cancer Survivor Study among 5-year survivors of glioma diagnosed between 1970 and 1999. Outcomes were evaluated by diagnosis decade (1970s, 1980s, 1990s) and by treatment exposure in the first five years from diagnosis [surgery only, chemotherapy (with or without surgery), and cranial radiation (with or without surgery or chemotherapy)]. Relative Risk (RRs) with 95% CIs estimated long-term outcomes using multivariable piecewise exponential models. **Results:** Among 2,684 eligible survivors (median age at diagnosis, 7 years [range, 0 to 20 years]; median time from diagnosis, 24 years [range, 5 to 48 years]), the proportion exposed to cranial radiation decreased from 51% (1970s) to 45% (1980s) and 25% (1990s) while the rate of recurrence within > 5 years but ≤15 years of diagnosis decreased from 9.8% (1970s) to 8.8% (1980s) and 5.0% (1990s). The 15-year cumulative incidence rate of all-cause late mortality was 10.3% (1970s), 6.5% (1980s), and 6.0% (1990s) ($p < 0.001$, comparison of cumulative incidence curves). The 15-year cumulative incidence rates of severe, disabling or life-threatening (grade 3-5) CHCs also decreased between 1970 and 1999: 19.7% (1970s), 17.8% (1980s), and 14.2% (1990s) ($p < 0.0001$). Lower rates of SN were not observed. In a multivariable analysis adjusted for age at diagnosis, attained age, race, sex and diagnosis decade, later diagnosis (1990s vs. 1970s) was associated with lower risk of late mortality (RR 0.86, 95% CI 0.74-0.99), grade 3-5 CHCs (RR 0.65, 95% CI 0.51-0.82) and SN (RR 0.64, 95% CI 0.44-0.94). In addition, when treatment exposure was added to the multivariable model, the effect of diagnosis decade was attenuated and no longer significant. Exposure to radiation or chemotherapy both increased risk compared to surgery alone: all-cause mortality (radiation RR 4.95, 95% CI 3.79-6.47; chemotherapy RR 2.88, 95% CI 1.85-4.48), grade 3-5 CHCs (radiation RR 4.02, 95% CI 3.28-4.94; chemotherapy RR 1.66, 95% CI 1.13-2.45), SNs (radiation RR 4.02, 95% CI 3.06-6.13, chemotherapy RR 2.08, 95% CI 1.03-4.23)). The effect of delayed radiation (> 1year to ≤5 years from diagnosis) on all-cause late mortality, grade 3-5 CHCs, or SNs was not different compared to radiation within one year of diagnosis. **Conclusions:** Late mortality and CHCs decreased in childhood glioma survivors diagnosed from 1970-1999 largely due to therapy changes, particularly avoidance of cranial radiation, without increased late recurrence. 10008 **Oral Abstract Session**

Joint effects of general population polygenic risk scores (PRS) and radiation treatment on subsequent neoplasm risk among childhood cancer survivors: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Todd M. Gibson, Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, MD*

Background: We examined whether PRS from general population studies are associated with risk of subsequent neoplasms (SNs) in childhood cancer survivors and evaluated joint associations between PRS and radiation treatment (RT), an established SN risk factor. **Methods:** Common genetic variants associated with risk of basal cell carcinoma (BCC), breast cancer, thyroid cancer, squamous cell carcinoma (SCC) or melanoma in general population studies were used to calculate cancer specific PRS among 5,911 5 year cancer survivors diagnosed < 21 years of age and between 1970-1986 in the CCSS. We examined associations between each PRS and SN risk using conditional logistic regression in nested case control studies, with incidence density sampling and matching on childhood cancer type, age at diagnosis, sex, RT dose to the SN site, and chemotherapy exposure. Further analyses matching only on non-treatment factors assessed joint associations considering potential combinations of PRS and RT exposure. We calculated the relative excess risk due to interaction (RERI) to determine whether joint associations were consistent with additivity of the individual risk factors (RERI > 0 indicates a more-than-additive joint association). **Results:** Among survivors (median age at follow-up 40 years, range 3-67; 62% exposed to RT), cancer specific PRS were associated with risk of subsequent BCC (N = 626; quartile 4 versus 1, OR [95% CI] = 1.9 [1.5-2.4]), breast cancer (N = 277; 4.5 [2.8-7.1]), thyroid cancer (N = 149; 1.9 [1.2-3.1]), and melanoma (N = 76; 2.7 [1.3-5.6]). Both PRS and RT were independently associated with SN risk, but joint analyses using a common reference group (PRS < median, RT < 1 Gy) found that both risk factors together resulted in more-than-additive increases in risk of BCC (RERI [95% CI] = 6.9 [2.0-11.8], breast cancer (6.6 [2.2-10.1], and thyroid cancer (4.8 [0.5-9.2]). Specifically, BCC risk was increased 28.8-fold for both PRS ≥ median and RT ≥ 1 Gy together, but only 3.3-fold for PRS ≥ median alone and 19.7-fold for RT ≥ 1 Gy alone. Similarly, breast cancer risk was increased 14.1-fold for both risk factors together, 2.5-fold for PRS ≥ median alone, and 6.5-fold for RT ≥ 1 Gy alone, and thyroid cancer risk was increased 12.3-fold for both risk factors together, 2.4-fold for PRS ≥ median alone, and 6.0-fold for RT ≥ 1 Gy alone. In joint analyses using more detailed RT categories, we found more-than-additive joint associations at both low and high RT doses. **Conclusions:** General population PRS were associated with SN risks after childhood cancer. More-than-additive increased risks with the combination of PRS and RT suggest that established markers of genetic susceptibility remain important in the context of treatment-related risks and may be useful in further refining risk assessment and follow-up guidelines for survivors. Tazemetostat in patients with tumors with alterations in EZH2 or the SWI/SNF complex: Results from NCI-COG Pediatric MATCH trial Arm C (APEC1621C). *First Author: Susan N. Chi, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: The NCI-Children's Oncology Group (COG) Pediatric Molecular Analysis for Therapy Choice (MATCH) trial assigns patients, age 1-21 years, with relapsed or refractory solid tumors, lymphomas, and histiocytic disorders to phase 2 treatment arms based on genetic alterations detected in their tumor. Arm C evaluated the EZH2 inhibitor tazemetostat in patients whose tumors harbored *EZH2* hotspot mutations or SMARCB1 or SMARCA4 loss by immunohistochemistry. **Methods:** Tazemetostat 1200 mg/m^2/dose PO BID was administered to the first 13 patients; after study amendment due to second malignancy noted in the pediatric phase 1 trial, the dose for patients with non-CNS tumors was reduced to 520 mg/m^2/dose PO BID. Patients were treated for 28-day cycles until PD or intolerable toxicity (max 26 cycles); response assessments occurred every 2-3 cycles. Primary and secondary endpoints were ORR and PFS, respectively. **Results:** Twenty eligible and evaluable patients (median age 5 years; range 1-21) were enrolled between Nov 2017 and Sept 2020. SMARCB1 loss was detected in 16/20 (80%) tumors: atypical teratoid rhabdoid tumor (ATRT, n = 8), malignant rhabdoid tumor (MRT, n = 4), epithelioid sarcoma (ES, n = 2), renal medullary carcinoma (RMC, n = 1) and hepatocellular carcinoma (HCC, n = 1). *EZH2* mutations were identified in 3/20 (15%) tumors: Ewing sarcoma (n = 2), ependymoma (n = 1). One patient with Langerhans cell histiocytosis (LCH) had SMARCA4 loss. Centrally reviewed, one objective response (PR) was observed (LCH [SMARCA4], 26 cycles at 1200 mg/m^2/dose BID). Five other patients had a best response of stable disease (ES [SMARCB1], 26 cycles, 520 mg/m^2/dose BID; ATRT [SMARCB1], 13 cycles,1200 mg/m^2/dose BID; RMC [SMARCB1], 12 cycles, 520 mg/m^2/dose BID; ES [SMARCB1], 9 cycles,1200 mg/m^2/dose BID; ATRT [SMARCB1], 6 cycles, 1200 mg/m^2/dose BID). No other patients received > 2 cycles. Six-month PFS was 35% (95% CI 15.7%, 55.2%); OS was 45% (95% CI 23.1%, 64.7%). Treatment-related adverse events were consistent with AEs previously reported with tazemetostat, including anemia, thrombocytopenia, elevated LFTs, abdominal pain, dyspnea, infection, and intracranial hemorrhage. Three patients had bromide elevations. **Conclusions:** In this cohort of children with relapsed tumors harboring EZH2 mutations or loss of SMARCB1 or SMARCA4, tazemetostat did not produce significant objective responses (ORR: 5%, 90% CI 1%, 20%). However, we observed prolonged stable disease of > 6 months (range: 6-26 cycles) in 33% of patients across different histologic diagnoses, including two patients who received the full two years of study therapysuggesting a potential effect of tazemetostat on disease stabilization. Future studies will incorporate tazemetostat in combination with chemotherapy or immunologic agents for patients with these aggressive and difficult to treat tumors. Clinical trial information: NCT03213665. Research Sponsor: U.S. National Institutes of Health.

Matched external control analysis of event-free survival (EFS) in patients with high-risk neuroblastoma (HRNB) receiving eflornithine (DFMO) maintenance. *First Author: Javier E. Oesterheld, Levine Children's Hospital at Carolinas Medical Center, Charlotte, NC*

Background: Long term survival in HRNB patients remains a challenge with relapse as the primary cause of mortality. DFMO has been evaluated as a chemopreventative therapy in a single arm study designed to compare EFS outcomes with published rates for the Phase 3 Children's Oncology Group ch14.18 immunotherapy trial, ANBL0032. In order to address the limitations associated with comparison to a historical control group, we used ANBL0032 patient-level data and propensity-score matching (PSM) to simulate a randomized study comparing EFS of patients treated with DFMO after ch14.18 (treated) to ANBL0032 patients who did not subsequently receive DFMO (control). **Methods:** A phase 2 trial enrolled a total of 140 HRNB patients in remission at the completion of disease treatment from 2012 to 2016. Patients received 2 years of continuous treatment with DFMO 750 ±250 mg/m^2 BID and were followed for up to 7 years. ANBL0032 enrolled a total of 1328 HRNB patients from 2001 to 2015 who were assigned to treatment with ch14.18 immunotherapy and followed for up to 10 years. With FDA input, we defined selection rules to identify like groups of treated and control patients eligible for matching, covariates of potential prognostic importance, and matching algorithm details. PSM was used to balance cohorts on their baseline demographic and characteristics, matching each treated patient with the 3 most closely scored control patients with an exact match on MYCN. The Kaplan-Meier method and Cox regression analyses were used to compare EFS (primary) and overall survival (OS) (key secondary) endpoints. Multiple sensitivity analyses were performed to further investigate the primary comparison. **Results:** A total of 92 treated patients and 852 control patients met selection criteria, with 91 and 516, respectively, having complete covariate data required for the analysis. Eighty-seven (94.6%) of the treated group had verified participation in ANBL0032 immediately prior to enrollment in the DFMO trial. EFS from end of immunotherapy was significantly improved in the matched DFMO group (n=90) vs. control group (n=270), with a hazard ratio of 0.48 (95% CI: 0.27, 0.85) and a p-value of 0.0114. Four-year EFS was 84.4% (95% CI 75.2, 90.5) in the DFMO group versus 72.8% (95% CI 67.0, 77.7) in the control group. OS rates were also higher for DFMO group in the matched population, with a hazard ratio of 0.36 (95% CI: 0.16, 0.79) and a p-value of 0.0105. EFS sensitivity analyses demonstrated consistent results, including those challenging selection criteria for the control population. **Conclusions:** Patients in remission after standard upfront therapy treated with DFMO had approximately half the risk of relapse compared to matched control patients. The PSM comparisons represent the most statistically robust findings to date supporting the benefit of DFMO as a maintenance treatment for HRNB. Clinical trial information: NCT02395666, NCT00026312. Research Sponsor: Beat Childhood Cancer Foundation, Pharmaceutical/Biotech Company.

STRIVE-02: A first-in-human phase 1 trial of systemic B7H3 CAR T cells for children and young adults with relapsed/refractory solid tumors. *First Author: Navin R. Pinto, Seattle Children's Hospital, Seattle, WA*

Background: B7H3 (CD276) has limited expression in normal tissues and high cell-surface expression in pediatric solid malignancies providing rationale for immunologic therapeutic targeting. We present a first-in-human experience of B7H3 chimeric antigen receptor T cells (CAR-T) for children and young adults (CYA) with relapsed or refractory solid tumors (R/RST). **Methods:** CYA patients with R/RST were enrolled onto a Phase 1 trial (NCT04483778) to examine the safety of autologous T cells genetically modified to express scFV-IgG4hinge-CD28tm-4-1BB-zeta B7H3-specific CAR with the methotrexate resistance/selection cassette DHFRdm and the tracking/suicide construct EGFRt. All patients received lymphodepleting fludarabine and cyclophosphamide prior to infusion of cryopreserved CAR-T at the prescribed dose level. The maximal tolerated dose or biologically effective dose (BED) was determined based upon observed toxicity through day 28 from initial CAR-T infusion and using a 3+3 statistical design. **Results:** Sixteen subjects (age 11-24, median 17 years) enrolled and received dose level (DL) 1 (0.5 x 10^6 CAR-T/kg, n = 3) or DL2 (1 x 10^6 CAR-T cells/kg, n = 6). No dose limiting toxicity was observed following first infusion, most common toxicities were fatigue and cytokine release syndrome (CRS) (n = 2, maximum CTCAE grade 2). Maximum circulating CAR-T expansion on first infusion was 4.98 cells/uL (range 0.23-4.98 cells/uL) with median persistence of 28 days (range 14-90). Best overall response of Stable Disease was observed in 3 of the 9 subjects infused. Given observed expansion and persistence, DL2 was determined to be the BED. A second infusion at DL2 in one subject demonstrated CAR T expansion to 1590 cells/uL (86% of circulating CD3 cells) with CTCAE grade 2 CRS and transient dose limiting CTCAE grade 4 liver enzyme elevation. A partial metabolic response on FDG-PET by PERCIST criteria was observed in this subject at Day 28. **Conclusions:** B7H3 CAR T cells are safe and demonstrate anti-tumor activity in CYA with R/RST. CAR-T cell expansion and persistence may be necessary to achieve objective responses. STRIvE-02 Arm B will explore dual expression of CD19 CAR with B7H3 CAR, using lymphocytic CD19 expression to drive CAR expansion and persistence. Clinical trial information: NCT04483778. Research Sponsor: Seattle Children's Therapeutics.

Pediatric EBV-negative monomorphic post–solid organ transplant lymphoproliferative disorders [EBV(-)M-PTLD]: Characteristics, treatment, and outcome from 11 pediatric academic centers. *First Author: Zeinab A.M. Afify, Primary Children's Hospital, University of Utah, Salt Lake City, UT*

Background: Pediatric EBV(-)M-PTLD comprises < 15% of M-PTLD. Two-year-overall survival of pediatric EBV(+) PTLD is 83%. No large multi-institution pediatric-specific reports are available for EBV(-)M-PTLD. **Methods:** Retrospective study of characteristics, treatment, and outcome of pediatric solid organ recipients diagnosed with EBV(-)M-PTLD at age ≤21 years (y) in 11 pediatric transplant centers in US and UK. **Results:** Thirty-three patients transplanted with solid organs between 1991-2017 developed EBV(-)M-PTLD. Twenty-two (66%) were male. Median age (range) at organ transplantation was 2.6y(0.1-17), diagnosis of EBV(-)M-PTLD 14y(3-20), interval from transplant to PTLD 8.3y (2.3-18). Transplanted organs were heart (n = 10), kidney (n = 17), liver (n = 4), small bowel (n = 1), liver and small bowel (n = 1). Immunosuppressive therapy at the time of diagnosis of PTLD was available on 31 patients. All were receiving a calcineurin inhibitor except one who was on sirolimus alone. Tacrolimus was given in 27 patients, alone (n = 3), or in various combination with mycophenolate (n = 8), azathioprine (n = 9), prednisone (n = 8), or everolimus (n = 1). Four of these receiving tacrolimus received 3 immunosuppressive drug combinations. Cyclosporine was given in 3 patients, with mycophenolate (n = 1), prednisone (n = 1), or both (n = 2). Murphy stages were I (n = 1), II (n = 7), III (n = 22), and IV (n = 3). Lactate dehydrogenase was elevated in 19/31 (61%) and > 2X upper limit of normal in 10/31 (32%) tested. Pathological diagnoses were diffuse large B-cell lymphoma (n = 30) and B-NHL NOS (n = 3). Treatment included: rituximab alone (n = 1), low-dose cyclophosphamide, prednisone, and rituximab (CPR; n = 9), pediatric mature B-NHL-specific regimen [FAB/LMB with (n = 12) or without (n = 1) rituximab], EPOCH-R (n = 2), R-CHOP (n = 3), modified R-CHOP (n = 2), COP (n = 1), and R-COP (n = 2). At a median 2.9y (0.3-11y) from diagnosis, 26/33 (79%) were alive and in complete remission (CR). Three experienced relapses at 1, 3, and 6.5y after CPR, rituximab alone, and B-NHL therapy, respectively. All achieved a sustained second CR with additional B-NHL therapy. Of the 7 deaths: 6 were from progressive disease despite escalation to intensive B-NHL therapy following initial COP (n = 1), R-COP (n = 1), CPR (n = 2), and B-NHL therapy (n = 2), and one cardiac transplant recipient from presumed cardiotoxicity. There was one graft rejection that was successfully treated. **Conclusions:** This collaboration represents the first multi-institution series of pediatric EBV(-)M-PTLD. Overall survival was comparable to that reported for pediatric EBV(+) PTLD, but inferior to DLBCL in immunocompetent children. These preliminary data reflect a wide range of therapeutic regimens used over 20 years and strongly support an organized collaborative effort to collect data prospectively. Research Sponsor: None.

10013 **Poster Discussion Session**

Survival of patients with neuroblastoma before versus after reduction of therapy due to the change in age cut-off from 12 to 18 months in Children's Oncology Group (COG) risk stratification. *First Author: Wendy B. London, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: In 2006, COG reclassified subgroups of toddlers diagnosed with neuroblastoma from high-(HR) to intermediate-risk (IR), when the age cut-off for increased risk was raised from 365 days (12 mo) to 547 days (18 mo) (London, *J Clin Onc* 2005). The aim of this retrospective study was to determine if excellent outcome was maintained after a reduction of therapy. **Methods:** Children < 3 yrs old at diagnosis, enrolled on a COG biology study from 1990-2018, were eligible (n = 9,189). Therapy was reduced for two "cohorts of interest" based on the age cut-off change: 365-546 days old with INSS stage 4, *MYCN* not amplified, favorable INPC, hyperdiploid tumors (12-18mo/Stage4/FavBiology); and, 365-546 days old with INSS stage 3 tumors with non-amplified *MYCN* and unfavorable INPC (12-18mo/Stage3/NotAmp/UnfavINPC). Log rank tests compared event-free (EFS) and overall survival (OS) curves. **Results:** In the cohorts of interest, patient (pt) characteristics were similar for ≤2006 vs > 2006. For 12-18mo/Stage4/FavBiology, 5-year EFS and OS (± std error) before (≤2006; n = 40) versus after (> 2006; n = 55) the reduction in therapy were similar: 89±5.1% versus 87±4.6% (p = 0.7), and 89±5.1% versus 94±3.2% (p = 0.4), respectively (Table). For 12-18mo/Stage3/NotAmp/UnfavINPC, the 5-year EFS and OS were both 100%, before (n = 6) and after (n = 4) 2006. For the combined cohorts for ≤2006 versus > 2006, EFS and OS were 91±4.4% versus 88±4.3% (p = 0.6), and 91±4.5% versus 95±2.9% (p = 0.5), respectively. Within HR pts diagnosed ≤2006, EFS/OS were 91±4.4%/91±4.5% for (12-18mo/Stage4/FavBiology plus 12-18mo/Stage3/NotAmp/UnfavINPC) vs 38±1.3%/43±1.3% for all other HR pts < 3 yrs old (p < 0.0001; Table). Within IR pts diagnosed > 2006, EFS/OS were 88±4.3%/95±2.9% for (12-18mo/Stage4/FavBiology plus 12-18mo/Stage3/NotAmp/UnfavINPC) vs 88±0.9%/95±0.6% for all other IR pts < 3 yrs old (p = 0.9). **Conclusions:** Our 19 year study demonstrates that excellent outcome is maintained among toddlers with Stage4/FavBiology and Stage3/Not Amp/Unfav INPC neuroblastoma with a significant reduction of therapy from high- to intermediate-risk treatment. Importantly, pts were likely spared acute toxicity and late effects known to be associated with HR therapy. Efforts to identify additional pt cohorts who may not require HR therapy to achieve long-term survival are critical to improve the long-term health of children with neuroblastoma. Research Sponsor: Little Heroes Pediatric Cancer Research Foundation, Other Foundation, U.S. National Institutes of Health.

Modifiable risk factors for late mortality among five-year survivors of childhood cancer: A report from the Childhood Cancer Survivor Study. *First Author: Stephanie B Dixon, St. Jude Children's Research Hospital, Memphis, TN*

Background: The impact ofmodifiable lifestyle and cardiovascular risk factors (CVRFs) on risk for late mortality in adult survivors of childhood cancer is not well established. **Methods:** All-cause and health-related late (>5 years from cancer diagnosis) mortality (HRM; excludes death from primary cancer and external causes) were evaluated in five-year survivors diagnosed <21 years of age using the National Death Index through 2017. Modifiable lifestyle (smoking status, alcohol use, physical activity, body mass index [BMI]; combined to create a score [0-4] and categorized as unhealthy [0-2], moderate [2.5 or 3], healthy [3.5 or 4]) and CVRFs (hypertension [HTN], diabetes [DM], dyslipidemia) were assessed as time-varying covariates. Standardized mortality ratios (SMRs) and absolute excess risk of death per 1000 person-years (AER) with 95% confidence intervals (CIs) were estimated. Multivariable models estimated the relative risk (RR) of death adjusted for demographic and socioeconomic variables. **Results:** Among 20,051 adult survivors (median age 40.0 years, range 18.7 – 67.7), 19% reported ≥1 CVRF (13% HTN, 9% dyslipidemia, 5% DM) and few reported a healthy lifestyle (29% healthy, 40% moderate, 31% unhealthy). There were 1476 deaths due to health-related causes. While all survivors experienced an increased risk of HRM compared to the US population, risk was lower among those with a healthy vs. unhealthy lifestyle (SMR 3.5, 95% CI 3.1-3.9 vs. 6.2, 5.7-6.7) and very high among underweight survivors (11.1, 9.3-13.3) and those with both HTN and DM (13.0, 9.2-18.0). Stratified by lifestyle score, the excess risk of HRM was lowest in those with a healthy lifestyle across survival time (Table). Similar trends were seen when stratified by 0, 1 and 2 CVRFs. In multivariable models, compared to survivors with no CVRFs and healthy lifestyle, no CVRFs and unhealthy lifestyle was associated with a 50% increased risk of HRM (RR 1.5, 95% CI 1.2-1.8) and unhealthy lifestyle plus HTN a 2-fold increased risk of HRM (2.2, 1.6-2.8). Regardless of lifestyle group, ≥2 CVRF increased risk for HRM at least 2-fold (p-values <0.001). **Conclusions:** A reduction in excess deaths is observed among adult survivors of childhood cancer with a healthy lifestyle and no CVRFs as they age. Interventions that target improved lifestyle choices and prevention or aggressive treatment of modifiable CVRFs may reduce risk for late mortality. Research Sponsor: U.S. National Institutes of Health, American Lebanese Syrian Associated Charities.

Benefits, harms, and burden of colorectal cancer screening among childhood cancer survivors previously treated with abdominal-pelvic radiation. *First Author: Jennifer M Yeh, Boston Children's Hospital and Harvard Medical School, Boston, MA*

Background: Survivors of childhood cancer treated with abdominal-pelvic radiation are at increased risk for colorectal cancer (CRC). The Children's Oncology Group recommends early initiation of CRC screening at age 30, yet the benefits and burden are unknown. **Methods:** We used incidence and mortality data from the Childhood Cancer Survivor Study to modify the SimCRC model from the Cancer Intervention and Surveillance Modeling Network (CISNET) to reflect high CRC and competing mortality risks among survivors, assuming the elevated cancer risk arises from higher adenoma onset. Strategies evaluated varied by modality (no screening, colonoscopy, multitarget stool DNA [mtsDNA] testing, fecal immunochemical testing [FIT]), screening start age (25, 30, 35, 40, 45) and screening interval (every 3, 5 or 10 yrs for colonoscopy; every 1, 2 or 3 yrs for mtsDNA and FIT). Abnormal stool test results were followed up with colonoscopy. Screening performance and complication rates were based on published studies. Analyses assumed full uptake and adherence to all screening and follow-up procedures. To identify the optimal strategy for each modality, we estimated the number of colonoscopies required per additional life-year gained and compared it to benchmarks for screening strategies recommended by the US Preventive Services Task Force for average-risk individuals. **Results:** Among a simulated cohort of 20-yr-old 5-yr survivors with a history of abdominal-pelvic radiation, the cumulative CRC risk at age 50 was 0.8%, approximately twice that predicted among general population average-risk individuals (0.4%). In the absence of screening, 73 per 1000 survivors would be diagnosed with CRC in their lifetime and 29 would die from the disease. All screening strategies evaluated were estimated to yield substantial reductions in the lifetime number of CRC cases (45-71 cases averted per 1000) and deaths (23-28 deaths averted per 1000). The estimated lifetime number of colonoscopies ranged from 1781 to 14,625 per 1000. The lifetime number of colonoscopy complications was relatively low at 9 to 20 per 1000. Based on the burden-to-benefit ratios, colonoscopy every 10 yrs starting at age 30, mtsDNA every 3 yrs starting at age 30, or FIT every 3 yrs starting at age 25 were the optimal screening strategies identified (Table). **Conclusions:** Early initiation of screening may substantially reduce CRC mortality among high-risk childhood cancer survivors. These estimates of the balance of screening benefits and burden can inform follow-up care guidelines. Research Sponsor: American Cancer Society, U.S. National Institutes of Health.

Outcomes of Hispanic and non-Hispanic white pediatric and young adult patients with B-cell acute lymphoblastic leukemia after commercial tisagenlecleucel. *First Author: Panayiotis Vandris, Stanford University School of Medicine, Stanford, CA*

Background: Population-level data show significantly inferior outcomes for Hispanic children, adolescents, and young adults (CAYA) diagnosed with B-cell acute lymphoblastic leukemia (B-ALL) relative to non-Hispanic whites (NHW). Here, we compare outcomes between Hispanic and NHW CAYA patients with relapsed and/or refractory (RR) B-ALL receiving tisagenlecleucel, a CD19-specific chimeric antigen receptor (CAR) T cell therapy. **Methods:** We used data from the Pediatric Real World CAR Consortium retrospective cohort of 200 patients who underwent cell shipment for standard-of-care tisagenlecleucel between August 2017 and March 2020 (N=15 US institutions). Race/ethnicity was identified by medical record review. Patients reported as belonging to more than one racial/ethnic group were classified as multiracial and excluded from analysis. Baseline factors, outcomes, and safety post-infusion were characterized for Hispanic vs. NHW infused patients. Outcomes included complete response (CR) rate, overall survival (OS), duration of response (DOR), and duration of B-cell aplasia (DBA). A multivariate Cox model for OS was constructed, including all baseline factors. **Results:** Among 185 infused patients, 90 (48.6%) were NHW and 70 (37.8%) were Hispanic. Among 15 non-infused patients, 3 (20.0%) were NHW and 5 (33.3%) were Hispanic. Hispanic patients were significantly older at diagnosis (mean: 10.7 vs. 8.3 years, p=0.02) and had significantly shorter time from diagnosis to infusion (mean: 34.4 vs. 46.4 months, p=0.04). Hispanic and NHW patients did not significantly differ across sex, leukemia type, number of prior lines of therapy, receipt of prior CD19-directed therapy, level of disease burden pre-infusion, and number of relapses pre-infusion. Hispanic and NHW patients did not significantly differ across 1-month CR, 6-month OS, 1-year OS, 18-month OS, 6-month DOR, 1-year DOR, 6-month DBA, and 1-year DBA (Table). On multivariate analysis including the above covariates, OS did not significantly differ for Hispanic patients (HR=1.04, p=0.92). Hispanic and NHW patients did not significantly differ across grade ≥ 3 cytokine release syndrome, grade ≥ 3 neurotoxicity, grade 4 neutropenia, tumor lysis syndrome, or number of infections post-infusion. **Conclusions:** Outcomes were similar between Hispanic and NHW CAYA RR B-ALL patients receiving tisagenlecleucel in the real-world setting. Increasing access to CAR therapy among Hispanic CAYA B-ALL patients could help mitigate population-level disparities in outcomes observed after receipt of conventional therapies. Research Sponsor: None.

Outcomes for Hispanic vs. NHW patients.

Outcome (%)	Hispanic	NHW	P-value
1-month CR	81.4	88.8	0.19
6-month OS	89.7	83.4	0.82
1-year OS	71.9	71.2	0.62
18-month OS	68.2	71.2	0.62
6-month DOR	74.2	72.8	0.34
1-year DOR	62.3	60.7	0.42
6-month DBA	59.5	64.7	0.87
1-year DBA	52.1	50.0	0.85

10017 **Poster Discussion Session**

Racial and ethnic differences in presentation and clinical outcomes for pediatric rhabdomyosarcoma (RMS). *First Author: Princess Ekpo, Pediatric Oncology Branch, National Cancer Institute, Bethesda, MD*

Background: Race and ethnicity are recognized risk factors for many cancer types, including several pediatric cancers. Though racial and ethnic disparities in the presentation, treatment, and survival of certain cancers have been widely demonstrated, there is conflicting evidence about whether such disparities exist in RMS, the most common pediatric soft tissue sarcoma. Understanding the role of race and ethnicity in the presentation, treatment, and prognosis of RMS is important to promote improved survival in patients of all racial and ethnic groups. **Methods:** Patient, tumor, and treatment characteristics of patients enrolled on Children's Oncology Group studies D9602, D9802, D9803, ARST0331, ARST0431, ARST0531, and ARST08P1 were compared across racial and ethnic groups using a chi-square test. Significant characteristics underwent pairwise analysis, comparing the Non-Hispanic Black (NHB) and Non-Hispanic White (NHW) groups. Outcome analyses were performed using the Kaplan-Meier method and Wilcoxon signed-rank test. **Results:** Race and ethnicity incidence among the 2157 study patients were as follows: 8 (0.4%) American Indian or Alaska Native, 56 (2.6%) Asian, 271 (12.6%) Hispanic, 4 (0.2%) Native American or other Pacific Islander, 275 (12.8%) Non-Hispanic Black, 1335 (61.9%) Non-Hispanic White, and 208 (9.6%) unknown. Thirteen patient and tumor factors relating to presentation and treatment were evaluated for differences by race and ethnicity; the following five were significant: age, IRS group, tumor invasiveness, metastatic disease, and FOXO1 fusion partner. Pairwise comparison of NHB and NHW patients for these factors demonstrated that NHBs are more likely than NHWs to present at age 10 years or greater ($p = 0.002$) and that NHB patients are more likely to present with invasive tumors ($p = 0.012$). Incidence of metastatic disease at diagnosis was not significantly different between the groups ($p = 0.202$). No differences in treatment, including extent of surgical resection ($p = 0.259$) or use of radiation therapy ($p = 0.920$), were found. Neither event free survival nor overall survival were significantly different across the entire cohort (EFS $p = 0.457$, OS $p = 0.159$) or in subset analysis by risk group (low risk: EFS $p = 0.856$, OS $p = 0.558$; intermediate risk: EFS $p = 0.907$, OS $p = 0.493$; high risk: EFS $p = 0.218$, OS $p = 0.397$), by age (< 1y: EFS $p = 0.489$, OS $p = 0.546$; 1-9y: EFS $p = 0.417$, OS $p = 0.112$; ≥10y: EFS $p = 0.556$, OS $p = 0.609$), in invasive tumors (EFS $p = 0.704$, OS $p = 0.872$), or in metastatic disease (EFS $p = 0.270$, OS $p = 0.373$). **Conclusions:** These data indicate that while differences in the presenting features of RMS exist between racial groups, with NHB patients exhibiting higher risk features, patients treated on these clinical trials did not experience differences in outcomes by racial group. This suggests NHB patients may experience a survival benefit from clinical trial enrollment. Research Sponsor: U.S. National Institutes of Health.

Barriers to effective childhood cancer control in Kenya (BECK) study, 2019-2020: A mixed methods study in a national tertiary facility and 10 regional cancer treatment centers. *First Author: Valerian Mwenda, National Cancer Control Program, Ministry of Health, Nairobi, Kenya*

Background: Globally, 80,000 children die from cancer annually; 80% in low- and middle-income countries (LMICs). Childhood cancer cure is possible in more than 80% of cases, in all economic settings. This study aimed to identify barriers to effective management of childhood cancers in Kenya, for program and policy intervention. **Methods:** We reviewed childhood cancer cases diagnosed at Kenyatta National Hospital in the period 2015-2019. We also assessed capacity of ten recently established regional cancer centres for childhood cancer diagnosis and treatment. We conducted focused group discussions among childhood cancer survivors' caregivers and key informant interviews among childhood cancer specialists and policy makers from the Ministry of Health and the National Cancer Institute of Kenya. We estimated diagnostic delays, mapped service availability and deductively summarized the qualitative data into main themes. **Results:** We abstracted 1,764 cases; median age 6 years (IQR 9); 1013 (57.5%) were male. Most affected age group was 0-4 years (47.3%). Most common cancer types were retinoblastoma (23.3%), nephroblasoma (10.4%) and acute lymphoblastic leukaemia 10.3%). Cases managed at KNH decreased between 2015 and 2017, and then recovered. The median total delay (symptoms onset to treatment initiation) was 32 days (range 0-3666). Regional cancer centres lacked specialized workforce for childhood cancer care. Caregivers identified inadequate cover by National Health Insurance and disorganized care process as major challenges. At health system and policy level, low awareness, fragmented referral systems and in-effective policy implementation are major challenges to childhood cancer control. **Conclusions:** Increasing number of specialized personnel, creation of a differentiated financing package for childhood cancer and restructuring of referral and the care process can improve childhood cancer outcomes in Kenya. Identifying trends for high symptom burden across the care continuum in adolescents and young adults (AYA) with hematologic malignancies. *First Author: Sarah Elizabeth Monick, University of Chicago Medicine, Chicago, IL*

Background: Cancer in adolescence and young adulthood is a non-normative life event associated with profound long-term physical and psychosocial consequences. Prior studies specifically demonstrate AYA patients with hematologic malignancies experience high symptom burden with poor quality of life. Here, we describe trends and factors associated with high symptom burden in patients treated at a multi-disciplinary AYA leukemia clinic at an academic medical center. **Methods:** The Edmonton Symptom Assessment Scale [ESAS] (measuring physical symptoms) and Brief Symptom Inventory-18 [BSI-18] (measuring psychological distress) were administered at baseline, 3 months, and 6 months from initial survey. Baseline demographic and treatment characteristics were collected. All patients had leukemia or lymphoma, were on treatment or in survivorship, and had access to a palliative care provider who was integrated into the clinic. Data was analyzed using Wilcox ranked sum test and linear mixed-effects model testing. **Results:** Of the 31 patients (median age 29 years, range 18-43) who completed surveys, 25 (80%) completed surveys at 6 months; 48% were female, 58% were white, 16% lived alone, 28% were single, 37% had children, 54% completed college, and 35% had an annual household income ≥ $75,000. Phases of care included 52% on intensive frontline/salvage treatment, 19% in maintenance (i.e. lower intensity) therapy, 16% as recent stem cell transplant (SCT) recipients (< 1 year since date of transplant), and 13% in survivorship. Overall, ESAS scores among patients were similar regardless of care phases; however, patients on frontline/salvage therapy reported higher fatigue than those in maintenance ($p = 0.01$). Moderate-severe symptoms (defined as ESAS > 3), including tiredness, anxiety, poor appetite, and poor feeling of well-being, were reported regardless of phase of care. At 6 months, there was no significant change in BSI-18 scores compared to baseline, while tiredness ($p = 0.02$), depression ($p = 0.01$), and constipation ($p = 0.02$) improved; no ESAS scores worsened. Age ≥ 30 was associated with worsening anxiety ($p = 0.01$) at 6 months vs baseline, while no statistically significant differences in ESAS scores were observed among race, education, relationship status, presence of children, living arrangement, or income. **Conclusions:** AYA patients with hematologic malignancies experience high symptom burden independent of demographic characteristics or phase of care. These findings highlight the need for standard symptom screening at each visit and the importance of incorporating supportive care throughout the continuum. Research Sponsor: None.

Neuropathy and neurocognitive impairment in long-term survivors of pediatric cancer treated without central nervous system (CNS) directed therapy. *First Author: AnnaLynn Williams, St. Jude Children's Research Hospital, Memphis, TN*

Background: Survivors of pediatric cancer, including those without CNS-directed treatment, are at risk of neurocognitive impairment and peripheral or autonomic neuropathies; conditions that co-occur in non-cancer populations. Using the St. Jude Lifetime Cohort, we investigated associations between these sequelae to inform contributors to long-term cancer-related neurocognitive impairment. **Methods**: Clinically assessed survivors of pediatric cancer (N=2,138, mean age 31 [SD 13], 23[11] years from diagnosis, 51% male) not treated with CNS-directed therapy completed neurocognitive testing. Modified total neuropathy score peripheral sensory and motor subscales were combined with functional tasks and severity graded using a modified NCI CTCAE. Cardiac autonomic neuropathy was defined as impaired heart rate reserve (<80% age-sex-predicted or ≤62% with beta blocker). Separate log binomial regression models estimated risk of neurocognitive impairment (age adjusted z-score <10^{th} percentile) associated with grade 2+ sensory, motor or autonomic neuropathy. Path analysis examined if pain with daily interference mediated associations between motor or sensory neuropathy and neurocognitive impairment. **Results**: 838 (39%) survivors had autonomic, 115 (5.4%) had motor and 162 (7.6%) had sensory neuropathy. Compared to those with no neuropathy, survivors with motor or sensory neuropathy had a higher risk of impairment in sustained attention, visual-motor processing speed, short- and long-term memory, and executive function (Table, p's<0.01). Autonomic neuropathy was associated with a higher risk of impairment in visuo-motor processing speed (p=0.03). Pain partially mediated associations between sensory neuropathy and sustained attention (10% mediated, p=0.04), visual-motor processing speed (8% p=0.02), and executive function (14% p=0.02). Pain was not related to motor neuropathy. **Conclusions**: Peripheral and autonomic neuropathies are associated with significant risk of neurocognitive impairment in adult survivors of pediatric cancer. Research is needed to further understand shared mechanisms (e.g., pain, inflammation) to design targeted interventions to improve neuropathic symptoms and neurocognitive function. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Relative risk (95% confidence interval) of neurocognitive impairment associated with neuropathy (vs. none).[1]

	Motor	Sensory	Autonomic

Vitamin A and association with asparaginase-associated pancreatitis in children with acute lymphocytic leukemia. *First Author: Cheng-Yu Tsai, Stanford University, Palo Alto, CA*

Background: Asparaginase is a key component of treatment of acute lymphoblastic leukemia (ALL), which is the most common cancer in the pediatric population. However, asparaginase is associated with many toxicities, including pancreatitis, which is observed in up to 10% of patients and can lead to severe sequelae. **Methods:** We performed analysis of (1) transcriptomic data from (a) asparaginase-treated leukemic cells, and (b) the pancreas of mice that were induced with a chemical form of pancreatitis; (2) the US FDA Adverse Reporting System (FAERS) and electronic health records (TriNetX); (3) global plasma metabolomic screen and dietary intake evaluation from ALL patients; and (4) experimental animal studies to identify factors that impact asparaginase-associated pancreatitis (AAP). **Results:** Connectivity map analysis showed that asparaginase-induced gene signatures are potentially reversed by the retinoids (vitamin A and its natural and synthetic analogs). Analysis of TriNetX and FAERES demonstrated a 2-fold reduction in AAP risk with concomitant exposure to vitamin A. Further, we performed a case-control metabolomic study of 50 subjects with ALL enrolled in the Dana-Farber Cancer Institute DFCI ALL clinical trial protocols 05-001 (NCT00400946) and 11-001 (NCT01574274). All subjects were given a single dose of pegylated *E. Coli* asparaginase during induction therapy. Twenty-four subjects developed pancreatitis within 9 months from the start of induction therapy and were considered cases. The median time to develop pancreatitis among cases was 3.68 months (interquartile range: 3.58 months). Twenty-six control subjects were identified among patients who did not develop pancreatitis within the same evaluation period. The controls were matched for age, sex, and initial ALL risk. The screening revealed that the plasma levels of carotene diol isomers, from the start of induction to its end, were reduced by about 60% in the cases compared to the controls. A detailed 30-day dietary recall showed that the cases had received less dietary vitamin A than the controls during induction therapy. Notably, the median value for the composite intake of vitamin A constituents, termed the RAE (retinol activity equivalents) was 656.92 mcg per day among the controls, but was 34.6% lower among in the cases (median of 429.40 mcg per day, which is just above the recommended dietary allowance level of 400 mcg per day for the 4–8 year-old age group). In mice, asparaginase administration as a single agent was sufficient to reduce circulating and hepatic retinol levels. **Conclusions:** Based on these data, we propose that circulating retinoids maintain pancreatic health, that asparaginase reduces circulating retinoids, and AAP is more likely to develop with reduced dietary vitamin A intake. The systems approach provides the impetus to examine the role of dietary vitamin A supplementation for preventing or treating AAP. ADVL1514, a phase 1 study of ABI-009 (nab-sirolimus) in pediatric patients with recurrent or refractory solid tumors, including CNS tumors as a single agent and in combination with temozolomide and irinotecan: A Children's Oncology Group pediatric early-phase clinical trial network study. *First Author: Stuart Cramer, Prisma Health Children's Hospital- Midlands, Columbia, SC*

Background: nab-Sirolimus (formerly know ABI-009 and nab-rapamycin) is a novel human albumin-bound preparation of sirolimus, a potent mTOR inhibitor. We report results of a Phase I study of ABI-009 alone and in combination with irinotecan and temozolomide in children with relapsed/refractory solid or CNS tumors. **Methods:** Patients (age 1-21 years) with relapsed/refractory solid or CNS tumors were eligible. Using a rolling 6 design, ABI-009 was administered intravenously as a single agent on Days 1 and 8 of cycle 1 (cycle = 21d), then subsequent cycles ABI-009 was administered in combination with temozolomide (125 mg/m^2/dose, maximum 250 mg/dose) orally once daily x 5 on Days 1-5 and irinotecan 90 mg/m^2/dose orally once daily x 5 on Days 1-5. Three dose levels (DL) of ABI-009 were investigated (DL1: 35mg/m^2/dose, DL-1: 20mg/m^2/dose, and DL-2: 15mg/m^2/dose). The maximum tolerated dose (MTD) or Recommended Phase 2 Dose (RP2D) was established based on dose limiting toxicity (DLT) observed during Cycle 1 and 2. At the RP2D, additional patients were enrolled for pharmacokinetics (PK). **Results:** 33 patients were enrolled (32 eligible and 1 ineligible); 11 did not experience DLT but were not evaluable for toxicity due to progressive disease or physician decision to discontinue protocol therapy prior to completion of cycle 2; 17 [median age 13 (2-20) years] were evaluable for determination of MTD during dose escalation, 6 were enrolled on the PK cohort, of which 3 were evaluable to toxicity. At DL1, 2/5 patients experienced DLT (thrombocytopenia during cycle 1 (n = 1) and cycle 2 (n = 1)); at DL-1, 2/6 patients experienced DLT (thrombocytopenia in cycle 1); at DL-2, 1/6 patients experienced DLT (thrombocytopenia in cycle 1). PK expansion enrolled at DL-2 and 1/3 participants evaluable for toxicity had a DLT (mucositis). Overall, at DL-2, 2/9 patients (22%) had DLT. One patient with Ewing Sarcoma had a partial response and remained on study for 35 cycles; Patients (one each) with Ewing Sarcoma, Wilms Tumor, and Pineoblastoma had stable disease, ranging from 3-6 cycles. **Conclusions:** Thrombocytopenia was dose limiting for ABI-009 alone and in combination with temozolomide and irinotecan. The MTD for ABI-009 is 15mg/m^2/dose days 1 and 8 in combination with 5 daily doses of temozolomide 125 mg/m^2/dose and oral irinotecan 90 mg/m^2/dose. One patient had a partial response, 3 patients had prolonged stable disease. Pharmacokinetics and pharmacodynamics are pending and will inform future trials. Clinical trial information: NCT02975882. Minimal residual disease comparison between Ig/TCR PCR versus NGS assays in children with Philadelphia chromosome-positive acute lymphoblastic leukemia: A report from the COG AALL1631 study. *First Author: Thai Hoa Tran, CHU Ste-Justine, University of Montreal, Montreal, QC, Canada*

Background: Minimal residual disease (MRD) assessment by immunoglobulin/T-cell receptor (Ig/TCR) polymerase chain reaction (PCR) is currently being used in the international pediatric Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph$^+$ALL) trial EsPhALL2017/AALL1631 for risk stratification. MRD concordance has previously been demonstrated between Ig/TCR PCR and flow cytometry in Ph$^+$ALL. We sought to assess concordance of MRD assessment between conventional Ig/TCR PCR and next-generation sequencing (NGS) assays. **Methods:** MRD was assessed in all pts on AALL1631 by Ig/TCR PCR at end-induction IB; those with MRD <5x10^{-4} were classified as standard-risk (SR) and randomized to treatment with imatinib and one of two chemotherapy regimens without hematopoietic stem cell transplant (HSCT), whereas pts with end-induction 1B MRD ≥ 5x10^{-4} were considered high-risk (HR) and assigned to HSCT after consolidation chemotherapy. Residual diagnostic and end-induction IB samples from consenting pts were assessed for NGS MRD by the clonoSEQ assay (Adaptive Biotechnologies) in blinded fashion and subsequently compared to Ig/TCR MRD to determine concordance as related to MRD-based HSCT recommendations (*ie*, MRD ≥ 5x10^{-4} consistent with HR group assignment). MRD values were calculated using the kappa statistic for agreement above chance. **Results:** Sixty-seven pts had matched samples available for MRD assessment at end-induction 1B by both Ig/TCR PCR and NGS (Table). NGS MRD was evaluable for all 67 pts and stratified as 62 SR (<5x10^{-4}) and 5 HR (≥5x10^{-4}). In contrast, Ig/TCR PCR results were inevaluable for 3 pts (unsatisfactory sample quality) and indeterminate (positive, but not quantifiable) in 4 pts. Of the remaining 60 pts, 55 met SR and 5 HR criteria using Ig/TCR PCR. There was only 1 discordant case between the two methods for MRD-based HSCT recommendation among these 60 pts with a kappa statistic for agreement above chance of 0.88. **Conclusions:** NGS and Ig/TCR PCR assays were highly concordant in MRD assessment for risk stratification at a threshold of 5x10^{-4} in pediatric pts with Ph$^+$ALL enrolled on AALL1631. Of note, the NGS assay yielded MRD results amenable for risk stratification in 100% pts compared to 89.6% for the Ig/TCR PCR methodology. These data support the use of NGS MRD testing for risk stratification in pediatric Ph$^+$ALL. Research Sponsor: Heme-ITSC grant.

Menin inhibitors as targeted therapeutics in KMT2a rearranged infant leukemia and the identification of effective treatment combinations. *First Author: Ritul Sharma, University of Calgary, Calgary, AB, Canada*

Background: *KMT2a* rearrangements are a hallmark of infant (less than 1 year of age) leukemia and are associated with poor prognosis. Menin is a ubiquitous protein that binds to the N-terminal of the KMT2a-fusion protein to mediate the oncogenic activity of *KMT2a*-rearranged leukemia cells. In this study, we evaluated the effect of multiple menin inhibitors and effective drug combinations for the treatment of KMT2A-rearranged infant leukemia. **Methods:** FISH analysis and immunoblotting confirmed the presence of *KMT2a*-fusion in the primary patient samples and cell lines studied. Lymphocytes from healthy donors were used as controls. Cells were treated with various concentration of multiple menin inhibitors for 72 hours and growth inhibition was measured using alamar blue assay. Infant leukemia cells were treated with a panel of FDA-approved agents (n = 221) to identify potential synergy, additive- and antagonistic-effects with specific menin inhibitors. Therapeutic drug interaction properties were established by calculating combination indices (CI) using the Chou-Talalay method. Mode of cell death and cellular target modulations were determined by western blot analysis. The effect of targeting menin in the context of the leukemogenic bone marrow microenvironment was determined through stromal cell co-cultures. **Results:** A comprehensive analysis of menin inhibitors on infant leukemia cell lines and primary patient cells exhibited significant and quantitatively diverse responses in cells with distinct molecular properties. Within the panel of menin inhibitors, infant B-ALL cells were found to be more sensitive to MI-463, MI-503 and MI-136 with a mean IC_{50} of 5.9μM, 6.1μM and 10.2μM, respectively. On the other hand, MI-3 exhibited an IC_{50} of 35.6μM. The cytotoxic effect of menin inhibitors on normal lymphocytes was minimal, suggesting a favourable therapeutic window ($p < 0.0001$). High-throughput screening with a library of > 200 FDA-approved drugs revealed significant sensitivity of distinct infant leukemia cells to proteasome, HDAC and CDK9 inhibitors. Among these, substantial drug synergy was observed between menin and proteasome inhibitors. For example, carfilzomib synergised with menin inhibitors over a broad range of concentrations with a CI value of 0.7. **Conclusions:** In this study, we present and discuss the initial proof-of-concept preclinical data for the effective anti-leukemic activity of menin inhibition against KMT2A-rearranged infant leukemia cells. Furthermore, the comprehensive drug screen and drug combination studies identified a spectrum of mechanistically-validated synergies, providing usable data for the formulation of multi-agent clinical studies for this currently unmet need in pediatric oncology. 10025 **Poster Session**

Progression-free survival and patterns of response in patients with high-risk neuroblastoma (HR-NB) treated with irinotecan/temozolomide/dinutuximab/granulocyte-macrophage colony-stimulating factor (I/T/DIN/GM-CSFS) chemoimmunotherapy. *First Author: Benjamin Lerman, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Encouraging responses to chemoimmunotherapy with I/T/DIN/GM-CSF have been observed in trials for patients (pts) with relapsed/refractory HR-NBL, but factors associated with response have not been identified and duration of response has not been assessed. We aimed to evaluate timing and duration of response among pts with relapsed HR-NBL treated with I/T/DIN/GM-CSF and identify factors associated with response. **Methods:** We performed a multicenter retrospective cohort study of pts treated with I/T/DIN/GM-CSF. Eligibility criteria included: diagnosis of relapsed HR-NBL prior to age 30; objective response [OR; complete, partial, or minor response (CR, PR, or MR) by International Neuroblastoma Response Criteria (INRC)] or stable disease (SD) after initial therapy; receipt of I/T/DIN/GM-CSF for relapse or progression outside a clinical trial from 1/1/15-6/1/20. Logistic regression was used to identify factors associated with OR. Kaplan Meier analysis was used to determine progression-free survival (PFS). **Results:** We enrolled 143 pts with a median age at diagnosis of 51 months. Tumors were MYCN amplified in 52 (36%) and ALK was wild type in 73/94 (78% of tumors in which ALK status was known). 79 (55%) had received prior anti-GD2 therapy. I/T/DIN/GM-CSF comprised first relapse therapy in 96 pts (67%), second relapse therapy in 23 (16%) and subsequent therapy in 24 (17%). 70 (49%) achieved OR following I/T/DIN/GM-CSF therapy [29% CR, 15% PR, 5% MR], 30 (21%) achieved SD and 43 (30%) progressed. Median cycles received was 5 (range 1-31). 121 patients (85%) had their best response upon first disease evaluation. Later disease evaluations showed improved INRC classification in 14% of pts with initial SD, 33% with MR, and 41% with PR. Median time to OR was 2 months (range 1-21). Of the 105 relapse/progression events after starting I/T/DIN/GM-CSF (73% of pts), 59 (56%) occurred during therapy. Of the 42 pts who achieved CR with I/T/DIN/GM-CSF, 5 (12%) relapsed during I/T/DIN/GM-CSF and 17 (40%) relapsed after discontinuation. I/T/DIN/GM-CSF was discontinued in 83 pts (58%) due to suboptimal response or PD, and in 19 (13%) for toxicity. Median PFS among objective responders was 15.5 months. Among those in CR, median PFS after discontinuation of I/T/DIN/GM-CSF was 11.8 months (range 0.7-70.6). Multivariable models did not identify clinical or biologic factors associated with OR. **Conclusions:** 49% of pts receiving I/T/DIN/GM-CSF for relapsed HR-NBL achieved OR. Among responders, median response duration was 15.5 months. Pts with SD on first disease evaluation were unlikely to achieve OR, but > 1/3 of pts with MR/PR on first evaluation ultimately achieved CR. No identifiable clinical or biologic factors were associated with OR. Research Sponsor: None.

Modulation of radiation biomarkers in a randomized phase II study of ^{131}I-MIBG with or without radiation sensitizers for relapsed or refractory neuroblastoma: A report from the NANT Consortium. *First Author: Kevin M. Campbell, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: ^{131}I-metaiodobenzylguanidine (^{131}I-MIBG) has demonstrated efficacy as a single agent for patients with neuroblastoma. Recent trials have focused on ^{131}I-MIBG combination strategies, though little is known about the impact of combination agents on markers of radiation exposure. **Methods:** NANT11-01 (NCT02035137) was a multicenter, open label, randomized phase II clinical trial that evaluated ^{131}I-MIBG therapy alone (Arm A) or in combination with vincristine/irinotecan (Arm B) or vorinostat (Arm C) for patients with resistant/relapsed neuroblastoma. We collected blood samples at baseline, 72 hours, 96 hours, and 15 days after ^{131}I-MIBG infusion and determined levels of plasma FLT3 ligand, serum amylase, and gene expression for selected RNA transcripts (apoptosis, DNA damage response and cell cycle related). We evaluated marker association with treatment arm, clinical response using NANT response criteria, toxicity, and whole-body radiation dose. **Results:** The cohort included 99 patients who had at least one biomarker available for analysis (32 Arm A; 35 Arm B; 32 Arm C). We observed both positive and negative significant modulation in most biomarkers between baseline, 72 hours, and 96 hours following ^{131}I-MIBG. Patients in Arm C had the lowest degree of modulation in FLT3 ligand. Elevated baseline levels of FLT3 ligand were significantly associated with improved Curie response but not overall response. Lower baseline BCL2 levels were associated with higher overall and Curie response. Patients with increased FLT3 ligand at 96 hours after ^{131}I-MIBG therapy were significantly more likely to have grade 4 thrombocytopenia .Peripheral blood gene expression of the BCL2 family of apoptotic markers (BCL2/L1 and BAX) was significantly associated with grade 4 hematological toxicity. Whole-body radiation dose and PRKDC fold change at 72 hours were significantly correlated. No other individual biomarkers were correlated with whole body radiation dose at 72 or 96 hours post ^{131}I-MIBG. **Conclusions:** Peripheral blood biomarkers relevant to radiation exposure demonstrate significant modulation over time after ^{131}I-MIBG treatment. Biomarkers related to hematopoietic damage and apoptosis were associated with hematological toxicity. Patients treated with vorinostat and ^{31}I-MIBG had differential modulation of FLT3-ligand Further use of these biomarkers may improve our ability to care for patients treated with ^{131}I-MIBG. Research Sponsor: Alex's Lemonade Stand Foundation.

Impact of diagnostic and end-of-induction Curie scores in tandem autologous hematopoietic cell transplant for patients with high-risk neuroblastoma: A report from the Children's Oncology Group. *First Author: Keri A. Streby, Nationwide Children's Hospital/The Ohio State University, Columbus, OH*

Background: Diagnostic mIBG (meta-iodobenzylguanidine) scans are an integral component of response assessment in children with high-risk neuroblastoma. The role of end of induction (EOI) Curie Scores (CS) has been previously described in patients undergoing a single autologous hematopoietic cell transplant (AHCT) as consolidation therapy. We now examine the prognostic significance of CS in patients randomized to tandem or single AHCT on the Children's Oncology Group (COG) trial ANBL0532. **Methods:** A retrospective analysis of mIBG scans obtained from patients enrolled in COG ANBL0532 (n = 652) was performed. Evaluable patients (n = 179) had mIBG-avid, International Neuroblastoma Staging System (INSS) stage 4 disease, did not progress during induction therapy, consented to consolidation randomization, and received either a single (n = 99) or tandem AHCT (n = 80). In addition, evaluable patients had paired mIBG scans at time of initial diagnosis and EOI. Optimal CS cut points maximized the outcome difference (≤ vs > CS cut-off) according to the Youden index. Log-rank tests compared EFS subgroups, with $p < 0.05$ considered statistically significant. 3-year EFS is presented ± standard error. EFS was estimated for relative reductions in CS of 50% and 75% from diagnosis to EOI. **Results:** For recipients of tandem AHCT, the optimal cut point at diagnosis was CS = 12, with superior EFS from study enrollment for patients with CS<12 (74.2±7.9%; n = 31) vs CS > 12 (59.2±7.1%; n = 49) ($p = 0.002$). At EOI, the optimal cut point was CS = 0, with superior EFS from EOI for patients with CS = 0 (72.9±6.4%; n = 48) vs CS > 0 (46.5±9.1%; n = 32) ($p = 0.002$). The cut point at diagnosis for recipients of single AHCT was CS = 21 ($p = 0.04$), while the EOI CS had an optimal cut point of 2, but without a significant difference in EFS ($p = 0.29$). Absolute CS at diagnosis and at EOI had a greater impact on outcome than the relative reduction in CS between diagnosis and EOI, for both single and tandem AHCT. **Conclusions:** In the setting of tandem transplantation for children with high-risk neuroblastoma, Curie scores at diagnosis and end-induction may identify a more favorable patient group. Patients treated with tandem AHCT who exhibited a CS<12 at diagnosis or CS = 0 at EOI had superior EFS compared to those with CS above these cut points. Similar to prior reports, a CS<2 was the optimal cut point for single transplant recipients. Clinical trial information: NCT00567567. Research Sponsor: U.S. National Institutes of Health.

10028 **Poster Session**

Naxitamab-based chemoimmunotherapy for resistant high-risk neuroblastoma: Results of "HITS" phase II study. *First Author: Shakeel Modak, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Chemoresistant disease is an obstacle for cure of high-risk neuroblastoma (HR-NB). Anti-GD2 monoclonal antibodies (MoAb) dinutuximab and naxitamab in combination with cytokines are FDA-approved to consolidate remission and for chemorefractory osteomedullary HR-NB, but responses in progressive disease (PD) are rare. We investigated the combination of Humanized anti-GD2 MoAb naxitamab (Hu3F8), Irinotecan, Temozolomide and Sargramostim (GMCSF) in a phase II "HITS" protocol against resistant HR-NB (NCT03189706). Noteworthy differences between HITS and COG protocol ANBL 1221 included higher MoAb and temozolomide dosage and overlap of naxitamab with GMCSF. **Methods:** Patients were treated at Memorial Sloan Kettering (MSK) on protocol and at Hospital Sant Joan de Déu (HJSD) per protocol on compassionate basis. Salient eligibility criteria included evaluable or measurable chemoresistant disease. Prior anti-GD2 MoAb or irinotecan/temozolomide (IT) therapy was permitted. Each cycle, administered 3-5 weeks apart, comprised irinotecan 50 mg/m^2/day intravenously (IV) plus temozolomide 150 mg/m^2/day IV or orally (days 1-5); naxitamab 2.25 mg/kg/day IV, days 2,4,8 and 10, and GMCSF 250 mg/m^2/day subcutaneously, days 6-10. Toxicity was measured by CTCAE v4.0 and responses by International Neuroblastoma Response Criteria. Objective responses (OR) were also noted. The primary endpoint of the phase II trial was complete (CR) and partial response (PR) after 4 cycles with a desirable rate of 40%; type I and II errors of 10% (undesirable=20%). **Results:** Of 90 heavily prior-treated patients (38 at MSK evaluated on trial, 52 at HJSD), 8 had HR-NB refractory to induction chemotherapy while 82 had up to 6 prior relapses (median=1). 503 cycles (median 5/patient) were administered. Toxicities included myelosuppression and diarrhea expected with IT, pain and hypertension expected with naxitamab, plus febrile neutropenia in 4%. No other >grade 2 unexpected toxicities occurred; treatment was outpatient. Primary endpoint was reached in the phase II trial: INRC response = 30.6%, lower boundary = 20.4%. In the entire cohort, best responses were CR (26%), PR (11%), mixed response (9%), stable disease (27%) and PD (27%). OR were noted in 64%, with soft tissue (48%) and skeletal MIBG uptake (66%). CR in BM was seen in 57%. OR occurred in patients with *MYCN*-amplified (25%), refractory (100%) and relapsed (61%) HR-NB; and patients who had previously received I/T (64%) or naxitamab (68%). In patients who had previously received dinutuximab/IT, OR rate to HITS was 42% (5/12). Human anti-human antibody did not develop in any patient (n=50). **Conclusions:** Naxitamab-based chemoimmunotherapy was safe without immunogenicity. It was effective against chemoresistant HR-NB in all disease compartments even in patients with multiple prior relapses, and in patients who previously received anti-GD2 MoAbs and/or IT. Research Sponsor: Band of Parents, Pharmaceutical/Biotech Company.

Phase 1 clinical trial of durvalumab in children with solid and central nervous system tumors. *First Author: Leo Mascarenhas, Cancer and Blood Disease Institute, Children's Hospital Los Angeles, Keck School of Medicine, University of Southern California, Los Angeles, CA*

Background: Immune checkpoint inhibitors targeting PDL-1 have shown clinical benefit in adults with cancer. We conducted a first in pediatrics, phase 1 clinical trial to assess safety, pharmacokinetics (PK), and pharmacodynamics of durvalumab in children with solid and central nervous system malignancies. **Methods:** This single center investigator-initiated trial enrolled eligible patients considered incurable with measurable/evaluable disease (exception: osteosarcoma in 3rd remission), no prior exposure to checkpoint inhibitors and adequate organ function on 2 dose levels: 10 mg/kg (DL1) and 15 mg/kg (DL2), utilizing a standard 3+3 design. The primary objectives were to assess safety and PK of durvalumab. Durvalumab was administered intravenously (IV) Q2 weeks for a maximum of 24 doses (12 cycles) on study or until disease progression/unacceptable toxicity. Patients were assessed for dose-limiting toxicity (DLT) in the first 28 days. The tolerable dose level was expanded to obtain PK on at most 6 patients age ≥12 years (yrs) and 6 patients < 12 yrs weighing < 35 kg). Soluble PDL-1 (sPDL1) and anti-drug antibody (ADA) levels were also assessed. **Results:** Fifteen patients (8M/7F) were enrolled (3 DL1, 12 DL2) with median age of 12.7 (2.9-16.6) yrs. Diagnoses included 5 osteosarcoma, 4 ependymoma and 1 each of glioblastoma, astrocytoma, rhabdomyosarcoma, synovial sarcoma, hepatoblastoma and adrenocortical carcinoma. Of the 14 patients evaluable for DLT, 3 were on DL1 and 11 on DL2. Only 1 DLT was observed, Grade (Gr) 3 intracranial hemorrhage (ICH). Median number of cycles administered was 3 (1-12). There were no treatment related deaths. There were 72 treatment-related adverse events (TRAEs) observed in 11 patients in a total of 73 cycles administered on the trial. The most common TRAE was AST elevation (7 instances in 4 patients). All TRAEs were < Gr 3 except for 1 instance each of Gr 3 AST elevation, anemia, and ICH. All 15 patients had PK, sPDL1 and ADA samples analyzed. PK for DL2 in patients ≥35 Kg and < 35 Kg were comparable to PK in adults dosed with durvalumab 10 mg/kg IV Q2W. Mean (SD) DL2 Cmax 292 (102) mg/mL, Ctrough 85.1 (27.7) mg/mL, AUC 2220 (986) day*mg/mL in pts ≥35 Kg and Cmax 442 (338), Ctrough 120 (123), AUC 2470 (1870) in pts < 12 yrs weighing < 35 kg. sPDL1 was completely suppressed in all patients 2 weeks after a single dose of durvalumab. No ADA were detected in any patients. Five patients (2 osteosarcoma, 3 ependymoma) completed > 6 cycles and 3 (1 osteosarcoma, 2 ependymoma) completed all 12 cycles of treatment. One objective response (PR) was seen in a patient with anaplastic ependymoma by RECIST1.1. Four patients were alive at the time of data cut-off with a median follow up of 30.5 (8.8-58.1) months. **Conclusions:** Durvalumab at 15 mg/kg IV Q2W was well tolerated in children with drug exposures comparable to adults receiving10 mg/kg IV Q2W. A signal for activity was noted in ependymoma where 3 of 5 children benefitted clinically. Clinical trial information: NCT02793466. Research Sponsor: AstraZeneca.

Efficacy and safety of larotrectinib in pediatric patients with tropomyosin receptor kinase (TRK) fusion-positive cancer: An expanded dataset. *First Author: Leo Mascarenhas, Cancer and Blood Disease Institute, Children's Hospital Los Angeles, Keck School of Medicine, University of Southern California, Los Angeles, CA*

Background: Neurotrophic tyrosine receptor kinase (*NTRK*) gene fusions are oncogenic drivers in various tumor types across all ages. Larotrectinib is a first-in-class, central nervous system (CNS)-active, highly selective tropomyosin receptor kinase (TRK) inhibitor approved for pediatric and adult patients (pts) with TRK fusion-positive cancer, demonstrating an objective response rate (ORR) of 88% across 78 pediatric pts with non-CNS cancers (van Tilburg et al, SIOP 2021). We report an analysis of the efficacy and safety of larotrectinib in an expanded dataset of pediatric pts with TRK fusion-positive cancer. **Methods:** Pediatric pts (< 18 years) with non-CNS TRK fusion-positive cancer in larotrectinib clinical trials (NCT02637687, NCT02576431) were included and ORR (RECIST v1.1) was investigator (INV)-assessed. Data cut-off was July 20, 2021. **Results:** A total of 94 pts were included in this analysis. Tumor types included infantile fibrosarcoma (52%), other soft tissue sarcoma (40%), congenital mesoblastic nephroma (2%), thyroid cancer (2%), bone sarcoma (1%), breast cancer (1%), and melanoma (1%). Pts had gene fusions involving *NTRK1* (43%), *NTRK2* (3%), or *NTRK3* (54%). Median age was 2.2 years (range 0–18 years). Of the 62 (66%) pts who received prior systemic therapy, 32 (52%) received ≥2 lines. The INV-assessed best ORR for the 93 evaluable pts was 84% (95% confidence interval [CI] 75–91): 35 (38%) complete response (CR; including two pending confirmation and 10 pathological CR), 43 (46%) partial response (two pending confirmation), 11 (12%) stable disease, two (2%) progressive disease, and two (2%) not determined. The median time to response was 1.8 months. Overall, median duration of response was 43.3 months (95% CI 23.4–NE); median follow-up was 26.0 months. Median progression-free survival and overall survival (OS) were 37.4 months (95% CI 22–NE) and not reached, respectively; median follow-up was 21.2 and 30.3 months, respectively. The 36-month OS rate was 93% (95% CI 86–99). Treatment duration ranged from 1+ to 63+ months. At data cut-off, 31 pts had progressed; 18 continued treatment post-progression for ≥4 weeks. There were no treatment-related deaths. Treatment-related adverse events (TRAEs) occurred in 81% of pts (23% were Grade [G] 1, 28% G2, 25% G3, and 5% G4). The most common TRAE was increased aspartate aminotransferase (31 pts [33%]). Four pts (4%) discontinued treatment due to TRAEs. Neurological TRAEs occurred in 12% of pts (5% were G1, 4% G2, and 2% G3). The most common neurological TRAE was headache (5 pts [5%]). **Conclusions:** In this expanded dataset, larotrectinib continues to demonstrate rapid and durable tumor-agnostic efficacy, extended survival, and a favorable safety profile in pediatric pts with TRK fusion-positive cancer. These results highlight the importance of identifying *NTRK* gene fusions in pediatric solid tumors. Clinical trial information: NCT02576431, NCT02637687. Research Sponsor: Bayer HealthCare and Loxo Oncology.

Risk-adapted local therapy and intensive chemotherapy in patients with high-risk rhabdomyosarcoma. *First Author: Michael W. Bishop, St. Jude Children's Research Hospital, Memphis, TN*

Background: Outcomes for patients with metastatic RMS remain poor. Dose escalation of radiation may reduce risk of local failure, and maintenance therapy has prolonged survival in intermediate risk patients. We investigated a multimodal chemotherapeutic regimen with risk adapted local therapy and the addition of maintenance therapy following intensive chemotherapy to improve the outcome for patients with high-risk RMS. **Methods:** We conducted a phase 2 multi-center trial for patients with newly diagnosed high-risk (stage 4) RMS. Patients received 54 weeks of chemotherapy (vincristine/irinotecan, interval compressed vincristine/doxorubicin/cyclophosphamide and ifosfamide/etoposide, and vincristine/dactinomycin/cyclophosphamide) followed by 4 cycles of anti-angiogenic maintenance therapy (bevacizumab, sorafenib, cyclophosphamide). Primary tumor local control consisted of surgery and photon/proton radiation therapy (RT) dependent on the degree of resection (negative margin – no RT, positive margin – 36 GyRBE, unresected ≤5cm – 50.4 GyRBE, unresected > 5cm – 59.4 GyRBE). RT was administered at Week 4 or 20 based on size/location, and to radiographically visible (non-CR) sites of metastatic disease at end of treatment. **Results:** Thirty-nine eligible patients with high-risk RMS (64% *FOXO1* fusion positive, 74% with nodal disease, 67% Oberlin score > 1) were enrolled. Two of 13 patients with Oberlin score ≤ 1 were *FOXO1* fusion positive whereas 23 of 26 patients with Oberlin score > 1 were fusion positive. Seventeen patients received maintenance therapy as planned (progression, n = 12; received alternate maintenance regimen, n = 4; other, n = 6) with a median of 4 cycles (range 1-4). Common toxicities of maintenance included palmar-plantar erythrodysesthesia (n = 9), rash (n = 7), and cystitis (n = 6). At a median follow-up of 43.5 months for survivors, 3-year EFS was 29.5% (95% CI 15.4-45.1%). Fusion positive status significantly predicted EFS (negative, 60.6% vs. positive, 9.6%, p = 0.019), whereas low Oberlin score approached significance for EFS (≤1, 56.6% vs. > 1, 16.4%, p = 0.064). The cumulative incidence of local failure was 17.5% (95% CI 6.9-32.2%). Twenty-one patients achieved CR of all metastatic sites and did not receive metastatic site RT. Of those, 7 experienced disease recurrence in a pre-existing metastatic soft tissue site. Among 4 patients who received metastatic site RT at the end of treatment, one patient experienced disease recurrence in a pre-existing metastatic site. **Conclusions:** The addition of maintenance therapy to intensive chemotherapy and risk adapted radiotherapy did not improve EFS in this population. Consolidative radiation should be considered for soft tissue metastatic sites regardless of radiographic response. Clinical trial information: NCT01871766. Research Sponsor: American Lebanese Syrian Associated Charities.

Predictors of differential outcomes according to response to induction chemotherapy in high-risk neuroblastoma. *First Author: Elizabeth Sokol, Ann & Robert H Lurie Children's Hospital of Chicago, Chicago, IL*

Background: Response to induction chemotherapy has been shown to predict outcome in patients with high risk neuroblastoma, with those achieving a complete response (CR) having superior outcomes. Little is known about what factors impact survival within groups of patients with favorable and unfavorable end-induction response. We evaluated whether conventional prognostic factors remain prognostic in subsets of patients defined by response to induction. **Methods:** Patients from four COG high risk trials (A3973, ANBL02P1, ANBL0532, and ANBL12P1) were included. End-induction response was determined according to the 1993 International Neuroblastoma Response Criteria (INRC). Patients were categorized as having end-induction responses of CR, partial response (PR) or better, less than PR without progressive disease (PD), and PD. Univariate Cox models calculated OS hazard ratios for clinical and biological variables in subsets defined by response category. **Results:** 1,244 patients were included. Among all patients, age >5 years, INSS stage 4 disease, adrenal primary site and unfavorable histology by INPC were associated with inferior OS (see Table). Among patients who achieved a CR, stage 4 disease was the only factor that remained significantly associated with worse OS. Among those who achieved PR or better, age >5 years, stage 4 disease and unfavorable histology remained significantly associated with inferior OS. For those with less than PR but without PD, adrenal primary site, *MYCN* amplification and 1p LOH were significantly associated with inferior OS. For those with PD, *MYCN* amplification and 1p LOH were associated with worse OS, but older age was associated with better OS. **Conclusions:** Specific prognostic factors in neuroblastoma are associated with differential survival in groups defined by response to induction. Age, stage, and histology appear to be associated with OS for patients with more favorable response to induction, whereas *MYCN* and 1p LOH play a greater role in patients with unfavorable response to induction. These data can help to further define prognosis for patients with variable responses to induction. Research Sponsor: None.

Hazard ratios for death (95% CI) according to clinical and biological variables for all high risk patients and for subsets defined by response to induction.

Variable	All Patients (n=1244)	CR (n=258)	PR, VGPR, or CR (n=992)	MR or NR (n=139)
INSS Stage 4	2.63* (1.91,3.63)	2.82* (1.54,5.16)	3.11* (2.10,4.59)	1.10 (0.35,3.49)

Metronomic oral maintenance chemotherapy in patients with localized high-risk rhabdomyosarcoma (RMS) and RMS-like tumors: A report from a randomized, multicenter, phase III trial CWS-2007HR. *First Author: Ewa Koscielniak, Klinikum Stuttgart-Olgahospital, Stuttgart Cancer Center, Zentrum für Kinder-, Jugend- und Frauenmedizin, Pediatrics 5 (Oncology, Hematology, Immunology), Stuttgart, Germany*

Background: Low dose maintenance therapy as consolidation after multimodal standard therapy has been shown to improve survival in patients with sarcoma. It is however unclear which drugs and how long would be optimal. We investigated whether adding oral maintenance chemotherapy after standard multimodal therapy (ST) in patients with localized RMS and RMS-like sarcoma defined as high and very-high risk (HR and VHR), according to CWS stratification, would improve survival. **Methods:** Patients (pts) age > 6 months < 21 years, with 1. embryonal RMS N0, incompletely resected, (Group II or III), tumor size > 5cm and/or ≥10 years, in unfavorable primary sites and all N1 (HR RMS Group), 2. alveolar RMS N0/N1 (VHR RMS Group) 3.Unidfferentiated sarcoma (UDS), extraskeletal Ewing sarcoma (EES) and primary non resectable (Group III) synovial sarcoma (SS) (HR RMS-like Group) in complete remission after ST including 9 cycles of ifosfamide, vincristine and actinomycin D +/- doxorubicin, surgery and/or radiotherapy were eligible for randomization to stop treatment (S-arm) or receive maintenance chemotherapy (M-arm) with eight 10-days courses consisting of trofosfamide (2x 75mg/m^2/day) and idarubicine (1 x 5mg/m^2/day 1,4,7,10) alternating with trofosfamide and etoposide (2x 25mg/m^2/day). The study was designed with 80% power and a two-sided alpha level of 5% to detect an increase in 3 yr EFS from 60 to 75%. Randomisation was stratified according to risk groups. To reduce possible imbalances in the number of treatment assignments, a permuted block design was used. The initial calculated sample size was 145 pts in each group (recruitment period six years). Due to the lower than planned recruitement rate, the accrual was extended to 10 years and sample size recalculated to 98 pts in each group. **Results:** Between 1.7.2009 and 30.6.2019, 441 pts were eligible at diagnosis and 337 at the end of ST. 195 pts were randomized: 99 were assigned to the S-arm and 96 to M-arm. The distribution of the following clinical features:age, gender, tumor size, IRS-Group, T-Status, N-Status, histology and localisation showed no significant difference between the treatment groups. In the intent to treat population, with a median follow up of 4.9 years (IQR 3.0-5.7) in surviving pts, 3yr EFS and OS in M-arm vs S-arm were respectively: EFS 66.2% (95% IC 57.1-76.79) vs 75.0% (95% IC 66.8-84.3) (p 0.07) and OS 81.9% (95% IC 74.2-90.4) vs 84.6 (95% IC 77.5-92.4) (p 0.15). Toxicity grade 3 (no grade 4) in the M-arm was: hematological in 51 %, febrile infection 5%, sensory neuropathy in 1% pts. **Conclusions:** The addition of maintenance therapy with trofosfamide, etoposide and idarubicine after ST does not improve EFS and OS in patients with high risk RMS and RMS-like sarcomas. Clinical trial information: 2007-0001478-10. Research Sponsor: Kinderkrebstiftung Germany.

Phase I results of the INFORM2 combination study of nivolumab and entinostat in children and adolescents: INFORM2 NivEnt. *First Author: Cornelis Martinus van Tilburg, Hopp Children's Cancer Center Heidelberg (KiTZ), German Cancer Research Center (DKFZ) and Heidelberg University Hospital, Heidelberg, Germany*

Background: Pediatric patients with relapsed or refractory high-risk solid and CNS tumors have dismal survival. To date treatment with immune checkpoint inhibitors in this population has been disappointing. This study exploits the immune enhancing effects of entinostat on nivolumab in biomarker enriched subpopulations. The study aims to determine the pediatric recommended phase II dose (pRP2D) and to evaluate activity and safety. **Methods:** This is an exploratory non-randomized, open-label, multinational seamless phase I/II trial in children and adolescents with relapsed / refractory or progressive high-risk solid and CNS tumors. The phase I is divided in 2 age cohorts: 12–21 years (y) and 6–11y and follows a 3 + 3 design with two dose levels for entinostat (dose level 1: 2 mg/m^2 and dose level 2: 4 mg/m^2 once per week) and fixed dose nivolumab (3 mg/kg every 2 weeks). Patients entering the trial on pRP2D can seamlessly enter phase II which consists of a biomarker defined four group basket trial: high mutational load (group A), high PD-L1 mRNA expression (group B), focal MYC(N) amplification (group C), low mutational load and low PD-L1 mRNA expression and no MYC(N) amplification (group D). **Results:** The first patient was enrolled in May 2020 and at the time of the data cut (21-JAN-2022), 19 patients were treated. The median age at enrollment was 14 y. In the 12 – 21y cohort 15 patients were enrolled and four patients in the 6 – 11y cohort. The most frequent treatment-related AEs to date were thrombocytopenia in six (32%), nausea and vomiting both in four (21%), and neutropenia in three patients (16%). Five patients (26%) experienced grade 3/4 mostly reversible treatment-related AEs, e.g. neutropenia/leukopenia. No treatment related deaths were reported. In the 6 – 11y cohort dose escalation is ongoing. In the 12 – 21y cohort, one DLT (CTCAE grade 3 thrombocytopenia) was observed in six patients on dose level two, which was determined as the pRP2D of the combination. At the time of the data cut, 10 patients (six in arm D and four patients in which the biomarker group was not yet determined) had received at least one RECIST/RANO response evaluation by central review in phase II. One patient (17%) in arm D with metastatic relapsed renal cell carcinoma (RCC) harboring a typical PRCC-TFE3 fusion showed a PR after two cycles and finally achieved an ongoing CR. Extensive explorative analyses of immune signatures derived from INFORM RNA-Seq and WES data revealed that both the primary diagnosis and the current relapse samples harbored a remarkable high immune cell infiltration, especially CD8+ T-cells. **Conclusions:** The first and ongoing global INFORM2 trial has identified the pRP2D for the nivolumab and entinostat combination in the older age cohort with good tolerability. A patient with metastasized relapsed RCC experienced a CR. The role of immune infiltration as a potential predictive biomarker is currently being explored. Clinical trial information: NCT03838042. A fully automated MRI-based deep-learning algorithm for classifying germinomas and nongerminomatous germ cell tumors. *First Author: Yanong Li, Beijing Tiantan Hospital, Beijing, China*

Background: Intracranial germ cell tumors (iGCTs) are classified into two pathological subtypes (Germinomas [GEs] and nongerminomatous germ cell tumors [NGGCTs]), with distinct treatment strategies and prognosis. Accurate preoperative determination of iGCT subtypes is essential for clinical decision-making and prognosis assessment. We aim to develop and validate a deep-learning algorithm to automatically segment the iGCTs and classify their subtypes using preoperativeT2-weighted (T2W) images. **Methods:** Brain MR imaging and corresponding pathologic information were retrospectively obtained for 594 iGCTs, including 269 GEs and 325 NGGCTs from Beijing Tiantan Hospital (between January 1, 2008, and October 31, 2020). The retrospective set was subdivided into the training (n = 416) and test (n = 178) sets to develop and test a 3D nnU-Net using T2W images (here we named iGCT-net) for iGCT segmentation and its subtypes (GEs and NGGCTs) classification, simultaneously. A prospective cohort (n = 73, 56 GEs and 17 NGGCTs) was designed as a simulation set to test the model in a simulated clinical application. Dice scores were computed to assess tumor segmentation. Accuracy, sensitivity, specificity, and area under the curve (AUC) were used to assess the GEs and NGGCTs classification. Sensitivity analysis on subgroups with tumor locating at suprasellar, pineal, and basal ganglia in test and simulation set, respectively. **Results:** For tumor segmentation, the iGCT-net achieved a dice score of 0.73 and 0.80 in test and simulation sets, respectively. For GEs and NGGCTs classification in the test set, the iGCT-net achieved an accuracy of 90.96%, sensitivity of 86.84% and specificity of 82.26%, and AUC of 84.87%. The iGCT-net showed 83.65% accuracy in the simulation set, with sensitivity of 83.56% and specificity of 83.72%, and AUC was 81.17%. In sensitivity analysis, the accuracies of the iGCT-net presented for the suprasellar region, pineal region, and basal ganglia region were 86.84%, 92.92%, and 61.73% in the test set, and 92.31%, 88.89%, and 72.27% for suprasellar region, pineal region, and basal ganglia region in the simulation set. **Conclusions:** We developed and validated a fully automatic deep learning algorithm to segment iGCT and classify GEs and NGGCTs with a high accuracy using only T2W images based on a large dataset. Research Sponsor: Grant number: 2020-2-1072.

Multiomics analysis of pediatric solid tumors within the INFORM precision oncology study: From functional drug profiling to biomarker identification. *First Author: Dina ElHarouni, Hopp Children's Cancer Center Heidelberg (KiTZ), Faculty of Biosciences, Heidelberg University, Clinical Cooperation Unit Pediatric Oncology, German Cancer Research Center (DKFZ) and German Consortium for Translational Cancer Research (DKTK), Heidelberg, Germany*

Background: Within the INFORM (INdividualized Therapy FOr Relapsed Malignancies in Childhood) registry over 1200 childhood malignancies were molecularly profiled using next generation sequencing to identify therapeutic targets. Nevertheless, high evidence targets were only detected in 5% of cases and only 50% of the patients were identified with druggable pathways, while the remaining cases lacked druggable alterations. Thus, an ex-vivo functional drug response profiling platform for pediatric solid tumors has been established within the INFORM program to identify novel biomarkers and unravel molecular mechanisms associated with drug response profiles for clinical translation. **Methods:** Solid tumors from 97 paediatric patients were screened against a library of 76 drugs. A quality control classification decision tree was designed to select the samples for further analysis. Whole exome sequencing, low-coverage whole genome sequencing, and RNA-seq were used to analyze the molecular profiles of the samples. Molecular features were filtered to retain oncogenic and druggable events. Five data feature views (mutations, mRNA, gene fusions, CNVs, and drug responses) were used to train a Multi-Omics Factor Analysis (MOFA) model to identify prominent latent factors. **Results:** 81 samples passed the quality control inclusion criteria of which 76 samples had available omics data profiles. Quantitative drug profiling measurements were reported using the selective asymmetric drug sensitivity score.The multi-omics analysis captured five entity-specific omics signatures of Ewing sarcoma, Wilms tumor, BCOR sarcoma, neuroblastoma and ependymoma. Moreover, the analysis revealed sensitivity to navitoclax in neuroblastoma samples with PHOX2B-GATA3 overexpression, and an association between MEK inhibitor sensitivity and an expression signature in Wilms tumors. **Conclusions:** The combination of functional drug and multi-omics profiling enabled the identification of novel biomarkers for drug sensitivities in pediatric solid tumors. As we continue to expand the number of patient samples evaluated with our drug sensitivity platform, this dataset will provide insights for novel drug targets, and could unravel key molecular events and mechanisms acting towards personalized therapies. Combined IL-6 and IL-8 inhibition to overcome mesenchymal stem cell (MSC)-induced resistance to antimetastatic drugs in osteosarcoma. *First Author: S. Rubina Baglio, Amsterdam UMC, location VUMC, Amsterdam, Netherlands*

Background: Mesenchymal stem cells (MSCs) play a key role in the progression of osteosarcoma (OS). In response to tumor-associated signals, including tumor-secreted extracellular vesicles (EVs), MSCs increase the expression of inflammatory cytokines promoting tumor cell aggressiveness. Previous data has demonstrated that IL-6 and IL-8 signaling mediate metastasis in OS. The aim of this study was to evaluate tumor EV-induced alterations of MSCs and identify combination therapies that can counteract MSC-induced resistance to antimetastatic drugs. **Methods:** Tumor EV-induced alterations of the MSC transcriptome were analyzed by RNA-seq. Gene set enrichment analysis (GSEA) was applied to discriminate TGFβ-dependent and independent pathways. EV RNA-induced expression changes were identified by transfecting purified EV-RNA in MSCs and by using a selective dsRNA antagonist. We selected candidate targets to block MSC-induced drug resistance and evaluated their effect in an orthotopic xenograft model of OS. Ladarixin (an allosteric inhibitor of the CXCL8/IL-8 receptors CXCR1 and CXCR2; 30 mg/kg 6x per week i.p.) and tocilizumab (anti-IL6 receptor antibody; 100 µg/mouse every other day i.p.) were administered starting from day one until the experimental endpoint. Metastasis were quantified by histological examination. This study was funded by the Dutch Cancer Society (KWF), POR FESR Campania 2014-2020 and Dompé Farmaceutici SpA. **Results:** EVs from aggressive cancer cell lines induced an inflammatory MSC (iMSC) phenotype, characterized by increased expression of chemokines, including IL-8 as the most upregulated. Apart from IL-6, these alterations were mostly independent from TGFβ signaling and related to pattern recognition receptor (PRR) activation. We demonstrated that tumor EV-associated non-coding RNAs trigger TLR3 signaling in MSCs activating an innate immune response leading to high induction of IL-8 and other chemokines. Ladarixin and tocilizumab combination significantly reduced metastasis formation in a spontaneous metastasis model and overcame iMSC-induced resistance observed with single antimetastatic treatments. No effect was observed on primary tumor growth. **Conclusions:** EV-associated TGFβ together with EV-RNA induce iMSCs development in OS. Ladarixin in combination with tocilizumab reduced metastasis formation in a xenograft mouse model of OS, and, importantly, may prevent the occurrence of iMSC-induced tumor resistance to antimetastatic drugs. Phase I study of ^{131}I-MIBG with dinutuximab for patients with relapsed or refractory neuroblastoma: A report from the new approaches to neuroblastoma therapy (NANT) consortium. *First Author: Thomas Cash, Aflac Cancer & Blood Disorders Center, Children's Healthcare of Atlanta, Emory University School of Medicine, Atlanta, GA*

Background: ^{131}I-metaiodobenzylguanidine (MIBG) is one of the most active salvage therapies for patients with relapsed or refractory (R/R) high-risk neuroblastoma (HRNB). Preclinical neuroblastoma studies show cooperative effects when radiation is combined with anti-GD2 monoclonal antibody (mAb). We hypothesized that MIBG would synergize with the anti-GD2 mAb dinutuximab to provide improved anti-tumor responses. The primary aims of Part A of this study were to determine the maximum tolerated dose (MTD) and/or recommended Phase II dose (RP2D) of MIBG administered with dinutuximab in children with R/R HRNB and to define and describe the toxicities. **Methods:** Patients 1-29 years of age with R/R HRNB who had MIBG uptake in ≥ 1 site were eligible. Prior anti-GD2 mAb therapy was allowed provided it was not administered with MIBG and not permanently discontinued due to toxicity. One prior MIBG therapy was allowed. MIBG was administered on day 1 at one of three dose levels (DLs): 12, 15, and 18 mCi/kg (DL1-DL3, respectively) with an expansion cohort at the RP2D. Doses were escalated using a rolling six design starting at DL1. The primary endpoint was dose-limiting toxicity (DLT) during course 1. Dinutuximab (17.5 mg/m^2/dose) was administered intravenously on days 8-11 and 29-32 and GM-CSF (250 mcg/m^2/dose) subcutaneously on days 8-17 and 29-38. Autologous peripheral blood stem cells were infused to all patients on day 15 (+/- 2 days). A maximum of 2 courses per patient were allowed. Response rate was defined as the proportion of patients with a complete or partial response. **Results:** Thirty-one patients were enrolled. Fourteen were evaluable for dose escalation (4 on DL1, 4 on DL2, and 6 on DL3); 5 evaluable patients were treated in the DL3 expansion. The median age was 7.4 years (range: 3.1 – 22.0) and 20 (65%) were male. Twenty-seven (87%) patients had previously received a median of 8.5 cycles of chemoimmunotherapy (range: 2 – 21). Eight patients previously progressed while receiving anti-GD2 mAb including 7 in DL3. Five (16%) patients had previously received MIBG. No patient at any dose level experienced DLT. Common grade 3/4 treatment-related toxicities were expected hematologic toxicities attributable to MIBG and non-hematologic toxicities attributable to dinutuximab or GM-CSF. Among 26 response-evaluable patients, the centrally-confirmed response rate was 31% across all dose levels: 2/6 (33%) in DL1, 3/5 (60%) in DL2, and 3/15 (20%) in DL3. There were 3 minor responses, 1 in DL2 and 2 in DL3. **Conclusions:** The RP2D of MIBG in combination with standard doses of dinutuximab and GM-CSF is 18 mCi/kg. This radioimmunotherapy regimen is well-tolerated without additive toxicity. Preliminary efficacy data are encouraging in this heavily pre-treated patient population. A phase 2 trial of this regimen is planned in patients with R/R HRNB. Clinical trial information: NCT03332667. Research Sponsor: United Therapeutics Corporation, Other Foundation, Aflac Cancer & Blood Disorders Center.

Predicting outcomes with circulating adrenergic neuroblastoma mRNAs in children with relapsed and refractory neuroblastoma: A BEACON-Neuroblastoma biomarker study. *First Author: Lucas Moreno, Division of Pediatric Oncology & Hematology, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: Children with relapsed and refractory neuroblastoma (RR-NBL) have poor outcomes. Early identification of children at greatest risk of relapse could mean timelier modifications of treatment to improve outcomes. High levels of adrenergic neuroblastoma mRNAs in blood of children with stage M neuroblastoma receiving frontline treatment predict poor outcome (Viprey PMID: 24590653). Since these markers have not been thoroughly studied in the RR-NBL population, we have prospectively evaluated the prognostic potential of the adrenergic neuroblastoma mRNAs paired-like homeobox 2B *(*PHOX2B*)* and tyrosine hydroxylase (TH) in blood from children with RR-NBL treated in the BEACON-Neuroblastoma trial (NCT02308527). **Methods:** Blood samples collected at baseline from 88 children were analysed by reverse transcriptase polymerase chain reaction (RTqPCR) for PHOX2B and TH mRNAs. The prognostic power of these mRNAs was evaluated using Kaplan-Meier survival curves and Cox proportional hazards regression. Progression-free (PFS) and overall survival (OS) were calculated from the date that the blood sample was taken at screening to the date of an event; progression, disease recurrence, death or censored alive at the last clinical evaluation. **Results:** Of the children in this cohort, 58 (66%) had relapsed and 30 (34%) had refractory disease. Twenty-three (26%) had *MYC-N* amplified tumours. TH and PHOX2B mRNAs were detected in 55% and 60% of blood samples respectively; the correlation coefficient between TH and PHOX2B was 0.75. Higher levels of TH, PHOX2B mRNAs or both combined were associated with reduced PFS and OS (Table). For TH, median PFS for children with TH levels below the median was 12 months (95%CI, 4.6–13 months) versus 5.5 months (95%CI, 1.8–9.4 months) for those children with TH levels above the median. For PHOX2B, median PFS for children with PHOX2B levels below the median was 11.5 months (95%CI, 7.6–34 months), compared to 5.7 months (95%CI, 1.8–10.5 months) where levels were above the median. **Conclusions:** TH and PHOX2B mRNAs in blood collected at baseline identify children with refractory or relapsed neuroblastoma at greatest risk of progression or death. In the RR-NBL setting, this simple blood test could be used to stratify treatment strategies. Clinical trial information: NCT02308527. Research Sponsor: Cancer Research UK, Imagine for Margo, Solving Kids Cancer.

Summary of RTqPCR data for TH and PHOX2B mRNAs in blood (n=87) taken at baseline from children treated in BEACON-Neuroblastoma.

	PFS			OS

Update on phase 1 study of tazemetostat, an enhancer of zeste homolog 2 inhibitor, in pediatric patients with relapsed or refractory integrase interactor 1–negative tumors. *First Author: Susan N. Chi, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: A defining feature of malignant rhabdoid tumors (MRTs), epithelioid sarcoma (ES), and poorly differentiated chordomas (PDC) is loss of integrase interactor 1 (INI1) expression, which induces dependence on enhancer of zeste homolog 2 (EZH2). Tazemetostat (TAZ) is a selective EZH2 inhibitor approved by the US Food and Drug Administration for patients (pts) aged ≥16 y with metastatic or locally advanced ES ineligible for complete resection. Pediatric dose escalation and interim efficacy and safety data for the dose expansion were previously reported. Updated efficacy, safety, subgroup analyses, and translational results are reported here. **Methods:** NCT02601937 is a phase 1 multicenter study evaluating TAZ monotherapy ≤2400 mg/m^2 daily in pediatric pts with relapsed or refractory INI1$^-$ tumors (MRT, atypical teratoid rhabdoid tumor [ATRT], select tumors with rhabdoid features, other INI1$^-$ tumors, and SS18-SSX synovial sarcoma). Primary endpoint for dose expansion was objective response rate (ORR). Secondary endpoints included safety/tolerability, duration of response (DOR), progression-free survival (PFS), and overall survival. Selected exploratory flow data using 250,000 cells from peripheral blood were available for up to 25 pts. **Results:** Phase 1 enrolled 109 pts (escalation, n=46; expansion, n=63; Table) with mean ages of 5.4 y in the dose escalation and 7.4 y in the dose expansion. ORRs were 7% (3/46) in the dose escalation and 14% (9/63) in the dose expansion. Per tumor category in the dose expansion, ORRs were 24% (5/21) ATRT, 33% (2/6) PDC, 22% (2/9) ES, and 0% in non–CNS RTs (n=21) and other tumors (n=6). ORR for pts with prior radiotherapy was 14% (11/80) vs 3% (1/29) with prior radiotherapy (P>0.05). In the dose expansion, median PFS was 8 wk (95% CI: 8–13), OS was 21 wk (95% CI: 13–38), and DOR was 35 wk (95% CI: 24–121). Grade 3–4 treatment-related treatment-emergent adverse event rates were 15% (7/46) in the dose escalation and 22% (14/63) in dose expansion. Differences between responders (R) and nonresponders (NR) at C1D1 for neutrophil counts were significant (P<0.05). All R (6/6) had <125,000 total neutrophils at C1D1 vs 42% (8/19) of NR; 50% (3/6) of R had >50,000 total CD3 T cells vs 0% (0/19) of NR. **Conclusions:** TAZ showed promising antitumor activity in ATRT, ES, and PDC. Potential synergism between prior radiotherapy and TAZ requires further investigation. TAZ was generally well tolerated. The biological/clinical significance of differences in peripheral blood cell counts between R and NR at C1D1 needs further investigation. Clinical trial information: NCT02601937. Research Sponsor: Epizyme, Inc.

Phase I trial of lorlatinib in combination with topotecan/cyclophosphamide in children with ALK-driven refractory or relapsed neuroblastoma: A new approaches to neuroblastoma therapy consortium study. *First Author: Kelly C. Goldsmith, Children's Healthcare of Atlanta, Emory University, Atlanta, GA*

Background: Lorlatinib, a macrocyclic ATP-competitive ALK inhibitor, exerts potent activity against neuroblastoma (NB) xenograftsharboring the most common *ALK* mutations. We performed a first-in-child phase 1 study of lorlatinib for patients with refractory/relapsed (R/R) ALK aberrant high-risk NB. We previously reported on Part A of the study, where safety of single agent lorlatinib was determined, showing complete responses (CR) to lorlatinib at the recommended phase 2 dose (RP2D) of 115 mg/m2 in pts < 18 years and 150 mg in pts > 18 yrs. Part B of the study aimed to determine the safety, pharmacokinetics (PK), RP2D, and explore the anti-tumor activity of lorlatinib in combination with topotecan and cyclophosphamide in pts with R/R ALK-driven NB. **Methods:** Patients with R/R NB ages 1-17 years with *ALK* mutations or amplification were eligible; prior ALK inhibitor (ALKi) treatment was allowed. Lorlatinib was orally administered once daily on days 1-28 with topotecan (0.75 mg/m^2/day) and cyclophosphamide (250 mg/m^2/day) administered intravenously days 1-5 and GCSF starting day 6. Two lorlatinib dose levels (DL) of 95 mg/m^2/day (DL4B) and 115 mg/m^2/day (DL5B) were assessed using a 3+3 dose escalation design with the primary endpoint of dose limiting toxicity (DLT) in Course 1. We report lorlatinib safety, PK, and objective response rate (ORR) for patients enrolled on Part B. **Results:** Between 10FEB2020 and 03DEC2021,9 eligible pts enrolled on Part B with a median age of 6.7 years (3.7-12.7). Three pts were enrolled onto DL4B and six onto DL5B (2/3 pts on DL4B and 4/6 pts on DL5B had received prior ALKi therapy) with no DLT's observed in course 1. One patient on DL5B experienced a neuropsychological DLT in Course 3. Most common treatment-related adverse events were hematological, febrile neutropenia, high cholesterol, hypertriglyceridemia, and neuropsychological effects. The median number of courses received was 6 with a range of 1-8 on DL4B and 1-7 on DL5B. Of the 8 patients evaluable for response, ORR was 50%: 2/3 pts on DL4B and 2/5 pts on DL5B. Preliminary PK data demonstrate comparable dose level-associated lorlatinib steady state exposure between Part B chemotherapy combination and Part A monotherapy cohorts, supporting that chemotherapy had no effect on lorlatinib exposure that there are no overlapping toxicities. **Conclusions:** Lorlatinib in combination with topotecan and cyclophosphamide is well tolerated, and early data suggest encouraging objective anti-tumor activity. These data support the current integration of lorlatinib into up-front high risk neuroblastoma therapy for patients with ALK-driven neuroblastoma. Clinical trial information: NCT03107988. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Pharmaceutical/Biotech Company.

10042 **Poster Session**

Phase II trial of gemcitabine and nab-paclitaxel for recurrent osteosarcoma: A report from the National Pediatric Cancer Foundation. *First Author: Lars M. Wagner, Duke University Medical Center, Durham, NC*

Background: The combination of gemcitabine and docetaxel is often used to treat patients with recurrent osteosarcoma. A retrospective study of 35 such patients has reported an objective response rate of 17% and 4-month progression-free survival (PFS) of 56% with this combination (BMC Cancer 2016;16:280). Nab-paclitaxel is a nanoparticle taxane that has activity against osteosarcoma xenografts and may have less myelosuppression than docetaxel. The combination of gemcitabine and nab-paclitaxel is now frontline therapy for pancreatic cancer. We conducted a prospective multi-institutional phase II trial of this drug combination for patients with recurrent osteosarcoma. **Methods:** Patients with relapsed/refractory osteosarcoma with measurable disease and age ≥ 12 years and adequate organ function were included. A Simon's two-stage design was used to identify a 4-month progression-free survival (PFS) of > 35%. Patients received nab-paclitaxel 125 mg/m^2 and gemcitabine 1000 mg/m^2 weekly x 3 in 4-week cycles. **Results:** Eighteen patients with a median age 16 years (range 12- 26) received a total of 56 total cycles.(median 2, range 1 - 12). The median number of prior treatment regimens was 3 (range 1-7). Two patients (11%) experienced a partial response, and 6 (33%) received more than 2 cycles. The 4-month PFS was 30% (95% CI 14-62 %). Six patients required dose reductions for neutropenia (n = 4), pleural effusion (1), or neuropathy (1). Two patients were removed from study secondary to neutropenia despite dose reduction and myeloid growth factor support, and one patient came off study due to severe peripheral edema. **Conclusions:** In this prospective study, the combination of gemcitabine and nab-paclitaxel administered on this schedule showed only limited activity for patients with heavily pretreated recurrent osteosarcoma. Toxicity led to dose modifications in 33% and discontinuation in 17% of patients. When compared to a historical retrospective study, the substitution of nab-paclitaxel for docetaxel did not appear to increase activity or decrease toxicity for this patient population. Clinical trial information: NCT02945800. Research Sponsor: National Pediatric Cancer Foundation.

Patterns of relapse after immunotherapy in patients with high-risk neuroblastoma. *First Author: Scott Moerdler, Department of Pediatrics, Rutgers Cancer Institute of New Jersey, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ*

Background: While the addition of anti-GD2 immunotherapy led to improvement in outcomes in patients on the Children's Oncology Group (COG) ANBL0032 study, relapse remains a concern. Prior studies demonstrated the prognostic importance of time to first relapse, however, the effect of immunotherapy on timing and patterns of relapse in neuroblastoma (NBL) have yet to be evaluated. The purpose of this exploratory analysis was to describe the impact of immunotherapy on patterns of relapse in patients with high-risk NBL, including a descriptive comparison of sites of relapse based on post-consolidation treatment received [dinutuximab with cytokines and isotretinoin (DIN) vs isotretinoin alone (ISO)]. **Methods:** A retrospective, descriptive analysis of patients on ANBL0032 was performed, including patients randomized to DIN or ISO and those non-randomly assigned to DIN after ISO arm closure. Pt characteristics including age, stage, *MYCN* amplification status, tumor grade, mitosis-karyorrhexis index (MKI) and ploidy were summarized descriptively and relapse sites were tabulated. For DIN patients who subsequently relapsed, overall survival (OS) was calculated starting from the time of first relapse after enrollment on ANBL0032 ("post-relapse OS"). Kaplan-Meier OS curves were generated based on site of relapse. **Results:** The analytic cohort included 1,431 (DIN = 1,327; ISO = 104) patients. Among DIN patients, 492 relapsed, many in > 1 site. In the randomized cohort (n = 248), 122 relapsed (DIN = 68/144; ISO = 54/104). The frequencies (DIN; ISO) by site of relapse in the randomized cohort were: bone (53%; 54%), CNS (16%; 11%), lymph node (13%; 17%), abdominal (10%; 17%), paraspinal (6%; 2%), liver (3%; 4%), other soft tissue (22%; 7%). A higher proportion of ISO patients had marrow relapse (29.4% DIN; 48.2% ISO); however, the proportion of DIN patients with lung relapses appeared higher (9% vs 2%). Among all relapsed patients, the proportion with bone relapse did not appear to differ between treatment groups, regardless of *MYCN* status. Among patients with *MYCN* amplified disease, the proportion with marrow relapse did not appear to differ based on treatment [21/149 (14.1%) DIN; 3/20 (15.0%) ISO]; however, among patients with *MYCN* non-amplified disease, the proportion with marrow relapse appeared higher in the ISO group [16/23; 69.6%] vs the DIN group [52/193 (26.9%)]. **Conclusions:** In this exploratory analysis of patients on COG ANBL0032, the pattern for site of relapse appears to differ between patients treated with DIN vs ISO. While immunotherapy remains the treatment of choice in this population, the findings from this retrospective exploratory analysis warrant further investigation to decrease the risk for post-immunotherapy relapse. Clinical and biological features prognostic of survival after relapse of INRGSS-stage MS pattern neuroblastoma: A report from the International Neuroblastoma Risk Group (INRG) project. *First Author: Kevin M. Campbell, Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA*

Background: Neuroblastoma (NB) presenting with INRGSS MS metastatic pattern highlights the extreme heterogeneity within NB and subsequent difficulty in risk assignment. Depending on tumor biology, patients with stage MS disease may be classified as very-low risk or as high-risk. While outcomes at initial diagnosis have been well-described, outcomes after relapse are less well defined. **Methods:** From the INRG Data Commons, we investigated clinical and biological characteristics of patients diagnosed 1984-2021 with stage MS pattern NB (INSS stage 4s, INSS stage 4 or INRG stage MS) who subsequently experienced disease relapse or progression, excluding patients whose first event was death. Using Kaplan-Meier methods, post-relapse overall survival (OS)± standard error (SE) was calculated from the time of first relapse/progression until death or last contact, overall and by era of diagnosis: < 2000 vs ≥2001. Univariate Cox models were used to identify factors prognostic of post-relapse OS. **Results:** 209 patients met eligibility criteria,103 diagnosed < 2001 and 106 ≥2001. Of patients diagnosed ≥2001, 89% (n = 94) were < 365 days old at diagnosis; tumors were *MYCN* amplified in 21% (21/102) and diploid in 31% (20/64). Of this same cohort, time from initial diagnosis to relapse was < 6 months in 40% (n = 42), 6-12 months in 25% (n = 26), and > 12 months in 36% (n = 38) of patients. Of 60 patients with known site of relapse/progression diagnosed ≥2001, 73% (44) were metastatic (29) or primary plus metastatic (15). Among these, 16% (5/32) remained stage MS pattern while 84% (27/32) had metastatic sites beyond MS sites. Five-year post-relapse OS±SE was 53±3.5% overall (n = 209), and higher for those diagnosed ≥2001 (62±5.0%; n = 106) compared to those diagnosed < 2001 (44±4.9%; n = 103) (p = 0.0046). In patients diagnosed ≥2001, factors prognostic of superior post-relapse OS included: age < 365 days; not Hispanic; *MYCN* non-amplified; no 1p loss/aberration, hyperdiploidy; low/intermediate MKI; LDH < 1400 U/L, favorable INPC histology; and < 12 months from initial diagnosis to first relapse. **Conclusions:** Most patients with relapsed stage MS NB have metastatic relapse and these relapses more commonly occur at sites outside liver, skin, and bone marrow. Patients diagnosed ≥2001 with MS pattern NB have substantially better post-relapse OS compared to those diagnosed < 2001. In the cohort of patients with MS pattern NB diagnosed ≥2001, most of the well-accepted prognostic factors for OS at diagnosis are also prognostic of post-relapse OS. Research Sponsor: None.

Outcomes of patients with bilateral retinoblastoma: A report from the RIVERBOAT Consortium. *First Author: Debra L. Friedman, Vanderbilt University Medical Center/Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: Retinoblastoma (RB) is the most common tumor of the eye in childhood. Intraocular RB cure rates approach 100%. Therefore, treatment advances have focused on globe salvage preserving functional vision. The Research Into Visual Endpoints and RB Health Outcomes After Treatment (RIVERBOAT) consortium was established to examine patient health outcomes, including vision, in the contemporary therapy era. **Methods:** Patients with RB treated at consortium centers from 2007 to the present were identified. Medical record abstraction was performed for disease presentation, treatment, and outcomes. A subset of the patients returned to centers and completed functional vision questionnaires (Child Vision Function Questionnaire for ages 0 – 7 and Cardiff Visual Ability Questionnaire for Children for ages >8) and had visual acuity assessed. For participants who could not yet return for a study evaluation, medical record abstraction alone was performed. **Results:** Among 463 participants enrolled to date, 193 (42%) had bilateral disease. Two each had metastatic RB, trilateral RB, and secondary osteosarcoma. One patient each with metastatic RB and trilateral RB is deceased, with overall survival for the cohort of 99%. The eye group distribution (International Intraocular Retinoblastoma Classification) was 14% A, 22% B, 14% C, 28% D, 19% E and 3% not classified. Primary enucleation was performed in 43 (22%), secondary enucleation in 48 (25%) and bilateral enucleation in 1(0.5%). Intravenous chemotherapy (IV) alone was administered in 58%, intra-arterial chemotherapy (IAC) alone in 4%, with 31% receiving both. Among 145 patients who did not require secondary or bilateral enucleation, the distribution was 16% A, 21% B, 16% C, 28% D, 15% E, and 4% non-classified eyes. This salvage was achieved with IV alone, IAC alone, or both in 55%, 5% and 30% respectively and with ophthalmic therapy only in 10%. The mean percentage of patients receiving IAC per year increased from 6% in 2008 – 2013 to 11% in 2014 – 2022 and was stable at 11% in 2018 – 2022. Among 53 patients who have reported functional vision to date, the mean scores were 0.81 for < 3 years 0.80 for 3-7 years and -1.31 for those >8 years, all considered to be good functional vision. Among 50 eyes in 37 of these 53 patients, 33 had normal vision (20/20-20/40) across A to E groups. Moderate vision loss (> 20/40 – 20/70) was noted in 1 C and 1 B eye and low vision (> 20/70 - < 20/200) in 6 group B, C or D eyes. Nine B or D eyes were legally blind (>20/200). No patients had two legally blind eyes. **Conclusions:** In this cohort of RB patients with bilateral disease treated between 2007 and 2022, 52% have been successfully treated without enucleation. Self-reported functional vision in 53 of these patients with all group eyes was good. Only 6 of 50 eyes in 37 patients met criteria for legal blindness and 66% of eyes had normal vision. With cohort accrual ongoing, we will determine if these promising outcomes continue. Research Sponsor: U.S. National Institutes of Health.

10046 **Poster Session**

Outcomes of patients with unilateral retinoblastoma: A report from the RIVERBOAT Consortium. *First Author: Debra L. Friedman, Vanderbilt University Medical Center/Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: Retinoblastoma (RB) is the most common tumor of the eye in childhood. Intraocular RB cure rates approach 100%. Therefore, treatment now focuses on globe salvage preserving functional vision. The Research Into Visual Endpoints and RB Health Outcomes After Treatment (RIVERBOAT) consortium was established to examine patient health outcomes, including vision, in the contemporary therapy era. **Methods:** Patients with RB treated at consortium centers from 2007 to present were identified. Medical record abstraction was performed for disease presentation, treatment, and outcomes. A subset of the patients returned to centers and completed functional vision questionnaires (Child Vision Function Questionnaire - ages 0 – 7 and Cardiff Visual Ability Questionnaire for Children - ages > 8) and had visual acuity assessed. For participants who could not yet return for a study evaluation, medical record abstraction alone was performed. **Results:** Among 463 participants enrolled to date, 270 (58%) had unilateral disease. One patient with metastatic RB did not survive, resulting in overall survival of 99.6. There was one case of secondary leukemia. The eye group distribution (International Intraocular Retinoblastoma Classification) was 0.4% A, 5.6% B, 7.0% C, 36.0% D, 49.0% E and 2.0% not classified. 131 (49%) patients underwent primary enucleation and are not included in further analyses. Among the remaining 139 patients, 3% were treated with local ophthalmic therapy only, 22% with intravenous chemotherapy (IV) only, 53% with intra-arterial chemotherapy (IAC) only, 22% with IV and IAC, and 35% required secondary enucleation. Globe salvage after chemotherapy was successful in 100% A, 93% B, 82% C, 72% D, and 48% E eyes. This salvage was achieved with IV only, IAC only, or both in 22%, 58% and 20% respectively. The mean percentage of patients receiving IAC per year increased from 13% (2008 – 2013) to 21% (2014 – 2017) to 28% (2018 – 2022). In 29 patients without enucleation who reported functional vision to date, the mean scores (survey theoretical ranges) were 0.72 for < 3 years (0.57 to 0.87), 0.82 for 3 -7 years (0.56 to 0.94) and -2.72 for > 8 years (-2.53 to -0.51), all considered good functional vision. In 20 of these 29 patients, 4 eyes had normal vision (20/20-20/40) across A to D groups. Moderate vision loss (> 20/40 – 20/70) was noted in 3 D eyes and low vision (> 20/70 - < 20/200) in 1 D eye. Twelve B through E eyes met criteria for a legally blind eye (>20/200). **Conclusions:** In this cohort of RB patients with unilateral disease treated from 2007 - 2022, 66% required primary or secondary enucleation. Among 29 patients with globe salvage, self-reported functional vision was good, but 12 eyes in 20 of the patients were legally blind. IAC only or IV plus IAC was most used in those who avoided secondary enucleation. With ongoing cohort accrual and increased IAC use, it will remain to be determined if globe salvage with functional vision will improve. Research Sponsor: U.S. National Institutes of Health.

Informatics tools to implement late cardiovascular risk prediction modeling for population health management of high-risk childhood cancer survivors. *First Author: David H Noyd, The University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: Marked improvements in outcomes for children with cancer and robust cohort studies with longitudinal follow-up inform evidence-based guidelines for survivors at risk for late cardiomyopathy. Clinical informatics tools to integrate data from multiple sources have the potential to catalyze population health management. **Methods:** The Oklahoma Childhood Cancer Survivor cohort was constructed from an institutional cancer registry of survivors diagnosed between 2005 and 2014 (n=382). Data elements (cumulative anthracycline, cumulative chest-directed radiotherapy, alkylator, and platinum exposures) were extracted from Passport for Care (PFC) to implement previously validated late cardiovascular risk prediction modeling from the Childhood Cancer Survivor Study (CCSS) for cardiomyopathy. Risk groups were compared to the Children's Oncology Group (COG) Long-Term Follow-up Guidelines. Standard query language facilitated extraction of echocardiogram data from the electronic health record to determine adherence, defined as an echocardiogram within 27 months and 63 months from the last day of therapy for high and moderate risk survivors, respectively. **Results:** Sixty-nine percent (n=264) of survivors from the cancer registry were documented in PFC, of whom 29%, 56%, and 15% were classified as low, moderate, high risk, respectively, based on the CCSS late cardiomyopathy risk calculator. Concordance was modest for high and moderate risk groups (Kappa = 0.42 and 0.46, respectively) and good for the low risk group (Kappa = 0.77) compared to COG risk groups. There was excellent adherence to echocardiogram guidelines with 93% and 81% of moderate and high-risk survivors, respectively. There were significant differences based on risk group (p=0.02) and age at diagnosis (p<0.01). **Conclusions:** Clinical informatics tools represent a feasible approach to leverage discrete data elements regarding key treatment exposures from PFC to successfully implement previously validated late cardiovascular risk prediction models on a population health level. PFC promotes adherence to echocardiogram surveillance and serves as a platform for future interoperability to generate real-world data to improve survivorship-focused care. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Thyroid gland definitive ultrasound screening in childhood cancer survivors following radiotherapy. *First Author: Julia A. Baran, Division of Endocrinology and Diabetes, The Thyroid Center, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Childhood cancer survivors (CCS) are at risk for radiotherapy (RT) late effects, including second malignancies. Optimal screening for thyroid cancer (TC) in CCS post-RT remains controversial. We assessed the clinical benefit of thyroid ultrasound (US) surveillance in CCS exposed to RT. **Methods:** 316 CCS (175 males) were prospectively surveilled with thyroid US between 2002 and 2021 at the Children's Hospital of Philadelphia. Patients were screened upon referral to the Survivorship Program. Thyroid US, clinicopathologic features, and endocrine-related outcomes were ascertained. Outcomes were compared using primary CCS diagnosis age cohorts of ≤ 3, > 3 to ≤ 10, and > 10 years. Risk factors for thyroid nodule(s) and TC were evaluated using Kruskal Wallis and ANOVA [OR (95% CI)]. **Results:** The most common CCS diagnoses were leukemia (32%), CNS tumor (26%), and neuroblastoma (18%). Patients received TBI (43%) and/or RT to craniospinal (43%), chest (13%), and neck regions (7%). About 48% (n = 152) of patients presented thyroid nodule(s) (Table). Forty-six patients underwent surgery, and 28 had TC, including 19 with ATA low-risk, 2 with ATA intermediate-risk, and 7 with ATA high-risk disease. Of the 9 patients with intermediate- or high-risk disease, 5 were ≤ 3 years, 3 were > 3 to ≤ 10 years, and 1 was > 10 years at the time of RT exposure. Eight patients with TC demonstrated pathogenic variant(s). RT exposure at ≤ 3 years old conferred 2-fold increased risk for nodule(s) compared to RT at > 10 years [OR = 2.14 (1.44-2.84) p = 0.03]. Female sex [OR = 1.73 (1.25-2.21) p = 0.02] and greater interval between RT and first US [OR = 1.10 (1.04-1.15) p = 0.001] were additional independent risk factors. **Conclusions:** Younger age at RT exposure is associated with increased risk of and shorter latency for developing TC. Thyroid US surveillance appears most beneficial in CCS exposed to RT ≤ 3 years old in an effort to diagnose TC at an earlier stage prior to metastasis. Research Sponsor: Children's Hospital of Philadelphia Frontier Program Grant for the Thyroid Center.

Improvements in life expectancy among childhood cancer survivors: Uneven gains and remaining challenges. *First Author: Jennifer M Yeh, Boston Children's Hospital and Harvard Medical School, Boston, MA*

Background: Childhood cancer survivors are at risk for shortened lifespan. Projections of life expectancy (LE) by diagnosis can provide benchmarks for assessing improvements over time. **Methods:** We developed a simulation model to project risk for common, life-threatening chronic health conditions (CHCs; heart failure, myocardial infarction, valvular disease, stroke, secondary breast cancer, colorectal cancer, glial tumors, sarcomas) and excess mortality among 5-year survivors, based on patient characteristics (sex, age at diagnosis, diagnosis) and treatment exposures (chemotherapy, radiation dose). Risk was estimated using statistical models and Childhood Cancer Survivor Study data. Age-related CHC risks (SEER, NHLBI) and competing mortality (CDC Wonder) were based on national databases. We used model calibration to identify parameter sets that generated outcomes consistent with observed data. Model outcomes included conditional LE and 10-year survival probability at age 40. For comparisons to the general population, we simulated age-, sex-, and diagnosis year-matched individuals who faced only competing mortality rates. **Results:** Among a cohort representative of the CCSS (mean diagnosis age, 7.4 yrs), compared to the general population, the gap in LE among survivors diagnosed in the 1970s vs. 1990s decreased from 17 yrs (25%) to 11 yrs (17%). Changes in LE among survivors diagnosed in the 1990s vs. 1970s varied by diagnosis, with leukemia, lymphoma, and CNS tumor survivors estimated to live an additional 8 to 11 yrs (Table). In contrast, considerably smaller gains were estimated for sarcoma and renal tumor survivors (1–3 yrs) and a loss for neuroblastoma (-3 yrs). Among survivors who reached age 40, the probability of surviving an additional 10 years increased from 89% to 92% between 1970s vs. 1990s, with the greatest gains for lymphoma and CNS tumors. **Conclusions:** Although temporal changes in pediatric oncology are projected to result in LE gains among survivors, considerable variation is projected across diagnoses. These findings highlight the uneven success of improving treatments for all cancers. Research Sponsor: American Cancer Society, U.S. National Institutes of Health.

The relationship between chronic health conditions and employment transitions among survivors of childhood cancer: A report from the Childhood Cancer Survivor Study (CCSS). *First Author: Neel S. Bhatt, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Chronic health conditions are prevalent among adult survivors of childhood cancer. The impact of health on maintaining full-time (FT) employment, a common indicator of socioeconomic independence, has not been studied in this population. **Methods:** Self-reported employment status (FT, part-time [PT], unemployed [any reason], not in labor force) was assessed at two timepoints (2002-04 [T1] and 2015-16 [T2]) in adult (≥25y old) survivors of childhood cancer diagnosed between 1970-86. Sex-stratified Poisson regression, adjusted for race and ages at diagnosis and T2, was used to study associations between timing and severity of chronic health conditions (graded per the CTCAE v4.03) and transitions from FT to PT or unemployed. **Results:** Survivors employed FT at T1 (males=1712, median age [min-max]: 34y [25-53]; females=1337, 33y [25-53]) who reported employment status at T2 were included. At T2 (median time from T1 11.5y [9.4-13.8]), 83% males and 70% females remained employed FT, but 4% and 10% transitioned to PT, and 11% and 12% to unemployed (additional 2% and 8% left the labor force), respectively. Male and female survivors with grade 2 or 3-4 neurologic conditions acquired before T1 or between T1-T2 were at a higher risk of moving from FT to PT or unemployed compared to those with grade 0-1 conditions. Males and females with grade 3-4 respiratory conditions prior to T1 and cardiac and musculoskeletal conditions acquired between T1-T2 were also at higher risk for moving to PT or unemployed (Table). Additional predictors for males included grade 2 vision (before T1 RR 2.3, 95% CI 1.5-3.3; between T1-T2 RR 1.7, 95% CI 1.1-2.7) and endocrine (before T1 RR 1.4, 95% CI 1.1-1.9; between T1-T2 RR 1.7, 95% CI 1.3-2.3) conditions. **Conclusions**: A substantial portion of adult survivors of childhood cancer with health conditions of varying severity leave FT employment. Increased awareness of all stakeholders may facilitate access to clinical counseling and occupational provisions for flexible and supportive work accommodations to reduce work-related barriers for childhood cancer survivors. Research Sponsor: U.S. National Institutes of Health.

Multivariable relative risks (95% CI) for transition from FT employment (at T1) to PT or unemployment (at T2) associated with chronic health conditions (*=not estimable).

Associations between global longitudinal strain (GLS), N-terminal-prohormone brain natriuretic peptide (NT-proBNP) and subsequent cardiomyopathy (CM) in a clinically assessed cohort of childhood cancer survivors exposed to cardiotoxic therapy. *First Author: Matthew J. Ehrhardt, St. Jude Children's Research Hospital, Memphis, TN*

Background: Among survivors exposed to anthracycline or chest radiation (RT) who have an ejection fraction (EF) of ≥50%, the utility of GLS and NT-proBNP to identify survivors who are at highest risk for future CM is unknown. **Methods:** Survivors participating in the St. Jude Lifetime Cohort, ≥5 years from cancer diagnosis and at risk for CM per the International Guideline Harmonization Group (IGHG), underwent baseline surveillance echocardiography. A baseline GLS and NT-proBNP was also performed for survivors with an EF ≥50%. Multivariable Cox regression models estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for risk of CM (graded per modified Common Terminology Criteria for Adverse Events v4.0) based on abnormal baseline GLS (≥ -18) and/or NT-proBNP (>age-sex-specific 97.5th percentiles) adjusted for age at baseline assessment, age at diagnosis, sex, race, hypertension, diabetes, obesity, and IGHG risk group (Table footnote). **Results:** Among 1598 at-risk survivors (median age 35.1, range 9.4-68.8 years), all had GLS and 1110 NT-proBNP at baseline. 165 (10.3%) developed CM ≥ grade 2 at a median follow-up of 5.2 (0.7-10.0) years. IGHG moderate- and high-risk survivors exposed to anthracyclines were at increased risk of CM at follow-up if both baseline GLS and NT-proBNP were abnormal (HR=3.4, 95% CI: 1.9-5.8; Table) or GLS was abnormal and NT-proBNP not assessed (HR=3.8, 95% CI: 2.0-7.2), or when GLS was normal and NT-proBNP was abnormal (HR=1.9, 95% CI: 1.1-3.4). Abnormal GLS and/or NT-proBNP were not associated with increased risk of CM in IGHG low-risk survivors or in those defined as moderate- to high-risk due to chest RT only. **Conclusions:** Among long-term survivors of childhood cancer exposed to >100 mg/m^2 anthracycline, abnormal GLS and NT-proBNP identified those survivors at increased risk of future CM despite an EF ≥50% on surveillance echocardiography. Conditional surveillance strategies utilizing GLS and NT-proBNP may benefit moderate- to high-risk survivors. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Long-term medical and functional outcomes of medulloblastoma survivors: A population-based, matched cohort study. *First Author: Hallie Coltin, Division of Haematology/Oncology, The Hospital for Sick Children, Toronto, ON, Canada*

Background: Most medulloblastoma survivors suffer from late treatment-related sequelae. There are no population-based studies examining such late effects in a dedicated cohort of medulloblastoma survivors. **Methods:** Using a provincial pediatric cancer registry, all 5+ year medulloblastoma survivors diagnosed between 1987-2015 at <18 years of age in Ontario, Canada were identified and matched to cancer-free population controls based on age, sex, and geographical location. Cases were followed from the index date (five years from latest of diagnosis, or relapse/subsequent malignancy prior to age 18 years) until December 31, 2020 or censorship (death, or relapse/new cancer after age 18 years). Clinical data were linked to administrative health databases to estimate the cumulative incidences and cause-specific hazard ratios (HR) of mortality, hospitalizations, strokes, hearing loss requiring a hearing aid, and receipt of homecare services between cohorts, accounting for matching and competing risks. We evaluated demographic, disease, and treatment predictors of mortality using Cox proportional hazards models. **Results:** Of 389 medulloblastoma diagnoses in the study period, 159 (40.9%) were excluded, most commonly due to early death prior to the index date. Two hundred thirty cases were matched to 1150 controls (Table). Ten-year survival probability after index was 92.4% in cases and 99.4% in controls (HR 21.5, 95% CI 9.8-54.0). Cases were at higher risk for hospitalizations (HR 3.4, 95% CI 2.7-4.3), stroke (HR 45.6, 95% CI 12.8-289.8), hearing loss (HR 96.3, 95% CI 39.7-317.3), and requiring homecare services (HR 7.9, 95% CI 5.8-10.9). By 10 years after index, 4.8% (95% CI 2.2-9.0) of survivors had experienced a stroke compared to 0.1% (95% CI 0.01-0.7) of controls. None of the candidate predictors were significantly associated with mortality on univariate analyses. **Conclusions:** Survivors of childhood medulloblastoma experienced an increased risk of mortality and serious morbidity compared to population controls. Consideration for mitigation strategies or early interventions for preventing neurovascular sequelae and hearing loss is warranted, as is dedicated supports for survivors. Research Sponsor: Garron Family Cancer Centre.

Characteristics of cases and controls.

Long-term medical and functional outcomes of ependymoma survivors: A population-based, matched cohort study. *First Author: Hallie Coltin, Division of Haematology/Oncology, The Hospital for Sick Children, Toronto, ON, Canada*

Background: Ependymoma is the third most common pediatric central nervous system tumour. Treatment approaches are intensive and may include surgery, radiation, and chemotherapy. There are no longitudinal population-based cohort studies evaluating the long-term medical and functional outcomes of survivors of childhood ependymoma. **Methods:** Using a provincial pediatric cancer registry, all 5+ year ependymoma survivors diagnosed between 1987-2015 in Ontario, Canada were identified and matched to cancer-free population controls based on age, sex, and geographical location. Cases were followed from the index date (5 years from latest of diagnosis, or relapse/subsequent malignancy prior to age 18 years) until December 31, 2020 or censorship (death, or relapse/ new cancer after age 18 years). Clinical data were linked to administrative health databases to estimate the cumulative incidences and cause-specific hazard ratios (HR) of mortality, hospitalizations, strokes, hearing loss requiring a hearing aid, receipt of homecare services, and subsequent malignant neoplasms (SMNs) between cohorts, accounting for matching and competing risks. **Results:** Of 166 ependymoma diagnoses in the study period, 70 (42.2%) were excluded, most commonly due to early death prior to the index date. Ninety-six cases were matched to 480 controls (Table). The 10-year survival probability after the index date was 92.8% in cases and 99.6% in controls (HR 9.3, 95% CI 2.3-45.2, p=0.002). Compared to controls, cases were at higher risk of hospitalization (HR 3.2, 95% CI 2.2-4.6, p<0.0001), stroke (HR 33.3, 95% CI 5.7-629.1, p<0.0001), and receiving homecare services (HR 4.1, 95% CI 2.5-6.5, p<0.0001). Cases were at high risk of hospitalizations, strokes, hearing loss, and SMNs, with cumulative incidences of 64.7% (95% CI 46.6-78.0), 9.7% (95% CI 3.4-19.9), 13.5% (95% CI 5.3-25.5), and 12.8% (95% CI 4.7-24.9) at 20-years post index date, respectively. **Conclusions:** As survival of pediatric ependymoma improves, establishing the burden of late morbidity is critical. Dedicated screening programs for late sensory and neurovascular sequelae are warranted, as are interventions during and following treatment to mitigate the risk of developing such complications. Research Sponsor: Garron Family Cancer Centre.

Protein, fat, and animal food intakes and premature aging in adult survivors of childhood cancer: St. Jude Lifetime (SJLIFE) cohort. *First Author: Yikyung Park, Washington University School of Medicine, St. Louis, MO*

Background: Childhood cancer survivors are a growing population who appear to be at higher risk for premature aging and age-related chronic health conditions than their peers with no history of cancer. Diet affects many hallmarks of aging, such as inflammation, metabolic dysfunctions, and molecular and epigenetic changes, leading to impairment in physical and cognitive functions and premature death. High consumption of animal foods that are high in protein and fat increase risk for many age-related chronic diseases. However, some studies found protein intake was beneficial for physical frailty in elderly and cancer survivors. **Methods:** Adult survivors (> = 18 years old) of childhood cancer survivors enrolled in the SJLIFE Cohort between 2007 and 2017 completed a 110-item food frequency questionnaire at study entry (n = 3,322). Survivors' sociodemographic, cancer, cancer treatments, and medical history data were abstracted from medical records. Health conditions self-reported after cancer diagnosis were clinically validated. Premature aging was assessed using the Deficit Accumulation Index (DAI) based on 45 aging-related health conditions. DAI is categorized into low (< 0.2), medium (0.2-0.34) and high (> 0.35) aging risk groups. Odds ratios (OR) and 95% confidence intervals (CI) were estimated using multinomial logistic regressions adjusting for potential confounders. **Results:** The average age of survivors at baseline was 31 years. Approximately half of the survivors were women, and 82% were white, non-Hispanic. 20% and 8% of survivors were at medium and high risk for aging, respectively. Survivors at high risk for aging tended to be female, smokers, have low socioeconomic status, and received radiation therapy to head and neck, chest, spine or abdomen compared to those at low aging risk. Higher protein intake was associated with a less risk of premature aging (OR = 0.74, 95% CI: 0.58-0.95 for high aging risk group; OR = 0.91, 95% CI: 0.78-1.07 for medium aging risk group, per increment of 5% of total energy intake). On the other hand, higher fat intake was related to an increased risk of premature aging (OR = 1.14, 95% CI: 1.01-1.29 for high aging risk group; OR = 0.99, 95% CI: 0.91-1.08 for medium aging risk group, per increment of 5% of total energy intake). However, substituting monounsaturated fat for other types of fat was associated with a lower risk of premature aging (OR = 0.81 95% CI: 0.70-0.95 for high aging risk group). Red meat (OR = 1.11, 95% CI: 0.87-1.42 for high aging risk group) and dairy intake (OR = 0.99, 95% CI: 0.72-1.38 for high aging risk group) was not related to risk of premature aging. **Conclusions:** Consuming protein and fat from healthy foods may lower the risk of premature aging in childhood cancer survivors. Research Sponsor: St. Jude Children's Research Hospital-Washington University St. Louis Implementation Sciences Collaborative.

Treatment exposure-based risk-stratification for care of survivors of childhood cancer: A report from the Childhood Cancer Survivor Study. *First Author: Michaela Ann Dinan, Yale Cancer Center, New Haven, CT*

Background: Treatment exposure-based risk-stratification oflong-term cancer survivors is needed to allocate tailored health care in survivorship clinics. Investigators from the United Kingdom (UK) developed a treatment exposure-based algorithm that stratifies survivors into low, medium, and high risk groups. Because this algorithm has not been validated, we sought to use the large, diverse population of the Childhood Cancer Survivor Study (CCSS) to validate risk for poor outcomes. **Methods:** Five-year survivors of childhood cancer (diagnosed between 1970-1999 at < 21 years of age) were categorized into low, medium, and high risk groups based on treatment exposures and diagnoses (Table). Primary endpoints included cumulative health-related (i.e., non-recurrence, non-external) late mortality and cumulative incidence of grade 3-5 chronic conditions (CTCAEv4.03) conditional on reaching age 20 without the outcome. Siblings were a comparison group for chronic conditions. Cox proportional hazards models among survivors estimated hazard ratios (HRs) and 95% confidence intervals (CI) adjusted for sex and race. **Results:** A total of 21,504 survivors were analyzed with a median follow-up of 22 years. Application of the risk stratification algorithm resulted in 3,152 low risk, 6,443 medium risk, and 11,909 high risk survivors. Among those who survived to age 20 without any grade 3-5 conditions, the risk of developing one by age 35 was 12.2% (95% CI 1.0-14.7%), 14.2% (12.8-15.7%) and 25.4% (24.2-26.6%) for low, medium, and high-risk patients, respectively, and 6.9% (6.1-7.9%) for siblings. HRs of grade 3-5 conditions for medium (HR 1.8, 95% CI 1.6-2.1) and high (HR 3.9, 95% CI 3.5-4.4) risk relative to low risk survivors, respectively, were elevated. Cumulative health-related mortality was similarly associated with risk categories; conditional on being alive at age 20, survivors within low, medium, and high risk groups had cumulative incidences of 2.3% (95% CI 1.7-3.1%), 3.3% (2.8-3.9%) and 6.1% (5.6-6.6%), respectively, by age 35. **Conclusions:** Risk categorizations based on treatment exposures were effective at providing generalized risk stratification within the CCSS with respect to risk of grade 3-5 conditions and health related mortality, particularly for identifying high risk survivors. These risk groups may be useful to physicians in determining follow-up intervals and guiding management and long-term surveillance of these survivors. Research Sponsor: U.S. National Institutes of Health.

Risk Stratum	Diagnosis	Treatments
Low	ALL	Chemo only with DED < 100 mg/m^2
	Wilms Tumor	No RT & DED = 0
	Non-CNS tumors	Surgery Only
Medium	Anyone not in Low or High Risk	
	CNS	No RT
High	Any	Auto or Allo Transplant
		Cranial RT > 24Gy; direct RT to neck, chest, abdomen, or pelvis
		CED > = 10 g/m^2; Cisplatin > 400 mg/m^2, DED > 250

RT = Radiation Therapy; DED = Doxorubicin Equivalent Dose; CED = Cyclophosphamide Equivalent Dose.

The impact of clinical trial enrollment on specialty palliative care utilization in pediatric patients with high-grade gliomas. *First Author: Holly Roberts, University of Michigan Medical School, Ann Arbor, MI*

Background: In pediatric oncology patients, palliative care has been shown to provide numerous benefits, including less intense clinical care in the last month of life, improved symptom management, and dedicated family communication. Pediatric patients with high grade glioma (HGG) represent a patient population particularly well suited for early involvement of palliative care given their high symptom burden and relatively poor prognosis. However, a recent study revealed that pediatric patients with primary malignant central nervous system (CNS) tumors missed multiple opportunities for appropriate palliative care involvement throughout their disease courses. We hypothesize that clinical trial enrollment may lead to a lack of or delay in involvement of palliative care in children and young adults with HGG. **Methods:** We identified a cohort of 43 deceased pediatric patients with HGG who received care at our institution. IRB exemption was obtained. For each patient, the electronic medical record was reviewed to collect patient demographics, cancer diagnoses and outcomes, clinical trial enrollment, non-clinical trial treatments, and palliative care involvement. Statistical analysis was performed comparing patients enrolled in trials to those not enrolled, employing Fisher's exact tests for categorical data and t tests for numerical data. **Results:** Overall, 72% (31/43) of patients had at least one visit with a specialty palliative care provider. 56% (24/43) of patients enrolled in a clinical trial with HGG-directed therapy. 71% (17/24) of patients who enrolled in a clinical trial received specialty palliative care compared to 74% (14/19) of non-trial participants ($p = 1.000$). Similarly, among patients who received palliative care there was no statistically significant difference in the timing of palliative care involvement, measured from the date of first palliative care contact to date of death, for patients who enrolled in a clinical trial (mean = 177 days) compared to those who did not (mean = 113 days, $p = 0.180$). Of the 24 patients enrolled in clinical trials, only 7 (29%) had palliative care involvement prior to initiation of study treatment. **Conclusions:** As our understanding of the genomic landscape of pediatric brain tumors increases, it can be expected that patients electing to enroll in targeted therapy clinical trials will also increase. As such, it is reassuring that our data suggest that trial participation does not interfere with the receipt of specialty palliative care in children with HGG. While not statistically significant, initial palliative care involvement trends toward occurring in closer proximity to death in the patients who are not enrolled on a clinical trial. Overall, it is encouraging that in our pediatric HGG patient cohort, enrollment in clinical trials does not appear to have an adverse impact on specialty palliative care involvement. Erdafitinib in pediatric patients with advanced solid tumors with fibroblast growth factor receptor (*FGFR*) gene alterations: RAGNAR study pediatric cohort. *First Author: Olaf Witt, Hopp Children's Cancer Center (KiTZ), University Hospital of Heidelberg and German Cancer Research Center, Heidelberg, Germany*

Background: *FGFR* gene alterations have been observed in pediatric patients with cancers and represent potentially targetable genomic variants. Gliomas (high- and low-grade) and soft tissue sarcomas are among the pediatric solid tumors that may harbor *FGFR* alterations. Erdafitinib is a selective pan-FGFR inhibitor approved in patients with locally advanced or metastatic urothelial carcinoma with susceptible *FGFR2/3* alterations. RAGNAR (NCT04083976) is an ongoing single-arm, open-label, phase 2 histology-agnostic study investigating the efficacy and safety of erdafitinib in patients with advanced solid tumors exhibiting *FGFR* alterations after failure of standard systemic therapies. Here we describe the pediatric study cohort. **Methods:** The pediatric cohort (n = 26, planned) includes patients (≥ 6- < 18 y) with advanced solid tumors (measurable disease per RECIST v.1.1 or RANO [brain tumors]) with *FGFR* mutations, gene fusions, or internal tandem duplication (patients with *FGFR* amplification are not eligible) identified via local test reports or central molecular testing. Eligible patients will have received ≥ 1 lines of prior systemic therapy, have exhausted or be unable to tolerate standard-of-care therapies, and have documented disease progression and measurable disease. In addition, up to 6 patients in this cohort will be allowed to be treatment naive. Children and adolescents will be treated with oral erdafitinib, allowing pharmacodynamically guided uptitration based on serum phosphate levels to maximize efficacy. Treatment will continue until progressive disease. The primary end point is overall response rate (ORR) assessed by an independent review committee. Secondary efficacy end points include ORR assessed by the investigator, duration of response, disease control rate, clinical benefit rate, progression-free survival, and overall survival. Other secondary end points are pharmacokinetic exposure parameters, incidence/severity of adverse events, and change from baseline in patient-reported health status. End-of-treatment visit will occur 30 days after the last dose of erdafitinib. A follow-up phase will continue until death, withdrawal of consent, loss to follow-up, or end of study. As of January 2022, 3 patients have been enrolled. Clinical trial information: NCT04083976. Research Sponsor: Janssen Research & Development.

TPS10059 **Poster Session**

Trial in progress: A phase I trial of dual EZH 1/2 inhibitor valemetostat tosylate (DS-3201b) in pediatric, adolescent, and young adult patients with malignant solid tumors. *First Author: Ayumu Arakawa, Department of Pediatric Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: Enhancer of zeste homolog enzymes (EZH1 and EZH2) form parts of the polycomb repressive complex 2 and regulate gene expression by catalyzing the tri-methylation of lysine 27 residue of histone H3. SMARCB1/INI1 is one of the core components of the SWI/SNF chromatin remodeling complex, with the loss of SMARCB1/INI1 causing the oncogenic activation of EZH2 and EZH1. The inhibition of EZH2 or both EZH2 and EZH1 can be effective against various hematological malignancies and SMARCB1/INI1-deficient solid tumors. Valemetostat tosylate (DS-3201b; valemetostat) is a potential first-in-class dual inhibitor of EZH1 and EZH2 that targets epigenetic regulations by inhibiting both EZH1 and EZH2 enzymes. A phase 2 single-arm study showed that valemetostat demonstrated promising response rates in Japanese patients with relapsed or refractory adult T-cell leukemia/lymphoma (Yoshimitsu M et al., presented at ASH Annual Meeting, 2021). Tumors characterized by SMARCB1/INI1 deficiency (a SWI/SNF mutation), such as malignant rhabdoid tumors, epithelioid sarcoma, or synovial sarcoma are quite frequently observed during childhood and adolescence, among whom valemetostat is expected to show antitumor effects. **Methods:** This open-label multi-center phase I trial evaluates the safety and efficacy of valemetostat in pediatric, adolescent, and young adult patients with refractory/relapsed solid tumors. The inclusion criteria are relapsed, refractory, or progressive metastatic disease; >3 and <19 years of age during the dose escalation cohort and < 29 years of age in the expanded cohort; performance status of >50 (assessed by Karnofsky Performance score in patients >16 years old, and Lansky Performance score in patients <15 years old); and adequate organ function. Valemetostat is administered orally once a day without interruption. Three dose levels (150, 200, and 250 mg/1.7 m^2) are assessed using a 3+3 design during the dose escalation cohort. After determining the recommended phase 2 dose (RP2D) during dose escalation cohort, up to 30 patients will be further enrolled, and the safety and efficacy data of valemetostat are determined in the expanded cohort. The primary endpoint is the incidence of dose limiting toxicity, whereas the secondary endpoints include safety, pharmacokinetics, overall response rate, progression-free survival. The overall response rate of the tumors with SMARCB1/INI1 deficiency or SWI/SNF mutation is also evaluated as a secondary endpoint. Exploratory endpoint includes overall survival. Enrollment into this trial began in March 2020, and enrollment into the dose escalation cohort was completed. Enrollment into the expanded cohort began in November 2021. Clinical Trial Information: jRCT2031190268. Research Sponsor: Japan Agency for Medical Research and Dvelopment.

TPS10060 **Poster Session**

CaboMain: A phase 2 study of cabozantinib as a maintenance agent in patients with ultra-high risk pediatric solid tumors. *First Author: Nilay Shah, Nationwide Children's Hospital, Columbus, OH*

Background: Patients with relapsed or refractory pediatric solid tumors have one-year progression-free survival (PFS) <25% even if a remission is achieved [1-9]. Maintenance treatments may extend survival for these patients but have not been tested. Many tyrosine kinase inhibitors (TKIs) target oncogenic pathways active in pediatric cancers and are being evaluated in children with cancer. The multitargeted TKI cabozantinib inhibits MET, VEGFR, AXL, RET, ROS1, KIT, TRKB, FLT3, and TIE2. Preclinical studies and clinical use suggest that cabozantinib may be active against childhood cancers [10-20]. A pediatric Phase 1 study defined a dose of 40 mg/m^2/day[21], currently used in an ongoing pediatric Phase 2 study for measurable relapsed/refractory solid tumors, NCT02867592 . However, cabozantinib has not been tested as a maintenance agent against cancers in children. We hypothesize that cabozantinib, in patients with ultra-high-risk pediatric solid tumors with minimal disease burden, can prevent recurrent tumor formation or induce a durable remission. **Methods:** Trial Design: Single arm, open-label, multisite investigator-initiated Phase 2 trial for patients with a "best response," defined as no progression at least 28 days after end of prior therapy. Primary objective: Evaluate the effect of cabozantinib administered for up to 12 months on 1-year PFS. Statistical design and measure: Bayesian time-to-event optimal phase 2 design with a single interim analysis designed to detect 20% increase in PFS at 1 year with 80% power. Secondary objectives include 2- and 5-year PFS; 1-, 2-, and 5- year OS, duration of response, and safety and tolerability. Exploratory objectives include patient-reported outcomes, predictive biomarkers, PK and PD measurements. Treatment: Patients will take cabozantinib tablets on a continuous dosing schedule, partitioned into 28-day cycles, at an initial dose of 40 mg/m2/day (per dosing nomogram), for up to 365 days. Assessments are defined; radiographic assessment every 3 cycles. Dose modifications will be based on toxicities per protocol. Patients will continue on therapy until progression, toxicities not relieved by dose reduction, or end of planned therapy. Major eligibility criteria: Three strata: Neuroblastoma with residual disease at end of upfront therapy ("Best Response 1", BR1) or after any relapse, n=36. Pediatric CNS tumors, defined in the protocol, n=30. Other pediatric solid tumors, as defined in the protocol, n=36. Patients must be ≥ 18 months and ≤40 years of age at enrollment, have completed prior therapy ≥ 4 weeks and ≤ 12 weeks prior to enrollment and demonstrate radiographic BR at time of enrollment. Measurable or evaluable disease is not required. Enrollment: Protocol is open to enrollment as of February 12, 2022. At time of abstract submission, we have not yet enrolled the first patient. Clinical trial information: NCT05135975. Research Sponsor: Exelixis.

TPS10061 **Poster Session**

Naxitamab and granulocyte macrophage colony stimulating factor (GM-CSF) in combination with irinotecan and temozolomide in patients with high-risk neuroblastoma with primary refractory disease or in first relapse: An international, single-arm, multicenter phase 2 trial. *First Author: Godfrey Chi-Fung Chan, Hong Kong Children's Hospital, The University of Hong Kong, Hong Kong, Hong Kong*

Background: Neuroblastoma (NB) is the commonest extracranial solid tumor in children. At diagnosis, > 50% have high-risk (HR) disease with poor prognosis despite intensive therapy; thus, there is a high unmet medical need. Naxitamab is an anti-GD2 monoclonal antibody indicated under accelerated approval in the US with GM-CSF for the treatment of relapsed/refractory HR NB in the bone and/or bone marrow in patients (pts) ≥1 year of age with a partial response, minor response, or stable disease to prior therapy. Irinotecan and temozolomide (IT) are commonly used salvage chemotherapies following failure of frontline therapy. The objective of this study is to investigate the efficacy and safety of naxitamab plus IT in pts with HR NB with primary refractory disease or first relapse. **Methods:** Trial 203 (NCT04560166) is an international, single-arm, multicenter phase 2 trial for HR NB patients ≥12 mo of age, with either evaluable primary refractory disease or first relapse following induction and consolidation therapy. The primary endpoint of the study is the centrally-assessed overall response rate (ORR) (complete [CR] or partial response) at or before completion of 4 cycles of treatment. Key secondary endpoints include ORR after 2 cycles of treatment, duration of response (DoR), CR rate, time to first subsequent therapy or death, progression-free survival (PFS), and overall survival (OS). 52 pts will be enrolled to provide 82% power to demonstrate that response rate is significantly higher than 20%. Key inclusion criteria are documented HR NB at time of diagnosis; received frontline induction/consolidation therapy; active disease despite previous aggressive chemotherapy; and measurable tumor (CT/MRI) that is either MIBG-avid/PET-positive or have MIBG scan with uptake at ≥1 site. Key exclusion criteria include prior treatment with duration ≤3 wks (chemotherapy), ≤6wks (autologous stem cell transplant or therapeutic ^{131}I-MIBG), ≤4wks (radiation therapy), or progressed while on anti-GD2; residual NB in the bone marrow only; and CNS/leptomeningeal disease in the prior 6 mo. In addition, there should not be < 50% performance status per Lansky or Karnosky scale and life expectancy < 6 mo. Pts will receive irinotecan 50 mg/m^2/day IV and temozolomide 100 mg/m^2/day orally (both on Days 1-5) in combination with naxitamab 2.25 mg/kg/day IV (Days 2, 4, 8 and 10) and GM-CSF 250 ug/m2/day sc (Days 6-10) in 21 days cycle. Response rates will be assessed using the 2-sided binomial test at the 5% significance level; DoR, PFS, and OS will be estimated using Kaplan-Meier analysis. Adverse events will be graded per CTCAE. Clinical trial information: NCT04560166. Research Sponsor: Y-mAbs Therapeutics.

TPS10062 **Poster Session**

FIREFLY-1 (PNOC 026): A phase 2 study to evaluate the safety and efficacy of tovorafenib (DAY101) in pediatric patients with *RAF*-altered recurrent or progressive low-grade glioma or advanced solid tumors. *First Author: Daniel Landi, Department of Neurosurgery, Duke University, Durham, NC*

Background: *RAF* gene fusions (*BRAF* and *RAF1*) and BRAF V600E mutations are oncogenic drivers found on a mutually exclusive basis in most pediatric low-grade gliomas (LGGs). In addition, *RAF* fusions (*BRAF* and *RAF1*) have also been identified in other pediatric solid tumors. Tovorafenib (DAY101) is an investigational, oral, highly selective, CNS-penetrant, small molecule, type II pan-RAF inhibitor. In contrast to type I BRAF inhibitors, tovorafenib does not induce RAS-dependent paradoxical activation of the MAPK pathway. In the phase 1 PNOC014 study in pediatric patients with recurrent/progressive LGG, tovorafenib was well tolerated and 7/8 patients with tumor harboring *RAF* fusions had meaningful clinical benefit. Recently, a child with a novel *SNX8-BRAF* fusion spindle cell sarcoma demonstrated a rapid and deep response when treated with tovorafenib. **Methods:** FIREFLY-1 (NCT04775485) is an open-label, multicenter, phase 2 study evaluating the safety and efficacy of tovorafenib monotherapy in pediatric patients with *RAF*-altered recurrent or progressive LGG or advanced solid tumors. The initial design included only patients with LGG (arm 1). Two new arms have now been added; arm 2 will allow tovorafenib treatment for patients with LGG harboring an activating *RAF* alteration after completion of enrollment to arm 1 and prior to tovorafenib regulatory approval; arm 3 will enroll patients with advanced solid tumors harboring an activating *RAF* fusion. Eligible patients are 6 months to 25 years of age, who have received ≥1 prior line of systemic therapy with documented radiographic progression, have evaluable and/or measurable disease by appropriate criteria, a Karnofsky or Lansky performance score of at least 50, and adequate organ function. Patients are excluded if their tumor has other driver mutations, they have neurofibromatosis type 1, central serous retinopathy, retinal vein occlusion, clinically significant active cardiovascular disease, or are currently being treated with a strong CYP2C8 inhibitor or inducer other than those allowed per protocol. Approximately 140 patients in total will be enrolled including 60 in arm 1, 60 in arm 2 and 20 in arm 3. Tovorafenib will be administered at 420 mg/m^2 (not to exceed 600 mg) weekly (days 1, 8, 15 and 22) for 26, 28-day cycles (in the absence of disease progression or unacceptable toxicity). They may then continue tovorafenib or enter a drug holiday period. The primary endpoint is overall response rate, as defined by the RANO criteria (arm 1) or RECIST v1.1 (arm 3) and as determined by an independent radiology review committee. Secondary endpoints (arms 1 and 3) include safety and tolerability, pharmacokinetics, duration of response, time to response and progression-free survival. Tovorafenib is available in tablet or liquid suspension formulations. Clinical trial information: NCT04775485. Research Sponsor: Day One Biopharmaceuticals.

TPS10063 **Poster Session**

A pilot clinical study of VAL-413 (oral irinotecan HCl) in patients with recurrent pediatric solid tumors. *First Author: Dennis Brown, Edison Oncology Holding Corp., Menlo Park, CA*

Background: Intravenous irinotecan hydrochloride (IRN-IV) is approved for the treatment of adult colorectal cancer. IRN-IV is also widely used off-label for a range of adult and pediatric solid tumors including recurrent Ewing sarcoma, rhabdomyosarcoma, neuroblastoma, hepatoblastoma, Wilms tumor, gynecologic cancers, lung cancer and medulloblastoma. Previously, a regimen of IRN-IV administered as a 60-min i.v. infusion daily for 5 days, every 21 days has been recommended use in treating children with solid tumors *(*Blaney. *ClinCanRes,* 2001*).* Protracted administration schedule of intravenous irinotecan is inconvenient for patients, so oral regimens utilizing IRN-IV have been developed *(*Wagner. *ClinSarcRes,* 2015*).* Unfortunately, the palatability of the intravenous preparation is poor, leading to reduced compliance especially in younger pediatric patients. Development of an advanced formulation to improve tolerability and patient compliance is an important unmet clinical need. VAL-413 is a novel formulation developed to improve palatability of oral irinotecan. **Methods:** Eligibility: Up to 20 patients ≥ 1 year and ≤ 30 years of age with recurrent pediatric solid tumors and adequate bone marrow, renal and liver function, for whom irinotecan therapy is a treatment option will be enrolled. Trial Design: Two different dose levels of VAL-413, 90mg/m2/day or 100mg/m2/day will be studied in combination with a fixed-dose of temozolomide using a standard 3 + 3 phase I design. In the event that the starting dose of 90 mg/m2/day is not tolerable due to toxicity, a lower dose of 75 mg/m2/day may be implemented. Treatment: During the first cycle of treatment, each patient will receive 4 daily doses of VAL-413 and one daily dose of the intravenous preparation of irinotecan taken orally (IRN-IVPO). During all subsequent cycles, only VAL-413 will be given with temozolomide in 5-day courses administered every 21 days, as tolerated. Outcome Measures: Toxicity is assessed by NCI CCTCAEv5; tumor response is assessed by RECIST 1.1. A palatability survey instrument will assess palatability of VAL-413 vs. IRN-IVPO; and comparative intrapatient pharmacokinetics of irinotecan and its metabolites will be assessed in all patients. This trial is ongoing (CT.gov: NCT04337177). Enrolment of the first dose level is ongoing, with no DLT observed to date. Clinical trial information: NCT04337177. Research Sponsor: Edison Oncology Holding Corp.

10500 **Oral Abstract Session**

Democratizing germline genetic testing and its impact on prostate cancer clinical decision-making. *First Author: Neal D. Shore, Carolina Urologic Research Center, Myrtle Beach, SC*

Background: Approximately 10-15% of prostate cancer (PCa) patients (pts) have a pathogenic germline variant (PGV). Identification of a PGV has important implications affecting decisions regarding cancer screening, treatment selection, and family cascade testing. There exists limited data documenting real world recommendations post germline genetic testing (GGT). This study was designed to collect clinician reported outcomes from PCa pts who underwent GGT. **Methods:** An IRB-approved, nationwide, prospective registry recruited unselected PCa pts from 15 community and academic urology practices. Pts underwent an 84-gene panel test, with clinical outcomes collected via clinician-completed case report forms > 1-month post GGT. Statistical significance was determined by two-tailed Fisher's exact test. **Results:** 982 predominantly white (75.9%), non-metastatic (80.7%) males with PCa were recruited; 56.9% met National Comprehensive Cancer Network (NCCN) GGT criteria. Average age was 65.3 years at PCa diagnosis. PGVs, most commonly *CHEK2* (17) and *BRCA2* (10), were identified in 100 (10.2%) pts; 34 (34%) of these did not meet NCCN GGT criteria. Among PGV positive pts, 241 recommendations were made (Table). They were more likely to have changes to treatment ($p < 0.0001$), follow up ($p < 0.0001$) and cascade testing recommendations ($p < 0.0001$) than those with negative/variant of uncertain significance (VUS) results. There were no significant differences in changes to treatment ($p = 0.4471$) or follow up ($p = 0.861$) for pts who met NCCN criteria versus those who did not. 7 pts with PGVs received targeted therapy or were referred to a clinical trial. 5 pts with VUS results were also referred to a clinical trial. Among these 12 pts, 6 (50%, 2 *CHEK2* PGV, 1 *ATM* PGV, 1 VUS each *ATM*, *BLM*, *CHEK2*) did not meet NCCN GGT criteria. Referral to a genetic counselor was the most common follow up recommendation for those with PGV (38 patients, 38%) and VUS results (66, 13.7%). The most commonly reported impact to health outcomes for those with negative results was knowledge/reassurance (38, 7.88%). **Conclusions:** This study showed that GGT did influence PCa pts care. Appropriately, pts with PGVs received a greater number of recommendations for relatives, changes to follow up and treatment. Research Sponsor: Invitae.

10501 **Oral Abstract Session**

Rates of germline genetic testing and DNA damage response mutations found through population-based recruitment of men with incident metastatic prostate cancer. *First Author: Hiba Khan, University of Washington, Seattle, WA*

Background: Approximately 10% of men with metastatic prostate cancer (mPC) have germline DNA damage response gene mutations (gDDRm), indicating candidacy for precision treatment. Consequently, national guidelines recommend germline genetic testing be offered to all men with mPC. It is currently unclear what the rates of testing are in the community, and barriers to testing are not well understood. We conducted a population-based study to better understand current rates of germline genetic testing in men with newly diagnosed mPC, and to determine whether removing major barriers of cost and access could expand uptake of germline genetic testing. **Methods:** This is a prospective observational study that identifies men ages 35-79y with mPC residing in a 13-county area of Washington State through the Surveillance, Epidemiology, and End Results (SEER) program (NCT04254133). Men with new diagnoses of mPC are contacted by mailed invitation and follow-up phone inquiry. Interested men are then invited to provide informed consent and complete a questionnaire about personal and family health history. A saliva collection kit for a 30-gene targeted panel of cancer predisposition genes (Color Genomics) is mailed to participants' homes free of charge. Results are issued by phone and/or email with genetic counseling support, including discussion about cascade genetic testing if relevant. **Results:** As of Feb 9, 2022, 484 men with incident mPC diagnosed 1/2018-6/2021 were identified through SEER. 430 men were reached via a letter to their home address sent > 3 months after diagnosis. 175 of 430 (40.6%) men expressed interest and completed the questionnaire, the majority preferring to complete testing through mail after a phone-initiated introduction to the study. 164 of 175 men completed the consent process and were eligible. Of these 164 men, 45 (27.4%) reported prior genetic testing, and reports were requested and reviewed to ensure adequate testing. Ultimately, 121 of 164 (73.8%) participants initiated and 101/121 (83.5%) have completed genetic testing through the study. Nine percent (9/101) of participants completing testing as part of the study were found to have gDDRm. **Conclusions:** We used a population-based approach to understand the proportion of men with mPC undergoing germline genetic testing through clinical care, and the subsequent uptake of genetic testing when access and cost barriers are removed. The uptake of guideline-based germline genetic testing among men with mPC in the community prior to study enrollment is only 27.4%. With study interventions in the form of free testing through mail, and phone-based support, 83.5% of men in this community successfully completed testing. Further work in this study will aim to elucidate and attempt to eliminate other barriers in germline genetic testing to further improve testing rates in this community. Research Sponsor: U.S. National Institutes of Health.

10502 **Oral Abstract Session**

Mutation spectrum and rates of variants of uncertain significance among African American males undergoing prostate cancer germline testing: Need for equity in genetic testing. *First Author: Veda N. Giri, Departments of Medical Oncology, Cancer Biology, and Urology, Cancer Risk Assessment and Clinical Cancer Genetics Program, Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA*

Background: Germline testing (GT) for prostate cancer (PCA) is central to metastatic disease management, PCA screening strategies, and hereditary cancer assessment. African American (AA) males have a higher burden of PCA, yet have lower engagement in germline testing which limits understanding of genetic contribution to PCA. Here we evaluated the germline spectrum of AA and White males with PCA undergoing clinical multigene panel testing (MGPT) to inform germline testing strategies with attention to equity. **Methods:** Study participants included AA men and White men with PCA who underwent a 14-gene MGPT between April 2012 - December 2020 at a clinical diagnostic laboratory (Ambry Genetics). Exclusions were men with known pathogenic variants reported in their families or who had prior genetic testing. MGPT included: *ATM, BRCA1, BRCA2, CHEK2, EPCAM, HOXB13, MLH1, MSH2, MSH6, NBN, PALB2, PMS2, RAD51D, TP53.* Sanger or next generation sequencing analysis was performed per standard clinical testing protocol. Variant classification was per ACMG 5-tier system. Descriptive statistics summarized results with counts and percentages for categorical variables and mean and standard deviation for continuous variables. Data were compared with Fisher's exact, Chi-squared, two proportion z-test, or two sample t-test, as appropriate. Significance level was set a priori at 0.05. **Results:** The dataset included genetic and clinical data from 427 males who had undergone MGPT: White males (n = 190; 45.5%) and AA males (n = 237; 55.5%). Mean age at diagnosis was 59 + 9.3 years. Among men whose Gleason score was indicated (72%), 47% had Gleason > = 8. Majority of men indicated having a $1^{st}/2^{nd}$ degree relative with PCA (68.97%) or $1^{st}/2^{nd}$ degree relative with any cancer (99.2%). In the entire cohort, 8.2% tested positive for a pathogenic/likely pathogenic variant; AA males (n = 14, 5.91%) and White males (n = 21, 11.05%). VUS only was reported in 21.31% of the overall cohort with a significant difference noted between AA and White males (25.32% vs. 16.32%, respectively; $p = 0.0238$). Mutation spectrum in AA males included: *BRCA2* (n = 7), *PALB2 (n = 3), ATM* (n = 3), and *BRCA1* (n = 1). Among White males, a wider spectrum of mutations was observed: *BRCA2* (n = 6), *ATM* (n = 5), *HOXB13* (n = 5), *CHEK2* (n = 2), *TP53* (n = 1), and *NBN* (n = 2). The proportion of AA males with multiple VUS was significantly higher than for Caucasian males (5.1% vs. 0.53%, $p = 0.003$). **Conclusions:** Clinical germline testing among AA males reveals a narrow spectrum of mutations in key DNA repair genes, with important implications for precision therapy and hereditary cancer assessment. Furthermore, AA males had significantly higher rates of multiple VUS, indicating critical need for greater inclusion of diverse populations in genetic studies to discern the pathogenic spectrum contributing to PCA aggressiveness and risk. Research Sponsor: None.

10503 **Oral Abstract Session**

Implementing systematized patient-facing Lynch syndrome (LS) risk assessment in oncology using the electronic health record (EHR) system. *First Author: Chinedu Ukaegbu, Dana Farber Cancer Institute, Boston, MA*

Background: Lynch syndrome (LS) is the most common inherited cause of colorectal (CRC) and endometrial cancers. Significant provider and institutional level barriers limit LS detection, even in oncology patients with LS-associated cancers. PREMM5 is a validated tool based on personal and family cancer history that is recommended by national professional societies for LS risk assessment. This project's goal was to study the feasibility of patient-facing LS risk assessment using a PREMM5 screener embedded in an electronic health record (EHR) system, as a means of improving LS identification. **Methods:** The PREMM5 LS screener intake questions were adapted to be completed by patients rather than healthcare providers. Screener adaptation and implementation involved iterative review by multidisciplinary experts and multilevel stakeholder engagement. The patient-facing PREMM5 LS screener was embedded in the EHR (Epic) at the Dana-Farber Cancer Institute (DFCI) to enable remote (via the EHR patient portal) and on-site completion (in clinic waiting rooms). All new gastrointestinal (GI) cancer patients seen at DFCI for initial oncology consultation from 6/2020-12/2021 were invited through the portal to complete the screener. PREMM5 scores ≥2.5% were considered "positive", with genetics referral recommended. Beginning 2/2021, the EHR generated an automated provider-facing alert for positive screens. **Results:** 35% (1504/4262) of new GI cancer patients completed the screener. 367/1504 (24%) had a positive PREMM5 screen (mean age 53 years), of whom 66% were male, and 62%, 12% and 10% had CRC, neuroendocrine and pancreas cancer respectively. 97% (357/367) of screen positives completed the PREMM5 screener remotely through the portal. 102/367 (28%) received a genetics referral as a result of their positive PREMM5 screen (not including 75 genetics referrals outside this workflow), 13 of whom had a pathogenic variant (PV) on germline testing, including 4 with LS (*MSH2, MSH6, PMS2*), and others with PVs in *ATM, BRCA2*, *CHEK2*, *NTHL1*, *RAD50* and *RECQL4*. **Conclusions:** A practice-wide patient-facing EHR-integrated PREMM5 risk assessment workflow is feasible and identified nearly 1 in 4 general GI oncology patients as warranting genetic evaluation, resulting in the identification of numerous actionable germline PVs. This method of deployment could make genetic risk assessment more accessible to non-genetics providers. The suboptimal screener completion rate and 28% genetics referral rate among positive screens suggest the need for additional refinements, including patient and provider engagement and outreach to positive screens who do not follow up with appointments for genetic evaluation. Research Sponsor: None.

10504 **Oral Abstract Session**

Clinical implications of germline genetic testing stratified by ethnicity in a large colorectal cancer cohort. *First Author: Brandie Heald, Invitae, San Francisco, CA*

Background: Germline genetic testing for patients (pts) with colorectal cancer (CRC) is currently recommended for those diagnosed prior to age 50, as well as other select cases based on personal and/or family history criteria. Whether universal germline multi-gene panel testing (MGPT) should be performed in all pts with CRC remains uncertain given the lack of large-scale studies examining MGPT in CRC across a diverse population. The present study aims to determine the yield, and potential clinical impact, of MGPT across a large CRC cohort. **Methods:** We conducted a de-identified retrospective cohort study of all pts with CRC who underwent MGPT (excluding patients who underwent testing limited to ≤10 genes) at a commercial laboratory between 03/2015-05/2021. We collected pts demographics from test requisition forms and results of germline MGPT. Clinically actionable PGVs were defined as variants in genes with reported CRC or polyposis risk, as well as other actionable genes associated with clinical management and/or therapeutic implications. **Results**: A total of 34,210 pts with a history of CRC underwent germline MGPT. These pts were primarily female (60.7%), White (70.6%), and 50 or older (68.8%), with 35.5% reporting an extra-colonic malignancy. Of this cohort, 4,577 (13.4%) were found to carry at least one PGV, with 2,925 (8.6%) having a PGV associated with increased risk of CRC or polyposis. Of all positive pts, 3,038 (66%) had PGVs with precision therapy or clinical trial implications while another 33% had PGVs with published management implications. Among pts under the age of 30 when tested, 23.3% had a clinically actionable PGV compared to 14.7% at age 30-39, 11.7% at 40-49, 12.9% at 50-59, 11.6% at 60-69, 8.9% 70-79, and 7.8% over the age of 80. When compared to pts identified as White, PGVs were more frequently identified in pts of Ashkenazi Jewish descent ($p < 0.001$) and less frequently identified in those who identified as Hispanic ($p < 0.001$). VUS was more frequently identified in pts identified as Black, Asian, or Hispanic ($p < 0.001$). **Conclusions**: This is the largest study to date examining MGPT in CRC, where we demonstrate high rates of clinically actionable variants across all age groups, self-reported racial/ethnic groups, and panel sizes, with 13% of all CRC pts having a PGV with precision therapy, clinical trial and/or published management implications.- This is likely an underestimate as patients with strong clinical suspicion of hereditary CRC (Lynch, FAP) often receive a targeted panel of <10 genes and were excluded. The lower rate of PGVs in Hispanic pts and higher rate of VUS in Black, Asian and Hispanic pts underscores the historical underrepresentation of these pts and ongoing need to mitigate the associated healthcare disparities. Overall, this work supports consideration of broadening germline genetic testing criteria for patients with CRC. Research Sponsor: None.

10505 **Oral Abstract Session**

The frequency of second primary malignancies and colonic polyps in Lynch syndrome with MSI tumors following immune checkpoint blockade. *First Author: Emily Harrold, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Lynch syndrome (LS) is caused by germline mutations in DNA mismatch repair genes and is characterized by microsatellite instability (MSI) status of associated tumors. MSI sensitizes tumors to immune checkpoint inhibition (ICI). The incidence of second primary malignancies and colonic polyps in LS patients with MSI tumors following ICI has not been evaluated. **Methods:** The Memorial Sloan Kettering LS database was queried for all patients with cancer who received ≥1 cycle of ICI using an IRB approved protocol. LS was confirmed by presence of a germline pathogenic/likely pathogenic alteration in a DNA mismatch repair gene (*MLH1, MSH2, MSH6, PMS2, EPCAM*). Tumor and matched normal DNA sequencing was performed via MSK-IMPACT, an IRB approved protocol (NCT01775072). MSI status was assessed using MSIsensor. **Results:** At our center, 131 patients with LS received ICI mostly (73.3%) in the context of metastatic cancer. While 108 patients received ICI for an MSI tumor, 23 LS patients received ICI for a MSS (Microsatellite Stable) tumor (4 hepatobiliary, 3 colorectal, 3 CNS, 2 endometrial, 2 gastroesophageal, 2 renal, 2 sarcoma, 5 other). Five patients (3.8%) developed ≥1 second primary malignancy while on or following ICI comprised of an MSI small bowel adenocarcinoma, MSI upper tract urothelial cancer, 2 MSS prostate cancers, MSS HCC and MSI sebaceous neoplasm; 1 patient developed both MSS prostate cancer and MSI urothelial cancer on ICI. All five patients' primary malignancy was MSI. Only a minority of patients underwent surveillance colonoscopies post completion of ICI (31.3%, (41/131)). Of these 41, nine (22%, (9/41)) were identified to have polyps including 8 tubular adenomas and 1 tubulo-villous adenoma. Median time to development of a polyp was 22 months (95% CI 16.82-27.18) from last colonoscopy and 13 months (95% CI 4-25 months) from last ICI. Notably amongst the 23 LS patients whose tumors were MSS, 14 had progression on ICI. **Conclusions:** Herein, we demonstrate that in LS-patients in receipt of ICI for cancer treatment, the risk of a second primary cancer and polyps remain high following treatment with ICI. Biological mechanisms underlying immune escape warrant further investigation. Surveillance strategies should be continued for LS patients post ICI. Research Sponsor: None.

10506 **Oral Abstract Session**

Effect of lung cancer screening on the incidence of advanced lung cancer in the United States: A SEER database analysis. *First Author: Maxwell Oluwole Akanbi, McLaren Flint, Flint, MI*

Background: In 2013, the USPSTF recommended screening for lung cancer with low-dose chest computed tomography (LDCT). This was based on the results of the National Lung Screening Trial which showed a 20% relative reduction in mortality from LDCT compared with chest radiography. In Feb/March 2015, the Centers for Medicare and Medicaid (CMS) provided screening guidelines and they and private insurers started covering the cost of LDCT. The impact of this recommendation in the real-world setting is unknown. We investigated the impact of LDCT recommendations on the incidence of advanced lung cancer (a-LCa) in the US general population. We sought to verify that the implementation of LDCT will yield an earlier lung cancer diagnosis and thereby reduce the incidence of later stages of lung cancer. **Methods:** From the Surveillance, Epidemiology, and End Results (SEER) 18 registries database, we identified adults 55-80 years diagnosed with regional or metastatic (advanced) lung cancer from 2004 to 2018. Age-adjusted incidence rates (AAIR) of advanced lung cancer in 2004-2014 (Pre-LDCT) and 2015-2018 (Post-LDCT) were compared using interrupted time series (ITS) regression analyses. Analyses were stratified by sex, race, and residence. **Results:** A total of 400,343 patients who met the study criteria were included. Of these, 219,828 (55%) were women and 76% (n = 304,801) were non-Hispanic White. At all periods, the AAIR of a-LCa was highest in non-Hispanic Blacks. Overall, there was a 41% decline in the AAIR of a-LCa in the post-LDCT period compared to the pre-LDCT era (Annual decline of 7.6 vs 4.5 /100,000 person-years (PY) for 2015-2018 vs 2004-2014, $p < 0.01$). Women experienced a more accelerated decline in the AAIR of a-LCa compared to men (53% versus 30%). By race, the annual rates of a-LCa declined most rapidly among non-Hispanic Blacks (55%, 9.5/ 100,000 PY, 2015-2018 vs 4.7/100,000 PY, 2004-2014, $p < 0.01$), and the slowest rate of decline was among Hispanics (41%, 4.6/100,000 PY,2015-2018 vs 2.7/100,000 PY, 2004-2014, $p < 0.01$). By residence, non-metropolitan dwellers experienced a greater decline in annual rates of a-LCa compared with metropolitan dwellers (non-Metropolitan: 69%, 10.1/100,000 PY, 2015-2018 vs 3.2/100,000 PY 2003-2014, $p < 0.01$: Metropolitan dwellers: 37%, 7.2/100,000 PY 2015-2018 vs 4.5/100,000 PY, $p < 0.01$). **Conclusions:** Using population-based data we found a significant decline in rates of a-LCa following the adoption of LDCT for lung cancer screening in the US. Rates of decline in the incidence of a-LCa, however, varied among subgroups. Non-Hispanic Blacks, women, and rural dwellers experienced the most decline in annual rates of a-LCa from 2015 to 2018. Our study shows the overall benefit of LDCT in marginalized communities. However, the impact of our findings on lung cancer mortality will still need further study. Research Sponsor: None.

10507 **Oral Abstract Session**

Clinical validation of a deep-learning–based model to predict lung cancer risk from chest X-rays. *First Author: Anika Walia, Boston University, Boston, MA*

Background: Screening with chest CT prevents lung cancer death, but only 5% of eligible Americans are screened. The updated 2022 Centers for Medicare and Medicaid Services (CMS) criteria expand eligibility to 50-77 year-olds, current or former (<15 years) smokers, with a ≥20 pack-year history. However, smoking quit date and pack-years are often not available in the electronic medical record (EMR), stymying identification of high-risk smokers for lung cancer screening (LCS). We previously developed a free, open-source deep-learning model (CXR-LC) that identifies smokers at high risk of lung cancer better than the 2015 CMS criteria, based on a chest X-ray (CXR) image automatically extracted from the EMR. CXR-LC was developed in the PLCO trial, an asymptomatic LCS population. The present study externally validates CXR-LC using existing CXRs obtained through usual care and compares CXR-LC to the expanded 2022 CMS lung screening eligibility criteria. **Methods:** Current or former smokers who had a routine clinical CXR in 2013-2014 were included. Patients with known lung cancer or who were undergoing LCS were excluded. Smoking status and 2022 CMS LCS eligibility were determined by manual review of the EMR. The primary outcome was 6-year incident lung cancer, identified using International Classification of Disease (ICD) codes and confirmed through discharge summaries and pathology reports. The CXR-LC model and the 2022 CMS eligibility criteria were compared for prediction of 6-year incident lung cancer. **Results:** Among 10,784 patients (mean age 63.1± 6.8 years; 61.0% male), CMS eligibility could be determined in 45% (4,886/10,784), with 55% missing pack-year or quit date data. In this population, 3.9% (191/4,886) developed lung cancer. The 2022 CMS criteria missed 57% (109/191) of lung cancers, while CXR-LC missed 8.9% (17/191, $p < 0.001$). After adjusting for sex, race, and prevalent COPD, the hazard ratio for CXR-LC eligibility (3.6, 95% CI [2.2,6.0]) was greater than for CMS eligibility (2.7, 95% CI [2.0,3.7]). In the 5,897 patients for whom CMS eligibility could not be determined, CXR-LC eligible patients had a 3-fold higher rate of lung cancer than CXR-LC ineligible patients (3.8% vs. 1.3%, $p < 0.001$). All CXR-LC eligible groups had 6-year lung cancer incidence >3.5%, above accepted screening risk thresholds of >1.5% and >2%. **Conclusions:** Using routine CXRs from the EMR, CXR-LC identified high-risk smokers who may benefit from LCS with CT, complementary to the 2022 CMS eligibility criteria. Research Sponsor: None.

Six-year incident lung cancer (number of cancers/number of patients) by CXR-LC and 2022 CMS eligibility.

	CMS Eligible, % (n/N)	CMS Ineligible, %(n/N)	CMS Eligibility Unknown, % (n/N)	Total, % (n/N)
CXR-LC Eligible	8.9 (77 / 861)	3.7 (97/2,633)	3.8 (193/5065)	4.3(367/8559)
CXR-LC Ineligible	6.2 (5 / 81)	0.9 (12/ 1,311)	1.3 (11/833)	1.3 (28 / 2,225)
Total	8.7 (82/942)	2.8 (109/3944)	3.5 (204 / 5897)	3.7 (395/10784)

10508 **Oral Abstract Session**

Trends in stage I lung cancer. *First Author: Aashray Singareddy, Washington University in St. Louis, St. Louis, MO*

Background: The American Cancer Society has recently reported an increase in the percentage of patients with localized lung cancer from 2004 to 2018 with a corresponding improvement in survival for all patients combined. We analyzed the recent trends in stage distribution for lung cancer including tumor and demographic factors. **Methods:** We selected patients with lung cancer from the National Cancer Database (NCDB) public benchmark report diagnosed between 2010 and 2017. Patients with unknown stage were excluded. Stage distribution using the AJCC 7th edition of the TNM system was evaluated according to year of diagnosis, histology, age, gender, race, insurance and income. **Results:** Among the 1,447,470 patients from 1,384 hospitals identified in the database, 56,382 (3.9%) were excluded due to unknown stage or incorrect histology, leaving 1,391,088 patients eligible. The percentage of patients with stage I progressively increased from 23.5% in 2010 to 29.1% in 2017 while stage IV decreased from 45.5% to 43.1% during the same period (Table). The increased in percentages of stage I from 2010 to 2017 were 25.9% to 31.8% in non-small cell lung cancer (NSCLC) and 5.0% to 5.4% in small cell lung cancer (SCLC). Although the increased percentage of stage I lung cancer was observed in all subsets of patients, there were significant imbalances according to demographic and socio-economic factors. In the year 2017, the major gaps in stage I included insurance (31.4% for Medicare, 26.4% for private insurance, and 12.9% for uninsured), income (32.4% for the highest annual income and 25.4% for the lowest) and race (29.9% in whites and 24.3% in blacks). **Conclusions:** There has been a significant increase in the percentage of stage I lung cancer at diagnosis from 2010 to 2017 which occurred mostly in NSCLC. Disparities in diagnosis and access to treatment may account for the differences in the percentage of patients with stage I among selected demographic populations. The staging trends and recent treatment improvements may lead to better survival for lung cancer. Research Sponsor: None.

	Stage I	Stage II	Stage III	Stage IV
2010	37,757 (23.5%)	15,270 (9.5%)	34,437 (21.5%)	72,910 (45.5%)
2011	39,077 (24.2%)	15,071 (9.3%)	34,640 (21.4%)	72,817 (45.1%)
2012	40,729 (24.5%)	15,291 (9.2%)	35,538 (21.4%)	74,580 (44.9%)
2013	43,279 (25.2%)	15,838 (9.2%)	35,462 (20.7%)	76,859 (44.8%)
2014	45,211 (25.7%)	15,926 (9.0%)	36,661 (20.8%)	78,441 (44.5%)
2015	48,855 (26.9%)	16,393 (9.0%)	37,055 (20.4%)	79,605 (43.8%)
2016	51,928 (28.1%)	16,242 (8.8%)	36,006 (19.5%)	80,722 (43.7%)
2017	54,793 (29.1%)	16,278 (8.6%)	36,258 (19.2%)	81,159 (43.1%)
Total	361,629 (26.0%)	126,309 (9.1%)	286,057 (20.6%)	617,093 (44.3%)

Constitutional *BRCA1* methylation and risk of incident triple-negative breast cancer and high-grade serous ovarian cancer. *First Author: Per Eystein Lonning, K.G. Jebsen Centre for Genome-Directed Cancer Therapy, Department of Clinical Science, University of Bergen, and Department of Oncology, Haukeland University Hospital, Bergen, Norway*

Background: About 25% of all triple-negative breast cancer (TNBC) and 10–20% of high-grade serous ovarian cancers (HGSOC) harbor *BRCA1* promoter methylation. While constitutional *BRCA1* promoter methylation has been observed in normal tissues of some individuals, the potential role of normal tissue methylation as a risk factor for incident TNBC or HGSOC risk is unknown. **Methods:** The objective of this study was to assess potential correlation between white blood cell (WBC) *BRCA1* promoter methylation and subsequent risk of incident TNBC and HGSOC. To do so, we analyzed samples from women participating in the Women's Health Initiative (WHI) study who had not been diagnosed with either breast or ovarian cancer prior to study entrance. A total of n = 636 women developing incident TNBC and 509 women developing incident HGSOC were matched with cancer-free controls (n = 1838 and 2979) in a nested case-control design. Cancers were confirmed after central medical record review. Blood samples, collected at entry, were analyzed for *BRCA1* promoter methylation by massive parallel sequencing. Associations between *BRCA1* methylation and incident TNBC and incident HGSOC were analyzed by unconditional logistic regression. **Results:** Age at entry was 62 (median; range 50 to 79) years, with median interval to diagnosis of 9 (TNBC) and 10 (HGSOC) years. The presence of methylated *BRCA1* alleles was significantly associated with higher risk of incident TNBC (OR 2.44, 95% CI 1.79–3.33; P < .001) and incident HGSOC (OR 1.87, 95% CI 1.32–2.61; P < .001). Restricting analyses to individuals with > 5 years between sampling and cancer diagnosis yielded similar results (> 5 years; TNBC: OR 2.53, 95% CI 1.81–3.54; P < .001; HGSOC: OR 1.81, 95% CI 1.21–2.63; P = .003). Across individuals, methylation was not haplotype-specific, arguing against an underlying *cis*-acting factor. Within individuals, *BRCA1* methylation was observed on the same allele, indicating clonal expansion from a single methylation event. **Conclusions:** Constitutional normal tissue *BRCA1* promoter methylation is significantly associated with risk of incident TNBC and HGSOC with implications for prediction of these cancers not associated with germline mutations. These findings warrant further research to determine if constitutional methylation of tumor suppressor genes are pan-cancer risk factors. Research Sponsor: NIH, Norwegian Research Council.

Whole genome germline sequencing: Its role in general health screening in family practice, the first study in the UK. *First Author: Ros A. Eeles, Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom*

Background: Whole genome sequencing (WGS) is now possible due to improvements in next generation sequencing technology. This gives the opportunity to incorporate genetic data into family practice health screening. The fulfilment of the potential of WGS lies in its future implementation into family practice. This study aimed to set up a model pathway to undertake WGS for actionable findings and assess its potential role in enhancing health screening. **Methods:** A pilot study comprised of 100 healthy participants from 2020-2022, recruited from a family practice, consented to routine baseline blood tests, cardiac assessment (ECG and echocardiogram), abdominopelvic ultrasound, all performed at the practice. Review of past medical, and family history was done from electronic health records (EHR). Germline genetic testing consisted of 84 cancer and 77 cardiac genes and whole genome sequencing (566 actionable genes reported), including higher penetrance monogenic mutations, recessive carrier alterations and pharmacogenomics. A multidisciplinary clinical team reviewed integrated results through an iterative process, which fed back to participants. **Results:** Twenty of 100 individuals (20%) had an actionable genetic variant in either cancer (10 individuals), thrombophilia (8) or cardiac rhythm disorder genes (2). Eighty percent of the participants had a variant in an autosomal recessive gene. Pharmacogenomics results yielded significant variants in 30%. **Conclusions:** The majority of patients had a significant change in management for themselves or their families. Whole genome sequencing as part of health screening in family practice is feasible and is likely to have significant beneficial health management implications. This study is the first of its kind in family practice and shows how this can be implemented. Research Sponsor: Oppenheimer Foundation, Other Government Agency.

10511 **Clinical Science Symposium**

Multicenter retrospective study of clinical genetic testing in patients with sarcoma. *First Author: Helen Catherine Wilbur, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins Hospital, Baltimore, MD*

Background: Sarcomas are rare and diverse malignancies with a subset developing in the context of heritable cancer predisposition syndromes. Data surrounding the frequency of inheritance and patient/genomic findings are limited. We aimed to describe the characteristics of patients with sarcoma referred for clinical genetic testing and to determine the prevalence of pathogenic/likely pathogenic germline variants (PGV/LPGV). **Methods**: We performed retrospective chart reviews of patients with sarcoma referred to Michigan Medicine Cancer Genetics Clinic between 12/2006 and 1/2020 and Vanderbilt Hereditary Cancer Clinic between 1/2005 and 1/2019. Reviewers obtained medical/family history, cancer phenotype, and results of germline genetic testing. Descriptive analyses were performed to assess the prevalence of germline variants classified as pathogenic/likely pathogenic according to American College of Medical Genetics criteria. Associations with clinical factors were tested for using Fisher's exact test or Wilcoxon rank-sum test. **Results**: One-hundred sixteen patients with sarcoma underwent genetic evaluation during a 15-year period. Mean age at time of visit was 46 years (SD, 17.6 years; range, 1-80 years). Sixty-nine patients (59%) were female. The most common reasons for referral were personal history of multiple malignancies (n = 69, 59.4%), first degree relative (FDR) with malignancy (n = 67, 57.7%) and young age at diagnosis (age ≤ 18, n = 18, 15.5%). Forty-eight patients (41.4%) had both a history of multiple malignancies and a FDR with a malignancy. Eight patients had a FDR with sarcoma (6.9%). Of the 110 patients who underwent germline testing, 53 patients (48.2%) had a PGV/LPGV. Identified germline variants and frequencies are listed in the Table. There was no statistical significance between young age at diagnosis, history of personal malignancies, FDR with sarcoma, FDR with one or more malignancies, or multiple FDRs with malignancy and presence of a PGV/LPGV. **Conclusions**: In this multicenter study, approximately half of patients with sarcoma referred for cancer genetic testing had a PGV/LPGV associated with hereditary predisposition to cancer. There was no identified positive predictive factor for germline variants. Though *TP53* was the most common, over 20 genetic variants were identified, supporting the consideration of multigene panel testing. Our study is limited to patients who were both referred to and attended genetic evaluation. Yet, the high frequency of pathogenic germline variants observed highlights the necessity for further investigation of the prevalence of and predictive factors for germline mutations in all sarcoma patients. Identified germline variants. Research Sponsor: None.

Germline Variant	Number of Patients (%)
TP53	11 (10.0)
MSH2	6 (5.5)
BRCA2, ATM	5 (4.5) each
FLNC	3 (2.7)
BARD1, MSH6, MUTYH, FH, RB1, CDKN2A	2 (1.8) each
CHEK2, MITF, PTEN, SDHB, NTHL-1, RECQL4, SCN5A, SMAD4, PMS2, POLE, POT1	1 (0.9) each

10512 **Poster Discussion Session**

A multicenter study of clinical impact of variant of uncertain significance reclassification in breast, ovarian, and colorectal cancer susceptibility genes. *First Author: Sukh Makhnoon, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Up to 10% of all cancers are attributable to germline mutations and identifying mutation carriers is critical for cancer prevention. Clinical interpretation of genetic test results is complicated by variants of uncertain significance (VUS) with unknown impact on health, which can be clarified through reclassification. However, there is little empirical evidence regarding VUS reclassification in oncology care settings, including the prevalence and outcomes of reclassification, racial/ethnic differences, and the proportion of patients who undergo cancer preventive healthcare management as a result of VUS reclassification. **Methods:** Retrospective analysis of persons carrying VUS (with or without an accompanying pathogenic or likely pathogenic [P/LP] variant) in breast, ovarian, and colorectal cancer genes who underwent genetic counseling at four geographically dispersed cancer care settings (in Texas, Florida, Ohio, and New Jersey) between 2013 and 2019, and followed until 2020. **Results:** Among 2,715 individuals, 3,261 VUS and 313 P/LP variants were reported and 11% (300/2,715) had a P/LP in addition to VUS. In total, 8.1% of all individuals with VUS experienced reclassifications, 87.1% of which were downgraded to benign or likely benign and 12.9% were upgraded to P/LP. Reclassification rates varied significantly among cancer care settings from 4.81% to 20.19% (overall $p < 0.001$). The reclassification pattern across genes suggests that VUS in most genes underwent reclassification at a rate proportional to their prevalence in the overall sample and occurred commonly in *ATM, BRCA2, BRCA1*, and *CHEK2*. Compared to their prevalence in the sample, reclassification rates were higher for Blacks (13.6% vs 19.0%), lower for Asians (6.3% vs 3.5%), and proportional for Whites and Hispanics. Median time to reclassification decreased steadily between 2014 and 2019 from 3.08 to 0.91 years. Overall, 11.3% of all reclassified VUS resulted in clinically actionable findings and 4.6% subsequently changed individuals' clinical managements including prophylactic surgeries and intensive screenings for cancer prevention and early detection. **Conclusions:** In this large multisite study, VUS reclassification changed clinical management for 0.4% of all individuals. VUS reclassification may alter clinical management, has implications for precision cancer prevention, and highlights the need for standardized clinical practice guidelines and policies for returning reclassified results to patients. Cascade testing of first-degree relatives of patients with pancreatic cancer with confirmed germline genetic mutations: A simulation modeling study. *First Author: Mary Linton Bounetheau Peters, Division of Medical Oncology, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Universal germline genetic testing is recommended for all patients with pancreatic ductal adenocarcinoma (PDAC). In addition to treatment implications for the patient, it is valuable for family members of the PDAC patient to undertake germline testing to understand their familial cancer risk. We evaluated the potential effectiveness of cascade testing of first-degree relatives (FDRs) of PDAC patients to guide MRI-based screening for PDAC. **Methods:** We used a microsimulation model of PDAC to estimate the potential life expectancy (LE) benefit of cascade genetic testing of FDRs of PDAC patients. Analysis was performed for eight mutations of interest (ATM, BRCA1, BRCA2, PALB2, Lynch, TP53, CDKN2A, STK11) with relative risk of PDAC ranging from 1.6 – 24. FDRs were defined by their sex, age, and information state (not informed, informed but not tested, test negative, or test positive). Family size and composition, communication of genetic testing results, and uptake of cascade testing were based on published studies. For each FDR group, we simulated multiple MRI-based screening strategies, defined by starting age (FDR age at patient diagnosis to age 75) and frequency (once or annual until age 75), and identified the strategy that resulted in the highest LE. **Results:** Each PDAC patient would have an average of 4.35 living FDRs. 1.32 of these living FDRs would be informed of the patient's test results but not undergo testing themselves, and 1.03 would test positive for the mutation of interest. For lower risk mutations (ATM, BRCA2, PALB2), FDRs would only undergo screening if they test positive. For Lynch syndrome, not tested FDRs would undergo screening starting at age 65 or 70, whereas FDRs who test positive would start at 50 or 55. For STK11, the highest risk mutation, FDRs would start screening annually as soon as they are informed of the patient's test results. The total LE gain for cascade testing of FDRs ranged from 0 (BRCA1) to 1.05 years (STK11). **Conclusions:** For each PDAC patient identified to have a germline genetic mutation, cascade testing of FDRs could add up to a year life expectancy for the family, in addition to the value of the germline information to the PDAC patient's care. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Screening selection and life expectancy gain in days for *CDKN2A* family.

	Brothers	Sisters	Sons	Daughters	Total Family LE Gain (days)	Total Family LE Gain (days) given Genetic Testing for all FDRs
Test Positive for *CDKN2A* (RR 12.7)	Annual screening, start at notification (6.8 days)	Annual screening, start at notification (11.8 days)	Annual screening, start at notification (35.2 days)	Annual screening, start at notification (33.9 days)	135.02	226.87
Informed but not Tested (RR 6.8)	Annual screening, start at notification (5.4 days)	Annual screening, start at notification (0.3 days)	Annual screening, start age 50 (24.5 days)	Annual screening, start age 55 (17.1 days)		

10514 **Poster Discussion Session**

Double jeopardy? A closer look at cancer histories of individuals with multiple germline pathogenic variants. *First Author: Carolyn Horton, Ambry Genetics, Aliso Viejo, CA*

Background: Germline multigene panel testing has led to the increased detection of multiple co-occurring pathogenic variants (PV) in the same individual. As this occurrence is still relatively rare, reports of these individuals have been limited. Therefore, we sought to describe the clinical features of individuals with multiple PV identified at a single high-volume diagnostic laboratory. **Methods:** We performed a retrospective review of demographics and clinical data for individuals with > 1 pathogenic or likely pathogenic variant (PV) who underwent hereditary cancer panel testing (5-67 genes) between May 2012 and April 2017. In recessive genes (i.e. *MUTYH*), PV were only included when biallelic. PVs with reduced penetrance (*APC* p.I1307K; *CHEK2* p.I157T, p.S428F, p.T476M) were excluded. In individuals with the most common combinations of genes, personal cancer history and age at cancer diagnosis was evaluated. **Results:** A total of 555 individuals were identified with multiple PVs. Most individuals were female (85.1%), had a personal history of cancer (73.3%) and 26.3% had two or more primary cancers. *CHEK2* was most often seen in co-occurrence with a PV in a different gene (137 observations), followed by *ATM* (120 observations), *BRCA2* (110 observations), and *BRCA1* (88 observations). Among cases in which clinical information was provided (n = 545), the five most frequent co-occurring combinations were in *ATM/CHEK2* (25), *ATM/BRCA2* (23), *BRCA1/CHEK2* (19), *CHEK2/CHEK2* (16), and *BRCA2/CHEK2* (14). Individuals with co-occurring PVs in *CHEK2/CHEK2* had the youngest age at first cancer diagnosis (mean = 41.5y; median = 42y), the highest rate of breast cancer diagnoses and other cancer diagnoses (100.0% and 70.6% of individuals, respectively), and the highest proportion of individuals with > 1 primary cancer (52.9%). **Conclusions:** Our results indicate that individuals with two PVs in *CHEK2* have an average age of cancer onset that is similar to individuals with either a *BRCA1* or *BRCA2* concurrent PV. Additionally, individuals with two PVs in *CHEK2* were more likely to have multiple primary cancers as compared to others in the cohort with concurrent PVs including those with either a *BRCA1* or *BRCA2* concurrent PV (Table). Continued studies, including comparisons to individuals with one PV, will provide valuable insight to aid in counseling and management of individuals with multiple germline PV. Research Sponsor: None.

PV Gene Combination	Total individuals	n Female (%) *n Male (%)*	Mean age 1st cancer diagnosis (median)	n breast cancer (%)	n other cancer (%)	n > 1 primary cancer (%)
ATM/CHEK2	25	23 (92.0%) *2 (8.0%)*	42.5 (44)	20 (80.0%)	7 (28.0%)	5 (20.0%)
ATM/BRCA2	23	18 (78.3%) *5 (21.7%)*	47.9 (49)	13 (56.5%)	7 (30.4%)	4 (17.4%)
BRCA1/CHEK2	19	17 (89.5%) *2 (10.5%)*	42.1 (43)	10 (52.6%)	7 (36.8%)	4 (21.1%)

Rates of pathogenic variants in common cancer genes among different racial/ethnic groups. *First Author: Peter D. Beitsch, Dallas Surgical Group, Dallas, TX*

Background: Racial/ethnic disparities have been well-documented in access to cancer screening and treatment, as well as treatment outcomes. Less is known regarding the proportion of higher and lower penetrance genetic pathogenic variants (PVs) in these populations. **Methods:** Patient data was obtained from the Informed Genetics Annotated Patient Registry (iGAP), an IRB-approved multi-center longitudinal, observational study designed to capture genetic and genomic lab agnostic test results and their utilization and impact on treatment practices and outcomes from patients at Breast Clinics. 1323 patients self-declared race/ethnicity and underwent germline genetic testing at any lab. Analyses were limited to 24 cancer susceptibility genes (*ATM, BARD1, BRCA1, BRCA2, BRIP1, CDH1, CHEK2, NBN, PALB2, PTEN, STK11, TP53, APC, BMPR1A, CDK4, EPCAM, MLH1, MSH2, MSH6, MUTYH* biallelic, *PMS2, RAD51C, RAD51D, SMAD4*), 21 of which have clinical management guidelines from the NCCN (excluding *NBN, BARD1, CDK4*). Descriptive statistics were used to assess and compare data from these populations and germline genetic testing results. **Results:** The PV rate among racial/ethnic groups were as follows: Caucasian 110/991 (11.1%), Asian 5/93 (5.4%), Hispanic 26/87 (29.9%), African/Black 6/59 (10.2%), Ashkenazi 5/25 (20%), Other 1/17 (5.9%). There are significant differences in PV rates between Hispanic ethnicities and all other categories (p-value < 0.001 for all) and significant differences in PV rates between Asian race and all other categories (p-value 0.05 Caucasian, 1.9e-7 Hispanic, 0.03 Ashkenazi, 0.05 Other) except African/Black (p-value 0.06). The *BRCA1/2* PV rates were: Caucasian 30/991 (3.0%), Asian 1/93 (1.1%), Hispanic 12/87 (13.8%), African/Black 3/59 (5.1%), Ashkenazi 1/25 (4.0%), Other 1/17 (5.9%). There are significant differences in *BRCA1/2* PV rates between Hispanic ethnicities (p-value < 0.001 for all) and all other categories, and between Asians and Caucasians (p-value 0.04). **Conclusions:** Racial/ethnic groups varied by PV rate and proportion of both *BRCA1/2* and overall PV rate. The higher proportion of PVs in Hispanics could be due to the greater representation of Hispanics from New Mexico which may harbor Ashkenazi ethnicity. Further studies are needed to understand whether these differences are a result of disparate access to testing, true population differences, lack of data in non-Caucasian populations skewing variant classification, or other factors. Research Sponsor: Medneon, Invitae.

10516 **Poster Discussion Session**

Racial and regional disparities in metastatic breast cancer. *First Author: Sachi Singhal, Propesct CCMC, LLC dba Crozer Chester Medical Center, Chester, PA*

Background: Breast cancer is the most commonly diagnosed malignancy in American women, with about 281,500 new reported cases this year, 3.8 million women living with an active or history of breast cancer, and a lifetime occurrence of 1 in 8 women in this nation. Racial disparities persist despite the advent and implementation of screening by national agencies. AA females are less likely to be diagnosed with breast cancer, and yet bear an arbitrarily high burden of mortality of this malignancy. Socioeconomic variables and lifestyle are the most plausible explanations of this discrepancy. Even in clinical trials, there remains an underrepresentation of all ethnic minorities. Encouragement of guideline based screening for all along with constant follow ups, access to health insurance and a more uniform representation in trials are the cornerstone of eliminating these disparities. **Methods:** Data for this study was obtained from the 2016-18 Nationwide Inpatient Sample (NIS) which comprises 20% of the total US hospital discharges. We identified all patients with a primary diagnosis of Malignant Neoplasms of Breast. In-hospital mortality, race and hospital regions for the given patients were studied. Baseline characteristics of participants were summarized using descriptive statistics. The patient population was stratified as per race, hospital region, gender, therapy they received and family history. Logistic regression was performed to derive the odds ratio while adjusting for different variables. Further details: https://www.hcup-us.ahrq.gov/. **Results:** 99, 543 patients with metastatic breast cancer were identified, and almost 99% of them were females. 67% of the population was comprised of Caucasians, 16.91% African Americans (AA), 9.14% Hispanics and 3.28% Asians and Pacific Islanders (API). AAs had the most reported deaths at 5.54%, followed by APIs at 4.80% and Caucasians 4.09% ($p < 0.0001$). The odds of dying were significantly higher in AA population when compared to Caucasian population (OR 1.391 (1.286-1.504)), and the odds were consistently higher across all regions of the US. In terms of regional variation, it was seen that races identifying as "others' " had significantly higher odds of dying in the North East (OR 1.646 (1.238-2.189)) and the West (OR 1.503 (1.059-2.133)). **Conclusions:** It is crucial to identify racial disparities in diagnosis, treatment and mortality before we devise a blueprint to tackle this incongruity. This highlights the significance of universal screening and better health insurance coverage in addition to recognition of reasons behind these differences. Research Sponsor: None.

10517 **Poster Discussion Session**

Ancestry-specific risk of triple-negative breast cancer (TNBC) associated with germline pathogenic variants (PV) in hereditary cancer (CA) predisposition genes. *First Author: Michael J. Hall, Fox Chase Cancer Center, Philadelphia, PA*

Background: TNBC represents ~15% of invasive BC. Ancestry-specific variabilities in TNBC risk are well-described, with African American (AA) women experiencing higher incidence and mortality from TNBC than women of other races/ethnicities. Increased risk of TNBC has been associated with both rarer (e.g. *RAD51C/D, BARD1*) and more commonly detected (e.g. *BRCA1/2, PALB2*) germline PV in hereditary CA predisposition genes, but less is known about ancestry-specific TNBC risks for PV carriers. **Methods:** We examined clinical and genetic records from women referred for multigene CA panel testing (9/2013-5/2020). Multivariable logistic regression was used to test associations of PV in 13 genes with risk of TNBC after accounting for age, ancestry, and personal/family CA history. We analyzed each gene in the full cohort, and in subcohorts defined by self-reported ancestry. Effect sizes are expressed as odds ratios with 95% confidence intervals. Seven genes are not reported in ancestry-stratified analyses due to small numbers of PV carriers with TNBC. **Results:** From 627,219 individuals referred for multigene panel testing, 115,337 (18.4%) women with personal history of BC were identified, of whom 17,951 (15.6%) reported TNBC. Personal history of TNBC was reported more frequently in women of African ancestry (26.9%) than in women of European (13.9%) or Asian (11.7%) or Latinx ancestry (14.9%). Ancestry-stratified risks of TNBC associated with germline PVs are seen in the Table. **Conclusions:** While small samples sizes limit some gene-specific analyses, comparable ancestry-specific risks of TNBC were seen across the racial/ethnic groups examined here. Research Sponsor: None.

10518 **Poster Discussion Session**

Association of germline genetic testing results with chemotherapy regimens received by women with early-stage breast cancer. *First Author: Allison W. Kurian, Stanford University School of Medicine, Stanford, CA*

Background: Germline genetic testing is widespread after breast cancer diagnosis and increasingly informs treatment decisions; however, guidelines do not advise selecting chemotherapy regimens based on genetic testing results. It is unknown whether women with pathogenic variants (PVs) in *BRCA1, BRCA2* (*BRCA1/2*) or other cancer risk genes receive different chemotherapy regimens than women with negative genetic testing results. **Methods:** We linked Surveillance, Epidemiology and End Results (SEER) registry records from Georgia and California to clinical germline genetic testing results from four participating laboratories (Ambry, Bioreference/GeneDx, Invitae, and Myriad). For this analysis, we included patients who: 1) were diagnosed with stages I-III breast cancer, either hormone receptor-positive and HER2-negative (HR+HER2-) or triple-negative, in Georgia or California from 2013-2017; 2) received chemotherapy based on SEER records; and 3) linked to a genetic testing result. We further selected cases by genetic testing results: 50% PVs in *BRCA1/2* or another cancer risk gene, 25% variant of uncertain significance (VUS) only and 25% negative. We extracted details of chemotherapy regimens from SEER text fields completed by registrars. We categorized regimens by drug classes reported (anthracycline, taxane, platinum, nitrogen mustard, other). We used multivariable models that controlled for age, race/ethnicity, stage, grade, surgical procedure, radiotherapy receipt and geographic site to test whether PV carriers received a more intensive chemotherapy regimen. For HR+HER2-, a more intensive regimen was defined as at least three drugs including an anthracycline and for triple-negative, as at least four drugs including an anthracycline and a platinum (versus fewer drugs). **Results:** 2,293 women were included, 1,451 with HR+HER2- and 842 with triple-negative disease. On multivariable analysis, receipt of a more intensive chemotherapy regimen was associated with having a *BRCA1/2* PV among women with HR+HER2- disease (odds ratio 1.22, $p = 0.036$), but not among women with triple-negative disease. Moreover, platinum use was elevated in *BRCA1/2* PV carriers with HR+HER2- disease (from an adjusted model: *BRCA1/2* PV 10.9%, other PV 3.6%, VUS 5.6%, negative 5.7%), while in *BRCA1/2* PV carriers with triple-negative disease, platinum use did not vary significantly by genetic results (*BRCA1/2* 27.7%, other PV 27.7%, VUS 20.9%, negative 20.7%; $p = 0.025$ for interaction between genetic result and subtype). **Conclusions:** Compared to women with negative genetic testing results, women with *BRCA1/2* PVs more often received a platinum and/or an anthracycline in chemotherapy regimens for early-stage, HR+HER2- breast cancer. This suggests potential over-treatment. No differences in chemotherapy regimen by genetic testing result were observed in triple-negative disease. Research Sponsor: U.S. National Institutes of Health.

10519 **Poster Discussion Session**

Heart toxicity effects (HTE) of anthracyclines-containing regimens (ACRs) in patients with breast cancer (BC) carrying mutational signature of homologous recombination deficiency (HRD). *First Author: Lorena Incorvaia, Dept.of Surgical,Oncological and Oral Sciences,Section of Medical Oncology,University of Palermo,Italy, Palermo, Italy*

Background: *BRCA1/2* genes (*BRCA*) play a prominent role in the Homologous Recombination Repair (HRR) pathway. Following the technological progress and deeper knowledge on *BRCA*-related cancers, the demand for genetic testing is rapidly increasing. Beyond *BRCA1/2*, other genes are involved in the HRR, including *ATM*, *PALB2*, *RAD51*, and *BARD1*. Due to the important role in the cellular repair process, deleterious variants in HRR genes may cause inadequate DNA damage repair in cardiomyocytes. The role of *BRCA1/2* as predisposing condition to cardiac dysfunction is debated, and the contribution by no-*BRCA* genes is still unknown. **Methods:** This is a multicenter, retrospective, study to investigate the risk of heart-insults from anthracyclines on adjuvant setting in BC patients carrying germline pathogenic or likely pathogenic variant (PV) (classes IV and V) in *BRCA* and no-*BRCA* HRR pathway genes. We collected genetic and clinical data, and evaluated the left ventricular ejection fraction (LVEF) at cardiac ultrasound, before starting ACR therapy, and at subsequent time points, according to clinical indications. **Results:** Three hundred and sixty (360) BC patients, aging 22 to 80, were included in this study; 131 patients were carriers of germline PVs in HRR pathway genes: 52 in *BRCA1* gene (39.7%), 48 in *BRCA2* gene (36.6%), and 31 harbored PVs in no-*BRCA* HRR pathway genes (23.7%), including PVs in *PALB2*, *CHEK2*, *ATM*, *RAD51C*, *RAD50* and *BARD1* genes. In the cohort of 229 patients without PVs, 47 showed variant of uncertain significance (VUS, class III), and 173 had genetic testing not informative. When LVEF between the groups was compared, the difference was not significant for the pre-treatment values. Notably, individuals carrying *BRCA* or other HRR gene deleterious variants, showed a statistically significant reduction of LVEF > 5% at the second timepoint (3 month), compared to the LVEF pre-treatment values ($p = 0.001$). A marked LVEF reduction was in mutated patients treated with risk-reducing bilateral salpingo-oophorectomy prior to age 40, body mass index > 25, and type-II diabetes mellitus. The latter risk factor was probably related to increased risk developing insulin-resistance reported for *BRCA*-mutated patients. **Conclusions:** Our data suggest that PVs in *BRCA* or other genes involved in HRR pathway, can lead to impaired homologous recombination, thus increasing sensitivity of cardiac cells to DNA damaging chemotherapy in BC patients. In this subgroup of patients, other measurements such as the global longitudinal strain (GLS), and a more in-depth assessment of risk factors, could be proposed to optimize cardiovascular risk-management and to improve long-term survival. Germline mutational landscape of non-highly penetrant Fanconi anemia genes unveiled from sequencing of 5,044 patients with solid tumor cancer. *First Author: Kevin J. McDonnell, City of Hope, Duarte, CA*

Background: Nearly two dozen Fanconi anemia (FA) genes work in concert to mediate critical DNA repair steps. Previous investigations have well described germline pathogenic variation and associated solid tumor cancer predisposition in the highly penetrant (HP)-FA genes, *BRCA1 (FANCS), BRCA2 (FANCD1)* and *PALB2 (FANCN)*. To date, understanding of pathogenic variation and cancer association among non-HP-FA genes remains incomplete. In this study we investigated the germline mutational landscape of non-HP-FA genes in patients with a personal/family history of a solid tumor. **Methods:** Unselected, consented patients with a personal/personal history of solid tumor cancer underwent germline testing through a sponsored program of universal access. Testing used a custom panel to detect pathogenic single nucleotide variants, short insertions/deletions and exon-level deletions/duplications of 155 cancer-predisposition genes including 15 non-HP-FA genes [*FANCA, FANCB, FANCC, FAND2, FANCE, FANCF, FANCG, FANCI, FANCJ (BRIP1), FANCL, FANCM, FANCO (RAD51C), FANCP (SLX4), FANCQ (ERCC4)* and *FANCU (XRCC2)*]. Here we summarize germline pathogenic variant frequency in non-HP-FA genes and describe the mutational landscape across solid tumors. Additionally, we report the clinical actionability (on- and off-label FDA approved drug availability and/or clinical trial eligibility) of identified variants. **Results:** 5044 patients consented and completed germline genetic testing. 1014/5044 (20.1%) of patients carried a pathogenic variant in a cancer predisposition gene. 116/1014 (11.4%) of germline positive patients carried a pathogenic variant in a non-HP-FA gene. Non-HP-FA genes with highest frequencies included: *FANCA* (28 patients), *FANCM* (19 patients), *BRIP1* (FANCJ) (19 patents) and *FANCC* (14 patients). Testing identified germline non-HP-FA pathogenic variants in eighteen different tumor types. The tumor types associated with the highest percentages of associated germline non-HP-FA pathogenic variants included: squamous cell cancers (8.2%), bladder/urothelial cancer (5.0%), breast cancer (3.5%) and ovarian/fallopian tube cancers (3.5%). Moreover, 19 patients carrying a non-HP-FA germline pathogenic variant qualified for an on- or off-label FDA-approved drug; 101 patients achieved clinical trial eligibility by virtue of their non-HP-FA variant. **Conclusions:** Our study offers a landscape view of germline pathogenic variants in non-HP-FA genes in patients with a history of a solid tumor. Furthermore, this investigation provides a basis for further examination of associations between these germline pathogenic variants and solid tumor cancer predisposition. Finally, importantly, our work underscores the value of expanded germline non-HP-FA gene testing to optimize therapeutic and clinical trial opportunities for cancer patients. Comparison of characteristics and outcomes of young onset versus average onset pancreatobiliary adenocarcinoma. *First Author: Thejus Jayakrishnan, Cleveland Clinic Taussig Cancer Institute, Cleveland, OH*

Background: Young-onset gastrointestinal malignancies appear to be increasing in incidence but most investigations have focused on colorectal cancer and there are limited data on young-onset pancreatobiliary cancers (YO-PBA). We evaluated trends and characteristics of YO-PBA in comparison to average-onset disease (AO-PBA). **Methods:** The study cohort comprised patients with PBA (pancreatic adenocarcinoma, intra- and extra-hepatic cholangiocarcinoma) diagnosed between 2004 and 2017 from the National Cancer Database. YO-PBA was defined as diagnosis at age < 50 years and AO-PBA as >50 years. Logistic regression was used to assess factors associated with YO-PBA status, and cox proportional hazards modeling was performed to associate demographic and clinical factors with overall survival. **Results:** Of 360,764 patients analyzed, 20,822 (5.8%) were YO-PBA with a median age at diagnosis of 45 years (IQR 42 – 48) vs 70 (62-78) years for AO-PBA. The number of patients with YO-PBA increased by 33.3% during the study period compared to 111.8% for AO-PBA. Characteristics associated with YO-PBA were (p-values<0.001 for all): male sex (6.3% YO-male out of all male patients vs 5.2% YO-female out of all female patients, OR 1.2), Black race (7.9% YO-Black vs 5.0% YO-White, OR 1.4), lower income (6.4% YO-lowest household income based category vs 5.5% highest, OR 1.3), and lower education (6.9% YO-lowest educational status category vs. 4.9% highest, OR 1.4). YO-PBA were more likely to present with stage-IV disease (6.4% YO-Stage IV of all stage IV vs 5.4% YO-Stage I-III, OR 1.2, p-value<0.0001), but more likely to undergo surgery (7.4% YO-surgery patients vs 5.4% YO no-surgery patients). Median OS was YO 11.0 (95% CI 10.8 – 11.3) vs. AO 7.1 months (95% CI 7.0 – 7.1). Effects of patients' characteristics on OS differed significantly between YO and AO-PBA cohorts (interaction p-values < 0.001), and were analyzed separately (table). Notably, Black patients experienced worse outcomes in both age groups. **Conclusions:** Young-onset pancreatobiliary cancers (YO-PBA) reported in NCDB have increased over the years. YO-PBA is associated with better survival compared to AO-PBA. Socioeconomic disparities significantly impact incidence and outcomes. More work is needed to help address these health disparities, especially for those with young-onset cancer. Research Sponsor: None.

Characteristics	YO – HR (95% CI)*	AO – HR (95% CI)*
Sex – Male vs Female	1.11 (1.09-1.15)	1.01 (1.00-1.09, p=0.005)
Race – Black vs Others	1.23 (1.07-1.42,p=0.005)	1.25 (1.20-1.31)
Insurance – Government vs Private	1.34 (1.30-1.39)	1.30 (1.29-1.31)
Income category – Lowest vs Highest income group	1.33 (1.27-1.39)	1.18 (1.17-1.19)
Education – Lowest vs Higher	1.20 (1.15-1.26)	1.09 (1.08-1.11)
Treatment center – Academic vs Non-academic	0.87 (0.85-0.90)	0.77 (0.76-0.77)

*p-value < 0.001 unless specified. HR higher than 1 means worse prognosis.

10523 **Poster Discussion Session**

Germline predisposition in oncologic and dermatologic melanoma cohorts. *First Author: Pauline Funchain, Cleveland Clinic Foundation - Taussig Cancer Institute, Cleveland, OH*

Background: Melanoma has recently been suggested to be a highly heritable cancer with high twin-twin concordance. In contrast, prior studies on patients with familial atypical multiple mole melanoma (FAMMM) syndrome, multiple primary melanomas and early age of onset, all known to be associated with germline *CDKN2A/CDK4* pathogenic variants, suggest that individuals with melanoma who carry germline alterations are rare. We studied the overall prevalence of germline cancer predisposition in a large prospective oncologic cohort with comparison to other defined cohorts of individuals with melanoma with available germline data. **Methods:** Individuals who presented to medical oncology clinic with a diagnosis of melanoma and personal or family history of multiple cancers were offered germline testing with a commercially available next generation sequencing panel (Invitae, San Francisco, CA). Eligibility criteria required ≥ 2 melanomas in an individual or family; melanoma and other cancer(s) in an individual; melanoma and at least 2 other cancers in 1st- or 2nd-degree relatives; age ≤35 at diagnosis; or limited family structure. Comparative analysis of germline NGS data from 3 additional selected and non-selected melanoma datasets was performed. **Results:** In a cohort of 400 oncology patients with melanoma who consented to commercial germline testing of 85 cancer-associated genes, a germline pathogenic/likely pathogenic (gP/LP) positive rate of 15.3% (n = 61) was observed. Genes previously associated with inherited melanoma (*BAP1, BRCA1/2, CDKN2A, MITF, TP53*) comprised less than one-third of gP/LP variants (20, 32.7%); the majority of germline variants were in cancer predisposition genes not traditionally associated with melanoma (e.g. *BRIP1, CHEK2, MSH2, PMS2, MLH1, RAD51C, BLM*). Family history of non-cutaneous cancer (42, 69%) and personal history of melanoma with ≥ 1 non-cutaneous cancer (22, 36%) were the most common eligibility criteria met in gP/LP variant carriers. Analysis of germline data from other large oncologic and dermatologic melanoma datasets yielded gP/LP variant positive rates of 10.6% in an unselected oncologic melanoma cohort (TCGA, n = 470), 15.8% in a selected commercial testing cohort (Invitae, n = 12,571), and 14.5% in a highly selected, primarily dermatologic subset (Boston-Athens, n = 289). **Conclusions:** In oncologic and dermatologic cohorts, germline testing of selected individuals with melanoma yields rates of clinically impactful P/LP variant detection which exceed consensus standards for pretest probability. Most P/LP variants were found in genes associated with non-cutaneous cancers. Obtaining a family and personal history of cancer, particularly non-cutaneous cancers, and referring for broad panel-based germline testing in all individuals with melanoma are recommended. Research Sponsor: Gross Family Melanoma Registry.

Increase in incidence of advanced-stage breast cancer in Asian women versus White women: Can this be explained by the lower utilization of mammograms? *First Author: Cheng-I Liao, Department of Obstetrics and Gynecology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan*

Background: To examine trends in postmenopausal breast cancer and mammogram utilization in Asian and White women in the United States. **Methods:** Data on postmenopausal breast cancer was obtained from the United States Cancer Statistics Public Use Database from 2001 and 2018. Rates of mammogram screening for women ages 18 and older were evaluated using the Behavioral Risk Factor Surveillance System (BRFSS) between 2000 and 2018. Obesity rates for women ages 18 and older were extracted from BRFSS between 2001 and 2016. SEER*Stat 8.3.8 and Joinpoint regression program 4.8.0.1 were used to calculate incidence trends. Breast cancer incidence and trends were described using average annual percent change (AAPC). Mammogram screening trends were described using average biennial percent change (ABPC). Obesity trends were described using AAPC. Age groups were divided into five-year or ten-year intervals. **Results:** The incidence of metastatic postmenopausal breast cancer in women was 19.48/100,000 in 2018 has increased by 1.03% annually over the past eighteen years (p = 0.000). In 2018, the incidence of advanced-stage breast cancer in Asian and White women was 12.17/100,000 and 19.17/100,000 respectively. Over time, the incidence of advanced-stage breast cancer has increased in Asian women by 2.19% annually (p = 0.000), but remained stable in White women. In a subset analysis of early-stage breast cancer, there was no difference in both Asian and White women. Using the BRFSS data, we evaluated the utilization of mammograms. In the overall population, 20.92% were newer screened and this was higher in Asian women at 40.99% compared to 18.17% in White women in the year 2018. Given the potential association of obesity and breast cancer, we then evaluated the rate of obesity in these two groups. Our data showed that the incidence of obesity was low in Asian women at 12.8% compared to 28.13% in White women. **Conclusions:** There is an increased incidence of advanced-stage breast cancer in Asian women in the U.S. Although Asian women are less obese but they are also less likely to undergo screening compared to White women. Research Sponsor: None.

Simulation modeling as a tool to support clinical guidelines and care for breast cancer prevention and early detection in high-risk women. *First Author: Jinani Jayasekera, Lombardi Cancer Center MedStar Georgetown University Hospital, Washington, DC*

Background: To evaluate the incremental short- and long-term benefits and harms of primary prevention with risk reducing medication in high-risk women receiving screening mammography. **Methods:** We adapted an established, validated Cancer Intervention and Surveillance Modeling Network (CISNET) breast cancer discrete event microsimulation model developed to synthesize data the impact of using risk-reducing medication and annual mammography among women with a 3% or higher five-year risk of developing breast cancer. We also examined the effects of supplemental MRI. The model follows a simulated cohort of millions of US women from birth to death. We used large observational and clinical trial data to derive input parameters for cohort-specific birth rates, breast cancer risk, incidence and stage, screening performance, survival by age, stage, and subtype, treatment efficacy, and other cause mortality. Breast cancer risk was modeled based on family history, breast density, age and history of past breast biopsy. We compared two strategies, annual 3D mammography alone vs. annual 3D mammography and a 5-year course of risk reducing medication at various starting ages, and adding MRI to each approach. Outcomes included the benefits of risk-reducing drugs (avoiding breast cancer) and screening (stage, breast cancer death). Harms included drug side effects and screening false positives and overdiagnosis. Sensitivity analysis tested the impact of uncertainty in model inputs and assumptions on results. **Results:** Compared to mammography alone, adding risk reducing medication could decrease invasive breast cancer incidence by 30%, and breast cancer deaths by 30% (Table). However, due to reduction in breast cancer incidence, risk reducing medication could result in a 3% increase in false positive results; adding MRI increases benefits but also increases false-positive results. Benefits and harms of risk reducing medication and breast cancer screening strategies for women at high-risk of developing breast cancer. **Conclusions:** Risk-reducing mediation reduces the risk of hormone-receptor positive breast cancer, and combining this with mammography (and/or MRI) improves earlier detection. Additional work is ongoing to incorporate adverse effects of therapy. Simulation modeling can be used to provide individualized data to facilitate discussions about breast cancer prevention and early detection among high-risk women seen in clinical practice. Research Sponsor: U.S. National Institutes of Health.

	Strategy		
Screening Outcomes Per 100,000 Women Screened	Annual 3D Mammography Screening	Annual 3D Mammography Screening + 5-years of Risk Reducing medication	% Incremental Effects of Risk Reducing Medication
Invasive breast cancer incidence	518	365	30% decrease
De-novo Stage IV diagnosis	15	11	27% decrease
Breast cancer deaths	109	76	30% decrease
False positives	6927	7145	3% increase
Overdiagnosis	33	34	-

10526 **Poster Session**

Characterization of time to diagnosis indicates shorter interval for screenable versus symptom-driven cancers. *First Author: Vladimir Gainullin, Exact Sciences Corporation, Madison, WI*

Background: Cancer screening provides a straightforward diagnostic path compared to non-screening, which often requires complex evaluation for patients with non-specific symptoms. The time to diagnosis (from clinical presentation or screening event to definitive diagnosis) captures the clinical efficiency of the journey. The study characterizes time to diagnosis for cancers with and without USPSTF Grade A/B screening recommendations. This could inform the value of screening in diagnostic management and care efficiency improvements. **Methods:** The Geisinger Health System Phenomics Initiative Database provides deidentified EHR and tumor registry data. Patients aged 50-74 with encounters at least biennially for six years prior to a cancer diagnosis were frequency-matched to a non-cancer control group by diagnosis year. From 18 months prior to diagnosis, equally-sized random samples were drawn (with replacement) from a time-bounded sliding window at monthly intervals. Aggregated procedure and diagnostic code counts for cancer and non-cancer samples were used to calculate the Bray-Curtis dissimilarity (BCd) statistic. The start of the diagnostic path was defined as the earliest date with a monotonically-increasing statistically-significant difference in BCd (95% CI), and was stratified into cancers with and without screening and by stage. **Results:** 8188 new cancer cases were identified between 2010-2019; 40% had an established screening modality (breast, lung, colorectal, cervical), 55% of which were screened prior to diagnosis. The time to diagnosis for non-screenable cancers was 6 months versus 3 months for screenable cancers. The BCd for procedures differed by 0.029 (95% CI: 0.021-0.037) between the two groups at 6 months prior to diagnosis. Stages I and IV had a time to diagnosis of 3 months across all cancers versus 7 and 6 months for stages II and III, respectively. **Conclusions:** We report the first known quantification of time to diagnosis across multiple cancers. Screenable cancers were associated with shorter time to diagnosis than non-screenable cancers. Stage II and III cancers took longer to diagnose than stage I and IV, likely related to early detection by screening in the former and severe symptom presentation in the latter. These novel data highlight improved time to diagnosis as another achievable benefit from expanded, multi-cancer screening. Research Sponsor: Exact Sciences.

Renal cell carcinoma in renal transplant recipients: Is there a role for screening? *First Author: Binoy Yohannan, U. Texas Medical School, Houston, TX*

Background: Renal transplant (RT) recipients are at an increased risk of developing renal cell carcinoma (RCC), mainly due to iatrogenic immunosuppression and changes in immune surveillance. Most RCCs in RT recipients arises from the native kidney, but rarely may arise from the allograft. RCC post-RT can adversely affect allograft function and long-term survival. Screening for RCC in RT recipients is controversial and is not routinely done. **Methods:** We performed a retrospective chart review of RT recipients who underwent transplantation between January 1, 1999, and December 31, 2019. The following data were collected: Baseline demographic variables, cause of end-stage renal disease (ESRD), duration of dialysis prior to RT, type of RT (cadaveric vs. living donor), immunosuppressive regimen, site of RCC (native kidney vs transplanted kidney), time from RT to diagnosis of RCC, stage and Fuhrman grade, tumor histology, RCC treatment, and RCC-related mortality. RCC stage at diagnosis and survival were compared between patients who were screened versus those who were not. **Results:** Among 1998 RT recipients who underwent transplantation at Memorial Hermann Hospital (MHH) Texas Medical Center (TMC); 16 patients (0.8%) developed RCC. An additional 4 patients with RCC who underwent RT elsewhere but received follow up at MHH TMC were also included. Therefore, a total of 20 patients with post-RT RCC were identified, of whom 75% were men. Subject races included White (20%), Black (50%), Hispanic (20%), and Asian (10%). The median age was 56 years. Median duration of dialysis prior to RT was 36 months (range, 1–120). Median time to RCC diagnosis post-RT was 96 months (range, 16–312). Histologies included clear cell (75%), papillary (20%), and chromophobe (5%) RCC. RCC developed in the native kidney in 60% and in the allograft in 40% of the patients. Post-RT RCC patients were divided into those who underwent regular screening (n = 12) and no screening (n = 8). The regular screening group (n = 12) underwent ultrasound or computerized tomography annually or every 2 years. All of these patients had early-stage disease at presentation: stage I (n = 11) or II (n = 1). All patients who had RCC detected by screening were cured by nephrectomy (n = 10) or cryotherapy (n = 2). In patients who had no screening post RT, 37.5% had stage I, 25% had stage III, and 37.5% had stage IV RCC. Two patients with stage IV RCC died from metastatic disease. The RCC-related mortality was 0% in patients who were screened, compared to 25% in patients who had no screening. **Conclusions**: All RT recipients who had RCC diagnosed based on screening had an early diagnosis and no RCC-related mortality. Screening for RCC in RT recipients is an effective tool for early diagnosis and to reduce RCC-related mortality. Further research into the cost-effectiveness of screening is imperative. Comparison of simulated outcomes between stool- and blood-based colorectal cancer screening tests. *First Author: A. Fendrick, University of Michigan, Ann Arbor, MI*

Background: The Centers for Medicare & Medicaid Services (CMS) recommends covering blood-based biomarker tests with proposed minimum performance thresholds for colorectal cancer (CRC) screening test every 3 years for average-risk, asymptomatic Medicare beneficiaries ages 50–85 years. A blood-based test is a non-invasive screening method to detect CRC but is limited by low sensitivity to detect adenomas. Using the CRC-AIM microsimulation model, predicted life-years gained (LYG) and CRC incidence and mortality reduction were compared between a blood-based test meeting the CMS minimum thresholds and stool-based screening tests (fecal immunochemical test [FIT], fecal occult blood test [FOBT], and multitarget stool DNA [mt-sDNA]). **Methods:** Outcomes of blood- and stool-based tests were simulated for average-risk individuals free of diagnosed CRC at age 40 and screened between ages 45–75 years per USPSTF recommendations. Per CMS proposed criteria, CRC sensitivity and specificity for a blood-based test were set at 74% and 90%, respectively, and adenoma sensitivity was set at 10%. Published adenoma and CRC sensitivity and specificity were used for each stool test. For the primary analysis, adherence was assumed to be 100%. For secondary analysis, adherence was set at 30–70%, in 10% increments. Outcomes were per 1000 individuals. **Results:** At 100% adherence, LYG was 229 for a blood test and ≥305 for stool tests, corresponding to at least 25% lower LYG for a blood test relative to all stool tests (Table). Absolute CRC incidence and mortality reductions were at least 19% and 18% lower, respectively, for a blood test vs all stool tests. Secondary analysis indicates that at identical adherence rates that are less than 100%, a blood test had lower LYG vs all stool tests (Table). When the adherence of any test was 50%–70%, a blood test resulted in at least 20% lower LYG vs any stool test, and absolute reductions in CRC incidence and mortality were at least 9% and 10% lower, respectively, vs any stool test. **Conclusions:** This model suggests that if blood-based CRC screening tests do not sufficiently detect advanced adenomas, clinical outcomes will be inferior to stool-based testing due to lack of cancer prevention. Further discovery efforts to identify blood-based markers associated with both invasive and preinvasive neoplasia are needed to address this deficiency. Research Sponsor: Exact Sciences Corporation.

LYG with each screening modality and differing adherence rates.

Adherence	Annual FIT	Annual FOBT	Triennial mt-sDNA	Triennial blood test
100%	332	305	312	229
70%	308	273	299	210
60%	295	257	292	200
50%	277	234	282	187
40%	252	207	270	172
30%	218	171	248	150

Lung cancer risk prediction nomogram in Chinese female non-smokers. *First Author: Guo Lan-Wei, The Affiliated Cancer Hospital of Zhengzhou University, Henan Cancer Hospital, Zhengzhou, China*

Background: About 53% of lung cancers in females are not attributable to smoking worldwide. The aim was to develop and validate a simple and non-invasive model which could assess and stratify lung cancer risk in female non-smokers in China. **Methods:** A large-sample size, population-based study was conducted under the framework of a population-based Cancer Screening Program in Urban China (CanSPUC). Data on the lung cancer screening in Henan province, China, from October 2013 to October 2019 were used and randomly divided into the training and validation sets. Related risk factors were identified through multivariable Cox regression analysis, followed by establishment of risk prediction nomogram. Discrimination [area under the curve (AUC)] and calibration were further performed to assess the validation of risk prediction nomogram in the training set, and then validated by the validation set. **Results:** A total of 151,834 eligible subjects were included, with a mean age of 55.34 years. Subjects were randomly divided into the training (75,917) and validation (75,917) sets. Elder age, history of chronic respiratory disease, first-degree family history of lung cancer, menopause, and history of benign breast disease were the independent risk factors for lung cancer. Using these five variables, we plotted 1-year, 3-year, and 5-year lung cancer risk prediction nomogram. The AUC was 0.762, 0.718, and 0.703 for the 1-, 3- and 5-year lung cancer risk in the training set, respectively. In the validation set, the model showed a good predictive discrimination, with the AUC was 0.646, 0.658, and 0.650 for the 1-, 3- and 5-year lung cancer risk. **Conclusions:** We developed and validated a simple and non-invasive lung cancer risk model in female non-smokers. This model can be applied to identify and triage patients at high risk for developing lung cancers in female non-smokers. Research Sponsor: None.

Designing a decision aid for cancer prevention. *First Author: Shakira R Milton, Centre for Cancer Research, The University of Melbourne, Melbourne, VIC, Australia*

Background: Australian guidelines recommend those aged 50 to 70-years-old without contraindications, consider taking low-dose aspirin (100 mg – 300 mg per day) for at least 2.5 years to reduce their risk of colorectal cancer. To increase uptake of the new guidelines, we hypothesized that a decision aid (DA) would help facilitate a discussion between clinicians and patients about aspirin chemoprevention. We aimed to design a DA with clinician and consumer input including state-of-the-art expected frequency trees (EFTs). We aimed to explore clinicians' opinions about using EFTs with their patients during consultations and gain consumers feedback on DAs including their understanding and their hypothetical decision to take aspirin or not. **Methods:** Semi-structured interviews were conducted with relevant clinicians including familial cancer clinic staff (geneticists, oncologists and genetic counsellors), gastroenterologists, pharmacists, and general practitioners (GPs). Focus groups were conducted with consumers in the target age range of the guidelines. DAs were developed through an iterative process. The clinician and focus group interview schedules covered ease of comprehension, design, potential effects on decision making, and approaches to implementation of the DA. Coding was inductive and the focus group interviews were independently coded by two researchers. Themes were developed through consensus between the authors. Final versions of the DAs were proposed to consumers for their final approval after all changes were made. **Results:** Sixty-four interviews were completed with clinicians between March and October 2019. Twelve consumers, aged 50 to 70 years, participated in two focus groups in February and March 2020. The clinicians agreed that the EFTs would be helpful to facilitate a discussion with patients but suggested including an additional estimate of the effects of aspirin on all-cause mortality. Clinicians agreed that patients would benefit from being shown the EFT in a consultation. The consumers felt favorable about the DA, especially if used with a clinician, and suggested some additional changes to the design and wording to improve ease of comprehension. **Conclusions:** We have designed a DA using novel approaches to communicate risks and benefits of low dose aspirin for cancer and cardiovascular disease prevention. The DAs are currently being trialled in the SITA trial in general practice to determine its impact on informed decision-making and aspirin uptake. Robust artificial intelligence-powered imaging biomarker based on mammography for risk prediction of breast cancer. *First Author: Eun Kyung Park, Lunit Inc., Seoul, South Korea*

Background: Accurate risk assessment allows the precise personalized screening of breast cancer. Conventional statistical risk models have been used that estimate the probability of breast cancer incidence with patient demographics, detailed personal and family history. The purpose of this study was to investigate the feasibility of the AI-powered Imaging Biomarker in mammography (IBM) which was developed to predict the risk of future breast cancer beyond the mammographic breast density. **Methods:** We trained and developed the deep learning risk model, the AI-powered IBM, using a total of 36,955 examinations from 21,438 patients, who underwent at least one mammogram using Hologic or Siemens machines and pathology-confirmed breast cancer outcomes. To discover the feasibility of the AI-powered IBM, mammograms and various clinical information including pathology-confirmed breast cancer outcomes were collected, which were only used for external validation. C-indices and receiver operating characteristic (ROC) curves for 1- to 5-year outcomes were obtained. We compared 5-year ROC area under the curves (AUCs) of our AI-powered IBM and statistical risk models including the Tyrer-Cuzick model and the Gail model, which were most commonly used and widely known, using DeLong's test. **Results:** A total of 16,894 mammograms were collected for external validation, of which 4,002 were followed by a cancer diagnosis within 5 years. Our AI-powered IBM obtained C-index of 0.758, and the model demonstrated the risk of breast cancer with AUC of 0.895 (95% CI: 0.880, 0.909) at 1-year, 0.839 (0.824, 0.852) at 2-year, 0.807 (0.794, 0.819) at 3-year, 0.783 (0.7947, 0.819) at 4-year. The 5-year AUC of our AI-powered IBM was 0.808 (0.792, 0.822). Our AI-powered IBM showed significantly higher 5-year AUC than the Gail model (AUC: 0.572, $P< 0.001$) and the Tyrer-Cuzick model (0.569, $P< 0.001$). **Conclusions:** A deep learning AI-powered IBM using mammograms has a substantial potential to advance toward the robust risk prediction of breast cancer over conventional risk models. This approach for risk stratification of breast cancer might be feasible to improve personalized screening programs. Research Sponsor: Lunit Inc.

Factors associated with the decreasing rate of oropharyngeal cancer in young adults in the United States. *First Author: John K Chan, Palo Alto Medical Foundation, Palo Alto, CA*

Background: To evaluate trends of HPV-associated oropharyngeal cancers and HPV infections in the United States. **Methods:** Data was extracted from the United States Cancer Statistics Public Use Database (USCS) between 2001 and 2017 and the National Health and Nutrition Examination Survey (NHANES) between 2011 to 2016. Data on oropharyngeal squamous cell carcinoma (OSCC) was obtained from the USCS database. HPV vaccination and screening (oral washings) data were obtained from NHANES. Based on CDC guidelines, HPV strains were further subdivided into high-risk strains (16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66 and 68). **Results:** Based on USCS, oropharyngeal cancer incidence rates have increased in males by 1.64% every year ($p < 0.001$) while remaining stable in females over the last 17 years. Oropharyngeal cancers have increased for all age groups over the age of 55, with the largest increase seen in those between the ages of 65-69 years old ($p < 0.001$). However, individuals between the ages of 30-34 had the largest decrease in oropharyngeal cancers over the same time period ($p = 0.016$). Based on race, Whites had the highest incidence rates at 5.12/100,000 followed by 2.99 in Blacks, 2.32 in Hispanics, and 1.11 in Asians. By geographical region, the incidence was found to be the highest in the Midwest with 4.68/100,000 and the lowest in the West at 3.78. Our intersectional analysis showed that White males in the South aged 65-69 had the highest incidence of oropharyngeal cancers at 40.57/100,000 and this same group aged 60-64 had the highest annual increase at 4.65% ($p < 0.001$). Using the NHANES database, we showed that those with greater than 4 lifetime sexual partners have a 3-fold higher risk of high risk HPV infection compared to those with 4 or under (7.1% vs 1.9%, $p < 0.0001$). 8.8% of current smokers are infected with high risk oral HPV compared to only 3.9% of non smokers ($p < 0.001$). The incidence of any HPV infection for those <39 years old was 5.9% in 2011 and 4.7% in 2016 ($p = 0.4723$). In contrast, the incidence in those > 39 years old was 6.6% in 2011 and 6.4% in 2016 ($p = 0.99$). On multivariate analysis, males have a 4-fold higher risk of high risk HPV infections compared to females (4.45, 95% CI: 2.94 - 6.74, $p < 0.0001$). Those with five or more sexual partners have 7-fold higher rate of high risk oral HPV infections compared to those without any sexual partners (7.15, 95% CI: 1.94 - 26.3, $p = 0.0039$). Furthermore, current smokers (1.81, 95% CI: 1.17 - 2.77, $p = 0.0081$) and three to four drinks per day (1.63, 95% CI: 1.05 - 2.55, $p = 0.0312$) have an increased risk of high risk oral HPV infections. **Conclusions:** Over the last 18 years, oropharyngeal cancers are increasing in individuals over the age of 55, particularly White males residing in the South. Individuals with greater than 4 lifetime sexual partners, current smokers, and those who consume three to four drinks per day have increased HPV infectivity rates. Research Sponsor: None.

The role of health information technology in improving awareness of HPV and HPV vaccine among U.S. adults: Insights from the health information national trends survey. *First Author: Gideon T Dosunmu, University of South Alabama Medical Center, Mobile, AL*

Background: Despite advances in cancer prevention and wide-spread availability of Human papilloma virus (HPV) vaccines, US adults continue to have suboptimal HPV vaccination uptake with less than 50% vaccinated. Strategies aimed at enhancing HPV-related awareness are considered one of the most effective ways to improve HPV vaccine adoption and potentially eliminate HPV-related cancers. Health information technology (HIT) may influence HPV-related awareness and subsequently drive vaccine adoption. This study assessed the impact of HIT utilization on HPV and HPV vaccine awareness. **Methods:** Data was obtained from Health Information National Trends Survey (HINTS 5 cycles 1 and 2). Cross-sectional sample of 6,522 individuals aged 18 years or more was analyzed. The independent variables were use of smartphone, computer, or electronic means to (i) look up health information, (ii) fill a prescription online, (iii) communicate with a doctor or doctor's office, (iv) look up test results of and (v) track health care charges. The dependent variables were HPV and HPV vaccine awareness. Chi-square analysis was used to evaluate group differences, and a multiple logistic regression was used to analyze the association between HIT utilization and HPV-related awareness controlling for sociodemographic and health-related factors. **Results:** Of the total sample, awareness of HPV and HPV vaccine was 62.7% and 61.8% respectively. In adjusted multivariable logistic regression analysis, those who utilized a smartphone, computer, or electronic means to look up health information (aOR 2.23; 95% CI 1.68 – 2.97, $p < 0.001$), communicate with healthcare provider (aOR 1.53; 95% CI 1.23 – 1.91, $p < 0.001$), look up test results (aOR 1.67; 95% CI 1.35 – 2.08, $p < 0.001$), and track health care charges (aOR 1.61; 95% CI 1.26 – 2.05, $p < 0.001$), were more likely to endorse HPV awareness than those who did not. Similar positive associations were observed for HIT utilization and HPV vaccine awareness. **Conclusions:** Our findings showed a positive association between HIT utilization and HPV-related awareness. Amid a background of sub-optimal HPV vaccination and explosion in technology, these results emphasize the potential for the role of HIT in preventive medicine. Strategies that integrate HIT into vaccine interventions and communications should be encouraged as a medium to expand HPV awareness and vaccine coverage. Research Sponsor: None.

Cost-effectiveness of targeted genomic risk provision to prevent skin cancer: Results of a randomized trial. *First Author: Chi Kin Law, NHMRC Clinical Trials Centre, University Of Sydney, Camperdown, NSW, Australia*

Background: Many melanomas and keratinocyte cancers (KC) are preventable by reducing sun exposure and improving sun protection behaviors. Recent evidence indicates a melanoma prevention program involving personalized genomic risk information provision can reduce self-reported sunburns at 12 months in Australian adults with no history of melanoma. This was alongside genetic counselling and educational materials on skin cancer prevention and early detection. However, the economic impact of this approach was unclear. This study aimed to determine the cost-effectiveness of the program to prevent melanoma and KC. **Methods:** A decision-analytic Markov model was developed to simulate the lifetime cost-effectiveness of personalized genomic risk provision compared with standard prevention advice alone, from a health system perspective. We used data from the Melanoma Genomics Managing Your Risk Study Randomized Control Trial. Traditional risk was measured by a validated melanoma risk prediction model involving hair color, nevus density, history of non-melanoma skin cancer, family history of melanoma, level of sunbed sessions. Quality-adjusted life years (QALY) gained was the primary outcome measure used to estimate an incremental cost-effectiveness ratio (ICER). Both deterministic and probabilistic sensitivity analyses (PSA) were undertaken. **Results:** The cost of the genomic testing and risk counselling program was AUD$189 (USD$132) per participant. Genomic risk provision targeting high-traditional risk individuals was the most cost-effective lifetime strategy with an ICER of AUD$23,033 (USD$16,059) per QALY gained and an 80% probability of being cost-effective at a willingness-to-pay threshold of AUD$50,000, compared with standard preventive advice (Table). When genomic risk provision was extended to low-traditional risk groups the ICER was $43,746 (USD30,500) per QALY gained with a 45% probability of being cost-effective. **Conclusions:** Genomic risk provision targeted to individuals at high-traditional risk of melanoma is a cost-effective strategy for the prevention of melanoma and KCs. Long-term sustainability of the program's effect should be examined in future research. Clinical trial information: ACTRN12617000691347. Research Sponsor: Australian National Health and Medical Research Council.

Modelled strategies for comparison	Total lifetime costs (AUD)	Incremental costs (AUD)	QALYs	Incremental QALY	ICER	Probability of being cost-effective
Standard prevention advice alone	3507		19.194			
Genomic risk provision targeting high traditional-risk individuals	3586	79	19.198	0.004	23033	0.8024
Genomic risk provision targeting high traditional-risk individuals	3586		19.198

Increase in postmenopausal women with distant stage breast cancer in the United States over the last 18 years: Who is the most at risk? *First Author: Arya Aliabadi, Division of Gynecologic Oncology, Department of Obstetrics and Gynecology, University of California Los Angeles, Los Angeles, CA*

Background: In the United States, Asian women have traditionally been considered at low risk for breast cancer; yet it is unknown how distant stage disease has trended by geographic, demographic, and modifiable risk factors since 2001. **Methods:** Data were obtained from the United States Cancer Statistics (USCS) program from 2001-2018, the Behavioral Risk Factor Surveillance System (BRFSS) from 2000-2018. SEER*Stat 8.3.9.2 and the Joinpoint regression program 4.9.0.0 were used to calculate the incidences and trends of distant stage breast cancer per 100,000 women. The trend was presented as average annual or biennial percent change (AAPC or ABPC). **Results:** Using the USCS program, the overall incidence of postmenopausal breast cancer decreased from 367.90 to 345.07 (per 100,000); however, the incidence of distant stage cancer increased from 16.75 to 19.77 (per 100,000) over 18 years. The incidence is the highest for Black, followed by White, Hispanic, and Asian women at 27.14, 19.86, 14.15, and 11.98 (per 100,000) in 2018, respectively. The annual increase is highest in Asian, followed by Black, White, and Hispanic women at 2.28%, 1.44%, 1.17%, and 0.87% ($P < 0.001$), respectively. On intersection analysis, postmenopausal Asian women living in the Northeast have the highest annual rise at 2.54% ($P = 0.004$). BRFSS data revealed that the proportion of women non-compliant with screening mammograms decreased from 36.03% in 2000 to 20.93% in 2018. In 2018, Asian women were the most non-compliant followed by Hispanic, Black, and White women at 40.99%, 40.06%, 21.67%, and 18.17%, respectively. Over time, White, Black, and Hispanic women improved on compliance by 3.43%, 3.32%, and 1.24% ($p < 0.05$) on screening rates biennially; however, Asian women have not made any improvement (ABPC 0.80%, $p = 0.410$). On intersectional analysis, the most non-compliant group in 2018 were Asian women in the Midwest at 54.48%. We then evaluated upstream social determinants of breast cancer, such as obesity. While the baseline incidence of obesity in Asian Americans is low compared to other racial groups, it has increased from 9.22 in 2001 to 13.67 (per 100,000) in 2016. Specifically, the incidence of obesity increased the most in postmenopausal Asian 65 to 74-year-olds at 3% compared to White, Hispanic, and Black Americans of the same age group at 2.5%, 2.2%, and 1.1% ($p < 0.05$), respectively. **Conclusions:** Although the incidence of breast cancer has decreased in the United States since 2001, the rate of distant stage breast cancer continues to rise. Postmenopausal Asian women with distant stage breast cancer are increasing at the highest rate compared to other racial groups. Further, Asian women are more non-compliant with screening mammograms and have an increased rate of obesity. Tailored interventions are warranted to enhance primary and secondary prevention and decrease distant stage cancer in this high-risk group. Research Sponsor: None.

Awareness of the link between HPV, cervical cancer, and HPV vaccination: An online survey among Polish women. *First Author: Artur Kotowski, Polish Association for Good Clinical Practice GCPpl, Warsaw, Poland*

Background: In 2019 cervical cancer (CC) was the 7th most common malignant neoplasm in Polish women. Its incidence has been declining over the years, nonetheless the 5-year survival rate is still significantly lower than the EU average. Vaccination against human papillomavirus (HPV) is not included in the mandatory immunization schedule in Poland and is not reimbursed yet. The aim of the study was to assess women's awareness of the risk factors of CC (including the role of HPV) and the possibility of cancer prevention through HPV vaccination. **Methods:** The questionnaire prepared by the study team was aimed at women and conducted online using social network sites. The single/multiple-choice questions included knowledge about CC, HPV and HPV vaccination. Statistical analyses were performed using MS Excel 2016 and Medistica pvalue.io 2021 software in general population and age- dependent subgroups. **Results:** The total number of 3262 women participated in the study. The age subgroups were: aged ≤ 18 years (group 1): 1090 (33.4%), aged 19-25 years (group 2): 1615 (49.5%) and > 25 years (group 3): 557 (17.1%). Overall 81.4% of the respondents correctly associated HPV as the key factor of CC, 85.0% believed that CC could be prevented and 80.0% had heard of HPV vaccination before. In the last two parameters a statistically significant difference in age subgroups was observed ($p < 0.001$). Only 21.2% of the total number of respondents were vaccinated (26.2%, 22.0% and 9.2% in age groups 1, 2 and 3 respectively, $p < 0.001$). In all studied populations the following factors had the greatest influence on the decision to get vaccinated: parents' advice – 54.8%, pediatrician recommendation – 15.7%, possibility of free vaccination offered by municipality – 11.6%, teachers' advice - 9.7%, gynecologist recommendation - 8.2%. The main reasons behind not getting vaccinated were: high price (63.0%) and disbelief in efficacy (41.5%); only 12.2% respondents were afraid of possible side effects. 65.0% of the unvaccinated respondents declared willingness to get vaccinated in the future (71.5%, 66.1% and 52.0% in age groups 1, 2 and 3 respectively $p < 0.001$), 28.5% of the respondents were not confident of their decision at the time of submitting answers. **Conclusions:** As oncogenic types of human papillomavirus play a vital role in pathogenesis of CC, the HPV vaccination and cytological screening together with awareness-raising campaigns should be considered the best strategy for the prevention of CC, its early detection and increase in survival rates. Vaccine willingness remains at high level especially among young women, however the effectiveness of vaccination should be emphasized and the HPV free vaccination programs should be introduced by the state. The educational role of gynecologists needs to be enhanced. Research Sponsor: None.

At-risk patient and healthcare provider perspectives on clinical trial participation for ductal carcinoma in situ. *First Author: Elizabeth J. Adams, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Significant challenges exist in recruiting newly diagnosed ductal carcinoma in situ (DCIS) patients to participate in presurgical intervention trials. Perceived motivators and barriers to participation have not been formally studied from the patient or healthcare provider (HCP) perspective. Based on our experience in the Promise Study (NCT02694809), we hypothesized that delaying surgery and concern for side effects are barriers to trial participation and that access to new treatments and financial benefits are motivators. To improve recruitment, we conducted focus groups to better understand barriers and motivators for trial participation in our patient population. **Methods:** Three focus groups with post-menopausal women (PMW) without history of DCIS, one focus group with patients previously treated for DCIS, and two HCP focus groups were conducted. Due to COVID-19, the focus groups took place online via videoconferencing and included participants from across the United States. A third-party facilitator generated discussion on predetermined topics including knowledge of DCIS, clinical trial recruitment materials, hormone replacement therapy, healthcare delivery and clinical trials during COVID-19, and perceived motivators and barriers to trial participation in general and specifically for women with DCIS. Here, we focus on comparing perceived influential factors for patient participation in DCIS clinical trials in PMW and HCP focus groups. Qualitative thematic analysis was completed on focus group transcripts in NVivo. **Results:** PMW had no knowledge of DCIS prior to the focus groups and believed DCIS should be removed promptly. PMW believed barriers to DCIS clinical trial participation included the potential for the study drug to cause harm, distrust of medicine, and the fact that DCIS is not life-threatening. PMW identified helping future DCIS patients, accessing better treatment, and easing anxiety as motivators for DCIS trial participation. HCPs believed patients were motivated by increased monitoring by the medical team, financial incentive, and access to newer treatment. HCPs believed that delays in DCIS surgery, the potential for the intervention to be harmful or ineffective, and the trial causing patient anxiety were barriers. Neither group emphasized time commitment as a barrier to DCIS trial participation. PMW were not motivated by financial incentives. **Conclusions:** Knowledge about DCIS is lacking in PMW. PMW and HCPs agreed that the risk of harm caused by study interventions is a deterrent to trial participation and that access to superior treatment is a motivator. However, PMW and HCPs did not agree on other motivators and barriers which could lead to missed recruitment opportunities. Providing educational materials on DCIS and addressing motivators and barriers to clinical trial participation may increase recruitment to presurgical DCIS trials. Clinical trial information: NCT02694809. Research Sponsor: U.S. National Institutes of Health.

Cross-ancestry polygenic risk score for breast cancer risk assessment. *First Author: Placede Tshiaba, MyOme, Inc, Menlo Park, CA*

Background: Breast cancer (BC) risk is influenced by many common variants with small effects. Polygenic risk scores (PRS) weight these variants based on genome-wide association studies (GWAS) and aggregate them into a single measure. PRS has primarily shown benefit in Caucasian women. We established a cross-ancestry polygenic model (caPRS) which assesses risk of breast cancer across multiple ancestries. **Methods**: Performance of multiple BC polygenic models, both published and developed in-house, were evaluated for each of five ancestry groups: European, African, South Asian, East Asian, and Admixed American. To account for ancestry-specific mean and variance, we computed principal components (PCs) for all women by projecting their genotypes onto PCs calculated on individuals in the 1000 Genomes Project (1KGP). We next centered each ancestry-specific PRS by subtracting the PRS predicted from a linear regression of PRS against the first four PCs in unaffected individuals. Each centered PRS was then divided by the SD of the corresponding 1KGP population. We defined a cross-ancestry polygenic model as a linear combination of the best performing PRS model for each ancestry group weighted by fractional ancestry. Association of the caPRS with breast cancer risk was tested in a validation cohort of >130,000 women consisting of multiple independent cohorts (the Women's Health Initiative, the Multiethnic Cohort, the ROOT cohort and the UK Biobank) using a multivariate logistic regression model that included caPRS, age, self-reported ancestry, personal history of ovarian cancer (when available) and first-degree family history of BC. Discrimination was assessed by the odds ratio (OR) per SD and the area under the receiver-operator curve (AUC). **Results**: This study included women with African/Black, East Asian, Caucasian/White, Hispanic/Latino, South Asian and 'Other' self-reported ancestry. The ancestry-specific models included in the caPRS ranged in size from 173 to >800,000 variants. The caPRS was associated with BC risk for women in each self-reported ancestry (Table). The caPRS offered a modest increase in performance over a commonly implemented 313-SNP PRS in non-European ancestries, most significantly in African/Black women where the OR per SD increased from 1.24 (1.08 - 1.43), p-value 2.3x10-3. **Conclusions**: The caPRS performed well for women of any ancestry and allows flexibility to update ancestry-specific models. These results suggest the caPRS has the potential to improve the clinical utility of existing clinical risk predictors. Research Sponsor: None.

Self-reported ancestry	Ntotal	Ncases	AUC	OR per SD (95% CI)	p-value
Caucasian/White	104,312	7,133	0.70	1.66 (1.62-1.70)	<10-324
African/Black	7,883	233	0.63	1.30 (1.14 - 1.48)	1.3 x 10-4
Hispanic/Latino	1,051	519	0.63	1.59 (1.39 - 1.82)	4.7 x 10-13
East Asian	1,690	879	0.61	1.44 (1.31 - 1.59)	6.9 x 10-14
South Asian	1,251	46	0.70	1.49 (1.10 - 2.02)	0.010

Multiomic approach to examining gut microbiome sampling methods in breast cancer and control subjects. *First Author: Christina Ann Nowicki, Rush University, Chicago, IL*

Background: It is well known that estrogen exposure is a major risk factor for breast cancer (BC). Estrogen levels can be affected by the gut microbiome through enterohepatic circulation. No studies regarding gut microbiome changes in BC have examined the colonic mucosal microbiome; and there is no data on which types of gut microbiome studies would be most relevant to the study of the microbiome in BC. **Methods**: We examined differences in the gut microbiome composition in BC and control subjects using the following sample types: Home-collected stool, endoscopically collected stool, and colonic biopsy samples (for all groups, n=48 total, n=24 BC, n=24 controls). Here, we used both operational taxonomic unit (OTU) and amplicon sequence variant (ASV) based approaches in QIIME2 for 16S rDNA sequencing analysis. Alpha diversity metrics (Chao1, Pielou's Evenness, Faith PD, Shannon, and Simpson) and beta diversity metrics (Bray-Curtis, Weighted and Unweighted Unifrac) were calculated. LefSe was used to analyze differences in the abundance of various taxa between sample types. **Results:** Alpha and beta diversity metrics were different between the three sample types when using both OTU or ASV-based analysis, however there were some minor differences between analysis types in these samples. Comparing the 3 sample types, Actinobacteria and Firmicutes (Log10 LDA score >4) were the predominant phyla in home stool samples, while Bacteroidetes and Proteobacteria (Log10 LDA score >4) were higher in abundance in the colonic biopsy samples. **Conclusions:** Our data shows that alpha and beta diversity metrics differ between sampling methods (home-collected stool, endoscopically collected stool, and colonic biopsies) when looking at the composition of the gut microbiome in BC. Results remained the same regardless of ASV or OTU-based analysis. Research Sponsor: U.S. National Institutes of Health.

Alpha and beta diversity metric p-values for home-collected stool, endoscopically-collected stool, and colonic biopsies using ASV and OTU-clustering approaches.

Beta Diversity	ASV (DADA2)	OTU (De novo 99%)	OTU (De novo 97%)	OTU (Open Reference 99%)	OTU (Open Reference 97%)	OTU (Normalized Open Reference 97%)

A novel NGS kit solution for multi-cancer early detection using circulating cell free DNA based methylation analysis. *First Author: Grace Q. Zhao, AccuraGen, Menlo Park, CA*

Background: Cancer patient survival can be greatly improved by early detection. Cell-free DNA (cfDNA)-based cancer detection using targeted methylation sequencing (TMS) holds great promise. Here, we report the performance of the first cfDNA TMS kit for early cancer detection. **Methods:** We developed a comprehensive multi-cancer TMS panel, named "Omni1" (900kb) containing ~3000 cancer specific hypermethylation markers for the detection of the 16 most prevalent solid tumor cancer types in the US. These selected biomarkers all have high signals in cancer, low signals in normal tissue and close to zero background in plasma. The TMS analysis is empowered by Point-n-Seq DNA enrichment and soft bisulfite sequencing technology. Across the different cancer types, the Point-n-Seq Methylation Index (PMI) derived from the Omni1 panel showed over 10 times the difference in the genomic DNA of tumor compared to normal tissues. 8 to 32 early-stage plasma samples from each of the 7 most prevalent cancer types were used for assay testing. cfDNA extracted from each donor was subjected to our Point-n-Seq TMS analysis with the Omni1 panel. The TMS workflow took around five hours, from cfDNA to a sequencing ready library. 6M reads were assigned to each sample resulting in ~1400X average raw coverage across the target regions. **Results:** A computational model to calculate the methylation index and the thresholds were established on independent training data sets for each cancer type. For the testing, specificity was set at 89% (CI = 0.81, 0.97, n = 55 self-claimed healthy individuals). The detection rate for stage I (n = 55) and stage II (n = 56) of all 7 cancer types combined is 65% (CI = 0.53,0.78) and 75% (CI = 0.64, 0.86) respectively. Even within this small sample size, it was clear that the detection sensitivity varied among different cancer types, and it increased from stage I to II: colorectal (65%, n = 20; 75%, n = 12), lung (75% n = 8; 92%, n = 12), pancreas (80%, n = 10; 100%, n = 10), ovary (60%, n = 5; 80%, n = 5), breast (40%, n = 7; 100%, n = 3), and prostate cancer (0%, n = 2; 22% n = 9) for stage I and II respectively. A decrease in sensitivity from stage I to II in liver (100%, n = 3; 60%, n = 5) is possibly due to variability from the small sample size. For the cases of CRC, the detection rates obtained from Omni1 are comparable to the stand-alone CRC560 panel (170 kb). **Conclusions:** In this study we demonstrated that by leveraging an economy-size panel, a robust methylation sequencing kit, and a straightforward analysis methodology, early cancer detection for multiple cancer types can be done with just 1ml plasma. The kit strategy provides an easy-to-use and distributable solution, without the complications of developing a lab-specific test that uses a large methylation panel and a high sequencing cost. Trends in the incidence of early-onset invasive colorectal cancer between 1990 and 2018, stratified by race/ethnicity, gender, and anatomic sub-sites among Pennsylvania residents. *First Author: Inimfon Jackson, Albert Einstein Medical Center, Philadelphia, PA*

Background: Recent data report a rising incidence of colorectal cancer in the younger population and epidemiological evidence is useful to enable clinicians understand evolving trends and better counsel patients on the potential risks/benefits of early screening. We explored the trends in incidence of early-onset invasive colorectal cancer by race/ethnicity, gender, and anatomic sub-sites. **Methods:** Repeated cross-sectional analyses were conducted among adults < 50 years diagnosed with invasive colorectal cancer between 1990-2018 in Pennsylvania using data from the Pennsylvania Department of Health Cancer Registry. Temporal trends in invasive cancer with age adjusted incidence rates according to race/ethnicity, gender, and anatomical sub-sites were assessed using the Enterprise Data Dissemination Informatics Exchange (EDDIE). **Results:** 16,154 cases of early-onset invasive colorectal cancer were diagnosed between 1990 and 2018. There was an increased incidence of invasive colorectal cancer in the general population especially when stratified by gender, race/ethnicity and among those < 40 years of age. While rates among Whites nearly doubled from 5.4 per 100,000 (95% Confidence Interval (CI): 4.9–6.0 per 100,000) population to 9.0 per 100,000 (95% CI: 8.2– 9.7 per 100,000) population, the rates in the Black population have been decreasing in recent years from a peak of 10.4 per 100,000 (95% CI: 8.4–12.7 per 100,000) population in 2011 to 7.3 per 100,000 (95% CI: 5.7–9.3 per 100,000) population in 2018. However, the Hispanic rates have remained stable. Across anatomical subsites, the rectum, rectosigmoid and sigmoid colon were found to have rising trends in incidence rates over time. **Conclusions:** There is increased awareness on the need for early diagnosis of colorectal cancer in the young Black population. However, we found trends toward increasing incidence rates among Whites while rates in the Black population are now decreasing. These findings accentuate the need for quality provider-patient communication during primary care visits with a goal to improve adherence to the new colorectal cancer screening guidelines regardless of race/ethnicity. Clinical validation of a multicancer detection blood test by circulating cell-free DNA (cfDNA) methylation sequencing: The THUNDER study. *First Author: Qiang Gao, Liver Cancer Institute and Zhongshan Hospital, Fudan University, Shanghai, China*

Background: The development of ultra-sensitive genomic and epigenomic assays enables the early detection of multiple cancers in parallel. However, large-scale prospective clinical validation data are rare. Here, we report clinical validation data from the THUNDER (The Unintrusive Detection of EaRly-stage cancers, NCT04820868) study, which evaluates the performance of ELSA-seq among 6 cancer types in lung, colorectum, liver, esophagus, pancreas and ovary, which account for 50% of cancer morbidity and 62% of cancer mortality. **Methods:** This prospective case-control study consists of four stages: marker discovery, model training, validation, and independent validation. A customized panel covering 161,984 CpG sites was established using public data and in-house data. Cancer patients were pre-specified into the training and validation sets, and healthy controls (HC) were age-matched. Two multi-cancer detection blood test (MCDBT-1 and MCDBT-2) models with different cut-offs were established from the retrospectively collected training set and tested in the validation set. An independent validation set was enrolled prospectively, matched by age, and tested with the locked MCDBT-1/2 models. An interception model was then applied based on the model performance and China cancer incidence data to infer potential positive predictive value (PPV) and clinical utility in real-world practice. **Results:** In total, the training set consisted of 399 cases and 626 HC; the validation set consisted of 301 cases and 123 HC; and the independent validation set consisted of 505 cases and 505 HC. In the training set, the specificities were 98.9% (95% confidence interval [CI], 97.7%–99.5%) and 99.7% (98.8%–100.0%) for MCDBT-1/2 models, respectively. In the independent validation set (n = 856, the rest to be sequenced and reported), MCDBT-1 and MCDBT-2 yielded sensitivity of 76.2% (72.0%–80.0%) and 70.2% (65.8%–74.4%) in 6 cancers with specificity of 96.3% (93.9%–97.9%) and 99.3% (97.8%–99.8%), respectively. Stage I–III sensitivity was 68.5% (63.1%–73.5%) and 60.8% (55.3%–66.2%) for MCDBT-1/2 models, respectively. The prediction accuracy of top predicted origin was 79.1% (74.5%–83.2%) and 83.0% (78.4%–87.0%) for MCDBT-1/2, respectively. The interception model projected an estimated PPV of 3.1% and 12.4% for MCDBT-1/2 models, respectively. MCDBT-1 could reduce 5-year cancer mortality by 20.3%–24.6% and reduce late-stage incidence by 51.7%–61.7%, and MCDBT-2 could reduce 5-year cancer mortality by 15.9%–19.9% and reduce late-stage incidence by 40.9%–49.2%. **Conclusions:** cfDNA methylation-based MCDBT-1/2 models can effectively identify multiple cancers simultaneously at early stages with promising sensitivity, specificity, and accuracy of predicted origin. Their performances are to be further validated in a prospective interventional study (NCT05227534). Research Sponsor: Guangzhou Burning Rock Dx Co., Ltd.

Adapting an evidence-based cancer survivor lifestyle program for cancer prevention and control in African American and Hispanic/Latino communities. *First Author: Jamila L. Kwarteng, Medical College of Wisconsin, Milwaukee, WI*

Background: Cancer is the second leading cause of death in Wisconsin with higher mortality rates observed for Black/African American (B/AA) and Hispanic/Latino(a) (Hisp/Lat) communities. Affordable lifestyle interventions targeting healthy nutrition and physical activity patterns tailored to the needs/interests of these communities are critically needed to prevent and control cancer. In this project, we adapted the evidence-based Moving Forward lifestyle program for B/AA breast cancer survivors, which included a program workbook, in-person education/supervised exercise classes, and text messages. We sought to address cancer prevention among B/AA and Hisp/Lat community members in the general population by implementing the program within an urban public recreation system for sustainability. **Methods:** To help guide the adaptation process, project partners included an academic cancer center, an urban public recreation system, the state department of public health, and a community advisory board. Our approach comprised of focus groups with B/AA and Hisp/Lat residents, surveys collected at community events, and an After-Action Review of a 4-week program pilot. **Results:** One-hundred community members (58 B/AA and 42 Hisp/Lat) participated in the adaptation phase through eight focus groups (N = 27), 48 surveys, and 25 pilot participants. Seven key program content adaptations were targeted: 1) integrate information on basic cancer biology; 2) explain the association between cancer, nutrition and physical activity; 3) address other diseases besides cancer (heart disease, diabetes); 4) provide cooking demonstrations with culturally relevant tips to facilitate dietary changes; 5) update workbook images and content to reflect race/ethnicity of targeted populations; 6) add information on cancer screening; 7) provide information on local healthy eating and exercise resources. Key adaptations related to conducting the program within a public recreation system included: 1) dividing the program into two 8-week sessions to meet the public recreation system program calendar; 2) eliminating the text message component; 3) providing the program workbook/classes in English and Spanish; and 4) integrating different exercise approaches to meet needs/interests of different age groups, genders, and different fitness levels. **Conclusions:** Community-academic partnerships and ongoing community engagement led to meaningful adaptations to a cancer prevention and lifestyle program to address cancer disparities in the B/AA and Hisp/Lat communities. Research Sponsor: U.S. Department of Health and Human Services Office of Minority Health.

Interception versus prevention in cancer screening in a Medicare population: Results from the CRC-MAPS model. *First Author: Girish Putcha, Freenome, South San Francisco, CA*

Background: This study examines the impact of detecting cancer (interception) versus adenomas and cancer (prevention + interception) on clinical outcomes in a screen-naive Medicare cohort for a hypothetical colorectal cancer (CRC) screening test or a multicancer early detection (MCED) test that includes CRC. **Methods:** CRC-MAPS, a validated microsimulation model of the adenoma-carcinoma pathway that reproduced incidence reduction (IR) and mortality reduction (MR) consistent with CISNET models and a randomized controlled trial, was used to simulate perfect adherence to a hypothetical annual screening test among previously unscreened individuals free of diagnosed CRC. Four scenarios were examined: two cancer interception and two cancer prevention + interception. Individuals were screened from age 65 to 75. CRC IR and MR outcomes compared to no screening were aggregated from age 65 until death. Threshold analysis (#5) identified the ≥10mm adenoma sensitivity needed for a base-case cancer interception test (#1) to yield CRC MR equivalent to a near-perfect cancer interception test (#2). **Results:** The base-case interception scenario (#1) resulted in 5.6% CRC IR and 21.7% MR compared to 5.2% CRC IR and 25.9% MR for the near-perfect interception scenario (#2). The threshold analysis demonstrates that when the base-case interception scenario's ≥10mm adenoma sensitivity is increased from 1% to just 2.43% (#5), the resulting MR is equivalent to a near-perfect interception test. Accordingly, the cancer prevention + interception scenarios (#3, #4) resulted in CRC IR and MR outcomes 9.7-12.9x and 2.5-3.4x (respectively) as favorable as either cancer interception scenario due to adenoma detection. **Conclusions:** This analysis highlights that even small improvements in the detection of precancerous lesions for certain cancers (e.g., adenomas for CRC), which enable cancer prevention, can yield clinical benefits that meaningfully exceed those from tests that primarily detect cancer. Future studies will explore both benefits and burdens of different screening tests. Moreover, this approach will be applied to better understand the clinical utility of MCED tests. Research Sponsor: Freenome Holdings, Inc.

Scenario	Specificity	Adenoma Sensitivity	CRC Sensitivity	CRC IR	CRC MR
1. Cancer Interception (base-case)	99%	1-5mm: 1% 6-9mm: 1% ≥10mm: 1%	60%	5.6%	21.7%
2. Cancer Interception (near-perfect)	99%	1-5mm: 1% 6-9mm: 1% ≥10mm: 1%	99%	5.2%	25.9%
3. Cancer Prevention (with FIT-like adenoma sensitivity) + Interception	99%	1-5mm: 5% 6-9mm: 10% ≥10mm: 20%	60%	54.4%	63.6%
4. Cancer Prevention (with improved FIT-like adenoma sensitivity) + Interception	99%	1-5mm:10% 6-9mm: 20% ≥10mm: 30%	60%	67.0%	73.8%
5. Threshold analysis	99%	1-5mm: 1% 6-9mm: 1% **≥10mm: 2.43%**	60%	10.3%	25.9%

Socioeconomic status for predicting COVID-19-related changes in cancer prevention behaviors. *First Author: Mohamed I Elsaid, The Ohio State University College of Medicine, Columbus, OH*

Background: Disruptions of daily life activities during the CVOID-19 pandemic have adversely affected cancer-prevention behaviors. Socioeconomic status (SES) impacts on changes in cancer prevention behaviors have not been fully investigated. To tackle this gap, we examined the effects of SES on COVID-19 related changes in cancer prevention behaviors. **Methods:** We invited participants from previous studies conducted at the Ohio State University Comprehensive Cancer Center who agreed to be re-contacted to participate in a survey assessing the impact of COVID-19 on various behaviors between June and November 2020. Participants reported current cancer prevention behaviors, including physical activity, daily fruit and vegetable intake, alcohol consumption, and tobacco use. In addition, participants reported qualitative changes in current behaviors relative to pre-COVID levels. We combined current behaviors with COVID-related changes to construct a 24-point cancer prevention score. Participants were classified into low, middle, or high SES based on household income, education, and employment status. Adjusted multinomial logistic regression was used to examine the association between SES and COVID-19 related changes in cancer prevention behaviors. **Results:** The study sample included 6136 eligible participants. The average age was 57 years, 67% were female, 89% were non-Hispanic White, and 33% lived in non-metro counties. The proportion of participants in the lowest cancer prevention behavior quartile decreased significantly with higher SES [low SES vs. high SES; 32% vs. 28%; P-value < .001]. Relative to pre-COVID-19 levels, higher SES was significantly associated with increases in post-COVID-19 prevalence of more physical activity [low SES vs. high SES; 12% vs. 28%; P-value < .001], higher fruit and vegetable intake [low SES vs. high SES; 12% vs. 14%; P-value < .001], and more alcohol consumption [low SES vs. high SES; 15% vs. 22%; P-value < .001]. Higher SES was associated with lower tobacco use prevalence [low SES vs. high SES; 5% vs. 2%; P-value < .001]. Relative to the highest prevention score quartile, the adjusted odds of scoring in the lowest prevention score quartile were: adjusted odds ratio (aOR) 1.55 (95% CI: 1.27 - 1.89) and aOR 1.40 (95% CI: 1.19 - 1.66), respectively higher for low and middle SES. Low SES was significantly associated with higher odds of less frequent physical activity (aOR = 1.87; 95% CI: 1.49 - 2.35) and less fruit and vegetable consumption (aOR = 1.56; 95% CI: 1.15 - 2.12). Middle SES relative to high SES was associated with lower odds of more alcohol consumption (aOR = 0.64; 95% CI: 0.49 - 0.85) and higher odds of binge drinking (aOR = 1.32; 95% CI: 1.09 - 1.59). **Conclusions:** The adverse impacts of COVID-19 on cancer prevention behaviors were seen most in those with lower SES. Public health efforts are currently needed to promote cancer prevention behaviors, especially amongst lower SES adults. Increasing primary care utilization prior to cancer diagnosis in association with cancer mortality. *First Author: Edmund Men Qiao, Department of Radiation Medicine and Applied Sciences, University of California San Diego, La Jolla, CA*

Background: Primary care physicians (PCPs) are significant contributors of early cancer detection yet few studies have investigated whether consistent primary care translates to improved downstream outcomes. We evaluated the impact of prior PCP utilization on metastatic disease at diagnosis and cancer-specific mortality (CSM) for a general cancer cohort and 12 tumor subtypes. **Methods:** We identified cancer patients ≥40 years, diagnosed from 2004-2017 within the Veterans Health Administration. For our 5-year pre-diagnostic period, we binned PCP visits into *none* (0 visits), *some* (1-4), and *annual* (5). Multivariable logistic regression assessed the effect of PCP utilization on metastatic disease at diagnosis and Fine-Gray regression with non-cancer death as a competing event evaluated their effect on cancer-specific mortality (CSM). These were repeated for each subtype. **Results:** Among 245,425 patients, mean age was 66 years with 5.7-year median follow-up. Compared with 0 visits, *some* PCP utilization was associated with 26% reduced odds of metastatic disease at diagnosis (odds ratio (OR), 95% confidence interval (CI): 0.74 [0.71-0.76] P<0.01) and 12% lower risk of CSM (hazard ratio (HR), 95% CI: 0.88 [0.86-0.89] P<0.01). *Annual* PCP utilization was associated with 39% reduced odds of metastatic disease (OR, 95% CI: 0.61 [0.59-0.63] P<0.01) and 21% lower risk of CSM (HR, 95% CI: 0.79 [0.77-0.81] P<0.01). Among subtypes, prostate cancer had the largest effect size for PCP utilization on metastatic disease at diagnosis (OR_{annual}, 95% CI: 0.32 [0.30-0.35] P<0.01) and CSM (HR_{annual}, 95% CI: 0.51 [0.48-0.55] P<0.01). Pancreas cancer had the lowest effect size on metastatic disease at diagnosis (OR_{annual}, 95% CI: 0.87 [0.73-1.04] P: 0.12) and CSM (HR_{annual}, 95% CI: 0.89 [0.82-0.97] P<0.01). The table displays additional subtypes. **Conclusions:** Increased PCP utilization prior to cancer diagnosis is associated with a significant decrease in metastatic disease at diagnosis and CSM, with annual utilization associated with the greatest decrease. These results are consistent when stratifying by tumor subtype. Consistent primary care must be emphasized for patients at risk of cancer. Research Sponsor: None.

Project BRA: Breast cancer risk assessment. *First Author: Lauren Elizabeth Nye, University of Kansas Cancer Center, Westwood, KS*

Background: In Kansas, breast cancer (BC) incidence is similar in Black and white women, yet Black women are 42% more likely to die from the disease. In models where screening is equal, there is no difference in survival from early-stage BC. Barriers to BC early detection in Black women include provider lack of knowledge in cancer risk, performing risk assessments and providing culturally sensitive education to patients. Our team developed a didactic and case-based learning intervention using Project ECHO (Extension for Community Health Outcomes) to improve provider knowledge on performing BC risk assessment and enhance risk stratified screening in Community Health Clinics (CHCs). A Community Advisory Board (CAB) was established to address barriers to early detection. **Methods:** CHCs participated in five 1-hour ECHO sessions June thru August 2021. Session topics focused on calculating BC risk, community resources, and cultural sensitivity and were led by experts in breast oncology, risk, genetics, screening, and health care equity. Pre/post surveys administered to participants assessed knowledge and satisfaction and continuing education credits were offered. A CAB member survey gained insight into organizational characteristics and community reach. Asset mapping identified barriers, resources, and opportunities to promote BC screening. Descriptive statistical analyses and the RE-AIM framework were used to assess reach and scalability of the ECHO. **Results:** Seventy-seven individuals from 16 CHCs registered to participate with a mean of 26 attendees at each session and 34% attending two or more. Participants were physicians (19%), advanced practice providers (18%), nurses (29%), and allied health professionals (34%). Sixty-three (82%) completed the baseline survey and 10 (13%) completed the post-ECHO survey. At baseline, 32% of participants reported lack of training and time as barriers to performing risk assessment. While post-ECHO survey responses were low, 60% reported their knowledge greatly or moderately improved across all topics. Participants reported clinical practice change in assessing personal history of cancer and collecting family history beyond first degree relatives. CAB members reported a broad range of expertise in community engagement and development (44%), direct patient care (15%), healthcare access (15%) and patient advocacy (26%). CAB education and collaboration led to support for tomosynthesis for women screened in our state funded BC screening program, Early Detection Works (EDW). Ongoing asset mapping identified gaps in access for Black women to the EDW program. **Conclusions:** Project BRA demonstrated successful participation in a limited series Project ECHO and achieved perceived changes in knowledge on performing BC risk assessment. Next steps include incorporating CAB informed opportunities to expand risk-based screening across Kansas and advocate for improved access to risk stratified screening. Human papillomavirus (HPV) vaccine hesitancy trends in the United States. *First Author: Eric Adjei Boakye, Henry Ford Health System, Detroit, MI*

Background: Despite the human papillomavirus (HPV) vaccine being safe and effective at preventing HPV-associated cancers, vaccine update is low. Several factors have been identified as barriers to getting the HPV vaccine. However, it is unclear if these factors have changed since vaccine licensure. Thus, we assessed trends in the top five reasons for vaccine hesitancy in the last decade in the US. **Methods:** We analyzed the 2010–2019 National Immunization Survey–Teen data, a national survey representative of the US adolescent population. We identified adolescents (n = 16,383) who had received zero dose of the HPV vaccine (unvaccinated adolescents). Parents of unvaccinated adolescents were asked how likely they will vaccinate their child in the next 12 months. Parents who responded with "not too likely", "not likely at all" or "not sure/don't know" (vaccine hesitant) were asked what the reasons are for their hesitancy. The top five most cited reasons for vaccine hesitancy: "not necessary", "safety concerns", "lack of recommendation", "lack of knowledge", and "not sexually active" were included in the study. Joinpoint regression estimated yearly increases/decreases in these reasons using annual percent changes. **Results:** The proportion of unvaccinated adolescents whose parents cited "safety concerns"' as a reason for HPV vaccine hesitancy decreased from 2010 to 2012 but increased significantly from 2012 to 2019 at an average of 8.6% annually. The proportion of unvaccinated adolescents whose parents cited "not sexually active" as a reason for HPV vaccine hesitancy decreased on average by 33.1% from 2010-2012 and then at an average of 11.5% in the remaining years. The proportion of unvaccinated adolescents whose parents cited "not necessary" as a reason for HPV vaccine hesitancy decreased from 2010-2012 but significantly decreased by an average of 11.0% yearly from 2012-2019. The proportion of unvaccinated adolescents whose parents cited "lack of recommendation" and "lack of knowledge" as reasons for HPV vaccine hesitancy decreased over the 10-year period though not statistically significant. **Conclusions:** There was a decrease in most of the reasons cited by parents for vaccine hesitancy except vaccine safety which has been increasing from 2012 to 2019. These findings suggest an urgent need to combat the rising sentiment of safety concerns among parents of unvaccinated children to increase HPV vaccine confidence. Research Sponsor: None.

Validation of the *PREDICT* breast cancer tool in a multiethnic population of U.S. women after a second primary breast cancer. *First Author: Zhengyi Deng, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background: *PREDICT* is a widely used clinical tool to estimate prognosis based on treatment after a diagnosis of early-stage breast cancer (BC). However, it has not been validated for use in women diagnosed with a second primary BC. **Methods:** Women diagnosed with one or two BCs between 2000-2013 were identified from the US Surveillance, Epidemiology, and End Results (SEER) program. Validation analyses were conducted separately among women with one and two BCs. For each group, absolute and relative differences in predicted (P) and observed (O) 5-year BC-specific mortality were estimated stratified by estrogen receptor (ER) status. For women with two BCs, mortality prediction was based on demographic and tumor characteristics of their second BCs. Model discrimination was evaluated by receiver-operator curve (ROC) and area under the curve (AUC). **Results:** 6,729 women diagnosed with a second BC and 357,204 women with only one BC were included. Among women with one ER-positive BC, the predicted (P) and observed (O) BC mortality were comparable [absolute difference (P-O): -0.22%, 95%CI: -0.29%, -0.15%]. For women diagnosed with a second ER-positive disease, the model largely underestimated the BC mortality (P-O: -6.24%, 95%CI: -6.96%, -5.49%). An underestimation of 3%-15% in absolute BC mortality was observed in subgroup analyses based on age, race/ethnicity [P-O for Non-Hispanic (NH) White, NH Black, and Hispanic were -5.63%, -9,3%, and -9.24%], chemotherapy (P-O: -9.06, 95%CI: -10.79, -7.4), radiation therapy (P-O: -5.06, 95%CI: -6.29, -3.93) and tumor characteristics. *PREDICT* overestimated BC mortality for women diagnosed with one ER-negative BC (P-O: 4.54%, 95%CI: 4.27%, 4.86%) but it performed well for women diagnosed with a second ER-negative BC (P-O: -1.69%, -3.99%, 0.16%). However, in subgroup analyses among women with two BCs the tool underestimated mortality for women with a second ER-negative disease if their first cancer was diagnosed before age 50 years (P-O: -3.27, 95%CI: -6.48, -0.06), was poorly differentiated (P-O: -4.08, 95%CI: -7.09, -1.2), or ER-negative (P-O: -4.68, 95%CI: -7.62, -1.39). The overall AUCs for first and second ER-positive and ER-negative BCs ranged between 0.73 and 0.82. **Conclusions:** The *PREDICT* tool largely underestimated the 5-year BC-specific mortality in women diagnosed with a second ER-positive breast cancer and in many subgroups of women diagnosed with a second ER-negative cancer. Novel prognostic tools are needed for women diagnosed with a second breast cancer. Research Sponsor: Breast Cancer Research Foundation.

Dietary influence on physical functioning in the Women's Health Initiative (WHI) randomized Dietary Modification (DM) trial. *First Author: Rowan T. Chlebowski, Lundquist Institute for Biomedical Innovation at Harbor-UCLA Medical Center, Torrance,, Duarte, CA*

Background: In the WHI DM randomized trial, randomization to the dietary intervention group was associated with a 21% lower breast cancer mortality (P = 0.02) (JCO 2020), and while not an intervention target, with higher physical activity as well. Therefore, we examined whether these lifestyle changes attenuate age-related physical functioning decline. **Methods:** From 1993-1998, 48,835 postmenopausal women, aged 50-79 years, were randomized to dietary intervention or usual diet comparison groups through 8 years intervention and 19 years cumulative follow-up. Breast cancer findings, as primary outcome, have been reported. Physical functioning was assessed using the RAND 36-Item Short Form Health Survey (SF-36), which assessed limitations of 10 hierarchical physical activities, scored from 0 to 100, with a higher score indicating less limited physical function. The trajectory of longitudinal physical functioning was the primary study outcome, assessed by comparing findings in the two randomization groups, overall, and by baseline physical activity and age decade. Additionally, findings were reported against a disability threshold (when assistance in daily activities is required). **Results:** Physical functioning was assessed nearly half a million times during the study (n = 495,317) with 11.0 (median) assessments per participant. Physical functioning score was significantly better in the intervention versus comparison groups during the 8-year intervention and extended follow-up through 12 years (median) (P = 0.001), representing a reduction in age-related functional decline. The intervention effect subsequently lost significance at 19 years and both randomization groups crossed the disability threshold at similar times. Differences between randomization groups in physical functioning emerged after stratification by physical activity and age decade (P-interaction = 0.007). Among all participants physically active at entry, the intervention initially had a statistically significant, favorable influence on physical functioning which attenuated post-intervention. In contrast, among younger, physically inactive women 50-59 years of age, the intervention had a persistent, statistically significant, favorable influence on physical functioning with associated delay in crossing the disability threshold. **Conclusions:** In the primary prevention setting of the WHI DM randomized trial, with long-term follow-up, a dietary intervention which has been shown to reduce breast cancer mortality also significantly reduced age-related functional decline through 12 years. Among all participants, the intervention effect was attenuated with longer follow-up. However, reduction in age-related functional decline was sustained in younger women in the intervention group who were inactive at entry, a potential target population for future behavior interventions. Clinical trial information: NCT00000611. Research Sponsor: U.S. National Institutes of Health.

An ultrasensitive approach for cancer screening and tissue of origin prediction based on targeted methylation sequencing of cell-free DNA. *First Author: Tiancheng Han, Genecast Biotechnology Co., Ltd., Wuxi, China*

Background: Cancer-specific therapy requires the identification of the tumor origin. Detecting cancer and identifying the tumor origin in early stage can improve the survival and prognosis of cancer patients. However, early diagnosis of cancer is challenging as the early symptoms of cancer are mild or even absent. In order to improve the diagnostic efficacy and the patient compliance, we developed a two-stage model for cancer diagnosis and tissue of origin (TOO) classification, using DNA methylation profile evaluated through non-invasive blood-based testing as biomarker. **Methods:** cfDNA samples from 302 healthy and 598 cancer patients of 8 cancer types (colorectal, lung, liver, pancreatic, gastric, esophagus, breast and ovarian) were sequenced by our in-house-designed DNA methylation panel and randomly split into a training dataset (213:426) and a testing dataset (89:172). The testing dataset was reserved to evaluate the performance of models and would not be used during the feature selection and model development process. Methylation levels of cfDNA samples were measured by the methylated fragment ratios (MFRs) in methylated-correlated blocks (MCBs). We first selected pan-cancer markers by comparing the MFR values of MCBs between the healthy and the diseased individuals and developed a binary classifier (hyper-methylation score). Sample correctly predicted by the hyper-methylation score in the cancer group were then used for TOO marker selection and model fitting. TOO biomarkers were obtained by a series of pairwise comparisons of MFR values between any two cancer types. A deconvolution model was built to estimate the composition of ctDNA, which implied the tumor origin. **Results:** The hyper-methylation score model based on 135 MCB biomarkers achieved an area under the curve (AUC) of 0.89 in the training dataset and 0.85 in the testing dataset. Under a specificity of 94.8%, sensitivity was 66.2% in the training dataset. Using the 282 cases successfully being predicted, 583 TOO markers were selected to build the deconvolution model. In the testing dataset, the specificity was 95.5%, and the overall sensitivity was 66.3%. With increasing stage, sensitivity increased in all cancer types: 34.6%, 57.1%, 62.5% and 84.8% in stage I, II, III and IV respectively. In stage I-III, sensitivity was 52.3%. TOO classes were predicted in the 114 true positives from the hyper-methylation score model, producing a top 1 accuracy (true class matched the most probable class) of 75.4% and a top 2 accuracy (true class matched the first or the second most probable class) of 84.2%. Top 1 accuracy was 71.1% in stage I-III, vs. 84.0% in stage IV. Top 2 accuracy was 82.2% in stage I-III, vs. 90.0% in stage IV. **Conclusions:** Our cfDNA-based epigenetic method achieved outstanding performance either in pan-cancer detection or in TOO classification, and is a promising tool for early-stage cancer diagnosis. Predictors of use of prevention strategies among women at high-risk for breast cancer. *First Author: Kara Landry, University of Vermont, Burlington, VT*

Background: Uptake of chemoprevention and prophylactic surgery among women at high risk for breast cancer is low, despite proven efficacy. We evaluated breast cancer risk factors as predictors of uptake of prevention treatment (PT) to better understand potential associations with these decisions. **Methods:** An IRB approved registry established in 2003 at the University of Vermont of high-risk women was used to evaluate the association between both modifiable (obesity, sedentary lifestyle and alcohol use) and non-modifiable (age, history of benign breast disease [BDD], genetic predisposition) risk factors and uptake of PT. Women were eligible for inclusion in this analysis if they had one of the following risk factors (BDD, strong family history, > 20% lifetime modeled risk or genetic predisposition) and completed questionnaires regarding diet and physical activity. Alcohol use was assessed using a health questionnaire and physical activity was assessed using a 7-Day Physical Activity Recall questionnaire. We used logistic regression to estimate odds ratios (OR). **Results:** 504 women were included and had been followed for median of 13 years. Mean age was 44.5 years (range 19 – 75), 98% were Caucasian, and mean BMI was 26.9 (range 17-57). 78% had a family history of breast cancer, 60% had >20% lifetime modeled risk, 14% had a history of benign breast disease (BBD), and 9% of women had confirmed genetic risk in high or moderate risk genes. Women may have had more than one risk factor. 55% were physically active and 55%. 4.2% were sedentary and 12.3% consumed > 1 alcoholic beverage daily. 20.8% of the cohort participated in PT (8.1% took chemoprevention, 2.0% underwent prophylactic bilateral total mastectomy and 10.7% underwent risk reducing salpingo-oophorectomy). Among non-modifiable risk factors, age, genetic predisposition (OR_{adj} 8.66, 95% CI 2.30–32.33, p < 0.0001), and history of benign breast disease (OR_{adj} 4.09, 95% CI 1.89–8.86, p < 0.001) were associated with uptake of PT. Increasing age was associated with increasing uptake (ptrend was > 0.0001) and highest among women aged 60-69 years (OR_{adj}8.19, 95% CI 2.87-23.37 relative to women aged < 40). Women with a strong family history were significantly less likely to take up PT (p = 0.04). BMI, physical activity status and alcohol use were not associated with uptake of PT. **Conclusions:** Like other studies, we found a low uptake of PT among women at high risk for developing breast cancer. We found that modifiable risk factors were not associated with uptake of PT, which might suggest that high-risk women with modifiable risk factors could be targeted for interventions designed to modify risk (i.e. chemoprevention, weight reduction, etc). Interestingly, women with a strong family history may be less likely to take up PT, and studies to further examine this relationship may identify opportunities for interventions to improve uptake. Higher obesity and lower screening rates in Hispanic women and associated increased breast cancer in the United States. *First Author: Michelle Ann P. Caesar, California Pacific Medical Center Research Institute, San Francisco, CA*

Background: To evaluate trends in postmenopausal breast cancer and mammogram utilization in Hispanic and White women in the United States. **Methods:** Data on postmenopausal breast cancer was obtained from the United States Cancer Statistics Public Use Database between 2001 and 2018. Rates of mammogram screening for women ages 18 and older were evaluated using the Behavioral Risk Factor Surveillance System (BRFSS) from 2000 and 2018. Obesity rates for women ages 18 and older were extracted from BRFSS between 2001 and 2016. SEER*Stat 8.3.8 and Joinpoint regression program 4.8.0.1 were used to calculate incidence trends. Breast cancer and obesity incidence and trends were described using average annual percent change (AAPC). Mammogram screening trends were described using average biennial percent change (ABPC). Age groups were divided into five-year or ten-year intervals. **Results:** Over the past eighteen years, early-stage breast cancer in Hispanic women has increased annually by 1.06% (p = 0.000) and advanced-stage has also increased annually by 0.81% (p = 0.000). In contrast, there was no increase in early-stage cancer in White women, however, advanced stage increased by 1.06% annually (p = 0.000). Compared to White woomen, Hispanic women are more likely to be unscreened with mammograms (18.17% vs. 40.06%). Over time, the unscreened population is decreasing at 3.43% for White women compared to only 1.24% in Hispanic women (p = 0.000, p = 0.001). Overall in the U.S., the never-screened population has decreased biennially by 2.88% (p = 0.000). In 2016, 33.16% of Hispanic women and 28.13% of White women were considered obese, and this obesity rate has been increasing at 2.6% and 2.4%, respectively (p = 0.000). **Conclusions:** Our data showed that early- and advanced-stage breast cancer has been increasing in Hispanic women in the United States. Hispanic women were also more likely to be obese and less likely to undergo screening compared to White women. Research Sponsor: None.

LVEF decline in relation to body composition among women treated for breast cancer: WF-97415. *First Author: Kerryn Reding, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Despite an improvement in survival from breast cancer (BC), many women experience cardiotoxicity. Left ventricular ejection fraction (LVEF) is reduced by an average of 9.7% in women receiving anthracyclines. Obesity and central adiposity at BC diagnosis may influence risk of LVEF decline. We sought to examine associations between body composition and LVEF decline in the UPBEAT (Understanding and Predicting Fatigue, Cardiovascular Decline, and Events After Breast Cancer: WF-97415) study, which was conducted in collaboration with NCI Community Oncology Research Program. **Methods:** The analytic cohort was comprised of 167 women treated for stage I-III BC with chemotherapy and/or radiation in the UPBEAT prospective study, in whom LVEF was obtained at baseline (pre-treatment) and 3 months. Linear regression was used to examine LVEF decline in relation to 1) waist circumference (WC) and body mass index (BMI) at baseline and 2) changes in WC and BMI during BC treatment. All models were adjusted for age and race. **Results:** In this cohort (mean [SD] age: 55.7 [10.8] yrs; in whom 75% were white; 19% were Black), the mean (SD) LVEF at baseline was 60.7 (6.7)% with a mean decline of 2.7 (7.2)% from baseline to 3-months. Both WC and BMI at BC diagnosis were associated with LVEF decline during follow-up (Table). For each additional inch in WC, EF decreased by 0.25% points at 3 months (P=0.024); for each additional kg/m^2 in BMI, EF decreased by 0.2% points at 3 months (P=0.007). Reduced BMI during treatment was associated with LVEF decline, whereas a change in WC was not. Each kg/m^2 reduction in BMI was associated with a 0.4% point decrease in LVEF (p=0.037). Anthracycline use was associated with a 1.89% point decline in LVEF at 3 months versus non-users (p=0.049). After additional adjustment for anthracycline use, baseline WC remained statistically significantly associated with LVEF decline to the same degree. **Conclusions:** These data show that central adiposity at BC diagnosis is associated with LVEF decline during treatment, even after controlling for anthracyclines. Loss of central adiposity was not associated with LVEF decline, whereas BMI loss during treatment was. This suggests that shifts in body composition during BC treatment, potentially via loss of muscle mass, are important to monitor in patients. Future work should examine how changes in body composition, particularly changes in skeletal muscle and adipose tissue depots, influence cardiac dysfunction in BC patients during treatment. Funding: 2UG1CA189824, R01CA199167, 2UG1CA189828. Research Sponsor: U.S. National Institutes of Health.

	Mean (SD)	Median [Min, Max]

Early mortality in real-life nationwide epidemiological study on lung cancer in non-academic French public hospitals. *First Author: Didier Debieuvre, Groupe Hospitalier de la région Mulhouse Sud Alsace, Mulhouse, France*

Background: Each decade since 2000, the French College of General Hospital Pulmonologists (CPHG) conducts a real-life nationwide prospective epidemiological, observational, multicenter study on lung cancer (LC). In 2020, the CPHG constituted the third cohort, KBP-2020-CPHG. We reported here the data on one-month and three-month mortality among general population of this cohort and compared them with 2010 cohort. **Methods:** Collection of all consecutive LC histologically or cytologically confirmed between 01/01 and 12/31/2020 in non-academic public hospital pulmonology or oncology units in France. A Scientific Committee controlled inclusion exhaustivity and quality in each center. **Results:** 82 centers collected 8,999 patients in 2020. One-month mortality was 8.8% (734/8,999) and 9.7% (680/7,051) in 2010. Three-month mortality was 21.5% (1,771/8,999) in 2020 and 23.3% (1,624/7,051) in 2010 (Table 1). According to sex, mortality at one and three months mainly affected men (525/734; 71.5% and 1,259/1,771; 71.1% respectively). Mean age at diagnosis was older than in the cohort population (67.8 y-o); respectively 69.9 and 69.8 at one and three months. At diagnosis, patients were in poorer ECOG mainly grade 2 (211/697; 30.3%) or 3 (194/697; 27.8%) for one-month and mainly grade 1 (549/1,703; 32.2%) or 2 (547/1,703; 32.1%) for three-month mortality. Among ECOG grade 3 and 4, 34.8% (194/557) and 57.1% (93/163) were dead at one month respectively; 63.5% (350/551) and 83.4% (136/163) respectively were dead at three months. According to histology, adenocarcinoma was the most common (308/734; 42%), followed by small cell lung cancer (170/734; 23.2%) at one-month; adenocarcinoma was also the most common (822/1,771; 46.4%), followed by squamous cell carcinoma (380/1771; 21.5%) at three-month mortality. Most patients who died early were stage 4, metastatic/disseminated (respectively 625/702; 89% and 1,488/1,715; 86.8% for one- and three-month mortality). In patients with COVID19 infection (n=547), mortality at one and three months was respectively 36.4% (174/478) and 46.7% (228/488). **Conclusions:** Early mortality has not improved over the two decades and remains high. KBP-2020-CPHG study was performed during COVID-19 pandemic, which may have generated delays in diagnosis and limited access to care and hospital. Early mortality at one and three months concerned mostly men, mean age nearly 70 y-o, adenocarcinoma, metastatic disease and frail patients. This confirms the potential value of LC screening program in a targeted population. Racial and ethnic disparities in lifestyle changes during the COVID-19 pandemic: Exploring the socioeconomic and psychosocial mechanisms. *First Author: Ming Wen, University of Utah, Salt Lake City*

Background: Obesity, physical inactivity, excessive alcohol consumption, and poor diet are all modifiable risk factors for cancer. These unhealthy behaviors are disproportionally concentrated in racial and ethnic minorities and these disparities may have been exacerbated during the COVID-19 pandemic. This study examined racial and ethnic disparities in weight gain and other undesirable lifestyle changes during the COVID-19 pandemic and explored mechanisms underlying these lifestyle disparities. **Methods:** We used data from the 2020 *Health, Ethnicity and Pandemic Study*, a national survey representative of US households conducted in October 2020. Racial and ethnic minorities were oversampled. Participants were asked to report lifestyle behaviors before and during the COVID-19 pandemic. We examined two outcomes in this study: weight gain and experiencing any undesirable lifestyle changes (i.e., reduced exercise time, increased alcohol drinking, or increased fast-food meal consumption). The primary exposure was race-ethnicity (non-Hispanic (NH) white, NH black, Hispanic, NH Asian, NH other race). Four sets of mediators were examined: socioeconomic status (education, household income, and undesirable job changes), family and friend social relationship change, perceived and experienced racism, and psychological distress. Weighted multivariable logistic regression models were performed. Mediation effects were examined with variance decomposition method. **Results:** A total of 2,709 participants were included in our sample. Compared with white respondents, black (OR = 1.71; $p < 0.001$) and Hispanic respondents (OR = 2.17; $p < 0.001$) were more likely to experience weight gain, controlling for age and sex. Among the hypothesized mediators, undesirable job changes during the pandemic, experiencing worse family relationship, and higher levels of psychological distress were all linked to higher odds of weight gain, but none of these variables played a salient role in mediating the black-white and Hispanic-white disparities in weight gain during the pandemic. As to the odds of experiencing undesirable lifestyle changes, black (OR = 1.76; $p < 0.001$), Hispanic (OR = 2.12; $p < 0.001$), and Asian respondents (OR = 1.42; $p < 0.01$) all exhibited disadvantages relative to white respondent. These disadvantages were largely attributable to perceived racism toward one's own group and psychological distress for all three minority groups. **Conclusions:** Racial and ethnic minorities were more likely to experience unhealthy lifestyle changes relative to white individuals during the pandemic in the United States, which can be partly attributable to higher levels of perceived racism and psychological distress. The long-term effects of racial/ethnic disparities of lifestyle change during the pandemic on cancer prevention warrant further research. Research Sponsor: The Health, Ethnicity, and Pandemic (HEAP) study was funded by the Center for Reducing Health Disparities at University of Nebraska Medical Center, The Chinese Economists Society, and Calvin J. Li Memorial Foundation.

Impact of the COVID-19 pandemic on stage at diagnosis of patients with breast cancer: An analysis of 11,752 patients from Oncoclínicas. *First Author: Cristiano Augusto Andrade de Resende, Grupo Oncoclinicas, São Paulo, Brazil*

Background: As a reaction to the COVID-19 pandemic, a nation-wide lockdown was enforced in Brazil in March 2020, cancer care was impacted, and cancer screening reduced. Therefore, an increase in cancer diagnoses at more advanced stages was expected. In this study, we extracted data from our nationwide real-world database to evaluate the impact of the COVID-19 pandemic on the stage at diagnosis of breast cancer (BC) cases. **Methods:** We explored curated electronic medical record data of female patients, over 18 years of age, diagnosed with BC and with established disease stage based on the AJCC 8th edition, who started treatment or follow-up in the Oncoclínicas (OC) between Jan 1, 2018, and Dec 31, 2021. The primary objective was to compare stage distribution at first visit during COVID-19 pandemic (2020-2021) with a historical control cohort from a period prior to the pandemic (2018-2019). We investigated stage distribution according to age at diagnosis and tumor ER/HER2 subtype in univariate models. Associations were considered significant if they had a minimum significance ($P < 0.1$ in Chi-square test). The historical numbers of patients with BC at OC make it possible to identify differences in the prevalence of stages in the order of 5% comparing pre and post pandemic periods with a statistical power greater than 80%. **Results:** We collected data for 11,752 patients with initial diagnosis of BC, with 6,492 patients belonging to the pandemic (2020-2021) and 5,260 patients to the pre-pandemic period (2018-2019). For both ER+/ HER2- and HER2+ tumors, there was a lower percentage of patients with early-stage (defined as stage I-II) in the years 2020-2021 vs 2018-2019 and a considerable increase in advanced-stage disease (defined as stage IV). For triple negative BC (TNBC), there was a significant higher percentage of patients with advanced-stage disease in the pandemic vs pre-pandemic period (table 1). Age over 50 years was associated with a greater risk of advanced stage at diagnosis after the onset of the pandemic, with an absolute increase of 7% (P two-sided <0.01) **Conclusions:** We observed a substantial increase in cases of advanced-stage BC in OC institutions as a result of delays in BC diagnoses due to the COVID-19 pandemic. The impact appeared greater in older adults, potentially because of stricter confinement in this group. Research Sponsor: None.

SUBTYPE	STAGE	2018-2019	2020-2021	P two-sided
ER+ HER2-	Stage I-II	69%	67%	0.061

Trends in oncological disease burden: A comparative study between higher and lower-middle-income countries. *First Author: Georgina Hanbury, Imperial College Healthcare NHS Trust, London, United Kingdom*

Background: Cancer is a major cause of morbidity and mortality worldwide. Ten million cancer-related deaths were recorded in 2020, a rise of 66% over the preceding two decades. Malignancies of the breast, lung, prostate and colon account for over 40% of new cancer diagnoses worldwide. This study observes trends in oncological disease burden among higher (HIC's) and lower-middle-income countries (LMIC's) between 2000 and 2019. **Methods:** Mortality to incidence ratios (MIR) were calculated using the Global Burden of Disease database by extracting age standardized mortality and incidence rates per 100 000 for breast, lung, prostate and colorectal cancer for the years 2000-2019. The European Union (EU) 15+ countries were taken to represent HIC's. 8 of the LMIC's in the World Bank group were included as their data quality rating was 3/5 or higher. This cohort comprised Egypt, Sri Lanka, Ukraine, El Salvador, Republic of Moldova, Philippines, Kyrgyzstan and Nicaragua. Breast, lung, colorectal and prostate cancer were included as the tumor types with highest global incidence. Median MIR (with interquartile range) were computed for each LMIC and EU15+ groups for males and females for each of the four tumor types. **Results:** Between 2000 and 2019 median MIR for the LMIC group was higher than for EU15+ group for all four cancer types in males and females. Wilcoxon rank sum of the 2019 data showed a statistically significant difference (p <0.001) in MIR between HIC's and LMIC's (table 1). For breast, prostate and colorectal cancer the difference in median MIR between LMIC group and EU15+ decreased over the observation period, for lung cancer the difference increased. **Conclusions:** Globally there are wide geographical variations in MIR. Cancer outcomes appear consistently worse in LMIC's compared to HIC's. Availability of cancer screening, access to treatment and risk-factor prevalence may contribute to the above trends. Identifying these regional disparities provides an opportunity to target resource allocation to regions that would derive the greatest benefit. Research Sponsor: None.

Median MIR values in 2019 in each tumor type.

	Breast	Lung		Colorectal		Prostate
	Female	Male	Female	Male	Female	Male
HIC's	0.224	0.879	0.800	0.418	0.404	0.286
LMIC's	0.423	1.022	1.012	0.655	0.669	0.513
Difference	0.290	0.143	0.212	0.238	0.265	0.227

Patient-reported disruptions to cancer care in the U.S. during the COVID-19 pandemic: A national cross-sectional study. *First Author: Sharanya Iyer, Case Western Reserve University, Cleveland Heights, OH*

Background: Disruptions to cancer care during the COVID-19 pandemic due to disease mitigation efforts, supply-chain issues, and fear of COVID-19 have all been reported, but study of their extent has been limited. The purpose of this study is to evaluate the extent and associations with patient reported disruptions to cancer treatment and other care during the COVID-19 pandemic using nationally representative data. **Methods:** This cross-sectional study uses data from the 2020 National Health Interview Survey (NHIS), an annual, cross-sectional survey of US adults. Adults who reported requiring current cancer treatment or other care related to their cancer in the second half of 2020 were included. Rates of patients with self-reported changes, delays, or cancellations to cancer treatment or other cancer-related care due to the COVID-19 pandemic were calculated and their associations with demographic and other variables were analyzed. All data were adjusted using sample weights and specific variables to account for stratification and other survey characteristics using the Stata svy command. Chi-square testing was used to compare proportions across variable groups. Univariable logistic regression analysis was utilized to assess variable associations with change, delay, or cancellations to cancer care during the COVID-19 pandemic. Multivariable logistic regression analysis was used to create a model adjusted for select demographic variables. **Results:** A sample-weighted 2,867,326 adults (n=574) reported requiring cancer treatment and/or other cancer care since the start of the COVID-19 pandemic. Of these, 189 (32.1%) reported any change, delay, or cancellation due to the pandemic. On univariable analysis, patients who were younger, female, had comorbidities, and uninsured were significantly more likely to report care disruptions. On adjusted analysis, younger age and female sex remained significant predictors. In a sample-weighted subset of 1,600,587 patients (n=331), 291 (87.9%) reported virtual appointment use. There was no association with disruptions across breast, prostate, lung, and colorectal cancer groups. **Conclusions:** Approximately 1/3 of patients experienced disruptions to cancer care during the COVID-19 pandemic. Patients with younger age or female sex were more likely to have disruptions in care, which may reflect risk stratification strategies in the early stages of the pandemic. The longitudinal impact of these disruptions on outcomes merits further study. Research Sponsor: None.

Significant variables from multivariable logistic regression analysis for any change to cancer treatment or other care during the COVID-19 pandemic adjusted for race, urban-rural classification, household income, insurance status, and number of comorbidities.

Factors associated with the occurrence of myocardial infarction in patients treated for melanoma. *First Author: Xianying Pan, Department of Pharmacoepidemiology, Bristol Myers Squibb, Princeton, NJ*

Background: Treatments for melanoma increasingly involve the use of immune checkpoint inhibitors (ICIs), which are associated with cardiac toxicities. Our study aims to examine predictors of myocardial infarction (MI) in melanoma patients receiving treatment. **Methods**: The United Healthcare (Optum Clinformatics) Closed Claims + Lab Results Database (01/2007 – 03/2021) was used to examine factors potentially associated with the occurrence of hospitalized MI in melanoma patients. Adult patients were included if they: 1) had ≥12 months of continuous insurance coverage at baseline; 2) had ≥2 outpatient or ≥1 inpatient claims with an International Classification of Diseases (ICD) code indicative of melanoma; 3) received ≥1 type of cancer treatment (surgery, chemotherapy, radiotherapy, ICI, or targeted therapy); 4) had a claim with a melanoma ICD code within 5 days before the first cancer treatment; and 5) had no history of MI at baseline. Baseline was defined as the year prior to the first date of treatment; MI occurrence was identified from inpatient claims. We conducted a time-to-event (MI) analysis using a multivariate Cox proportional hazards regression model, with backward selection and death as a competing risk. **Results**: A total of 42,101 patients (58.8% male; median age of 68 yrs at baseline) were included in the study. Of these, 954 patients (2.3%) experienced a MI, and 5,578 (13.2%) died before having a MI. Compared with patients who underwent surgery only, those who received multiple treatments with an ICI were more likely to have a MI (hazard ratio [HR] = 1.25, 95% confidence interval [CI]: 1.01-1.55; Table). Men had a higher risk than women (HR = 1.47, 95% CI: 1.27-1.71), as did older people (compared with 65-74-yr-olds, HRs were 0.24, 0.49, 1.41, and 2.06 for <55-, 55-64-, 75-84-, and ≥85-yr-olds, respectively; all $P<.05$). Being Asian and having certain comorbidities at baseline were also associated with a higher MI risk (Table). **Conclusions**: In this retrospective cohort analysis of patients with melanoma, we observed an increased risk of MI among patients who received multiple treatments with ICIs, compared with surgery only. More research is needed to further elucidate predictors of MI events related to cancer treatment. Research Sponsor: Bristol Myers Squibb.

Patient characteristics and treatment types associated with hospitalized MI.

Factor of interest	Comparator	Hazard ratio*	95% Confidence interval*	*P*-value
Treatment (vs surgery only)	Multiple treatments with ICIs	1.25	1.01-1.55	.04
	Multiple treatments without ICIs	1.08	0.94-1.24	.29
Race (vs White)	Asian	1.89	1.14-3.14	.01
	Black	1.08	0.79-1.47	.62
	Hispanic	0.94	0.63-1.38	.73
Comorbidity (yes vs no)	Diabetes	1.48	1.28-1.72	<.001
	Hypertension	1.32	1.14-1.53	<.001
	Chronic kidney disease	1.55	1.29-1.85	<.001
	Peripheral vascular disease	1.37	1.06-1.78	.02

*The Cox model included all covariates in the table, as well as age, sex, and geographic region (death was the competing risk).

The increasing incidence of alcohol-related cancers in young adults in the United States: Who is most at risk? *First Author: Atharva Rohatgi, Palo Alto Medical Foundation Research Institute, Palo Alto, CA*

Background: To evaluate incidences and trends of alcohol-associated cancers in United States adults over the last 18 years. **Methods:** Data was extracted from the United States Cancer Statistics database from 2001 to 2018. SEER*Stat Joinpoint Regression program 4.8.1 was used to calculate incidences and trends. Average annual percentage change (AAPC) was used to describe trends. Based on the ICD-O-3 criteria, liver, colon, oral cavity, esophagus, and pharynx cancers were classified as alcohol-related cancers. **Results:** Over the last 18 years, the incidence of alcohol-associated cancers decreased overall in males and females by 0.9% every year ($p < 0.001$). Alcohol-associated cancers increased significantly in younger patients under the age of 39 years old ($p < 0.001$). Based on race, Black men and women had the highest incidence at 135.17/100,000 followed by 132.50 in White individuals, 105.84 in Hispanic individuals, and 104.28 in Asian individuals. By region, the incidence was found to be the highest in the Midwest at 132.89/100,000 and lowest in the West at 120.33. Based on cancer types, the most common alcohol related cancer was colorectal cancer with an incidence at 36.49/100,000 in 2018, followed by oral cavity cancers at 11.69, liver cancer at 6.76, esophagus cancer at 4.51, and larynx cancer at 2.92. Of all these types of cancers, liver cancer had the highest annual increase at 2.43% ($p < 0.001$). Using a projection model, we found that liver cancer is estimated to surpass colorectal cancer by the year 2035. On intersectionality analysis, White men and women in the Northeast between the ages of 75-79 had the highest incidence of alcohol-associated cancers at 584.10/100,000 in 2018. However, over the last 18 years, White men and women in the South between the ages of 20-24 had the highest annual increase at 4.08% ($p < 0.001$). **Conclusions:** Over the last 18 years, alcohol-related cancers increased in the younger patients, particularly those residing in the South. Liver cancer is increasing at the highest rate. Research Sponsor: None.

A five-year epidemiological profile of patients with cancer managed by a Haitian cancer program. *First Author: Joseph Bernard, Innovating Health International, Port-Au-Prince, Haiti*

Background: Cancer epidemiology in Haiti is poorly understood. The national cancer registry is not functional, and data reported by GLOBOCAN are estimations that do not totally reflect the reality of cancers in Haiti. The aim of this study was to present the five-year epidemiology of malignancies managed by one of the main cancer programs in Haiti. **Methods:** A retrospective study was conducted on patients aged 15 years old and above with pathological and/or clinical diagnosis of cancer managed from January 2016 to December 2020 at Innovating Health International (IHI), a cancer center located in Port-au-Prince, Haiti. The chart review collected variables such as age, gender, date of admission and cancer type in order to present this epidemiological profile of cancers. **Results:** Overall, 3060 patients with cancer were managed during the study period. 84.4% of the patients were female and 15.6% male. The mean and median ages of the study population were respectively 52.5 [range: 15 –92] and 53.0 years. Adolescents and young adults (15-39 years old) represented 18.9 % of this cohort and geriatric cases (≥ 65 years old) were 21.0%. Breast cancer was the most common type (n = 1391, 45.5%%), followed by gynecological cancers (n = 746, 24.4%) with cervical cancer representing 77.5 % of these cases (n = 578); gastrointestinal cancers (n = 252, 8.2%) dominated by colorectal (n = 92, 36.5%) and gastric cancer (n = 58, 23.0%); head and neck cancers (n = 129, 4.2%); hematological malignancies (n = 128, 4.2%) with lymphomas representing 60.9% of the cases (n = 78); sarcomas (n = 114, 3.7%), urological cancers (n = 73, 2.4%) with prostate cancer representing 56.1% of the cases; skin cancers including melanoma (n = 60, 1.9%); lung cancer (n = 24, 0.8%); thyroid cancer (n = 13, 0.4%) and central nervous system (CNS) cancers (n = 6, 0.2%). 4.1% of the patients (n = 124) had a cancer of unknown primary (CUP). Breast (53.5%), cervical (28.9%) and gastrointestinal (5.0%) cancers were the most common types among women, while gastrointestinal (25.8%), hematological (16.1%), head and neck (14.7%) and urological (12.6%) cancers were the most diagnosed among men. **Conclusions:** Cancer mainly affects Haiti's young, active and female population. Breast and cervical cancers were the most prevalent in this retrospective cohort regardless of the age group. The under-representation of prostate and other urological malignancies, lung cancer, acute leukemias and CNS cancers was likely due to underdiagnosis, misdiagnosis, under-referral or early mortality. An active cancer registry is needed to better evaluate the real cancer burden in Haiti. Research Sponsor: None.

An update on the overall epidemiology, clinical characteristics, and outcomes from the COVID-19 and Cancer Consortium (CCC19). *First Author: Dimpy P Shah, University of Texas Health Science Center San Antonio, San Antonio, TX*

Background: Despite mitigation and treatment strategies, COVID-19 continues to negatively impact patients (pts) with cancer. Identifying factors that remain consistently associated with morbidity and mortality is critical for risk identification and care delivery. **Methods:** Using CCC19 registry data through 12/31/2021 we report clinical outcomes (30-day case fatality rate [CFR], mechanical ventilation use (MV), intensive care unit admission (ICU), and hospitalization) in adult pts with cancer and laboratory confirmed SARS-CoV-2, stratified by patient, cancer, and treatment-related factors. **Results:** In this cohort of 11,417 pts (with 4% reported vaccination prior to COVID-19), 55% required hospitalization, 15% ICU, 9% MV, and 12% died. Overall outcome rates remained similar for 2020 and 2021 (Table). Hydroxychloroquine was utilized in 11% and other anti-COVID-19 drugs (remdesivir, tocilizumab, convalescent plasma, and/or steroids) in 30%. Higher CFRs were observed in older age, males, Black race, smoking (14%), comorbidities (pulmonary [17%], diabetes mellitus [16%], cardiovascular [19%], renal [21%]), ECOG performance status 2+ (31%), co-infection (25%), especially fungal (35%), and initial presentation with severe COVID-19 (48%). Pts with hematologic malignancy, active/progressing cancer status, or receiving systemic anti-cancer therapy within 1-3 months prior to COVID-19 also had worse CFRs. CFRs were similar across anti-cancer modalities. Other outcomes (ICU, MV, hospitalization) followed similar distributions by pt characteristics. **Conclusions:** Unfavorable outcome rates continue to remain high over 2 years, despite fewer case reports in 2021 owing to multiple factors (e.g., pandemic dynamics, respondent fatigue, overwhelmed healthcare systems). Pts with specific socio-demographics, performance status, comorbidities, type and status of cancer, immunosuppressive therapies, and COVID-19 severity at presentation experienced worse COVID-19 severity; and these factors should be further examined through multivariable modeling. Understanding epidemiological features, patient and cancer-related factors, and impact of anti-COVID-19 interventions can help inform risk stratification and interpretation of results from clinical trials. Research Sponsor: American Cancer Society and Hope Foundation for Cancer Research, U.S. National Institutes of Health.

Development of key performance indicator (KPI) for real-time monitoring of treatment of early breast cancer to control socioeconomic and indigenous systemic bias. *First Author: Euan Thomas Walpole, Cancer Alliance Queensland, Woolloongabba, Australia*

Background: Disparity in outcome for different cancer groups exist particularly for indigenous and poor socioeconomic background. Patient and treatment data on a population basis was examined. **Methods:** Population data for the state of Queensland, Australia (population 5.2M) collected by Cancer Alliance Queensland as part of government cancer registry roles plus additional linked data available as a gazetted quality assurance committee was examined to find patients with early breast cancer treated with surgery, chemotherapy (CT) and radiotherapy (RT) between 2005-2015. **Results:** A cohort of 8279 women received treatment with 89.3% having the surgery, CT, RT sequence. Time to completement threshold was 37 weeks using empirical cutpoint estimation in Stata. Overall survival (OS) was 94% at 5 years if < 37 weeks versus 88.5% if not. ($p < 0.001$). Multivariate analysis of socioeconomic and clinical characteristics for survival was also significant for increasing age, indigenous status, socioeconomic disadvantage, multiple co morbidities and advancing disease stage. Private hospital cases had a better outcome. When delay is analysed between treatments, only time to CT from surgery > 9.5 weeks was significant for OS (HR 1.42 $p < 0.001$). Indigenous status, socioeconomic status and private facility no longer were significant. Multiple co morbidities and advanced stage were still significantly associated with poorer survival. Funnel plots of treatment centre show the association with public hospital treatment and lower volume centre with delay. **Conclusions:** This data is retrospective so can inform local service evaluation but implementation of a KPI for delay to adjuvant chemotherapy of 9.5 weeks can provide real time targets for patient care. We measured delay in the recent 5 years (before survival available) which shows consistent delays and it will included as a reporting function of MDT management software. Whilst the increased use of neoadjuvant CT will assist, systematic reporting of this KPI has potential to remove treatment biases for indigenous and lower socioeconomic patients. More recent data will be available for presentation. Research Sponsor: Queensland State Government, Australia.

Exploring "the healthy immigrant effect" among elderly Asian patients with cancer: A nationwide population-based assessment. *First Author: Manan Nayak, Dana-Farber Cancer Institute, Boston, MA*

Background: Asian Americans are the fastest-growing immigrant group in the U.S. As the oldest immigrant group on average, they are at heightened risk for cancer and other diseases. This study explored whether the risk is mitigated by the healthy immigrant effect (HIE), an epidemiological phenomenon that has been well documented among Latino immigrants. Evidence of a healthy immigrant effect among Asians as a whole or in specific Asian subgroups is limited, and almost none focus on the elderly with a cancer diagnosis. This original research study examines the evidence for an HIE in a large ethnically diverse sample of elderly persons with a cancer diagnosis. **Methods:** This is a retrospective observational study utilizing data collected across 14 regions of the U.S. SEER-Medicare Health Outcomes Survey (SEER-MHOS), a linked dataset sponsored by the NCI and the Center for Medicare & Medicaid Services. Logistic regression analyses were conducted to examine HIE among Asians in the aggregate and subgroups of Asians for smoking and body mass index (BMI), using survey language and ethnic concentration as proxies for nativity. **Results:** Asians, in the aggregate, had comparable social backgrounds and had better health behaviors (i.e., lower smoking and BMI) than non-Hispanic Whites. When Asians were disaggregated, Hawaiians and Japanese had higher smoking and obesity rates than Chinese. A protective effect was observed among Asians in the aggregate living in an ethnic enclave with lower smoking prevalence and lower BMI. Chinese respondents opting to complete surveys in their native language or living in ethnic enclaves were less likely to be overweight, but no significant associations were found in relation to their smoking. **Conclusions:** Support for a healthy immigrant effect was largely consistent for Asians in the aggregate with respect to both language and ethnic concentration, but support was mixed among subgroups of Chinese patients. The presence of the HIE suggests that the health status and needs of recent Asian immigrants seeking oncologic care may be different than Asians who have been in the U.S. longer. These findings suggest a need for community-based efforts to encourage preservation of a healthier living style observed among first-generation immigrants. Research Sponsor: None.

Analysis of genomic alterations in pan-cancer from a large real-world Chinese population. *First Author: Zhouhuan Dong, Department of Pathology, The Chinese PLA General Hospital, Beijing, China*

Background: Effective targeted therapy sorely depends on comprehensive and precise genomic profiling. Besides, single nucleotide variations (SNVs) and InDels, gene fusions, as drivers and therapeutic targets of great importance, are not yet well characterized in Chinese patients. **Methods:** Formalin-fixed, paraffin-embedded (FFPE) tumor tissues from 1,384 pan-cancer patients were collected and sequenced using next-generation sequencing (NGS) targeting 40 cancer genes including SNV, fusion and assessing copy number variation (CNV) (AmoyDx HANDLE Classic Panel). qPCR and fluorescence in situ hybridization (FISH) were further applied to verify NGS detected fusion genes. **Results:** 1,384 patients were recruited including 890 lung cancers, 272 colorectal cancers, 174 gastric cancers, and 48 endometrial cancers. The prevalence of fusion genes (5.49%), including *ALK*-fusion (2.67%), *ROS1*-fusion (0.94%), *RET*-fusion (0.72%), *NRG1*-fusion (0.29%), and *NTRK*-fusion (0.07%), was nearly double the frequency of previously reported data from East Asians. Prevalence of fusion genes varied in different types of cancers. For instance, *ALK* (3.7%), *ROS1* (1.5%), *RET* (1.0%) and *NRG1* (0.2%) fusions were largely found in patients with non-small cell lung cancer (NSCLC), and were rarely detected in other cancer types. Further analysis of genomic alterations in fusion-positive patients revealed that, *TP53* (21%) was the most frequently co-occurred mutated gene with *ALK* fusion, while *RET* fusions and *ROS1* fusions were rarely accompanied by other mutated genes. In addition, two patients with *RBPMS-NRG1* fusion were accompanied by *BRAF* and *RB1* mutations, whereas no co-occurred mutation was found in patients with other partners of *NRG1*. Patients with inconsistent results of RNA-based NGS and FISH validation fusions are still being followed for treatment and survival, updated data will be available at the time of the presentation. **Conclusions:** Genomic alterations in real-world Chinese populations have specific characteristics, especially fusion genes. Further characterization of these variants is essential for clinics to guide appropriate targeted therapies. Research Sponsor: None.

Prevalence of incidental pathogenic germline variants detected in cfDNA in patients with oncogene-driven non-small cell lung cancer. *First Author: Laura Mezquita, Hospital Clinic-DIBAPS, Barcelona, Spain*

Background: Preliminary data has highlighted inherited predisposition to lung cancer (LC) related to certain pathogenic germline variant (PGV) in cancer predisposing genes, including patients (pts) with tumors harboring somatic driver oncogene alterations (alt); however, the frequency of PGV in LC is unknown. Liquid biopsy assays may be able to identify incidental PGV (iPGV) in pts with solid tumors at scale. Here, we report the prevalence of iPGV in genes predisposing to cancer in pts with advanced non-small cell LC (aNSCLC) relative to driver alt status. **Methods:** Genomic results were retrospectively queried from 31126 pts with aNSCLC who had Guardant360 testing as part of routine clinical care from 10/2020-12/2021. iPGVs were defined as being non-synonymous, non-VUS alt in selected genes known to increase lifetime cancer risk (Table) with variant allele frequency (VAF) >30% and pathogenicity defined by a proprietary bioinformatics pipeline. Clinical factors such as age, gender, histology, and diagnosis status (new/progressing) were extracted from test requisition forms. The driver group included guideline-recommended and emerging somatic mutations (m) in *EGFR/KRAS/BRAF/MET/HER2*, fusions (f) in *ALK/ROS1/RET/NTRK1-3* and amplifications (a) in *HER2/MET*. **Results:** Out of 31126, 720 (2.3%) of pts had predicted iPGV, of whom 54% were female, with a median age of 64 (22-100); most pts were newly diagnosed (66%). Among them, 92% of pts had iPGVs identified in the homologous recombination and repair (HRR) pathway, 3% in mismatch repair (MMR) pathway and 5% *EGFR* iPGVs. A total of 335 (47%) pts with iPGVs had somatic driver alt (Table**):** 20% of pts with iPGV had *KRAS*m (n=144/720; 67 *G12C*), 12% *EGFR*m (n=87; 28 *ex19del*, 35 *ex21(L858R)*), 2.5% *BRAF*m (n=18), 2.5% *MET*m ex14 skip (n=18), 0.1% *HER2*m (n=1), 0.8% *ALK*f (n=6), 0.1% *ROS1*f (n=1), 0.1% *RET*f (n=1), 0.1% *HER2*a (n=1), and 0.4% *MET*a (n=3). *ATM* iPGVs were enriched in pts with driver alt. (45% driver vs 27% non-driver, p<0.0001) while *BRCA1* iPGVs were more frequently observed in pts without driver alt. (17% vs 8%, p<0.0001). Distribution of other iPGVs was similar across driver/non-driver groups. **Conclusions:** In this large cohort, 2.3% of pts with aNSCLC were iPGV-carriers; 47% of pts had oncogene-driven tumors, particularly with *KRAS, EGFR, BRAF* and *MET* alt. iPGV and lung carcinogenesis need further evaluation to define the role of genetic predisposition in LC risk and to determine the highest risk individuals to explore screening and therapeutic strategies, such as in pts with other solid tumors. Research Sponsor: None.

Sociodemographic trends in COVID-19 mortality in patients with cancer: A nationwide analysis. *First Author: Sree Jambunathan, University of Toledo College of Medicine and Life Sciences, Toledo, OH*

Background: The COVID-19 pandemic has caused unprecedented disruptions in medical care, especially in those with cancer. Prior studies have demonstrated a higher risk of mortality in patients with cancer and COVID-19, which could be due to factors such as immunosuppression and higher burden of co-morbidities. However, there are limited studies examining the impact of sociodemographic factors including race, gender, rurality, and region on mortality in patients with COVID-19 and cancer. This study aims to characterize and analyze sociodemographic trends in COVID-19 mortality in patients with cancer. **Methods:** Data on patients with COVID-19 and cancer listed on death certificates from the Multiple Cause of Death Centers for Disease Control and Prevention Wide-Ranging Online Data for Epidemiologic Research (CDC WONDER) database were extracted. Age-adjusted mortality rates (AAMR) were calculated and compared across sociodemographic groups. **Results:** A total of 18,467 total deaths occurred in patients with COVID-19 and cancer listed on multiple cause of death certificates in 2020, with overall AAMR of 4.4 (95% CI: 4.4-4.5). AAMR for patients with COVID-19 and cancer was significantly higher in Non-Hispanic (NH) Black or African American (7, 95% CI: 6.8-7.3), NH American Indian or Alaska Native (6.4, 95% CI: 5.4-7.3), and Hispanic or Latino (5.4, 95% CI: 5.2-5.7) groups than NH White (4, 95% CI: 3.9-4.1) and NH Asian or Pacific Islander (2.5, 95% CI: 2.3-2.7). AAMR was also higher in males (5.9, 95% CI: 5.8-6.1) and those in Northeast (5.6, 95% CI: 5.4-5.8) and Midwest (5.3, 95% CI: 5.2-5.5) census regions. Those in medium metro counties had significantly lower AAMR (3.8, 95% CI: 3.7-4) compared to other locations based on the NCHS Urban-Rural Classification Scheme for Counties. **Conclusions:** AAMR in patients with any cancer and COVID-19 was significantly higher in NH Black or African American, NH American Indian or Alaskan, and Hispanic or Latino race/ethnicity groups, as well as in males. Regional and rurality disparities also exist. This study highlights persistent disparities in COVID-19 and cancer outcomes and identifies groups at higher risk of mortality. Future studies examining sociodemographic trends in COVID-19 mortality in patients with specific cancers are necessary. Research Sponsor: None.

AAMR of patients with COVID-19 and cancer listed on multiple cause of death certificate.

Race	Age Adjusted Mortality Rate (95% CI)
NH Asian or Pacific Islander	2.5 (2.3-2.7)
NH White	4 (3.9-4.1)
Hispanic or Latino	5.4 (5.2-5.7)
NH American Indian or Alaska Native	6.4 (5.4-7.3)
NH Black or African American	7 (6.8-7.3)

Characteristics of patients with neuroendocrine tumors in the United States: A study of 392,412 patients. *First Author: Ravali A. Reddy, Department of Obstetrics and Gynecology, Stanford University School of Medicine, Palo Alto, CA*

Background: To evaluate the characteristics and trends amongst patients with neuroendocrine tumors in the United States. **Methods:** Data was obtained from the United States Cancer Statistics database from 2001 to 2018. SEER*Stat 8.3.9.2 and Joinpoint regression program 4.9.0.0 were used to calculate characteristics and trends of these cancers per 100,000. The age-adjusted incidences were determined based on the standard population in the United States from 2000. **Results:** Of 392,412 patients with neuroendocrine tumors, 53.1% were identified in women and 46.9% in men. White, Black, Hispanic, Asian/Pacific Islander and unknown race comprised 73.6%, 14.1%, 7.8%, 2.7%, and 1.7% of the patient population respectively. The majority (64.7%) of tumors originated from the digestive system, followed by 24.5% from the respiratory system. In 2018, the incidence of all neuroendocrine tumors was higher in older (70-79 years) patients as compared to younger (< 50 years) ones at 30.17 vs. 2.79/100,000, in women as compared to men at 8.36 vs. 7.77/100,000, and in White patients as compared to Black, Hispanic, and Asian/Pacific Islander patients (10.82, 10.15, 5.08 and 4.80/100,000 respectively). Amongst different types of neuroendocrine tumors, those originating from the digestive system had the highest incidence at 6.72/100,000 in the year 2018 with colon tumors being the most common subtype. On trend analysis, the groups with the highest annual percent increase included: younger (< 50 years) patients increasing at 5.06%, Hispanic patients rising at 6.44%, and appendiceal tumors increasing at 12.89% per year. On intersection analysis, Black patients between the ages of 70-79 had the highest incidence at 33.39/100,000, while younger (< 50 years) Hispanic patients had the largest increase at 6.22% per year. **Conclusions:** The incidence of neuroendocrine tumors has increased over our study period. The highest incidence was found in older Non-Hispanic Black patients, with younger Hispanic patients having the highest annual percent increase. Further studies are warranted to better characterize the reasons for these trends and disparities amongst minority patients affected by these tumors. Research Sponsor: None.

Genetic ancestry correlates of the cancer somatic mutational landscape from tumor profiling data of 50,000 patients with cancer. *First Author: Francisco De La Vega, Tempus Labs, Inc., Chicago, IL*

Background: The incidence and mortality of cancer vary widely across race and ethnicity. This is attributed to an interplay of socioeconomic factors, environmental exposures, and genetic background. Cancer genomic studies have underrepresented minorities and individuals of non-European descent, thus limiting a comprehensive understanding of disparities in the diagnosis, prognosis, and treatment of cancer among these populations. Furthermore, the social constructs of race and ethnicity are far from precise categories to understand the biological underpinnings of such differences. In this study, we use a large real-world data (RWD) patient cohort to examine associations of genetic ancestry with somatic alterations in known cancer driver genes. **Methods:** We inferred genetic ancestry from approximately 50,000 de-identified records from cancer patients of diverse histology who underwent tumor genomic profiling with the Tempus xT next-generation sequencing (NGS) assay. Our cohort includes patients with brain, breast, colorectal, hematopoietic, lung, and ovarian cancers, among others. We used 654 ancestry informative markers selected to overlap the target regions of the 648-gene Tempus xT NGS assay to infer global ancestry proportions at the continental level: Africa (AFR), America (AMR), Europe (EUR), East Asia (EAS), and South Asia (SAS). We imputed race/ethnicity categories using ancestry proportions on subjects lacking such metadata. **Results:** Most patients were of European descent (72%), however, continental genetic ancestry inference identified 4.7 and 3.8-fold more patients with substantial (> 50%) AFR and AMR ancestry, correspondingly, compared with TCGA. We observed higher percentages of AFR ancestry patients with prostate, breast, and colorectal cancer (1.8-3.1%) and AMR ancestry patients with colorectal cancer (2.4%) compared to the overall cohort-level distributions ($p < 0.05$). Using imputation, we identified 60% and 121% more patients as likely Black and Hispanic/Latino, respectively. We observed several associations between genetic ancestry with tumor mutation burden (TMB), e.g., a reduction in median TMB in Asian breast cancer patients (Asian TMB mean = 2.3 m/Mb vs 4.4 for Black, 3.3 for Hispanic, and 4.2 for White; $p < 0.0001$), in paired tumor/normal sequencing data. Furthermore, we found associations between ancestry and nonsynonymous somatic mutations in cancer genes, e.g. in *CTNNB1* with EAS ancestry (OR = 1.18) and *EGFR* with EAS (OR = 1.24), AMR (OR = 1.30), and EUR (OR = 0.89) ancestries (all $p < 0.001$) in lung cancer patients. **Conclusions:** Our results support the use of genetic ancestry inference on RWD to improve upon the social constructs of race and ethnicity, allowing us to better understand the impact of shared germline genetic or exposure backgrounds into cancer mutational processes that influence incidence, progression, and outcomes. Human papillomavirus-associated cancers in Taiwan over the last 18 years: The potential impact of screening, vaccination, and smoking. *First Author: Cheng-I Liao, Department of Obstetrics and Gynecology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan*

Background: Human papillomavirus (HPV) is a causative agent of many human cancers. This study aims to determine the incidences and trends of HPV-associated cancers in the Republic of China. **Methods:** HPV-associated cancers included: cervical carcinoma, oropharyngeal squamous cell carcinoma (SCC), anal/rectal, vulvo-vaginal, and penile SCC. Deidentified data were obtained from Taiwan's National Health Insurance Research Database from 2001 to 2018. SEER*Prep 2.6.0, SEER*Stat 8.3.9.2, and Joinpoint regression program 4.9.0.0 were used to calculate incidences and trends of HPV-associated cancers per 100,000. The age-adjusted incidence was adjusted by the WHO 2000 standard population. **Results:** A total of 55,248 HPV-associated cancers were identified. Of these, 34,730 (62.9%) were identified in women and 20,518 (37.1%) in men. The majority (60.0%) were cervical followed by oropharyngeal at 37.6%, and other HPV-associated cancers comprised 2.4%. Over the 18-year study, the overall age-adjusted incidence of HPV-associated cancers decreased from 13.41 to 8.92 (per/100,000) with an annual decrease of 2.02% ($P< 0.001$). More specifically, cervical cancer incidence decreased from 20.42 to 7.70 per 100,000 with an annual decrease of 5.6% ($P< 0.001$). Other cancers, such as vaginal and vulvar, decreased 2.34% ($P< 0.001$) and 1.82% ($P< 0.001$), respectively. With respect to oropharyngeal SCC, the incidence was over 12-fold higher in men compared to women (8.37 vs. 0.67/100,000) with both sexes increasing at 3.61% ($P< 0.001$) and 3.59% ($P< 0.001$) annually. Anal/rectal SCC increased at 3.55% ($P< 0.001$) whereas penile cancer decreased at 2.52% ($P< 0.001$). Of note, all HPV-associated cancers among non-smokers decreased 2.02% ($P< 0.001$) annually, whereas they increased in smokers at 1.00% ($P> 0.05$) per year. This increase in incidence was particularly evident in oropharyngeal SCC and cervical carcinomas. **Conclusions:** Women comprised over 60% of HPV related cancers, with cervical cancer being most common followed by oropharyngeal cancer. Over the last 18 years, cervical and vulvovaginal cancers decreased, but the rates of oropharyngeal cancers in men was 12-fold higher than women and continues to increase. Public awareness and education of these trends are needed toward prevention and screening. Research Sponsor: None.

The disproportionate burden of cancer associated with social behaviors in young women in the United States. *First Author: Caitlin Ruth Johnson, California Pacific Medical Center Research Institute, San Francisco, CA*

Background: To evaluate the incidences and trends of social determinant risk factor-associated cancers in the United States from 2001 to 2018. **Methods:** Social determinant risk factor-associated cancers, as classified by the CDC, were included: obesity, alcohol, tobacco, physical inactivity, and human papillomavirus (HPV). Data was obtained from the United States Cancer Statistics program from 2001-2018. SEER*Stat 8.3.9.2 and Joinpoint regression program 4.9.0.0 were used to calculate incidences and trends of cancers per 100,000. The age-adjusted incidence (AAI) was adjusted by the US 2000 standard population. **Results:** Over the 17-year study period, a total of 28,175,859 cancers were identified. Of these, 51.4% developed in men and 48.6% in women. Over 65.8% were risk factor-associated cancers and 34.2% were unrelated to these factors. Of note, over 60.1% of risk factor-related cancers developed in women compared to 39.9% in men. Although the incidence of risk factor associated cancers did not significantly change at 413.2/100,000 in women, this incidence decreased by 1.15% annually ($P< 0.001$). The age-specific incidences decreased in older (> 50 years) men and women. Of the younger (20-45 years) group, these risk factor-associated cancers increased from 91.5 to 97.3/100,000 with an annual increase of 0.4% ($P< 0.001$) in younger women; there was no change for younger men on trend analyses over the study period. **Conclusions:** Over 65% of cancers in the US were associated with social determinants of health. There is a disproportionate burden of risk factor-associated cancers in women with increasing rates in younger age groups. Further research is needed to better understand the rationale of these important trends. Research Sponsor: None.

Impact of germline mutations on surgical decision-making in women with DCIS. *First Author: Rachel E Ellsworth, Murtha Cancer Center Research Program, Uniformed Services University of the Health Sciences,, Windber, PA*

Background: Ductal carcinoma in situ (DCIS) is both a malignant, yet pre-invasive disease of the breast. While the majority of DCIS have a low risk of recurrence, a subset of women with germline pathogenic variants (PV) in cancer predisposition genes are at increased risk for breast cancer recurrence. Uptake of genetic testing and treatment with risk-reducing surgeries (RRS), including bilateral mastectomy (BM), in women with DCIS, has not been well-studied. The aim of this study was to determine the prevalence of PVs in women with DCIS and the impact on surgical decision making. **Methods:** All women diagnosed with unilateral DCIS 2001-2020 enrolled in the Clinical Breast Care Project were identified. Demographic, genetic test results and surgical procedures were extracted from the database. Test-eligibility was assigned using National Comprehensive Cancer Network (NCCN) criteria. Panel genetic testing was performed in the research setting using DNA from 465 women. Statistical analyses were performed using Fisher's exact tests and Chi-square analyses with $p < 0.05$ defining significance. **Results:** The overall PV frequency in women with DCIS was 8.1%. Within the test-eligible group, 35.1% pursued clinical genetic testing, including 13.2% who pursued testing only after a second cancer event. Of the 39 women with PV, 20 (51.3%) were detected only in the research setting, with 11 (28.2%) of these women not eligible for genetic testing based on NCCN criteria. In the 419 women who did not undergo BM at diagnosis, recurrence was significantly higher ($p = 0.001$) in women with PV (33.3%) compared to those without PV (11.6%). **Conclusions:** Genetic testing is suboptimal in women with a primary diagnosis of DCIS. Twenty percent of women with PV, who may have benefited from BM, did not undergo genetic testing at the time of diagnosis and recurred. These data suggest that genetic testing at the time of diagnosis should be standard for all women with DCIS. Research Sponsor: Uniformed Services University of the Health Sciences.

Mainstreamed genetic testing of patients with breast cancer: Experience from a single surgeon's practice in a large U.S. academic center. *First Author: Kanhua Yin, Massachusetts General Hospital, Boston, MA*

Background: Germline genetic testing for cancer susceptibility has proven to be a powerful tool in cancer risk assessment, screening, and prevention but a huge gap exists between the number of germline genetic testing candidates and the number of patients actually tested. This study aimed to evaluate the impact of mainstreamed genetic testing (MGT) model into a single academic breast surgeon's practice on genetic test completion. **Methods:** Before September 2019 (pre-MGT phase), a breast surgery practice at Massachusetts General Hospital followed a traditional model of pre-test consultation with a genetic professional. After September 2019 (post-MGT phase), the same practice offered eligible patients with immediate testing in the same visit. We evaluated the appointment completion in the pre-MGT phase and compared the test uptake and test results between the two phases. **Results:** We identified 204 patients in the pre-MGT phase and 202 patients in the post-MGT phase. In the pre-MGT phase, the median waiting time for genetic counseling was seven days for patients with a newly diagnosed cancer, 211 days for patients with a remote personal history of cancer, and 224 days for non-cancer patients who had a family history. A total of 105 (51.5%) patients completed a genetic counseling appointment (Table). In the post-MGT phase, a significantly higher proportion of patients (88.1%, $p < 0.001$) consented to genetic testing, while the proportion of patients who tested positive was lower (pathogenic variant: 11.9% vs. 20.0%; variant of uncertain significance: 19.9% vs. 28.0%; $p = 0.047$). **Conclusions:** Implementing MGT can reduce the number of clinical visits, significantly shorten patients' wait time to test initiation, and increase the completion of genetic testing. Research Sponsor: None.

Prevalence and spectrum analysis of germline *DICER1* variants of solid tumors: Decoding the mysterious signals of the genome. *First Author: Pibao Li, Shandong Provincial Third Hospital, Jinan, China*

Background: DICER1 syndrome is a rare genetic condition predisposing to multiple cancer types and causes by germline *DICER1* variants. Deleterious mutations identified were mostly located in the RNase III domain. VUSs found in other domains may be also crucial in the inheritance of high-risk neoplasms although there is insufficient evidence. Our study aimed at describing the spectrum of *DICER1* variants detected in solid tumors to improve the identification of potentially high-risk *DICER1* variants. **Methods:** Germline mutations including SNV, small INDEL in 448 patients with solid tumors were analyzed by next-generation sequencing (NGS) panel. The pathogenicity of germline mutations was categorized based on American College of Medical Genetics and Genomics (ACMG) guidelines. **Results:** In total, 3 (0.67%) patients (diagnosed as bladder cancer, schwannoma, and medulloblastoma) were identified harboring truncating pathogenic (P)/likely pathogenic (LP) germline mutations in the RNase III domain. The remaining 445 (99.33%) patients carried 447 uncertain significance (VUS) mutations, of which 416 (92%) were missense mutations lied in different domains and 52% (234/450) located in exon 20-23. The median age was 60 years old with an age range from 0 to 90. The higher frequency cancer type contained lung cancer (35.9%), glioma (10.0%), liver cancer (8.4%). In addition, the two highest frequencies of *DICER1* missense variants were c.3334A > G (p. Asn1112Asp, n = 58) and c.3227G > A (p. Ser1076Asn, n = 53), which lied in unknown functional domain of the protein and had been reported in Clinvar. Their clinical significance and pathogenicity remain further study. **Conclusions:** In our study, *DICER1* germline mutations mostly occurred in exon 20-23 and 92% were missense mutations. We reported 3 new cases of tumors associated with *DICER1* syndrome, which expanded the DICER1-related tumor spectrum. Understanding the clinical significance of germline *DICER1* VUS could improve the identification of potentially high-risk variants. Reclassifying these variants could make them useful for predictive, prognostic, and preventive purposes in clinical practice. Research Sponsor: None.

10579 **Poster Session**

Co-occurrence of germline pathogenic variants in Chinese patients with solid tumors. *First Author: Yan Zhang, The Sixth Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China*

Background: Germline mutations play an important role in cancer risk and susceptibility. With the growing implementation of next generation sequence of multiple gene panel, an increasing number of cases that carry two or more inherited cancer-predisposing alleles in the same individual are being described. However, understanding the impact of these combined mutations on the patient's phenotype can be particularly challenging. To further understand these combined mutations, we analyze the genetic susceptibility mutations of Chinese solid tumor patients to explore the characteristics of multiple germline variants. **Methods:** Genetic mutations were reviewed in cancer patients who underwent hybridization capture based next-generation sequencing (NGS). The pathogenicity of germline mutations was categorized based on American College of Medical Genetics and Genomics (ACMG) guidelines, and only pathogenic and likely pathogenic variants were included in this study. **Results:** Germline variants were identified in 1267 individuals, including 1244 patients harbored one germline mutations and 23 patients carried ≥2 germline mutations, and there was no age difference in the two groups (57 vs 55, $p = 0.62$). In the ≥2 germline mutations group, genes most frequently involved were *BRCA1/2* (12/47, 25.5%), *CHEK2* (4/47, 5,1%), *TP53*(4/47, 5,1%) and *MUTYH* (4/47, 5,1%). Most of these variants affected DNA damage repair pathways [57% homologous recombination repair (HR), 15% mismatch repair (MMR)]. Besides, double variants in HR and HR pathway were found in 8 patients, HR and MMR pathway were found in 5 patients. Surprisingly, the 50-year-old man with colorectal cancer with three pathogenic variants of the [*FH -BRCA2- FANCD2*] genes showed a high aggregation of tumors associated with leiomyomatosis and renal cell cancer and HBOC. **Conclusions:** We found over 56.5% patients with multiple pathogenic variants in DNA damage repair pathways, which may have important implications for the treatment strategy for these patients. Next-generation sequencing technologies now provide the opportunity to perform simultaneous parallel testing of large numbers of inherited cancer genes, which could guide the clinician as to what the effect of each combination of mutations might be. Implementation of universal, pan-cancer germline genetic testing in patients with cancer in Jordan. *First Author: Hikmat Abdel-Razeq, King Hussein Cancer Center, Amman, Jordan*

Background: Detection of pathogenic germline variants (PGVs) has a significant and growing impact on the management of patients with many types of cancer. Most research to date evaluated individuals of European background, which can result in skewed genetic testing criteria and variant interpretation. Additional data are needed from diverse populations. This study aimed to investigate a universal germline testing strategy and the pattern and frequency of PGVs among all newly diagnosed cancer patients at a single center in Jordan. **Methods:** In this prospective, observational study, consecutive patients newly diagnosed with cancer were classified as meeting or not meeting National Comprehensive Cancer Network (NCCN) germline genetic testing criteria. All patients underwent an 84-gene panel test, independent of age, stage or family history. Demographics and clinical history were collected and analyzed from information provided by the clinicians on the test requisition form. Descriptive statistics were employed, and statistical significance was determined by two-tailed Fisher's exact test and unpaired t test. **Results:** In total, 1377 cancer patients of Arabic background were enrolled, of which 831 (60.3%) met NCCN criteria (Table). PGVs were identified in 210 (15.3%). Excluding the 29 patients who were carriers for autosomal recessive conditions, 192 PGVs were identified in 181 (13.1%) patients. PGVs were most commonly identified in *APC* (p.I1307K variant, 55, 28.6%), *BRCA2* (35, 18.2%), *BRCA1* (21, 10.9%), and *TP53* (12, 6.3%). While patients who met NCCN testing criteria were more likely to have a PGV (p<0.0001), 44 (24.30%) patients with PGVs did not meet criteria. Among those with PGVs, 177 (97.8%) were potentially eligible for increased screening per NCCN/expert opinion guidelines, 69 (38.1%) targeted therapies, and 89 (49.2%) clinical trials; this included 41 (22.7%), 6 (3.3%), and 14 (7.7%) patients, respectively, that did not meet NCCN testing criteria. 1445 variants of uncertain significance (VUS) were identified in 833 (57.7%) patients, but no difference in VUS rate was observed between those meeting and not meeting criteria (p=0.7354). **Conclusions:** Overall PGV rate among cancer patients from one center in Jordan was similar to that reported in the literature. While the VUS rate was high, similar rates were observed in those meeting and not meeting criteria. Testing restricted to guidelines could have missed approximately a quarter of patients with PGVs, >95% of whom might qualify for increased screening, targeted therapies, and/or clinical trials. Research Sponsor: Invitae.

Constitutional MLH1 promotor hypermethylation: Clinical characteristics and testing frequency of a poorly recognized mechanism for Lynch-associated malignancies. *First Author: Rakesh Biswas, Inova Schar Cancer Institute, FAIRFAX, VA*

Background: MSI-H colorectal cancer is most often a result of deleterious mutations in mismatch repair genes, but can also occur through repressed gene transcription due to hypermethylation of the MLH1 promoter, often associated with BRAF V600E mutations. However, there is a subset of patients who have a "constitutional epimutation", resulting in hypermethylation of MLH1 throughout normal tissue. We observed a young patient develop a second primary Lynch associated malignancy (see Table 1) who was found to have a constitutional epimutation in MLH1 that prompted us to review the frequency with which the test was ordered and the positivity rate, as well as outline the clinical history in the positive cases. **Methods:** We reviewed all of the testing ordered for MLH1 hypermethylation of peripheral blood (MLHPB) at the Mayo Clinic Laboratory between 09/01/2020 and 09/01/2021. To the best of our knowledge, this is the only clinically available testing lab in the United States. We reviewed positive casesfor characteristics including the number of malignancies, age of diagnosis, and family history. **Results:** 33 MLHPB total tests were ordered in the United States at the Mayo Clinic laboratories between 09/01/2020 and 09/01/2021. Three of the tests were positive, including the single test ordered by our institution, and one of the two additional positive tests was available for detailed review. Our institution's positive test case was a 41 year old women who developed T4N2M0 colorectal cancer 5 years after being treated for endometrial cancer. She had endometrial cancer with absence of MLH1 and PMS2 staining and had a negative germline cancer risk panel at age 36. Five years later, she developed a T4N2 colorectal cancer after which repeat germline testing with RNA sequencing was negative and she was found to have constitutional MLH1 promoter hypermethylation. We were able to obtain clinical information about two of the three individuals with positive tests (See Table). **Conclusions:** Recognition of constitutional MLH1 hypermethylation may allow for earlier recognition of Lynch related malignancies in affected patients and families. Testing appears infrequent and this condition often goes unrecognized. Specific consensus guidelines may improve recognition and cancer screening in this population. Research Sponsor: None.

Pathogenic *TP53* variant allele frequency across different somatic tissues in two patients with mosaic Li-Fraumeni. *First Author: Tin-Yun Tang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The integration of germline genetic testing, frequently from blood, into routine oncological care has increased the frequency at which pathogenic *TP53* mutations are found in a variant allele frequency (VAF) range suggestive of either mosaic Li-Fraumeni Syndrome or clonal hematopoiesis of indeterminate potential (CHIP). Mosaic LFS is a rare and poorly described phenomenon wherein a pathogenic *TP53* mutation is dispersed in low levels through multiple somatic tissues after stochastically developing during early embryogenesis. In comparison, CHIP is restricted to the bone marrow niche. Germline mosaicism in Li-Fraumeni Syndrome (LFS) is inferred when genomic DNA from a second source recapitulates the exact same *TP53* mutation. Given the challenges with sample acquisition, mosaicism has not been previously described in depth in the medical literature. **Methods:** Two pediatric patients with LFS-associated cancers (glioblastoma, osteosarcoma & ALL respectively) underwent clinical genetics evaluation and were found to have pathogenic *TP53* mutations. Initial genetic testing was performed in a CLIA/CAP environment through a send out test or internally. A broad array of somatic tissues was collected at autopsy with subsequent DNA isolation and amplicon sequencing in triplicate to determine the mean VAF of the pathogenic *TP53* allele. **Results:** For both patients, the initial germline test suggesting mosaic LFS had a VAF between 20-30%. Confirmatory intent fibroblast culture in Patient 1 was reported as negative by an external clinical lab and Patient 2's VAF was much lower. The VAFs for the rest of the somatic tissues as well as in their corresponding cancers are reported below (Table) as means and standard error of the triplicate. Despite the negative fibroblast culture, Patient 1 did demonstrate mutant *TP53* in other tissues, confirming mosaicism. **Conclusions:** The proportion of pathogenic alleles is highly heterogeneous amongst different somatic tissues in mosaic LFS patients. Although CHIP exclusion through germline testing of cultured skin fibroblasts is common, our patients' skin samples were amongst the tissues with the lowest VAFs. Mosaicism should be highly suspected when tumor sequencing demonstrates an identical mutation to the putative germline mosaic one even with equivocal fibroblast culture results. Research Sponsor: Clinical Translational Science Collaborative of Cleveland, UL1TR002548.

Mean VAF percentage in tissue samples with standard error.

DNA Source	Patient 1 *TP53* c.901_902dupCC	Patient 2 *TP53* c.635_636delTT

Trends in and determinants of germline *BRCA1/2* testing in patients with breast and ovarian cancer. *First Author: Kelsey S. Lau-Min, Division of Hematology/Oncology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA*

Background: Germline *BRCA1/2* testing (GT) is instrumental in identifying patients with breast and ovarian cancer who may be eligible for biomarker-driven poly ADP ribose polymerase inhibitor (PARPi) therapy. Little is known about recent trends and determinants of GT since PARPi were approved for these patients. **Methods:** We performed a retrospective cohort study of patients with breast and ovarian cancer who were eligible for GT (diagnosed with breast cancer under age 45, triple negative breast cancer under age 60, male breast cancer or ovarian cancer) between 1/2011 and 3/2020 in the nationwide Flatiron Health EHR-derived deidentified database. Duration of follow-up was at least one year for each patient. Spline regressions estimated the annual prevalence of GT within one year of diagnosis. Multivariable log binomial regressions estimated adjusted relative risks (RR) of GT by patient and tumor characteristics. Multiple imputation with chained equations was conducted for missing data. **Results:** Among 2,982 eligible patients with breast cancer, 1,682 (56%) underwent GT within one year of diagnosis with a median time of 42 days. GT increased from 37% in 2011 to 68% in 2020, with a significantly higher RR after PARPi were approved for breast cancer in 1/2018 (RR 1.35, 95% CI 1.20-1.51). In multivariable analyses, there were no appreciable differences by sex, race or ethnicity, but there was a negative linear relationship between GT and age (RR 0.93, 95% CI 0.90-0.96 for every 5 years). After adjusting for age, the 87 breast cancer patients with Medicare were also less likely to undergo GT despite being eligible (RR 0.67, 95% CI 0.48-0.95 vs commercial insurance). Among 5,563 eligible patients with ovarian cancer, 1,968 (35%) underwent GT within one year of diagnosis with a median time of 101 days. GT increased from 23% in 2011 to 53% in 2020, with a significantly higher RR after PARPi were approved for ovarian cancer in 12/2014 (RR 2.25, 95% CI 2.01-2.52). Although insurance status was not a significant determinant of GT in patients with ovarian cancer, older age (RR 0.95, 95% CI 0.93-0.97 for every 5 years) and Black race (RR 0.80, 95% CI 0.66-0.98 vs white race) were associated with a lower likelihood of GT in multivariable analyses. All results remained similar in pre-planned sensitivity analyses restricted to the post-PARPi approval period, limiting to patients who remained alive one year after diagnosis and using the non-imputed dataset. **Conclusions:** GT remains underutilized in patients with breast and ovarian cancer. Although GT has increased since PARPi were approved for this population, significant disparities by age, race and insurance status persist but differ by tumor type. This study is limited by potential misclassification due to missing GT performed outside the Flatiron Health network. Multifaceted patient-, clinician- and system-level strategies are needed to ensure that all eligible patients receive GT. Research Sponsor: None.

10584 **Poster Session**

Retrospective analysis of non-BRCA gene pathogenicity variation in Chinese patients with ovarian cancer. *First Author: Li yuan Guo, Harbin Medical University Cancer Hospital, Harbin, China*

Background: Ovarian cancer (OC) is the most lethal gynecologic cancer. Pathogenic (harmful) variants (PV) in *BRCA1* and *BRCA2* are the strongest hereditary risk factors for the development of ovarian cancer. To date, there is little information regarding the frequency of non-*BRCA* gene PV in Chinese women with OC that undergo genetic cancer risk assessment. In this study we analyzed wild-type *BRCA1/2* OC patients (pts) registered in our database. **Methods:** Peripheral blood of 766 women, diagnosed with ovarian cancer, were taken from the recruited cases with the consent of performing germline genetic testing. Germline mutations including SNV, small INDEL were analyzed by next-generation sequencing (NGS). The pathogenicity of germline mutations was categorized based on American College of Medical Genetics and Genomics (ACMG) guidelines. **Results:** Of 766 OC pts, 460 pts (60%) underwent *BRCA1/2* testing only, while 306 pts (40%) consented in multigene panel testing (MGPT). *BRCA1/2* detection rate was 16.8% (129/766), while the detection rate for non-*BRCA* genes was 7.5% (23/306). There was a significant statistical difference in average age that the non-*BRCA* gene pathogenicity variation group was higher than the *BRCA* gene pathogenicity variation group (62 vs. 57, p=0.018). Wild-type B*RCA1/2* OC pathogenic variants (PV), were diagnosed in *BLM* (n=4, 17.4%), *ERCC5* (n=2, 8.7%), *MUTYH* (n=2, 8.7%), *RAD51C* (n=2, 8.7%), *RAD51D* (n=2, 8.7%), *ATM* (n=1, 4.4%), *BRIP1* (n=1, 4.4%), *CDH1* (n=1, 4.4%), *CHEK2* (n=1, 4.4%), *ERCC4* (n=1, 4.4%), *LZTR1* (n=1, 4.4%), *MSH3* (n=1, 4.4%), *PALB2* (n=1, 4.4%), *PMS2* (n=1, 4.4%), *RAD50* (n=1, 4.4%) and *SLX4* (n=1, 4.4%) genes. Of all the 23 non-*BRAC* gene pathogenicity variations, 57% (13/23) lay in the Homologous Recombination Repair (HRR) pathways. Moreover, a 48-year-old woman with ovarian cancer with two pathogenic variants of the [*BRCA2- MUTYH*] genes was detected in the retrospective cohort study. **Conclusions:** *BLM*, *ERCC5*, *MUTYH, RAD51C* and *RAD51D* genes are the main contributors to hereditary wild-type *BRCA1/2* OC in our cohort. The average age of non-*BRCA* gene pathogenicity variation group was higher than the *BRCA* gene pathogenicity variation group. Therefore, multi-gene PANEL detection is recommended for ovarian cancer patients, especially for older patients. Research Sponsor: None.

NGS analysis of germline mutation profile of patients with hepatocellular carcinoma in China. *First Author: Xiaobing Wu, Eastern Hepatobiliary Surgery Hospital, Shanghai, China*

Background: Hepatocellular carcinoma (HCC) is the fourth most common cause of cancer-related death worldwide with very poor prognosis. Many studies have focused on oncogene characteristics, however, the germline landscape of Chinese HCC patients has not been fully clarified. The purpose of this study is to assess the inherited genetic factors regarding germline mutations in Chinese HCC patients. **Methods:** Genetic mutations were reviewed in 1670 Chinese HCC patients who underwent hybridization capture based next-generation sequencing (NGS). The pathogenicity of germline mutations was categorized based on American College of Medical Genetics and Genomics (ACMG) guidelines. **Results:** Of 1670 patients with HCC, 110 (6.7%) patients were identified to carry 111 pathogenic variants(P) or likely pathogenic variants(LP) in 112-cancer predisposition gene panel, and there was no age difference between P/LP group and non-P/LP group (average age: 57 vs 56, p = 0.64). The most frequently germline mutated genes were *BRCA1/2* (11.7%), followed by *ATM*(4.5%), *BLM*(4.5%), *ERCC2*(4.5%), *ERCC3*(4.5%) and *BRIP1*(3.6%), *ERCC4*(3.6%), *FANCD2*(3.6%), *MUTYH*(3.6%), *RAD50*(3.6%). Of all the 111 germline mutations, 47% (n = 52) lay in the Homologous Recombination Repair (HRR) pathways. Both in P/LP group and non-P/LP group, the most frequently somatic mutated genes were *TP53*, *TERT* and *MUC16*. 7/110(6.4%)of patients in P/LP group were high TMB(≥10 mutations/megabase) and 131/1560(8.5%) in non-P/LP group. There was no statistical difference in TMB between P/LP and non-P/LP group. **Conclusions:** Taken together, we have presented the spectrum of pathogenic germline mutations in Chinese HCC patients. P/LP germline variants in cancer predisposition genes were detected in 6.7% of those patients, and predisposition genes associated with HCC risk needs further investigation. Inherited genetics should not be overlooked in HCC as there are important implications for precision treatment, future risk of cancers, and familial cancer risk. Research Sponsor: None.

Genetic counselling and testing for breast and ovarian cancer in Asia: A multinational survey of unmet needs. *First Author: Ava Kwong, Surgery Centre & Cancer Genetics Centre, Hong Kong Sanatorium & Hospital, Hong Kong, Hong Kong*

Background: Enabling equitable access to healthcare services among women remains a challenge in Asia. Differences in the presentation and treatment stage contribute to disparities in cancer outcomes. Genetic testing provides accurate risk assessment to help guide personalised preventative and treatment options. However, there is a critical need for research to further our understanding of barriers in leveraging optimal benefits of genetic testing and counselling (GT&C) to address cancer among women. **Methods:** A team of multinational experts was assembled to form the Asian Consensus and Recommendations on Genetic Testing and Counselling (ACROSS) Consortium to assess the challenges in adoption of GT&C for patients with breast and ovarian cancer in Asia. Critical publications were identified, and a pre-meeting questionnaire was developed. The questionnaire was refined to align with the objectives over iterations, and final approval was obtained from the steering committee. Survey responses were gathered from oncologists from ten countries across Asia. The expert committee discussed the survey results to highlight (1) current knowledge, attitude, and practices; (2) unmet needs and gaps; and (3) recommendations for addressing critical obstacles. **Results:** Adoption of GT&C for cancer is low in Asia. Lack of time, resources, and access to genetic counsellors are major difficulties faced. In most cases, the practising oncologists provide pre-test genetic counselling and communicate test results. For breast cancer (BC), most experts preferred germline testing only, with few opting for somatic testing if germline testing was negative. The agreement was lower among the ovarian cancer (OC) experts, with advocates for either germline or somatic testing or both. There was a lack of consensus on clinical criteria for selecting suitable candidates for genetic testing and the use of multiple gene panel germline testing. The need for government-aided subsidies and training programmes was highlighted. **Conclusions:** Recommendations from the expert panel included (1) development of guidelines and criteria to identify candidates suitable for GT&C; (2) training healthcare professionals with required competencies; (3) improving accessibility and affordability; (4) increased patient education and awareness; and (5) adoption of GT&C into the national healthcare system. The consortium agreed that a multifaceted plan of action combining the expertise of clinicians, scientists, and policymakers is required to facilitate uptake of GT&C in Asia. Research Sponsor: AstraZeneca.

Key survey findings.

Topic	BC (%)	OC (%)
Routine GT&C	65	52
Limited access to genetic counsellors	56	63
Practical constraints	88	85
Pre-test counselling (self)	56	56
Germline testing only	76	19
Multigene panel (all major genes)	50	67
Results communicated (self)	65	78
Aware of regional/national training programmes	47	63
Aware of government-aided subsidies	24	15

DNA damage repair (DDR) germline mutations (GMs) in pancreatic ductal adenocarcinoma (PDAC): A mono-institutional retrospective study. *First Author: Maria Bensi, Oncologia Medica, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli–IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy*

Background: GMs in DDR genes, in particular BRCA1/2, are associated with increased risk of cancer, including PDAC. Their identification is crucial for the clinical relevance, the best treatment choice, and the family implications in cancer prevention. However, there are few data regarding the epidemiology and the prognostic role of DDR GMs in PDAC patients (pts). The aim of our study is to determine the prevalence of DDR GMs, their correlation with clinicopathological features and their prognostic role. **Methods:** Unselected PDCA pts, assessed by BRCA1/2 GM analysis or multigenic panel at our Institution, were retrospectively analyzed. We divided the overall population into three groups based on GMs: pts with pathogenic variants (PVs), pts with variants of uncertain significance (VUS) and pts with no alterations. Clinicopathologic characteristics and treatment data were collected. The incidence of DDR GMs variants and their association with overall survival (OS) were evaluated. Univariate and multivariate analyses for OS were performed. **Results:** From September 2019 to August 2021, 200 PDAC pts were tested for DDR GMs: all pts were evaluated for BRCA 1/2; 140 pts were tested for further DDR GMs by a multigenic panel. Twenty-five pts (12.5%) had PVs, 45 (22.5%) pts had VUS and 130 (65%) pts had no GMs. BRCA 1-2 PVs were found in 10 pts (5%). Out of 91 pts with metastatic disease, the rate of PVs BRCA1/2 was 8.8%. Among 140 pts tested with multigenic panel, further PVs included: 7 (5%) ATM, 5 (3.6%) MUTYH, 1 (0.7%) TP53, 1 (0.7%) BARD1, and 1 (0.7%) MSH6. The most frequent VUS were: CHECK2 (5%), APC (3.6%), ATM (3.6%) and BRCA2 (3.6%). Regarding cancer family history, a statistically significant difference was reported between the 3 group (76% in PV pts, 82% in VUS pts and 60% in pts with no GMs; p 0.01). No difference was found concerning age (p 0.69), stage at diagnosis (p 0.31) and platinum-exposure (p 0.27). Out of 189 evaluable pts, median OS was 23 months. A significant difference in OS was observed in the 3 groups (30 months in PVs pts, 14 months in VUS pts and 24 months in pts with no GMs, p 0.0006). No factor, including the presence or the type of GMs, age, stage and family history, was significantly associated with OS at the multivariate analysis. **Conclusions:** In our study, we observed a high incidence of DDR GMs PV (12.5%), beyond BRCA 1/2, regardless of age, stage and family history. Despite retrospective nature of our analysis, small population, and single-institution evaluation, our findings confirm the importance of genetic testing for BRCA1/2 and, where available, of a multigenic test in all PDAC pts, due to the therapeutic implications and cancer risk prevention in patients relatives. The prognostic role of DDR GMs and the impact of VUS remain unclear. Research Sponsor: None.

Universal genetic testing versus guideline-directed testing for hereditary cancer syndromes among traditionally underrepresented patients in a community oncology program. *First Author: Jeremy Clifton Jones, Mayo Clinic, Jacksonville, FL*

Background: Detection of pathogenic germline variants (PGVs) has implications for cancer screening, prognostication, treatment selection, clinical trial enrollment and family testing. Published guidelines provide indications for PGV testing, determined by clinical and demographic factors, but these leave a significant number of cases missed by guideline-directed testing (incremental PGV). We have previously shown that 50% of patients with PVGs would not have been detected with guideline-based testing alone. In this project, we aimed to determine the feasibility and generalizability of this approach within a more racially/ethnically diverse cohort from a community cancer practice. **Methods:** We completed a prospective study of proactive germline genetic sequencing among patients with solid tumor malignancies at a community-based oncology practice in downtown Jacksonville, FL between June 2020, and September 2021. The patients were unselected for cancer type, stage, family history, race/ethnicity, and age. PGVs identified using an 84-gene NGS platform were stratified by penetrance. National Comprehensive Cancer Networks (NCCN) guidelines were used to determine incremental PGV rates. **Results:** 221 patients were enrolled, median age 63.0 years, 21.7% male. 56.6% of patients were white (non-Hispanic), 32.6% were black/African American, 5.4% were Hispanic. 39.8% of patients were commercially insured, 52.4% insured by Medicare/Medicaid and 2.7% uninsured. The cohort was comprised predominantly of breast cancer (61.5%), lung cancer (10.4%) and colon cancer (7.2%) patients. A total of 27 PGVs were identified in 23 patients. We found no significant difference in the rate of PGVs based on race/ethnicity. The overall rate of variants of uncertain significance (VUS) was numerically higher in black/African American patients (61.1%) compared with other ancestry (45%). 13 of 23 (56.5%) patients with detected PGVs did not meet NCCN guidelines for germline genetic screening (incremental PGVs). **Conclusions:** This prospective study found that universal multi-gene panel testing among patients from a racially/ethnically diverse cohort from a community cancer practice was associated with an increased detection of heritable variants with treatment implications over the predicted yield of targeted testing based on guidelines. This study is the first to evaluate this approach in an exclusively community-based practice. Clinical trial information: NCT04456140. Research Sponsor: Mayo Clinic Center for Individualized Medicine.

Integrated germline and somatic cancer testing provides opportunity to identify cancer risk and resolve variant origins. *First Author: Kingshuk Das, Invitae, San Francisco, CA*

Background: Germline and somatic genetic testing are established tools for the management of cancer patients. Somatic testing is primarily used to inform therapy and germline testing is used to diagnose hereditary cancer predisposition syndromes. While somatic testing can detect germline variants, the interpretation and reporting algorithms are optimized to predict therapeutic efficacy. As a result, germline variants may be missed or only interpreted in context of their potential to act as a therapeutic target. We retrospectively reviewed a series of patients who received both germline and somatic testing to examine the opportunities for concurrent germline testing to improve somatic reporting. **Methods:** Our study reviewed data from 43 patients with solid cancer diagnoses who were otherwise unselected and underwent testing with a 435-gene somatic genetic test and an 83-gene germline test. The most frequent cancers were pancreatic (18), ovarian (8), and prostate (7). **Results:** Out of the 43 patients, 7 (16%) harbored a pathogenic or likely pathogenic germline variant (PGV) in a cancer susceptibility gene. PGVs were identified in *MLH1, MSH6, CHEK2, PALB2, CDKN2A, NBN,* and *MUTYH*. Notably, 3 of these genes (*CHEK2, PALB2, MUTYH*) were not considered therapeutic targets, and therefore were only included as ancillary findings near the end of the preliminary somatic test reports (generated prior to integration of germline test results). In addition, 40 of 43 (93%) patients had at least one variant detected by somatic testing in at least one of the germline panel genes (mean number variant genes = 4.1, maximum = 10); all of these variants were within the reportable range of the germline assay, and therefore germline test results were able to resolve their germline versus somatic origins. The genes that most frequently had somatic variants identified were *TP53* (79% of patients), *CDKN2A* (37%), *SMAD4* (30%), and *FLCN* (21%). **Conclusions:** Due to the size of commonly ordered somatic gene panels, there is a high probability of detecting variants in hereditary cancer predisposition genes (> 90% of patients in this study) that can provide either therapy or cancer risk information or both. Given that a significant proportion (16% in this study) of cancer patients harbor PGVs (which can further inform treatment, disease surveillance, preventive measures, and risk assessment for family members), it is crucial to resolve the somatic versus germline origin of these variants. Since interpretation and reporting algorithms for somatic testing are optimized for therapy prediction, and variables such as specimen tumor purity, tumor ploidy, and variant allele fraction render estimates of variant origin unreliable for diagnostic purposes, it is important to take advantage of germline testing concurrently in patients receiving somatic testing to glean this critical information. Research Sponsor: None.

Germline screening rates and patterns for patients with pancreatic cancer at an academic medical center. *First Author: DeJuana Coleman, University of Virginia Cancer Center, Charlottesville, VA*

Background: Current National Comprehensive Cancer Network guidelines recommend germline genetic testing for all pancreatic cancer patients irrespective of family history. Germline testing provides insight on inherited pathogenic variants that may influence care. Approximately 10% of pancreatic adenocarcinoma (PDAC) patients have pathogenic mutations which may have treatment implications and warrant the introduction of targeted therapy approaches. Patients with germline BRCA1/2 or PALB2 mutations have increased sensitivity to platinum chemotherapy and PARP-inhibitor therapies. Germline testing results may have important implications for patients' family members for earlier targeted screening. A better understanding of the current state of testing is needed to develop systems to improve screening rates. We conducted a retrospective review of clinical practice patterns at an academic cancer center to assess the current uptake. **Methods:** Patients with pancreatic adenocarcinoma seen at the University of Virginia Health System within the 2021 calendar year were identified. Retrospective review of genetic counseling referral and germline genomic screening for individual patients was performed. **Results:** 210 patients with pancreatic adenocarcinoma were identified. 39 (19%) PDAC patients had a referral to genetic counseling placed in the electronic medical record and 44 (21%) completed germline screening. Of the patients referred to genetics, 17/39 patients (44%) met with a genetic counselor which led to germline screening, 3/39 (8%) patients were referred and saw genetics after receiving germline testing results. Among patients who completed germline screening, 27/44 (61%) had testing initially ordered by their oncologist with referral to genetic counseling based on testing results 3/27 (11%). **Conclusions:** Despite guideline recommendations, germline testing rates are low among this PDAC population. Genetic counselors are essential members of a multidisciplinary team and guide patient discussions and decision making with regards to germline testing. Typical practice has involved referral to meet with a genetics counselor prior to testing; however many patients elect not to schedule a visit and consequently do not obtain germline screening. Barriers may include costs associated with genetic counseling/testing, time constraints, and patient understanding of the relevance of testing for their cancer care. We observed that offering germline testing to PDAC patients with referral to genetic counseling based on results and patient preference is a viable practice pattern. Upfront clinician driven germline testing may offer an opportunity to improve access to germline screening. Prospective clinical trials are needed to increase rates of germline testing and genetic counseling for PDAC patients. Research Sponsor: None.

Oncologist knowledge of cost of genetic testing. *First Author: Shayna Weiner, University of Michigan, Ann Arbor, MI*

Background: Genetic testing allows patients and their families to identify hereditary cancer syndromes. Financial barriers to genetic testing are a major concern for patients offered genetic risk assessment. The cost of germline genetic testing has decreased substantially over the last several years. It is not clear, however, that oncologists are knowledgeable about the cost of genetic testing. The purpose of this study was to investigate oncologists' knowledge of genetic testing costs. **Methods:** We deployed a survey to all oncologists who are members of the Michigan Oncology Quality Consortium, a physician-led quality improvement collaborative whose members represent 95% of the oncologists in Michigan. The modified Dillman method was used to achieve the maximum response rate. Responses were collected from December 2020 through May 2021. The responses to the question, "If a patient were to ask you how much it would cost for them to have clinical genetic testing for hereditary cancer syndromes, what would you tell them?" were independently coded by three investigators into one of three categories – correct and helpful, correct and not helpful, or incorrect and not helpful. We investigated associations between the number of years in practice and how important was cost as a barrier to genetic risk assessment. **Results:** The response rate to the survey was 61.2% (194/317). Only 25% of respondents provided an answer that was deemed to be both correct and helpful to a patient, for example "approximately $250 if out of pocket." Nearly 40% of respondents gave an answer that was correct but was non-specific and would not help a patient decide about pursuing genetic testing. This category included responses such as deferring to a genetic counselor or that cost varies based on insurance. About 28% gave an incorrect response, such as "several thousand dollars" or responded, "I don't know." No associations were found between cost response category, number of years in practice, or reported responses that financial barriers play a role in referral patterns. **Conclusions:** The majority of oncologists in our statewide sample do not have an accurate understanding of the cost of germline genetic testing. Lack of precise information about the costs of testing may lead patients to believe that genetic testing is either not important or not within reach. Furthermore, providing incorrect information can have a downstream effect and prevent patients and their families from pursuing genetic counseling. Improving oncologists' knowledge about the cost of testing may decrease barriers to uptake of genetic risk assessment. Research Sponsor: U.S. National Institutes of Health, PI funded.

Physician Response	Count (%)
Correct and Helpful	48 (24.7)
Correct and Not Helpful	76 (39.2)
Incorrect and Not Helpful	54 (27.8)
Missing	16 (8.2)

Relative disclosure of information on hereditary cancer syndromes: A systematic review and meta-analysis. *First Author: Muhammad Danyal Ahsan, Weill Cornell Medicine, New York, NY*

Background: Evidence-based guidelines recommend that patients (probands) diagnosed with a hereditary cancer syndrome share the information with blood relatives as relatives can have 50% risk for harboring the same pathogenic mutation. This information offers the opportunity for relatives to undergo genetic counseling, genetic testing, early detection, and prevention of cancer. Limited literature on this topic suggests underutilization of recommended family member disclosure. We sought to evaluate rates of familial disclosure of hereditary cancer syndrome information in the first meta-analysis on this topic. **Methods:** We conducted a systematic review and meta-analysis in accordance with PRISMA guidelines (PROSPERO no.: CRD42020134276). We searched key electronic databases to identify studies evaluating hereditary cancer cascade relative disclosure. Eligible trials were subjected to meta-analysis. **Results:** Thirty studies met inclusion criteria. This review included 3,779 probands and 12,751 at-risk relatives. Among 12,751 included relatives, 72% (CI 64-79%) received information about the hereditary cancer syndrome identified in their family and 28% (CI 19-37%) underwent genetic testing. On meta-analysis, there was a higher rate of disclosure among female vs male relatives (79% [73% - 84%] vs 67% [57% - 75%]) and a higher rate among first-degree vs. second degree relatives (83% [77% - 88%] vs 58% [45 – 69%]). The data regarding the contribution of race/ethnicity to disclosure were limited and inconsistent, with two studies demonstrating non-White vs. White relatives being less likely to have results disclosure and two studies finding no correlation; however, both studies finding no difference were limited by small sample sizes. Finally, one study found that higher proband annual income was associated with improved familial disclosure. **Conclusions:** Despite a growing understanding of the importance of cascade genetic counseling and testing, probands do not disclosure information on hereditary cancer syndromes to most at-risk relatives. Very few relatives complete genetic testing, representing a critical missed opportunity for precision cancer prevention. Future studies are needed to elucidate barriers to hereditary cancer syndrome disclosure and create innovative strategies to facilitate this essential process. Research Sponsor: None.

Determining concordance of LFSPRO *TP53* germline carrier risk predictions to standard genetic counseling practice. *First Author: Elissa B. Dodd-Eaton, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Li-Fraumeni Syndrome (LFS) is a hereditary cancer syndrome associated with a germline mutation in the *TP53* tumor suppressor gene and an increased risk of developing a spectrum of cancers throughout a carrier's lifetime. Early cancer detection in patients with *TP53* mutations can dramatically improve cancer survival rates. However, it can be difficult to identify patients at risk of LFS due to the overlap of the multiple cancer types with other inherited cancer syndromes. Risk prediction modeling has been widely accepted by the clinical community, however, currently there is not an available tool to assist in risk prediction of LFS during genetic counseling sessions. LFSPRO is a statistical model that has previously been validated on large research cohorts in predicting the likelihood of a proband having LFS based off detailed patient and family history information. To improve the clinical utility of LFSPRO, a user-friendly interface is still needed. Additionally, we aim to evaluate concordance between LFSPRO's abilities in predicting the likelihood of a proband having LFS and currently established clinical testing criteria. **Methods:** We developed a Shiny App to create a user-friendly interface for genetic counselors (GCs) to run LFSPRO. Determining concordance of LFSPRO to standard germline testing criteria and the clinical utility of the LFSPRO Shiny App is underway by GCs within the Department of Clinical Cancer Genetics at MD Anderson Cancer Center through prospective data collection and completion of user surveys. Following a standard genetic counseling session, individuals identified as concerning for a potential germline *TP53* mutation are evaluated with LFSPRO to compare performance of the model to established *TP53* testing guidelines. Concordance is then evaluated in prediction of *TP53* mutation carrier status from LFSPRO, current clinical criteria and clinical judgment. Data collection began 12/21/2021 and is currently ongoing. **Results:** Close collaboration with GCs and clinicians on the development of the LFSPRO Shiny App has achieved automated de-identified input data, clear pedigree drawing, important demographic data, interpretable risk results and risk visualizations to be used at the GC's discretion. To date, 29 individual's family data have been run through LFSPRO. Of these, 11 have not currently completed *TP53* testing and concordance cannot be determined. Of the 18 remaining, 14 individuals' LFSPRO results were concordant with current clinical criteria. Further data collection is needed to appropriately analyze concordance. **Conclusions:** The LFSPRO Shiny App aims to provide an additional tool for GCs and clinical providers to assess patient risk for LFS. This ongoing study will help establish the clinical utility of LFSPRO in a single institution's genetic counseling practice with the potential to be applied to other patient care settings in the future. Genetic epidemiology of breast cancer (BC) risk genes from a diverse real-world oncology practice in Brazil. *First Author: Bernardo Garicochea, Grupo Oncoclinicas, São Paulo, Brazil*

Background: As germline testing in BC is becoming more accessible, a large body of evidence from distinct populations is revealing different prevalence of affected genes or recurrent and founder mutations. We evaluated a series of Brazilian BC patients from diverse regions of the country that were studied in a single laboratory facility for likely pathogenic/pathogenic variants (PV) and variants of unknown significance (VUS) in BRCA1/2 and other BC susceptibility genes (ATM, BARD1, CDH1, CHEK2, PALB2, RAD51C, RAD51D and TP53). **Methods:** We used multi-gene NGS panels covering from 35 to 105 genes, including copy number alterations, to perform sequencing in patients with diagnosis of BC from 2016 to 2021. With patient consent, we extracted clinical and pathological data from curated Real-World Database of Oncoclínicas Group to classify tumors according to hormone receptor (HR) and HER2 status and assess family history of cancer. Primary endpoint was prevalence of PV and VUS in BRCA1/2 and other breast cancer risk genes. **Results:** In total, 1,520 patients with BC were included in the analysis, 99% were female, median age at genetic testing was 46 years and 84% had family history of cancer. BC subtype was available in 717 cases (43% HR+/HER2-, 26% HER2+, 31% triple negative). Median age at genetic testing in HR+/HER2- population was 49 years and 44 years in HER2+ and triple-negative cases. Overall, 11.7% (CI95% 10.1-13.4) of the population had at least one PV in any BC risk gene: 50 in BRCA1, 49 in BRCA2, 22 in TP53 (17 had Brazilian founder p.R337H haplotype), 19 in PALB2, 18 in CHEK2, 15 in ATM, 7 in other genes (BARD1, CDH1, RAD51C, RAD51D) and 4 patients had co-existing PV in 2 BC risk genes. BRCA1/2 PVs were found in 7% of BC patients and BRCA1/2 VUS in 3%, being higher in triple-negative cases (11% PVs) than HR+/HER2- (5% PVs) and HER2+ (3%). For other BC risk genes, 5% of the patients had a PV, without differences according to BC subtype, and the prevalence of VUS was 14%. The prevalence of TP53 Brazilian founder mutation in BC was 1.2%. Median age of genetic testing was younger in population with BRCA1 PV (43 years) than BRCA2 PV (47 years) and other genes PV (46 years). **Conclusions:** In this real-world cohort of BC patients enriched for high-risk features such as young age at diagnosis, positive family history and triple-negative disease, the prevalence of BRCA1 and BRCA2 PV was very similar and represented only 56% of all PV detected. Different from other studies, TP53 mutations are the third most common germline alteration in the Brazilian population, with close to 80% of the cases presenting the founder mutation p.R337H. BC with epidemiologic high-risk features should be offered a germline test in Brazilian patients due to the considerable chance of a PV detection. Research Sponsor: None.

Patient-reported outcomes among males undergoing prostate cancer germline testing: Interim results from the Prostate Cancer Genetic Risk, Experience, and Support Study (PROGRESS) Registry. *First Author: Veda N. Giri, Departments of Medical Oncology, Cancer Biology, and Urology, Cancer Risk Assessment and Clinical Cancer Genetics Program, Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA*

Background: Indications for prostate cancer (PCA) germline testing (GT) have greatly expanded, necessitating thousands of men to seek genetic evaluation through traditional genetic counseling and alternate delivery approaches. Therefore, there is an important need for patient-reported outcomes among men undergoing genetic testing which has been understudied. PROGRESS (Prostate Cancer Genetic Risk, Experience, and Support Study) was therefore developed to garner men's experience with PCA germline testing. Here we provide an interim update on recruitment and results from registry participants. **Methods:** PROGRESS is a patient-driven registry of clinical, genetic, and patient-experience information among men undergoing PCA genetic testing. Survey covers demographic information, PCA history, mode of genetic counseling, satisfaction, decisional conflict, intention to share genetic results with family and physicians, attitude towards genetic testing, knowledge of cancer genetics, medical literacy, and numeracy. Descriptive statistics summarized results with counts and percentages for categorical variables and mean and standard deviation for continuous variables. All analyses were performed with SAS 9.4 (Cary, NC). **Results:** Current enrollment is 217 participants. Among 140 men with complete demographics, 93.57% are White, 98.6% non-Hispanic/Latino, 85% with bachelor's degree or higher. Among 143 respondents, 60% reported a diagnosis of PCA. Among 85 men who reported on Gleason score, 24.7% had Gleason > = 8. Regarding family history, 23.5% reported a $1^{st}/2^{nd}$ degree relative with PCA and 58.1% reported a $1^{st}/2^{nd}$ degree relative with any cancer. Among 150 men who reported genetic results, 40.7% had a genetic mutation, 18% reported having a VUS, and 10.7% reported not knowing their results. Among 185 men who reported on mode of genetic evaluation, 58.4% met with a genetics professional and 21.7% reported their doctor had discussed genetic testing. Satisfaction was high (n = 121) (highest score 30; mean score 27.92 + 2.73) and decisional conflict was low (n = 138) (mean score 26.07 + 10.18; range 16-80). Majority of 140 respondents discussed their results with their family (93.6%). Knowledge of cancer genetics was modest, with correct responses among 140 respondents of 50.1% + 28.1. **Conclusions:** Current participants of the PROGRESS Registry report high satisfaction with their genetic evaluation process. However, resources are needed to increase knowledge and understanding of genetic results. Greater engagement of African American males is critically needed to garner diverse perspectives and develop resources for men and their families applicable across populations. Target goal of the registry is 500 males; men can be referred to participate in the PROGRESS Registry at www.progressregistry.com. Germline mutations in ATM, CHEK2, and other known/potential breast cancer susceptibility genes among BRCA-negative Uruguayan patients with breast cancer. *First Author: Lucia Beatriz Delgado, Hospital de Clínicas, Montevideo, Uruguay*

Background: Breast cancer (BC) is the most frequent and the leading cause of death from cancer in Uruguayan women. In a previous study, we found BRCA1/2 germline mutations in less than 25% of the Uruguayan breast/ovarian cancer families studied. Due the impact and relevance of genetic testing in BC prevention and with the commitment to assure a wide accessibility, we developed genetic testing facilities at the University Hospital with the aim of analyzing and characterizing germline mutations in non BRCA known susceptibility and likely susceptibility genes. **Methods:** We studied 104 families who met the National Comprehensive Cancer Network (NCCN) criteria of hereditary BC. Analysis by next generation sequencing of BRCA1/2 genes revealed that 23 out of 104 cases studied (22%) carried pathogenic variants. Germline DNA from 42 cases BRCA negative was sequenced and analyzed for nine additional susceptibility genes (ATM, BARD1, CDH1, CHEK2, NBN, PALB2, PTEN, STK11 y TP53) included in a genetic panel. Also, in 24 cases negative for this panel we analyzed large deletions in BRCA1/2 by multiplex ligation-dependent probe amplification (MLPA) testing. In addition, to identify novel non-canonical causative genes, we extended our analysis to a complete exome sequencing of cases tested negative in genetic panels and MLPA analysis. **Results:** Among the 42 cases BRCA negative the sequencing of the extended genetic panel revealed 12 (28.8%) variants, 8 of uncertain significance (VUS) and 4 pathogenic, 2 novel (one in the ATM gene: NM_000051: c.614T > G and other in p53: NM_000546: c.245insT) and 2 previously reported (one in PALB2: NM_024675: c.2186insA and one in PALB2/1: NM_024675c.G7T genes). Regarding the VUS, it is worth highlighting the one found in exon 12 of CHEK2 (NM_007194: c.1333T > C) which was unusually frequent (16.7%) in our cohort when compared with public databases. Analysis of large deletions in BRCA1/2 in 24 cases without mutations in the genetic panel were negative for MLPA testing. Otherwise, complete exome sequencing of germline DNA from 22 cases negative for BRCA1/2 and for the genetic panel, revealed 18 variants, 16 that generate stop codons and 2 that generate loss of the termination codon (stoploss), suggesting a high potential for pathogenicity. Some striking examples are represented by the PSG2, CEP 135 y CEP 162, ZNF17 and ZNF260 genes. **Conclusions:** Of the 42 BRCA-negative cases, 4 (9.5%) carried a PV in a cancer susceptibility gene. The negative results obtained with MLPA in cases negative for BRCA and the extended genetic panel suggest that large deletions of BRCA are not a relevant cause of cancer susceptibility in this cohort. Otherwise, whole exome sequencing of 22 cases negatives for the previous genetic test showed pathogenic or probably PV in genes with no current evidence of association with breast and ovarian cancer. Evaluation of Lynch syndrome risk models in a multicenter diverse population. *First Author: Jenny Lu, Harvard University, Cambridge, MA*

Background: Lynch syndrome (LS) is the most common cause of hereditary colorectal cancer (CRC) with an increased CRC lifetime risk of 70-80%. LS affects 1:250 individuals and is caused by pathogenic variants in the mismatch repair (MMR) genes. Statistical prediction models such as MMRpro and PREMM5 are widely used to identify LS carriers. However, these models are trained and validated in mostly white populations, and there remains a gap in understanding their performance in Hispanic populations. The purpose of this study was to evaluate the performance of MMRpro and PREMM5 on a large Hispanic cohort from the Clinical Cancer Genomics Community Research Network (CCGCRN). **Methods:** We validated MMRpro and PREMM5 on 3,490 CCGCRN families, of which 1,122 are Hispanic and 2,062 Non-Hispanic. The two models were evaluated for discrimination using the C-statistic, calibration using the observed to expected ratio (O/E), and overall performance using the root Brier score and negative and positive predictive value (NPV/PPV) at the 5% carrier probability threshold. Evaluations were stratified by ethnicity, and 95% confidence intervals were obtained via bootstrapping for all measures. **Results:** The C-statistic is 0.90 for both MMRpro (95% CI: 0.88, 0.92) and PREMM5 (95% CI: 0.87, 0.92). When stratified by ethnicity, the C-statistics are 0.96 (95% CI: 0.94, 0.97) and 0.86 (95% CI: 0.83, 0.89) for Hispanics and Non-Hispanics, respectively, in MMRpro, and 0.96 (95% CI: 0.94, 0.97) and 0.84 (95% CI: 0.79, 0.88) in PREMM5. Both models underpredict mutation probabilities, with O/E ratios ranging from 1.79 to 1.96. At a 5% threshold, variations in PPV between Hispanics and Non-Hispanics are observed in both models: 0.72 (95% CI: 0.63, 0.80) and 0.43 (95% CI: 0.37, 0.50) in Hispanic and Non-Hispanic groups in MMRpro; 0.50 (95% CI: 0.43, 0.57) and 0.25 (95% CI: 0.20, 0.30) in PREMM5. We observe less variation and higher values in NPVs in both models. **Conclusions:** Overall, MMRpro and PREMM5 perform well in this cohort in predicting the probability of having a pathogenic variant in an MMR gene, with modest underprediction. While these results offer reassurance for the clinical use of MMRpro and PREMM5 in Hispanic populations, further validation studies in underrepresented racial and ethnic populations are crucial. Scenery of multilocus inherited neoplasia alleles syndrome (MINAS) in a single Brazilian institution. *First Author: Andre Marcio Murad, Personal. Oncologia de Precisao e Personalizada, Belo Horizonte, Brazil*

Background: Genetic testing of hereditary cancer using comprehensive gene panels can identify patients with more than one pathogenic mutation in high and/or moderate-risk-associated cancer genes. This phenomenon is known as multilocus inherited neoplasia alleles syndrome (MINAS), which has been potentially linked to more severe clinical manifestations.To determine the prevalence and clinical features of MINAS in a large cohort of adult patients with hereditary cancer homogeneously tested with the same gene panel. **Methods:** A cohort of 1,234 unrelated patients with suspicion of hereditary cancer was screened using a validated NGS panel including 20 genes associated with hereditary cancer. **Results:** One hundred and forty two (8.7%) patients harbouring probably pathogenic or pathogenic mutatations and 9 harbouring two pathogenic mutations in dominant cancer-predisposing genes were identified, representing 6.3% (9/142) of patients with pathogenic mutations. All (9/9) of these cases presented clinical manifestations associated with only one of the mutations identified. One case showed mutations in MEN1 and MLH1 and developed tumours associated with both cancer syndromes. Interestingly, three of the double mutants had a young age of onset or severe breast cancer phenotype and carried mutations in moderate to low-risk DNA damage repair-associated genes; two of them presented biallelic inactivation of CHEK2. We included these two patients for the sake of their clinical interest although we are aware that they do not exactly fulfil the definition of MINAS since both mutations are in the same gene. **Conclusions:** Genetic analysis of a broad cancer gene panel identified the largest series of patients with MINAS described in a single study. Overall, our data do not support the existence of more severe manifestations in double mutants at the time of diagnosis although they do confirm previous evidence of severe phenotype in biallelic CHEK2 and other DNA repair cancer-predisposing genes. Research Sponsor: None.

Variants of unknown significance (VUS) in patients with hereditary CRC without a known pathogenic variant. *First Author: Marija Stojovska, Center for Biomolecular Pharmaceutical Analyses, UKIM-Faculty of Pharmacy, Skopje, Macedonia*

Background: Nearly 5-10% of all newly diagnosed colorectal cancer (CRC) cases develop due to the presence of a highly penetrant pathogenic variant in one of the hereditary colorectal cancer (hCRC) associated genes. NGS technology raised the opportunity for fast and efficient detection of these variants, but still in ~20-30% of patients with hCRC the genetic defect remains unknown. Recent data shows that 6-8% of these cases harbor pathogenic/VUS variant in low/moderate penetrance genes not directly associated with hCRC. **Methods:** A total of 109 patients with hCRC (43 with polyposis and 66 with non-polyposis syndromes) were analyzed by NGS covering coding and exon/intron sequences of 109 genes, of which 25 associated with known hCRC syndromes and 83 other cancer predisposition genes. **Results:** Pathogenic variants were detected in 63/109 (57.7%) of analyzed patients; 54/63 (85.7%) of these had a pathogenic variant in one of the genes associated with hCRC (APC, MMR genes, MUTYH, NTHL1, BMPR1A) and 9/63 (14.3%) had a pathogenic variant detected in genes not directly related to hCRC (CHEK2, FANCL, FANCM, ERCC2, BRIP1, FLCN, BLM). In 26/109 (23.8%) patients a rare VUS variant was detected, of which 14/26 (53.8%) in double strand repair (DRG) genes (BLM, CHEK2, PALB2, ATM, MRE11A, BRIP1, FANCM, FANCL and ERCC2), 8/26 (30.8%) in one of the known hCRC genes (APC, MSH6, PMS2 and POLE) and 4/26 (15.4%) in other cancer predisposition genes (KIT, NSD1, CDH1, EZH1 and FH). VUS variants in DRG genes were more common in patients with MSI- HNPCC (9/15, 60%), compared to patients with polyposis syndromes (6/15, 40%). The VUS variants in other cancer predisposition genes were dominantly present in patients with oligopolyposis. Most (21/26, 80.8%) VUS variants were detected as single variants, while only five patients (5/26, 19.2%) had two different variants in two different genes. In 20/109 (18.3%) patients who presented primarily with MSI- HNPCC or oligopolyposis phenotypes, no pathogenic and/or VUS variants were detected in the 109 analyzed genes. **Conclusions:** Genetic basis of hereditary CRC was not clearly defined in a large proportion (42.3%) of patients in our cohort. Although a VUS variant was detected in a significant portion (23.8%), a major fraction (18.3%) of patients had no known genetic variant detected. The presence of a high frequency of VUS variants in DRG genes indicates that this pathway plays an important role in CRC carcinogenesis. Although we cannot exclude the presence of deep intronic and/or regulatory region pathogenic variants in the analyzed genes, it appears that the current list of identified cancer predisposition genes responsible for the hereditary CRC is far from being complete. The influence of environmental factors in conjunction with polygenic inheritance might also play a key role in a fraction of hCRC in our population. Research Sponsor: Center for biomolecular pharmaceutical analysis.

***TP53* pathogenic variants with low allele fraction in germline genetic testing.** *First Author: Yanqing Wu, Department of Interventional Oncology, The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China*

Background: Blood or saliva DNA generally considered to be representative of germline genome in genetic cancer risk assessment. However white blood cells from these samples may also include somatic origin DNA due to post-zygotic variation or, most commonly, clonal hematopoiesis (CH). Low variant allele fraction (VAF) found in germline genetic testing suggest the possibility of somatic variant and may lead to misinterpretation of genetic risk. *TP53*, of which germline pathogenic variants are associated with Li-Fraumeni syndrome (LFS), is frequently mutated in CH. This analysis investigated characteristics of *TP53* pathogenic variants with low VAF. **Methods:** We reviewed the prevalence and distribution of *TP53* pathogenic variants(PVs) detected in 11,277 advanced cancer patients who underwent clinical testing with a clinical NGS pan-cancer panel. Potential somatic PVs were defined as variants with low VAF from 10% to 35%. The VAF were evaluated in matched tumor tissue samples if available. **Results:** *TP53* pathogenic variants were detected in 36 (0.32%) patients from blood or saliva samples, VAF between 10% and 35% were identified in 8(22.22%) patients and 7 of them were performed NGS sequencing in matched tumor tissue samples. The average VAF of tissue samples were 9.31times lower than blood or saliva samples(21.69% vs 3.88%). **Conclusions:** *TP53* pathogenic variants with low allele fraction in blood or saliva samples indicate the possibility of somatic variant, a reduced VAF in matched tumor tissue samples may contribute to confirmation for suspicion of somatic origin. Research Sponsor: None.

Effects of healthcare provider recommendation for genetic testing. *First Author: Emerson Delacroix, University of Michigan, Ann Arbor, MI*

Background: This pilot study was conducted to elucidate the barriers and drivers for genetic testing by combining validated measures to inform the content of a clinical trial aimed at increasing uptake of clinically appropriate genetic testing amongst individuals with a personal history of cancer. Previous research shows that the rate of recommendation of genetic testing varies among Healthcare Providers (HCPs) despite national guidelines. Here we evaluate the rate and effect of HCP recommendation on the uptake of clinical cancer genetic testing. **Methods:** Data for these analyses were obtained from a cross-sectional survey completed by 794 adults (> 18 years) who were diagnosed with cancer in the past 10 years and were seen at an academic medical center within the past two years. Statistical analysis includes logistic regression and crosstabulation with SPSS and R statistical software. **Results:** Provider recommendation of genetic testing was found to be a very strong indicator of receiving genetic testing across all cancer types (OR = 146.4, p = < .001). HCPs more frequently recommended genetic testing to females (OR = 12.5, p = < .001), younger patients (OR = 1.05, p = < .001). While females are more likely to receive a recommendation, there were no significant differences on genetic testing uptake when a HCP recommended it for any gender. **Conclusions:** Without the recommendation of their provider, patients were significantly less likely to receive genetic testing that could affect their cancer treatment, surveillance, or family members. More aggressive patient health education is needed in cancer affected patients to decrease knowledge deficits and increase motivation for cancer genetic testing uptake. Education to providers regarding genetic testing recommendation guidelines could increase motivation to refer patients for genetic testing and counseling. Research Sponsor: U.S. National Institutes of Health.

10602 **Poster Session**

A pilot study to increase cascade genetic testing in families with hereditary cancer syndromes. *First Author: Steven J. Katz, University of Michigan, Ann Arbor, MI*

Background: There is great need to build and evaluate tools and strategies to improve cascade genetic risk evaluation in families at high risk for hereditary cancer. The Genetic Information and Family Testing (GIFT) Trial (CA254822) is a population-based intervention that examines features of a virtual platform that provides genetic risk education (GRE) and low-cost genetic testing (GT) to relatives of adult patients diagnosed with cancer in 2018-19 in Georgia and California and tested positive for a clinically relevant germline pathogenic variant (PV). We present findings of a pilot study intended to inform the GIFT Trial protocol and platform features. **Methods:** We surveyed 277 women diagnosed with breast cancer in 2017, reported to the Georgia SEER registry, and received genetic testing (95% of whom had a clinically relevant PV). We then invited respondent patients to enroll in the intervention phase which provided online GRE, human pretest genetic navigator support, and an offer of low-cost GT through Color Health, Inc. to all untested 1st or 2nd degree relatives. Respondent patients were eligible for the intervention if they reported a PV on genetic testing and had at least one relative who had not received GT. Enrolled patients invited relatives through the platform by providing email addresses. Family clusters were block randomized to free vs $50 test costs at the time of the initial patient invitation. **Results:** At study midpoint, 117 of 277 patients (42%) had returned surveys: median age was 51 and 22% were African American. The most frequent PVs reported by the patients were *BRCA1/2* (41%), *CHEK2* (21%), and *PALB2* (8%). Half (54%) had previously encouraged all of their brothers to get GT and 71% had encouraged all of their sisters to get GT. Three-quarters (78%) strongly agreed it was important for relatives to understand their genetic risk for cancer, and half (54%) strongly agreed they would like to make it easier for relatives to get genetic testing. The median number of patient-reported untested relatives in a family was 8.5 (25th-75th percentile: 4-14). Most respondent patients were eligible for the intervention phase (N = 108, 93%). About one-quarter had enrolled in the intervention at midpoint (16 of 53 in no-cost arm vs 16 of 55 in $50 arm). Patients in the no-cost arm invited 21 relatives, 10 of whom had enrolled with 8 ordering GT (38% of invited relatives). Patients in the $50 arm invited 38 relatives, 18 of whom had enrolled with 17 ordering GT (45% of invited relatives). Overall, about half of enrolled relatives (46%) were men . **Conclusions:** Breast cancer patients with PVs make substantial efforts to communicate with family members about genetic risk; but they strongly endorse the need for additional support to facilitate this complex communication. Interim pilot findings suggest that a low-cost online navigator-supported intervention can directly engage relatives with little difference in GT uptake by test cost arms. Research Sponsor: None.

Outcomes of the BRCA quality improvement dissemination program in three health systems. *First Author: Erica M. Bednar, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The BRCA Quality Improvement Dissemination Program (BQIDP) was disseminated to 3 community-based health systems' oncology clinics in 2017. The BQIDP occurred over 3 years and aimed to increase rates of guideline-recommended referral (ref), genetic counseling (GC), and germline genetic testing (GT) for patients diagnosed with invasive epithelial ovarian, fallopian tube, and primary peritoneal cancer (OC) and triple-negative breast cancer diagnosed at age 60 or younger (TNBC). The BQIDP applied virtual implementation facilitation to support sites' development, implementation, and tracking of quality improvement (QI) interventions. Interventions were adapted from prior QI initiatives and published interventions. **Methods:** Baseline metrics (patients diagnosed 1/1/2015 to site's BQIDP launch date Autumn 2017) were compared to metrics of patients diagnosed during BQIDP implementation (site launch dates Autumn 2017 to Autumn 2020). Two-sample test of proportions was used to assess for statistically significant change in rates pre and post BQIDP implementation at each site. QI interventions targeted provider and patient education, retrospective and prospective case finding with alerts to providers and patients, case finding by review of somatic test results and genetic counselor tumor board attendance, streamlined ref and scheduling processes, and infusion-suite based GC. **Results:** All clinics increased rates compared to baseline (Table). Statistically significant improvement was noted for patients with OC in receipt of GC at Site A, ref and receipt of GC at site B, and receipt of GC at site C. Statistically significant improvement was noted for patients with TNBC in ref and GT at sites A and B. **Conclusions:** Improved rates of ref, GC and GT for patients with OC and TNBC were observed at all 3 sites compared to baseline. Baseline ref, GC, and GT metrics for patients with TNBC were higher than for patients with OC at all sites. Tailored and facilitated QI efforts can promote patients' receipt of guideline-recommended cancer genetics services in health system oncology clinics. Research Sponsor: MD Anderson Moon Shots Funding.

Hereditary cancer screening at an urban safety net hospital. *First Author: Sydney Brehany, University of Colorado School of Medicine, Aurora, CO*

Background: Individuals with hereditary cancer syndromes (HCS) have a high lifetime risk of developing cancer. However, the rate at which at-risk individuals undergo genetic evaluation is low, particularly for individuals that belong to populations that are historically underserved. We sought to characterize the demographic factors that may be associated with receipt of recommended HCS evaluation and follow-up. **Methods:** All patients with pathologically confirmed breast, ovarian, or fallopian tube cancers and qualifying for hereditary breast and ovarian cancer (HBOC) testing based on NCCN guidelines from 2016 to 2021 at an urban safety-net hospital were included in this analysis. Institutional review board approval was obtained. Demographic and oncologic data, as well as HBOC genetic testing outcomes were collected through retrospective chart review using a standardized data collection tool. Univariate logistic regression models were constructed to test the association of variables with receiving hereditary cancer genetic testing. **Results:** A total of 312 patients were included in the analysis, 90% of which had breast cancer. Forty percent were non-English speaking, 31% were non-White, and 25% were uninsured. Overall, 70% of patients were referred for genetic counseling and 65% underwent testing. Our analysis showed higher association of genetic testing uptake with Spanish language [odds ratio (95% confidence interval)] [1.74 (1.04, 2.93)], stage II disease [2.15 (1.11, 4.16)], and having a referral to genetic counseling [9.21 (5.32, 15.96)]. A lower rate of genetic testing was associated with patients identifying as Black [0.36 (1.87, 0.70)], having Medicare insurance [0.29 (0.14, 0.61)], a higher Charlson Comorbidity Index [0.31 (0.13, 0.73)], and older age [0.94 (0.92, 0.96)]. Uninsured patients had a similar association with genetic testing uptake as patients with Medicaid. Variables seeming to have no association with genetic testing uptake include family history of cancer, type of cancer, performance status, substance use, and Latinx ethnicity. A pathologic variant was found in 13% of our population. A variant of unknown significance (VUS) was found in 33% of Hispanic or Latinx patients and in 46% of non-Hispanic or Latinx patients who received testing, for a combined VUS prevalence of 39%. **Conclusions:** Our analysis shows that genetic testing rates for patients meeting HBOC syndrome criteria at an urban, safety-net institution were higher than expected, particularly for Spanish speaking patients and those with Medicaid or no insurance. We hypothesize this may be due to the emphasis our institution places on the care of uninsured patients through programs to make services accessible, as well as strong engagement with the Spanish speaking community. These results can help guide future interventions to target patient groups with lower rates of genetic testing, as well as maintain the successes seen among our diverse population. Genetic risk assessment in primary care settings: An evaluation of NCCN guidelines. *First Author: Kara J. Milliron, University of Michigan, Ann Arbor, MI*

Background: Lynch syndrome (LS) and hereditary breast and ovarian cancer (HBOC) have a population prevalence of 1/279[1] and 1/400[2], respectively. Despite this, >80% of patients referred for cancer genetic counseling report personal or family history of breast cancer[3]. This disparity may be due to increased media attention for HBOC, lower levels of provider awareness of LS, and less discussion of colorectal cancer within families compared to breast cancer[4]. However, potential biases in National Comprehensive Cancer Network (NCCN) criteria for genetics evaluation (GE) have not been studied. This project examined the performance of NCCN guidelines for identifying individuals meeting criteria for GE ascertained through primary care (PC) settings. **Methods:** Individuals scheduled for routine PC appointments at three Michigan Medicine affiliated practices from 10/24/18 through 1/24/22 were emailed a link to complete an online personal and family history (P/FHx) risk assessment module (INHERET) collecting information about cancer diagnoses (age/cancer type) in 1st, 2nd, and 3rd degree relatives. The module was written at a 4th grade reading level and could be accessed on any internet-connected device. NCCN guidelines were applied to determine if patients met criteria for GE of HBOC and/or LS. **Results:** A total of 465 individuals completed the module; nearly one in three (30.6%, 142/465) met NCCN criteria for GE of HBOC or LS. Of those meeting criteria, 132 (92.9%) had no personal history of cancer. The most common indication for GE was HBOC (29.5%, 137/465) and 30 patients (6.5%) met HBOC referral criteria solely based on Ashkenazi Jewish ancestry. Only 17/465 (3.7%) individuals met NCCN criteria for GE of LS. Interestingly, 12/17 (70.6%) who met criteria for GE of LS also met criteria for GE of HBOC. The completion rate was not 100% and cannot be determined; it is not known how many patients were offered the option of completing the module. This limits the study, as ascertainment bias cannot be assessed. **Conclusions:** Nearly one-third of PC patients who completed the P/FHx module met NCCN criteria for genetic evaluation of HBOC and/or LS. Referrals for HBOC outnumber those for LS, even though LS is just as common[1, 2, 3]. Further evaluation of NCCN criteria is needed to evaluate whether patients may be over-referred for HBOC and/or under-referred for LS. Unfortunately, we were not able to confirm receipt of email invitations or accurately calculate completion rate of the P/FHX risk assessment module, which limited our ability to assess for ascertainment/response bias. Research Sponsor: U.S. National Institutes of Health.

Demographics of patients meeting NCCN guidelines for GE of HBOC and/or LS.

	Demographic n	NCCN criteria met
All patients	465	30.6% n = 142
Male	130	22.3% n = 29
Female	335	33.7% n = 113
Age <50	385	31.9% n = 123
Age ≥50	80	23.8% n = 19
European ancestry	286	36.4% n = 111
Black/African American ancestry	15	33.3% n = 5
Asian ancestry	105	11.4% n = 12
Multiracial or Other ancestry	55	38.2% n = 21

Risk-stratified FIT for urgent colonoscopy in Lynch syndrome: A clinical service throughout the COVID-19 pandemic. *First Author: Anne G Lincoln, King's College London, London, United Kingdom*

Background: Lynch syndrome (LS) is an inherited disorder characterized by pathogenic variants within mismatch repair genes resulting in an increased risk of colorectal cancer (CRC). In England, the fecal immunochemical test for Haemoglobin (FIT) is currently used in non-LS symptomatic and screening populations to guide subsequent colonoscopy. Herein, we report results from a national emergency clinical service implemented during the COVID-19 pandemic which used FIT to prioritize colonoscopy in LS patients while endoscopy services were limited. **Methods:** Regional genetic and endoscopy services across England were invited to participate. Patient eligibility was determined by 1) Diagnosis of Lynch Syndrome 2) Planned colonoscopic surveillance between 1 March 2020 and 31 March 2021. Requests for FIT testing from participating NHS Trusts were sent to the NHS Bowel Cancer Screening South of England Hub's Research Laboratory in Surrey. The Hub sent patients a FIT kit (OC-Sensor™ (Eiken, Japan)), instructions for use, a questionnaire, and a pre-paid return envelope. Lab reports with feecal haemoglobin (f-Hb) results were returned electronically for clinical action. LS patients were risk-stratified for colonoscopy based upon the following f-Hb thresholds: (1) f-Hb ≥10μg of Haemoglobin (Hb)/g (μg/g) faeces: triaged for colonoscopy via an urgent two-week wait (2WW) pathway, (2) f-Hb ≤10μg/g: schedule patients for colonoscopy within 6-12 weeks, where local endoscopy service availability permits. **Results:** Fifteen centers across England participated in the clinical service from 9th June 2020 to 31st March 2021. An uptake rate of 64% was observed from this cohort (375/588 invites), though 21 cases were removed from analysis due to repeat FITs, insufficient sample, missing clinical data, or FIT completed after colonoscopy. Of the remaining 354 patients analyzed, 269 patients (76%) had a f-Hb of <6μg/g. 6% (n=23) of patients had a f-Hb that was at or between greater than the limit of detection of the assay (≥6μg/g) yet below 10μg/g.18% (n=62) had FIT results of ≥10μg/g and met criteria for urgent colonoscopy triage via the 2WW pathway. Of the 62 urgently triaged patients, 22 had detectable adenomas, 6 had advanced adenomas (AAs), and 4 were diagnosed with CRC (table). **Conclusions:** The utility of FIT during the pandemic has demonstrated clinical value for LS patients requiring CRC surveillance. Further longitudinal investigation on the efficacy of FIT in people with LS is warranted and will be examined as part of the multi-center prospective research study "FIT for Lynch Syndrome" (ISRCTN15740250) which is presently recruiting patients in the UK. Research Sponsor: 40tude Curing Colon Cancer Charity.

Summary of findings by varying f-Hb cut-offs where ≥10μg/g is FIT +.

Cut-off (μg/g)	Adenomas	Advanced Adenomas	CRC	No Abnormalities Detected (NAD)	Pending or missing colonoscopy	Total (%)
<6	60	15	2	85	107	269(76)
6-9.9	4	1	0	10	8	23(6)
≥10	22	6	4	24	6	62(18)

Fertility preferences, concerns, and preservation among young women with breast cancer who carry germline genetic pathogenic variants compared with non-carriers. *First Author: Rebecca M. Lewinsohn, Harvard Medical School, Boston, MA*

Background: Young women with breast cancer who carry germline genetic pathogenic variants predisposing to breast and other cancers, including *BRCA1* or *BRCA2*, may face unique challenges when making fertility decisions. Limited data exist on differences in fertility preferences, concerns, and preservation strategies between carriers and non-carriers. **Methods:** Participants in the Young Women's Breast Cancer Study, a prospective cohort of women diagnosed with breast cancer at ≤ 40 yrs, who completed a baseline survey with a modified Fertility Issues Survey were included in this analysis. Genetic variant status was determined by medical record review complemented by survey self-report. We excluded carriers whose test date was after baseline survey completion or unknown. Fisher exact and Wilcoxon signed-rank tests were used to compare categorical and continuous variables, respectively, between carriers and non-carriers. **Results:** Of 1052 eligible women, 118 (11%) tested positive for a pathogenic variant (59% *BRCA1*, 32% *BRCA2*, 4% *TP53*, and 5% other unique pathogenic mutations) and 934 (89%) tested negative or were not tested. Carriers' median age was 36 yrs (range 23-40) vs 37 (range 17-40, p = 0.01) in non-carriers. Similar proportions (p = 0.67) of carriers (38%, [45/118]) and non-carriers (37%, [343/934]) desired more biologic children before diagnosis. Desire declined after diagnosis similarly in both groups (carriers, 25% [29/118] vs non-carriers, 26% [242/934], p = 0.46). Among these women (n = 271), concern about passing on cancer risk to offspring was common and, although numerically higher among carriers, this difference was not statistically significant (carriers, 55% [16/29] vs non-carriers, 40% [96/242], p = 0.12). In contrast, among those not interested in or unsure about future fertility (n = 738), concern about cancer risk heritability was infrequently reported as affecting fertility decisions (carriers, 11% [9/83] vs non-carriers, 9% [56/655], p = 0.54). The same proportions (p = 0.89) of carriers (36% [43/118]) and non-carriers (36% [339/934]) were somewhat or very concerned about becoming infertile after cancer treatment, and fertility preservation strategy utilization was similar between groups (carriers, 11% [13/118] vs non-carriers, 12% [111/934], p = 0.21). **Conclusions:** Young women with breast cancer who carry germline pathogenic variants are similarly concerned about future fertility and as likely to pursue fertility preservation as non-carriers. Concern about cancer risk heritability was common among both carriers and non-carriers desiring future fertility, suggesting a gap between perceived and actual risk. Genetic counseling should be included in fertility discussions for all young women with breast cancer, with tailored, risk-mitigating recommendations for those who carry genetic variants. Research Sponsor: Susan G. Komen Foundation and Breast Cancer Research (BCRF).

Building a multidisciplinary consortium in Iowa to advance genetic counseling and testing in patients with cancer. *First Author: Sandra Megally, Association of Community Cancer Centers, Rockville, MD*

Background: As cancer clinicians develop increasingly complex treatment plans, the results from somatic and/or germline tests are guiding personalized treatment decisions. Many patients with cancer do not get optimal genetic counseling/testing when indicated. To ensure that cancer clinicians are following the latest clinical recommendations around genetic counseling/testing, the Iowa Oncology Society (IOS), working in collaboration with the Association of Community Cancer Centers (ACCC), developed a multiphase initiative to inform quality improvement (QI) opportunities. **Methods:** In 2021, IOS launched a multidisciplinary consortium to advance genetic counseling and testing in oncology. Engaging a diverse group of stakeholders, IOS held a focus group to explore the current landscape, conducted three educational lunch and learn sessions, produced a podcast, and hosted a working group meeting. These meetings and activities were designed to explore ways to overcome common barriers in care delivery and identify effective practices to coordinate cancer genetic counseling and testing in clinical practice. **Results:** Through this initiative, IOS identified several key improvement opportunities for cancer clinicians treating patients in Iowa. Since 43 percent of Iowa's population is rural, this initiative also identified practical strategies for oncology practices in low-resource areas. The following insights and suggestions were generated from this initiative: 1) Cancer programs may implement creative ways to collect patient history and screen patients for hereditary cancer syndromes. 2) Clinicians may use more effective education materials when referring patients for genetic counseling. 3) Clinicians may clarify language/communication to reduce confusion about somatic vs. germline test results. 4) Cancer programs may form partnerships with local genetic counselors and/or organizations that offer telehealth services. IOS summarized these ideas and disseminated education and resources to guide cancer clinicians in assessing and improving their own practices. **Conclusions:** This multiphase initiative represents a framework for a state oncology society to engage other stakeholders and lead interdisciplinary efforts to improve care for patients with cancer. As the landscape of genetic counseling evolves, IOS supports legislative efforts aimed at having Medicare recognize certified genetic counselors (CGCs) as healthcare providers. IOS plans to build on this initial work to advance cancer genetic counseling and testing throughout the state by developing additional programming in 2022. Research Sponsor: self-funded by Iowa Oncology Society.

Clinical characteristics of patients with *PMS2* mutations. *First Author: Samiksha Pandey, William Beaumont Hospital, Royal Oak, MI*

Background: Lynch syndrome is a hereditary cancer predisposition syndrome caused by mutations in mismatch repair genes, *MLH1, MSH2, MSH6*, and *PMS2.* The cancer risks and clinical presentation of *PMS2* associated Lynch syndrome is not well defined. This study outlines the characteristics of patients with *PMS2* mutations identified in a large academic center. **Methods:** Patients with a pathogenic or likely pathogenic *PMS2* variant identified between June 1, 2009 and Dec 31, 2021 were selected from a database at the Nancy and James Grosfeld Cancer Genetics Center at Beaumont Health. Data on demographics, cancer type and molecular testing were retrospectively analyzed. **Results:** A total of 92 patients from 61 families were found to carry a pathogenic or likely pathogenic variant in *PMS2.* The mean age at testing was 54 (19 to 95). A majority (50) of the family were Caucasian, while the rest were African American (2), Middle Eastern (2), Multiracial (8). The most common variant was c.137G > T (p.Ser46Ile), seen in twelve of 61 families. Forty-two patients (45.6%) had a personal history of cancer, with a mean age at diagnosis of 63. Of these forty-two patients, four had multiple malignancies, including one patient with six separate cancers. The most common malignancies were breast (16), colon (12), followed by uterine cancer (8), pancreatic (4), prostate (3) and other cancers. The mean age of diagnosis of breast cancer was 56 (41 to 78), colon cancers was 57 (32 to 75), uterine cancer 59 (50 to 72). Tumor *IHC* was performed in thirteen cases and 11 demonstrated loss of *PMS2* protein expression. *MSI* was performed in 8 cases and 5 were unstable and 3 were stable. **Conclusions:** This study reveals the the clinical spectrum of cancers in *PMS2* related Lynch syndrome. The most common cancers were breast, colon and uterine cancer, with older age of diagnosis. There was evidence of a more severe phenotype, exemplified by a patient with six cancers, suggesting higher penetrance. Further research is needed to better characterize the clinical presentation of *PMS2* related Lynch syndrome. Research Sponsor: None.

Hysterectomy as a risk-reducing procedure in *BRCA1* and *BRCA2* women. *First Author: Ana Teresa Pina, IPO Lisboa EPE, Lisboa, Portugal*

Background: *BRCA1/2* pathogenic variants (PV) are associated with an increased lifetime risk of developing several malignancies, particularly breast (BC) and ovarian (OC) cancers. The association between *BRCA1/2* and endometrial cancer (EC) is controversial. Therefore, adding hysterectomy (HT) to risk-reducing (RR) bilateral salpingo-oophorectomy (BSO) is of uncertain benefit. In our multidisciplinary group this decision is personalized and takes in account other gynaecological pathologies or, for BC survivors, tamoxifen treatment. Objectives of this study are to assess the risk of EC on *BRCA1/2* families registered in our program and to discuss the role of prophylactic HT in *BRCA1/2* carriers. **Methods:** Pathologic confirmed EC cases were extracted from the prospective follow up cohort of 949 women diagnosed with a *BRCA1/2* PV through the hereditary breast, ovarian and prostate program at our centre. Data was collected from the medical records. **Results:** Of the 949 women, 345 (36.3%) were diagnosed with a *BRCA1* PV, 603 (63.5%) with a *BRCA2* PV and 1 (0.1%) with PV in both genes. Of all women, 648 (68.3%) had a previous cancer diagnosis while 291 (30.7%) were in primary risk management. Excluding non-melanoma skin cancer, EC was the fourth most frequent neoplasia: BC (553, 85.3%), ovarian, fallopian and peritoneal cancer (117, 18.1%), thyroid cancer (15, 2.3%) and EC (8, 1.2%). BSO with HT was performed in 372 (39.1%) women: RR in 259 (69.6%; *BRCA1* 36.7%, *BRCA2* 63.3%, history of cancer 75.7%, no history of cancer 24.3%) and therapeutic in 113 (30.4%; ovarian/fallopian cancer 92.0%, uterine cancer 8.0%). BSO alone was performed in 174 (18.3%), being RR in 170 (97.7%; *BRCA1* 34.7%, *BRCA2* 65.3%, history of cancer 72.9%, no history of cancer 27.1%). HT alone was performed in 3 (benign disease). Regarding family phenotype, we found another 2 cases of EC in possible *BRCA* carriers. For these 10 cases of EC, median age of diagnosis was 58.5 years (42-75), 7 in *BRCA1* and 3 in *BRCA2* patients (pts). Pathology: endometrioid (5), serous (1), mixed (2, 1 endometrioid and serous and 1 endometrioid, squamous cell and seromucous) and carcinosarcoma (2). Six (out of 10) pts had previous BC: 4 *BRCA1* (2 triple negative, 2 luminal-like) and 2 *BRCA2* (2 luminal-like), 4 of them had previous tamoxifen use (2 *BRCA1*, 2 *BRCA2*). In 1 case the diagnosis of EC occurred after RR BSO (*BRCA1*, no tamoxifen use) and another during the RR surgery (*BRCA2*, tamoxifen use). There was no significant association of EC with *BRCA1* or *BRCA2* (two-sided $p = 0.149$). EC was the cause of dead in 5 pts (50%), all *BRCA1*. **Conclusions:** EC was the fourth most frequently cancer registered in our cohort of *BRCA1/2* women. *BRCA1* women, representing around 1/3 of all cohort, had 70% of all EC diagnoses. This apparent excess of *BRCA1* EC diagnoses was not statistically significant. Tamoxifen may be a confounding factor. While an association was not confirmed at this time, our data also reinforces the need to discuss HT with our *BRCA1/2* pts. Research Sponsor: None.

Questioning a Li-Fraumeni Syndrome diagnosis: Characterization of a commonly observed germline *TP53* variant, p.Arg156His. *First Author: Bita Nehoray, City of Hope, Duarte, CA*

Background: Germline pathogenic variants (PV) in the *TP53* gene are associated with Li-Fraumeni syndrome (LFS). Increased use of multi-gene panel testing has identified *TP53* variants suspected to have reduced penetrance, a departure from the significantly increased cancer risks expected with LFS, posing challenges in variant classification and clinical management. *TP53* c.467G>A (p.Arg156His), R156H, is a variant with over 250 observations across multiple laboratories with prior discordant classification. R156H was recently downgraded by laboratories from likely pathogenic (VLP) to variant of uncertain significance (VUS). Characterization of R156H to clarify clinical significance has the potential to impact care for many. **Methods:** R156H carriers were identified through the Li-Fraumeni & TP53: Understanding & Progress (LiFT UP) study (https://liftupstudy.org) from 2019-2022. Clinical data were collected and reviewed for phenotypic characterization and to determine whether LFS Classic and/or Chompret criteria were met, and to assign Li-Fraumeni spectrum classification (Kratz et al.). **Results:** Proband/family characteristics are in the Table. Twenty R156H carriers were identified in 11 families. Seventeen carriers had a personal history of cancer; 8 had a LFS core cancer. All core cancers were breast except for an astrocytoma and a pediatric sarcoma. Two breast cancer cases also carried a *BRCA2* PV. The average age at first cancer diagnosis was 40.5 years (range 6-71). No families met Classic LFS criteria. One proband met Chompret criteria due to breast cancer <31 years (who also carried a *BRCA2* PV). Ten families were classified as attenuated LFS per Kratz et al. **Conclusions:** Most families in our case series did not meet LFS criteria, raising the question of appropriate clinical management and the willingness to de-escalate LFS surveillance. Our series supports the downgrade to VUS, but the presence of a few non-breast LFS core cancers warrants work to determine if R156H is a reduced penetrance PV. Recruitment of these families is ongoing through the LiFT UP study to perform segregation analyses and cancer risk estimations. This work may guide evaluation of other variants presenting similar challenges. Research Sponsor: U.S. National Institutes of Health.

Impact of COVID-19 on individuals with paraganglioma/pheochromocytoma history and/or hereditary risk. *First Author: Samantha Greenberg, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Patients with paraganglioma/pheochromocytoma (PPGL) or hereditary predisposition to PPGL often need screening with biochemical labs, imaging and physical exam. Given the rarity of PPGL and hereditary PPGL, care is often provided through specialty centers. Subsequently, patients may have experienced restrictions on travel and delayed scheduling of non-elective procedures due to COVID-19. This study aimed to analyze the impact of COVID-19 on seeking PPGL management. **Methods:** Patients with a personal history of PPGL or hereditary PPGL risk from the University of Michigan, Brigham Women's Hospital, and Huntsman Cancer Institute were sent a survey in 2021. The survey included questions regarding tumor history (Y/N), gene status, demographics, and experience with COVID. The survey assessed whether they missed any exams related to PPGL diagnosis or screening. Comparative analyses utilized regression and chi-square tests. Patient factors measured in analyses evaluated COVID surveillance (labs, imaging, doctor visit) as the primary outcome and age, institution, gene status, sex, and PPGL history as predicting variables. **Results:** In total, 241 respondents across three institutions completed the survey. The cohort was primarily female (n = 158, 65.6%). A majority of the cohort identified as White (n = 222, 92%) and non-Hispanic (n = 226, 93.8%). PPGL history was reported in 158 patients (65.6%), 43 of which were pheochromocytoma and 113 were paraganglioma, primarily in the head and neck (n = 78). At time of survey completion, 209 (87%) respondents answered COVID-related questions. Thirty-nine respondents (19.2%) reported missing doctor visits, while 31 (15.3%) report missing HPPGL imaging and 33 (16.3%) report missing lab tests. There were no differences by institution ($p > 0.05$) on patient reported missed visits. Logistic regression analysis showed no difference in missing visits based on having a hereditary PPGL predisposition gene or sex of respondent (all p-values > 0.05). There was no difference based on PPGL history, though it is unknown if patients missed PGL follow-up or screening. Individuals who missed imaging (Y/N) were more likely to report missing their lab tests (OR = 1.8, $p < 0.01$) and doctor visit (OR = 1.25, $p < 0.01$). Age was a significant predictor for missing doctor visits ($p = 0.02$) with an odds ratio of 1.002 per 1 year increase in age. **Conclusions:** Though institutions had different COVID-19 restrictions and guidelines by state, there was no difference on missing surveillance or screening. Over 15% of respondents reported missing at least one aspect of PPGL care, indicating a need to re-engage those with PPGL and hereditary PPGL to return to typical screening and surveillance. Patients who miss one aspect of surveillance are likely to have missed other aspects of surveillance and will require evaluation of all aspects of screening to return up to date on needed visits and procedures. Research Sponsor: None.

Adjusting the TMIST study design to accommodate slower than expected accrual: ECOG-ACRIN EA1151. *First Author: Etta Pisano, American College of Radiology, Philadelphia, PA*

Background: The ECOG-ACRIN Tomosynthesis Mammographic Imaging Screening Trial (TMIST), which opened in 2017, is a randomized trial designed to assess whether Tomosynthesis Mammography (TM) should replace Digital Mammography (DM) for breast cancer screening. It is hypothesized that women assigned to TM for 3-5 screening rounds will have fewer advanced breast cancers than the women assigned to DM. Advanced cancers are those that have distant metastases or positive nodes, are invasive tumors greater than or equal to 2.0 cm in size, or are invasive tumors greater than 1.0 cm in size that are triple negative or HER 2+. The initially planned enrollment of 164,946 women was due to be completed by the end of 2020, with follow-up concluded by 2025. There were substantial challenges in meeting this timeline, including the organizational and funding structure of the NCI National Clinical Trials Network which is dependent upon sites using their existing staffing resources (not always readily available at the time of study activation). This led to longer than anticipated start of enrollment for most interested sites and lower than anticipated annual enrollment per participating site based ultimately on the staffing support that could be allocated to manage TMIST. In addition, research staffing shortages and periodic research operations closures due to COVID-19 have also impacted enrolling TMIST sites, though unevenly, since the start of the pandemic. Enrollment plateaued at approximately 2,100 subjects per month by the end of 2020. With that accrual rate expected, the trial design was modified to reduce the sample size so that the study could be completed by 2027. **Methods:** With the approval of the NCI CIRB, we changed how the primary endpoint measure for TMIST is assessed from the number of advanced cancers that occur by 4.5 years after randomization to the time from randomization to occurrence of advanced cancers. All advanced cancers occurring within 7 years of randomization are now included and all participants followed for at least three years. In addition, the power of the study of the study was modified from 0.9 to 0.85, while the originally assumed effect size at 4.5 years was retained These changes allowed a reduction of sample size to 128,905, with subject recruitment projected to end in 2024. As of February 14, 2022, there are 125 sites open, 114 in the U.S. and 11 in other countries, with an additional 31 sites planning to open. As of February 14, 2022, a total of 63,845 women have been enrolled in the trial worldwide at 115 sites, with 20% of US participants self-identifying as belonging to minority racial and ethnic groups and 70% consenting to optional blood and/or buccal cell collection. Clinical trial information: NCT03233191. Research Sponsor: U.S. National Institutes of Health.

TPS10615 **Poster Session**

NRG-CC008: A nonrandomized prospective clinical trial comparing the non-inferiority of salpingectomy to salpingo-oophorectomy to reduce the risk of ovarian cancer among BRCA1 carriers [SOROCk]. *First Author: Warner King Huh, Department of Obstetrics and Gynecology, University of Alabama at Birmingham, Birmingham, AL*

Background: Studies of ovarian cancer screening in the general population have not demonstrated a reduction in ovarian cancer mortality. High-grade pelvic serous carcinomas (HGSCs) have traditionally been thought to originate from the ovarian surface epithelium. However, more recent data strongly suggests that most HGSCs originate from precursor lesions found in the distal fallopian tube. Serous tubal intra-epithelial carcinoma (STIC) lesions are found in association with HGSCs in 50-60% of cases and other early serous precursor lesions can be identified in an additional 25% of cases. The Society of Gynecologic Oncology has recently issued recommendations that salpingectomy can be considered at the completion of childbearing in indiviuals at increased genetic risk of ovarian cancer who do not agree to salpingo-oophorectomy. They also indicated that approximately 30% of *BRCA1* mutation carriers choose not to remove their ovaries, and the mean age at RRSO for those who do is in the late 40s, much later than recommended age per guidelines. The purpose of this study is to compare risk-reducing approaches in high-risk women with deleterious germline *BRCA1*mutations; specifically, to demonstrate the non-inferiority of bilateral salpingectomy compared to bilateral salpingo-oophorectomy to reduce the incidence of ovarian cancer among deleterious germline *BRCA1*mutation carriers. **Methods:** This is a non-randomized prospective trial to determine if bilateral salpingectomy is non-inferior to bilateral salpingo-oophorectomy in terms ovarian, primary peritoneal, and fallopian tube cancer risk among gBRCA1m carriers between 35 and 50 years old. Individuals choose the treatment they want to receive in collaboration with their physician(s). The primary endpoint is the time to development of incident HGSC, specifically ovarian, primary peritoneal, or fallopian tube cancers. Secondary endpoints include measurement of health-related quality of life, estrogen deprivation symptoms, sexual function, menopausal symptoms, cancer distress, Medical Decision Making, and adverse events. **Results:** As of 1/31/2022, 116 individuals have been enrolled into this trial. A recent amendment was put forward to allow the following individuals to also participate in this trial: 1) Individuals who are receiving hormonal therapy for maintenance therapy (eg, tamoxifen, AIs, etc), 2) Individuals with a history of any prior cancer and have completed chemotherapy, at least 30 days ago, and 3) Individuals who are considering Assisted Reproductive Technologies (eg, IVF). Furthermore, there is ongoing consideration of allowing general Ob/Gyn providers to recruit patients to this trial and perform procedures, with proper pathology training and sign off at their hospitals. NCI grant UG1CA189867. Clinical trial information: NCT04251052. Research Sponsor: U.S. National Institutes of Health.

TPS10616 **Poster Session**

A phase 3 study to determine the breast cancer risk reducing effect of denosumab in women carrying a germline *BRCA1* mutation (BRCA-P Study). *First Author: Nizar Bhulani, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Women with *BRCA1* mutations have a 50-70% lifetime risk of developing breast cancer. Currently, prophylactic mastectomy is the only strategy that significantly reduces breast cancer risk. Recent evidence suggests that the RANK/RANKL signaling pathway plays a pivotal role in the development of *BRCA1*-mutated tumors. Targeting the RANK pathway has been shown to attenuate breast epithelial proliferation *in vitro* and *in vivo,* and to profoundly reduce mammary tumor formation in mouse models. The RANKL inhibitor, denosumab, an FDA approved drug for the treatment of osteoporosis, is potentially an ideal chemopreventive agent for women with a germline *BRCA1* mutation because it: (a) could potentially reduce breast cancer risk, and (b) concomitantly protect bone health in women who have already undergone bilateral salpingo-oophorectomy or in naturally postmenopausal women. The BRCA-P study will evaluate the reduction in the risk of any breast cancer (invasive or DCIS) in women with a germline *BRCA1* mutation who are treated with denosumab compared to placebo. Sub-studies include measurement of bone turnover markers; epigenetic profiling of tumor tissues; measuring denosumab's effect on bone and breast density; measurement of serum RANK, RANKL, OPG, progesterone, LH and FSH; and measurement of quality of life. **Methods:** This is a randomized, double-blind, placebo-controlled, multi-center international phase 3 study to determine the breast cancer risk reducing effect of denosumab in women carrying a germline *BRCA1* mutation. Eligibility: Women with a confirmed *BRCA1* germline mutation; ages $\geq$ 25 years and $\leq$ 55 years; no evidence of breast or ovarian cancer; no preventive breast surgery planned at randomization; ECOG performance status 0-1. Eligible participants will be randomized 1:1 to receive 120 mg of subcutaneous denosumab or placebo every 6 months for 5 years. Thereafter, all participants will be followed up for 5 years. Primary endpoints: Time to the occurrence of any breast cancer (invasive or DCIS). Secondary endpoints: Time to invasive triple negative breast cancer; time to other *BRCA1* mutation associated malignancies, time to clinical fractures. Statistically, a 35% reduction in breast cancer risk would be detected with an 80% power and a two-sided significance level of 5% if 167 breast cancer cases are observed. We expect to observe the number of events needed if 1459 subjects per group (2918 in total) are randomized. The study is currently enrolling participants in Austria, Australia, Israel and Spain. The study will shortly begin accrual in Germany, United Kingdom, and at more than 30 sites across the United States. Globally, the trial is coordinated by the Austrian Breast & Colorectal Cancer Study Group and by the Alliance for Clinical Trial in Oncology in the US. EudraCT: 2017-02505-35. Clinical trial information: NCT04711109. Research Sponsor: U.S. Department of Defense; The National Cancer Institute, Pharmaceutical/Biotech Company.

TPS10617 **Poster Session**

A randomized phase III study assessing the efficacy of liquid biopsy in early diagnosis of recurrence and second malignancies in lung cancer survivors. *First Author: Sana Raoof, Memorial Sloan Kettering, New York, NY*

Background: Lung cancer survivors are highly enriched for extensive smoking histories and have an increased risk of subsequent primary cancers, including those of the larynx, mouth and throat, esophagus, pancreas, bladder, thyroid, stomach, small intestine, colon, rectum, and kidney. Guideline-concordant surveillance after definitive treatment for lung cancer consists of periodic chest CT scans, which do not visualize the majority of second malignancies that this population ultimately develops. Disadvantaged and minority patients are diagnosed with recurrence and second primary cancers at later stages due to reduced compliance with survivorship surveillance. To address these issues, we propose utilizing multi-cancer early detection (MCED) liquid biopsies. MCED liquid biopsies are part of a rapidly growing field of research that assesses parallel cancer screening for multiple cancer types with point of care blood, urine, or saliva sampling. We selected a methylation-based screening liquid biopsy for multiple reasons: 1) it has the highest PPV and specificity of any test clinically validated in the multi-cancer detection setting thus far, 2) it produces a tissue of origin, allowing for targeted workup of positive findings, and 3) it requires only a single test, which we believe will minimize attrition among vulnerable populations with decreased access to healthcare. We designed a 9,000-patient prospective, multi-institutional randomized clinical trial to assess the efficacy of liquid biopsy in early diagnosis of recurrence and second malignancies in lung cancer survivors. To ensure over 25% of participants are of minority status, we have recruited multiple community hospitals to the study in partnership with Memorial Sloan Kettering Cancer Center. Patients included in this study are survivors of non-metastatic non- small cell lung cancer, status-post definitive treatment (surgery or radiation) with no evidence of disease for at least one year. Participants will be randomized 1:1 to standard surveillance or standard surveillance plus six-monthly methylation-based liquid biopsy tests over a two-year study period, and strict guidelines on follow-up of positive liquid biopsy testing will be provided to reduce harms from false positives or over-diagnosis. **Methods:** The primary endpoint of this study is the incidence of late stage cancer (distant recurrence or new primary cancer of stage III/IV). Secondary endpoints include cancer-specific mortality, eligibility for definitive interventions once cancer is diagnosed, and utilization of liquid biopsy versus standard of care scans. This is the first randomized controlled trial of screening liquid biopsy in a survivorship population and the first trial utilizing liquid biopsy in a large minority population. Research Sponsor: GRAIL.

TPS10618 **Poster Session**

Longitudinal immunological responses of COVID-19 vaccination in patients with solid tumors on active treatment: A pilot study. *First Author: Lifen Cao, University Hospitals at Cleveland Medical Center, Cleveland, OH*

Background: Coronavirus disease 2019 (COVID-19), caused by betacoronavirus SARS-CoV-2, is associated with an increased risk of severe infection or death in cancer patients compared to the general population. The CANVAX trial recently demonstrated that short term immune responses to SARS-CoV-2 vaccines are modestly impaired in patients with cancer— particularly those who receive myelosuppressive chemotherapy. Because little is known regarding longitudinal antibody or T-cell responses in cancer patients who receive cytotoxic chemotherapy or non-myelosuppressive targeted systemic therapy, the aim of this longitudinal study is to assess immune B and T cell responses to SARS-CoV-2 over a 12-month period in solid tumor patients who receive chemotherapy or non-immunosuppressive therapy compared to healthy individuals without cancer. **Methods:** This is an ongoing prospective non-interventional clinical trial (NCT05238467). Approximately 100 patients will be enrolled into three different arms. Accrual began in May 2021 and 37 patients have been enrolled. Eligible patients must not have prior COVID-19 infection < 6 months from study enrollment and have a diagnosis of a solid tumor (breast, genitourinary, or gastrointestinal cancers), who either: received myelosuppressive chemotherapy within 60 days prior to initial or booster COVID vaccination, or who started on chemotherapy within 30 to 60 days after the initial or booster COVID vaccination (Arm A); or received non-immunosuppressive treatments (Arm B); or have no history of cancer or prior history of cancer but beyond 12 months from completion of curative cancer treatment (Arm C, control cohort). Whole blood will be collected in accordance with standard operating procedures. Blood samples analyzed for the presence of antibodies against the major antigenic components of SARS-CoV-2 including the spike glycoprotein (S), receptor binding domain (R) and nucleocapsid phosphoprotein (N). Antibody levels will be quantified utilizing quantitative ELISA. T-cell responses will also be quantified. The primary endpoint is seroprotection rate with an antibody titer protective (1:40) at any point: baseline, 2, 6, and 12 months. The secondary endpoint is to evaluate differences in longitudinal immunological responses to SARS-CoV-2 over a 12-month period. The difference of the seroprotection rate among 3 cohorts of participants will be examined using chi-square test. Moreover, the effect of treatment (chemotherapy, endocrine, TKIs) on seroprotection will be estimated using multivariable logistic regression controlling the effects of confounders, such as age, gender and cancer type. COVID antibody titers measured over time (baseline, 8 weeks, 6, 9, 12 months after the second vaccination) will be analyzed using mixed-effect models. Clinical trial information: NCT05238467. Research Sponsor: Institutional Fund.

Development and assessment of the effectiveness of an LGBT cultural sensitivity training for oncologists: The COLORS training. *First Author: Matthew B. Schabath, Moffitt Cancer Center, Tampa, FL*

Background: Published studies report oncologists have limited knowledge about LGBT health and cancer needs but also report high interest in receiving education regarding the unique health needs of LGBT patients with cancer. As such, our group developed the Curriculum for Oncologists on LGBT populations to Optimize Relevance and Skills (COLORS), an interactive web-based LGBT cultural sensitivity training for oncologists that focused on focused on improving knowledge and communication skill-building. We report here on the results from two single-arm feasibility/acceptability trials and one randomized pragmatic trial (RPT) demonstrating effectiveness of the COLORS training. **Methods:** The first single-arm trial included 44 oncologists from three cancer centers in Florida and the second single-arm trial included 50 oncology fellows recruited through ASCO. The RPT included 225 oncologists randomly selected for equal distribution across the U.S., and participants were randomly assigned to either the COLORS training or a publicly available, web-based LGBT comparison training. Each of these studies included pre- and post-training assessments of LGBT-related knowledge, attitudes, and affirming practices. The RCT included a 3-month follow-up assessment to gauge retention of LGBT-affirming knowledge, attitudes, and practices over time. **Results**: Both single arm trials demonstrated that the COLORS training was feasible, acceptable, and results from the pre- and post-training assessments suggested the training improved knowledge, attitudes, and affirming practice behaviors. In the RPT, those randomized to COLORS demonstrated significant improvements in LGBT-related attitudes pre- to post-training ($p < 0.01$), and no significant changes in attitudes were observed among those randomized to the comparison training ($p = 0.98$). Both trainings yielded significant ($p < 0.01$) increases from pre- to post-training in LGBT-affirming practice behaviors. Likewise, both trainings yielded significant ($p < 0.01$) improvements in knowledge from pre- to post-training. Similar significant findings were observed when we analyzed the 3-month follow-up assessment. **Conclusions:** Results from the prior single-arm trials and the current RCT demonstrate that the COLORS training is effective in improving oncologist knowledge, attitudes, and affirming clinical practices related to the care of LGBT patients with cancer. Part of this work was funded by the Bristol Myers Squibb (BMS) Foundation and BMS Company. Research Sponsor: Bristol Myers Squibb Foundation (BMSF), Florida Academic Cancer Center Alliance (FACCA).

Challenges faced by female oncologists in sub-Saharan Africa. *First Author: Miriam Claire Mutebi, Aga Khan University Hospital, Nairobi, Kenya*

Background: Recent articles by ASCO and ESMO have identified challenges facing female oncologists in western contexts. The challenges female oncologists face in sub-Saharan Africa (SSA) have yet to be explored. This study was launched by the AORTIC Education and Training Committee to determine the most common and substantial challenges faced by female oncologists in SSA and identify potential solutions. **Methods:** A diverse panel of 32 female oncologists from 20 countries in SSA was recruited through professional and personal networks. Following an initial meeting to review terminology, a modified three-round Delphi process took place. Participants iteratively reviewed a list of previously identified challenges facing women in oncology in SSA and identified new challenges. The survey was conducted via REDCap, a secure-web-based software platform. Participants reflected on personal experiences or those of colleagues, and were asked to indicate their agreement with each listed challenge, as well as propose solutions. Descriptive statistics identified the most common challenges. Following the third survey, a focus group was held to enrich study data. A thematic analysis is being conducted on the focus group transcript to identify key themes, and a subsequent modified Delphi process is being executed to build consensus around potential solutions to identified challenges. **Results:** Response rates for the 3 modified Delphi rounds were 66%, 66%, and 53%. The challenge with the greatest agreement was, "pressure to maintain a work-family life balance and meet social obligations". These were felt to be unique to women in SSA due to an extended family network with several responsibilities beyond the nuclear family. The next two top-scored challenges were "lack of female support and networks", and "micro-aggressions" (Table). **Conclusions:** Female oncologists in SSA experience many of the challenges that have been previously identified by similar studies in other regions, with different degrees of perceived importance. Some challenges have a different lived experience for female oncologists in SSA. The second part of this study will include thematic analysis of the recent focus group and explore potential solutions to mitigate these challenges, which will add insight and potential paths forward to optimizing a diverse workforce in SSA. Research Sponsor: None.

Top 10 challenges facing female oncologists in Africa: Delphi study results

Challenge	Total Score
Pressure to maintain a work-family balance and meet social obligations	74
Lack of female support and networks	73
Micro-aggression	71
Delivered by women, led by men (skewed work distribution at level of leadership)	70
Lack of mentors	69
Lack of support (e.g., financial, research)	68
Lack of access to support, including staff, infrastructure, operating times, leadership/management support	67
Being perceived as less competent than male counterparts	67
Dysfunctional and leaky pipeline	67
Glass ceiling	66

11002 **Clinical Science Symposium**

Examination of speakership gender disparity at an international oncology conference. *First Author: Jessica Caro, Perlmutter Cancer Center, NYU Langone Health, New York, NY*

Background: Gender disparity is an important issue in medicine, as women occupy a minority of academic leadership positions despite increased representation in the physician workforce. One important aspect is the gender gap of speakers at academic meetings, which limits opportunities for career advancement and mentorship. This underrepresentation of women is largely anecdotal in oncology. We hypothesized that original research is less frequently presented by women at the annual ASCO meeting. We sought to examine presentation patterns from recently featured ASCO speakers, categorized by presentation type and gender. **Methods:** We conducted a retrospective, observational review of data from the 2018-2021 ASCO annual meetings. Mixed-gender coders extracted data from the ASCO Annual Meeting library and institutional public websites. Speaker-identified gender was unavailable; binary gender was determined by presenter name, pronouns, and video files. For original research, we collected data on last authors as well as these roles are also considered meritorious. Cochran–Mantel–Haenszel tests were used to investigate the association of gender and roles adjusted for each stratification variable individually. Common odds ratios (ORs) were estimated for each association. Breslow-Day Tests were used to test the homogeneity of these ORs among the different levels of each stratification variable. No adjustments for multiple testing were used. **Results:** We reviewed 4267 unique presentations, including those which highlighted original research (Poster Discussion, Oral Abstract, Clinical Science Symposium, Plenary) vs. education (Case-Based Panel, Education Sessions, Highlights of the Day). For original research, women were significantly more likely to have an ASCO-appointed role (discussant, speaker, or chair) than a first or last author role (48% vs. 32.7% of presentations, $p < 0.0001$), even after adjusting for conference year (OR 0.53, 95% CI: 0.45-0.61), session type (0.52, 0.45-0.61), degree (0.50, 0.43-0.58), academic rank (0.55, 0.47-0.64), and geographic region (0.58, 0.50-0.68). There was no difference between in-person and virtual conferences ($p = 0.584$). For education sessions, women comprised 46.1% ($n = 626$), nearly half, of these speaking roles (all ASCO-appointed) compared with men. 38% of the data was independently re-reviewed to confirm accuracy; 96.4% concordance was observed in presenter gender. **Conclusions:** Women are less likely to present highlighted original research and are more likely to have an appointed educational role at ASCO annual meetings. This likely reflects broader gender disparity within academia. Future analyses could be improved by examining speaker-identified gender. As high-profile original research can elevate careers, examining factors contributing to this observed disparity may reveal important approaches to address gender leadership gaps in oncology. Research Sponsor: None.

11003 **Poster Discussion Session**

Medical student clinical cultural awareness in cancer care of sexual and gender minorities. *First Author: Cherry Au, Rush University Medical Center, Chicago, IL*

Background: Health disparities in lesbian, gay, bisexual, transgender, and queer/questioning (LGBTQ+), or sexual and gender minorities (SGMs), patients are a known in health care. SGMs have higher cancer risk but lower rates of screenings, resulting in a higher likelihood of late-stage disease. Relevant gaps in medical school curricula regarding SGMs must be addressed to prevent these disparities. The purpose of this study is to evaluate medical students' (MS) clinical cultural awareness in cancer care of SGM patients. **Methods:** This study was a cross-sectional survey distributed to medical degree students actively enrolled at a large urban academic center. This survey was adapted from a study by Schabath et. Al. The survey had 38 questions on demographics, attitudes, and knowledge of SGM topics. Questions were scored on a Likert scale from 'strongly disagree' to 'strongly agree' with 'don't know' and 'prefer not to answer' as options. Results are reported using descriptive statistics. **Results:** There were 238 responses. Most respondents were white (63.9%), cis-gender female (57.6%), and heterosexual (78.6%). Distribution according to year are as follows: MS1 36.6%, MS2 14.7%, MS3 27.3%, and MS4 19.3%. Attitudes are listed in the table below. Four of the seven questions on knowledge had "Don't Know" as the most common response. Notably, 47.1% of respondents did not know if screening gay/bisexual men with anal pap is associated with increased life expectancy. Students were interested in learning guidelines regarding SGM cancer screening and considerations for patients who are on hormone therapy. **Conclusions:** While most medical students are comfortable treating LGBTQ+ patients, most are not confident in their knowledge. This difference is most profound in knowledge of transgender patients. Schools must consider longitudinal education in SGM topics to improve student knowledge to produce confident and competent providers. Participants Responses to Attitude Items. Research Sponsor: None.

Question	Strongly Agree, n (%)	Agree, n (%)	Neutral, n (%)	Disagree, n (%)	Strongly Disagree, n (%)	Don't know, n (%)	Prefer not to answer, n (%)
I am comfortable treating LGB patients	132 (55.5)	85 (35.7)	11 (4.6)	4 (1.7)	0 (0.0)	4 (1.7)	0 (0.0)
I am confident in my knowledge of the health needs of LGB patients	31 (13.0)	95 (39.9)	54 (22.7)	42 (17.6)	10 (4.2)	4 (1.7)	0 (0.0)
I am comfortable treating transgender patients.	86 (36.1)	102 (42.9)	24 (10.1)	15 (6.3)	3 (1.3)	5 (2.1)	1 (0.4)
I am confident in my knowledge of health needs of transgender patients.	8 (3.4)	60 (25.2)	70 (29.4)	77 (32.4)	16 (6.7)	4 (1.7)	1 (0.4)
I would be interested in education regarding the unique health needs of LGBTQ patients	159 (66.8)	58 (24.4)	11 (4.6)	4 (1.7)	3 (1.3)	0 (0.0)	1 (0.4)
I would be willing to be listed as an LGBTQ-friendly provider	165 (69.3)	50 (21.0)	15 (6.3)	1 (0.4)	0 (0.0)	5 (2.1)	0 (0.0)

Seeking racial equity in hematology and oncology: A fellow-led educational series to promote reflection and action. *First Author: Jacob Newton Stein, UNC Hospitals Hematology/Oncology, Chapel Hill, NC*

Background: With the murder of George Floyd and health disparities laid bare by the COVID pandemic, the US is reckoning with racial injustice. Across medicine and oncology, institutions are grappling with how to address systemic racism and improve care for patients of color. At the University of North Carolina (UNC), trainees developed an educational curriculum to raise awareness of implicit bias and introduce methods to address racial inequities. We present our findings on feasibility and acceptability of a fellow-led course on racism in medicine at a major academic medical center. **Methods:** UNC oncology fellows adapted a curriculum on implicit bias and racism in medicine in spring 2021. Our aims were 1) to improve knowledge and awareness about implicit bias and systemic racism and 2) introduce methods to address racial inequities. We used lived experiences and collated materials from scientific literature and lay media to illustrate key points. Sessions were: 1) Introduction and Implicit Bias, 2) Implicit Bias in Action: A Case Study, 3) Race-Based Metrics: Journal Club, 4) Career Perspective on Equity in Oncology. Videos, journal articles, and group discussion were employed to appeal to many learning styles. **Results:** Four sessions were held virtually for the Divisions of Oncology and Hematology. Attendance ranged from 28 to 35 per session. A post curriculum survey assessed perception of racial inequality in medicine and the series' effects using a Likert scale. Twenty-nine participants completed the survey, 12 of whom were fellows. Of all participants, 71% reported that the course improved knowledge or awareness of racial inequities "some" or "a great deal" and 61% reported that it improved their comfort level addressing racial inequities "some" or "a great deal." All participants endorsed at least "some" racial inequity in medicine. Notably, over 75% of participants indicated interest in further sessions. **Conclusions:** Formulation of an educational curriculum by fellows and delivered in a division wide setting was feasible and well received by participants with robust discussion and interest in further work. Fundamental to this series' effectiveness was creating a space for discussion and reflection among colleagues. The goals of improving knowledge and introducing methods to address racial inequities were met. Importantly, our course was integrated alongside institutional efforts on DEI. We were limited by a lack of pre-course survey results due to a technical error. Given the current groundswell of interest and focus in improving racial equity in our society, we encourage other institutions to take similar steps to highlight issues of systemic racism and continue to move our field in the right direction. Research Sponsor: None.

11005 **Poster Discussion Session**

The parent penalty: Parental leave and return to work in trainees and early-career faculty in oncology. *First Author: Sindhu Janarthanam Malapati, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: Prime childbearing years occur during medical training and early career, leaving physicians with tough choices between family planning and career growth. Restrictive parental leave (PL) policies can affect physician well-being and limit decisions about reproduction. We evaluated Medical and Radiation Oncology trainees and early career faculty to assess policies and practices regarding PL and return to work. **Methods:** An anonymous 48 question cross-sectional survey developed by researchers with expertise in gender equity was distributed via email and social media channels between May and June 2021 to oncology trainees and physicians within 5 years of terminal training. Descriptive statistics were used to compare study groups. **Results:** 255 physicians completed the survey-54% female, 65% Medical Oncology and 35% Radiation Oncology, 71% trainees and 29% early career faculty. 46% (117) had no formal PL policy during training. PL impacted selection of first job for 37% (94) participants. Of all responders, 114 used PL, either in early career (18%), as a trainee (69%) or both (13%). Duration of PL during training was ≤4 weeks in 37%, 4-6 weeks in 19%, 6-8 weeks in 12% and ≥8 weeks in 24%. 27% of those who took PL as a trainee had to extend training to allow for this. Only 27%(31) of those who took PL had resources available at workplace to assist with transitioning back to work, primarily from informal mentoring by faculty/colleagues (65%, 20). Other important findings are summarized in the Table. **Conclusions:** In this study evaluating parental leave in oncology trainees and early faculty, almost half of the participants had no formal parental leave policy during training and majority of those who took parental leave during training had parental leave only for 6 weeks or less. Most participants experienced a parental leave penalty: guilt when seeking help and feeling overwhelmed at return to work. Policies and practices around parental leave need to be restructured to meet the needs of the evolving oncology workforce. Research Sponsor: Centennial Scholar, University of Wisconsin.

Feelings endorsed by those who took Parental leave	N=114
Felt pressured to work while on PL (including research/ administrative)	50% (57)
Option for part time/ lighter rotations at return to work	19% (22)
Extra call/ clinic/ hospital service/ presentations after PL	32% (36)
Felt that accommodations they required for PL/ lactation placed extra demands on co-workers	48% (55)
Felt guilty asking co-workers for help	60% (68)
Overwhelmed with demands of work and home	79% (90)
Negative feeling regarding returning to work	35% (40)

11006 **Poster Discussion Session**

Global oncology and cancer disparities education. *First Author: Victoria Forbes, UConn Health Center, Farmington, CT*

Background: Comprehensive patient care requires an understanding of medical guidelines and the intersectional context of the patient's identity and experiences. Hematology/Oncology programs must explicitly teach topics addressing various disparities of care to prepare trainees for informed care. We have developed a Global Oncology and Disparities of Cancer Program to address this gap. **Methods:** The telementoring program was piloted in 2019 at Dartmouth and has evolved to include didactics, discussion, and evaluations. Participants from across the globe include medical students, residents, Hematology/Oncology Fellows, Faculty, Global Health Scholars, and cancer clinicians. US Hematology/Oncology trainees from Dartmouth and the University of Connecticut consistently participate in the international program. Monthly sessions from September 2021-June 2022 include: Esophageal and GI Cancers in Rwanda, HCC and Cholangiocarcinomas, Gastric Cancer, ASCO International, Global Med ED in Haiti, Breast Cancer in Kosovo, Breast Cancer Risk Factor Prediction Tools Research, Shared Decision Making in Breast Cancer, Hemoglobinopathies, and Health Disparities and Capacity-Building in Rwanda. A pre-course survey was sent to identify participant's demographics, barriers, and expectations. We will administer a post-course survey. **Results:** We have preliminary data for our ongoing project. However, we anticipate complete data collection and analysis before the ASCO Meeting. 24 participants were enrolled. 12 (52%) of the participants were located outside of the US in locations such as Haiti, Kosovo, and France. Using a 5-point Likert scale, 11 (46%) participants were "not at all" or only "slightly" aware of obstacles faced by Oncology patients and caregivers in seeking access to healthcare in the US. 7 (29%) participants answered similarly regarding those in low- and middle-income countries. Meanwhile, participants rated ''gaining different perspectives'' as their most important reason for attending with 19 (79%) rating this as "very important" or above. For anticipated improvement from the course, understanding risk factors and cancer biology internationally and recognizing disparities in healthcare between domestic and international settings were the highest rated with 18 (75%) expecting an improvement to a "large degree" or higher. **Conclusions:** We developed a virtual educational experience to enhance participants' ability to address disparities of care through challenging Global Oncology topics. Our course is ongoing however initial surveys show a need and desire for this content from participants. We intend to analyze the course surveys to shape future courses. This program can serve as a model for Hematology-Oncology programs to address unmet needs in the curriculum and prepare trainees to provide more complete care to improve cancer outcomes. Research Sponsor: None.

11007 **Poster Discussion Session**

A collaborative model for continuing medical education: Impact of a distance learning curriculum for existing radiation oncology centers in Africa and Latin America. *First Author: Meridith Leigh Balbach, Vanderbilt University School of Medicine, Nashville, TN*

Background: We aimed to evaluate the outcomes and generalizability of a distance learning curriculum on intensity modulated radiotherapy (IMRT), a course developed for radiotherapy clinics across Africa and Latin America (LATAM) at no cost, as measured by a knowledge-based multiple-choice exam, learner self-evaluation, and open-ended feedback. **Methods:** Following needs identification studies, a curriculum entitled "IMRT 2.0" was created for an audience that included medical physicists, radiation oncologists, radiation therapists, and trainees. Volunteer educators delivered 27 hour-long sessions 1-2 times weekly for four months using video conferencing to African and LATAM programs in English and Spanish, respectively. Recordings and educational materials were shared following each session. Pre- and post-course multiple choice examinations were administered to LATAM participants, and pre- and post-course Likert scale self-evaluation and open-ended feedback were collected for both programs. Paired sample t-tests and chi-squared tests were performed for all available paired quantitative and categorical data, respectively. Pearson correlation coefficient, multivariate linear regression, and spline regression models were used to explore impact of course attendance on outcomes. **Results:** 25 centers across Africa (12 + 1 sister institution in Pakistan) and LATAM (12) were recruited, the majority (92%) of which were recently transitioning or planning to transition to IMRT, yielding a total of 332 enrolled participants. 27 sessions were delivered with a mean of 44 (std dev 22.5) and 85 (std dev 25.4) participants per session for the African and LATAM programs, respectively. Paired pre- and post-course data demonstrated significant improvement in both knowledge ($n = 51$, $p < .001$) and overall self-confidence ($n = 85$, $p < .001$). Synchronous participation did not predict greater score improvement or increase in self-confidence. Thematic analysis suggests that participants found great value in this course and look forward to future learning. **Conclusions:** A volunteer-driven course on IMRT is generalizable across regions in different languages and serves as an effective hub to arm participating centers with the knowledge and confidence they need to enhance patient care at their institutions. This benefit may propagate as participants become the next generation of trainers. Other fields and specialties aiming to reduce global health care disparities through training efforts could consider adopting this approach. Research Sponsor: Elekta Corporate Giving Committee.

11008 **Poster Discussion Session**

Mapping global oncology priorities: A survey of the directors of the NCI-designated cancer centers. *First Author: Laura Prakash, Clinical Monitoring Research Program Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD*

Background: By 2040, an estimated 69% of all cancer deaths globally will occur in LMICs. Recognizing this, ASCO formed the Academic Global Oncology Task Force in 2017 to help formalize the global oncology (GO) field. Their recommendations included: better engagement with the National Cancer Institute (NCI) Center for Global Health (CGH), increased funding, and development of forums to highlight global cancer research and control activities. To further clarify how GO programs are defined and to better understand the perspectives and needs of cancer research leaders, CGH conducted a survey of the 71 Directors at the NCI-Designated Cancer Centers (NDCC). **Methods:** A 19-question survey was designed using Microsoft Forms and sent to the NDCC Directors via email. Responses were collected from July to September 2021. Two coders reviewed the qualitative responses to categorize the data into thematic areas. Analyses were conducted in Microsoft Excel. **Results:** Seventy of 71 (99%) NDCC Directors responded to the survey. 41 NDCCs (59%) reported dedicated GO programs or plans to create such a program within 5 years. Additionally, 16 Directors reported GO activities without a dedicated program, while 13 reported no GO activities. The Directors described GO as having high/extremely high (39%) or moderate (50%) importance relative to other priorities, across all types of NDCCs (basic, clinical, or comprehensive). Eight NDCCs (11%) described GO as a low priority or non-priority. 31 NDCCs (44%) reported dedicated funding for GO activities. Directors estimated interest in GO to be higher among junior faculty and trainees than senior and mid-career faculty. Future goals for established or developing GO programs included: recruitment of leadership, formalizing a strategic vision, establishing partnerships, and increasing the number of activities with international collaborations. Barriers noted were limited funding, limited capacity and expertise, and prioritizing the needs in domestic NDCC catchment areas. **Conclusions:** Despite variation across NDCCs, GO interest is strong as expressed by Center Directors. Strategic planning, increased funding, and improved collaboration within and between NDCCs were reported as necessary to strengthen GO at NDCCs. Continued leadership from ASCO, the NCI, and other international organizations can help facilitate dialogue and increase the prioritization of GO activities at NDCCs. Research Sponsor: U.S. National Institutes of Health, Funded by the NCI Contract No. 75N91019D00024.

Assessing the landscape in medical oncology medical education scholarship: A scoping study. *First Author: Ruijia Jin, University of British Columbia, Vancouver, BC, Canada*

Background: Medical oncology and medical education have both expanded exponentially over the past 50 years; as such, it is important to understand the current status of postgraduate medical oncology education and develop ways to advance this field. This study undertakes a scoping review of medical education literature in medical oncology to inform future scholarship in this area. **Methods:** MEDLINE (Ovid), Embase (Ovid), ERIC (EBSCO), and Web of Science (UBC Core Collection) were searched to find peer-reviewed English language articles on Postgraduate Medical Education in Medical Oncology published between 2009 and 2020. The review was designed in accordance with updated methodological guidance for the conduct of scoping review. Articles were classified by learning specialty, learner training level, region of authorship, single or multi-institution, year of publication, whether the journal was an education journal, quantitative vs qualitative design, study methodology, and category or topic. A modified Kerns framework for curriculum development was used to assess the type of curriculum intervention, Boyer's definition of scholarship was used to classify the type of scholarship, and the CanMEDS Framework was used to map the domains of physician competency each study aims to address. Results were interpreted using descriptive statistics and collated and summarized utilizing predetermined conceptual frameworks. **Results:** 2959 references were initially found across the 4 databases. After title and abstract screening, 305 articles remained; after full text review, a total of 144 articles were included in our final analysis. These data showed that postgraduate medical oncology graduate medical education scholarship is increasing and most commonly observed in the United States. Quantitative studies were most common with surveys used as the most popular study approach. In terms of CanMEDS framework, Professional and Medical Expert comprised the large majority of education focuses, while very few articles addressed Leader or Health Advocate. Curriculum development, professional development, and attitudinal skills (communication skills, ethics) were the dominant research themes, while no articles discussed teacher training. **Conclusions**: By investigating the body of current literature, this research identifies areas of highest priority in postgraduate medical oncology graduate medical education and opportunities for growth. Whereas areas like professionalism and attitudinal skills are well-studied, research is lacking in leadership, health advocacy and teaching training. This study provides guidance for future medical education scholarship in medical oncology and establishes a benchmark to examine changes in medical oncology educational scholarship over time. Online scaffolds: A constructivist approach to oncology fellow learning. *First Author: Sam Brondfield, University of California-San Francisco, San Francisco, CA*

Background: Oncology is a vast and fast-paced field. Fellows must expend significant effort to learn and stay updated. Up-to-date learning tools covering core oncology content in a digestible manner are lacking. Additionally, passive lectures are common in oncology, while constructivist approaches that may improve learning are rare. Therefore, we piloted updatable online modules ("scaffolds") as a learning tool for oncology fellows. **Methods:** Author SB, a University of California, San Francisco (UCSF) solid-tumor oncologist, designed 12 scaffolds (breast, non-small cell lung, small cell lung, head/neck, salivary/thyroid, upper gastrointestinal, lower gastrointestinal, germ cell, bladder/renal/adrenal, prostate, melanoma, and sarcoma) using Google Slides between 12/2018 and 6/2019. The scaffolds included bullet points and tables/figures synthesized from the ASCO self-evaluation program textbook's solid tumor chapters and the National Comprehensive Cancer Network (NCCN) guidelines. We emailed scaffold links to all UCSF and Stanford oncology fellows in 2019-2020, including instructions for fellows to update the scaffolds without exceeding 20 slides per scaffold, 5 lines per slide, or 7 words per line. The scaffolds were reintroduced to new fellows at the beginning of each academic year. SB audited to ensure no erroneous information was added. In December 2021 we reviewed updates tracked in Google Slides and conducted one UCSF and one Stanford focus group with four 1st-3rd year fellows each. **Results:** Between 7/2019 and 12/2021, fellows made 60 updates to the scaffolds, with a mean of 5 updates per scaffold ranging from new trials to changes in management. During the same period, the auditor made 9 updates and found no erroneous fellow updates. Fellow updates occasionally exceeded specified limits, requiring correction. Content analysis revealed that fellows considered the scaffolds to be accessible and succinct learning tools that 1) addressed a dearth of similar resources, 2) served as effective preparation for clinical work and examinations, 3) provided structured information for rapid review, and 4) made subsequent interactions with complex resources such as NCCN guidelines easier. Barriers to fellows updating the scaffolds included lack of ownership and low confidence in judgment regarding appropriate updates. **Conclusions:** In this two-institution pilot, oncology fellows used and subsequently updated online scaffolds in a constructivist fashion. This model has the potential to fill a crucial gap in available learning resources and can be applied to other specialties. Assigning scaffolds to fellows with faculty mentorship may facilitate ownership and bolster fellow confidence in updating these tools. Individual institutions may update their own versions of the scaffolds to align with institution-specific needs. Research Sponsor: UCSF Education Innovations Funding Grant.

11011 **Poster Discussion Session**

Implementation and efficacy of a fellow-led, case-based noon lecture series. *First Author: James Dickerson, Stanford Hospital & Clinics, Stanford, CA*

Background: For new fellows, learning clinical oncology represents an enormous challenge. Few data support specific didactic approaches. The senior author (TPJ) developed a novel curriculum, emphasizing deliberate practice as part of a design grounded in Ericsson's "expert performance approach". These noon conferences are case based with a focus on key clinical trials and NCCN guidelines. In comparison to didactics given directly by faculty, these conferences are primarily presented by a senior teaching fellow with an invited faculty member adding additional commentary as an "expert discussant". We surveyed fellows to assess perception of efficacy and also created a board style test to evaluate knowledge gains. **Methods:** The curriculum began in 2020. After one year, we surveyed fellows with a five-point likert scale survey to quantify their perception of the curriculum. In 2022, we created a pair of 18-question lung cancer specific board style tests for the five teaching sessions on lung cancer. Prior to the first conference, the pre-test was sent to fellows electronically; after the final lecture the other 18-question test was sent out. Differences in the overall cohort's test score were examined via a paired student t-test. **Results:** On the 2021 survey, 59% of fellows responded (17 of 29). Of the respondents, 83% attended at least half of the lectures (14 of 17). When asked to compare this conference series to traditional lecture-based series, 59% (10 of 17) agreed with the statement that "this series is one of the very best I've encountered" and all said it was at least "better than average." 94% of respondents (16 of 17) said the series equipped them for clinical practice to either a "significant" or "remarkable" degree. 94% of respondents (16 of 17) agreed the conferences helped them learn to "think like oncologists." For the five session lung cancer block, fellows reported attending an average of 3.6 ± 1.4 sessions (n = 13). On the 18-question pre-test (n = 19), the average score ± one standard deviation was 73% ± 15%. For the post-test (n = 13), the average was 68% ± 17% (p = 0.48). **Conclusions:** We developed a novel curriculum to replace traditional didactics. Fellows perceived the curriculum to be exceptionally strong as compared to traditional lecture series, felt it prepared them well for practice, and said it taught them to think like oncologists. Pre/post knowledge assessments did not show an improvement in knowledge. Distribution to larger numbers of fellows–especially early learners–may better power a study to detect improvements in learning. Research Sponsor: None.

Coupling gamified continuing education with confidence-based assessment to address knowledge gaps and assess attitudes towards liquid biopsy for cancer screening among primary care providers. *First Author: Jillian L Scavone, Vindico Medical Education, Thorofare, NJ*

Background: Blood-based liquid biopsy assays offer a simplified approach to detect cancer early, guide clinical decision making, and predict treatment success. Given their novelty, primary care providers need education to improve knowledge and confidence regarding their use. The use of gamification in continuing medical education (CME) has been shown to increase engagement and knowledge transfer, and confidence-based learning can improve the educational experience by identified areas in which learners lack comfort. **Methods:** We provided a gamified CME activity based on the principles of confidence-based learning designed to educate primary care providers (PCPs) on the latest advances regarding the use of liquid biopsy for cancer screening. The game coupled knowledge questions with self-assessment of confidence to gage awareness of these topics. Pre- and post-test was used to quantify the impact of the education. The CE activity was available for credit from March 31, 2021 to March 31, 2022. **Results:** As of January 2022, 389 PCPs have participated. Overall, participants scored an average 76% on gaming questions related to the rationale behind the use of cell free DNA (cfDNA) for cancer screening and the benefits of liquid biopsy over tissue biopsy, demonstrating relatively high baseline knowledge on these topics. Self-reported confidence among those who answered correctly, however, was only 3.4 out of 5.0, suggesting a lack of comfort with the concepts despite answering correctly. On topics related to specific studies that demonstrated the clinical utility of liquid biopsy, participants scored only 59% and confidence scored averaged 3.17 out of 5.0, demonstrating a lack of knowledge and comfort on these topics. Across all topics, providers scored a 61% on a pre-test. Post-learning, providers scored 89%, highlighting the impact of the education on knowledge gaps. Moreover, while 52% of participants had never ordered a liquid biopsy for cancer screening prior to the education, 69% report being likely or extremely likely to do so because of the education provided. **Conclusions:** Integration of gamified and confidence-based learning into CE activities is an impactful way to identify and address knowledge gaps while also informing the need for future education. In this study, while self-report of confidence generally correlated with knowledge scores, confidence scores were only average even among those who answered correctly, demonstrating the need for skills-based learning that may improve comfort with liquid biopsy in the clinical setting. Research Sponsor: This activity is supported by an educational grant from GRAIL, Inc.

Impact of social media on the emotional health and burnout of pediatric and adult oncology professionals: A SWOG and COG survey. *First Author: Scott Moerdler, Department of Pediatrics, Rutgers Cancer Institute of New Jersey, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ*

Background: Social media (SoMe) engagement is common in oncology, especially for patients and support groups, allowing for education and support. However the impact on oncology professionals remains unknown. The purpose of this study was to evaluate professional SoMe use and its potential associations with wellbeing and burnout. **Methods:** An electronic survey was developed and piloted by pediatric and adult oncologists. Questions included demographics, details of SoMe use, and emotional health assessments including a 2-item burnout questionnaire. The survey was distributed to all members of SWOG Cancer Research Network and Children's Oncology Group via Qualtrics. Data was analyzed as of 2/6/2022. **Results:** The initial survey demographic and emotional health questions were completed by 1558 individuals. Of these, 1069 (68%) reported not using SoMe professionally, while 489 (31%) did. SoMe engagers were primarily female, born 1976–1984, attendings, from academic institutions, and balanced across adult and pediatrics (Table). Among those who use SoMe professionally, 54% (267/489) reported burnout, compared to 66% (701/1069) in the non-SoMe group ($p = 0.0001$). Remaining emotional health outcomes were similar between groups: choosing this job/career again, time for personal/family life, and career satisfaction ($p > 0.1$ for all). An additional section on the impact of SoMe on emotional health was completed by 473 SoMe engagers. While 49% (233/473) reported that SoMe has no impact on burnout, 18% (86/473) felt that SoMe helps alleviate burnout. SoMe use was reported to have somewhat/extremely positive impact on wellness (defined as physical, mental, emotional, spiritual wellness) by 28% (131/473). Networking and recognized shared experiences were the top areas of SoMe that improved wellness. Close to half (208/473, 44%) responded that SoMe does not negatively impact wellness. Professional anxiety, amount of time spent online, and keeping up to maintain an online presence were the most frequently noted aspects that negatively impact wellness. Nearly half (232/473, 49%) somewhat/strongly agree that SoMe provides a sense of community. One limitation includes distribution to engaged cooperative group members which may impact results. **Conclusions:** This analysis suggests that social media engagement might help provide a positive impact on the wellness and reduce burnout among oncology professionals. We hope to further explore themes with qualitative interviews to better understand the impact of SoMe on our emotional health. Our goal is to develop educational interventions based on these salient positive and negative factors. Research Sponsor: None.

	No SoMe (n = 1069)	Yes SoMe (%) n = 489
Female (%)	78%	72%
Born 1976 – 1984 (%)	27%	50%
Role: Attending Physician (%)	35%	45%
Practice Type: Academic Institution (%)	74%	75%
Field: Adult Oncology (%)	33%	41%
Pediatric Oncology (%)	54%	41%
Other (%)	13%	17%

Factors associated with altmetric attention scores for randomized phase III cancer clinical trials. *First Author: Michael Kevin Rooney, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The rise of the internet and social media has created new opportunities for the rapid sharing of scientific findings among professional and public communities. Altmetric Attention Scores (Altmetrics) are real-time measures of scientific impact and attention through various public outlets, including news, blogs, and social media. Distributions and patterns of Almetrics for high-impact clinical cancer research remain under-reported. Our goal was to describe the relationship between Altmetrics and other characteristics of published trials. **Methods:** We identified all two-arm superiority phase III cancer randomized controlled trials (RCTs) with a publication date between 2015-2020 from HemOnc.org. For included trials, we tabulated the followed the data: Altmetric score as of February 11, 2022; positive study (yes/no); FDA registration trial (yes/no); primary endpoint (categorized as overall survival (OS), progression-free survival (PFS), event-free/disease-free survival (EFS/DFS), or other); journal tier (defined as tier 1: *NEJM, Lancet, JAMA*; tier 2: *JCO, Blood, Lancet Oncology, JAMA Oncology, Annals of Oncology* or Tier 3: other). Univariable testing was performed with Pearson correlation, Wilcoxon rank sum, and Kruskal-Wallis testing to identify associations between predictor variables and Altmetrics. For factors with significant univariable associations, we generated a multiple linear regression model to identify clinical trial factors predictive of Altmetric attention scores, with alpha = 0.05 defining statistical significance. **Results:** Of 673 publications identified per inclusion/exclusion criteria, Altmetric scores were found for 638 (95%). The median score was 38.9 (IQR 12.4-126.7) – well above the 95th percentile for all Altmetric scores. On univariable testing, positive studies ($P < 0.001$), registration trials ($P < 0.001$), those published in tier 1 journals ($P < 0.001$), and trials with primary endpoint of OS ($P = 0.002$) were associated with increased Altmetric scores. On multivariable testing, positive studies ($P = 0.006$), registration trials ($P < 0.001$), studies published tier 1 journals ($P < 0.001$), and those reporting on OS ($P = 0.03$) persisted as significantly associated with increased engagement as measured by Altmetric scores. **Conclusions:** Social media and other online platforms represent an increasingly important avenue for the sharing of scientific and medical research. In this cross-sectional observational study, we found that certain characteristics of cancer clinical trials and publications are predictive of impact as measured by Altmetric scores. Specifically, positive registration trials published in traditionally defined high-impact journals and those reporting on OS as a primary endpoint tend to have the greatest Altmetric attention scores. The significance and consequences of these relationships warrant further investigation. Research Sponsor: None.

11015 **Poster Session**

Burnout among early-career medical oncologists: A single-institution experience. *First Author: Anmol Singh, MD Anderson Hematology/Oncology Fellowship, Houston, TX*

Background: Burnout is a psychological syndrome defined by the Maslach Burnout Inventory (MBI) as emotional exhaustion, depersonalization, and a low sense of personal accomplishment. Risk of job-related burnout for early-career medical oncologists can significantly impact career longevity and health outcomes for providers and patients alike. Because little is known about burnout specific to early-career academic oncologists, we sought to characterize the prevalence of burnout and associated factors among Assistant Professors at MD Anderson Cancer Center (MDACC). **Methods:** For this IRB-approved retrospective study, an electronic survey was developed for Assistant Professors in medical oncology at MDACC. Participants were all involved directly in patient care with at least some clinical effort. Our survey included nine questions validated in the MBI addressing equally the 3 aforementioned domains of burnout. An additional 31 questions were formulated to assess personal and professional factors that may contribute to burnout at our institution (clinical workload, research expectations, communication, COVID, and home-life). Each question was scored on a scale of 1 to 5, with higher scores correlating to higher levels of burnout. Descriptive statistics were used to describe the prevalence of burnout, and logistic regression analyses were performed to identify characteristics associated with burnout. **Results:** Among 70 (of 86 total) Assistant Professors who responded, mean duration on faculty was 3.1 years (standard deviation +/-1.8). Mean clinical effort was 67% (range, 19-95). Gender identifications were 44% female, 54% male, and 2% non-binary. 54% of respondents reported symptoms of burnout already, including 21% endorsing severe burnout. Severe burnout was more common for solid tumor providers than liquid tumor providers (55% vs 13%, $p = .03$). Using the MBI, severe emotional exhaustion (25%) was more prevalent ($p < .0001$) than depersonalization (6%) or lack of personal accomplishment (17%). Sentiments of being "emotionally drained" (20%), fatigue to face another day on the job" (37%), and "becoming more callous" (30%) were especially concerning among early-career faculty. Emotional exhaustion was associated with a feeling of less autonomy over personal decision making ($p = .03$) and female gender ($p = .04$). **Conclusions:** Burnout exists with high prevalence among early-career medical oncologists in this single-institution analysis. Emotional exhaustion was the specific manifestation of burnout in this population. Further validation of these data nationwide is anticipated. Interventions focusing on reducing emotional exhaustion are under development to reduce medical oncology-specific burnout in an academic setting for faculty retention and for deliverance of optimal care to patients with cancer. Research Sponsor: None.

11016 **Poster Session**

Feasibility of virtual stress management and resiliency training (SMART) for oncology fellows during the COVID-19 pandemic. *First Author: Colt Williams, Mayo Clinic, Rochester, MN*

Background: Stress Management and Resiliency Training (SMART) is a validated resilience training program designed to reduce stress, improve emotional resilience, and decrease burnout. The prevalence of burnout among practicing oncologists is as high as 40%, but unknown among oncology trainees. We implemented a virtual format of the SMART program to the Hematology/Oncology fellowship at Mayo Clinic to assess the feasibility of such a delivery, measure baseline rates of burnout in this group, and to investigate if a virtual method of delivery is as effective as in-person delivery as described in the literature. **Methods:** The SMART project was a mixed-methods, prospective, single arm clinical trial. Hematology/Oncology Fellows at Mayo Clinic were invited to participate. Four one-hour training sessions were conducted virtually. Fellows were given access to SMART online video modules and a book which supported the content covered during virtual training, a companion resilience mobile app, and a paperback mindfulness journal. Stress, burnout, and emotional resilience were measured at baseline and three months post-intervention using the Perceived Stress Scale (PSS), Maslach Burnout Inventory (MBI), and Connor-Davidson Resilience Scale (CD-RISC2). Changes in mean scores on the PSS, MBI, and CD-RISC2 were assessed using the Wilcoxon signed-rank test. Program feedback and feasibility data were obtained during a virtual focus group. Audio transcripts from the focus group were codified for thematic analysis and verified by intercoder triangulation. A 6-month assessment will be due in March 2022. **Results:** 26 of 50 fellows invited participated in our study. At baseline, 24% of participants had measurable burnout and 92% had moderate to high stress. At 3-months, the number of participants with moderate to high stress decreased to 71%, while rates of burnout remained unchanged. The PSS demonstrated a decrease in mean stress (-10.9%, $p = 0.005$), while the MBI demonstrated decreased emotional exhaustion (MBI-EE -6.01%, $p = 0.04$), an improved sense of personal achievement (MBI-PA 28.1%, $p < 0.001$), but slightly worse feelings of depersonalization (MBI-DP 16.46%, $p = 0.05$). The CD-RISC2 suggested no change in global emotional resilience (-0.71%, $p = 0.82$). Thematic analysis of the focus group data revealed that participants overwhelmingly found the program beneficial (83% of all responses), 20% indicated improved stress, and 15% indicated improved work performance. **Conclusions:** Oncology fellows in this study had lower rates of burnout compared to practicing oncologists. Virtual implementation of the SMART program is feasible and resulted in improvements in stress and prevented worsened burnout. Outcomes were comparable to previously published studies conducted in-person. Focus group participants found the training beneficial, reported lower stress, and improved work performance. Research Sponsor: None.

11017 **Poster Session**

A systemic look at professional burnout and well-being within an urban cancer center as a roadmap to recovery. *First Author: Alyson B. Moadel, Albert Einstein College of Medicine, Bronx, NY*

Background: As the U.S. health care system's vulnerabilities have been laid bare by an unremitting pandemic, it behooves us to build in resiliency as we look towards recovery. The "burnout epidemic" facing oncology clinicians has been well documented prior to the pandemic. From a systemic perspective, however, data across the cancer service line is scant. In an effort to identify the stress points and strengths of an oncology service line, we present cross-sectional data from 2018 examining burnout, physical and emotional well-being, and self-care needs across all primary cancer center roles within a major urban cancer center in NYC. **Methods:** An anonymous online survey was completed by 310 of 646 (48%) cancer service providers comprised of physicians, nurses, clinical support staff, managers, and clerical staff. The abbreviated Maslach Burnout Inventory (MBI-9), the Mental Health Inventory (MHI), and the brief COPE were included. **Results:** Respondents ranged from nurses (15%) to clinical support staff (29%), with 79% identifying as female. In a snapshot view, 25% of the sample endorsed feeling burned out from work. Rates of emotional exhaustion were highest among nurses (41%) and lowest among physicians (14%), $p < 0.06$. Depersonalization rates ranged from 1% for physicians to 11% for nurses and clerical staff ($p < 0.003$). A breakdown of those who would not choose the same career over again: clerical (36%), management (28%), nurses/clinical support staff (23%) and physicians (11%), $p < 0.053$). Clinical levels of distress ranged from 20% (clerical staff) to 30% (nurses). Self-reported health (1-5) was lower among clerical staff and nurses (3.1) compared to physicians (3.9), $p < 0.001$. The majority of staff utilized adaptive coping strategies including positive reframing and planning, with religion and humor often endorsed. Interest in counseling and communication skills training ranged from 56%/57% among physicians to 84%/88% among clerical staff, respectively. **Conclusions:** This panoramic view of one cancer service line just prior to the pandemic points to particular systemic stresses in areas of emotional exhaustion, career choice questioning, and psychological and physical health. While levels of burnout fall within and below rates reported in the literature, it also points to fault lines affecting key service line positions, particularly nurses and clerical staff. At the same time, it highlights an underlying resiliency in coping and receptivity to self-care and development. In response to this internal needs assessment, our cancer center is working towards building a stronger foundation in which staff will not only survive the expected and unexpected stresses of working in health care but find meaning and joy in work. While we cannot predict the future, we can learn from the past. In this vein, a Well-Being Committee that includes representatives across the cancer service line was launched in 2022. Research Sponsor: Montefiore Einstein Cancer Center internal funds.

Impact of structured debriefing sessions on residents rotating on inpatient oncology. *First Author: Hina Dalal, Loyola University Medical Center, Maywood, IL*

Background: Participating in end-of-life (EOL) care may lead to physician distress and burnout. Residents rotating on inpatient oncology services often care for patients and families nearing the EOL. There is no standardized resident training for EOL care nor are there standardized methods to assist with resultant emotional distress. Studies have demonstrated that residents on hematology/oncology rotations experience acute empathy decline, which can lead to cynicism and depersonalization, contributing to burnout (McFarland, 2016). Our objective was to prospectively evaluate the impact of a structured debriefing session during a 4-week inpatient oncology rotation on residents' concerns about death and rotation satisfaction. **Methods:** During week 1, residents completed a 10-item Concerns about Dying (CAD) instrument (Mozer, 2004). During week 3, residents participated in a structured 60-minute debriefing session with a clinical psychologist or licensed social worker specializing in hematology-oncology. During week 4, residents completed the CAD and an end-of-rotation self-assessment. **Results:** 58 individual residents rotated through inpatient oncology at Loyola University Medical Center from 7/2020 – 1/2022. 15 residents were excluded as they did not complete both the pre and post surveys. Trainees had a lower CAD score at the end of their oncology rotation, indicating a more positive attitude towards death and dying. PGY1s had the greatest decrease in CAD score over 4 weeks. Anxiety (70%), relief (70%), satisfaction/pride (63%) and sadness (58%) were the most common emotions residents felt while providing EOL care. 42/43 (98%) residents were comfortable discussing EOL topics with a licensed counselor and 40/43 (93%) felt the debriefing had a positive impact on their rotation. 38/43 residents (88%) believed the debriefing reduced sentiments of cynicism and dissatisfaction caused by emotional distress related to EOL care. **Conclusions:** Resident concerns about death decreased during a 4-week inpatient oncology rotation in which a structured debriefing program occurred during week 3. Although the study protocol does not provide causation, it suggests the debriefing allowed residents to reflect on EOL care and enhance their ability to cope with distress. The favorable feedback from this pilot led to a permanent curricular change for the inpatient oncology rotation. Strategies to assess and manage emotional strain among residents providing EOL care remain limited and warrant further investigation. Research Sponsor: None.

CAD* scores during week 1 and 4.

Training Year	Number of residents (n)	Week 1	Week 4	Difference
PGY-1	28	4.0	2.6	-1.4
PGY-2	6	3.6	2.8	-1.0
PGY-3	9	3.3	2.6	-0.7
Overall	43	3.8 ($M = 3.8$, $SD = 0.3$)	2.6 ($M = 2.6$, $SD = 0.07$)	-1.1 Paired t-test analysis: $t(42) = 24$, $p < 0.001$

*Responses based on Likert Scale, '1' = disagree completely and '5' =agree completely, higher number indicates a more negative attitude toward death and dying.

11019 **Poster Session**

ASCO oral presenters five years later: Leaks in the pipeline? *First Author: Forrest Kwong, Oregon Health & Science University, Portland, OR*

Background: There is growing awareness of the challenges of retaining oncologists engaged in research, and this leaky academic pipeline is most notable for women in medicine. Studying academic oncologists is challenging due to their many affiliations, but with an estimated attendance of over 30,000 oncologists, the ASCO annual meeting is a highly sought-after stage for presenting new research. To better understand the continued research engagement of oncologists active in research, we used public data from ASCO annual meetings to follow a cohort of oral abstract presenters over 5 years. **Methods:** To define our initial cohort of oncologists engaged in research, we used the 2016 ASCO Annual Meeting Digital Program to identify first author oral abstract presenters. We tracked if each presenter was subsequently listed as an author of any research type (oral abstract session, poster session, education session, etc.) at the 2017, 2018, 2019, 2020 and 2021 ASCO conferences. We then filtered out researchers who were not listed as authors at ASCO in consecutive years to look at only those researchers who continued to have active ASCO involvement. To evaluate by gender, each presenter's name was referenced with the publicly available Wiki-Gendersort tool for an unbiased assignment. **Results:** 209 first author oral abstract presenters were identified at the 2016 ASCO conference. We found that 67.9% of the initial 209 researchers were listed as authors at ASCO in 2017, 55.5% continued to be authors in 2018, 46.9% in 2019, 42.6% in 2020, and only 38.3% were still listed as authors 5 years later in 2021. When looking at sustained first authorship, 8.1% of the initial 209 research cohort continued to be listed as first authors for 5 consecutive years through 2021. We also looked at the breakdown of other types of ASCO presentations and found that 122 of the initial 209 research cohort presented posters in 2016. Of these 122 researchers, 60 (49.2%) remained authors of posters throughout the consecutive 5 years. This is significantly higher than the number of researchers who continued to author oral abstracts in 2021 49.2% vs. 3.8% ($P < 0.0001$). When evaluating the differences between gender, there were approximately twice as many men presenters as women (122 men vs 65 women; 22 names were unisex or unknown). The rate of retention was similar for men (47 of the initial 122 males, 38.5%) and women (25 of the initial 65 females, 38.5%) at 5 years ($P = 1$). **Conclusions:** We conducted a descriptive study evaluating the rate of sustained activity in academic oncology over 5 years. Our research suggests that about one-third of ASCO presenters will continue to have sustained yearly authorship at 5 years post-oral abstract presentation. Compared to men, the leaky academic pipeline is comparable for women in the 5 years following an oral abstract presentation at ASCO. Research Sponsor: None.

Preventing healthcare professional burnout in oncology: How creative patient encouragement can go both ways. *First Author: Grace Lee, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Cancer treatment is a difficult process that not only affects the patients themselves, but also their caregivers and healthcare professionals (HCPs). A cancer diagnosis is often a life-changing experience for both patients and caregivers, who may feel vulnerable and stressed in the face of such a complex disease. HCPs in oncology, who are constantly present on the frontline between life and death, often experience emotional and physical exhaustion. Such burnout of HCPs can lead to adverse effects on patient care. Therefore, it becomes important to prevent and manage HCPs' fatigue to not only improve patient care, but also HCPs' quality of life. **Methods:** This study qualitatively examined the experiences of HCPs who collaboratively interacted with patients and caregivers in the clinical setting. The Pacemakers initiative was developed and piloted in a large urban academic medical center with the aim to promote creative encouragement and companionship among HCPs and patients/caregivers. HCPs held ceremonies with personal awards for patients/caregivers during their treatment course, and their experience with the ceremonies was evaluated qualitatively with a survey. A thematic analysis was subsequently performed on the HCPs' reflective essays ($N = 22$) to identify recurring themes (italicized) in their experiences. **Results:** In general, we found that the HCPs felt that they were *benefiting* from taking part in the creative patient encouragement ceremonies. Many described the experience as *motivating* or *inspiring* ($n = 15$), highlighting how such collaboration renews optimism and prevents burnout. The HCPs also reported *feeling acknowledged* for their behind-the-scenes work and support ($n = 5$) and grateful to be given the *opportunity to acknowledge their patients and caregivers* ($n = 13$), as well. Another common theme was that the HCPs felt that they were able to *connect emotionally* ($n = 14$) with the patients and caregivers, describing moments of shared laughter and tears. Lastly, the HCPs reported feeling a sense of *togetherness* with patients and caregivers ($n = 13$), often describing the relationship as akin to a team or family, and many stated that they were able to develop a *more personal connection* ($n = 15$) with patients and caregivers through the ceremonies. **Conclusions:** Overall, we find that the benefits of encouraging patients and caregivers extend to HCPs. The positive impact of identifying and celebrating small but meaningful joys in the clinical setting is considerable especially upon HCPs, who find such experiences to be rewarding and refreshing. HCP burnout is common in oncology, and the findings of this analysis suggest that inspiring mutual encouragement and fostering collaboration between HCPs, patients, and caregivers are critical in reducing and preventing such fatigue. Research Sponsor: None.

Alleviating the click fatigue on clinicians to improve referrals for colorectal cancer screening. *First Author: Robby Amin, Horizons: South Georgia's Cancer Coalition, Albany, GA*

Background: The impact of clinician burnout on patient care is pervasive across medical delivery systems. The effects are also felt in preventive care where cancer screening efforts rely on clinician referrals through the electronic medical records (EMRs). Though designed to support healthcare, EMRs are a significant source of clinician burnout given the number of clicks or navigation time needed to refer a patient. This is a barrier to Patient Navigation (PN) when ordered tests do not materialize into screenings or when clinicians order labs/imaging and the pending orders are not created. This causes frustration for all clinical staff involved, delays the workflow processes, and leads to missed opportunities for PN. We implemented an 'order set' intervention to reduce the click burden linked to colorectal cancer (CRC) screening referral among clinicians in South Georgia. **Methods:** The 'order set' intervention was developed to facilitate PN for a Colorectal Cancer Control Program (CRCCP) aimed at implementing Evidence-Based Interventions to increase CRC screening rates in Georgia. The 'order set' was designed to address workflow issues by consolidating steps associated with CRC screening. This reduced typing input and the need to click between multiple windows within the EMR while making a referral to PN. The intervention was piloted in the Albany Area Primary Health Care (AAPHC) system after modifications were made to the EMR and clinician workflows. The monthly CRC screening rates continue to be generated and tracked post-implementation. **Results:** The use of the 'order set' reduced the click burden from 78 to 7 inputs and clinician EMR interaction time from 110 seconds to 29 seconds. Providers from 4/7 clinics have adopted the 'order sets' when making referrals for CRC screening. Two clinics provided post-implementation screening data. The pre-implementation screening rates for one clinic were comparable (August = 59.3%, September = 57.6%) to post-implementation (October = 56.3%, November = 56.6%, December = 57.2%), while the second clinic showed some increase (August = 58.6%, September = 60%) vs. (October = 61%, November = 62.1%, December = 62.8%). **Conclusions:** The 'order sets' intervention reduced the time clinicians spent creating referrals for CRC screening, including fecal immunochemical tests (FIT) and colonoscopies. Additional follow-up and rollout to clinics participating in the program is underway to evaluate further the impact of the order sets on CRC screening outcome and process measures, including qualitative interviews with clinicians. There is significant potential in the application of order sets to various workflow processes to aid in preventative health efforts. Challenges linked to the COVID-19 pandemic and staff turnover affected acquisition of patient referral data. Research Sponsor: Center for Disease Control.

Piloting virtual mentorship: Evaluating acceptability and influence on wellness and professional identity in medical oncology (MO). *First Author: Andrea S. Fung, Cancer Centre of Southeastern Ontario, Kingston, ON, Canada*

Background: Despite extensive literature on the value of mentorship in academic medicine, little evidence exists to inform mentorship practices in MO. In 2021, the Canadian Association of Medical Oncologists (CAMO) piloted a national, 6-month virtual mentorship program consisting of 2 group mentoring events and additional 1-on-1 mentoring activities, to better support the needs of MO trainees. Feedback was obtained from participants to gain insight into how virtual mentorship might impact physician wellness and formation of professional identity, and to inform future iterations of CAMO's virtual mentorship strategy. **Methods:** All Canadian MO residents/fellows were invited to participate in the program. Electronic surveys were completed by participants at baseline, after each group event, and at program completion. Surveys evaluated the program content and format, and used validated questionnaires for evaluating physician wellness/burnout (Stanford Professional Fulfillment Index [SPFI]), and professional identity (Macleod Clark Professional Identity Scale [MCPIS]). Cohort characteristics and survey responses were summarized using descriptive statistics. Procedures for survey data collection and analysis were ethics approved. **Results:** At baseline, respondents (n = 38) were predominantly female (63%), and < 35 years (76%). 50% were married. On average, 78% of respondents ranked the virtual group mentoring events as meeting expectations. Program strengths identified by participants included meeting mentors outside of their own centre, meeting other trainees from across the country, and learning more about work-life balance/physician wellness. The main critique was insufficient time for interaction. Of the 34 MCPIS respondents, 94% were pleased to belong to the profession of MO, 91% identified positively with members of their profession and 77% felt like a member of the profession themselves. The average score on the SPFI scale was 2.73±0.71 (n = 34). Although 85% of respondents found their work meaningful, 71% satisfying, and 50% felt they were contributing professionally in valued ways, only 38% met criteria for professional fulfilment (score ≥3.00). 27% met criteria for burnout (score ≥1.33), 15% found their work physically exhausting and 9% found their work emotionally exhausting. **Conclusions:** CAMO's pilot virtual mentorship program highlights that technology can be successfully leveraged to facilitate mentoring. The majority of MO trainees identified positively with their profession, yet only 38% reached the threshold for professional fulfillment and nearly a third met criteria for burnout. Longitudinal follow-up among mentored trainees is needed to provide insight into whether mentorship may influence physician wellness and professional identity over time. Research Sponsor: None.

Effect of transition from inpatient oncology service to oncology consult service on fellow burn out and training. *First Author: Anosha Tariq, Jinnah Sindh Medical University, Karachi, Pakistan*

Background: The hematology-oncology inpatient service at the University of Louisville underwent a major change in July 2021 from a medical oncology service run by hematology/oncology fellows and attendings to a hospitalist-run service with hematology/oncology fellows and attendings sharing patient care responsibility as a consulting service. We planned this study because, to date, no published work has studied the effect of transitioning from an inpatient to consult service on fellow burnout, education, and training. **Methods:** A survey was distributed in July 2021, and a follow-up survey was sent in January 2022. The survey had 38 questions regarding the impact of the workload on time for study, research, personal and professional life, which were scored from 1 to 5. Two tail paired t-test was used to compare the difference in means. The survey also contained questions from the Mayo Clinic Resident Well-Being Index (RSWBI). This index has been validated to identify distress among fellows and allows for the comparison of local results with national data from RSWBI. In RSWBI, scores range from 0-7, with 0 being the lowest risk and 7 being the highest risk of burnout. A cut-off of a score ≥ 5 identifies individuals with a high degree of distress, is associated with an increased risk of error, suicidal ideation, and burnout, and has been validated in more than 1700 residents/fellows. **Results:** We distributed the survey to 2nd and 3rd-year fellows. 5/6 fellows completed the survey. 3 of them were male and 2 females. Change in inpatient service structure did not impact time for study, research, patient encounter, or ability to handle the volume of work. Improvement in adequate time preparing for clinic was statistically significant (P=0.03), and other improvements were also noted in concentration, time for family, and better personal and professional relationships (Table). RSWBI median score before the transition was 3.6, which improved to 2.0 after the transition to consulting service, which was similar to the national average where the median score was 2.0 among 8237 residents/fellows. 2 fellows (40%) were at high risk of distress before the transition. 1 fellow (20%) was at high risk of distress after the transition, which was comparable to the national average where 19.4% resident/fellows scored ≥5. **Conclusions:** These results show increased levels of distress in fellows that improved to the national average following transition from a primary inpatient medical oncology service to a consult service. Research Sponsor: None.

Outcome	Mean Jul 2021	Mean Jan 2022
Time for study/research	2.8	3.0
Time for patient encounter	3.6	3.8
Time preparing for clinic	3.0	4.0*
Handle work on call	3.6	3.8
Time for family	2.6	3.8
Compassion for coworkers/patients	3.4	3.8
Personal/professional relationships	2.6	3.8
Concentration	3.2	4.0
Use of alcohol or drugs	1.6	1.4

A needs assessment survey to inform a general practitioner in oncology (GPO) training program in Nepal. *First Author: Bishal Gyawali, Brigham and Women's Hospital, Boston, MA*

Background: Nepal is a low-income country with a population of over 30 million that faces a significant burden of cancer, with approximately 60,000 patients receiving a cancer diagnosis per year. However, a lack of cancer care providers is recognized as a major barrier to cancer care in Nepal. To address this gap, a national GPO training program may be an effective task-shifting strategy to increase the oncology workforce. A needs assessment survey was conducted to determine baseline oncology training for Nepalese General Practitioners (GPs) and the feasibility and desirability of establishing a GPO training program in Nepal. **Methods:** A survey was distributed to 171 GPs in Nepal. The survey was distributed via the REDCap electronic database, a secure-web-based software platform based at Queen's University in Kingston, Ontario, Canada. Reminders were sent out via social media accounts. The survey results were recorded anonymously from February to July 2021. **Results:** Data was collected from 71 GPs in Nepal. Data revealed significant gaps in oncology training, with only 6% of respondents reporting undergoing a mandatory oncology rotation during their training, and 15% indicating their training adequately prepared them to care for patients with cancer. Although respondents reported seeing an average of 1-5 cancer patients per day, only 9% reported providing chemotherapy treatment, and 36% indicated regular provision of follow-up cancer care. Only 1 in 5 general practitioners reported having radiation oncology services available at their institution or an institution within the same zone. 96% of GPs surveyed agreed that there is a need for a GPO program, and 71% reported they would be very interested in participating in this type of training. A majority of respondents indicated a preference for self-directed and small-group learning as the preferred modes of content delivery in a GPO training program. **Conclusions:** Our findings indicate a need and high level of desirability for a national GPO training program in Nepal. Further, the needs assessment provides insight into practitioner perspectives on information needs and content delivery. This data will be used to guide future curriculum development for the Nepal GPO program. Research Sponsor: ASCO Young Investigators Award.

Characterization of industry relationships in oncology. *First Author: Rebecca A. Harrison, BC Cancer, The University of British Columbia, Vancouver, BC, Canada*

Background: Collaborative relationships between academic oncology and the pharmaceutical industry are essential for therapeutic development in oncology. Despite this, formal training and mentorship in developing productive industry collaborations are not routinely included in oncology training. Since little research has been done to characterize and optimize the efficiency of these relationships, we sought to better understand the nature of such collaborations in order to identify areas for optimization. **Methods:** An electronic survey was administered to 1000 randomly selected ASCO members. The survey included 23 questions eliciting demographic and practice information, and 26 questions eliciting respondents' views around oncology-industry collaborations. Survey results were analyzed using descriptive statistics. **Results:** There were 225 survey respondents. Most were from the United States (70%), worked at an academic institution (60.1%), worked in medical oncology (81.2%), and had an active relationship with industry (85.8%). 26.7 % of respondents reported difficulty establishing a relationship with industry collaborators. Many relied on federal (39.5%) or departmental (30.2%) funding to supplement their research ventures. Partnerships were initiated by the respondents themselves (34.6%) or industry partners (31.9%) with similar frequency, whereas institutional affiliations (15.7%) and collaborative groups (5.8%) were reported as less common means for establishing collaborations. The majority (85.3%) of respondents stated these collaborations were of importance to their career. Inclusion in industry sponsored trials (71.1%) and commitment to research funding (66.3%) were considered early signs of a productive relationship, whereas lack of effective communication (86.1%) or little engagement by senior industry leadership (63.1%) were early red flags. Most respondents (75%) did not report having had mentorship in developing these relationships. Scientific integrity was generally thought to be preserved (92%) and there was little concern over the quality of the collaborative product (95%). Many shared concern over potential conflict of interest if a compensated relationship promoted an industry product for clinical care/research (60%), yet also stated these relationships did not shape their interactions with patients (67%). **Conclusions:** This study provides novel data characterizing the nature of collaborative industry-academia relationships in oncology. While respondents considered these collaborations an important part of clinical and academic oncology, formal education or mentorship around these relationships is rare. Further study exploring the structure of effective industry collaborations, optimizing methods to provide education in this area at all career stages, navigating conflict of interest issues in these relationships, and understanding industry perspectives is warranted. Research Sponsor: None.

Gaps in adolescent and young adult oncology education during medical and pediatric hematology/oncology fellowship training. *First Author: Adam Duvall, University of Chicago Medicine, Chicago, IL*

Background: There are limited data on the extent of adolescent and young adult (AYA) education in pediatric and medical oncology fellowship programs. The purpose of this study was to assess the prevalence and content of AYA-focused training during pediatric and medical oncology fellowship and identify knowledge gaps for targeted educational curricular development. **Methods:** An anonymous, web-based survey for educators and trainees was developed, piloted and optimized by a study team comprising pediatric and adult oncologists. The survey contained questions on respondent demographics, AYA curriculum, provider comfort in managing specific AYA care domains, and priorities for future AYA educational content. In October 2021, email invitations containing the survey link were sent to program directors (PDs) and associate program directors (APDs) at 251 hematology/oncology fellowship programs (with 119 pediatric and 178 adult PDs/APDs) identified through the American Medical Association's Fellowship and Residency Electronic Interactive Database Access. PDs were asked to participate and also distribute the survey to current fellows. The survey remained open for 3 months. Fisher's exact test was used to assess for associations between discrete variables including amount of current education vs level of importance and demographic groups. **Results:** Respondents represented 69 programs (27%). There were 130 respondents who completed curriculum and demographic questions and 112 who completed detailed topic questions. Respondents comprised 51 PDs/APDs (32 pediatric and 19 adult) and 58 fellows (33 pediatric and 25 adult). 85% of PDs (44/51) do not have a formal AYA curriculum. Of these, 80% (35/44) offer some topic-specific lectures, while 20% (9/44) provide little/no education in any topics. For nearly all topics, at least 45% of respondents reported little/no education. Although onco-fertility and survivorship are the most frequently taught topics, 36% and 42% of respondents, respectively, reported little/no education in these areas. Substance abuse is least commonly taught. Both PDs and fellows believe that AYA topics are more important for inclusion in future curricula despite how infrequently they are currently taught (very/extremely important for inclusion vs moderate/great deal of current amount of education, $p = 0.0001$ for all topics). Overall, respondents indicated the most important topics for inclusion in fellowship curriculum were onco-fertility (82%), survivorship (78%), and communication (77%). **Conclusions:** These data highlight the large gap in hematology/oncology fellowship education in AYA topics and a paucity of formal educational curricula. Efforts are needed to provide both medical and pediatric oncology fellows with the knowledge and skills required to provide optimal care for AYAs. Research Sponsor: None.

Efficacy of a novel journal club series at an academic hematology/oncology fellowship program. *First Author: Vivek Patel, Vanderbilt University Medical Center, Nashville, TN*

Background: Journal club (JC) is an essential tool in hematology/oncology fellowship to develop critical appraisal skills. The traditional JC format of reviewing an article followed by group discussion may not provide optimal education in appraising literature. We applied a novel JC curriculum and measured impact on fellow comfort with trial design, statistics, and endpoint interpretation. **Methods:** A novel JC curriculum was implemented for hematology/oncology fellows at Vanderbilt in the 2021-2022 academic year. JC for the prior year utilized the traditional format. We developed five focused learning objectives (LO's) for each JC and emphasized the goal was to not place the paper in clinical context but to focus on developing the foundational tools for critical appraisal skills. The sessions involved (1) 15 minute introductory lecture from a biostatistician to cover foundations of the LO's; (2) group discussion led by an upper year fellow to describe the paper in the context of the LO's; (3) question and answer session from the fellows to both the statistician and a clinical trial expert. We developed anonymous pre and post surveys to understand the impact of the novel JC curriculum on a 5-point Likert scale. Two sample unpaired t-test was used to compare mean differences. **Results:** A total of 15/22 fellows (68%) completed the pre-survey and 12/22 fellows (55%) completed the post survey. There was an even distribution of fellows by year in the pre survey and 33% first years, 41% second years, and 25% third years in the post survey. There was a statistically significant improvement in pre and post mean fellow comfort in understanding differences in trial types (2.9 vs. 4, $p < 0.001$), randomization strategy (2.6 vs. 4.25, $p < 0.001$), endpoints (3 vs. 4.1, $p < 0.001$), and interpretation of the statistical methodology of represented data (3 vs. 4.3, $p < 0.001$) on a 1-5 Likert scale (5 being entirely comfortable). In a subset analysis, we did a direct comparison of fellows who had previously participated in both JC formats ($n = 9$); the new format was rated as a more useful tool for learning data interpretation than prior with a mean of 4.8/5. When comparing fellow perception in the utility of traditional compared to the novel JC, there was a statistically significant mean improvement in utility of JC to prepare fellows to understand differences in trial types (1.9 vs. 4.1, $p < 0.001$), randomization strategy (1.4 vs. 4.5, $p < 0.001$), endpoints (2.7 vs. 4.5, $p < 0.001$), and interpretation of the statistical methodology of represented data (2.33 vs. 4.6, $p < 0.001$) favoring the novel JC. **Conclusions:** Fellows' comfort with trial design and content significantly improved with our novel JC. To our knowledge, this is the first time such a curriculum has been used in hematology/oncology training. Our successfully piloted novel JC model can be adapted to other fellowships to improve foundational skills in the critical appraisal of clinical trials. Research Sponsor: None.

Applying cognitive integration to oncology: A novel asynchronous foundational science curriculum for medical students during clerkships. *First Author: Sam Brondfield, University of California, San Francisco, San Francisco, CA*

Background: Cognitive integration (CI) connects foundational science (FS) to medical practice and improves clinical reasoning. While evidence supports CI in medical training, the clinical relevance of FS is often obscure to medical students, particularly in oncology, and few learning materials exist to support CI during clerkships. Providing effective and engaging tools to promote CI may enhance understanding of FS relevance to clinical medicine. We therefore aimed to create an online module to integrate FS into clerkships. **Methods:** Previous student feedback at our institution advocated for clinically relevant FS content. Applying Cognitive Theory of Multimedia Learning principles, we (an oncologist, a biochemist, and an instructional designer) created a cancer module grounded in the hallmarks of cancer (HoC), a key FS principle. To emphasize clinical relevance, we recorded patient interviews incorporating FS. The module, composed in Qualtrics, includes an introduction and four cases, each starting with a brief patient interview, followed by clinical text, images, questions, and explanations. Content co-created by the oncologist and biochemist combined clinical and FS perspectives and referenced the HoC throughout. We piloted a draft with a focus group of four students. The evaluation plan includes written learner feedback, a case-based pre/post-test, and review of clerkship assessments for evidence of CI. **Results:** We produced an FS oncology module with an estimated engagement time of two hours, which students may complete over multiple sittings. The development team met monthly over the course of one year. Filming and editing cost $100/hour. Overall, the project required approximately 60 faculty person-hours and 12 instructional designer person-hours. The patients interviewed for the module expressed gratitude for sharing their stories with students. The student focus group yielded unanimously positive feedback about the content, the multimedia format, the level of FS covered, and the use of authentic patient videos to enhance clinical relevance. Students strongly preferred this module compared to prior online learning activities. **Conclusions:** This novel interactive module can serve as a model for development of clerkship curricula promoting CI. Module creation based on real patients resulted in authentic story-telling and enhanced FS relevance. Content development involving a clinician and a basic scientist aligned with CI goals. Limitations include the need for funding and instructional design assistance. A randomized controlled trial comparing a series of novel FS modules to older recorded lectures may demonstrate improved outcomes. Involving learners in curriculum development may decrease faculty burden and increase student interest in FS. Research Sponsor: None.

Adapting a medical school cancer research education program to the virtual environment. *First Author: Omar Vayani, The University of Chicago Pritzker School of Medicine, Chicago, IL*

Background: As the number of patients with a cancer diagnosis grows in the United States, there is an increasing need for physician scientists with oncology-related research training to develop new approaches to screening, diagnosis, therapy, and survivorship. A single US medical school developed the National Cancer Institute-funded Scholars in Oncology-Associated Research (SOAR) cancer research education program. Due to the COVID-19 pandemic, SOAR transitioned from fully in-person in 2019 to virtual in 2020 and hybrid in 2021. This study examines whether the in-person, virtual, or hybrid formats provide better educational experiences as rated by participants. **Methods:** SOAR includes a seminar series, an 11-week full-time cancer research experience, weekly research cluster group meetings, and tumor board and interprofessional shadowing experiences. In 2019 all program activities were in-person. In 2020 all activities were virtual with the shadowing suspended. In 2021, seminars and tumor boards were virtual, shadowing was in-person, and all other activities were hybrid. Pre- and post-surveys were collected from all participants to assess understanding of oncology and associated medical specialties. How participant understanding of oncology and related specialties changed within each year's program was analyzed with a Wilcoxon rank-sum test. The Kruskal-Wallis test was used to examine change in understanding between the cohorts. **Results:** 37 students participated in SOAR (2019 n = 11, 2020 n = 14, 2021 n = 12). Self-reported understanding of oncology as a clinical ($p < 0.01$ for all) and research discipline ($p < 0.01$ for all) improved within all three cohorts. There was no significant difference between each cohort's improvement in research understanding ($p = 0.6158$). However, there was a trend towards more of an improvement in the in-person cohort ($p = 0.0796$) for clinical understanding. There was no significant difference between each cohort's improvement in understanding of oncology-related disciplines such as medical oncology, radiation oncology, pediatric oncology, surgical oncology, and survivorship as both clinical and research disciplines ($p > 0.1$ for all). **Conclusions:** A virtual cancer research education program can be as effective as an in-person or hybrid program for research education although it may be suboptimal for learning about clinical oncology. Given the ongoing challenges presented by the COVID-19 pandemic, flexibility is needed in delivering cancer research education programs such as SOAR. With modern research methodology and communications technology, cancer research is becoming increasingly diverse and flexible in terms of research environment. If program leaders are steadfast in their adaptation of research education programs to a virtual or hybrid environment, participant understanding of oncology as a clinical and research discipline remains robust. Research Sponsor: None.

Medical student readiness to treat LGBTQ patients. *First Author: Matthew B. Schabath, Moffitt Cancer Center, Tampa, FL*

Background: The lesbian, gay, bisexual, transgender and queer (LGBTQ) community experiences cancer health disparities. It is thus imperative that medical trainees receive training in the care of LGBTQ populations. Identifying gaps in trainees' knowledge and comfort in providing care for this population is important in preparing future physicians. **Methods:** A Likert-scale survey of US medical students at three institutions assessed attitudes, comfort and knowledge in providing care for LGBTQ patients. Results were quantified with descriptive and stratified analyses. Exploratory factor analysis found four factors in which attitude summary measure (ASM) scores were calculated; lower values indicate more agreeability with given attitude items. Total knowledge scores were calculated with higher values indicating greater knowledge. **Results**: Of 300 medical students who completed the survey, the majority were female (55.7%), white (54.7%), and heterosexual (64.3%). The majority of students felt comfortable (strongly agree/agree) participating in the care of patients who identify as lesbian (94.3%), gay (96.0%), and bisexual (96.3%); this percentage dropped to 82.3% for non-binary and 71.3% for transgender patients. Only 27.0% of students reported confidence in their knowledge of health needs of transgender patients. LGBTQ self-identification, percent of core rotations completed, and having LGBTQ friends/family were significantly associated with various ASM subscales (Table 1). Knowledge questions had high percentages of "neutral" responses, and students who identified as LGBTQ had significantly higher total knowledge scores. **Conclusions**: Overall, medical students feel comfortable and willing to provide care for LGBTQ patients. However, as in our prior study in oncologists, there is limited knowledge about specific LGBTQ health and cancer needs. More education and training in the needs of transgender and non-binary patients is indicated. Research Sponsor: None.

Stratified analysis for attitude summary measures and total knowledge scores.

Characteristic	Attitude Summary Measures				Knowledge Total Score
	Discuss Health Needs	Comfort in Treating	Education	Comfort of Inquiry	
LGBTQ Friends/Family–No	3.2 (2.8)	2.1 (2.7)	2.3 (2.9)	2.0 (1.0)	4.5 (1.0)
LGBTQ Friends/Family–Yes	2.4 (1.6)	1.2 (1.0)	1.5 (0.8)	1.8 (1.0)	5.0 (0.9)
No Completed Core Rotations	2.4 (1.9)	1.2 (1.0)	1.5 (0.7)	2.0 (1.0)	4.8 (0.8)
50% or Fewer Completed Core Rotations	2.5 (1.3)	1.7 (1.4)	1.8 (1.0)	2.0 (0.5)	4.9 (0.8)

Transdisciplinary research in energetics and cancer (TREC) training program for early career investigators. *First Author: Melinda L. Irwin, Yale School of Public Health, New Haven, CT*

Background: Given the rising prevalence of obesity, poor diet and physical inactivity, known in combination as "energy balance" or "energetics", as well as their associations with cancer incidence and mortality, innovative research, clinical care and training of scientists are needed to lower the prevalence of these risk factors and in turn, lower cancer incidence and mortality rates. **Methods:** With NCI support (R25CA203650) from 2016-2021, we developed and offered an annual one-week, in-residence Transdisciplinary Research in Energetics and Cancer (TREC) Training workshop, followed by a yearlong mentoring program, that focused on energy balance and cancer research across the cancer control continuum. **Results:** We recruited, educated, trained and mentored 123 early career investigators (TREC Fellows) from 64 different institutions and from diverse academic backgrounds (i.e., 20% basic, 33% clinical and 47% population sciences) in transdisciplinary research in energetics and cancer. Fellows accepted to the TREC Training Program worked with more than 20 expert international TREC Faculty on developing grant applications and original research toward key gaps in energy balance and cancer research. TREC Fellows have published over 270 manuscripts in peer-reviewed journals, with at least 62 published manuscripts including the TREC Fellow as first or senior author and including a TREC Faculty and/or Fellow as co-author. Since completing the Program, TREC Fellows have received at least 31 extramural grants, as principal investigator. Building upon the strengths of the previous five years, we were awarded a competitive renewal to continue the TREC Training Program through 2026. TREC Training program goals are: (1) to continue to offer a TREC Training Program for ~100 academically diverse early career investigators including a 5-day in-residence workshop focused on the Fellows research, networking, mentoring and professional development; (2) to evaluate the TREC Training Program and track TREC Fellows career development; and (3) to disseminate the TREC Training sessions, webinars and newsletter to the broader community of investigators. **Conclusions:** To our knowledge, no other in-residence training program exists that focuses on energetics and cancer research. Our vision is to continue the TREC mission of training scientists and clinicians to develop a cadre of well-trained, diverse researchers. The overall impact of this transdisciplinary training course will be defined by the degree to which TREC Fellows produce innovative research approaches and discoveries, thereby accelerating the dissemination and implementation of evidence-based approaches into everyday practice and patient care and improving the health of the population at risk for cancer as well as cancer survivors. Research Sponsor: U.S. National Institutes of Health.

Impact of learning program on treatment recommendations by molecular tumor boards and an artificial intelligence-based annotation system: A prospective study. *First Author: Kuniko Sunami, Department of Laboratory Medicine, National Cancer Center Hospital, Tokyo, Japan*

Background: Treatment recommendations (TRs) by molecular tumor boards (MTBs) based on comprehensive genomic profiling tests are crucial for enrolling cancer patients in genotype-matched trials. Our previous study of Japanese designated 'Core' hospitals using simulated cases showed that TRs for biomarkers with high evidence levels (ELs) were highly concordant between central consensus and MTBs, whereas those with low ELs showed low concordance, indicating that a learning program (LP) about obtaining information on matched trials, particularly for those with low ELs, is needed to improve the quality of TRs by MTBs (Kage H. ESMO 2021). Therefore, we conducted a nationwide prospective study to investigate the clinical utility of an LP for MTBs in designated 'Hub' hospitals and explore the efficacy of an artificial intelligence (AI)-based annotation system. **Methods:** Fifty simulated cases were randomly divided into 2 groups (pre- and post-tests) by the central statistician, stratified by high vs. low ELs. Each MTB at 'Hub' hospitals (group), treating physicians at 'Core' hospitals (individual), and an AI company were eligible. Each participant made TRs for the first 25 cases, then participated in the LP, and made TRs for the second 25 cases. The online LP shared the methodology of making the optimal TRs and showed central consensus TRs for simulated cases. The primary endpoint was the proportion of MTBs that met prespecified 'accreditation' criteria for the second 25 cases: > 90% concordance for high ELs and > 40% for low ELs. Expected and threshold proportions of 'accreditation' MTBs were 50% and 20%, respectively, and the planned sample size was 24 MTBs. The improvements in concordance rates in TRs on post-tests were key secondary endpoints. The concordance rate of TRs with the AI system was an exploratory endpoint. **Results:** From May to December 2021, 47 participants applied, and 42 (27 MTBs, 14 individuals, and an AI company) were eligible. The primary 'accreditation' rate of MTBs was 55.6% (95% CI, 35.3-74.5%, $p < 0.001$), and the 'accreditation' rate of individuals was 35.7% (95% CI, 12.8-64.9%, $p = 0.17$). TR concordance rates improved significantly, from 57.5% (95% CI, 51.7-63.1%) to 65.7% (95% CI, 59.2-71.6%) [odds ratio (OR): 1.23, $p = 0.04$]. A prespecified subgroup analysis showed an improved concordance rate for biomarkers with low ELs for MTBs (OR, 1.32: 95% CI, 1.00-1.73), but not for individuals (OR, 1.11: 95% CI, 0.75-1.63). TR concordance rates with the AI system were 80% (95% CI, 60.0-91.4%) and 84% (95% CI, 64.3-93.9%) for pre- and post-tests, respectively. **Conclusions:** This LP significantly improved the quality of TRs by MTBs, potentially leading to providing more matched trials to cancer patients. TRs by the AI system showed higher concordance with central consensus TRs than MTBs, suggesting the clinical utility of AI-based TRs over those by MTBs. Research Sponsor: Japanese Ministry of Health, Labour and Welfare.

A longitudinal study assessing the impact of ongoing COVID-19 pandemic among hematology-oncology trainees. *First Author: Sufana Shikdar, University of Oklahoma Health Science Center, Oklahoma City, OK*

Background: Hematology-Oncology (HO) trainees faced significant challenges due to the COVID-19 pandemic highlighted by a previous survey (Durani, Urshila, et al. "Impact of COVID-19 on Hematology-Oncology Trainees: A Quantitative and Qualitative Assessment." *JCO Oncology Practice* (2021): OP-21). Despite the positive impact of effective vaccines, the pandemic is still ongoing; thus, the challenges remain. Our aim is to evaluate how well the trainees have adapted to changes in their clinical training environment after the early phase of the COVID-19 pandemic. **Methods:** A cross-sectional internet-based survey (Shih, Grace, et al. "The impact of the COVID-19 pandemic on the education and wellness of US Pediatric Anesthesiology Fellows." *Pediatric Anesthesia* 31.3 (2021): 268-274) from December 10, 2021, to January 10, 2022, was obtained from the trainees enrolled in Accreditation Council for Graduate Medical Education (ACGME)-accredited HO fellowship programs in the United States in their fourth (PGY4), fifth (PGY5), and sixth (PGY6) postgraduate year. **Results:** The survey was completed by 102 trainees. Demographics of the participants are reported in Table . Interestingly, 51% reported an impact of COVD-19 on their employment plans, primarily due to the inability to interview in person (24%, n=23). Trainees experienced several stressors due to the pandemic, including fear of getting sick from a patient (71%) or a coworker (66%). Approximately 27% (n=26) experienced mental health issues requiring additional care. Less than one-third of the trainees were concerned about clinical expertise and procedural skills. Trainees also felt that the change of conference to virtual format impacted their learning activities compared to in-person education (66%, n=64). Most trainees (52%, n=53) reported limited involvement in COVID-related research and journal club education. Most had access to socialization (59%, n=60), virtual office hours (70%, n=72), and telehealth visits (83%, n=85). Female trainees (18%) were more likely to seek mental health care than the male trainees (7.8%) (P=.02). Female trainees (33%) also reported facing more challenges in their employment plans compared to males (16%) (P=.003). **Conclusions:** Our study highlights the challenges experienced by hematology-oncology trainees with the ongoing COVID-19 pandemic and reveals the gender gap related to employment plans and seeking mental health care. Research Sponsor: None.

Professional development in a Twitter hematology/oncology network for trainees. *First Author: Muhammad Salman Faisal, Roswell Park Cancer Institute, Buffalo, NY*

Background: While resources exist to address the needs of graduate medical trainees, online resources to assist trainees with specialty-specific professional development have not been fully developed or described in the past. The Hem-Onc Fellows Network (@HemOncFellows) is an online community for hematology-oncology trainees in all stages of training, including medical students, residents, fellows, and doctoral students. The network's goals are to provide professional development in hematology-oncology, create a community and safe space for hematology-oncology trainees, and amplify the voices and needs of trainees. **Methods:** The @HemOncFellows Twitter account was created in February of 2021. The hashtag #HOFellows was registered and certified with healthcare Symplur. The network hosts Twitter Spaces (TS) with guests every two weeks and distributes a newsletter. Fifteen TS were held between July 2021 and February 2022. For each TS, a specific topic of professional development was discussed. At least one content expert was invited to each TS to provide additional commentary. Demographics of TS participants and newsletter subscribers were gathered and qualitative and quantitative analysis was performed. **Results:** Since its inception, the Hem-Onc Fellows Network has grown to more than 2200 followers. Symplur has over 500 #HOFellows tweets from November of 2021 to early February of 2022. The network organized 15 TS: 14 in professional development topics and one meet-and-greet for new matched fellows in December. TS had an average of 41 participants per event. Most participants were United States-based but there were participants from 21 countries worldwide. Forty-eight participants attended three or more spaces, including 15 hem-onc fellows and 17 internal medicine residents. The newsletter has 48 subscribers. **Conclusions:** We demonstrate that implementing a trainee network on Twitter attracted participation and engagement from a diverse pool of trainees worldwide. TS represents a novel educational tool for engaging trainees and facilitating professional development. Research Sponsor: None.

The future of the oncology workforce: Presenters at an international trainee oncology conference. *First Author: Andrea Anampa-Guzmán, Universidad Nacional Mayor de San Marcos, Lima, Peru*

Background: In 2017, ASCO established the ASCO medical student and resident Abstract Forum. This study aimed to describe the characteristics of the ASCO medical student and resident abstract forum participants. **Methods:** We conducted a retrospective, observational study of Abstract Forum participants from 2017 to 2021. Descriptive statistics were used to summarize the participants' demographics by gender, stage of training, and institution location. We reported the publication rates and career paths of presenters. **Results:** The number of participants has more than tripled in the five years since the program's inception. Female participants are almost half of the total. In 2017, there was only one international participant. Over the subsequent five years, international members have steadily increased and represented nearly one-third of all participants in 2021. In the inaugural year, most forum participants were from institutions with ASCO Sponsored Oncology Student Interest Groups (OSIG), but in 2021 almost half were from institutions without OSIGs. The majority of participants were medical students, followed by internal medicine residents. Of a total of 179 abstracts presented between 2017 and 2021, 35 (19.55%) were subsequently published as full-text peer-reviewed manuscripts. Studies presented orally and studies presented by participants from the United States were significantly more frequently published as articles. 58.49% of medical student presenters that started residency chose Internal Medicine or Radiation Oncology. 50% of the student presenters that graduated internal medicine residency went to Hematology-Oncology fellowship. Most of the resident presenters that completed residency went to pursue careers in Hematology-Oncology (72.73%). **Conclusions:** The steady increase in participants since the program's creation demonstrates interest in the medical student and internal medicine resident community in these types of initiatives. The increase in international participants over the years highlights opportunities for ASCO to expand its global reach and efforts, particularly in low-income countries where trainees have the highest need for mentoring and organized support. Our study provides critical insights into the profile of participants of the Abstract Forum. Participation in this program should be encouraged, especially in countries with high cancer prevalence and mortality. Research Sponsor: None.

Google search engine analytics for cancer immunotherapy: What patients are searching for on the internet and where they find answers. *First Author: Neeraj V. Suresh, University of Pennsylvania Department of Otorhinolaryngology-Head and Neck Surgery, Philadelphia, PA*

Background: Immunotherapy in the treatment of cancer has been on the rise and is on the forefront of current cancer research. As such, patients are increasingly turning to the Internet and online resources to answer their questions. For any given Google search, artificial intelligence and machine learning algorithms generate a "People Also Ask" (PAA) section which returns the most commonly associated questions to the original search query, with corresponding websites to answer those questions. Using a search engine optimization (SEO) tool, we determined the most frequently searched terms and questions regarding cancer immunotherapy online, and the websites used to answer them. **Methods:** The top Google search queries and PAA questions with associated volume metrics were extracted for the terms "immunotherapy" and "cancer immunotherapy" using an SEO tool. PAA questions and corresponding websites were categorized by specific topic and Rothwell's classification system. Websites were further quality assessed using the Journal of the American Medical Association (JAMA) benchmark criteria. **Results:** Global searches for cancer immunotherapy increased significantly each year since 2015. Countries with the most search volume were the U.S. (44%), the U.K. (12%), and India (11%). PAAs (n = 674) and the most frequently searched questions regarding cancer immunotherapy, by average monthly search volume (searches per month), were on: definitions/how it works (n = 6.6K, 21.3%), side effects (n = 4.4K, 14.2%), cost (n = 2.9K, 9.4%), immunotherapy vs. chemotherapy (n = 1.8K, 5.8%), drug options (n = 1.7K, 5.5%), signs immunotherapy is working (n = 1.2K, 3.9%), different types of immunotherapy (n = 1.1K, 3.5%), route of administration (n = 800, 2.6%), efficacy/success rate (n = 800, 2.6%), and effect on life expectancy (n = 300, 1.0%). The top cancers that patients searched immunotherapy treatments for were: lung (n = 1.9K, 23.2%), melanoma (n = 1.5K, 18.3%), pancreatic (n = 700, 8.5%), breast (n = 600, 7.3%), and bladder (n = 500, 6.1%). The most queried immunotherapy drugs were Pembrolizumab/Keytruda (n = 87K), Nivolumab/Opdivo (n = 33K), and Ipilimumab/Yervoy (n = 11.1K). Websites used to answer PAA questions were mostly those of academic institutions (n = 294, 43.6%), commercial organizations (n = 167, 24.8%), and government databases (n = 126, 18.7%). **Conclusions:** The field of cancer immunotherapy is rapidly evolving and patients often look to the Internet to answer their latest questions. Using our findings, academic institutions, commercial organizations, and physicians involved in multidisciplinary cancer care can cater their patient communications and websites to more directly align with patients' most common questions and concerns on immunotherapy. Research Sponsor: None.

Evaluating the quality of clinical evidence in gastrointestinal cancers PubMed searches: How relevant are the results? *First Author: Ivy Riano, Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH*

Background: Bibliographic repositories have become increasingly important as clinical evidence is more accessible on the internet. Often, oncologists rely on published literature to guide patient care. However, with the proliferation of journals and increasing number of peer reviewed papers, current search strategies have the potential to retrieve large numbers of irrelevant or misleading articles. Moreover, access to current best evidence may require paid subscriptions. Here, we assessed the quality of retrieved medical literature pertaining to treatment of gastrointestinal cancers using the PubMed database. **Methods:** We interrogated 6 focused-therapy questions in 3 categories: medical oncology (MedOnc), surgical oncology (SurgOnc), and alternative medicine (AltMed). We extracted journal metrics of the first two pages (40 results) from each search. We defined the composite outcome "relevant result" as the product of removing results from 1) predatory journals (Beall's list), 2) non-English language, and 3) no free access publications. As a sensitivity analysis, we defined 2007 as a cutoff for "relevant" publications and Impact Factor (IF) > 3 or H-index > 50. **Results:** Two hundred and forty results were retrieved (80 per search type). Forty-eight percent of the journals were European (n = 115), 40% US-based (n = 96), and 94% were in English (n = 225). Most journals (n = 170; 70.8%) had an IF between 1-10, followed by ~21% with an IF > 10 (n = 51); yet ~45% (n = 107) were in the Clarivate Analytics top quartile. Sixty percent (n = 139) of articles were free to access. The articles had a median H-index of 117 [IR 59, 168]. When modelling the multivariate association with "relevant result", year of publication after 2007 had an OR = 1.07 (95% CI = 1.01-1.14; $p< 0.02$) and availability through GOLD Open Access by Clarivate Analytics had an OR = 1.09 (95% CI = 1.03-1.15; $p< 0.0008$). MedOnc retrieved more papers published in journals with IF > 10 (n = 31; 38.8%) than SurgOnc searches (n = 12; 15%; $p< 0.001$). Only the AltMed searches included non-peer reviewed publications (n = 4; 5%) and 4 results were from "predatory journals", all in MedOnc. **Conclusions:** Articles had a 7% higher chance of being considered a "relevant result" if they were published after 2007 and a 9% higher chance if available under GOLD Open Access. Publications identified as "relevant results" with an IF or H-index above the established cutoffs, had a 6% higher chance to be in the top 40 PubMed search results. In the sensitivity analysis the results remain virtually unchanged. Importantly, nearly 40% of papers indexed in PubMed do not have free full-text articles, making them unavailable to oncologists without access to a medical library or paid subscription. These results highlight the imperative to deliver relevant, freely accessible information that can impact the care of the cancer patients. Research Sponsor: None.

11038 **Poster Session**

The need to develop the career pathway in oncology as an opportunity to improve the satisfaction of young oncologists in Spain: A national survey by the Spanish Society of Medical Oncology (SEOM) + mir section. *First Author: Pablo Jiménez Labaig, Department of Medical Oncology. Cruces University Hospital, Barakaldo, Spain*

Background: A long-term planning of the oncologists' career path is essential to approach the continuous changes in the oncology field given the need of further subspecialization after the training period. Our aim is to evaluate the current professional development of young medical oncologists in Spain and seek improvement strategies to enhance their careers in order to guarantee commitment with research and improve in patient care and outcomes. **Methods:** The SEOM +MIR Section launched a national online survey in May 2021 aimed at young medical oncology consultants (<6 years of experience) and last year medical oncology residents. Spanish professionals were invited to participate via email through the SEOM database. A descriptive analysis was performed using R software v4.1.2. **Results:** A total of 162 responses were eligible. 103 (64%) were women. 129 (80%) were consultants and 33 (20%) were residents. 92 (68%) performed standard clinical care and 11 (7%) research activity. 118 (73%) were subspecialized in a main area of interest and almost half of them, 70 (59%), chose it because it was the only option available after finishing residency. 87 (54%) had considered different employment opportunities other than standard clinical care and 38 (23%) showed an interest in enhancing their research activity. 141 (87%) showed relevant concern about their employment stability (table attached). 82 (51%) had considered working abroad: 33 (44%) outside European Union. The main reasons were: 132 (81%) believed the professional standing in Spain was worse than other countries, 41 (25%) thought it might increase their professional development and 33 (20%) argued for better salary conditions abroad. Among them, 21 (13%) had signed at least 4 contracts and 66 (41%) had ≥5 employment contracts in the last 5 years. 27% of respondents indicated that the figure of the boss had been the most contributing professional in their professional career. The mentor (20%) and the tutor (18%) also stand out as relevant figures in terms of professional development. Up to 27% of the sample refers not to have obtained any help from the figures mentioned. **Conclusions:** An absence of engagement in the long-term career paths of young medical oncologists in Spain was observed. Research is not defined in the current early professional life. Furthermore, there is a lack of contractual quality and planning for the entry into the labour market of newly trained oncologists. The lack of such a career pathway has consequences that encourage the search for employment opportunities different from clinical care and in other countries. Research Sponsor: Spanish Society of Medical Oncology (SEOM).

Level of satisfaction of young oncologists with their job stability.

The impact of mentoring on early career faculty: Assessment of a virtual mentoring program. *First Author: Akanksha Sharma, Pacific Neuroscience Institute/Saint John's Cancer Institute, Los Angeles, CA*

Background: Participation in mentorship programs for early career physicians may be crucial to developing key skills and professional networks to navigate racial, ethnic and gender leadership disparities in medicine. A 6-month virtual facilitated peer mentorship program was developed and piloted through the Society for Neuro-Oncology (SNO) Women & Diversity Committee. The evaluation of the program's feasibility to positively impact early career physicians, investigators and trainees is presented here. **Methods:** We designed and conducted a virtual mentoring program pilot open to SNO's multidisciplinary members in residency, fellowship, or early career phase, leveraging peer-mentoring sessions with mid-to late-career physician mentors. A curriculum with online resources was provided recommending groups meet for 6 sessions: 3 involving the mentor and 3 dedicated to peer-mentoring. Group assignments were based on time-zones and interests. Pre- and post-participation surveys assessed mentee experience. Descriptive statistics were used to assess participant demographics and survey results. **Results:** Our call for participation was broad; all 20 mentee applicants participated in 5 groups. Mentees were 90% women and 60% were from diverse racial and ethnic backgrounds. Most were aged 31-40 (75%) and junior faculty (50%) in neuro-oncology (65%). The 5 senior mentors (3 men and 3 of diverse race and ethnic backgrounds) practiced either neuro-oncology (3), neurosurgery (1) or radiation oncology (1). The proportion who reporting having a signature lecture increased from 15% to 62% during the pilot. A large majority reported their participation was worthwhile (85%), that they would participate again (92%) and would recommend it to others (92%). Feedback themes included positive personal growth, peer support, networking and job opportunities, access to CV reviews, lack of and desire for late career female mentors, and virtual scheduling constraints. While the pilot was limited by several variables, it was timely to connect participants in Q3 of 2020 early in the COVID-19 global pandemic. The virtual meeting environment created a venue to share and discuss topics such as work-life balance, burnout, leading through change and social connection. Despite not achieving 100% professional concordance, participants found the experience worthwhile. The tools and curriculum of topics provided was implemented differently across groups, leading to varied experiences. Finally, we did not have 100% post pilot follow up despite multiple attempts limiting our complete understanding of the pilot. **Conclusions:** This virtual mentorship pilot program proved feasible and of value in development of early career women and diverse individuals. A resource toolkit has been designed to scale and diffuse. Research Sponsor: None.

Generating meaningful peer-to-peer engagement through a mentor-led, small group social learning experience on the evolving standards of care for advanced HER2+ breast cancer. *First Author: Latha Shivakumar, Association of Community Cancer Centers, Rockville, MD*

Background: Although the COVID-19 pandemic quickly created a spotlight on distance learning, identifying models that can deliver effective educational programs and best serve the needs of oncology clinicians remains a significant challenge. **Methods:** We conducted an educational program on the evolving standards of care for advanced HER2+ breast cancer hosted on a novel digital platform that offers a personalized social learning experience which prioritizes engagement, peer-to-peer learning, and mentorship within a small group setting. **Results:** 87 learners within 10 groups of professionally-connected clinicians participated. Learners progressed through foundational self-study modules, collaborated on asynchronous group challenges, and participated in synchronous live group discussions over six weeks (approximately 4 hours total). Quantitative and qualitative analysis of data extracted from these components highlights the impact of this program (Table). Notably, the learner population was more specialized and engaged than could be expected of a traditional CME program. Feedback suggests strong impact of the live group discussions on learners' intended practice changes. Additionally, analysis of group challenges and live group discussions revealed several key insights into learner thinking about treatment guidelines, including their differing opinions about the role of surgery/radiation in patient care, uncertainty about the mechanisms of action (MOAs) of discussed therapies, and their apprehension about implementing therapies that may impact the heart and lungs. **Conclusions:** The outcomes from this analysis highlight the utility of this type of social learning platform to create a safe, supportive learning environment that encourages multiple real-time and asynchronous interactions and shared experiences between clinicians who treat patients with advanced HER2+ breast cancer, as well as offering unique and convenient mentoring opportunities for clinicians interested in leading these digital small groups. Program impact. Research Sponsor: Daiichi Sankyo and AstraZeneca.

Quantitative Highlights

- **92% of participants specialized in oncology or hematology/oncology**
- **Average of 5 platform interactions per learner**
- **70% of learners completed all 5 self-study modules**
- **94% reported that they intended to make changes to their practice based on, or that their current practice had been reinforced by, the experience**

Qualitative Highlights

- **Differing opinions regarding the role of surgery and/or radiation in patient care**
- **Uncertainty about MOAs of available therapies**
- **Apprehension about certain therapies that may impact the heart and lungs**

11041 **Poster Session**

Quality and content of online cancer information: An analysis of NCI-designated cancer center YouTube videos. *First Author: Luke Kim, University of California, San Francisco School of Medicine, San Francisco, CA*

Background: The internet and social media have become a common source of medical information. Previous analyses have found that YouTube videos disseminate biased cancer related information of low to moderate quality. We analyzed online information disseminated by NCI-designated Cancer Centers (CC) through their YouTube pages. **Methods:** We searched CC websites and online search engines to identify CC-specific YouTube pages. Our sample included each CC's top 20 most-viewed videos uploaded during 2019, which were < 5 minutes long, and available in English or Spanish. We examined video content themes and speaker demographics. For patient education videos, we evaluated content understandability and quality of information using validated measures [i.e., Patient Education Materials Assessment Tool (PEMAT) and DISCERN]. Data was summarized using descriptive statistics. **Results:** A total of 31 of 64 clinical NCI-designated CC had dedicated YouTube pages. Only 6 (19%) CC had videos in languages other than English. A total of 402 videos were examined for content themes and demographic characteristics. 43% focused on patient education (n = 175), 36% research (n = 139), 24% survivorship (n = 95), and 13% clinical trials (n = 52). 32% (n = 119) of speakers were doctors and 18% (n = 65) patients. Perceived speakers' ethnicity was 57% White (n = 229), followed by Asian (15%, n = 60), Black or African American (8%, n = 32), and Latinx (4%, n = 16). Perceived gender of speakers was 49% women (n = 197) and 51% men (n = 203). Most videos were understandable (91%, n = 159), but only 21% (n = 36) provided high quality information. Videos discussing treatments lacked discussion of risks, alternate options, and effects on quality of life. **Conclusions:** Most patient education videos uploaded to NCI-designated CC YouTube pages have low to moderate quality information and limited ethnic diversity of speakers. With ongoing trends of increasing misinformation spreading through social media, CC have an opportunity to create and disseminate high-quality, reliable, and comprehensive educational videos that meet the informational needs of patients with cancer and their caregivers. Research Sponsor: None.

Are YouTube videos a reliable information source for young women with metastatic breast cancer? *First Author: Nina Morena, McGill University, Montreal, QC, Canada*

Background: Young women with metastatic breast cancer (MBC) are an underserved population, rendering them susceptible to media sources that lack in credibility and reliability. YouTube (YT) is the most commonly used search engine following Google. This study aims to assess the quality of MBC YT videos and to identify common themes in MBC experiences. **Methods:** A systematic review of YT videos with search terms "metastatic breast cancer young" was conducted in 08/2021. Title, date uploaded, length, poster identity, number of likes, dislikes, and comments were collected. Understandability, actionability were assessed using the Patient Education Materials Assessment Tool (PEMAT) for audiovisual (A/V) materials; information reliability/quality was assessed with DISCERN. Scoring was done by 3 reviewers. Themes, presence of sponsorships, healthcare professionals' and patients' narratives were also reported. **Results:** 101 videos were identified. Of these, 78.2% were sponsored. Average video length was 14.9 minutes (SD 22.5). Majority were posted by nonprofit groups and breast cancer advocacy organizations. Mean PEMAT A/V score was 78.8% (SD 15.3) and 43.1% (SD 45.2) for understandability and actionability, respectively. Overall, videos had moderate reliability and quality levels; mean DISCERN score was 2.44/5 (SD 0.7). Patient narratives were shared in 63.3% and healthcare professionals in 57.4%. Identified themes include treatment (66.3%), family relationship (45.5%), motherhood (37.6%), terminal status (31.6%), the path to diagnosis (28.7%), and spousal relationship (24.7%). **Conclusions:** YouTube videos about MBC are highly understandable but demonstrate low to moderate rates of actionability, with low reliability and quality scores. Many have a potential commercial bias. More research is needed to evaluate their impact on patient decisions and possible interventions provided by healthcare institutions. Research Sponsor: St Mary's Hospital Foundation.

Distribution of PEMAT and DISCERN scores.

Tool	Value	Mean	SD	Min	Max	Median	Mode
PEMAT Understandability	Total points (numerator)	7.6	1.9	3.0	12.0	7.0	7.0
	Total possible points (denominator)	9.9	1.2	5.0	12.0	10.0	10.0

Characterizing online engagement and academic impact of oncology research during the COVID-19 pandemic. *First Author: Chandrasekar Muthiah, Medical College of Wisconsin, Wauwatosa, WI*

Background: There is increasing use of social media as a platform to discuss research and educate. An article's impact can be assessed through the Altmetric Attention score (AAS), which considers the volume of social media mentions (Twitter, Facebook, Wikipedia, policy, etc), and the PlumX Impact score, which incorporates interactions on these platforms and citations. COVID-19 has encouraged novel literature in oncology, and these metrics may holistically evaluate the immediate impact of articles in addition to gradual accrual of citations. We explored the relationship between traditionally used bibliometrics (citations, impact factor) and new bibliometrics (AAS, PlumX) of the top 100 trending articles on cancer and COVID-19. **Methods:** The 100 articles with highest AAS featuring keywords "cancer" and "COVID-19" between March 1, 2019 and January 15, 2022 were identified via Altmetric explorer. AAS, journal, social media mentions, open access status and other characteristics were collected. Scopus database was utilized to identify PlumX scores and citation count. Analysis included Spearman correlation coefficients and ANOVA. **Results:** Of the 100 articles, 64% were original investigations, 18% editorials/perspectives, 6% guidelines/consensus articles and remaining article types < 6% each. Original investigations comprised of 41% retrospective cohort, 33% cross-sectional, 20% prospective cohort, and remainder < 4% each. Most articles were open access (91%), from cancer-focused journals (77%), and based in North America (36%); 25% were in Europe, 24% multi-continental, and remainder < 8% each. Most publications were in 2020 (56%) and 2021 (40%). AAS and PlumX did not correlate with number of citations or impact factor. Open access publications were associated with greater PlumX (p = 0.033) compared to closed access; this was not seen with AAS. ANOVA showed greater AAS in Australian articles (p = .004) and greater PlumX in North American articles (p = .04). Article type or publication year did not impact AAS and PlumX. **Conclusions:** In our analysis, Altmetrics and PlumX did not correlate to traditional bibliometrics (citation count, impact factor) in cancer and COVID-19 articles. This suggests that these tools may be complimentary rather than predictive of citations. However, this may change given likely insufficient time for citations to accrue for 2021 studies. There were more editorials/perspective articles compared to similar studies in other specialties, suggesting greater impact of such articles in oncology during COVID-19; this is perhaps due to reliance on expert opinion given paucity of data. Additionally, we noted that PlumX benefits from open access status. Overall, as the use of social media for research dissemination grows, researchers and journal editors may employ alternative metrics to better understand ways to increase the influence of oncology literature during the pandemic. Research Sponsor: None.

Comparing online engagement and academic impact of lung cancer research: An altmetric attention score and PlumX analysis. *First Author: Arun Muthiah, Rhode Island Hospital-The Warren Alpert Medical School of Brown University, Providence, RI*

Background: Social media has proven vital in the rapid dissemination of literature to medical professionals and the public. In recent years, seminal research articles have yielded breakthrough therapies for lung cancer, including targeted drugs and unique immunotherapy-based combinations. New metrics such as the Altmetric Attention score (AAS) and PlumX Impact score capture interactions through social media and other public forums and serve as swifter counterparts to citations, which can take years to accrue. In this study, we characterize and compare AAS, PlumX and traditional bibliometrics (citation count, impact factor [IF]) of the top 100 trending articles on lung cancer. **Methods:** The 100 articles with the highest AAS featuring the keywords "lung cancer" between 01/2019 and 12/2021 were identified via Altmetric explorer. AAS, open access status, article type, topic, year and continent of publication were collected. PlumX and citation count were identified via Scopus database. Analysis included Spearman correlation coefficients and ANOVA. **Results:** A majority of the 100 articles were original investigations, of which 40% were RCTs, 22% retrospective cohort, 14% prospective, 9% basic science, 8% cross-sectional and 6% genome-wide association studies. Most articles focused on NSCLC (59%) and were conducted in North America (44%); 13% were in Europe, 36% multi-continental and the remainder < 5% each. PlumX positively correlated with both citation count ($p < .001$, $r = .765$) and IF ($p < .001$, $r = .581$). AAS did not correlate with citation or IF. Articles on guidelines ($p < .001$) and screening ($p < .001$) were associated with higher AAS in comparison to other article types and topics, respectively. Basic science articles were associated with a higher PlumX ($p < .001$) in comparison to others article topics. Year and continent of publication did not impact PlumX or AAS. Open access status did not correlate with PlumX or AAS. **Conclusions:** In our study, PlumX scores strongly correlated with citations and IF for recently published articles on lung cancer; this mirrors trends in other specialties. PlumX may be predictive in terms of academic impact, making it valuable to the research community. Though AAS did not correlate with traditional bibliometrics, its association with guidelines and screening articles suggests AAS may reflect interactions amongst a broader community (oncologic and non-oncologic clinicians). With the growing use of social media, the continued exploration of alternative metrics will play a role in understanding readership and fields of interest in lung cancer and in anticipating academic impact. #SurgOnc: Global discussions about surgical cancer care on Twitter during COVID-19. *First Author: Sofia Gereta, Department of Medical Education, Dell Medical School, The University of Texas at Austin, Austin, TX*

Background: Social media platforms such as Twitter are highly utilized to communicate about cancer care. Although surgery is the primary treatment for solid malignancies, little is known about public perceptions or communication behaviors regarding this treatment modality. Further, prolonged lockdowns and widespread delays of planned operations during the COVID-19 pandemic have magnified the importance of virtual communication about surgical cancer care. **Methods:** Tweets referencing cancer surgery were collected from January 2018 to January 2022 using Twitter's Application Programming Interface. Account metadata was used to predict user demographic information and to compare tweeting metrics across users. Natural language processing models were applied to tweet content to resolve common topics of conversation and to classify tweets by cancer type. **Results:** There were 442,840 original tweets about cancer surgery by 262,168 users. Individuals accounted for most users (65%) while influencers accounted for the least (1.4%). Influencers made the most median impressions (19,139). Of 240,713 tweets discussing surgery for specific cancers, breast (20%) and neurologic (17%) cancers were most mentioned. When adjusting for national rates of procedures performed, tweets about surgery for neurologic cancers were the most common (231 tweets per 1000 procedures) whereas those for urologic cancers were the least common (15 tweets per 1000 procedures). Discussions about cancer surgery research made up 31% of tweets before the pandemic but only 11% of tweets during the pandemic. During the pandemic, concern regarding COVID-19 related delays was the most tweeted topic (23%). Cancer surgery research was most cited by oncologists, as well as in tweets about hepatopancreatobiliary and colorectal cancers. The cost of surgery was commonly mentioned in tweets about breast and gynecologic cancers and contained the most negative sentiment score (-0.7). **Conclusions:** Twitter was highly utilized to discuss surgical cancer care during the COVID-19 pandemic. During the pandemic, conversations shifted focus from research to survivorship and reflected real-time events such as COVID-19-related surgical delays. We identified the financial burden of cancer care as a commonly held concern among patients discussing cancer surgery on social media. Future public health outreach about cancer surgery may be optimized by coordinating with influencers and by targeting topics of concern like cost of surgery and undermentioned content like urologic cancers. Twitter's role as a platform for research dissemination was disrupted by the COVID-19 pandemic, and further tracking is needed regarding online research discussions after the pandemic. Research Sponsor: None.

Evaluation of trends in breast cancer–related content on TikTok. *First Author: Nanda Siva, West Virginia University School of Medicine, Morgantown, WV*

Background: Social media plays an important role in disseminating information to patients. It is important to investigate the healthcare content on popular platforms to understand the material consumed by patients that may influence their medical decision making. TikTok has over 1 billion monthly active subscribers and has become common ground to communicate healthcare information, including that of breast cancer. This study aims to provide an analysis of breast-cancer related information on TikTok. **Methods:** The most popular TikTok hashtag related to breast cancer was identified, and the top videos were gathered on January 23, 2022. Data was collected to reach a target of 100 videos. Exclusion criteria were non-English videos, repeated videos, or upload of movie/tv clip without educational info. The video source was characterized based on healthcare role, gender, and race. Healthcare provider was defined as an individual with a professional medical degree (MD, PA, RN, other). The videos were categorized into patient experience, educational, advertisement, and other. Specific content components, including chemotherapy, surgical intervention, mammogram, and self-breast exam, were tracked. **Results:** The hashtag "#breastcancer" was identified as the most popular, with 773.8 million views. The videos had a combined 258,886,300 views, 31,573,400 likes, 413,604 shares, and 567,520 comments. Of the 100 videos analyzed, 91 were uploaded by a layperson, 2 by a healthcare professional, and 7 by a company. The healthcare professionals consisted of one OB/GYN and one general surgeon. The racial designations of the main subjects in the videos were 87.2% White, 3.2% Black, 2.1% Hispanic, 4.3% Asian, and 3.2% undetermined. Content categorization revealed 81% patient experience, 22% educational, 6% advertisement, and 8% other. The major topics presented in the videos related to surgical treatment (39%), chemotherapy (37%), and radiation treatment (2%). **Conclusions:** An overwhelming majority of breast cancer related information on TikTok was not presented by qualified healthcare professionals and exhibited a lack of cultural diversity and inclusivity. Research Sponsor: None.

Are we doing it right? Mentorship challenges for oncology fellows and early-career faculty from backgrounds underrepresented in medicine. *First Author: Dame Idossa, University of California-San Francisco, San Francisco, CA*

Background: Physician workforce diversity can be a driver of institutional excellence, improving innovation and reducing health disparities. The current diversity of the hematology/oncology (HO) workforce does not reflect that of the US population. The role of mentorship in increasing HO fellows' interest in pursuing careers in HO has been described previously. However, the mentorship experiences of fellows and early career faculty from backgrounds underrepresented in medicine (UIM) in HO has not been fully characterized. Therefore, we compared the mentorship experiences of UIM and non-UIM trainees and early career faculty in HO subspecialties. **Methods:** We conducted cross-sectional online survey of HO subspecialists including current fellows and faculty within 5 years of end of training. The anonymous survey was distributed via email and social media channels in April 2020. Fisher's exact test and multivariable logistic regression models were used to conduct comparisons between study groups. **Results:** Of the 306 respondents, 64 (21%) were UIM and 161 (53%) identified as male. UIM participants were less likely to have a primary mentor (66%) than non-UIM participants (80%, $p = 0.015$). Among those who had a primary mentor, UIMs were more likely to meet infrequently (greater than every 3 months, $p = 0.007$). Furthermore, UIMs were more likely to report having mentors outside their own institution (47% vs 40% non-UIM, $p = 0.002$) and making compromises to gain access to mentorship (36% vs 23% non-UIM, $p = < 0.001$). In addition, UIM participants were less likely to have an advisor (38% vs 54% non-UIM, $p = 0.017$), a coach (13% vs 20% non-UIM, $p = 0.054$), or a sponsor (19% vs 26% non-UIM, $p = 0.046$). UIMs were also less likely to apply for grants (34% vs 42% non-UIM, $p = 0.035$) and awards (28% vs 43%, non-UIM $p = 0.019$). In multivariable models, UIM individuals were more likely to make compromises to gain access to mentors (OR = 1.96, $p = 0.047$) and this remained significant for females (OR = 2.17, $p = 0.005$). Lastly, US born individuals had higher odds of having a primary mentor than non-US-born individuals (OR = 2.43, $p = 0.004$). **Conclusions:** In the largest study to date characterizing the mentorship experience of HO trainees and junior faculty, we found that UIM individuals were significantly less likely to find effective mentorship and were less likely to apply for awards and grant support. Understanding the challenges of UIM trainees can help shape training environments in academic medicine to ensure these are grounded in diversity and inclusion. Given the importance of workforce diversity, training programs in HO must consider structured programs and other innovations to improve mentoring experiences of UIM trainees and junior faculty. Research Sponsor: University of Wisconsin Carbone Cancer Center.

Gender disparity in authorship of clinical trials leading to cancer drug approvals between 2008 and 2018: The glass ceiling of academic oncology. *First Author: Lynne O. Chapman, Baylor College of Medicine, Houston, TX*

Background: Authorship, expressly premier positions (first, corresponding, or senior author), in peer reviewed journals is widely acknowledged as scientific credit in academia. Yet, gender inequities and biases pervade this facet of the scientific ecosystem. We reviewed the authorship of pivotal FDA trials that established the standards of care in oncology over the past decade with the goal of defining the magnitude of gender disparity in the most influential literature of the field in recent years. **Methods:** We collected and assessed data from the primary publication of 231 trials that enabled FDA drug approvals in hematology and oncology from July 2008 to June 2018. Author gender was assigned from listed names using statistical probability and confirmed using institutional websites and online databases (genderchecker database, biographical paragraphs, and social media). Authors where gender was not clearly identified (1.23%) were excluded. To account for equal authorship contribution, we included co-authors as distinct data points, and credit was given to reports for any women in premier authorship positions (first, corresponding, or senior author) to avoid overestimating disparity. Descriptive statistics were used, and 95% confidence intervals (95%CI) were reported using modified Wald method. Proportions were compared using Fisher-exact and Chi-squared test. Unadjusted P values of < 0.05 were considered significant. **Results:** A total of 4664 (98.8%) authors were included in this analysis across 227 publications. Of these, 1287 (27.6%) were female with a median of 25.9% female authorship in total per trial. Female authorship was significantly higher for non-randomized (30.4% v 26.5% for randomized, $P = 0.007$) and phase 1/2 trials (29.9% v 26.3% for phase 3, $P = 0.009$) and varied with trial size ($P < 0.001$), with the proportion greater in trials with $\leq$100 patients versus those with $>$ 500 patients. Female authorship in fields of breast and gynecological oncology was higher (41.3%) than other cancers (26.0%, $P < 0.001$). Women were proportionally less likely to hold premier (9.2% v 18.2%, OR 0.46, 95%CI: 0.4 – 0.6, $P < 0.001$), first (3.2% v 6.3%, OR 0.49, 95%CI: 0.3 – 0.7, $P < 0.001$), senior (3.3% v 6.0%, OR 0.54, 95%CI: 0.4 – 0.8, $P = 0.002$) and corresponding (2.5% v 5.8%, OR 0.42, 95%CI 0.3 – 0.6, $P < 0.001$) authorship but not second author role (4.1% v 5.1%, OR 0.80, 95%CI 0.6 – 1.1, $P = 0.17$). **Conclusions:** The under-representation of women in premier authorship positions in pivotal clinical trials, demonstrated in our study, serves as a barometer of a biased academic infrastructure, amplifying existing calls to address barriers that limit the full inclusion of women in oncology. Research Sponsor: None.

11049 **Poster Session**

National impact of the COVID-19 pandemic on clinical trial staff attrition: Results of the SWOG Cancer Research Network Survey of Oncology Research Professionals. *First Author: Don S. Dizon, Lifespan Cancer Institute and Brown University, Providence, RI*

Background: Severe shortages in clinical trial staffing across the United States and internationally has been anecdotally noted, but data are lacking. To better assess the scope and impact of staffing shortages, SWOG conducted a Cooperative Group-wide survey of Oncology Research Professionals (ORP). **Methods:** The survey was developed by SWOG leadership and was granted an IRB exemption by Lifespan IRB (Providence, RI). The survey was disseminated by email in January 2022 to Head Clinical Research Associates (CRAs, n = 100) using an inclusive distribution list that goes to the site-identified administrative leader of each SWOG Member and National Community Oncology Research Program institution. The data were collected and managed using REDCap electronic data capture tools hosted at Lifespan. Descriptive statistics were performed and qualitative analysis conducted to identify major themes. **Results:** The response rate was 87% and 41 of 87 respondents completed the full survey (47%). The majority of respondents were female (89.6%), not Hispanic (87.8%) and White (85.1%). The proportion that identified as Hispanic or Asian was 12.8 and 6.9%, respectively. One participant identified as Black and another as American Indian/Alaskan native. The most common work setting was within an academic medical center (47.9%) and 57.8% held a management or leadership role at their institutions. The majority (79%) used an Institutional IRB for trials not overseen as part of the National Clinical Trials Network. Over 80% of respondents reported their institution is experiencing a personnel shortage due to COVID-19. Proportion who reported this negatively impacted IRB processes was 50%, financial review was 42%, and legal review was 26.9%. On a scale of 0 (none) to 6 (significant), the impact was most significant on audit activities and accrual to trials (both rated 5), transfer of data to sponsors and sponsor visits (both rated 4.5); all other aspects rated a 4, including screening procedures, regulatory activities, and data collection. Ranked reasons for attrition were desire for better pay, seeking better opportunities, and seeking more flexible working conditions. General burn out was ranked as the fourth most common cause. Important themes included increasing trial complexity, morale, lack of support (due to staff shortages), lack of opportunities for promotion, unfilled positions, and the lack of experience of new hires. **Conclusions:** Over 80% of research programs affiliated with SWOG report staffing shortages due to the COVID-19 pandemic and the impact of these shortages touch every aspect of clinical research. Initiatives to recruit, train, and retain staff are urgently needed. As in other areas of medicine (e.g. hospital nursing), the potential for post-pandemic persistence of this issue requires an immediate national response. Research Sponsor: U.S. National Institutes of Health.

Race- and sex-based variation in industry research and general payments to medical oncologists in the United States. *First Author: Imraan Jan, Department of Radiation Oncology, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Industry partnerships offer financial incentives, prestige, and can facilitate career advancement in oncology. However, not all physicians may have equal access to these opportunities. We hypothesized that physicians who are underrepresented in the medical oncology workforce based on race, ethnicity, and gender receive less industry funding. **Methods**: All US medical oncologists (MOs) who received $\geq$1 industry research payment between 2016 and 2020 according to the Open Payments database were included in this retrospective study. Information extracted from Open Payments included MO's name, institution, research payments (i.e. funding for a research project where the physician is a Principle Investigator), and general payments (i.e. fees not associated with research, such as consulting and travel fees). Additional web searches were conducted using institutional websites, NPPES NPI registry, LinkedIn, Doximity, Scopus, and NIH RePORTER to determine each MO's race, ethnicity, sex, academic rank, degrees, h-index, institutional NIH research funding rank, and individual receipt of NIH funding. Log-linear regression was performed to identify associations of both industry and general payment data. **Results**: Of 7,542 physicians meeting inclusion criteria, 69% were male, 65% White, 29% Asian, 2% Black, and 4% Hispanic, which is comparable to the American Medical Association Physician Masterfile figures for MO. The median sum research payment and general payment was $134,857 and $11,537 per physician respectively. Significantly higher mean research payments were associated with an MS (+72%; $P = 0.003$) or PhD degree (+30%; $P = 0.009$), h-index (+3%; $P < 0.001$), top 50 institution rank by NIH funding (+44%; $P < 0.001$), and associate professor rank (+95%; $P < 0.001$). Significantly lower mean research payment were observed for Black physicians (-36%; $P = 0.022$) and those with non-academic affiliation (-47%; $P < 0.001$). No significant association was observed between sex and research payment. Significantly higher mean general payments were associated with male sex (+46%; $P < 0.001$), MS degree (+171%; $P < 0.001$), h-index (+2%; $P < 0.001$), and Asian race (+72%; $P < 0.001$). Significantly lower mean general payments were associated with an affiliation with a non-academic practice (-31%; $P = 0.012$). **Conclusions**: Black physicians received smaller sums of industry research payments compared to White physicians. Female sex was associated with decreased general payments compared to male sex. Further exploring the underlying mechanisms determining access to industry payments may help facilitate greater equity and inclusivity in oncology. Research Sponsor: None.

11051 **Poster Session**

Trainee and program director perspectives of parental leave and parenthood in oncologic specialties. *First Author: Sara Beltran Ponce, Medical College of Wisconsin, Milwaukee, WI*

Background: Delays in pregnancy exacerbate infertility. Thus, trainees are forced to make complex family planning decisions while juggling all aspects of training. In addition to a lack of parental leave and financial constraints, trainees are often concerned with the perceptions of leave and parenthood. Two single specialty surveys found that most program directors (PDs) felt parenthood negatively impacted trainee performance, disproportionately for women. We aim to understand PD and trainee perspectives of parental leave and parenthood in oncologic trainees. **Methods:** Contact information for PDs in oncologic specialties was gathered from FRIEDA. Surveys were distributed to all eligible PDs with a request to forward a parallel survey to their trainees. Social media links for both surveys were shared on Twitter. Tests of association for descriptive analyses included Fisher's exact test, Chi-square test, or the Mantel-Haenszel Chi-Square test, as appropriate. All computations were performed using SAS version 9.4. **Results:** 195 PDs and 286 trainees completed the survey with 49% and 56% female and 89% and 41% parent respondents, respectively. Per PDs, 73% of programs have a maternity leave policy, 48% have a paternity leave policy, and 5% have a fertility services policy. PDs and non-parent trainees (NPTs) rated the negative impact of parenthood on overall education ($p < 0.001$ for PDs, $p < 0.001$ for NPTs) and academic productivity ($p < 0.001$ for PDs, $p < 0.001$ for NPTs) as higher for women trainees than men trainees. PDs and NPTs also rated the burden of parental leave on co-trainees as greater for women trainees as compared to men trainees ($p < 0.001$ for PDs, $p < 0.001$ for NPTs). Among PDs, no significant differences by gender or specialty were found in advising for or against parenthood in training, but PDs in surgical specialties reported providing less support for trainees starting a family ($p < 0.001$) and trainees in surgical specialties reported being less supported ($p < 0.001$). Women trainees were more likely than men trainees to indicate that they would have started a family sooner if not in medicine ($p < 0.001$). 89% of parent trainees would choose to have children in training again, and 84% would recommend parenthood in training. **Conclusions:** Although many programs have parental leave policies, a substantial number continue to lack them. Concerns about negative perceptions of parenthood by trainees are valid, particularly for women who are significantly more likely to be seen as having their education and academic productivity impacted by parenthood. In addition, specialty choice impacts the support given to trainees as they start families. Despite these barriers, the vast majority of parent trainees would still choose to have children in training and recommend this path to fellow trainees. Additional initiatives to normalize and support family planning in medical training for interested trainees are warranted. Research Sponsor: None.

Female representation in oncology leadership in Africa: Analysis of trends in the African organization for cancer research and training in cancer (AORTIC). *First Author: Miriam Claire Mutebi, Aga Khan University Hospital, Nairobi, Kenya*

Background: Board membership in oncology organizations and invitation to speak at major oncology conferences is an established indicator of gender disparities in oncology leadership. Recent studies note an upward trend in female board membership and female speakers at oncology conferences in European and American contexts. However, little is known about trends of female representation in board membership and at oncology conferences in Africa. AORTIC is the premier African cancer organization and hosts a biennial conference, during which its council members are elected for a two-year term. The conference hosts over 1000 participants and is highly regarded internationally. As the largest gathering of African oncologists, the conference presents a unique opportunity for insight into workforce disparities and trends. This study presents an analysis of female council membership and speaker participation at the 2015, 2017, 2019 and 2021 AORTIC conferences. **Methods:** AORTIC conference programmes and AORTIC elections for council membership in 2015, 2017, 2019 and 2021 were analyzed for gender representation. Speakers were divided into categories including keynote speakers, facilitators, session speakers, panelists, and oral abstract presenters. For each AORTIC session, data was collected on speaker name, gender, and affiliated country. Participants who presented multiple times were counted multiple times, as their role often varied between sessions. Personal data and country affiliation was determined through online biographies of speakers and/or visual confirmation of professional photographs. A simple descriptive analysis of the data and trends is presented here. **Results:** Since 2015, the proportion of female speakers and council members at AORTIC has increased. In 2015, females accounted for 44% of speakers, in contrast to 55% in 2021. In 2021, females made up over 50% of all speaker categories except keynote. The proportion of female council members also increased, from 42% in 2015 to 69% in 2021. Trends in geographic representation of speakers were also analyzed for gender, revealing an increase in female speakers residing in Africa. (Table) **Conclusions:** The proportion of female speakers and council members at Africa's largest cancer conference has increased significantly since 2015. Female speaker participation was higher than in North America and Europe in 2017 and surpassed 50 % in 2021. In addition, female council membership in AORTIC has surpassed 50%, up to 69% in 2021. These trends suggest a rise in female leadership in cancer research and training on the continent, indicating that strengthening local platforms in LMIC may be associated with improved gender assimilation. Research Sponsor: None.

Proportion of female speakers and council members at AORTIC.

Year	Female Speakers %	Female Council Members %
2015	44 %	42%
2017	44 %	58%
2019	51 %	56%
2021	55 %	69%

Recent trends of "manels" and gender representation among panelists at the ASCO annual meeting. *First Author: Sophia C. Kamran, Massachusetts General Hospital and Harvard Medical School, Boston, MA*

Background: Gender disparities in academic medicine are a long-acknowledged concern. Efforts to recognize this imbalance and increase inclusivity continue, particularly in academic medical conferences. In June 2019, NIH Director Francis S. Collins MD, PhD publicly called for an end to all-male speaking panels ("manels"). It is unclear whether academic oncology conferences followed suit. We investigated the prevalence and longitudinal trends of manels and gender representation at the ASCO Annual Meeting during 2018-2021. **Methods:** Using ASCO online programs, 2018-2021 faculty information was obtained. Data collected included perceived or self-reported gender, medical specialty, panel role (chair vs. non-chair), type of session, and topic. Primary outcomes included percentage of manels and proportion of female panelists over time. Female representation among chairs, specialties, and topics were evaluated. Cochran-Armitage test was used to analyze time trends in the proportion of manels and female representation. Fisher's exact test was used to compare each session type, topic, or specialty to other categories combined. P-values are based on a two-sided hypothesis. **Results:** During 2018-2021, there were 670 sessions total, 81 of which (12.1%) were manels. Among 2,475 faculty members, 1,181 (47.7%) were females. Over time, there was a significant decrease in the number of manels, from 17.4% in 2018 to 9.9% in 2021 ($p = 0.030$) and a corresponding increase in proportion of female panelists from 41.6% to 54.0% ($p < 0.001$). The largest decrease in manels occurred between 2018 (17.4%) and 2019 (10.5%). Among session type and topic, the highest proportion of manels was observed for leadership/special sessions (17.1%, $p = 0.419$) and translational/pre-clinical topics (19.6%, $p = 0.024$), respectively. The chair role was majority male (53.2%) in 2018 but increased to > 50% female representation in 2019-2021 ($p = 0.157$). The lowest proportion of female panelists were in pathology/radiology/dermatology specialties (combined 26.2%, $p = 0.001$). Female panelists were underrepresented for the topics of genitourinary cancers (38.6%, $p = 0.029$) and translational/pre-clinical sciences (36.7%, $p < 0.001$). Females were overrepresented in the topic of supportive oncology (70.3%, $p < 0.001$). There was a positive trend toward improved female representation among translational/pre-clinical sciences (27.4% in 2018 to 41.8% in 2021, $p = 0.031$), but with little improvement among genitourinary cancers (41.1% in 2018 to 40.7% in 2021, $p = 0.969$). **Conclusions:** The number of female ASCO panelists increased during the study period and surpassed 50% in 2021, with a corresponding decrease in the proportion of manels. Still, there are certain topics/specialties where female representation has remained stagnant. ASCO Annual Meeting organizers should continue to strive for diverse gender representation and the elimination of manels. Research Sponsor: None.

Where is your lactation room? Lactation policies and practices in oncology trainee and early career physicians. *First Author: Sindhu Janarthanam Malapati, University of Arkansas for Medical Sciences, Little Rock, AR*

Background: Training and early career years coincide with childbearing and raising young families, which places increased demands on new parents. With increasing numbers of female oncologists in the workforce, there is a need to assess and amend current workplace lactation policies. We surveyed Medical and Radiation Oncology trainees and early career faculty to assess policies and practices regarding lactation during training and early career. **Methods:** An anonymous 48 question cross-sectional survey developed by researchers with expertise in gender equity was distributed via email and social media channels between May and June 2021 to oncology trainees and physicians within 5 years of terminal training; program directors (PDs) were surveyed separately. Descriptive statistics were used. **Results:** Of the 255 complete responses, 26% (65) respondents breastfed for any length of time upon return to work. Of these, 54% (35) were trainees and 46% (30) early career faculty. 69% (45) had access to a designated lactation room; however, 57% (37) noted that duration of their pumping breaks was inadequate to access and use the lactation room. Most (60%, 39) did not feel comfortable asking for protected time to pump. Employment contracts did not specifically include pumping breaks for 66% (43), while 34% (22) were unsure about their contract policies surrounding lactation. Of all breastfeeding mothers, 77% (50) felt their colleagues to be supportive of their needs; a minority reported negative responses due to pumping breaks from faculty (11%), co-fellows/colleagues (8%) and clinic staff (15%). 51% (33) bought a wearable pump prior to return to work, of which 70% (23) found it financially burdensome. Most common reasons for buying a wearable pump were to improve efficiency during work hours (61%, 20) and lack of adequate pumping breaks (39%, 13). Among 23 PDs who responded to the survey, 65% (15) had a program policy regarding lactating trainees, 9% (2) blocked clinic appointments to allow pumping breaks, 91% (21) provided lactation rooms, 83% (19) reported the lactation rooms are easily accessible. **Conclusions:** Both infrastructure and time accommodations made for the lactating parent are inadequate. There is a disconnect between the trainee and PDs' perception of provided accommodations. Systemic changes that provide adequate time and space for lactation to busy clinicians and trainees is imperative to ensure retention of women oncologists in the workforce. Identifying predictors of equitable gender representation among hematology and oncology fellowship programs. *First Author: Sasirekha Pandravada, Advocate Lutheran General Hospital, Park Ridge, IL*

Background: While gender disparities have largely been bridged among hematology and oncology fellows at the national level, there exist many individual fellowship programs that still have marked gender disparity. Our study is the first to examine gender differences among fellows at an institutional level in order to model characteristics of hematology and oncology programs that lead to more equitable gender representation. **Methods:** For each of the 148 hematology or oncology fellowship programs listed in the Fellowship and Residency Electronic Interactive Database, we collected data on gender, faculty academic rank, and fellow postgraduate year as listed on individual program websites. Further, a program was identified as an academic center if it had an affiliated medical school. Zip code data was used to identify geographic region, local population density, and racial diversity of each program's surrounding neighborhood. Multiple linear regression was used to model which factors contributed to a program having a higher percentage of female fellows. **Results:** 3600 faculty and 1488 fellows were included in the analysis. While women were well represented nationally among fellows (46.4%), 52.4% of fellowship programs had fewer than 50% women, and 28.6% of programs had fewer than 35% women. An individual program was more likely to have more female fellows if it had a higher percentage of female assistant professors ($p<0.01$), associate professors ($p<0.01$), assistant professors overall ($p<0.01$), a female program director (PD) or associate program director (APD) ($p=0.02$), and a designation as an academic center ($p<0.01$). Notably, the percentage of female full professors had no significant impact ($p=0.11$) on whether a program was likely to have more female fellows. **Conclusions:** While women are well represented nationally among hematology and oncology fellows, nearly one in three fellowship programs still have significant gender disparity. Our multivariate model identified several significant factors that predict whether a program was likely to have gender parity among fellows: a higher percentage of female assistant professors, associate professors, assistant professors overall, a female PD or APD, and a designation as an academic center. Whether these factors together highlight the importance of accessible mentorship or direct female faculty role models requires further study. However, by beginning to identify these significant factors, we hope to aid fellowship programs focus efforts when trying to achieve equitable gender representation. Research Sponsor: None.

Gender representation among hematology and oncology fellows and faculty.

	Fellow (PGY4-PGY6)	Assistant Professor	Associate Professor	Full Professor	Program Director
% Female	46.4%	51.1%	44.8%	25.1%	48.6%
% Programs with <50% Female	52.4%	41.0%	58.1%	89.5%	-
% Programs with <35% Female	28.6%	18.1%	31.4%	75.2%	-

Exploring perceptions of gender bias in oncology: A survey study. *First Author: Nino Balanchivadze, Department of Hematology and Oncology, Henry Ford Cancer Institute, Detroit, MI*

Background: Gender inequalities contribute to burnout and have contributed to an ongoing exodus of women from academic oncology. Our aim was to explore the perceptions and experiences of oncology professionals regarding gender bias in the workplace with the hope of providing critical information to support equity initiatives. **Methods:** An anonymous, 22-question survey was sent via Survey Monkey to 1512 physicians with oncology-related specialties from National Cancer Institute (NCI) designated cancer centers whose emails were publicly available. Likert-scale questions (never-rarely-sometimes-often-very often) were analyzed with Kruskal-Wallis and Wilcoxon rank sum tests (percentages shown as frequency of having responded "sometimes-often-very often"). Chi-square test was used for categorical variables. **Results:** A total of 274 physicians completed the survey (response rate 18%): 152 (55.5%) self-identified as female (F); 112 (42%) as male (M); 7 (2.6%) as gender non-conforming or transgender; 3 (1.1%) chose not to answer. Most were White (59.9%), followed by Asian (20.4%), Middle Eastern (5.8 %), Multiracial (5.1%), Hispanic (3.6%), and Black (1.5%). The plurality (n = 103; 37.6%) were < 40 years old. Primary fields of practice included 118 (43.1%) in adult oncology, 45 (16.4%) in combined hematology/oncology, 44 (16.1%) in radiation oncology, 44 (16.1%) in adult hematology, and 23 (8.4%) in other specialties. Female gender was associated with experiencing gender bias more often than male gender in the following areas: clinical practice (80.9% F vs 20.6% M), research activities (73.0% F vs 15.2% M), having difficulty balancing work and non-work responsibilities (95.4% F vs 78.6% M), being held to higher standards compared to physicians of other genders (73.1% F vs 14.2% M), being mistaken as a non-physician (78.9% F vs 6.3% M), and being scrutinized by others while tending to child-care needs (48.8% F vs 23.2% M) (all $p < .001$). Female gender was associated with using techniques to navigate gender challenges more often than male gender, including wearing a white coat (55% F vs 7% M; $p < .001$), ensuring that "Doctor" is written on identification (33% F vs 3% M; $p = .002$), emphasizing a professional look (53% F vs 10% M; $p = .003$) and working harder to establish expertise in the field (72% F vs 18% M; $p = .003$). When asked about strategies to address workplace gender-related bias, 63% would like policies on gender-related discrimination, (66.4% F vs 65.2% M; $p = .93$), 62% would like policies that prioritize leadership representation (74.3% F vs 51.8% M; $p < .001$), and relatively few (37%) would prefer formal lectures/instruction for staff (38.2% F vs 37.5% M; $p > .99$). **Conclusions:** Self-identified female academic oncologists at NCI Cancer Centers reported facing gender-related challenges in daily practice at much higher rates than men. There is a clear need to identify root causes and create initiatives to promote gender equity in the field of oncology. Research Sponsor: None.

The impact of diversity, equity, and inclusion training in an independent community oncology practice. *First Author: Mark T. Fleming, Virginia Oncology Associates, U.S. Oncology Research, Norfolk, VA*

Background: Historically, Diversity, Equity, and Inclusion (DEI) efforts have largely been left out of private practice medical facilities – mainly present in large academic hospital centers. Virginia Oncology Associates (VOA), a member of The US Oncology Network, is an independent community oncology and hematology practice specializing in the diagnosis and treatment of cancer and blood disorders. VOA has approximately 600 total employees consisting of physicians and clinical and non-clinical staff. In August of 2020, VOA launched an initiative to foster a culture of inclusion with the creation of its Inclusion Council (IC). Sixteen employees', both clinical (3 physicians) and non-clinical, were chosen to participate. The council reports to VOA's joint policy board. **Methods:** The council partnered with an outside organization, Virginia's Center for Inclusive Communities, to launch a practice-wide DEI training program focusing on unconscious bias and microaggression. The training was initially planned to be in person, but due to the constraints of the COVID pandemic, the training was performed using a virtual platform. The members of IC attended three two-hour sessions while other staff members and physicians were mandated to participate in at least one training session. After completion of the sessions, a survey was sent to all employees and physicians to measure the impact of DEI training. All employees were also given the opportunity to provide additional, anonymous, written feedback. **Results:** Table. A total of 169 employees responded. 72% of respondents agreed or strongly agreed that the program increased awareness of unconscious bias and microaggression, 67% felt that the program helps foster a culture of inclusion in the workplace, and 66% of respondents felt that the program met expectations. **Conclusions:** DEI efforts are vital in all aspects of health care delivery and oncology settings. DEI training met staff expectations and positively fostered a culture of inclusion by bringing attention to unconscious bias and microaggression in a community oncology practice. Research Sponsor: None.

Summary of employee respondent's views on DEI training.

Training Impact N=168	Strongly Agree	Agree	Neutral	Disagree	Strongly Disagree
Increased Awareness of Unconscious Bias and Microaggression	33(20%)	87(52%	29(17%)	13(8%)	5(3%)
Help Foster Culture of Inclusion in Workplace	26(15%)	87(52%)	39(23%)	9(5%)	7(4%)
Met expectations	26(15%)	85(51%)	43(26%)	9(5%)	5(3%)

Self-identification of gender and race/ethnicity in hematology and oncology journal editorial boards: What is the state of diversity? *First Author: Ivy Riano, Norris Cotton Cancer Center, Dartmouth-Hitchcock Medical Center, Lebanon, NH*

Background: Underrepresentation of women and minorities persists in many aspects of the scholarly publication process as demonstrated by our initial findings presented at ASCO21. Having a gender-balanced and diverse editorial team promotes collaborative work and decreases the publication bias against women. In our initial study, gender and race/ethnicity were determined based on publicly available data. We aimed to add to our study by asking editors to self-report their gender and race to assess the diversity of editors at leading hematology and oncology journals by self-reporting. **Methods:** We identified 60 journals in oncology, hematology, radiation oncology, and surgical oncology with the highest impact factors. Editors-In-Chief (EiC) and Second-In-Command (SiC) editors (such as deputy, senior and associated editors) were included in the analysis. A demographic survey assessing gender, race/ethnicity, age, and job characteristics was sent to 793 participants via email. Data were analyzed with R software. **Results:** A total of 66 out of 793 editorial board members responded to the survey. Gender breakdown of respondents was 36 (54.5%) men and 30 (45.8%) women. Most respondents were between the ages of 40 and 60 (69.7%). Thirty-eight (57.6%) of the editors had ≤5 years of editorial experience. Of the 66 respondents, 44 (66.7%) self-identified as non-Hispanic white, followed by 14 (21.2%) as Asian and 3 (4.5%) as Hispanic. Only 1/66 (1.5%) editors self-identified as Black or Native Hawaiian/Other Pacific Islander, and 1/66 (1.5%) did not identify themselves with a racial group. **Conclusions:** Underrepresented groups in medicine (URM) and women occupied a minority of leadership roles on editorial boards in high-impact hematology and oncology journals. Notably, this study provides new insights into editorial board diversity by using self-reporting as a primary methodology. Limitations of the cross-sectional study is that URM and women are more likely to respond to surveys on diversity, equity, and inclusion potentially skewing the results. Diversity in editorial boards not only can enhance scientific discovery by encouraging submissions from researchers with diverse backgrounds but also promotes career advancement for women and URM. Research Sponsor: None.

Self-Reported Editor's Race/Ethnicity	Editor-In-Chief Female n (%)	Editor-In-Chief Male n (%)	Second-In-Command Female n (%)	Second-In-Command Male n (%)
White	3 (100.0)	3 (75.0)	20 (74.1)	18 (56.2)
Black	0 (0.0)	0 (0.0)	0 (0.0)	1 (3.1)
East Asia	0 (0.0)	0 (0.0)	4 (14.8)	5 (15.6)
South Asia	0 (0.0)	0 (0.0)	2 (7.4)	3 (9.4)

Experiences of researchers fulfilling VHA's "fourth mission" during the COVID-19 pandemic. *First Author: Kenneth Csehak, New York University, New York, NY*

Background: As the largest integrated healthcare system in the US, the Veterans Health Administration (VHA) is chartered "to serve as the primary backup for any health care services needed...in the event of war or national emergency" according to a 1982 Congressional Act. This mission was invoked during the COVID 19 pandemic to divert clinical and research resources, resulting in dramatic changes in the activities of investigators and research staff. This study uses established behavioral change frameworks to examine the experience of VHA cancer researchers during the pandemic. **Methods:** We conducted a mixed methods study on the effects of the pandemic on VHA researchers. We used an electronic questionnaire composed of Likert scale statements and open-ended questions, which was constructed using the 14 domains of the Theoretical Domains Framework (TDF) and the Capability, Opportunity, and Motivation (COM-B) model for behavior change. Likert scale statements were quantified and content analysis was performed on open ended responses. **Results:** The questionnaire was distributed electronically to 118 researchers participating in national VHA collaborations, with 42 responses (36%). Several significant themes and findings emerged. Only 36% of respondents did not feel that their research focus changed during the pandemic. (TDF: professional role and identity maps to COM-B Motivation). And 81% of respondents reported a diverse range of research interests (COM-B: M). Only 11 of 42 respondents (26%) reported prior experience with infectious disease research (TDF: skills maps to COM-B: C), and 31 of 42 (74%) agreed that they gained new research skills during the pandemic (COM-B: C). When asked to describe support structures helpful during the pandemic, 29% mentioned local supervisors, mentors and research staff (COM-B: C, M), 15% cited larger VHA organizations (COM-B: C) and 18% mentioned remote work abilities or telehealth (COM-B: O). Lack of timely communication from supervisors and remote work, particularly for individuals with caregiving responsibilities, were seen as limiting factors for research during the pandemic (COM-B: O). Although 83% of respondents agreed that they will be prepared to respond to future crises after COVID (COM-B: C), fewer than half (40%) of respondents felt professionally rewarded for pursuing research related to COVID, with 50% feeling neutral (COM-B: M). **Conclusions:** This study demonstrated the tremendous effects of the COVID 19 pandemic on research activities of VHA investigators. We identified perceptions of insufficient recognition and lack of professional advancement related to pandemic era research. Improving the structure of remote work and team communication represent high yield areas for improvement. It is essential to understand barriers and facilitators of crisis redeployment in the VHA, to make the transition effective and fulfilling for those carrying out the mission. Gender and early career faculty disparities in hematology and medical oncology board review lectures series. *First Author: Leen Mohammad Al-Kraimeen, Jordan University of Science and Technology, Irbid, Jordan*

Background: Studies show that women and early career faculty members have less access to career development opportunities and leadership positions. These disparities slow the process of change and may affect leadership roles, promotions, and career advancements in academic medicine. Here, we provide the first analysis of speakers' gender and early faculty disparities in hematology and medical oncology board review series. **Methods:** We performed a cross-sectional analysis of speakers at all major hematology and/or oncology board review series meetings, which were held in the United States between January 2017 and December 2021. Six major board review series were involved: Baylor/M.D. Anderson Cancer Center, the Brigham and Dana-Farber, George Washington School of Medicine and Health Sciences, Memorial Sloan Kettering Cancer Center, Seattle Cancer Care Alliance, and the American Society of Hematology. Details of the lectures were acquired via accessing brochures available on the institutions' official websites. Data on board certification and maintenance of certificate (MOC) were obtained from the American Board of Internal Medicine (ABIM) website. We extracted the number of publications from the PubMed website (MEDLINE). **Results:** Our analysis included 1224 board review lectures presented by 386 speakers. Of which, 315 (81.6%) were American Board of Internal Medicine (ABIM) certified, and MOC was active in 56.1% of speakers. Females accounted for 37.7% of all speakers, with a representation of less than 50% in 5 out of 6 board review series. The least proportion of female participation was among lectures discussing malignant hematology topics (24.8%), followed by solid tumors (38.9%), and benign hematology topics (44.1%). Faculty members with more than 15 years of experience since initial certification presented more than half of the lectures. The median time from initial hematology or medical oncology certification to lecture presentation was 12.5 years and 14 years, respectively, which varied significantly among different series ($p < 0.001$). Speakers' median number of publications was 84. We also investigated how frequently the same speaker gave lectures. Thirteen male speakers conducted more than or equal to 10 lectures across all board review series, compared to only two female speakers who did the same. An upward trend of improvement in females participation was found at all board review conference meetings across the years. **Conclusions:** Our data suggest that women and early career faculty members are underrepresented in hematology and oncology board review series. Therefore, efforts should be made to ensure equal participation of them in such important activities needed to advance academic careers. Research Sponsor: None.

Comparison of methodology in the collection of gender and race/ethnicity in hematology and oncology journal editorial boards. *First Author: Shruti Rajesh Patel, Stanford University, Stanford, CA*

Background: Reporting on disparities is strongly influenced by the methodology used to collect race/ethnicity and gender data. Incorporating gender and race into research has its challenges, as these variables are difficult to define. As underrepresentation of minorities and women continues to persist in many facets of academia, it is important to assess the accuracy of differing methodologies. While asking individuals to self-identify their race and gender remains the gold standard of reporting, low response rates and response bias have been shown to affect results. In our initial study on representation in editorial boards, gender and race/ethnicity were determined based on publicly available data which can lead to misclassification of editors. We aimed to add to our study by asking editors to self-report their gender and race in hopes to validate our methodology given the importance of considering gender and race in academia. **Methods:** Of the 60 highest impact journals in oncology, hematology, radiation oncology, and surgical oncology identified, race/ethnicity and gender determinations were made using two methods. All senior editors were sent a survey via email asking participants to self-report their gender, race/ethnicity, age, and job characteristics. Gender and race were also assigned to the editors by a diverse coding team based on publicly available data and the NIH's OMB Directive 15 as a framework. The self-reported data was then compared to data that was assigned by our team. **Results:** 66 of the 793 (8.3%) editorial board members included in the study responded to the survey. Of the 66 respondents, gender was assigned correctly 100% (66/66) of the time and race was assigned correctly 95.5% (63/66) of the time. Of the 66 respondents to the self-survey of the 793 editorial board members surveyed. A significantly lower proportion of men responded to the survey compared to the gender breakdown of the 793 editorial board members (54.5% vs 72.6%; $p = 0.000279$). The three incorrectly identified respondents self-identified as Native Hawaiian, White, and Middle Eastern. **Conclusions:** Multiple recent reports have demonstrated high rates of sexual harassment, gender bias, and exclusion in the field of oncology. Collecting data on racial/ethnic groups and gender is imperative to understand the academic landscape of oncology and work towards a more equitable environment. Notably, this data from our study supports the methodology of a diverse coding team assigning gender and race based on publicly available data and the NIH's OMB Directive 15 as a framework as an alternative to self-report. Our study also demonstrates the low response rates and significant discrepancies in the demographic of respondents seen in survey-based identification. Research Sponsor: None.

Primary efficacy and safety of letetresgene autoleucel (lete-cel; GSK3377794) pilot study in patients with advanced and metastatic myxoid/round cell liposarcoma (MRCLS). *First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Lete-cel is an autologous T-cell therapy targeting NY-ESO-1 tumors using a genetically modified, high-affinity T-cell receptor. MRCLS is a sarcoma with poor response to current immunotherapy approaches and limited treatment options. The cancer testis antigen NY-ESO-1 is expressed in 80–90% of MRCLS tumors, making this a promising target. This report summaries the primary efficacy and safety results of a pilot study of lete-cel in patients (pts) with advanced or metastatic MRCLS. **Methods:** This is an open label, study of lete-cel in pts with advanced or metastatic MRCLS following reduced-dose (Cohort 1 [C1]; 30 mg/m^2 fludarabine [flu] x 3d + 600 mg/m^2 cyclophosphamide [cy] x 3d) or standard dose (Cohort 2 [C2]; 30 mg/m^2 flu x 4d + 900 mg/m^2 cy x 3d) lymphodepletion (LD). Key eligibility criteria were: age ≥18 y; HLA-A*02:01; A*02:05, or A*02:06; advanced or metastatic NY-ESO-1+ MRCLS (≥30% of cells 2+/3+ by IHC); prior anthracycline treatment, and measurable disease. The transduced T cell dose range was 1– 8 $\times$ 10^9. Response was assessed at weeks 4, 8, 12, 24, then every 3 months (mo) until disease progression, death, or withdrawal. Investigator-assessed (IA) ORR by RECIST v1.1 was the primary efficacy endpoint. Secondary endpoints included safety, independently assessed ORR by RECIST v1.1, time to response (TTR), duration of response (DOR), progression-free survival (PFS). Overall survival (OS) was an exploratory endpoint. **Results:** 23 pts enrolled from March 2017 to February 2020. The median age was 47.0 yrs (range 33 to 72). 20 pts were dosed with T cells, 10 in each cohort with a median transduced T cell dose of 4.6 x 10^9. 8 of 20 pts (40%) had 1 line of prior therapy, 6 pts (30%) had 2 lines, and 6 pts (30%) had ≥3 lines. The median follow-up was 5.6 (C1) and 12.9 (C2) mo. In C1 the IA ORR was 20%, with best response (BR) of partial response (PR) in 2 pts and BR of stable disease (SD) in 8 pts. The median TTR was 1.9 mo, median DOR was 5.3 mo (95% CI: 1.9-8.7), and median PFS was 5.4 mo (95% CI: 2.0-11.5). In C2 the IA ORR was 40%, with BR of PR in 4 pts and BR of SD in 5 pts. The median TTR was 1.9 mo, median DOR was 7.5 mo (95% CI: 6.0-NE), and median PFS was 8.7mo (95% CI: 0.9-NE). OS is not yet mature. All pts experienced at least 1 treatment-emergent adverse event (TEAE). 55% of pts experienced serious TEAEs. 90% of pts had Gr ≥3 TE neutropenia, with 83% probability of resolution of initial Gr ≥3 occurrence by Day 30. Cytokine release syndrome occurred in 80% of pts, of which 25% were Gr 3, with 1st onset within 5d of infusion and median duration 7.5d. No Graft-vs-host disease, immune effector cell–associated neurotoxicity syndrome, Guillain-Barré Syndrome were reported. **Conclusions:** Treatment with a single dose of lete-cel showed anti-tumor activity, including response and long median PFS with an acceptable safety profile in pts with advanced and metastatic MRCLS. Clinical trial information: NCT02992743. Research Sponsor: GlaxoSmithKline.

Randomized phase II study of neoadjuvant checkpoint blockade for surgically resectable undifferentiated pleomorphic sarcoma (UPS) and dedifferentiated liposarcoma (DDLPS): Survival results after 2 years of follow-up and intratumoral B-cell receptor (BCR) correlates. *First Author: Emily Zhi-Yun Keung, The University of Texas MD Anderson Cancer Center, Houston, TX*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

11502 **Oral Abstract Session**

Phase I clinical trial to assess safety, pharmacokinetics (PK), pharmacodynamics (PD), and efficacy of NY-ESO-1–specific TCR T-cells (TAEST16001) in HLA-A*02:01 patients with advanced soft tissue sarcoma. *First Author: Xing Zhang, Melanoma and Sarcoma Medical Oncology Unit, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: NY-ESO-1 is a cancer/testis antigen with expression in a wide range of tumor types. TAEST16001 cells are genetically engineered autologous T cells that express high-affinity NY-ESO-1-specific T-cell receptor (TCR) targeting NY-ESO-1+ soft tissue sarcoma in the context of HLA-A*02:01. Here, we report preliminary results of TAEST16001 cells from an ongoing, dose-escalation and expansion study in HLA-A*02:01 positive patients with advanced soft tissue sarcoma expressing NY-ESO-1 antigen. **Methods:** This is an open, single arm, dose-escalation and expansion study to evaluate safety, tolerability, PK, PD and preliminary efficacy of TAEST16001 cells in patients with soft tissue sarcoma. Enrolled patients underwent apheresis, and their isolated T cells were expanded in vitro after transducing with a lentiviral vector containing NY-ESO-1 TCR. Prior to TAEST16001 cells infusion, patients were to receive lymphodepleting chemotherapy consisting of cyclophosphamide (15 mg/kg/day ´3 days) and fludarabine (20 mg/m^2/day´3 days). TAEST16001 cells were administered at 5 $\times$ 10^8 ± 30% (dose level 1), 2 $\times$ 10^9 ± 30% (dose level 2), 5 $\times$ 10^9 ± 30% (dose level 3) and 1.2 $\times$ 10^{10} ± 30% (dose level 4/expansion) transduced cells. After TAEST16001 cells infusion, patients were to receive interleukin-2 subcutaneous injection for 14 days. Tumor responses were assessed by RECIST/iRECIST. **Results:** As of 31 December 2021, 12 patients with advanced soft tissue sarcoma were enrolled (M:F 7:5; mean age = 37.9; median prior regimens = 2 (range 1-3)). TAEST16001 cells were well-tolerated with no dose limiting toxicity. The most frequently reported grade ^{3} 3 adverse events were lymphopenia (n = 12), leukopenia (n = 10), neutropenia (n = 11), anemia (n = 4), thrombocytopenia (n = 1), hypokalemia (n = 1), and fever (n = 1). Two patients presented with cytokine release syndrome (grades 2) and resolved after symptomatic treatment. None of the patients had neurotoxicity, or serious adverse events related to cell infusion. The maximum tolerated dose (MTD) was not reached. PK modelling indicated that T_{max} of TAEST16001 cells were 6.23 days after cells infusion, and there were no relationship between clinical response and C_{max}/$AUC_{0\text{-}28}$. Among 12 efficacy-evaluable patients, 5 patients had a partial response, 5 patients had stable disease, and 2 patients had progressive disease. The overall response rate was 41.7%. The median time to an initial response was 1.9 month (range, 0.9 to 3.0), and the median duration of response was 14.1 months (range, 5.0 to 14.2). **Conclusions:** TAEST16001 cells showed an acceptable tolerability profile overall. MTD was not reached. Emerging efficacy data encouraged the continued expansion study of TAEST16001 cells in advanced soft tissue sarcoma. Clinical trial information: NCT04318964. Research Sponsor: Guangzhou Xiangxue Pharmaceutical Company limited.

11503 **Oral Abstract Session**

A phase I/II study of prexasertib in combination with irinotecan in patients with relapsed/refractory desmoplastic small round cell tumor and rhabdomyosarcoma. *First Author: Emily K Slotkin, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Prexasertib (PRX) is an inhibitor of CHK1, prevents DNA repair leading to mitotic catastrophe, and can enhance the activity of DNA-damaging chemotherapy. Translocation driven sarcomas exhibit high levels of replication stress and have demonstrated susceptibility to CHK1 inhibition in preclinical models. Desmoplastic small round cell tumor (DSRCT) and rhabdomyosarcoma (RMS) are aggressive sarcomas of children, adolescents and young adults for which novel therapies are urgently required. **Methods:** We conducted a phase I/II trial of PRX with irinotecan (irino) in patients ≥ 12 months of age with relapsed or refractory DSRCT or RMS. Eligible patients could have any number of prior therapies, including irino. Dose level 1 was PRX 80 mg/m^2 on day 1 + irino 20 mg/m^2 for 10 days. Dose levels 2 and 2A were PRX 105 or 150 mg/m^2 (>21 years or ≤ 21 years) on day 1 and irino 20 mg/m^2 for 10 (level 2) or 5 (level 2A) days. All cycles were 21 days. The primary objectives were to determine the RP2D of PRX with irino, and to determine the best overall response rate (ORR) in 6 months at the RP2D (RECIST v1.1) in DSRCT, with 3 or more responses out of 16 considered promising. **Results:** 21 patients were enrolled (DSRCT: 19; 2 RMS:2). The RP2D was dose level 2A. Treatment was well tolerated with the most common adverse events being neutropenia (48%), nausea (48%), and fatigue (52%). Cytopenias were managed with the aid of growth factor support in all patients once the RP2D was established. The DSRCT expansion enrolled 13 of 16 planned patients due to discontinuation of PRX supply prior to study completion. Four patients remain on therapy at the time of this submission. Responses in DSRCT patients at all dose levels are shown in Table. Sixteen of 21 enrolled patients, and 5 of 6 patients achieving PR had previously received irino. The median (range) number of cycles was 7 (2-26). Both RMS patients treated at the RP2D experienced SD as best response. The estimated ORR at the RP2D was 23%, and lower boundary of the one-sided 90% confidence interval was 9%, exceeding the unpromising rate of 5%. The two-sided 90% confidence interval was 7 to 49%. In addition, 3 patients had a PR at doses lower than the RP2D, bringing the ORR for all dose levels (n = 19) to 32% (90%CI: 15 to 53%). **Conclusions:** The RP2D of PRX in combination with irino is PRX 105 or 150 mg/m^2 (>21 years or ≤ 21 years) on day 1 and irino 20 mg/m^2 for 5 days in 21 day cycles with myelosuppression successfully managed with growth factor support. The study met its primary objective to consider PRX + irino promising in DSRCT and should be further investigated. Clinical trial information: NCT04095221. Research Sponsor: Cycle for Survival.

Outcomes following preoperative chemoradiation +/- pazopanib in non-rhabdomyosarcoma soft tissue sarcoma (NRSTS): A report from Children's Oncology Group (COG) and NRG Oncology. *First Author: Aaron R. Weiss, Maine Medical Center, Portland, ME*

Background: Pazopanib is a multi-targeted tyrosine kinase inhibitor (TKI) with activity in advanced soft tissue sarcoma. ARST1321 was a phase II study designed to compare the near complete pathologic response rate (≥ 90% necrosis) following preoperative chemoradiation +/- pazopanib in children and adults with intermediate/high risk chemotherapy-sensitive body wall/extremity NRSTS. Enrollment was stopped early following a predetermined interim analysis that found the rate of near complete pathologic response to be significantly greater with the addition of pazopanib. As a planned secondary analysis of the study, we now report the outcome data for this cohort. **Methods:** ARST1321 was a jointly designed COG and NRG Oncology study open to enrollment July 2014-October 2018. Eligible adult (≥18 years) and pediatric (< 18 years) patients with newly-diagnosed unresected body wall/extremity NRSTS were enrolled into the Chemotherapy Cohort (> 5 cm, FNCLCC grade 2/3, protocol-designated chemotherapy-sensitive histology). Following a dose-finding phase, patients were randomized to receive (Regimen A) or not receive (Regimen B) pazopanib (< 18 years: 350 mg/m^2/day; ≥ 18 years: 600 mg/day) in combination with ifosfamide (7.5 gm/m^2/cycle) and doxorubicin (75 mg/m^2/cycle) + 45 Gy preoperative RT followed by primary resection at week 13, then further chemotherapy to week 25. **Results:** Eighty-five eligible patients were enrolled in the Chemotherapy Cohort and randomized to receive or not receive pazopanib. Median age 22.1 years (range: 5.7-64.2 years); 30 patients < 18 years. Most common histologies were synovial sarcoma (n = 42) and undifferentiated pleomorphic sarcoma (n = 19). As of December 31, 2021, at a median survivor follow-up of 3.3 years (range: 0.1 – 5.8 years), the 3-year event-free survival (EFS) for all patients in the intent-to-treat analysis was 52.5% (95% CI: 34.8%-70.2%) for Regimen A and 50.6% (32%-69.2%) for Regimen B (p = 0.8677); 3-year overall survival (OS) was 75.7% (59.7%-91.7%) for Regimen A and 65.4% (48.1%-82.7%) for Regimen B (p = 0.1919). **Conclusions:** Although the rate of near complete pathologic response was significantly greater with the addition of pazopanib to preoperative chemoradiation in children and adults with intermediate/high risk body wall/extremity NRSTS, outcomes were not statistically significantly different between the two regimens. Pathologic response could be a TKI-related phenomenon and may not be a good surrogate marker of outcome in future studies. Clinical trial information: NCT02180867. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

11505 **Oral Abstract Session**

Long-term outcomes in patients with localized Ewing sarcoma treated with interval-compressed chemotherapy: A long-term follow-up report from Children's Oncology Group study AEWS0031. *First Author: Thomas Cash, Aflac Cancer & Blood Disorders Center, Children's Healthcare of Atlanta, Emory University School of Medicine, Atlanta, GA*

Background: Children's Oncology Group study AEWS0031 demonstrated superior 5-year event-free survival (EFS) in patients with localized Ewing sarcoma (ES) receiving interval-compressed (IC) chemotherapy (every 2 weeks) compared to standard timing (ST) chemotherapy (every 3 weeks). We assessed the long-term outcome of patients treated on AEWS0031 to determine whether the survival advantage of IC chemotherapy was maintained at 10 years. **Methods:** AEWS0031 enrolled 568 eligible patients with localized ES. Patients were stratified into four groups by age (<18 years and ≥ 18 years) and primary site (pelvic and non-pelvic), and randomized to receive 14 cycles of alternating vincristine-doxorubicin-cyclophosphamide and ifosfamide-etoposide given every 3 weeks (ST; Regimen A) vs. every 2 weeks (IC; Regimen B). For this updated report, one patient was excluded due to uncertainty of original diagnosis giving a total of 567 patients in this analysis. Data for tumor measurements and histologic response were collected retrospectively from institutional reports. EFS and overall survival (OS) were estimated using the Kaplan-Meier method and compared using the log-rank test and Gray's test for cumulative incidence (CI). **Results:** The 10-year EFS for patients treated with IC chemo was 70% compared to 61% for ST chemo (p = 0.03), and the OS was 76% with IC chemo compared to 69% for ST chemo (p = 0.03). The 10-year CI of second malignant neoplasms (SMNs) for ST chemo was 4.2% [95% confidence interval: 2.4-7.5] compared to 3.2% (95% confidence interval: 1.6-6.3) for IC chemo (p = 0.5). There was a trend towards improved 10-year EFS in those receiving IC chemo both with non-pelvic (N = 477; 71% vs. 64%) and pelvic (N = 90; 67% vs. 43%) primary tumors. Similarly, the 10-year EFS was superior for patients treated with IC chemo in both the < 18 years (N = 500; 73% vs. 64%) and ≥ 18 years (N = 67; 53% vs. 37%) age groups. Among the 184 patients with available histologic response data, the 10-year EFS from the time of local control was 76% for those with < 10% viable tumor and 56% for those with ≥ 10% viable tumor (p = 0.01). Additional analysis comparing patients with any viable tumor vs. no viable tumor (NVT) by treatment regimen demonstrated that patients with NVT who received IC chemo had 10-year EFS and OS from local control of 91% and 97%, respectively. In the 210 patients for whom tumor volume calculations were possible, there was no difference in the 10-year EFS for patients with tumors < 200 mL vs. ≥ 200 mL. **Conclusions:** With longer term follow-up, IC chemotherapy for localized ES is associated with superior EFS and OS without an increase in SMNs. This study suggests patients ≥ 18 years with poor necrosis or pelvic primary tumors remain at high risk for relapse despite IC chemo, emphasizing the need for alternative treatment strategies to improve their outcomes. Clinical trial information: NCT00006734. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

11506 **Oral Abstract Session**

A phase Ib/II study of the combination of lenvatinib (L) and eribulin (E) in advanced liposarcoma (LPS) and leiomyosarcoma (LMS) (LEADER): Efficacy updates. *First Author: Tom Wei-Wu Chen, Department of Oncology, National Taiwan University Hospital, Taipei, Taiwan*

Background: There are limited treatment options for advanced LPS and LMS, the two most common histologies in soft tissue sarcoma. Patients (pts) treated with E had an improved overall survival (OS) compared to dacarbazine but with an unsatisfactory 4% objective response rate (ORR). Early studies of L, a multi-targeted anti-angiogenic inhibitor, had suggested efficacy in sarcoma pts. We hypothesized that the L+E could potentiate the treatment efficacy in advanced LMS and LPS. **Methods:** LEADER was a single-arm phase Ib/II study for advanced adult LMS and LPS pts who had received no more than 2 lines of systemic chemotherapy (NCT03526679). The phase Ib part (starting dose: L 18mg/day, E 1.1mg/m^2) had been reported and the recommended phase 2 dose (RP2D) was determined at L 14mg/day and E 1.1mg/m^2 D1, D8 every 21 days. The primary endpoint of the phase II part was ORR by RECIST 1.1, secondary endpoints included progression-free survival (PFS), 6-month PFS rate, and OS. Pts in phase Ib/II part were analyzed together for efficacy. **Results:** As of Nov 15 2021, 30 pts (F/M 20/10) had been treated with at least one cycle of L + E; 21 were LMS (9 uterine, 12 non-uterine) and 9 were LPS (5 dedifferentiated, 2 myxoid round cell, 2 pleomorphic). The median age was 59 (range 29-73); the median lines of treatment(s) received before enrollment was 1 (range 0-3). The ORR by RECIST 1.1 was 20 % (6/30) (95% CI 10-53%); the ORR for pts received L 18mg/day (2/6) and L 14mg/day (4/26) were not significantly different (p = 0.23). After a median FU time of 20.1 months, the median PFS and 6-month PFS rate was 8.56 mos (95% CI 4.40-not reached (NR)) and 59%, respectively. The median PFS for LMS (8.56 mos, 95% CI 4.17- NR) and LPS (11.36 mos, 95% CI 4.4-NR) were not significantly different (p = 0.73). The median OS and 12-month OS rate was 26.2 mos (95% CI 21.4-NR) and 89%, respectively, but LPS pts had significantly worse OS (HR 3.5, p = 0.04). Twenty pts experienced at-least one grade (gr) 3 or 4 adverse event (AE); gr 3 or 4 AEs occurred in > 1 pt included hypertension (n = 4); hand-foot-syndrome (HFS) (n = 5), proteinuria (n = 3), febrile neutropenia (n = 3), neutropenia (n = 11, without G-CSF support). Compared to L 18mg/day, pts treated with RP2D were associated with lower gr3/4 HFS and hypertension. There were no sustained grade 3/4 AEs for pts receiving long-term L+E. **Conclusions:** L + E had shown promising efficacy in advanced LMS and LPS. L at 14mg (vs 18mg) had a better AE profile without compromising activity. Future randomized study to confirm the efficacy of the combination is warranted. Clinical trial information: NCT03526679. Research Sponsor: National Taiwan University Hospital Clinical Trial Center, Pharmaceutical/Biotech Company.

11507 **Oral Abstract Session**

A phase 1b study of unesbulin (PTC596) plus dacarbazine for the treatment of patients with locally recurrent, unresectable, or metastatic relapsed/refractory leiomyosarcoma. *First Author: Brian Andrew Van Tine, Siteman Cancer Center, Washington University in St. Louis, St. Louis, MO*

Background: Leiomyosarcoma (LMS) is one of the most common subtypes of soft tissue sarcoma and is associated with high risk of relapse and a poor prognosis for advanced disease. In preclinical LMS models, unesbulin, a microtubule polymerization inhibitor, potentiated the activity of dacarbazine (DTIC) (Jernigan F, et al. *Mol Cancer Ther.* 2021;20:1846–1857). Here, we report preliminary safety and efficacy results from a Phase 1b dose escalation study evaluating the combination of unesbulin with DTIC in patients with advanced LMS (NCT03761095). **Methods:** In this single-arm, open-label, Phase 1b clinical trial, patients with advanced LMS received unesbulin orally at 200, 300, or 400 mg twice weekly (BIW) in combination with intravenous DTIC at 1,000 mg/m^2 once every 21 days. The primary objectives were to determine the maximum tolerated dose (MTD) and recommended Phase 2 dose (RP2D) of unesbulin in combination with DTIC and to characterize the safety profile of the combination. The time-to-event continual reassessment model (TITE-CRM) was used for dose finding. An expansion cohort with up to 12 additional patients is currently being enrolled. **Results:** As of the data cutoff on January 6, 2022, 29 LMS patients have been treated. Median prior lines of therapy were 3 (range 1–6). Of 27 evaluable patients, 12 had non-uterine and 15 had uterine LMS. The MTD/RP2D of unesbulin was determined to be 300 mg BIW with DTIC 1,000 mg/m^2 every 21 days using the TITE-CRM. At the RP2D, the most common treatment-related adverse events included fatigue, diarrhea, neutropenia, and thrombocytopenia. In the intent-to-treat population, the overall response rate (ORR) was 17.2% (5/29) and the disease control rate (DCR) (DCR = complete response + partial response + stable disease at 12 weeks) was 58.6%. At the 300 mg dose level, the ORR was 19% (4/21) and the DCR was 57.1%. Patients received a median of four cycles (range 1–12). The study is ongoing, with patients continuing to receive treatment. **Conclusions:** Unesbulin 300 mg BIW in combination with DTIC 1,000 mg/m^2 every 21 days was well tolerated and demonstrated promising efficacy in a heavily pre-treated patient population with advanced LMS; these results support further investigation. Updated clinical results will be presented as the data mature. A randomized, placebo-controlled, Phase 2/3 trial is planned. Clinical trial information: NCT03761095. Research Sponsor: PTC Therapeutics.

11508 **Oral Abstract Session**

Neoadjuvant chemotherapy in high-risk soft tissue sarcomas: Results of the expanded cohort of myxoid liposarcoma of the randomized clinical trial from the Italian Sarcoma Group (ISG), the Spanish Sarcoma Group (GEIS), the French Sarcoma Group (FSG), and the Polish Sarcoma Group (PSG). *First Author: Alessandro Gronchi, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: An ISG, GEIS, FSG and PSG randomized trial on 3 cycles of neoadjuvant epirubicine+ifosfamide (EI) versus a histology-tailored (HT) regimen in selected localized high-risk STS showed some superiority of EI in all histologies with the exception of Myxoid Liposarcoma (MLPS) where EI and HT regimens seemed equivalent (J Clin Oncol 2020; 38:2178-86). This MLPS cohort was expanded with the aim to assess the non-inferiority of the HT regimen compared to EI. **Methods:** This was a multicenter European randomized trial comparing EI versus a HT regimen. Patients (pts) had localized high-risk (grade = 3; size >5 cm; deeply seated) undifferentiated pleomorphic sarcoma, leiomyosarcoma, malignant peripheral nerve sheath tumor, synovial sarcoma or MLPS of extremities or trunk wall. Primary end-point was Disease Free Survival (DFS). Secondary endpoint was Overall Survival (OS). The MLPS cohort was expanded after the results of the 3rd interim analysis (Lancet Oncol 2017; 18:812-22) in order to reject the hypothesis that HT regimen trabectedin is associated with a HR of relapse = 1.25 with a non-inferiority design. To this aim, a Bayesian monitoring approach was used until the probability that the true HR is higher than 1.25 was greater than 80% or smaller than 5%. **Results:** From May 2011 to June 2020, 101 pts affected by high-risk MLPS were randomized, 56 to EI and 45 to HT regimen. The median follow-up was 66 months (IQ range 37-89). Median size was 107 mm (IQ range 84-143), 108 mm (IQ range 86-150) in the EI and 106 mm (IQ range75-135) in the HT arm. The DFS and OS probabilities at 60 months were 0.86 and 0.73 (HR:0.60; 95%CI: 0.24-1.46; log rank p = 0.26 for DFS) and 0.88 and 0.90 (HR:1.20; 95%CI:0.37-3.93; log rank p = 0.77 for OS), in the HT and EI arm, respectively. 5-yr observed and Sarculator-predicted OS were 0.89 (95% CI 0.82-0.97) and 0.80 in all patients (p = 0.020), 0.90 (95% CI 0.81-1.00) and 0.79 in the EI arm (p = 0.049) and 0.88 (95% CI 0.77-1.00) and 0.81 in the HT arm (p = 0.204) respectively. **Conclusions:** In the expanded cohort of MLPS, the HT neoadjuvant therapy trabectedin was not inferior to EI. While survival in both arms was better than predicted by Sarculator, it is left to understand whether this patient population, who had on average a lower Sarculator-predicted risk of death compared with the rest of the trial population, may benefit from a neoadjuvant therapy. Clinical trial information: NCT01710176. Research Sponsor: Eurosarc FP7 278472.

11509 **Clinical Science Symposium**

Correlative results from NCI protocol 10250: A phase II study of temozolomide and olaparib for the treatment of advanced uterine leiomyosarcoma. *First Author: Sminu Bose, Columbia University Irving Medical Center, New York, NY*

Background: uLMS is an aggressive sarcoma subtype of smooth muscle origin. Chemotherapy provides limited benefit for advanced disease. 18-25% of uLMS harbor deleterious alterations in homologous recombination (HR) DNA repair genes. uLMS exhibits high levels of replicative stress. These findings prompted a phase 2 study of O+T in pretreated uLMS where O+T demonstrated activity: ORR 27%, mPFS 6.9 mos (Ingham M. et. al. ASCO 2021: #11506) **Methods:** NCI protocol #10250 is a single-arm, multicenter, phase 2 trial evaluating O+T in advanced uLMS pts with progression on ≥1 prior line. Pre-treatment (Pre) and on-treatment (On) biopsies were collected from 22 pts. In prespecified analysis, we evaluated for a relationship between clinical outcomes and HR gene alterations by whole exome sequencing (WES), SLFN11/MGMT expression by RNAseq, and RAD51 foci formation (functional assay). HRD scores were calculated from WES using scarHRD. Gene expression was evaluated using a Spearman rank-order correlation analysis to identify genes associated with PFS ($p < 0.01$) and overexpressed in sensitive (S: PFS > 240d) or resistant (R: PFS < 240d) pts. Gene set enrichment analysis (GSEA) was performed (q = FDR-adjusted p value). Pts with available results: WES/RNAseq (16), Pre HRD score (13), Pre RAD51 foci (12). **Results:** 31% (5/16) pts had a mutation (Mut) or homozygous deletion (Hd) in the HR panel: ATRX Mut (2), ATR Mut, PALB2 Hd, RAD51B Hd. Pts with PALB2 and RAD51B Hd had longest PFS on study. Recurrent alterations also occurred in TP53 (56%) and RB1 (19%). Median HRD score in Pre samples was 51 (range 36-66) and 10/13 had HRD scores ≥ 42. Pre and On SLFN11 and MGMT RNA expression were not correlated with ORR/PFS. 6/13 Pre samples were HR-deficient by the RAD51 foci assay. Of pts with PFS ≥ 200d, 4/6 were HR-deficient. In Pre samples, 81 genes were overexpressed in S pts and 73 in R pts. In On samples, 146 genes were overexpressed in S pts and 127 in R pts. In On samples, GSEA identified the epithelial-mesenchymal transition enriched in S pts (q = 3.38e-7) and cell cycle pathways (E2F targets, G2M checkpoint) in R pts (q = 7.43e-4). Only 2 genes, CXCL10 and PCDH15, were differentially expressed between paired Pre and On samples (both increased in On). Gene expression signatures for replicative stress showed borderline association with worse PFS. **Conclusions:** Most uLMS tumors exhibit HR defects as measured by HRD scores. A subset of pts with greater benefit from O+T were identified by WES for HR genes and the RAD51 assay. There was no correlation between SLFN11 and MGMT expression and outcomes. GSEA identified pathways differentially expressed in S and R pts in On samples. O+T induced CXCL10 which has been associated with T-cell trafficking to tumors. A randomized phase 3 trial of O+T versus investigator's choice is planned. These results provide insight into which pts may benefit most from this novel drug combination. Clinical trial information: NCT03880019. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

11510 **Clinical Science Symposium**

Presence of immune infiltrates, increased expression of transposable elements, and viral response pathways in sarcoma associate with response to checkpoint inhibition. *First Author: Benjamin Alexander Nacev, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Response to checkpoint inhibition (CPI) in sarcoma is overall low and varies between and within subtypes. Understanding tumor intrinsic determinants of this response may improve efficacy and patient selection. The de-repression of transposable elements (TEs), which are epigenetically silenced repetitive DNA elements of viral origin, is linked to anti-tumor immunity through an antiviral inflammatory response. We hypothesize that baseline expression of TEs and epigenetic regulators correlates with overall response rate (ORR) in sarcoma CPI clinical trials. **Methods:** This is a retrospective analysis of bulk RNA-sequencing data from pretreatment biopsies of patients on CPI trials in sarcoma (pembrolizumab plus talimogene laherparepvec, nivolumab plus bempegaldesleukin, and pembrolizumab plus epacadostat). Sixty-seven samples from unique patients representing 12 subtypes were analyzed. The MCP counter deconvolution method and unsupervised clustering were used to group samples by immune phenotypes resulting in immune 'hot' and 'cold' clusters. ORR was defined by RECIST. To determine if baseline expression of TEs and epigenetic regulators significantly predicted immune types, we implemented a lasso penalized logistic regression. **Results**: Immune 'hot' tumors were characterized by increased immune infiltrates including CD8+ T-cells, B-cells, and NK cells vs 'cold' tumors. Patients with 'hot' vs 'cold' tumors had an ORR of 30.5% (11/36) vs. 3.2% (1/31) (p = 0.003; chi-squared). The best predictors of 'hot vs 'cold' was the increased expression of multiple TE families including MER45A, MER57F, and LTR21B (respective lasso coefficients, 0.27, 0.07, and 0.07). Expression of *IKZF1*, a chromatin-interacting transcription factor, was also predictive (lasso coefficient, 0.35) and increased expression correlated with improved ORR (p = 0.003; unpaired t-test). TE and *IKFZ1* expression was significantly correlated with CD8+ T-cell signaling and antiviral response pathways such as cGAS-STING (MER57F, r^2= 0.43, padj = 1.75E-4; *IKZF1*, r^2= 0.63, padj = 6.28E-9) and type II interferon (MER57F, r^2= 0.67, padj = 2.51E-10; *IKZF1*, r^2= 0.60, padj = 7.19E-8). Increased expression of cGAS-STING (p = 3.9E-4; unpaired t-test) and type II interferon pathways (p = 1.89E-10; unpaired t-test) was significant in 'hot' tumors. **Conclusions:** Immune 'hot' baseline immune profiles of sarcoma are associated with improved ORR to CPI and with increased expression of TEs and *IKZF1*. These differences in gene expression correlate with increased inflammatory signaling, which suggests a response to TE-encoded viral-like sequences that are typically epigenetically silenced. Induction of TE de-repression and *IKZF1* expression through epigenetic targeting warrants pre-clinical investigation as a strategy to promote CPI response in sarcomas. 11511 **Clinical Science Symposium**

Phase II trial of palbociclib in advanced sarcoma overexpressing *CDK4* gene excluding dedifferentiated liposarcoma (DD LPS): A study from the Spanish Group for Research on Sarcoma (GEIS). *First Author: Javier Martin Broto, Health Research Institute-Fundación Jiménez Díaz University Hospital, Autonomous University of Madrid (IIS-FJD, UAM), Madrid, Spain*

Background: CDK4/6 inhibitors showed a favorable progression-free survival (PFS) in DD LPS, a sarcoma bearing 12q 13-15 amplicon that implies *CDK4* amplification. The median PFS was 4 and 7 months (m) for palbociclib and abemaciclib, respectively. Preclinical experiments in 10 sarcoma cell lines and 6 PDX models, including only one DD LPS, showed higher efficacy of anti-CDK4 in cases with high expression of CDK4 and low expression of p16. This rationale supported the design of a phase II trial exploring palbociclib in a wide range of sarcomas, excluding DD LPS. **Methods:** Progressing pretreated advanced soft tissue sarcoma, excluding DD LPS, or osteosarcoma adult patients (pts), whose tumors overexpressed *CDK4* and underexpressed *CDKN2A* mRNA in a baseline mandatory biopsy, were enrolled. *CDK4* and *CDKN2A* expression were assessed by qRT-PCR, using an external control as reference (Universal human reference RNA; Agilent Technologies). The primary endpoint was 6-m PFS rate. Minimax Simon's two-stage with type 1 and 2 errors of 10%, and null and alternative hypothesis of H0 15%, H1 40%, 6-month PFS rates were specified. The study will warrant further investigation if 6 or more pts had a PFS > 6 m from 21 evaluable pts. Palbociclib was administered orally at 125 mg/ day 21 out of 28 days. Pre-screening intended to increase the probability of positive profile in the baseline biopsy. **Results:** A total of 214 pts with 236 *CDK4/ CDKN2A* determinations were assessed for enrolment; 141 for prescreening, in archive tumor sample, and 95 for screening, in a baseline biopsy. There were 38/141 (27%) and 28/95 (29%) pts with favorable mRNA profile from pre and screening, respectively. Twenty-two pts were enrolled with a median of previous systemic lines of 3 (1-5). There were 9 different sarcoma subtypes, including 2 osteosarcomas. With a median FU of 10 m (0.4-23.3), the median PFS was 4.2 m (95% CI 0.9-7.4), while the 6- and 12-m PFS rates were 30% (95% CI 9-51) and 18% (95% CI 12-48) respectively. From 19 evaluable pts (1 early death by COVID, 1 withdrew consent and for 1 it was too early to be assessed) 11 had stable disease (58%) and 8 progressed (42%) as the best response. Patients with CDK4 expression above the median value had significantly longer mPFS in the univariate analysis: 5.9 m (95% CI 1.4-10.4) vs 1.9 m (95% CI 0.6-3.2), p = 0.046; and longer OS: 15.5 m (95% CI 6.8-24.3) vs 10.6 m (95% CI 0-23.2), p = 0.047, respectively. The probability to find a positive profile in the screening was 29%, but this proportion increased up to 41% if in pre-screening had been positive. **Conclusions:** Palbociclib showed to be effective in a wide variety of sarcoma subtypes, other than DD LPS, selected by *CDK4/ CDKN2A* biomarkers. Clinical trial information: NCT03242382. Research Sponsor: Spanish group for research on sarcoma (GEIS), Pharmaceutical/Biotech Company.

11512 **Poster Discussion Session**

A phase 1, multicenter, open-label, first-in-human study of DS-6157a in patients (pts) with advanced gastrointestinal stromal tumor (GIST). *First Author: Suzanne George, Dana-Farber Cancer Institute, Boston, MA*

Background: GPR20 is selectively and abundantly expressed in GISTs, the most common sarcoma of digestive tract. DS-6157a is an anti-GPR20 antibody-drug conjugate with a novel tetrapeptide-based linker and DNA topoisomerase I inhibitor exatecan derivative (DXd). The target drug-to-antibody ratio is ~8. The DXd payload, when released, inhibits topoisomerase I and induces cell apoptosis. **Methods:** This study conducted in the US and Japan was designed to include a dose-escalation (Part 1) and a dose-expansion (Part 2) in adult pts with advanced GIST (NCT04276415). Part 1 evaluated safety, tolerability, efficacy, and pharmacokinetics (PK) to determine the maximum-tolerated dose (MTD) and/or recommended dose for expansion. Key eligibility criteria included ECOG PS of 0 or 1, measurable disease per RECIST v1.1, and adequate bone marrow, hepatic, and renal function. DS-6157a was administered every 3 weeks as monotherapy. Pts had tumor assessments per RECIST 1.1 every 6 weeks (wks) for 36 wks, then every 9 wks thereafter. **Results:** At data cutoff, 34 pts were available for full analysis: median treatment duration was 9.9 wks (range, 3-56 wks) and 5 pts (14.7%) were ongoing; median age 60.5 years (y) (range, 29-81 y); 19 pts (56%) were male; 47% of pts were Asian and 47% were white. Baseline GPR20 expression was highly prevalent, and dose-dependent PK exposure was confirmed within the range of dose levels. The MTD was 6.4 mg/kg. One pt with SDH-deficient GIST with both SDH B and NF1 mutations, had a confirmed PR with shrinkage of -75%; 18 pts (53%) experienced stable disease and 10 pts (29%) experienced progressive disease as best response. Median progression-free survival across all dose levels was 3.6 months (95% CI, 1.6, 6.9). Treatment-emergent AEs (TEAEs) occurred in all pts and treatment-related TEAEs (TRAEs) in 32 pts (94%). The most common (≥25%) all-grade (Gr) TEAEs were nausea (82%), decreased appetite (59%), fatigue (47%), anemia (44%), constipation (38%), decreased platelets (35%), and vomiting (32%). Gr ≥3 TRAEs occurred in 14 pts (41%); the most common were decreased platelets (21%) and anemia (18%). Serious TEAEs (SAEs) occurred in 9 pts (27%) and related SAEs in 4 pts (12%). Related Gr 4 SAEs in 2 pts included abnormal hepatic function, neutropenia, thrombocytopenia and leukopenia. There was 1 treatment related death (hepatic failure). Further investigations are on-going to understand the modest clinical efficacy observed. The study did not proceed to Part 2, because the data from Part 1 did not meet efficacy targets. **Conclusions:** DS-6157a was generally well tolerated with early signs of moderate clinical activity. While there were no objective responses in pts with KIT-mutant GIST, tumor shrinkage was observed in all 4 pts with KIT wild-type GIST treated at different doses, including a confirmed PR at the MTD in a pt with SDH-deficient GIST with both SDH B and NF1 mutations. Clinical trial information: NCT04276415. Research Sponsor: Daiichi Sankyo, Inc.

11513 **Poster Discussion Session**

Promising antitumor activity of olverembatinib (HQP1351) in patients (pts) with tyrosine kinase inhibitor- (TKI-) resistant succinate dehydrogenase- (SDH-) deficient gastrointestinal stromal tumor (GIST). *First Author: Haibo Qiu, Sun Yat-Sen University Cancer Center, Guangzhou, China*

Background: GIST is a rare mesenchymal tumor whose management has been transformed by approvals of TKIs. However, treatment resistance is a formidable challenge in managing locally advanced or metastatic GIST. Pts with SDH-deficient GIST are not sensitive to imatinib and other TKIs, are frequently multifocal, and typically have a multinodular architecture. Olverembatinib is a novel, potent, orally active third-generation TKI with promising activity against GIST in multiple preclinical GIST models. **Methods:** The aim of this phase Ib/II study was to evaluate the safety/tolerability, pharmacokinetics (PK), and efficacy (assessed per RECIST v1.1) of olverembatinib (NCT03594422) in pts with metastatic GIST whose disease was resistant or failed to respond to imatinib or other TKIs. Olverembatinib was administered orally once every other day (QOD) in 28-day repeated cycles. After 3 pts were treated at 20 mg, other pts were randomly allocated in a 1:1:1 ratio to 30, 40, and 50 mg regimens. **Results:** On the cutoff date of January 30, 2022, 39 pts (median age 52 [range 19-72] years) had received at least 1 dose of olverembatinib. The average (range) treatment period was 5.0 (0.2-35) months. PK analyses indicated an approximately dose-proportional increase in systemic exposure over the dose range of 20 to 50 mg. Thirty-one pts had *KIT* or *PDGFRA* mutations, 13 had stable disease for at least 2 cycles as the best response, 8 withdrew early, and 10 had progressive disease before Cycle 3. Very interestingly, 6 of 8 pts with *KIT* wild-type GIST were confirmed as SDH deficient: 2 pts had partial responses (PRs), 1 patient's tumor had shrunk by 35.9% and lasted for 16 cycles, and another patient's tumor had shrunk by 54.2% in the first evaluation. Four pts had stable disease as best response for 2, 6, 14, and 36 cycles. A total of 36 (92.3%) pts experienced treatment-emergent adverse events, most of which were mild or moderate. Ten (25.6%) pts experienced serious adverse events, of which intestinal obstruction attributed to GIST was the most reported. Common treatment-related adverse events (≥ 20%) included increased leukocyte (59.0%) and neutrophil (46.2%) counts, anemia (20.5%), constipation or asthenia (35.9% each), hyperuricemia (25.6%), hypoalbuminemia (23.1%), and elevated AST or ALT (20.5% each). **Conclusions:** Olverembatinib was well tolerated at doses of up to 50 mg QOD and showed antitumor activity in pts with TKI-resistant SDH-deficient GIST, with 2 PRs in 6 evaluable pts with SDH-deficient GIST and 1 with stable disease for 36 cycles. These promising findings warrant further investigation. Clinical trial information: NCT03594422. Research Sponsor: Ascentage Pharma Group Corp Ltd (Hong Kong).

11514 **Poster Discussion Session**

***KIT* resistance mutations identified by circulating tumor DNA and treatment outcomes in advanced gastrointestinal stromal tumor.** *First Author: Steven Bialick, University of Miami Miller School of Medicine/Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Tyrosine kinase inhibitors (TKIs) are the cornerstone treatment for advanced GIST via pharmacologic targeting of driver oncogenes such as *KIT*. Detection of *KIT* alterations through tissue-based next-generation sequencing (NGS) is common, but circulating tumor DNA (ctDNA)-based NGS is a less invasive alternative to identify driver and resistance mutations in advanced GIST. Patients (pts) with *KIT*-mutant GIST benefit from first-line (1L) imatinib; however, *KIT* resistance mutations may confer imatinib-resistance and differential sensitivity to subsequent TKIs. We sought to analyze ctDNA from GIST pts to determine whether certain resistance mutations were associated with superior outcomes with particular TKIs in the second-line and beyond (2L+). **Methods:** Under an approved institutional review board protocol, a retrospective analysis was performed with available ctDNA NGS results (Guardant360; Redwood City, CA) from pts (N = 104) who progressed on 1L imatinib between 2017-21. Using R statistical programming, we identified pts with primary *KIT* alterations (N = 64) and known resistance mutations in *KIT* exons 13 (N = 25) and 17 (N = 35). We studied the median time to treatment failure (mTTF), defined as the time from treatment start to treatment end (months) due to progressive disease or toxicity, for each 2L+ drug. Using Kaplan-Meier methods, we calculated Cox proportional-hazard ratios (HR) with confidence intervals (CI) and p-values for statistical significance. **Results:** 49% were male (median age 66; range, 31-94). Driver oncogenes were detected in 80% (N = 83), including *KIT*, *NF1*, *PDGFRA* and *BRAF*. Of those with a *KIT* alteration, 12 (19%) had *KIT* exon 9 mutations and 52 (81%) had *KIT* exon 11 mutations. *KIT* resistance mutations were observed in *KIT* exons 13 (N = 25; V654), 14 (N = 2; T670), and 17 (N = 45; D816, D820, N822, Y823). Pts with *KIT* resistance mutations received 2L+ therapy with avapritinib, dose-escalated imatinib, nilotinib, pazopanib, ponatinib, regorafenib, ripretinib, or sunitinib. mTTF for *KIT* exon 13 V654 pts treated with 2L+ sunitinib, imatinib 800mg, or other was 10.8, 7.5, and 3.7 months, respectively. TTF for sunitinib vs other 2L+ drugs showed a HR of 0.51 (CI 0.33-0.8), p = 0.003. mTTF for *KIT* exon 17 (non-V654) pts treated with 2L+ regorafenib, imatinib 800mg, or other was 4.6, 1.2, and 6.3 months, respectively. Comparison of mTTF for regorafenib vs other 2L+ drugs was not statistically significant. **Conclusions:** ctDNA is a noninvasive tool for detecting driver and resistance mutations in pts with advanced GIST. GIST pts with *KIT* exon 13 V654 resistance mutations had superior outcomes in the 2L+ setting with sunitinib. Regorafenib was not superior to other 2L+ TKIs in pts with *KIT* exon 17 resistance mutations, possibly due to their own activity against exon 17 resistance alterations. ctDNA-guided therapy warrants evaluation in a prospective clinical trial. Research Sponsor: None.

11515 **Poster Discussion Session**

INT230-6 monotherapy and in combination with ipilimumab (IPI) across a broad spectrum of refractory soft tissue sarcomas (STS) [Intensity IT-01; BMS#CA184-592]. *First Author: Matthew Ingham, Columbia University Irving Medical Center, New York, NY*

Background: INT230-6 is a novel intratumoral (IT) agent with a dual anti-cancer mechanism (tumor cytoreduction while stimulating antigen presentation and recruitment of T-cells). The drug is comprised of cisplatin (CIS) and vinblastine (VIN) co-formulated with an amphiphilic molecule that enables drug dispersion throughout tumors and passive diffusion into cancer cells following IT delivery. In the neoadjuvant setting, a single injection can cause necrosis in > 95% of the tumor and recruit TILs. Combining with anti-CTLA-4 improved responses in preclinical models. **Methods:** INT230-6 dose is set by the tumor's longest diameter and is proportional to the injected disease volume. INT230-6 is administered IT Q2W for 5 treatment sessions followed by maintenance every 9 weeks as monotherapy or with IPI 3mg/kg IV Q3W for 4 doses. Biopsies from injected tumors are obtained pretreatment and Day 28 for immunoprofiling. **Results:** 22 subjects with various advanced STS histologies with a median age of 64 and a median of 3 prior systemic therapies were enrolled (11 INT230-6 alone, 11 IPI combination). There were 178 image-guided IT INT230-6 injections (107 to deep tumors) at INT230-6 doses ranging from 5 to 242 mL (121mg CIS, 24.2mg VIN, doses which vastly exceed the usual IV doses of these drugs). PK analysis showed that > 95% of drug agents remain in the tumor. The most common (> 25%) all-grade related adverse events (AEs) in evaluable monotherapy subjects (n = 10) were pain (80%), decreased appetite (40%), nausea (40%), anemia (30%), fatigue (30%) and vomiting (30%). Tolerability was similar for the combination with IPI. Most events were low grade. The incidence of grade 3 AEs for the INT230-6 arm was 30% and for the IPI combination was 10%. There were no related grade 4 or 5 AEs in either cohort. RECIST metrics may not accurately reflect clinical benefit with this treatment given large volumes of INT230-6 is repeatedly injected into a tumor and local inflammation may occur. Paired biopsies showed reduction in proliferating tumor cells and an increase in T-cell infiltrates. The disease control rate at the first imaging timepoint for evaluable INT230-6 subjects (n = 9) was 56% and for evaluable IPI combination (n = 5) was 80%. Abscopal effects were seen in 2 monotherapy subjects, though most uninjected tumors were not tracked. The estimated 1-year overall survival was 88% for the IPI combo and 60% for the monotherapy cohort. **Conclusions:** IT INT230-6 is well tolerated as monotherapy and combined with IPI. STS, which is typically not sensitive to immunotherapy, may be amenable to INT230-6 or IPI combo to create antigens and promote a systemic immune response. Preliminary efficacy using INT230-6 alone is encouraging and will be evaluated in a global phase 3 trial. Further evaluation is needed to determine whether the addition of IPI may improve patient outcomes. Clinical trial information: NCT03058289. Research Sponsor: Intensity Therapeutics, Inc.

11516 **Poster Discussion Session**

A phase I/II trial of the PD-1 inhibitor retifanlimab (R) in combination with gemcitabine and docetaxel (GD) as first-line therapy in patients (Pts) with advanced soft-tissue sarcoma (STS). *First Author: Evan Rosenbaum, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In a phase III trial, GD had similar response and survival rates to doxorubicin when administered as first-line therapy to advanced STS pts. G and D have each demonstrated synergy with PD-1 blockade in pre-clinical or clinical studies. We hypothesized that GD plus R would be safe, tolerable, and have synergistic activity in STS. **Methods:** This is an ongoing open-label, single-center, phase I/II trial of R (INCMGA00012) combined with GD in pts with treatment-naïve unresectable or metastatic high-grade STS. Herein, we report the phase I results, which included a safety run-in followed by a 3+3 dose de-escalation design. G (900 mg/m^2) was administered on days 1 and 8 and D (75 mg/m^2) on day 8, in 21-day cycles. R (210 mg IV flat dose on the run-in portion and 375 mg on the dose de-escalation portion) was administered on day 1 of each cycle starting in cycle 2 and continued as monotherapy after completion of 6 cycles of GD. The primary endpoint of the phase I was to determine the recommended phase 2 dose (RP2D) of R plus GD. Secondary endpoints included describing the safety, assessing best overall response rate (ORR) by RECIST 1.1, disease control rate (DCR), and progression-free survival (PFS). **Results:** Thirteen pts were treated, 7on the run-in and 6 on the de-escalation portion. One pt progressed prior to starting R and was replaced. Median pt age was 53 (range 28 – 74) and 7 were female. Histologies included leiomyosarcoma (n = 6), undifferentiated pleomorphic sarcoma (2), dedifferentiated liposarcoma (2), pleomorphic liposarcoma (1), angiosarcoma (1), and myxofibrosarcoma (1). The Table lists treatment-related adverse events (TRAEs) that occurred in ≥ 20% pts in descending order of frequency. Additional Grade (Gr) 3 TRAEs occurring in 1 pt each, included: infusion reaction, leukopenia, anorectal infection, neutropenia, and pyelonephritis. Gr 3 pyelonephritis was the only dose-limiting toxicity. There were no Gr ≥ 4 TRAEs. One pt (Gr 3 elevated AST/ALT) required corticosteroids and cessation of study therapy. The RP2D was determined to be 375 mg of R plus GD. Twelve pts were evaluable for response. ORR was 17% (1 of 6; 95% CI 1 - 64%) and 50% (3 of 6; 95% CI 19% - 81%) in the run-in and de-escalation cohorts, respectively. DCR was 100% (6 of 6; 95% CI 52 - 100%) and 83% (5 of 6; 95% CI: 36 - 99%). PFS rates at 24 weeks were 60% (95% CI: 29 - 100%) and 44% (95% CI: 17 - 100%). **Conclusions:** R plus GD was generally safe and well tolerated with no unexpected safety signals to date. The phase II portion evaluating efficacy of R plus GD at the RP2D is ongoing. Clinical trial information: NCT04577014. Research Sponsor: Incyte Corporation.

11517 **Poster Discussion Session**

Interim analysis of a phase I study of SNK01 (Autologous Nongenetically Modified Natural Killer Cells with Enhanced Cytotoxicity) and avelumab in advanced refractory sarcoma. *First Author: Sant P. Chawla, Sarcoma Oncology Research Center, Santa Monica, CA*

Background: For patients (pts) with advanced sarcomas in the relapsed/refractory setting, there are very few if any effective salvage treatment options. The likelihood of response and/or tumor control only diminishes with each subsequent line of therapy. Monotherapy of PD-L1 inhibitors has shown modest to no activity in most sarcomas, especially in tumors that have little to no PD-L1 expression. Natural killer (NK) cells have recently been implicated in the antitumor response to immune checkpoint inhibitors with some evidence suggesting a role in PD-L1 negative tumors. SNK01 is a first-in-kind, autologous nongenetically modified NK cell therapy with highly enhanced cytotoxicity and over 90% activating receptor expression which can be consistently produced from heavily pretreated pts. Avelumab is an anti-PD-L1 immunotherapy with dual engagement of both the adaptive and innate immune systems. We hypothesized that this combination would be safe, and together better overcome the immunosuppressive tumor microenvironment. **Methods:** In this Phase I study (NCT03941262), cohort 4 is comprised of up to 18 pts treated with 800 mg of avelumab + 4 x 10^9 SNK01 cells every two weeks via IV Infusion. Pts were eligible regardless of PD-L1 status and permitted to continue treatment indefinitely until progression or unacceptable toxicity. The primary endpoint is safety. The secondary endpoints include overall response rate (ORR), progression free survival (PFS), and overall survival (OS). **Results:** As of February 1, 2022, 15 pts with advanced refractory sarcoma have been enrolled. Median age is 50 (range 20-75) and 8 were male. Pts had a median of 5 lines of prior therapy (range 1-8). The subtypes included 6 leiomyosarcoma, 2 osteosarcoma, 1 pleomorphic liposarcoma, 1 Ewing's sarcoma, 1 epithelioid sarcoma, 1 epithelioid mesothelioma, 1 endometrial stromal sarcoma, and 1 sarcoma NOS. There were three Grade 2 or 3 adverse events related to avelumab, but unrelated to SNK01. Best objective response by RECIST 1.1 was PR in 2 pts (ORR of 13.3%) and SD in 3 pts. Median PFS is 11.14 weeks. Several pts had PD-L1 negative disease and response appears to be independent of PD-L1 status. Of pts who progressed in this cohort, several reported an overall improvement in their QoL and some pts became eligible to be treated with additional salvage chemotherapy, resulting in some additional clinical response. **Conclusions:** SNK01 combined with avelumab was safe and well tolerated and appears to have some clinical activity against several types of heavily pretreated advanced sarcoma, independent of PD-L1 status. It may also keep rapidly progressing disease stable enough to allow additional cytotoxic chemotherapy. A proposed study expansion is planned. Clinical trial information: NCT03941262. Research Sponsor: NKGen Biotech.

11518 **Poster Discussion Session**

GALLANT: A phase 2 study using metronomic gemcitabine, doxorubicin, nivolumab, and docetaxel as second/third-line therapy for advanced sarcoma (NCT04535713). *First Author: Noufil Adnan, Sarcoma Oncology Center, Santa Monica, CA*

Background: In our experience, combinatorial therapy with lower doses of doxorubicin, gemcitabine, and docetaxel has been effective with a manageable toxicity profile in patients with advanced soft tissue sarcomas. Hypothesis: The addition of nivolumab will have synergistic effects and improve treatment outcomes. **Methods:** Primary objective: To assess progression-free survival; Secondary objectives: (1) To evaluate best overall response during treatment period confirmed in a 6-week follow-up, (2) PFS rate at 6 and 9 months, (3) Overall survival rate at 6, 12 months, and (4) Incidence of treatment-related adverse events (TRAEs). Inclusion criteria: Previously treated male and female subjects, > 18 years of age, pathologically confirmed diagnosis of locally advanced, unresectable, or metastatic sarcoma, measurable disease by RECIST v1.1, and acceptable hematologic and organ functions. Exclusion Criteria: History of autoimmune disorder. Treatment schedule: Metronomic doses of gemcitabine (600 mg/m2 max:1000 mg), doxorubicin (18 mg/m2; max: 32 mg), docetaxel (25 mg/m2; max:42 mg) on Day 1 and Day 8, and nivolumab (240 mg) on Day 1 only. Repeat treatment cycles may be given every three weeks if toxicity grade is <1. **Results:** This is an Interim Report on the modified Intent-to-treat population (n = 43). This population completed at least one treatment cycle and had a follow-up CT or MRI scan at week 6. The most common histological subtypes in this group include leiomyosarcoma (n = 15), pleomorphic sarcoma (n = 4), synovial sarcoma (n = 4), liposarcoma (n = 3), osteosarcoma (n = 3) and other (n = 10). Best Overall Response = 2 CR (surgical CR), 6 PR, 30 SD, 5 PD. The disease control rate (CR+PR+SD) was 88.4%. Median PFS was > 4.6 (range: 1-27) months; 4 month PFS rate 60%. Median OS 6.2 months, with 4-month OS 74%. Historically, the median PFS on preceding lines of therapy was 2 (range: 1-14) months. There were no unexpected side effects noted in this study. The most common grade 3/4 TRAEs include Fatigue (n = 13), Nausea (n = 9), Neutropenia (n = 8), thrombocytopenia (n = 6), Anemia (n = 6). **Conclusions:** The GALLANT protocol using metronomic Gemcitabine, Doxorubicin (Adriamycin), Nivolumab, and Docetaxel (Taxotere) (1) is an effective regimen as second/third-line therapy for advanced sarcoma with no unexpected side effects, and (2) may have synergistic activity when this metronomic chemotherapy is combined with an immune checkpoint inhibitor. Clinical trial information: NCT04535713. Research Sponsor: None.

11519 **Poster Discussion Session**

Phase I study of pegylated liposomal doxorubicin in combination with cyclophosphamide and vincristine in pediatric patients with relapsed/refractory sarcoma and other malignant solid tumors. *First Author: Suying Lu, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Pegylated liposomal doxorubicin (PLD) was found to have improved toxicity profile, especially with regards to reduced cardiotoxicity. The objectives of this study were to determine the maximum tolerated dose (MTD) and recommended phase 2 dose (RP2D) of PLD in combination with cyclophosphamide and vincristine (PCV regimen) and describe the toxicities and response of this regimen. **Methods:** This was an open-label, single-center, single-arm phase I study utilizing a "3 + 3" design. The primary endpoint was the MTD of PLD, and the secondary endpoints included safety, objective response rate (ORR), disease control rate (DCR), and progression-free survival (PFS). Efficacy was evaluated using RECIST 1.1. PFS was defined as the time from treatment until disease progression or death. This study included cohort A and cohort B. Three dose levels were studied in cohort A, PLD 30 mg/m^2 (L1), 40 mg/m^2 (L2) or 50 mg/m^2 (L3) d1 + cyclophosphamide and mesna at 1 g/m^2/d d1-2 + vincristine 1.5 mg/m^2/d (≯2mg) d1 every 3 weeks. As the endpoint of the study could not be reached, we changed the dose of cyclophosphamide and mesna to 1.5 g/m^2/d d1 in cohort B. **Results:** Eleven in cohort A and 34 in cohort B were enrolled, the median age was 6 years (range 1-15). Forty-three patients were eligible and evaluable for toxicity, and 35 (77.8%) patients were evaluable for response. Diagnoses were rhabdomyosarcoma (n = 29, 64.4%), Ewing's sarcoma (n = 4), and others. The median number of prior regimens was 2 (range 1-5). The most common adverse event (AE) was grade 3 or grade 4 neutropenia with a proportion of 90.9% and 65.5% in cohort A and cohort B, respectively. There was no significant difference in ORR (60% vs. 48%) and DCR (90% vs. 88%) between the two cohorts. The ORR (60% vs. 0, P = 0.019) and DCR (96.7% vs. 40%, P = 0.006) were significantly higher in Group 1 (rhabdomyosarcoma, Ewing's sarcoma, Wilm's tumor, fibrosarcoma, undifferentiated sarcoma) compared with Group 2 (neuroblastoma, osteosarcoma, embryonal sarcoma, epithelioid sarcoma, extrarenal rhabdoid tumor). The 12-month PFS of Group 1 was also better than Group 2 (79% vs. 60%, P = 0.041). **Conclusions:** The PCV regimen demonstrated an acceptable toxicity profile and promising clinical efficacy in pediatric patients with R/R rhabdomyosarcoma, Ewing's sarcoma, Wilm's tumor, fibrosarcoma, and undifferentiated sarcoma. Increasing the dose of cyclophosphamide did not improve the efficacy, but increased the toxicity. The RP2D for future studies is PLD 30 mg/m^2/d for one day. Clinical trial information: NCT04213612. Research Sponsor: None.

Response	Cohort A (n = 10)	Cohort B (n = 25)	P	Group 1 (n = 30)	Group 2 (n = 5)	P

Gemcitabine-docetaxel in patients with relapsed high-grade osteosarcoma after first-line treatment with high-dose ifosfamide: A retrospective multicenter study. *First Author: Maria Grazia Pionelli, Pediatric Onco-Hematology, A.O.U Città della Salute e della Scienza, University of Turin, Torino, Italy*

Background: Currently, there is no accepted standard chemotherapy regimen for recurrent osteosarcoma. We performed a retrospective study to evaluate the effectiveness, toxicity and clinical benefit of second line therapy with Gemcitabine (G) in combination with Docetaxel (D), in patients with relapsed high-grade osteosarcoma who have been previously treated with High-dose Ifosfamide (HD-IFO) during first-line treatment (ClinicalTrials ID: NCT04651179). **Methods:** Patients were eligible to the analysis according to the following criteria: episode of first relapse of osteosarcoma, previous first line treatment according to poor responders' arm of ISG-AIEOP OS 2 Protocol based on methotrexate, cisplatin, doxorubicin and HD-IFO (3gr/m2/day, day 1-5) ± Mifamurtide, presence of measurable disease according to RECIST 1.1, treatment with at least two cycles of Gemcitabine 900 mg/m2/day, days 1 and 8 and Docetaxel 75 mg/m2 day 8 every 21 days. Primary objective: overall survival (OS) at 12 months; secondary objectives: overall response rate (ORR) (complete response + partial response), progression-free survival (PFS) at 6-12 months, toxicity and quality of life. **Results:** 14 patients were included in the analysis. All patients were previously treated according to poor responders' arm of ISG-AIEOP OS 2 Protocol, 7/14 (50%) of them received Mifamurtide. Most of patients (12/14, 86%) received 4 GD cycles and the total number of cycles administered was 60. Median OS was 20 months (range 11-69); OS at 12 and 24 months was 84% (95% CI 65-100) and 51% (95% CI 22-79), respectively; ORR were 35,7% after six cycles. Median PFS was 12 months (range 2-69); 6-months and 12-months PFS were 86% (95% CI 67-100) and 56% (30-83) respectively. For 8/14 (57%) patients a surgical approach was feasible after 2 and 6 GD cycles. Previous use of Mifamurtide correlate with a better 6-months PFS rate (100% vs 57%, P = 0.0011). Also, amelioration of ECOG/Lansky score showed a positive correlation with both PFS (P = 0.01) and OS (P = 0.04). No extra-hematological toxicities grade ≥3 was observed according to CTCAE v4.03 criteria. **Conclusions:** This trial confirms that GD combination has an anti-tumor activity for relapsed high-grade osteosarcoma with a well-tolerated toxicity profile. Furthermore, GD guarantee a surgical tumor remotion for patients with a chemo-resistant disease such as patients previously treated with a poor responders' arm improving their OS and PFS rate. Promising results for patients previously treated with Mifamurtide need to be confirmed in future trials. Clinical trial information: NCT04651179. Research Sponsor: None.

11521 **Poster Discussion Session**

NRG-DT001 phase Ib trial of neoadjuvant navtemadlin (previously AMG232 and KRT232) concurrent with preoperative radiotherapy in wild-type p53 soft tissue sarcoma of the extremity and body wall. *First Author: Meng Xu Welliver, The Ohio State University James Cancer Center, Columbus, OH*

Background: NRG-DT001 is a phase Ib trial evaluating neoadjuvant navtemadlin with preoperative radiation therapy (RT) in patients (pts) with wild-type (WT) p53 soft tissue sarcoma (STS). The primary objective is to evaluate the safety and tolerability of the MDM2 inhibitor navtemadlin in combination with standard-dose RT in STS in two cohorts (A, extremity or body wall; B, abdomen/pelvis/retroperitoneum) to determine the maximum tolerated dose/recommended phase II dose (MTD/RP2D) of navtemadlin in combination with RT. This report contains the results for cohort A. **Methods:** Eligible pts had grade 2-3 STS ≥ 5 cm, age ≥ 18, and Zubrod performance status 0-1. Dose levels were 120 mg 2x/week (DL-1), 120 mg 3x/week (DL1), 4x/week (DL2), and 5x/week (DL3) 1 week prior to and during RT (50Gy/5 weeks). Surgery was 5-8 weeks after RT. A 3+3 design was used to make dose escalation/de-escalation decisions at each dose level. Five additional pts were enrolled to the MTD to ensure safety (expansion cohort) with a dose limiting toxicity (DLT) rate of ≤ 1/5 considered safe. The DLT observation period was from the start of navtemadlin until 4 weeks after completion of drug+RT. Tumor Tp53 mutation status was determined by NGS sequencing. All eligible and treated p53 WT pts who experienced DLT or completed the observation period were considered DLT-evaluable. DLT included all grade 4-5 AE definitely, probably, or possibly related to navtemadlin. Any grade 3 AE definitely, probably, or possibly related to navtemadlin was also considered DLT if any of the 2 following situations occurred: a delay of treatment > 2 weeks or ≥ 2 dose reductions due to the grade 3 AE. The decision to escalate or de-escalate was made by consensus of the study team in accordance with the protocol. **Results:** Between 11/3/2017 and 9/10/2021, 4 (3 WT), 7 (4 WT) and 7 (4 WT) pts were enrolled at DL1, DL2, and DL3 respectively. An additional 9 (5 WT) pts were enrolled on DL3 expansion cohort. Preoperative RT was completed for all except 1 pt (pt refusal/DL3). On DL1 and DL2, 100% of pts completed navtemadlin. On DL3 (including expansion cohort), 78% (7/9) completed navtemadlin (1 AE, 1 pt refusal). On DL1, DL2, and DL3, 3/3, 3/4 (1 disease progression), and 5/6 (1 consent withdrawal; 3 pending) completed surgery. There were no DLTs in any dose level (DL1 0/3, DL2 0/4, DL3 0/9), establishing DL3 as the MTD/RP2D. Tumor necrosis rates will be reported at the time of presentation. **Conclusions:** Neoadjuvant navtemadlin concurrent with standard dose preoperative RT is well tolerated in patients with WT p53 STS at extremity or body wall, and the 120 mg PO daily of navtemadlin, 5 days per week dose should be used to design future trials of RT with extremity STS. Incorporating NGS sequencing results as an integral biomarker in a clinical trial of neoadjuvant radiotherapy and a radiosensitizer is feasible. Clinical trial information: NRG-DT001 NCT03217266. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Preliminary results of a phase IB study of olaparib with concomitant radiotherapy in locally advanced/unresectable soft-tissue sarcoma from the French Sarcoma Group. *First Author: Paul Sargos, Institut Bergonié, Bordeaux, France*

Background: The poly(ADP-ribose) polymerase (PARP) inhibitor olaparib (O) has radiosensitizing properties in several tumor models including sarcomas. We studied safety and activity of O with external beam radiation therapy (EBRT) in patients with locally advanced soft-tissue sarcomas (STS). **Methods:** This phase I study first assessed four dose levels (DL1:25 mg, DL2:50 mg, DL3:100 mg, DL4:150 mg BID) of O administered in combination with EBRT (59.4 Gy in 33 fractions of 1.8 Gy) using a TITE-CRM design. Next, we recruited 15 additional patients in an expansion cohort to assess the tumor response or the histological response for patients with resectable disease. Tumor response was assessed by investigators according to RECIST 1.1 criteria. **Results:** A total of 41 patients (17 men, 24 women) were enrolled in both cohorts, of whom 19 (46.3%) underwent post-treatment surgery. We observed 1 DLT at DL1 (n = 5), 1 at DL2 (n = 7), 0 at DL3 (n = 11) and 1 at DL4 (n = 3) during the dose escalation. The recommended dose (RP2D) was 100 mg BID. Most common adverse events related to O and/or EBRT were acute dermatitis (G1/2 63.4% of patients, G3/4 34.1%), edema limbs (G1/2 36.6%), fatigue (G1/2 36.6%), nausea (G1/2 31.7%) and myositis (G1/2 29.3%). Among the 22 patients assessed for tumor response, 3 unconfirmed partial responses, 12 stable diseases, 5 progressive diseases, and 2 non-evaluable responses were recorded as best overall responses. The 6-month non-progression rate in that population was 9.1% [95%CI 1.1%-29.2%]. Six (31.6%) good histological responses and 9 (47.4%) poor responses were observed on the 19 patients who underwent surgery (4 responses non-available). **Conclusions:** This study shows that the combination of O with EBRT is well tolerated and lead to encouraging down-staging. A little less than half of the population was able to benefit from surgery with positive results in more than 30% of the cases and the rest of the population showed a promising stability of the disease at 6 months. We are currently awaiting a minimum of one year follow-up for the expansion cohort to assess survival. Clinical trial information: NCT02787642. Research Sponsor: Institut National du Cancer (INCa, Clip^2 program).

11523 **Poster Discussion Session**

Results of a phase I dose escalation and expansion study of tegavivint (BC2059), a first-in-class TBL1 inhibitor for patients with progressive, unresectable desmoid tumor. *First Author: Lee D. Cranmer, University of Washington/Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Desmoid tumors are known to have increased nuclear β-catenin levels. Tegavivint selectively disrupts the interaction of β-catenin and TBL1/ TBLR1, resulting in specific degradation of nuclear β-catenin. The primary objectives of this study were to determine the maximum tolerated dose (MTD), safety, and preliminary efficacy of tegavivint in patients (pts) with desmoid tumors. **Methods:** This study (*NCT03459469*) utilized an accelerated dose escalation schema for the first two dose levels followed by a 3+3 design to determine the MTD/recommended phase 2 dose (RP2D) of tegavivint, followed by a dose expansion phase. The study included adult pts with sporadic desmoid tumors that were progressive (20% increase in tumor volume, recurrent in one year from surgery, or symptomatic), unresectable, and measurable via WHO criteria. Tegavivint was administered IV weekly (three weeks on, one week off) up to two years. **Results:** 24 pts were enrolled. Dose escalation enrolled 17 pts in six dose levels from 0.5 - 5 mg/kg. In dose expansion, 7 additional pts were enrolled. Dose expansion cohort also included 6 pts in dose escalation that were escalated to RP2D and 3 pts treated at RP2D in dose escalation (n = 16 total). Median age was 43 years (18-66). Median time from diagnosis was 3.1 years with median of one prior systemic treatment (range 0-6). Median time on study was 9.4 months; 3 pts remain on study at data cut-off. No dose-limiting toxicities were observed; MTD was not determined. RP2D was declared at 5 mg/kg based on pharmacologically relevant plasma concentrations and preliminary efficacy. Trough plasma concentrations (C_{min}) exceeded *in vitro* IC_{50} efficacy estimates at 4 mg/kg and 5 mg/kg. Median half-life was 38 hours supporting once weekly administration. Treatment-related adverse events (TRAEs) occurring in ≥20% of pts included fatigue (71%), headache (38%), nausea (33%), constipation (21%), decreased appetite (21%), and dysgeusia (21%), mostly Grade 1-2. Grade 3 TRAEs of hypophosphatemia, stomatitis, increased ALT, diarrhea, and headache occurred in 5 separate pts. There were no grade 4-5 adverse events (AEs). One serious AE of Grade 2 extravasation occurred. Objective response rate (ORR) of 17% across all dose levels and 25% at RP2D (WHO and RECIST criteria) were observed. Median duration of response was 8.1 months (range 6 to 11.8 months) with all responses ongoing. The 9-month progression free survival rate was 76% (95% CI: 54 - 90%) among all pts and 79% (95% CI: 51 – 93%) among those treated at RP2D. Patient reported outcomes and correlative science will be included in the presentation. **Conclusions:** Tegavivint is well tolerated with mostly Grade 1/2 AEs and no serious toxicity associated with WNT inhibition. The ORR of 25% at the RP2D warrants continued development of tegavivint in desmoid tumors. Clinical trial information: NCT03459469. Research Sponsor: Iterion Therapeutics.

A report on the review of archived osteosarcoma and EWING sarcoma specimens at the Biopathology Center, BONE Sarcoma Committee, Children's Oncology Group. *First Author: Sonja Chen, Nationwide Children's Hospital, Columbus, OH*

Background: The Children's Oncology Group (COG) Biorepository at the Biopathology Center (BPC), Nationwide Children's Hospital, Columbus, OH contains archived tumor specimens submitted for COG study protocols. The BPC repository is utilized for numerous biology study aims with the goal of improved understanding of tumor pathophysiology, and impacts future clinical trials design and patient care. BPC pathologists perform quality assurance (QA) reviews of archival material before biospecimens are released for study. Since QA reviews are not routinely included in the submission process into the BPC, the quality and utility of tissue is often unclear. Therefore, a pathology quality assurance review was conducted to explore the utility of future testing on banked formalin fixed paraffin embedded (FFPE) Ewing Sarcoma and Osteosarcoma specimens. **Methods:** The BPC staff retrieved archival tumor cases for review between 06/2020 and 1/2022. One hematoxylin and eosin-stained slide per FFPE tissue block was digitally scanned for whole slide image (WSI) analysis and uploaded with a de-identified pathology report on a virtual slide-viewing platform. Five board certified pediatric pathologists with sarcoma expertise (AA, JB, SC, AS, JD) designed a digital QA review form and performed reviews. The QA review data collection form included diagnosis, volume of viable tumor, decalcification techniques, ancillary molecular/cytogenetic studies and a comment box to include additional noteworthy information. **Results:** During the study period, of the 1379 digitally prepared cases, 486 case reviews were completed, totaling 1192 digital slides reviewed. Of the reviewed cases, 465 (95%) were concordant with the diagnosis and had variable volumes of viable tumor (scant to adequate), while 33 (7%) of cases had no viable tumor (extensive necrosis or no tumor on the slide) and 21 (4%) had an alternative diagnosis (e.g. tumor submitted as osteosarcoma, re-classified as a chondromyxoid fibroma). Of the reviewed concordant cases, 271 (58%) were consistent with OS, 187 (40%) were consistent with ES and 7 (2%) were consistent non-ES round cell sarcomas (e.g. *BCOR* or *CIC*- rearranged sarcomas). **Conclusions:** Over ninety percent of reviewed specimens passed QA review, whereas the remaining failed due to diagnostic discordance or lack of viable tumor. Among cases with diagnostic concordance, variable volumes of tumor were present, including cases with scant viable tumors. Although QA reviews are time consuming, these results suggest QA reviews at tissue submission could potentially improve tissue quality available and timeliness of sample delivery for research. In addition, it would provide an opportunity for follow-up with sites to request submission of higher quality specimens and mitigate storage of tissue without potential for future use. Research Sponsor: COG.

Age as a factor in the molecular landscape and the tumor-microenvironmental signature of osteosarcoma. *First Author: Andreas Seeber, Department of Internal Medicine V (Hematology and Oncology), Medical University of Innsbruck, Comprehensive Cancer Center Innsbruck, Innsbruck, Austria*

Background: Osteosarcoma (OS) incidence is characterized by a bimodal age distribution, with peaks in early adolescence and in adults > 65 years of age. In contrast to adolescents, OS in adults is frequently considered as a secondary neoplasm (i.e., transformation of Paget's disease of the bone, radiation induced). Yet, the literature is scarce regarding the impact of age on the molecular landscape of OS. Herein, we sought to explore the association between age and the genomic profile as well as the tumor immune microenvironment (TME) in a large cohort of OS patients. **Methods:** 208 specimens were centrally analysed at the Caris Life Sciences laboratory with DNA seq (NextSeq, 592 gene panel or NovaSeq, whole-exome sequencing), RNA seq (Archer fusion panel or whole-transcriptome sequencing) and immunohistochemistry (IHC). RNA deconvolution and differential expression analyses were performed using the Microenvironment Cell Populations counter method for quantification of immune cell populations and gene expression profiling. The cohort was stratified into three distinct age groups (< 25 years [n = 83], 25-45 years [n = 58], > 45 years [67]). **Results:** Overall, the most frequently detected mutations were in *TP53* (37%), *RB1* (13%), *ATRX* (9%), *TERT* (6%), *PTEN* (5%), *PIK3CA* (4%) and *KMT2D* (3%). Copy number alterations were most frequently detected in *CDK4* (12%), *LRIG3* (11%), *FLCN* (11%), *MDM2* (9%), *CCND3* (9%), *VEGFA* (8%), *TFEB* (8%). Interestingly, age-based stratification revealed an increased frequency of *FLCN* (19.7 vs 4.7%, $p < 0.01$), *CCND3* (13.9 vs 3.1%, $p < 0.05$), and *HSP90AB1* (11.3 vs 0.0%, $p < 0.01$), alterations in patients < 25 years compared to > 45 years. TME analysis revealed that patients > 45 years have decreased B-cell abundance compared to patients < 25 years (2.9-fold decrease, $p < 0.05$) and 25-45 years (4.8-fold decrease, $p < 0.05$). Although not statistically significant, median transcriptional expression of PD-L1 was numerically increased in patients > 45 years (1.8-fold compared to 25-45 years, $p = 0.17$; 2.0-fold compared to < 25 years, $p = 0.27$), which was consistent with increasing rates of IHC PD-L1 expression with age (5.3%, 9.4%, and 17.5%, respectively, $p = 0.06$). **Conclusions:** To the best of our knowledge, this study represents the largest cohort of molecularly characterized OS. Age-associated differences in the genetic landscape and TME composition, including increased gene amplifications observed in younger patients and decreased B-cell abundance in older patients, might suggest fundamental underlying molecular and biological differences. Research Sponsor: None.

11526 **Poster Session**

Metzolimos metronomic cyclophosphamide (CP) and methotrexate (MTX) combined with zoledronic acid (ZA) and sirolimus (SIR) in patients with advanced solid tumor with bone metastasis and advanced pretreated osteosarcoma (OSS): A phase Ib study. *First Author: Maud Toulmonde, Institut Bergonié, Bordeaux, France*

Background: Advanced pretreated OSS has a very poor prognosis. Metronomic CP and MTX have shown little activity in pediatric cancers, including OSS. Preclinical data suggest that ZA could have a synergic effect when combined with mTOR inhibition in OSS. **Methods:** This is a prospective phase Ib study investigating the combination of SIR with CP, MTX and ZA trough a dose-escalation phase (3 + 3 design) in patients ≥ 18 years with bone metastatic solid tumors (part I) and an expansion cohort dedicated to patients ≥ 13 years with advanced pretreated OSS (part II). SIR was given at two dose levels (4 mg and 6 mg) continuously, in combination with CP 50 mg x 2 per day, 1 week on / 1 week off, MTX at 2.5 mg x 2 per day, on day 1 and day 4 every week, and ZA 4mg IV every 4 weeks. Primary endpoints were dose limiting toxicities (DLT), maximum tolerated dose and recommended phase II dose (RP2D) of SIR combined with CP, MTX and ZA for Part I, and 6-month non-progression rate (NPR) according to RECIST v1.1 for part II. Secondary endpoints included safety, 6-month objective response rate (ORR), one-year progression-free (PFS) and overall survivals (OS), and pharmacodynamics biomarker analyses. At least one non-progression at 6 months after centralized review of imaging was needed among 14 patients to consider activity of the combination. **Results:** From February 2015 to March 2021, 23 patients were included in the three participating centers. In part I, nine patients with breast (56%), prostate (33%) or biliary duct carcinoma (11%) were included. Median number of cycles was 2 (1-6). Two DLT were reported at dose level 2: one grade 3 neutropenia and one grade 3 anemia, therefore dose level 1 was the RP2D for part II. In part II, 14 OSS patients were included. Median age was 27 years (14 - 80). Median number of previous lines in the advanced disease was 1 (1-3). At the time of analysis, 11 patients had died. Reason for study discontinuation was progressive disease for 10 patients (72%), toxicity for two (14%) (one grade 2 platelet count decrease and one grade 5 unrelated lung infection), and investigator decision for two (14%), including one for cryotherapy of a residual lesion after an excellent partial response. Overall, 64 adverse events related to study drugs were reported, of which 14 (22%) grade 3, and 2 grade 4 (3%). They were mainly asthenia, nausea, mucositis oral, anemia, lymphocyte and platelet count decrease. Median follow up was 27.5 months [95% CI : 12.8-27.5]. Two non-progressions at 6 months (14%) were observed, including a partial response (7%). One-year PFS was 21.4% [95%CI 5.2-44.8] and median OS was 12.8 months [95% CI : 2.8-20.4]. **Conclusions:** The combination of SIR at 4 mg daily with CP, MTX and ZA has an acceptable toxicity profile and reached the initial targeted efficacy rate in advanced pretreated OSS patients. Clinical trial information: NCT02517918. Research Sponsor: Anticancer Funds.

The efficiency of anlotinib in osteosarcoma with chemoresistance: Exploratory therapy based on PDX models and next-generation sequencing. *First Author: Zuoyao Long, General Hospital of Northern Theater Command, Shenyang, China*

Background: It's urgent to find a new approach for the treatment of progressed osteosarcoma in neoadjuvant chemotherapy. Using patient-derived xenograft (PDX) models and next-generation sequencing (NGS), we have explored the efficiency of anlotinib in these patients. **Methods:** Frozen osteosarcoma tissues were used to establish PDX models. Ten samples of each PDX model were randomized to treatment or control group. The treatment group were gavaged at a volume of 0.1 ml/10g body weight for 4 weeks, while the control group were administered with vehicle at the same dose orally. Tumor volume and body weight were measured every 3 days, and the tumour were removed and weighed after 28 days. The number of mitotic cells and tumor necrosis rate were detected by Hematoxylin-Eosin (HE) staining. Immunohistochemistry (IHC) was used to evaluate the number of apoptotic cells and the expression of VEGFR-2, PDGFR-β, FGFR-1, c-Kit and their phosphorylated proteins, CD 31. Additionally, patients who had progressed during neoadjuvant chemotherapy (NAC) were treated with combination of anlotinib. After four cycles NAC, we performed salvage surgery and maintained with anlotinib. The change of tumor size was evaluated for tumor response. We used IHC and NGS to analyze the expression of drug targets. **Results:** 21 PDX models were established successfully from 43 samples. Tumor specimens from patients, who had pulmonary metastasis, local recurrence or chemoresistance, were easier to establish PDX models ($P < 0.001$, $P = 0.046$, $P = 0.013$). Six models were selected randomly for anlotinib. After anlotinib administration, the tumor inhibition rates were 18.82%, 45.98%, 85.86%, 83.38%, 84.57% and 86.42%. Anlotinib could not only inhibit the mitosis, induce tumor cell apoptosis and necrosis, but also decrease the expression of drug targets. The expression of VEGFR-2, PDGFR-β and CD31 were positively associated with tumor response. Five patients had received anlotinib during NAC. Four patients had tumor regression (69.4%, 28%, 19%, 8.7%), including two with high expression of VEGFR-2 mRNA or/and PDGFR-β and one with medium expression. **Conclusions:** Based on the results of PDX models and NGS, we suggested that osteosarcoma with high expression of VEGFR-2 or/and PDGFR-β was sensitive to anlotinib, which was alternative for patients progressed during NAC. Research Sponsor: None.

11528 **Poster Session**

A phase 2 study of anti-PD-L1 antibody (atezolizumab) in grade 2 and 3 chondrosarcoma. *First Author: Mohamad Adham Salkeni, National Cancer Institute, Bethesda, MD*

Background: Chondrosarcoma is one of the most common bone malignancies in adults, and the third most common in pediatric patients (pts). The most prevalent subtype, conventional chondrosarcoma, is a slow growing tumor that is historically known to be refractory to chemotherapy. Anecdotal reports indicated a role for anti-PD-(L)1 in the treatment of this disease. This is the first prospective report on the efficacy of the PD-L1-targeting agent, atezolizumab, in this rare disease. **Methods:** Patients (pts) ages 2 and older with unresectable grade 2 or 3 conventional chondrosarcoma were eligible. No prior anti-PD-(L)1 treatment was allowed, otherwise pts were eligible irrespective of prior therapies as long as protocol-specified washout period requirements were met. Pts received atezolizumab 1200 mg (15 mg/kg with 1200 mg cap in pediatric pts) once every 21 days. Imaging was carried out at end of cycle 3, and then every two cycles. Research biopsies were collected from adult pts prior to C1D1, prior to C3D1, and at progression. Immuno-pharmacodynamic (IO-PD) studies were performed on paired tumor samples and circulating immune cells to help elucidate signaling pathways mediating the immune response, with focus on subsets of effector cells in the tumor microenvironment. **Results:** A total of 9 pts (7 males, 2 females) were enrolled in 6 centers across the US and Canada. Six pts were Caucasian/White, 1 Asian, 1 Hispanic, and 1 unknown. Median age was 49 years (42-72). No objective responses were seen. Three pts (33%) experienced disease stability (SD) per RECIST 1.1, for a median duration of 21 weeks as of data cutoff (January 2022). A patient with SD remains on active treatment (tx) for 35 weeks. Three patients had no tx-related adverse events (AEs). Six pts (67%) experienced at least one tx-related AE. Two patients experienced > G2 AEs, but only one was considered tx-related (lymphopenia). Immune-related AEs were all G1/2 and included hepatitis (2), hypothyroidism (1), hyperthyroidism (1), and maculopapular rash (1). IO-PD studies are ongoing and will be reported at the conference if available. **Conclusions:** Atezolizumab was well-tolerated but demonstrated limited activity in this cohort of pts with few treatment options. Ongoing IO-PD studies will provide insight into atezolizumab's effect upon immune cell content and activation in the tumor microenvironment that will help design future immunotherapy trials in this disease and other sarcoma types. The study was funded by NCI Contract HHSN261201500003I. Clinical trial information: NCT04458922. Research Sponsor: U.S. National Institutes of Health, Supported in part by Roche/Genentech Inc. through a Cooperative Research and Development Agreement.

Checkpoint inhibitor and multireceptor tyrosine kinase inhibitor combination in relapsed refractory sarcomas: A single institution series. *First Author: Nupur Mittal, Rush University Medical Center, Chicago, IL*

Background: Adolescent and young adults (AYA) with primary metastatic and relapsed bone and soft tissue sarcomas (BST) have poor prognosis with progression free survival (PFS) rates < 15% and overall survival (OS) < 20%. These outcomes have not improved in the past three decades, highlighting the need for new treatment paradigms. Immunotherapy is effective for multiple malignancies via blockade of CTLA4 or PD-L1 by immune checkpoint inhibitors (CPI), like nivolumab (NIVO). Sarcomas often express PD-L1 as part of their complex pathogenic pathway. Additionally, combination with oral targeted therapies is an emerging strategy for adult malignancies. Encouraging early phase results with multi-tyrosine kinase inhibitors (TKI) of several pathogenic sarcoma pathways – including lenvatinib (LEN), cabozantinib (CABO), and pazopanib – have prompted our team to offer CPI in combination with a TKI for BST patients without chemotherapy options. **Methods:** Retrospectively identified AYA patients with relapsed heavily pre-treated BST who received CPI/TKI combination at our institution between January 2018 to date. **Results:** This is the first reported series of prolonged survival in metastatic and multiply relapsed BST with CPI and TKI therapy. Table summarizes the demographics, disease features, and survival for all patients. The regimen was well tolerated in all patients, except for a rash (n = 1) that resolved by reducing the CABO dose by 25%. All patients had previously been offered palliative care before this regimen. **Conclusions:** Our preliminary experience with CPI/TKI combination in multiply relapsed BST shows a PFS exceeding prior PFS periods with other therapies for all patients. The overall survival is more than historical controls for initial metastatic ASPS, initial metastatic EWS, and recurrent metastatic OST. Our report will inform colleagues about the potential of CPI/TKI combination for these patients with few options. Research Sponsor: None.

Real-world experience of tyrosine kinase inhibitors in patients (pt) with recurrent bone tumours (BT): A CanSaRCC study. *First Author: Tushar Shailesh Vora, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: Survival after relapse in osteosarcoma (OST), Ewing Sarcoma (ES) and chondrosarcoma (CS) remains dismal. Recent reports suggest a role of tyrosine kinase inhibitors (TKI) including regorafenib (R) and cabozantinib (C). We conducted a retrospective multi-centre pan-Canadian study to assess real-word outcomes with these novel treatments in recurrent BT. **Methods**: After ethics approval, data from pts treated in 7 different institutions was extracted from the CanSaRCC (Canadian Sarcoma Research and Clinical Collaboration) Database. Pt characteristics, treatment and outcomes were analyzed. Response was assessed per RECIST 1.1. PFS, OS were estimated using Kaplan-Meier. TTP was defined as time from TKI start to progression. **Results**: From June 2018-Dec 2021, 44 pts received R or C and best response by histology are listed in Table, with an overall clinical benefit rate of 63.6%. Median time to best response was 2.3 mo (range 1 – 17). 15 pts (34.1%) required dose reduction; most common reasons were hand-foot syndrome (13.6%), mucositis (9.1%) and hypertension (9.1%). At median FU of 6.4 mo (range 1.6 – 29), 25 pts (56.8%) died, 19 (43.2%) were alive with disease (AWD). Median PFS was 4.1 mo (95%CI 2.9 – 5.7), for OST was 5.0 (N = 25, 95%CI 2.6 – 10.6), for ES was 4.1 (N = 10, 95%CI 2-5.9), and for CS 4.0 (N = 9, 1 Progressed). Median OS was 10.5 mo (95%CI 7 – 14). By univariate analysis, age, line of therapy, gender, location of primary, or R vs. C did not correlate with PFS. **Conclusions**: Consistent with previous published studies, our pan-country real-world analysis shows that TKI have meaningful activity in the setting of recurrent BT with acceptable toxicities. Inclusion in earlier lines of treatment and/or maintenance therapy could be questions for future research. Research Sponsor: None.

Value of adjuvant radiotherapy in patients with localized Ewing sarcoma at the extremities: Report from the Ewing 2008 trial. *First Author: Philip Heesen, University of Zurich, Zurich, Switzerland*

Background: In patients with Ewing Sarcoma (EWS), adjuvant radiotherapy is often performed after surgery that could not obtain wide margins or after poor histological response to surgery. However, the benefit of adjuvant radiotherapy needs further investigation. Therefore, we compared event-free survival (EFS) between surgery (SX) alone and SX combined with radiation therapy (RT), performed a subgroup analysis and identified independent prognostic factors. **Methods:** The data from localized EWS patients with tumors at the extremities that were treated in the Ewing 2008 trial from 2009-2018 were included in this analysis. Patients received induction chemotherapy according to the protocol and then underwent local therapy. Patients receiving SX or adjuvant RT (combined SX/RT) were included in this analysis. Hazard ratios (HRs) (95% Confidence Intervals (CIs)) were calculated using Cox regression. **Results:** 360 out of 863 patients (41.7%) presented with an EWS at the extremities with 81 tumors at the upper extremity, and 279 tumors at the lower extremity. Most patients were treated with surgery only (223, 61.94%), while 125 patients (34.72%) were treated with SX plus RT. Adjuvant radiotherapy was conducted after a median time of 69 days (1st quartile, 3rd quartile; 54, 109). Median EFS at 5-years for all patients was 0.74 (0.69, 0.80), 0.76 (0.70, 0.83) for patients after surgery only, and 0.73 (0.64, 0.83) after combined RT/SX. After adjusting for sex, age, tumor volume, histological response and surgical margins, the HR for combined RT/SX vs SX alone was 0.69 (0.37, 1.26), p = 0.22. In patients with poor histological response to surgery (≥10% vital tumor cells) and with high tumor volume (≥ 200mL), additional radiotherapy did not decrease the hazards of any event, HR 0.72 (0.25, 2.06), p = 0.54. We identified high tumor volume, poor histological response to surgery as well as intralesional resection of the tumor as independent prognostic factors after adjusting for other known prognostic factors with HRs of 1.73 (1.04, 2.90), p = 0.03; 2.79 (1.69, 4.62), p < 0.0001 and 215.9 (13.17, 3538.61), p = 0.0002, respectively. Surgical complication was not a prognostic factor after adjusting for above mentioned variables, HR 0.85 (0.31, 2.34), p = 0.75. **Conclusions:** In our cohort, adjuvant radiotherapy was not superior compared to surgery alone in all patients with localized EWS at the extremities and neither in a subgroup of patients with high-risk factors. Poor histological response, intralesional tumor resection as well as high tumor volume were identified as independent negative prognostic factors. Clinical trial information: NCT00987636. Spine high-grade osteosarcoma in the era of radiotherapy with high-energy charged particles: A single institution retrospective analysis. *First Author: Gisberto Evangelisti, Spine Surgery Department, Orthopaedic Institute Rizzoli, Bologna, Italy*

Background: Limited are data on high-grade osteosarcoma occurring in the spine. Wide resection is recommended, but it is a difficult and high morbidity procedure in the spine. High-energy particle therapy has been recently used. The goal of this study was to examine treatment and outcome of patients with osteosarcoma in the mobile spine. **Methods:** Spine high grade osteosarcoma patients who underwent surgery at the Rizzoli Institute between 2009 and 2020 were identified. Treatment, outcome, and prognostic factors in patients treated in a single institution were examined. **Results:** Characteristics of the 20 patients (8 female; 12 male) included: median age, 39.7 years (range, 14-71 years), 5 (25%) with tumors in the cervical spine, 6 (30%) with tumors in the thoracic spine, and 9 with tumors in the lumbar spine (45%); 14 (70%) patients with localized disease and 6 (30%) with metastatic disease at the time of presentation. Nineteen patients (95%) underwent chemotherapy, the majority were treated with MAP (methotrexate, doxorubicin, cisplatin) regimen. In 12 patients undergoing preoperative chemotherapy (n = 11) or chemotherapy and radiotherapy (n = 1), the median tumor % necrosis was 20 (IQR 20 - 40), with none achieving a good histologic response (> 90%). All patients underwent surgery. Adequate surgical margins were achieved in 5 patients (25%). In patients with positive margins, radiotherapy was administered to 8 (40%) patients. Four patients with positive margins after resection received photon neoadjuvant or adjuvant therapy. Four patients received high-energy particles as adjuvant therapy after planned gross total excision. The median overall survival rate was 10.5 months (IQR 5.8 - 15.0) for patients with metastatic disease and 25.5 months (IQR 8.3 - 46.0) for patients with localized disease (P = .0501). Patients treated with planned intralesional gross total resection followed by adjuvant high-energy particle therapy had a significant higher disease-specific survival than patients with positive margins after resection with or without additional conventional radiotherapy (P = .023). **Conclusions:** Metastatic disease, is a poor prognostic factor for high grade osteosarcoma of the spine. Post-operative high-energy particle therapy improved overall survival in patients undergoing a planned gross total resection compared to intralesional resection in this series. Chemotherapy induced necrosis was low underscoring the need of more aggressive multidisciplinary approaches for these patients. Research Sponsor: None.

Subclonal somatic copy number alterations emerge and dominate in recurrent osteosarcoma. *First Author: Michael David Kinnaman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Multiple large-scale tumor genomic profiling efforts have been undertaken in osteosarcoma, however little is known about the spatial and temporal intratumor heterogeneity and how it may drive treatment resistance. **Methods**: We performed 30-80x whole genome sequencing (WGS) of 37 tumor samples from 8 patients with relapsed or refractory osteosarcoma. A set of high confidence single nucleotide variants (SNV), copy number alterations (CNA), structural variations (SV) were called for each sample using our pediatric expanded genomics pipeline and an evolutionary analysis was performed using a custom pipeline of computational tools. **Results**: Of the 8 patients in our cohort, 4 had localized disease at diagnosis (OSCE4, OSCE5, OSCE6, OSCE9) and 4 had metastatic disease at diagnosis (OSCE1, OSCE2, OSCE3, OSCE10). There were 17 samples from primary sites, 7 were pretreatment biopsies, 10 from on therapy primary resections. 20 samples came from metastatic sites, 15 of which were from lung metastases. Driver gene SNV's were identified in 5 of 8 patients, including *TP53* (OSCE1), *ATRX* (OSCE3, OSCE10), *RB1* (OSCE4), and *CDKN2A* (OSCE9). No new driver SNV's emerged post-therapy in any patient. HATCHet, an algorithm which infers clone specific copy number alterations, identified subclonal CNAs in all but one patient (OSCE2). In the 7 patients with subclonal CNAs, 6 had two copy number clones identified, and 1 patient (OSCE10) had three copy number clones identified. In 5 patients (OSCE1, OSCE4, OSCE5, OSCE6, OSCE10) there is a copy number clone that is subclonal in the primary tumor which emerges and dominates at subsequent relapses. The resistant clone in each of these cases had either *MYC* gain/amplification. Amplifications in CCNE1 (OSCE1), RAD21 (OSCE4, OSCE5, OSCE10), VEGFA (OSCE1, OSCE9), IGF1R (OSCE6) were also identified as potential drivers in the resistant copy number clones. In two of these patients (OSCE1, OSCE6), the treatment resistant subclone becomes the dominant copy number clone by the time of primary resection. SNV based phylogenies revealed monoclonal and polyclonal seeding of metastases and monophyletic and polyphyletic modes of dissemination. Over half the new mutations acquired in recurrent disease were attributed to HRD or cisplatin mutational signatures. **Conclusions:** Subclonal copy number clones emerge and dominate in relapsed osteosarcoma, with MYC gain/amplification a defining characteristic in our cohort. Selective pressure from neoadjuvant chemotherapy reveals this clone at the time of primary resection, implying genomic profiling at this timepoint may be more reflective of its metastatic potential. Platelet derived growth factor receptor alpha (*PDGFRA*) mutant gastrointestinal stromal tumours (GISTs): Clinicopathological characteristics and outcomes from a regional centre in the United Kingdom. *First Author: David M Favara, University of Cambridge, Cambridge, United Kingdom*

Background: GISTs are the most common mesenchymal tumours of the gastrointestinal tract with an annual incidence of 10-15 per million. 10% of GISTS have activating mutations in the *PDGFRA* gene. We report our 13 year experience of all the *PDGFRA*-mutated GISTs in our regional centre in Cambridge. **Methods**: *PDGFRA*-mutant GISTs were identified from the Cambridge GIST database. Demographics, clinical and histopathological features, survival and response to tyrosine kinase inhibitors of all the patients from 2008-2021 were reviewed. **Results:** n = 50 (male:female 1.5:1) Median age 68 years (range 19-87). 8% of patients were under the age of 40 years. Tumour size ranged from 1-26 cm with a median of 5 cm. Mitotic index ranged from 1-51 with a median of 1 mitosis/5mm2. 52% of GISTs were located in the gastric body. Histological subtypes: 44% epithelioid, 36% mixed and 20% spindle cell. 38% of cases had high KIT expression (immunohistochemistry), whilst 48% had patchy expression and 14% were negative. Most were DOG1-positive (94%). 76% had radical surgery, 60% had laparoscopic resection. 24% were assessed as being high risk GISTs using the modified AFIP model contrasted to 13% being high risk with prognostic contour mapping. 13% developed metastatic disease with liver being the most common metastatic site. The table shows *PDGFRA* mutational analysis results: 58% had a D842V mutation. None had a *KIT* mutation. With a median follow up of 55.1 months, 82% were alive. 6 patients died from metastatic GIST and 3 from other causes. Median time to metastatic disease in resected GISTs was 30.1 months and median time from metastatic diagnosis to death was 18.5 months. Patients who presented with metastatic disease had poor survival compared with patients with localised disease (p=0.001). 8 patients were treated with tyrosine kinase inhibitors including imatinib, sunitinib and regorafenib prior to 2020 with no objective responses. 3 patients were treated with Avapritinib since 2020 within the compassionate use programme. All 3 patients had partial responses and 2 patients are continuing Avapritinib with no grade 3 adverse events. **Conclusions:** We report the largest single centre *PDGFRA*-mutant GIST cohort from Europe. Male preponderance and exclusive gastric location were observed. KIT expression was patchy to negative in the majority of patients. 58% had *PDGFRA* D842V mutations for which Avapritinib has been recently approved. No objective responses were seen with imatinib, sunitinib or regorafenib. Our early experience with Avapritinib is promising. Research Sponsor: None.

Discontinuation of imatinib in patients with oligo-metastatic gastrointestinal stromal tumor who are in complete radiological remission: A prospective multicenter phase II study. *First Author: Ivar Hompland, Oslo University Hospital, Oslo, Norway*

Background: Life-long tyrosine kinase inhibitor (TKI) treatment is recommended for patients (pts) with metastatic GIST. We investigated whether highly selected pts with metastatic GIST may remain in durable complete remission after imatinib discontinuation. **Methods:** In this 1-group, prospective, multicenter phase II trial (NTC02924714) selected pts with overtly metastatic GIST discontinued imatinib treatment. Eligible pts had been treated with imatinib > 5 yrs for oligo-metastatic (≤3 metastases) disease, had no GIST progression and had undergone either R0/R1 resection or radiofrequency ablation (RFA) of all metastases, and had no longer detectable metastases on CT/MRI imaging, The primary endpoint was 3-yr progression-free survival (PFS), overall survival was a secondary endpoint. We estimated to achieve an improvement from 15% to 35% in 3-yr PFS compared to pts treated in the BRF-14 trial with a sample size of 31 pts. **Results:** The trial closed early due to slow accrual. Between January 5, 2017, and June 5, 2019, 12 pts (males, 7) with a median age of 67 yrs (range, 50-85) were enrolled. All pts had their primary tumor surgically removed (stomach, 4; small bowel, 6; large bowel/rectum, 2). Seven pts had *KIT* exon 11 mutation, 2 *KIT* exon 9 mutation, 1 *PDGFRA* exon 12 mutation, 1 had no mutation in *KIT/PDGFRA*, and 1 pt had unknown GIST mutational status. Eight pts had liver metastases, 3 peritoneal metastases, and 1 had both. Prior to enrollment all pts were in macroscopic complete remission after surgical metastasectomy (n = 7), RFA (n = 2), or both (n = 1), and 1 pt achieved complete radiological response with imatinib. At enrollment, 8 pts had imatinib 400 mg/d and 4 had < 400 mg/d. The median time of imatinib treatment before study entry was 8 yrs (range, 5-17). After imatinib discontinuation 7 (58%) pts progressed; the median time to progression was 10 mos (range, 2-31 mos). Five (42%) patients were progression-free after a median follow-up time of 42 mos (range, 30-59 mos). Median PFS was 23 mos and the estimated 3-year PFS 39%. Patients who progressed all achieved a second remission after restarting imatinib and were alive after a median follow-up time of 48 mos (range, 32 to 61 mos). **Conclusions:** The findings suggest that discontinuation of imatinib is safe in highly selected patients with oligo-metastatic GIST and that such patients may survive without detectable GIST progression for several years. The findings need to be viewed with caution due to the small pt numbers. Further study on imatinib discontinuation seem warranted. Clinical trial information: NCT02924714. Research Sponsor: None.

11536 **Poster Session**

Second primary malignancies (SPM) in patients with gastrointestinal stromal tumors (GIST): 10-year experience from the Ottawa Hospital (TOH). *First Author: Abdulhameed Alfagih, Division of Medical Oncology, Department of Medicine, The Ottawa Hospital, The University of Ottawa, Ottawa, ON, Canada*

Background: The secondary malignancies in patients with GIST are relatively high. We present our 10-year experience of SPM in patients with GIST from a regional Cancer Centre in Canada. **Methods:** A retrospective cohort study was performed in all GIST patients treated at TOH between January 2011 and December 2021. Patients were identified using ICD-10 codes and electronic medical records reviewed. Clinicopathological data were analyzed. Logistic regression analysis was used to evaluate associated factors with SPM. Survival analysis was estimated with the use of the Kaplan-Meir method and compared by log-rank test. **Results:** In total, 248 patients with GIST were identified. Of these patients, 61 (25%) had SPM; synchronous (9, 15%) and metachronous (52, 85%). Nine patients had two additional primary cancers other than GIST, and four patients had three additional primary cancers. The median age at diagnosis was 70 (range 44 – 90) years, and males were (59%). The most common SPMs were skin cancer (14, 17%), melanoma (5), and non-melanoma (9), followed by prostate cancer (13, 16%) and breast cancer (12, 15%). Colorectal cancer and hematological malignancies were found in (5, 11%) patients each, while RCC was found in (4, 6%). Thyroid cancer, lung cancer, neuroendocrine tumor, bladder cancer, thymoma, and other types of cancers were collectively found in 15 patients (24%). The majority (57%) of SPM diagnosed before GIST, 30% after GIST. The most common primary GIST locations were in the stomach (62%), followed by the small bowel (30%), and the most common histology was spindle cell (69%), followed by mixed histology (13%). The majority of GIST were localized (46 patients, 75%). Based on Miettinen risk classes for non-metastatic GIST, 74% had zero to low-risk disease, while 26% had moderate or high-risk disease. There was no association between SPM and GIST primary site (p = 0.4), TNM stage (p = 0.8), histology (p = 0.2), Mitosis (p = 0.5), and Miettinen risk class (p = 0.6). The median follow-up time was 53 months (range 1 – 132), and four patients lost follow-ups. Five years overall survival of SPM group vs. non SPM, 79.8% vs. 94.1%, (p = 0.03). Cox regression did not reveal a significant association with the covariants **Conclusions:** We observed that one out of four GIST patients have SPM. Skin, prostate, breast cancers were the most common SPM associated with GIST. Molecular studies are needed to explore the association/underlying mechanisms of GIST with these malignancies. Research Sponsor: None.

Regorafenib third-lined therapy in advanced GISTs: A single center analysis based on different genotypes. *First Author: Sile Chen, Dept of GI Surgery, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*

Background: The relationship between primary and secondary mutational status and efficacy of regorafenib in third-line therapy on GISTs is yet clear. **Methods:** From Jun 2017 to Dec 2021, a total of 62 patients with advanced GIST refractory to imatinib and/or sunitinib were enrolled in this study from the First Affiliated Hospital, Sun Yat-sen University. **Results:** Primary mutational was most common in KIT exon 11(40/62, 64.5%) , followed by *exon 9* (19.4%), *exon 17* (4.8%). Six cases (9.7%) belonged to *SDH* deficiency and one case (1.6%) was NF1-associated GISTs. Before receiving treatment of regorafenib, specimens obtaining for secondary mutations were as follows: 39 cases from surgery，12 from core-needle biopsy; ctDNA alone was performed in 9 cases and 2 patients refused to secondary mutational test. Excluding 6 patients with *SDH* deficiency, 14 patients (25.8%) had mutations in *exon 11+13*, 15 (27.7%) in *exon 11+17*, 7 (13.0%) in *exon 9+17*, 4 (7.4%) in *exon 11+13+17*. Exon 11 + 18, exon 11 + 13 + 18, exon 11 + 13 + 17 + 18, exon 9 + 16, exon 11 + 17 + 18 and NF-1 were found in 1 case, respectively (1.9%). Eight (14.7%) patients with primary *KIT* mutation were not detected any secondary mutation (2nd-not-detected) . There was no complete response, 4 of partial response (4/54, 7.4%), 27 of stable disease (50.0%). Progression disease was seen in 23 patients (42.6%) and 8 were not applicable (no assessable lesion) to imaging response assessment due to R0/1 surgery before using regorafenib. The median follow-up time was 19.0 months. The median progression-free survival (mPFS) was 5.4 months (0.2-29.1 months) and the median overall survival (mOS) was 20.3 months (0.2-37.0 months). For primary mutation analysis, it was found that *SDH*-deficient patients had longer mPFS (29.1 months) than those with mutations in *exon 9* or *exon 11* (5.4 and 4.8 months, respectively; P= 0.013). In terms of secondary mutations, patients with activation loop mutations *(exon 17+18)* showed both longer mPFS (7.3 months vs 1.9 months, P= 0.001) and longer mOS (20.3 months vs 7.7 months, P= 0.059) than those patients with non-activation loop mutations. Not any specific or new adverse reaction was found in all patients. By Cox-regression analysis, response to regorafenib and mutational status were independent predictors of PFS，response to regorafenib was also an independent predictor of OS. **Conclusions:** Regorafenib seems to have better treatment efficacy in GIST patients with *SDH* deficiency compared to those with primary KIT mutations, and better with secondary mutations in activation loop than those with non-activation loop mutations. It is necessary to carry out clinical research for later-line treatment choice based on different genotypes for imatinib-resistant GISTs. Research Sponsor: None.

A randomized phase 2 study of continuous or intermittent dosing schedule of imatinib re-challenge in patients with tyrosine kinase inhibitor-refractory gastrointestinal stromal tumors. *First Author: Hyung-Don Kim, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Resumption of imatinib is one of the available therapeutic options for patients with gastrointestinal stromal tumors (GIST) refractory to tyrosine kinase inhibitors (TKIs). Intermittent dosing of imatinib was suggested to delay outgrow of the imatinib-resistant clones in a preclinical study. **Methods:** A randomized phase 2 study was performed to evaluate the efficacy and safety of continuous or intermittent schedule of imatinib in GIST patients whose disease had progressed to at least imatinib and sunitinib. Patients were randomly assigned (1:1) to the intermittent dosing group that received 400mg daily imatinib based on a 1 week-on and 1 week-off schedule or the continuous dosing group that received imatinib 400mg daily without drug holiday. Disease control rate (DCR) rate at 12 weeks was the primary endpoint. Plasma samples were collected for circulating tumor DNA analysis at baseline, at 3 months of continuous or intermittent imatinib treatment and at the time of progressive disease. **Results:** Fifty patients received at least one dose of imatinib and were included in the full analysis set. Most patients (n = 46) had received prior regorafenib. DCR rate at 12 weeks was 34.8% and 43.5% in the continuous and intermittent groups, respectively. Median progression-free survival was 1.68 months and 1.57 months in the continuous and intermittent groups, respectively. The frequency of any grade anorexia, dysphagia, diarrhea, decreased neutrophil was lower in the intermittent group, whereas that of abdominal pain was higher in the intermittent group. Two patients in the continuous imatinib group underwent dose modification, and there was no patient who discontinued the study treatment because of adverse events related to study treatment. **Conclusions:** We confirmed that imatinib re-challenge was effective in TKI-refractory GIST patients. Intermittent dosing schedule may also be a clinically feasible treatment option for imatinib resumption in TKI-refractory GIST patients. Clinical trial information: NCT02712112. Research Sponsor: None.

Interruption of imatinib in advanced gastrointestinal stromal tumor after prolonged imatinib maintenance in the absence of gross tumor lesions. *First Author: Yoon-Koo Kang, Asan Medical Center, University of Uslan College of Medicine, Seoul, South Korea*

Background: Although current guidelines recommend indefinite imatinib treatment in advanced gastrointestinal stromal tumor (GIST) patients, prolonged imatinib treatment is often challenging. Imatinib-refractory progression-free survival (PFS) and overall survival were reportedly not different between those who interrupted imatinib and those did not. **Methods:** Clinical outcomes of 77 consecutive patients with recurrent or metastatic GIST who interrupted imatinib treatment after maintaining around 5 years of imatinib treatment in the absence of gross tumor lesions were retrospectively analyzed. Association between clinical factors and progression-free survival (PFS) following imatinib interruption was analyzed. **Results:** Median time from the absence of gross tumor lesions to imatinib interruption was 61.5 months (range 41.4–122.7 months). Since imatinib interruption, median PFS was 19.6 months, and the PFS rate at 60 months was 26.3%. Among patients who had progressive disease following interruption, imatinib re-introduction led to 88.6% objective response rate and 100% disease control rate, with the median imatinib-refractory PFS since re-introduction of 112.4 months. Complete removal of initial gross tumor lesion(s) (hazard ratio [HR] 0.32, 95% confidence interval [CI] 0.12–0.81, P = 0.016) and complete removal of residual gross tumor lesion(s) (HR 0.45, 95% CI 0.21–0.94, P = 0.033) by local treatment (vs. no local treatment or residual lesions after local treatment) were independently associated with favorable PFS. **Conclusions:** Interruption of imatinib may be considered with close surveillance in selected patients who maintained years of imatinib treatment in the absence of gross tumor lesions, especially for those who had complete removal of gross tumor lesions by local treatment. Selective internal radioembolization (SIRT) allows to control liver metastases of gastrointestinal stromal tumors (GIST) failing treatment with tyrosine kinase inhibitors (TKI). *First Author: Peter Hohenberger, Division of Surgical Oncology and Thoracic Surgery, Mannheim University Medical Centre, University of Heidelberg, Mannheim, Germany*

Background: The liver and the peritoneum are the main area of metastatic spread in GIST. Liver resection does not play a role for hepatic metastases in comparison to f.e. colorectal cancer. If hepatic metastases are the only or major area of tumor progression and are resistant to available TKIs due to a missing mutation in *KIT/PDGFRA/SDH* ('wildtype') or after treatment with $1^{st}/2^{nd}/3^{rd}/4^{th}$ line therapy, interventional radioembolization with yttrium-90 (^{90}Y) microspheres are promising treatment options, as radiation doses as high as 200Gy can be applied locally. We analyzed the long-term results of SIRT with respect to hepatic-progression-free survival (HEP-PFS) in a consecutive cohort of patients **Methods:** From 1/2008 to 1/2018, 2^6 pts (12f, 14m) with biopsy proven liver metastases of GIST which were the only (n = 13) or the dominant site of progression (n = 12) were treated by SIRT. Median age at GIST diagnosis had been 51.8 yrs and when receiving SIRT was 57.6yrs (range, 18–75yrs). The mutational status was 'wildtype' (n = 7, 2 NF-1), exon 11 (n = 7), exon $11+2^{nd}$ mutation (n = 7), exon 9 (n = 3), exon $9+2^{nd}$mut (n = 1), and, exon 13 (n = 1). All patients except of two had prior TKI therapy: 1 line n = 3, 2 lines n = 11, 3-4 lines n = 9. Follow-up after SIRT was done via dynamic MRI and contrast-enhanced (CE)-CT, the median follow-up is 33.6 mos (range, 12-108mos) and all patients were followed until death **Results:** .The median hepatic-progression free survival (HEP-PFS) after SIRT was 17 months (range, 5-53+, 95%CI 10.7-23.8 mos). Of the patients with concomitant extrahepatic disease, the extraHEP-PFS was median 10 months. Twelve patients received next-line TKI therapy for progressive extrahepatic disease, whereas six patients required this for progressive liver metastases. When comparing the results according to the mutational status, patients with a 'wildtype' tumor showed a better median HEP-PFS of 19 mos (range, 12-53+, 95%CI 16.7-21.2 mos.) in comparison to *KIT* exon 9/11/13 mutated patients with only 14 months (range, 4-34 mos., 95%CI 6.5-21.4 mos), $p < 0.11$ (Wilcoxon). **Conclusions:** 90Y radioembolization (SIRT) offers a safe and effective treatment for patients with liver metastases of GISTs being the dominant site of tumor progression and with no drug treatment options available. In patients known to have no mutation in *KIT/PDGFRA* (wt, also NF-1 associated) it looks whether the results might be even more promising and SIRT could be used in earlier treatment lines. Research Sponsor: None.

Patient reported outcomes and tolerability in patients receiving ripretinib versus sunitinib after imatinib treatment in INTRIGUE: A phase 3 open-label study. *First Author: Hans Gelderblom, LUMC Leids Universitair Medisch Centrum, Leiden, Netherlands*

Background: Ripretinib (R) is a switch-control tyrosine kinase inhibitor (TKI) indicated for the treatment of patients (pts) with advanced gastrointestinal stromal tumor (GIST) after prior treatment with ≥3 TKIs. In the INTRIGUE study (NCT03673501) there was no significant difference in median PFS (primary endpoint) between R and sunitinib (S). We present exploratory analyses of tolerability data and selected pt reported outcomes (PROs). **Methods:** Pts were randomized 1:1 to R 150 mg QD or S 50 mg QD 4 weeks on/2 weeks off.Dose modification was allowed for toxicity management. The event of interest was severe or life-threatening (grade ≥3) treatment-related adverse event prior to progression (sTRAE). Days with at least one sTRAE were summed for all treated pts and for pts with ≥1 sTRAE event. PROs were assessed using questions from EORTC QLQ-C30 and Dermatology Life Quality Index (DLQI) at cycle 1 (C1) day 1 (D1), D15, and D29; D1 and D29 of all other cycles; as well as at end of treatment. Differences in PRO scores between baseline and later assessments were calculated across visits. Long-term data will be presented. **Results:** Pts receiving R (n = 223) versus (vs) S (n = 221) experienced fewer sTRAEs (24% vs 51%, respectively). For all treated pts, the mean time with sTRAEs was 11 days for R and 42 days for S (ratio 0.27, P<0.0001). For pts with ≥1 sTRAE, the mean number of days with a sTRAE was 48 days for R vs 81 days for S (ratio 0.59, p = 0.037). Completion of PRO assessments across the two treatment arms was similar (baseline: R [n = 199], S [n = 199]; C1 D29: R [n = 167], S [n = 177]). Significant differences in self-reported functioning and symptoms were observed by C1 D29. For PROs relating to commonly reported sTRAEs, except constipation, pts in the R arm reported better outcomes than pts in the S arm. Pts in the R arm reported significantly (p<0.05) less decline compared to baseline in pt-reported role function as well as less increase, or improvement, in symptoms of fatigue, appetite loss, diarrhea, nausea/vomiting, and pain vs pts in the S arm. Moderate or severe effect of skin toxicity on pt life, as measured by DLQI in the R arm (n = 165) and in the S arm (n = 175), was observed in 6.6% of pts in the R arm vs 14.8% of pts in the S arm (p = 0.015). **Conclusions:** In the INTRIGUE study the total number of days with sTRAEs was fewer for pts receiving R vs S. Pts in the R arm also reported significantly less decline in pt-reported role function and less increase in symptoms related to commonly reported sTRAEs, except constipation, vs pts in the S arm. Outcomes in late-line systemic treatment in GISTs: Does sequence matter? *First Author: Prapassorn Thirasastr, University of Texas MD Anderson Cancer Center, Department of Sarcoma Medical Oncology, Houston, TX*

Background: Ripretinib (R) is approved for 4^{th} line treatment of GIST based on superior PFS and OS compared to placebo in a phase 3 study, with RR of 11.8% and PFS of 6.3 months (mo). In addition to having high potency against PDGFRA D842V, avapritinib (A) showed activity in 4^{th} or later lines for KIT mutated patients (pts). The RR was 17% and median duration of response was 10.2 mo from a phase 1 study. It is not known if pts receiving R benefit from A after progression or vice-versa. We retrospectively reviewed outcomes of R and A to determine if sequence affects outcomes. **Methods:** Pts diagnosed with GISTs and treated with both R and A at UTMDACC from Jan 2016 to Dec 2021 were included. Pts were separated into R-A (RA) or A-R sequence (AR) and outcomes were tabulated. Descriptive statistics were used to summarize characteristics and genetic profiles. Differences between RA and AR groups were calculated using Fisher's exact. Response was evaluated using RECIST. Kaplan-Meier and Log-rank test were used to estimate and compare PFS and OS between groups. **Results:** Twenty pts were included in the study; 12 in RA and 8 in AR. Median age was 55 years (R:29.7-76.3). Most pts had small bowel primary (11/20, 55%) followed by stomach (4/20, 20%). All baseline characteristics and mutations were equitably distributed between RA and AR. RR of R was 17% and 14% in RA and AR groups, respectively and RR of A was 33% and 29% in RA and AR, respectively (Table). None of the pts with secondary exon 13 mutations responded to R or A. The drug administration sequence did not affect RR (p = 0.7, 0.62 in R, A). The PFS of the second drug administered, was shortened. PFS did not differ based on type of KIT mutation. Median OS from diagnosis in RA and AR groups were 121.8 (58.2-NR) and 171.3 (73.3-NR) mo, respectively and median OS from start of RA and AR was 43.9 (23.0-NR) and NR (11.5-NR) mo, respectively. Neither difference was statistically significant. **Conclusions:** Both R and A are efficacious in later lines of treatment, with greater benefit from the agent used first. Although, the combined PFS was numerically higher in AR compared to RA (20.5 vs 15.2 mo), the OS was not different. Currently, R is the only drug approved in the 4^{th} or later lines in KIT-mutated GIST. Research Sponsor: None.

Health-related quality of life in patients with resectable undifferentiated pleomorphic sarcoma treated with neoadjuvant checkpoint blockade in a single institution randomized phase II clinical trial. *First Author: Heather G. Lyu, MD Anderson Cancer Center, Houston, TX*

Background: In SARC028, patients with undifferentiated pleomorphic sarcoma (UPS) had a 40% overall response rate to pembrolizumab. Based on this, we conducted a randomized, phase II, non-comparative trial of combination nivolumab (nivo/RT) and ipilimumab (ipi/nivo/RT) and demonstrated an 89% major pathologic response. Here, we report the health-related quality of life (HRQoL) metrics. **Methods:** In this study (NCT03307616), patients with resectable UPS were randomized (1:1) to receive one dose of nivo (3mg/kg) or one dose of combination nivo (3 mg/kg) and ipi (1 mg/kg), followed by combination of nivo (3 doses, 3mg/kg every 2 weeks) plus 50 Gy in 25 fractions (both arms). HRQoL was assessed using the MD Anderson Symptom Inventory (MDASI), European Organisation for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire (QLC) Core 30, and the Functional Assessment of Cancer Therapy – General (FACT-G) questionnaires. Questionnaire completion rates were calculated using the number of patients with at least one baseline and post-baseline assessment. Analyses included mean change from baseline scores to week 11 (preoperative) and week 54 (postoperative). **Results:** Ten patients were randomized from October 2017 to February 2020. HRQoL were collected at baseline (n = 10) and at week 11 for five (83%) nivo/RT and three (60%) ipi/nivo/RT patients. Three (60%) nivo/RT and three (100%) ipi/nivo/RT patients had week 54 assessments. MDASI scores indicative of symptom severity and interference of daily life both decreased for patients undergoing ipi/nivo/RT (0.8→0.67 and 0.9→0.46, respectively) while both increased in the nivo/RT group (1.6→2.22 and 1.9→3.33, respectively). Both arms had similar increases at 54 weeks. Patients undergoing ipi/nivo/RT experienced a greater decline in EORTC-QLC global health status at 54 weeks than those undergoing single agent therapy (-22.92 vs -8.33). The mean change in total FACT-G score did not differ between the two arms at 11 weeks (-4.0 vs -4.5), however, there was a significant decline for patients undergoing ipi/nivo/RT at 54 weeks (-20.3 vs -5.7). **Conclusions:** For patients with resectable UPS, combination immune checkpoint blockade with ipi/nivo/RT is associated with an improvement in short term HRQoL compared to single-agent nivo/RT. This finding warrants further study with more patients, controlling for baseline symptom scores. Combination therapy was associated with a slower recovery to baseline function, with ongoing decline in HRQoL at 54 weeks post treatment. Our study demonstrates the feasibility of collecting HRQoL metrics, which can be key factors in guiding patient management decisions. Clinical trial information: NCT03307616. Research Sponsor: Bristol Myers Squibb.

Extended progression-free survival and long-term safety of nirogacestat in patients with desmoid tumors. *First Author: Geraldine Helen O'Sullivan Coyne, Developmental Therapeutics Clinic/Early Clinical Trials Development Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD*

Background: Desmoid tumors are rare, locally invasive, soft-tissue neoplasms that can cause significant morbidity and frequently recur despite surgery or radiation. The ongoing phase II trial of nirogacestat, a gamma-secretase inhibitor, in patients (pts) with recurrent, refractory desmoid tumors (NCT01981551), has reported disease stabilization and multiple partial responses as assessed by RECIST criteria (Kummar JCO 2017). Herein, we report long-term outcomes, tolerability, and safety of this study. **Methods:** A total of 17 pts enrolled in this open label, single arm, phase II study, completing accrual in 2014. Pts received 150 mg nirogacestat orally twice a day in continuous 3-week cycles. Objective treatment response was defined by RECIST 1.1 at cycle 1 and every 6 cycles thereafter using CT (affected area) per the primary study objective; optional MRI assessment was concurrently performed. Yearly CT scans of the chest, abdomen, and pelvis were performed on pts starting in 2016. **Results:** As of Dec. 31, 2021, 4/17 (23%) pts remain on nirogacestat treatment for over 7 years. The objective response rate has not changed since the 2017 publication [31.25% (5/16 evaluable patients), with an exact two-sided Clopper-Pearson 95% confidence interval of 11.0-58.7%], but the observed extended progression-free survival (PFS) is notable; no RECIST disease progression has been observed for any of the 16 evaluable patients at any point on study. Median time on treatment was 4.14 years (range: 0.17-7.99 years). Most common adverse events remain hypophosphatemia (13/17, 76%; 8 grade 3 [gr3], 5 gr2), diarrhea (13/17, 76%; 1 gr3, 4 gr2, 8 gr1), nausea (11/17, 65%; 11 gr1), AST increase (11/17, 65%; 1 gr2, 10 gr1), and lymphopenia (11/17, 65%; 2 gr2, 9 gr1); no pts required a dose reduction after the second year of therapy. Bone fractures (fx) were reported in 4 pts (3 female/1 male) during the first 4 years of treatment (1 hip fx, 1 rib fx, 2 metatarsal stress fxs). Two of these 4 pts experienced a further fx approximately 1 year later (contralateral metatarsal; hip). Both pts with hip fx were > 10 years post-menopausal. Given median age at enrollment (34 years; range: 20-69 years) and reported fx events, bone health was evaluated with findings in keeping with expected range for age. No secondary malignancies have been identified to date. **Conclusions:** No patients receiving nirogacestat have progressed after a median of more than 4 years of treatment. The long duration of responses and lack of tumor progressions observed in this trial has informed the design of a phase III trial in pts with progressing desmoid tumors (NCT03785964) that is currently underway. Clinical trial information: NCT01981551. Research Sponsor: U.S. National Institutes of Health.

Serum glycoproteomic signatures and association with survival in patients with bone and soft tissue sarcoma treated with immune-checkpoint inhibitor therapy. *First Author: Daniel Serie, Venn Biosciences Corporation, Redwood City, CA*

Background: Glycosylation is one of the most ubiquitous and functionally important forms of post-translational modification. The role of differential glycosylation in serum proteins has so far been limited by the technical complexity inherent in generating and interpreting this information. InterVenn has built a novel platform that combines liquid chromatography/mass spectrometry with a proprietary artificial-intelligence-based data processing engine, allowing for highly scalable and reproducible interrogation of glycoproteins with site- and glycan-specificity. **Methods:** Using this platform, we interrogated 519 glycopeptide (GP) biomarkers derived from 70 serum proteins in pre-treatment samples from a cohort of 103 individuals (56 females, 47 males, age ranging from 18 to 84 years) presenting with one of 20 solid cancer types. All patients were treated with durvalumab and tremelimumab immune checkpoint inhibitor (ICI) therapy. Median follow-up for overall survival (OS) was 11.4 months, with 70 events total observed. OS associations were assessed for individual GPs via Cox regression models and leave-one-out-cross-validation (LOOCV) was employed to generate penalized multivariable prediction scores. Notably, 43 patients had a primary diagnosis of bone and soft tissue sarcoma, and stratified analyses were carried out in this population. **Results:** We identified 154 biomarkers significantly associated with OS in the full dataset after adjusting for multiple comparisons (FDR < 0.05). Of these, 7 were statistically significant at $p < 0.01$ in the sarcoma-only subset. LOOCV models built in all cancer types resulted in held-out scores that discriminated those likely to exhibit long-term survival post-ICI therapy from those unlikely to benefit (HR = 4.0, p = 4.91E-08, with 4 GPs included in the final model). Furthermore, LOOCV models including only sarcoma patients demonstrated even stronger predictive attributes (HR = 8.22, p = 2.10E-05, employing 2 glycopeptides). All 9 sarcoma patients with extreme glycosylation signatures for prediction of poor survival displayed quick clinical progression with little benefit from ICI therapy. Relative signal strength and comparative analyses demonstrated strong histotype-specificity inherent in the biomarkers employed for sarcoma vs all cancers. **Conclusions:** Our results indicate that glycoproteomic liquid biopsy holds potential as a predictive biomarker for identifying sarcoma patients who will derive the greatest benefit from ICI therapy. Research Sponsor: None.

Circulating tumor DNA (ctDNA) detection of molecular residual disease (MRD) as a potential biomarker in localized soft tissue sarcoma (STS). *First Author: Abdulazeez Salawu, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: Surgery and (neo)adjuvant radiotherapy are the mainstay curative treatments for localized STS. Despite treatment, approximately 50% of STS patients (pts) experience metastatic relapse and routine use of adjuvant systemic therapy (AST) remains controversial. The presence of ctDNA following curative treatment of STS is a potential biomarker for MRD and may identify patients who benefit from AST. Given the genomic heterogeneity of STS, a histology-agnostic approach to ctDNA detection in this population is desirable. **Methods:** Pts with localized, high risk (size ≥ 5cm, grade ≥ 2) disease were enrolled prior to (neo) adjuvant radiotherapy and surgery. Blood for ctDNA was collected at diagnosis; post-radiotherapy, post-surgery and every 3 months for up to 2 years. Whole exome sequencing (WES) of archival tumor- and matched buffy coat-DNA were carried out to identify somatic variants. Personalized and tumor-informed, multiplex PCR next generation sequencing-based ctDNA assay (Signatera™ assay) was performed on plasma obtained at the serial timepoints. A sample level positive call required ≥ 2 variants above a confidence calling threshold. Absolute ctDNA levels were expressed as mean tumor molecules per milliliter (MTM/ml) of plasma, based on variant allele frequencies and quantity of cell free DNA. Standard radiologic surveillance (every 3 months) was performed following surgery. The primary endpoint was a ctDNA detection rate of 70% at diagnosis. Secondary endpoints included MRD detection and correlation of ctDNA levels with disease relapse. **Results:** Seventy-six plasma samples from 10 pts [8 males and 2 females; median age 64 years (range 46–84)] were obtained prospectively. STS subtypes were undifferentiated pleomorphic sarcoma (n = 4), myxofibrosarcoma (n = 2), dedifferentiated liposarcoma (n = 2), myxoid liposarcoma (n = 1), and pleomorphic liposarcoma (n = 1). All tumors successfully underwent WES with adequate data quality for Signatera™ assay design. The personalized ctDNA assay was performed on a median of 7 plasma samples per patient (range: 5 – 10). ctDNA was detected in 7 pts (70%) at diagnosis, with median ctDNA level of 1.6 MTM/ml (range: 0.2 – 137.8), achieving the study primary endpoint. Immediate post-surgery samples were negative in all pts. However, ctDNA was detected in 2 out of 2 pts who developed metastatic disease during follow-up. **Conclusions:** Personalized tumor-informed ctDNA assays in localized high-risk STS at diagnosis are feasible. In this series, all patients had undetectable levels of ctDNA post-surgery and patients who experienced disease relapse demonstrated a detectable rise in ctDNA levels. Further interrogation of this approach for detection of post-treatment MRD as a possible biomarker of benefit from AST is ongoing. Research Sponsor: University Health Network, Toronto, Natera.

Pan-sarcoma analysis of DNA damage response pathway alterations and deficiency. *First Author: Steven Bialick, University of Miami Miller School of Medicine/Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Alterations in DNA damage response (DDR) pathways contribute to genomic instability and malignant progression and have been shown to be of clinical significance in several carcinomas and solid tumors. While some studies have identified ostensibly pathogenic variations in known and novel cancer genes with implications for sarcoma risk and treatment opportunities, there is limited information regarding the role of DDR pathway alterations in sarcoma. We identified a gene alteration in *ERCC2*, a gene that codes for a DNA helicase in the nucleotide excision repair pathway, in a patient with multiply relapsed epithelioid sarcoma (ES), prompting an investigation of DDR pathway alterations in sarcoma samples using a global next-generation sequencing (NGS) platform. **Methods:** Sarcoma patient samples (N = 5310), representing 38 pediatric and adult histologic subtypes, underwent NGS of DNA (592 gene panel or whole exome) and RNA (whole transcriptome sequencing, N = 3612) at a CLIA-certified laboratory (Caris Life Sciences, Phoenix, AZ). A threshold of 10 mut/Mb was used to identify high tumor mutational burden (TMB-H). IHC was performed for PD-L1 (SP142; 2+I5% = positive). Homologous recombination deficiency (HRD) scores were calculated as a composite of loss of heterozygosity, telomeric allelic imbalance, and large-scale transitions, using a positive threshold of 42 (N = 2138). HRD score association with biomarker status was evaluated overall and in sarcoma subtypes. **Results:** A pathogenic DDR pathway mutation was noted in 842 (15.9%) of the total samples. *ATRX* was by far the most commonly altered DDR gene (10% of all samples), with mutations observed across 25 sarcoma subtypes (11 subtypes with > 10% mutation rate: leiomyosarcoma [LMS], perivascular epithelioid cell tumor [PEComa], pleomorphic sarcoma [PLSARC], uterine sarcoma [OUSARC], osteosarcoma, spindle cell sarcoma, angiosarcoma, mesenchymal chondrosarcoma, sarcoma NOS, fibrosarcoma and ES). *CHEK2*, *ATM*, and *MUTYH* mutations were observed in 1-2% of sarcoma samples. More than 20 histologic subtypes showed distinct gene signatures with mutations occurring in > 3% of the samples investigated. *ERCC2* was mutated in 3% of ES and 6.5% in PEComa. Median HRD scores ranged between 20-58 across sarcoma subtypes. High rates of deficient HRD (HRDd ≥ 42) were observed in PLSARC (83.2%), OUSARC (73.7%), and dedifferentiated chondrosarcoma (71.4%), while low rates of HRDd were observed in Ewing sarcoma (0%) and clear cell sarcoma (10%). In the overall cohort, *ERCC2*, *ATRX* and *BRCA2* were significantly associated with increased HRD scores (p = 0.01). **Conclusions:**DDR pathway alterations are present in numerous histologic subtypes of sarcoma. A more comprehensive analysis of individual histologic subtypes is in progress. Further research will evaluate the clinical implications of these known and novel mutations to guide risk stratification and potential therapeutic options. Research Sponsor: None.

Prognostic value of *EZH2* expression for immunotherapy-based schemes in advanced soft-tissue sarcoma: A translational research from Spanish Group of Research on Sarcoma (GEIS). *First Author: David Silva Moura, Group of Advanced Therapies and Biomarkers in Sarcomas, Health Research Institute-Fundación Jiménez Díaz University Hospital, Madrid, Spain*

Background: Immunotherapy-based treatments had shown to be active in several solid tumors, including in selected subtypes of sarcomas. IMMUNOSARC (NCT03277924) is a phase Ib/II trial [from Spanish (GEIS) and Italian (ISG) sarcoma groups], that tested the combination of nivolumab (anti-PD-1 inhibitor) plus sunitinib (anti-angiogenic agent) in advanced sarcomas. Among the 65 soft-tissue sarcoma (STS) patients (pts) enrolled, 48% were free of progression at 6 months, meeting the trial's primary endpoint. EZH2 is the catalytic subunit of the Polycomb Repressive Complex 2 and it has been described to play an important role in the transcriptional repression of genes involved in T-cell migration and T-cell-mediated anti-tumor activity. The aim of this study was to explore the value of *EZH2* gene expression as potential prognostic biomarker of the activity of immunotherapy-based schemes. **Methods:** The expression of *EZH2* was evaluated in 64 paraffin tumor blocks, by direct transcriptomics, using HTG EdgeSeq Oncology Biomarkers Panel (HTG Molecular Diagnostics, Inc.; Tucson, AZ, USA). Data was normalized with DESeq2 and the cut-off of *EZH2* expression was calculated with MAXSTAT R package. Gene expression was correlated with progression-free survival (PFS) by RECIST, overall survival (OS) and clinical benefit (patients with response or stable disease vs patients with progressive disease as best response). **Results:** Among the 64 pts analyzed, 52 (81%) showed overexpression of *EZH2*, considering a cut-off of 570.15 read counts. Undifferentiated pleomorphic sarcoma (UPS) and epithelioid sarcoma were the subtypes with higher expression of *EZH2* with a median of read counts of 1888.04 (n = 10) and 1261.79 (n = 7), respectively. The lowest expressions were observed in extraskeletal myxoid chondrosarcoma (ECM) and alveolar soft-part sarcoma (ASPS) with a median of read counts of 461.42 (n = 4) and 680.84 (n = 7), respectively. Low expression of *EZH2* was associated with better PFS (16.8 months vs. 3.9 months; p = 0.001) and better OS (NR vs. 20.0 months; p = 0.006). Moreover, low expression of *EZH2* was also significantly associated with a clinical benefit of the patients treated with nivolumab plus sunitinib [relative risk (RR): 13; 95% CI: 3.0-56.9; p = < 0.001). **Conclusions:** Low expression of *EZH2* was associated with better outcome in advanced STS patients treated with immunotherapy-based schemes. These results might support the rationale for the combination of EZH2 inhibitors with immune-modulating agents for future studies. 11550 **Poster Session**

Clinical utility of circulating tumor DNA sequencing with a large panel in patients with advanced soft-tissue sarcomas. *First Author: Julie Blanchi, Institut Bergonie, Bordeaux, France*

Background: Preliminary studies have suggested that the detection, quantification, and profiling of ctDNA in patients with sarcoma is feasible and may improve prognostication, measure treatment response, and detect relapse. However, data related to impact of ctDNA profiling to tailor therapy in patients with advanced disease are lacking. **Methods:** Patients with advanced soft-tissue sarcomas (STS) have been included in two ongoing institutional molecular profiling studies (BIP: NCT02534649, STING: NCT04932525). Genomic analysis (ctDNA in all cases and tissue when available) was performed by using the Foundation One Liquid CDx Assay (324 genes, tumor mutational burden [TMB], microsatellite instability status). Each individual genomic report was reviewed and discussed weekly by a multidisciplinary tumour board dedicated to precision medicine, attended by experts in clinical oncology, molecular biology, and clinical genetics. Actionable targets were defined by the MTB according to the existing level of evidence (ESCAT), and molecular-based treatment suggestions were proposed where possible. **Results:** Between December 2020 and August 2021, 98 patients with metastatic STS underwent ctDNA profiling. Median time to assay results was 12 days. Results were contributive for 86 patients (88%). At least one actionable target (range 1-4) was detected in 35 patients (36%) including high tumor mutational burden (> 16 mutations/Mb) for 1 patient (1%) and alteration of the DNA repair response pathway for 12 patients (12%). Overall, the MTB recommended a matched therapy for 27 patients (28%). 40 patients underwent also NGS of tissue besides ctDNA profiling. The number of actionable alterations was similar in 26 (65%), whereas it was higher in tissue for 10 (25%) and in liquid for 4 (10%) patients. **Conclusions:** This large-scale study demonstrates that liquid biopsy with a large NGS ctDNA panel is an efficient approach to match patients to genomically directed clinical trials/targeted therapies in patients with advanced STS. Outcomes of patients treated with matched therapy will be presented at the meeting. Research Sponsor: None.

Using pan-sarcoma multiomic analysis for identifying sarcoma subtypes with immunogenic potential. *First Author: Galina Lagos, Brown University, Providence, RI*

Background: Immune checkpoint inhibitors (ICI) have limited efficacy for most sarcomas. Yet, responses are seen in particular sarcoma subtypes, highlighting the need for better predictive biomarkers. The T cell inflamed score (TIS), a gene expression signature reflective of an active tumor immune microenvironment, is associated with ICI response in multiple solid tumors. We evaluated the TIS across a large database of sarcomas to identify which histologic subtypes may benefit from ICI. **Methods:** Next generation sequencing of DNA (592 gene or whole exome)/RNA (whole transcriptome) was performed for 3605 sarcoma patient samples, representing 45 histologic subtypes (Caris Life Sciences, Phoenix, AZ). TIS (18 gene weighted coefficient composite value; Cristescu 2018) was calculated and the Microenvironment Cell Populations-counter tool (Becht 2016) was used to quantify immune cell populations. Results were compared to melanoma (n = 1255), a representative immunogenic tumor type. High TIS was defined as a score within the upper quartile of melanoma TIS (> 5.5). Percentage with high TIS are reported with 95% CI. **Results:** Median TIS was highest in inflammatory myofibroblastic tumor (IMT), epithelioid sarcoma (EPIS), myxofibrosarcoma (MFS), well differentiated liposarcoma, and solitary fibrous tumor (SFT). These did not differ significantly from melanoma (p > 0.06). Median TIS was lowest in embryonal rhabdomyosarcoma, desmoid tumor (DES), synovial sarcoma (SYNS), and Ewing sarcoma (ES). Histologic subtypes where > 10% of samples had a high TIS included IMT (29.9% ± 21.7%), MFS (23.3% ± 12.6%), pleomorphic sarcoma (PLSARC) (21.9% ± 5.8%), cutaneous angiosarcoma (ANGS) (18.4% ± 13.9%), spindle cell sarcoma (17.5% ± 7.6%), liposarcoma (LPS) (17% ± 10.7%), EPIS (15.4% ± 19.6%), visceral ANGS (13.2% ± 10.7%), pleomorphic LPS (13.6% ± 14.3%), fibrosarcoma (12.5% ± 13.2%), leiomyosarcoma (11.6%± 3.4%), malignant peripheral nerve sheath tumor (MPNST) (10.2% ± 7.7%), and perivascular epithelioid cell tumor (PEComa) (10% ± 10.7%). The relative abundance of immune and stromal cell populations was highly variable across sarcoma subtypes, yet a strong positive correlation between TIS and immune cell populations was observed for most subtypes (e.g. T cells, Spearman R range: 0.56 [P = 0.08] - 0.96 [P < 0.0001]). A notable exception was SFT, which had a relatively high median TIS but low abundance of CD8+ T cells and B cells. **Conclusions:** We found high median TIS and/or significant proportions of samples with a high TIS in sarcoma subtypes with previously demonstrated responsiveness to ICI, including MFS, PLSARC, LPS, and ANGS, while unresponsive tumor types such as RMS, DES, SYNS, and ES had low TIS. We further identified subtypes with high TIS but limited prior clinical data supporting ICI use, such as IMT, EPIS, MPNST, SFT, and PEComa. Our results warrant prospective exploration of TIS as a predictive biomarker for ICI use in sarcoma. Research Sponsor: None.

Distinct oncogenic signatures in malignant PEComa and leiomyosarcoma identified by integrative RNA-seq and H3K27ac ChIP-seq analysis. *First Author: Krinio Giannikou, Center for Functional Cancer Epigenetics, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Malignant perivascular epithelioid cell tumor (PEComa) and leiomyosarcoma (LMS) are two sarcomas with overlapping morphologic and immunophenotypic features which can make their diagnostic distinction challenging. We aimed to characterize the transcriptional and epigenetic landscape of PEComa and LMS to identify distinguishing features. **Methods:** We performed whole transcriptome RNA-sequencing on 19 PEComas and compared their gene expression profile to 259 sarcomas from The Cancer Genome Atlas (TCGA) including 104 LMS. ChIP-sequencing for H3K27ac, a histone modification associated with activation of nearby genes/open chromatin, was conducted on 9 malignant PEComas and 12 LMS and were compared with publicly available data from 4 other sarcoma subtypes (chordoma; osteosarcoma; undifferentiated pleomorphic sarcoma; rhabdomyosarcoma; n = 29 tumors). **Results:** Genome-wide epigenetic and transcriptional analyses revealed overlapping patterns between PEComa and LMS, which were distinct from other sarcomas. However, we also identified a set of highly expressed and epigenetically distinct transcripts which may represent diagnostic?biomarkers: e.g., *DAPL1, MLANA, SULT1C2, GPR143,* and *CHI3L1* for PEComa; and *MYOCD, WDFC2, DES, MYH11,* and *CNN1* for LMS; each of which showed >17x fold higher expression for each tumor entity by DESeq2 (FDR<0.0001). Gene Set Enrichment Analyses (GSEA) demonstrated enrichment in the KEGG Lysosome pathway for PEComa (FDR=0.11), whereas myogenesis and smooth muscle contraction pathways were enriched in LMS (FDR=0.09). Integrative transcriptomic and epigenetic analyses revealed a unique set of master core transcription factors for each tumor type including among others MYOCD for LMS; MITF for PEComa, which require further functional investigation. Twelve selected genes including new as well as known and standard diagnostic markers (e.g., DAPL1, MLANA, GPR143, PNL2, CHI3L1, DES, MYH11, ER, CD68, PU.1, pS6 and CNN1) were validated by immunohistochemistry (IHC) in multiple sections from PEComa and LMS (n = 26). The combination of three melanocytic markers (HMB45, MLANA, PNL2) and pS6 can distinguish LMS from PEComas (**** p<0.0001). IHC for CD68 and PU.1 macrophage markers did not show any difference regarding the degree of immune infiltration in PEComa vs. LMS. **Conclusions:** Our studies revealed novel epigenetic signatures translating into lysosomal and melanocytic proteins for PEComa and myogenic proteins for LMS, which may serve as useful diagnostic biomarkers in the distinction of these two sarcoma subtypes. A phase 1 dose-escalation/expansion clinical trial of mocetinostat in combination with vinorelbine in adolescents and young adults with refractory and/or recurrent rhabdomyosarcoma: Interim results. *First Author: Noah Federman, David Geffen School of Medicine UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA*

Background: Rhabdomyosarcoma(RMS) is the most common soft tissue sarcoma in children. Relapsed/refractory(R/R) RMS has a poor outcome and remains an area of unmet need. Histone deacetylase (HDAC) inhibitors have been shown to have activity in preclinical models of RMS. Mocetinostat (Mirati Pharmaceuticals) is an investigational oral HDAC inhibitor, that targets HDACs 1, 2, 3 and 11. Mocetinostat displayed high activity in in vitro RMS cell lines, RMS xenograft models and exerted synergistic activity in combination with vinorelbine. We report early interim results of the Phase 1 trial of mocetinostat with vinorelbine in R/R RMS. **Methods:** An investigator initiated Phase 1,open-label, dose escalation/expansion clinical trial. A modified intent to treat approach is used for efficacy analysis for a target accrual of 20 subjects in the dose expansion cohort. Subjects with R/R RMS were age ≥ 18 years old(yo) for the phase 1 dose escalation cohort and ≥12 yo for the phase 1 dose expansion. Mocetinostat 40mg, 70mg or 90mg was taken orally 3 times weekly with vinorelbine 25mg/m^2 IV on day 1,8, and 15 in 21 day cycles. Maximum tolerated dose of mocetinostat in the dose escalation phase was 40mg, which was selected for dose expansion. Subjects were treated until disease progression by RECIST 1.1 or unacceptable toxicity. **Results:** A total of 8(6 FOXO translocation(+), 1 (FOXO-), and 1 unknown) have been enrolled at time of submission. 5 in dose escalation cohort, and 3 in dose expansion. Median age was 19 yo(range 16-63), Median prior treatment regimens were 2(range 1-4). All patients had measurable metastatic disease. 6 of 8 subjects had prior exposure to vinorelbine in prior salvage chemotherapy or maintenance chemotherapy. As of 20JAN2022 safety cutoff, most common AEs (all grades) observed in 7 evaluable treated patients include neutropenia (n = 5), anemia(n = 5), and nausea(n = 4). The only grade 3 or 4 treatment related AEs were neutropenia, lymphopenia and anemia. Myelosuppression was transient, reversible and responsive to growth factors. No SAEs related to mocetinostat and/or vinorelbine have been reported. As of efficacy cutoff 20JAN2022, 7 of 8 patients are evaluable for response. 4 subjects had a partial response (PR), 2 subjects had stable disease (SD) and 1 subject had progressive disease for a clinical benefit rate of 86% (CR+PR+SD). Rapid responses were seen in the majority of patients at median of 1.5 months(mos). Of the 6 responders, 4 had duration of responses (DOR) > 6 mo with a median DOR of 8 mos (range 4-16mo). **Conclusions:** In this interim analysis, Mocetinostat plus vinorelbine shows high efficacy and acceptable safety profile in this heavily pretreated group of R/R RMS patients. This study is open to accrual and enrollment is ongoing. Clinical trial information: NCT04299113. Research Sponsor: Phase One Foundation, Pharmaceutical/Biotech Company.

A phase II study of gemcitabine docetaxel combination in metastatic/unresectable locally advanced relapsed synovial sarcoma. *First Author: Ghazal Tansir, All India Institute of Medical Science (AIIMS), Delhi, India*

Background: Synovial sarcoma (SS) is one of the commonest non-Rhabdomyosarcoma Soft Tissue Sarcomas (STS) in Adolescent and Young Adults. It is a chemosensitive, high-grade tumor with a tendency for local and metastatic recurrence. While the frontline therapy is doxorubicin, treatment options in later lines are scarce. Gemcitabine docetaxel combination has demonstrated its role in relapsed STS and promising potential in frontline setting in recent times. The major STS types in previous trials included leiomyosarcomas and pleomorphic sarcomas but in SS, this regimen has not been explored. We conducted this study on gemcitabine and docetaxel combination in relapsed metastatic/locally advanced unresectable SS. **Methods**: This is a phase II, single-arm study in patients (pts) of metastatic/locally advanced unresectable SS relapsed post atleast one line of treatment aged between 15-75 years, ECOG performance status (PS) 0-2, adequate organ function and measurable disease by RECIST 1.1. Treatment was gemcitabine 900 mg/m^2 on days 1 and 8 plus docetaxel 75 mg/m^2 on day 8 with G-CSF prophylaxis for maximum 6 cycles. Adverse event (AE) profile was analyzed by CTCAE 5.0, quality of life (QoL) assessed 4-weekly by EORTC QLQ-C30 questionnaire and response assessed by RECIST at 12 weeks. Primary endpoint, 3-month Progression-free survival rate (PFR) was required to be 40%. **Results:** 22 pts were enrolled between 3/2020 – 9/2021 with median age 32 (range 15-60 years); 13 (59%) patients were male; ECOG PS was 1 in 13 (59%) and 2 in 9. Extremity and lung were the commonest primary and metastatic sites respectively with 20 (90.9%) pts having metastases. 50% pts received the study treatment in 2nd line, 36.3% in 3rd line and the remaining in 4th line. The 3-month PFR was 45.4%, median PFS was 3 months, OS 67% at 7 months follow-up and Overall Response Rate (ORR) was 4.5% (1 PR). There was statistically significant worsening in QoL parameters of cognitive functioning, fatigue, dyspnea, appetite loss, nausea/vomiting at 12 weeks. Progression-free pts had better QoL in cognitive and emotional function, fatigue, pain and global health status. Beyond 12 weeks, 7 out of 10 non-progressors continued the treatment (1 patient each discontinued treatment due to death, change to TKI and enrolment in another trial). The most common AEs were fatigue, nausea/vomiting, mucositis, diarrhea, alopecia, anemia, transaminitis; Grade > 3 AEs (31.8%) included anemia, neutropenia, hyperbilirubinemia, transaminitis, mucositis. There was no febrile neutropenia. **Conclusions:** This is the first prospective study on gemcitabine docetaxel in patients of SS. The trial met its primary endpoint of 3-month PFR more than 40% which is promising in relapsed population. The improved QoL among progression-free pts is encouraging. Gemcitabine docetaxel regimen exhibits efficacy and safety to be considered for use in relapsed SS. Clinical trial information: CTRI/2020/02/023612. Research Sponsor: None.

Activity of regorafenib in patients with non-adipocytic soft tissue sarcoma (NASTS): Evaluation of heterogeneity of treatment effect on the updated analysis of pooled cohorts. *First Author: Marie-Cecile Le Deley, Centre Oscar Lambret, Lille, France*

Background: Results of the double-blind randomized phase 2 trial (NCT01900743), showed that regorafenib (REG) is an active treatment in patients (pts) previously treated with chemotherapy for an NASTS (cohorts B-leiomyosarcoma, C-synovial sarcoma, D-other sarcoma, Mir 2016), and in pts previously treated with pazopanib (PAZ) (cohort E, Penel 2019). We now present an updated analysis of progression-free survival (PFS) in all NASTS pts to assess the heterogeneity of treatment effect according to histological subtype and prior exposure to PAZ. **Methods:** Pts received REG 160 mg/d, 21/28 d, or placebo (PB). Pts receiving PB were offered optional cross over in case of centrally confirmed disease progression. The primary endpoint was PFS, according to RECIST-1.1, based on full blinded central review of imaging (including a re-review for cohorts B, C and D, because first analysis was based on a partial central review in these cohorts). Overall survival (OS) was a secondary endpoint. We performed a pooled analysis of cohorts B, C, D and E, on the intent-to-treat dataset, including a multivariate analysis with interaction terms to assess the heterogeneity of treatment effect according to covariates. **Results:** From 06/2013 to 10/2017, 175 pts were randomized (87 REG vs 88 PB; 56, 27, 55, 37 pts in cohorts B, C, D and E, respectively). The median age was 59 yrs (range, 20-81). There were 101 women (58%). Histological subtype was leiomyosarcoma in 80 pts (LMS; 41 REG vs 39 PB; 56 in cohort B and 24 in cohort E), synovial sarcoma in 28 (SS; 13 REG vs 15 PB; 27 in cohort C and 1 in cohort E), and other sarcoma in 67 (33 REG vs 34 PB; 55 in cohort D and 12 in cohort E). The median number of prior lines of systemic treatment was 2 (range, 1-6). Overall, 43 pts had received prior PAZ (21 REG vs 22 PB). Out of 88 pts assigned to PB, 69 switched to REG after progression (79%). We confirmed a significant PFS-benefit associated with REG in multivariate analysis of the pooled study population, with a HR = 0.48 (95%CI, 0.35–0.66, p < 0.001); median PFS = 2.1 vs 1.0 months, respectively. This benefit appears significant in each histological subtype. However, we observed a borderline interaction between histological subtype and treatment effect (p = 0.09): PFS benefit appears larger in pts with SS (HR = 0.21, 0.10-0.48, p < 0.001) and other sarcoma (HR = 0.49, 0.30-0.81, p = 0.006) than in LMS (HR = 0.59, 0.37-0.93, p = 0.022). PFS benefit appears rather homogeneous across strata of pts with vs without prior exposure to PAZ (interaction test, p = 0.26). Overall, in this study, regorafenib does not show any statistically significant OS-benefit (HR = 0.77, 0.57–1.05, p = 0.10), likely due to the fact that 79% of PB pts crossed over to REG at progression. **Conclusions:** The present study confirms the clinical PFS benefit associated with regorafenib in all NASTS pts, regardless of prior treatment with pazopanib. Clinical trial information: NCT01900743. Research Sponsor: Bayer HealthCare.

11556 **Poster Session**

Excess of blood TNFa-R as a sign of recurrence of G1 soft tissue sarcomas in older men and G3 soft tissue sarcomas in older women. *First Author: Irina V. Kaplieva, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation*

Background: Tumor necrosis factor alpha (TNFa) and its receptor (TNFa-R) play an important role in tumor genesis. However, their involvement in the recurrence of sarcomas is poorly studied. The purpose of this study was to analyze levels of TNFa and TNFa-R in the blood of patients with recurrent soft tissue sarcomas. **Methods:** The study included 64 male and female patients, mean age 63.4±5.2 years. Main groups included patients with recurrent G1 and G3 soft tissue sarcomas T2bN0M0; comparison groups included patients with primary G1 and G3 soft tissue sarcomas T2bN0M0. 95% of tumors were liposarcomas, with solitary rhabdamyosarcomas, myxofibrosarcomas, epithelioid and undifferentiated sarcomas. All recurrent patients had previously underwent surgical and radiation treatment for primary sarcomas and their relapses (up to 2 episodes), with the last surgery more than 1 year ago. Control groups (n = 10 each) included healthy donors of similar age. Levels of TNFa and TNFa-R were measured in the blood serum by ELISA before the treatment. **Results:** No significant differences were found between TNFa levels in patients with primary and recurrent soft tissue sarcomas and in donors. Levels of TNFa-R in men with primary G3 sarcomas were 1.5 times (p < 0.05) higher compared with donors, 1.7 times (p < 0.05) higher than in men with primary G1 sarcomas, and 1.3 times (p < 0.05) higher than in women with primary G3 sarcomas. TNFa-R increased by 1.7 times (p < 0.05) in all men with recurrent sarcomas regardless of the tumor grade, compared with the levels in healthy men; however, in G1 it was 1.9 times (p < 0.05) higher than in men with primary G1 sarcomas, while in G3 it did not differ significantly from the levels in men with primary G3 sarcomas. TNFa-R in women increased only in recurrent G3 sarcomas by 2.5 times compared to healthy women. No differences were observed in TNFa-R levels between men and women with recurrent G3 sarcomas. **Conclusions:** An excess of TNFa-R in the blood is characteristic for the recurrent soft tissue sarcomas G1 in older men and G3 in older women. At the same time, high grade tumors in men are accompanied by an increase in TNFa-R in the blood in both primary and recurrent sarcomas. Research Sponsor: None.

Surufatinib in U.S. patients with soft tissue sarcoma. *First Author: Sujana Movva, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Surufatinib is an inhibitor of VEGFR1, 2, & 3, FGFR1, and CSF-1R. A manageable safety profile, and statistically significant improvement in progression-free survival (PFS) in patients (pts) treated with surufatinib have previously been demonstrated in pts with advanced NETs of extrapancreatic (epNET) and pancreatic (pNET) origin in 2 phase 3 randomized trials conducted in China (SANET-ep; NCT02588170 & SANET-p; NCT02589821). Similar safety and efficacy were demonstrated in this phase 1 study (NCT02549937) in pts with NETs. Here we report the results of surufatinib in pts with soft tissue sarcoma. **Methods:** This study is a phase 1, dose escalation (ESC)/expansion (EXP) study to evaluate the safety and efficacy of surufatinib in the US and Europe (EXP only). ESC previously reported the recommended phase 2 dose as 300mg once daily. Enrollment into advanced, adult, soft tissue sarcoma EXP cohorts is ongoing. The primary endpoint is PFS rate at 4 months (mo). Soft tissue sarcoma histological subtypes include: angiosarcoma (AS), epithelioid sarcoma (ES), leiomyosarcoma (LMS), pigmented villonodular synovitis (PVNS), synovial sarcoma (SS) and undifferentiated pleomorphic sarcoma (UPS). **Results:** 32 adults with soft tissue sarcoma were enrolled (2 each AS and ES; 10 LMS; 1 PVNS; 9 SS; 8 UPS). The median age across all subtypes was 56.5 years (range 26-77), and the majority of pts were female (68.8%). 59.3% of pts received ≥ 3 prior lines of therapy (Tx) (median lines of Tx: 3 [range 1-6]). As of 15 Nov 2021, 1 pt (PVNS) remained on Tx. The PFS rate at 4 mo was 17.5%. The median PFS was 2.56 mo (95% CI; 0.92-2.92). The median duration on treatment (mDoT) for all pts was 11.2 weeks (wks) (0.4-39.0). The mDoT for LMS pts was 11.6 wks (3.1-36.0), mDoT for SS pts was 11.9 wks (0.4-27.9), and mDoT for UPS pts was 8.2 wks (2.7-27.9). Of 29 pts with ≥ 1 post baseline assessment, 6 pts (20.7%) achieved stable disease of ≥ 8.0 wks from start of Tx. No pts achieved a partial or complete response. The safety profile of surufatinib remains consistent with previously completed trials. All pts (n = 32) reported ≥ 1 adverse event (AE), and 21 pts (65.6%) reported AEs ≥ grade 3. The most common AEs of any grade were fatigue (53.1%), hypertension (43.8%), diarrhea (40.6%), anemia (25.0%), blood bilirubin increase (25.0%), headache (21.9%), and proteinuria (21.9%). The most commonly reported AEs ≥ grade 3 in > 1 pt were hypertension (21.9%), fatigue (12.5%), and anemia (9.4%). AEs leading to Tx discontinuation occurred in 9.4% of pts. **Conclusions:** Surufatinib demonstrated minimal antitumor activity as a single agent in heavily pretreated pts across various types of soft tissue sarcoma. The safety profile in pts with soft tissue sarcoma remains consistent with previously reported and ongoing studies with surufatinib. Clinical trials are ongoing with surufatinib globally, with active recruitment in PD-L1 combination studies. Clinical trial information: NCT02549937. Research Sponsor: HUTCHMED International Corporation.

Handling missing covariates in observational studies: An illustration with the assessment of prognostic factors of survival outcomes in sarcoma in irradiated fields (SIF). *First Author: Noémie Huchet, Institut Bergonié, Comprehensive Cancer Center, Bordeaux, France*

Background: Missing covariates are common in observational research. They can result in biased estimations and loss of power to detect associations. Limited data regarding prognostic factors of survival outcomes of SIF are available. We assessed prognostic factors of overall (OS), progression-free (PFS) and metastatic- progression-free (MPFS) survivals in SIF using 3 methods to account for missing covariates. **Methods:** We relied on the NETSARC database of the French Sarcoma Group: Cox models for OS/PFS and competitive hazard survival models for MPFS. Prognostic factors investigated were age, sex, tumor characteristics (histology, size, depth, grade), metastasis, surgery, surgical resection, expertise of the surgeon (NETSARC/other), pre-surgical imaging (Y/N) and neoadjuvant treatment. To account for missing covariates, we used multiple imputation (MI) by fully conditional specification (Bartlett 2015). The observed data are used to estimate the missing covariate and subsequently replace (impute) the missing value by that estimate. With the "missing-data modality" alternative approach, a category "missing" was created (e.g. yes/no/missing). With the "complete-case" alternative approach, analysis was restricted to patients with all covariates available. **Results:** Among the 504 patients, 169 had all covariates available (33%). Rate of missing data was greater than 20% for imaging, neoadjuvant treatment, and surgical resection. In the complete-case analysis (N = 169), factors associated with OS included R1/R2 (vs R0) surgical resection (p = 0.03). In opposite, MI (N = 504) revealed an association with metastasis (p = 0.03), and a time-varying effect for surgical resection (p < 0.001), with a risk increasing over time for R1/R2 vs R0). For PFS and MI, associated factors included higher grade and ungradable tumors (p = 0.002) and R1/R2 vs R0 resection (p < 0.001), not found with the complete-case analysis. For MPFS and MI, factors included metastasis (p = 0.03), higher grade tumor (p = 0.007) and R1/R2 resection (p = 0.001). Grade and resection were not found in the complete-case analysis. The missing-data modality led to slight differences with MI, including significant association due to missing covariate (e.g. tumors with size missing associated with shorter PFS). **Conclusions:** We identified prognostic factors of survival outcomes for SIF. The complete-case analysis led to reduced statistical power and population was non-representative of the full sample, introducing bias. In non-randomized studies, as the outcome may be related to variables with missing values, the missing-data modality method will typically result in biased estimates. Appropriate statistical methods for missing covariates, such as MI, should be considered in particular for observational studies. Research Sponsor: None.

Prevalence of ultra-rare undifferentiated round cells sarcoma of bone and soft tissue after genomic classification. *First Author: Emanuela Palmerini, Osteoncology, Bone and Soft Tissue Sarcomas and Innovative Therapies, Orthopaedic Institute Rizzoli, Bologna, Italy*

Background: Over the last decade, the category of undifferentiated round cell sarcomas (URCS), defined by the absence of Ewing sarcoma-associated translocations, has emerged. Aim of this study was to assess prevalence of each entity and outcome after genomic classification. **Methods:** Ewing sarcoma and other URCS diagnosed between 1920 and 2020 were reviewed. All URCS with available material were analyzed with FISH, RT-qPCR and/or Archer FusionPlex Sarcoma Panel. Demographic and treatment were collected. Survival was analyzed in patients with available follow-up. **Results:** 1995 cases identified, 20 cases lacked material for further genetic analysis and were excluded. 1975 cases were classified as follows: 1925 Ewing sarcomas (97.47%), 25 CIC-rearranged sarcomas (1.27%), 16 BCOR-CCNB3 rearranged sarcomas (0.81%), 2 EWSR1-NFATC2 sarcoma (0.1%), one each as CIC-LEUTX and FUS-NFATC2 rearranged sarcoma (0.05% each), and 5 as *unclassified* URCS (0.25%). A different presentation according to tumor type was shown in 43/50 ultra-rare tumors (Table). Forty-one/50 cases had available follow-up: 20/41 patients underwent surgery, 14/41 surgery+radiotherapy, 6 radiotherapy only, and no local treatment for 1 patient. Chemotherapy was administrated to 36/41 patients (Ewing sarcoma drugs in 16/22 CIC-DUX-4 and 8/11 BCOR-CCNB3; osteosarcoma drugs in 2/11 BCOR-CCNB3, and doxorubicin/ifosfamide in 2/22 CIC-DUX4 and 2/5 URCS; not specified in 6 cases). The 3-years overall survival (OS) was 32.7%f for CIC-rearranged sarcomas (75% in localize disease, 7,7% for the advanced disease, p 0.0084), 81.8% for BCOR-CCNB3 sarcomas (87.5% localized, 66.7% advanced; p 0.0734), and 60% for URCS (p 0.057). 1 patient with CIC-LEUTX sarcoma presenting with metastases died 13 months from diagnosis, 1 patient with FUS-NFATC2 and 1 with EWSR1-NFATC2 rearrenged sarcomas were alive without disease at 8 and 5 years from onset. **Conclusions:** Prevalence of URCS characterized by a combination of morphologic observation ad molecular techniques is provided. The majority of the cases underwent surgery or surgery combined with radiotherapy, and Ewing-like chemotherapy. The survival difference among different entities underscores the need of accurate subclassification of round cell sarcomas. Novel drugs for CIC-DUX-4 sarcomas presenting with metastases are needed. Synergistic activity of PARP inhibitors (PARPi) in combination with standard chemotherapy (CTx) in leiomyosarcoma. *First Author: Olga Vornicova, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Leiomyosarcomas (LMS) are genetically heterogeneous tumors that arise from smooth muscle. Currently, the mainstay of systemic treatment for patients with advanced/metastatic disease is doxorubicin (Dox) based CTx. Several genomic analyses of LMS reveal defects in homologous recombination (HR) DNA repair pathway in about half of patients, consistent with a druggable "BRCAness" phenotype. Thus, we sought to determine which combinations of standard CTx and PARPi might be synergistic promising therapeutic strategies for LMS. **Methods:** Dox, Docetaxel (Doc), Temozolomide (Tmz) were evaluated in combination with PARPi (Olaparib [Ola], Niraparib [Nira] and Talazoparib [Tala]) at 12 different drug concentrations. Four LMS cell lines of different origins (gynecological - GY, abdominal - A, extremity - E) were tested in a high throughput manner. All drug concentrations were chosen according to EC_{50}. Cells were incubated with each combination for 7 days. Viability was assessed by ATPlite Luminescence Assay System.Evaluation of drug combination effect was performed using a Bliss synergy score. This system quantifies the degree of synergy as multiplicative effect of single drugs as if they acted independently. With a synergy score of -5 to 5, the interaction between two drugs is considered as additive; <-5 antagonistic and > 5 synergistic, and therefore a promising combination. **Results:** Anticancer activity, ranging from additive to synergistic was seen with all combinations. Results were consistent among all cell lines, independent of site of cell line origin (Table) Most synergistic combination in the majority of LMS cell lines were Dox or Tmz when combined with Tala, reaching up to 15 % and 27% above Bliss respectively. In contrast, Doc showed only additive effect with all analyzed PARPi. **Conclusions:** The data suggest that the combination of Dox or Tmz with PARPi may represent promising treatment options for LMS patients. Recent clinical studies support this notion in uterine LMS. Importantly these results suggest that such approach may be extended to all sites of LMS. Pre-clinical studies are underway to identify the most promising combinations for future clinical trial design. Research Sponsor: Canadian Institute of Health Research (CIHR).

Results of a phase I trial of ganitumab plus dasatinib in patients with rhabdomyosarcoma (RMS). *First Author: Srivandana Akshintala, Pediatric Oncology Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD*

Background: Antibodies against the insulin-like growth factor type 1 receptor (IGF1-R) have shown transient objective partial responses (PR) in patients with RMS followed by rapid development of resistance. Preclinical data demonstrate that activation of the SRC family kinase YES acts as a bypass resistance mechanism to IGF-1R targeting. Co-targeting IGF-1R and YES results in sustained responses in murine RMS models. We developed a phase I/II trial of the anti-IGF-1R antibody ganitumab combined with the multi-kinase inhibitor dasatinib in patients with RMS (NCT03041701). During the phase II part of the study, ganitumab became unavailable, and the trial was terminated early. We report here the results of the completed phase I study. **Methods:** Patients with relapsed/refractory alveolar or embryonal RMS and measurable disease were eligible. A 3+3 dose escalation design was used to determine the maximum tolerated dose (MTD), and evaluable patients were assessed for response using RECISTv1.1 criteria. All patients received ganitumab 18 mg/kg intravenously every 2 weeks. Dasatinib was administered orally on a continuous schedule. Dose level (DL)1 was 60 mg/m^2/dose (max 100 mg) once daily; DL2 was 60 mg/m^2/dose (max 70 mg) twice daily. MTD was determined based on cycle 1 dose-limiting toxicities (DLTs) and responses were assessed every 2 cycles. **Results:** Thirteen eligible patients (5M, 8F), median age 18 years (range 8-29 years) with embryonal (n = 6) and alveolar (n = 7) RMS were enrolled at DL1 (n = 7) and DL2 (n = 6). Median number of prior systemic therapies was 3 (range 1-6), all had received prior radiation, 5 prior surgery, and 2 prior high dose chemotherapy with stem cell rescue. Of 11 patients evaluable for toxicity, 1/6 had a DLT at DL1 (grade 3 diarrhea) and 2/5 had DLTs at DL2 (grade 3 pneumonitis and grade 3 hematuria) confirming DL1 as MTD. Common non-DLTs at least possibly attributed to dasatinib, ganitumab, or both included thrombocytopenia (n = 12), anemia (n = 10), lymphopenia (n = 8), hypophosphatemia (n = 7), hypocalcemia (n = 6), elevated transaminases (n = 5), fatigue (n = 5), nausea (n = 5), and vomiting (n = 5). The most common grade 3-4 adverse events were cytopenias and electrolyte abnormalities. Of 9 patients evaluable for response, 1 had a confirmed PR at DL2 sustained for 5 cycles, and 1 had prolonged stable disease (SD) for 6 cycles at DL1. Patients received a median of 1.5 cycles (range 0-6). Analysis of correlative biology studies of ctDNA and target expression are ongoing. **Conclusions:** The combination of dasatinib and ganitumab was safe and tolerable at DL1 in patients with relapsed and refractory RMS. Once daily dasatinib at 60 mg/m^2/dose (max 100 mg) combined with 18 mg/kg ganitumab every 2 weeks was determined to be the MTD. PR and SD for > 4 months were observed in this phase I trial suggesting that the addition of a YES-targeting agent may delay the development of acquired resistance to IGF-1R antibody therapy in RMS. Clinical trial information: NCT03041701. Research Sponsor: U.S. National Institutes of Health.

Identification of response stratification factors from pooled efficacy analyses of afamitresgene autoleucel ("Afami-cel" [Formerly ADP-A2M4]) in metastatic synovial sarcoma and myxoid/round cell liposarcoma phase 1 and phase 2 trials. *First Author: Sandra P. D'Angelo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Afami-cel is an autologous, HLA-A*02-restricted, specific peptide enhanced affinity receptor, T-cell therapy engineered to target MAGE-A4+ solid tumors. The pivotal, 2-cohort, single-arm, Phase 2, SPEARHEAD-1 trial (NCT04044768) with afami-cel met its primary endpoint based on Cohort 1 data. As of September 1, 2021, in 47 patients (pts) with metastatic synovial sarcoma (SyS) or myxoid/round cell liposarcoma (MRCLS), the overall response rate (ORR) per independent review was 34% with encouraging durability (Van Tine, et al. Paper 30: CTOS 2021; Virtual). To identify potential stratification factors for response and assess whether response is a proxy for progression-free survival (PFS), we present pooled analyses using data from the prior Phase 1 trial (NCT03132922) and Cohort 1 of the SPEARHEAD-1 trial. **Methods:** Eligible pts (16–75 years) were HLA-A*02+ with MAGE-A4+ tumors. Pts received afami-cel after lymphodepleting chemotherapy. The pooled analyses evaluated ORR per RECIST v1.1 by investigator review, stratified by 7 factors, and safety. **Results:** In the pooled data, 69 pts received afami-cel ($2.12–9.99\times10^9$ transduced T-cells) and were evaluable for response (Phase 1, n = 18; Phase 2, n = 51); all expressed one eligible HLA-A*02 allele. Median (range) for: age was 42 years (19–76), number of prior lines of therapy was 2 (1–12), and tumor MAGE-A4 H-score was 230 (60–300). Median (range) H-score was higher in SyS (256 [60–300]) than in MRCLS (180 [112–230]). The pooled investigator-assessed ORR was 36.2% (40.7% in SyS; 10.0% in MRCLS). Responses occurred across a wide MAGE-A4 H-score range (134–300). Median (range) duration of response was 52 weeks (8.29–75.14). Response rate was higher in the 59 pts with SyS: with ≤2 vs ≥3 prior lines of therapy (55.2% vs 26.7%), baseline target lesion sum of longest diameters <10cm vs ≥10cm (53.1% vs 25.9%), MAGE-A4 H-score ≥200 vs <200 (46.3% vs 27.8%), without vs with bridging therapy (48.6% vs 29.2%), who were female vs male (46.4% vs 35.5%), aged ≥40 vs <40 years (45.7% vs 33.3%), and from North America vs Europe (42.6% vs 33.3%). In responders vs non-responders with SyS, respectively, median PFS was 58.3 vs 11. 0 weeks (log-rank p-value <0.0001); the probability of being progression-free at 24 weeks was 0.8 vs 0.2. The pooled benefit:risk profile of afami-cel was similar to that in the SPEARHEAD-1 trial (Van Tine, et al. Paper 30: CTOS 2021; Virtual.). **Conclusions:** We show that baseline tumor burden, prior systemic treatment history, and MAGE-A4 tumor expression levels are potential factors associated with response to afami-cel, although their true predictive value for response status awaits confirmation. Our findings will inform the ongoing clinical development of afami-cel in sarcoma, especially for prognostic studies with PFS or overall survival endpoints. Clinical trial information: NCT04044768, NCT03132922. Research Sponsor: Adaptimmune.

Phase 1b study of weekly split-dose selinexor in soft tissue sarcoma (STS). *First Author: Abdulazeez Salawu, Princess Margaret Cancer Centre, University Health Network, University of Toronto, Toronto, ON, Canada*

Background: Selinexor has demonstrated clinical activity in a variety of tumors including STS. Selinexor dosing at 60mg twice a week or 80mg once a week in later phase trials was associated with gastrointestinal and hematologic toxicities requiring frequent dose interruption and reduction. Preclinical *in vivo* studies show that selinexor use in a split-dose regimen or sustained-release formula is associated with less toxicity. This phase 1b study aimed to evaluate the safety and tolerability of split-dose selinexor in patients (pts) with advanced STS. **Methods:** Eligible pts with advanced STS of any histologic subtype, and ECOG performance status (PS) ≤ 1 were treated with split-dose selinexor (40mg, 20mg, 20mg in the morning, afternoon, and evening, respectively) on days 1, 8, 15 and 22 of a 28-day cycle, until unacceptable toxicity or disease progression. Antiemetic prophylaxis (oral dexamethasone and ondansetron) was given to all pts. The primary endpoint was the rate of grade ≥ 3 treatment-related adverse events (TRAE) by CTCAE v5.0. The secondary endpoint was assessment of quality of life (QoL) using the EORTC QLQ-c30 tool v3. Descriptive analyses of Global Health Status (GHS) QoL scores at screening (baseline) and cycle 2 day 1 (C2D1) were performed. Radiologic tumor assessments (by RECIST v1.1) were performed every 8 weeks while on treatment. **Results:** Nineteen pts [12 female and 7 male; ECOG 0/1, 8/11; median age 61 years (range 41 – 83)] were enrolled. The most frequent of 12 STS subtypes was leiomyosarcoma (n = 7, 37%). Among 18 patients evaluable for toxicity, there were no grade ≥ 3 TRAE. The most common grade ≤ 2 TRAE were dysgeusia (n = 11, 61%), nausea (n = 11, 61%), fatigue (n = 10, 56%) and vomiting (n = 10, 56%). Grade ≤ 2 hematologic TRAE were thrombocytopenia (n = 6, 33%), neutropenia (n = 4, 22%) and anemia (n = 1, 6%). Dose reduction was required in 3 pts (17%) due to intolerable grade 2 TRAE (fatigue, nausea, thrombocytopenia). No serious adverse event due to selinexor was noted. QoL scores were evaluable for 15 pts. The mean (± SEM) change in GHS QoL score from baseline to C2D1 was -10.6 (± 4.8). Among 16 pts evaluable for radiologic response, the best response was stable disease (SD) in 10 pts (63%), and progressive disease (PD) in 6 pts (37%). Durable clinical benefit (SD for > 16 weeks) was seen in 5 pts (31%; 95%CI 11.0 – 58.7%) The median PFS was 3.6 months (95%CI 1.7 – 7.3). **Conclusions:** Split-dose selinexor was well tolerated in this heterogeneous group of pts with advanced STS and warrants further interrogation. Updated toxicity, safety, efficacy and QoL data will be presented at the meeting. Clinical trial information: NCT04811196. Research Sponsor: University Health Network, Toronto, Pharmaceutical/Biotech Company.

Trabectedin and hypofractionated radiation for high-risk, localized, and metastatic soft tissue sarcoma: A retrospective study. *First Author: Narine Wandrey, University of Colorado Cancer Center, Aurora, CO*

Background: Soft tissue sarcomas (STSs) are a heterogeneous group of cancers with high unmet need. Trabectedin (T) is an FDA-approved chemotherapy that blocks cell cycling and DNA repair pathways. Combination T and conventional radiation (XRT) in STS nonrandomized phase 1/2 trials demonstrated objective response rates (ORR) of 36-72% in localized and low burden metastatic disease, while pre-treated metastatic STS treated with T alone has an ORR of 10-14%. We hypothesize that the combination of T and hypofractionated radiation (hXRT) will exhibit a tolerable safety profile and improve ORR relative to historical outcomes with T or hXRT alone. Here we report our experience in the treatment of oligometastatic STS with combined T and hXRT. **Methods:** We reviewed our institutional experience to identify patients treated with T and XRT. We included patients with high risk localized or metastatic STS (majority of patients had metastatic disease at time of treatment). All patients received at least 1 cycle of T and concurrent XRT to at least 1 lesion. ORR and local control rate (LCR) were determined for irradiated lesions by RECIST 1.1. **Results:** Between 2020 – 2021, 9 STS patients with 21 tumors were treated at the University of Colorado with XRT and concurrent T. The median age was 39.2 (range 26.0 – 64.6) years. 8 patients had metastatic disease at the time of treatment. Treated tumor sites included 1 lung,1 extremity, 2 liver, 2 retroperitoneal, 5 bone, and 10 peritoneal. The following histologic subtypes were included: myxoid liposarcoma (3), uterine leiomyosarcoma (2), non-uterine leiomyosarcoma (1), dedifferentiated liposarcoma (1), undifferentiated pleomorphic sarcoma (1), and synovial sarcoma (1). All metastatic patients were pre-treated with a median of 3 lines of systemic therapy. The median number of T cycles delivered was 5 (range 1 – 20). The median XRT prescription dose was 3000cGy (range 2000cGy – 5000cGy), with 8 patients having received hXRT (5 -10 fractions) and 1 having received conventionally fractionated XRT. 8 patients underwent 1 course of XRT, while 1 received 3 courses in combination with T. All patients had a Karnofsky performance status equal to or greater than 60. After a median follow-up 5.4 months, the LCR of treated lesions was 90.5%. The ORR (CR or PR) was 57.1% and median decrease in tumor diameter at time of maximum response was 52.0%. The median time until maximum response was 3.7 months. 2 patients experienced grade 3 toxicity (LFT elevation) attributable to T, and 2 patients experienced grade 3 toxicity due to XRT. There were no grade 4 or 5 toxicities. **Conclusions:** T in combination with hXRT appears to be safe and feasible in this patient population. Based on these data, a phase 1/2 prospective clinical trial is being planned in oligometastatic and high risk localized STS. Research Sponsor: None.

Local Control Rate	# of Treated Tumors (n = 21)
SD	7 (33.4%)
PR	7 (33.3%)

Radiomics of MRI scans enables differentiation of benign from malignant soft tissue sarcoma. *First Author: Lin Li, Case Western Reserve University, Cleveland Heights, OH*

Background: Accounting for >15,000 cases annually, soft tissue sarcomas (STSs) represent a large spectrum of tumors with varying histology and clinical course. However, diagnosis of STSs on MRI is challenging due to its heterogeneous imaging phenotypes, such as surrounding soft tissue edema, vascular lesion characteristics, and specific imaging signs, such as splitting of fat between muscles. The goal of this study was to evaluate the utility of radiomic feature analysis for characterizing subtle heterogeneity patterns on T2-weighted MRI to distinguish benign and malignant STSs. **Methods**: T2-weighted MRI of N = 176 patients with STS were retrospectively obtained from a single institution. (Table) Tumor regions were manually annotated by a radiologist. The radiomic features included textural features, e.g. gray-level co-occurrence matrix features, which quantify the correlation between textural patterns within annotated regions. Maximum relevance minimum redundancy feature selection was employed to identify top 10 radiomic features that are associated with STS malignancy. Then, the identified features were integrated to generate a radiomic risk score (RRS) via logistic regression on a 10-fold cross validation to differentiate benign and malignant STS. Multivariate analysis and the area under the receiver operating characteristic curve (AUC) were employed to evaluate the association of RRS and clinical parameters, including age, gender, and STS location, with STS malignancy. **Results**: Multivariate analysis illustrated that age and RRS are independent variables in predicting STS malignancy ($p < 0.05$). The RRS yielded AUC as 0.76 (confidence interval (CI): 0.69-0.83), age 0.71 (CI: 0.64-0.79) and the combination of the RRS and age 0.84 (CI: 0.78-0.90). **Conclusions:** The RRS generated by radiomic features was found to be a significant predictor of STS malignancy. Furthermore, RRS could provide complementary information to the clinical parameters in differentiating benign and malignant STSs. Epitheliod hemagioendothelioma (EHE) patient-derived model (PDX): Drug activity assessment and validation of novel biomarkers. *First Author: Silvia Stacchiotti, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: EHE is an ultra-rare sarcoma marked by two specific fusions, *WWTR1-CAMTA1* (~90%) and *YAP1-TFE3* (~10%). The clinical course of EHE ranges from indolent to highly aggressive, often associated with systemic paraneoplastic symptoms. Molecular predictors of clinical outcome are unknown. While surgery is the mainstay of treatment in the localized setting, management of advanced disease is challenging due to the rarity and poor sensitivity to conventional chemotherapy. This hampers the conduct of large prospective clinical trials. We report herein the first available EHE PDX (developed at the Istituto Nazionale Tumori, Milan, Italy) (INT), to assess the activity of old and new anticancer agents in EHE and inform future clinical studies. We also report on the preliminary results of a prospective observational study, ongoing in collaboration with The EHE Rare Cancer Charity (UK) and The EHE Foundation (US) aimed at identifying prognostic factors. **Methods:** A PDX of EHE in SCID mice was generated at INT from a patient (pt) suffering with the aggressive clinical variant, presenting with systemic symptoms. The PDX fully reproduces the originating clinical tumor in terms of morphology, biology (*WWTR1-CAMTA1* positive), overall transcriptomic profile. 2D (monolayer) and 3D (sferoids) cell cultures were established following PDX disaggregation. We have started assessing the comparative activity of currently available drugs (doxorubicin, sirolimus), while the efficacy of novel agents is undergoing. In parallel, we analyzed the presence of a selection of inflammatory cytokines in prospectively collected blood samples from EHE pts who entered an international observational study and we looked at their presence and modulation in the PDX model. **Results:** PDX experiments showed almost negligible activity of doxorubicin while sirolimus induced an 80% tumor volume inhibition. Biochemical analysis in tumors explanted from sirolimus-treated mice confirmed the down-regulation of mTOR downstream signaling. Among all cytokines, Growth and Differentiation Factor-15 (GDF-15) was found significantly over-expressed in serum of EHE pts (n = 23), particularly those with the most aggressive clinical variant, compared to healthy subjects (n = 23; $p< 0.01$). Consistently, EHE PDX and cell culture were found to release in the blood/culture medium GDF-15. Sirolimus was found to down-regulate GDF-15 release in both *in vivo* and *in vitro* EHE models. **Conclusions:** Our preliminary results indicate that this EHE PDX model is suitable *i)* for comparatively assessing the activity of anticancer drugs, and *ii)* for identifying and pre-clinically validating novel biomarkers. The role of GDF-15 in EHE progression deserves further investigation. Research Sponsor: Grant by the EHE Rare Cancer Charity (UK) and The EHE Foundation (US).

LTX-315 and adoptive cell therapy using tumor-infiltrating lymphocytes in patients with metastatic soft tissue sarcoma. *First Author: Morten Nielsen, National Center for Cancer Immune Therapy, Department of Oncology, Copenhagen University Hospital, Herlev, Denmark, Herlev, Denmark*

Background: Adoptive cell transfer (ACT) with tumor-infiltrating lymphocytes (TILs) is a potent treatment that can induce complete and durable tumor regression as documented in patients with metastatic melanoma. To our knowledge, ACT has not been utilized for patients with metastatic soft-tissue sarcoma (STS). LTX-315 is an oncolytic peptide that has been shown to increase TILs in malignant tumors after intratumoral injection. In this trial, patients with metastatic sarcoma were treated with the combination of LTX-315 and TIL - based ACT. **Methods**: Patients with progressive metastatic STS after a minimum of one systemic treatment were eligible for inclusion. In step 1, patients received up to five treatments over 2-3 weeks with LTX-315 injections. Afterwards, the injected tumor was surgically removed, and TILs were expanded *in vitro*. In step 2, patients received preparative chemotherapy followed by infusion of the expanded TILs, and follow-up treatment with subcutaneous IL-2. The impact of LTX-315 on tumor microenvironment was assessed by immunohistochemistry (IHC) on biopsies collected before and after injections. Clinical effect of the treatment was assessed by follow-up CT-scans using RECIST 1.1. Exploratory analyses aimed at identifying tumor reactive T cells in the expanded TILs and in peripheral blood (PBMC) in the patients before and after treatment. Expanded TILs or PBMC were cocultured with autologous tumor or selected neo-peptides and reactivity was assessed by measurement by Elispot or flow cytometry. **Results**: Six patients received intratumoral injections with LTX-315. In 3 out of 5 samples available for IHC, increased infiltration of CD4+ cells following LTX-315 injections was observed. Four patients received the full treatment with both LTX-315 injections and ACT. Total number of infused cells was 44-63x10^9, comprising 0,4-52% CD8+ T cells. Treatment was tolerated with manageable toxicity. After completed treatment, all four patients had stable disease as best overall response. Two patients with leiomyosarcoma and solitary fibrous tumor had stable disease for 25 and 20 weeks, respectively. In these two patients, and one additional patient, Elispot analyses showed presence of tumor-reactive cells in the PBMC following treatment. **Conclusions**: This trial demonstrates that the combination of LTX-315 and ACT is feasible and tolerable with manageable toxicity. CD4+ and CD8+ TILs can be expanded *in vitro* from sarcomas that have been pretreated with the oncolytic peptide LTX-315. Furthermore, the data suggest that LTX-315 can modulate the tumor microenvironment in sarcomas, thus potentially affect the expanded TILs that can be used for ACT. Further optimization of the treatment schedule will position LTX-315 as technology to invoke tumor specific T cells that can be cultured and infused as part of an adoptive transfer regimen for several subtypes of soft tissue sarcoma. Clinical trial information: NCT03725605. Research Sponsor: Lytix Biopharma AS.

Randomized, placebo-controlled, double blind, phase II study of zaltoprofen for patients with diffuse-type and unresectable localized tenosynovial giant cell tumors. *First Author: Akihiko Takeuchi, Department of Orthopaedic Surgery, Graduate School of Medical Sciences, Kanazawa University, Kanazawa, Japan*

Background:A tenosynovial giant cell tumor (TGCT) is a locally aggressive benign neoplasm arising from intra- or extra-articular tissue, and categorized localized (L-TGCT) or diffuse-type (D-TGCT). D-TGCT most commonly develops in the knee or ankle. We revealed that zaltoprofen, a nonsteroidal anti-inflammatory drug possessing the ability to activate peroxisome proliferator-activated receptor gamma (PPARγ), can inhibit the proliferation of TGCT stromal cells via PPARγ. PPARγ is a ligand-activated transcription factor that belongs to the nuclear hormone receptor superfamily. Therefore, we conducted a randomized trial to evaluate whether zaltoprofen was effective for patients with TGCT. **Methods:**This study was a randomized, placebo-controlled, double-blind, multicenter trial to evaluate the safety and efficacy of zaltoprofen for patients with L-TGCT or D-TGCT. For the treatment group, zaltoprofen 480 mg/day was administered for 48 weeks. The primary outcome was the progression-free rate (PFR) at week 48 after treatment administration. Disease progression was defined as follows requiring surgical interventions: 1) repetitive joint swelling due to hemorrhage; 2) limited range of joint motion; 3) invasion of adjacent cartilage or bone; 4) severe joint space narrowing; or 5) increase in tumor size (target lesion). This study was registered at the University Hospital Medical Information Network (UMIN) Clinical Trials Registry (UMIN000025901). **Results:**We allocated forty-one patients to zaltoprofen (n = 21; Z) or placebo (n = 20; P) groups. The mean age was 44 years (range, 26 to 66) in the group Z and 47 years (range, 24 to 69) in the group P. TGCTs located at a knee in 26 patients and at an ankle in 15 patients. The primary outcome of PFR for the group Z was not higher than that for the group P at week 48 (84.0% vs. 90.0%; p = 0.619). The objective tumor response was graded as partial response (PR) in 1 patient, stable disease (SD) in 19, and progressive disease (PD) in 1 for the group Z, and SD in 17 and PD in 3 for the group P. The mean musculoskeletal tumor society scoring system for group Z was significantly improved from baseline to week 48 (83.8% vs. 93.0%, p = 0.02), whereas that for the group P was not significantly improved (82.2% vs. 86.8%; p = 0.167). During the study period, one severe adverse event was observed (grade 3 hypertension) in the group Z. **Conclusions:**To our knowledge, this was the first study to evaluate the efficacy of zaltoprofen in patients with TGCT. The TGCT patients in zaltoprofen group did not have higher PER compared with those in the placebo group at week 48. Zaltoprofen appeared to improve the limb-function. Both groups presented with a stable disease course for 48 weeks, therefore, the long-term clinical course of TGCT should be clarified. Further analysis with long-term administration of zaltoprofen is considered for the future study. Clinical trial information: UMIN000025901. Research Sponsor: Japan Agency for Medical Research and Development (AMED).

The comparison of tumor microenvironment characteristics of well-differentiated and dedifferentiated liposarcoma and the association between immune cell infiltrations and recurrence of tumor. *First Author: Yuhong Zhou, Department of Medical Oncology, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Well-differentiated liposarcoma (WDLPS) and dedifferentiated liposarcoma (DDLPS) are common malignancies of adipocytic origin, which are in different differentiation stages. Both of them are characterized by high local recurrence rate. The tumor microenvironment (TME) is associated with the prognosis of tumor and immune-related cell infiltrations has been proved to be one of the mechanisms affecting the efficacy of immunotherapy. However, the difference between TME characteristics of WDLPS and DDLPS as well as the association between immune cell infiltrations and recurrence of WD/DDLPS has not been fully studied. **Methods:** 37 Chinese patients with liposarcoma were enrolled in this study, including 24 patients with WDLPS and 13 patients with DDLPS. Tissue samples from these patients were examined, who experienced previous recurrence or no recurrence. The density and percentage of the immune-related cell subsets in the TME were identified by multiplexed immunohistochemistry and multispectral imaging. Twenty cell lines derived from patients with liposarcoma in our center were used to analyze the correlation of immune-related cells content between patient tissues and cell lines. **Results:** Overall, DDLPS had more immune cell infiltrations than WDLPS. Compare to WDLPS, the density of CD8+ (the cytotoxic T cells identification) cells and CD163+ (M2 macrophages identification) cells and the percentage of FOXP3+ (Treg cells identification) cells was significantly more in DDLPS, with a Wilcoxon p-value of 0.02, 0.04 and 0.03, respectively. There was no significant difference in other protein markers between WDLPS and DDLPS. According to the multiple cut-off values (tertiles, quintile and tenths) of immune-related cells, the Chi-square test results equally suggested more immune infiltrations in patients with DDLPS. PD-1+ cells was significantly more (Wilcoxon p = 0.02), while FOXP3+ cells were significantly fewer (Wilcoxon p = 0.04) in patients without recurrence than those in patients with previous recurrence. Patients without recurrence had more CD3+ cells (the total T cells identification) and CD163+ cells infiltrations, although the both Wilcoxon p-value were not statistically significant. The total T cells, CD4+ T cells and Treg cells were more distributed in tumor tissues with no recurrence or recurrence for once, but less in patients with two or more recurrence. In addition, no strong correlation of immune-related cells content between patient tissues and cell lines were observed in our analysis. **Conclusions:** Our findings suggested that patients with DDLPS might benefit more from immunotherapy than patients with WDLPS due to the infiltrating TME of DDLPS. The increase of recurrence times might lead to a more repressive TME in liposarcoma. Research Sponsor: None.

Dose intensity and outcomes of VDC/IE chemotherapy for adolescent and adult patients with Ewing's family sarcoma. *First Author: Danielle Klingberg, Prince of Wales Hospital, Sydney, NSW, Australia*

Background: Ewing's family sarcoma (EFS) is a rare and aggressive malignancy with peak incidence in the second decade of life. Treatment is multimodal, involving local surgery and/or radiotherapy, and chemotherapy, typically with VDC/IE (Vincristine, Doxorubicin, Cyclophosphamide alternating with Ifosfamide, Etoposide). There is paucity of data in the adult setting, with treatment protocols extrapolated mainly from the paediatric setting. We assessed chemotherapy dose intensity and outcomes across four Australian sarcoma centres (three adult and one paediatric centre). **Methods:** Using the Australia New Zealand Sarcoma Association national database (ACCORD) and medical records, we identified patients aged ≥10 years diagnosed with EFS between 2010-2020. Clinical characteristics, treatment and survival information were collected for those receiving Ewing protocol with VDC/IE backbone. Received Dose Intensity (RDI) of chemotherapy was calculated using planned and actual doses received and time taken. RDI ≥85% was considered acceptable, consistent with published literature. We compared survival outcomes based on RDI. Clinical predictors of achieving an acceptable RDI were explored using logistic regression. **Results:** Of 146 patients with EFS identified, 76 received VDC/IE (59% male). The median age was 25 years, with age distribution 24% aged 10-19, 58% aged 20-39, and 18% aged 40-59. Majority had extraskeletal Ewing's (57%), non-extremity primary site (64%) and localised disease (stage, II 37%; III 28%; IV 28%). Treatment received included surgery (74%), radiotherapy (66%) and chemotherapy (100%). Over two-thirds (70%) completed their scheduled chemotherapy and 57% achieved an acceptable RDI (67% aged 10-19, 61% aged 20-39, 29% aged 40-59). Compared to those aged 10-19, the odds ratio (OR) of an acceptable RDI for patients aged 20-39 was 0.79 (95% CI 0.24-2.46, p = 0.70) and for patients aged 40-59 was 0.20 (95% CI 0.04-0.86, p = 0.04). The median number of chemotherapy cycles was 14 (range, 2-17). Dose reductions were mostly within 20% cumulative target dose (91%), and were predominantly for neutropenia (47%), thrombocytopenia (30%) and/or anaemia (28%), and less frequently for cardiotoxicity (7%). Median follow-up was 37.3 months. Two-year progression-free survival (PFS) rates were 56% for acceptable RDI, compared to 30% for low RDI (p = 0.001), with two-year overall survival (OS) rates respectively 88% versus 49% (p < 0.001). After adjustment for age, gender, Ewing's type, primary site and stage, RDI remained an important prognostic factor (PFS HR 0.39, 95% CI 0.18-0.82; OS HR 0.25, 95% CI 0.10-0.63). **Conclusions:** Survival outcomes in EFS were contingent on achieving an acceptable RDI. It was more difficult to maintain VDC/IE chemotherapy dose intensity in adults aged over 40 years, due to myelosuppression. Optimal treatment strategy for older adults remains to be defined. Research Sponsor: None.

PEC-PRO: A new prognostic score from a series of 93 patients with localized perivascular epithelioid cell neoplasms (PEComas) treated with curative intent. *First Author: Justine Gantzer, Medical Oncology Department, ICANS, Strasbourg, France*

Background: Perivascular Epithelioid Cell Neoplasms (PEComas) encompass a heterogeneous family of mesenchymal tumors. The current understanding of their natural history is limited. Previously described clinicopathological factors aimed to define benign or malignant variants, but there is a lack of prognostic factors associated with recurrence of surgically resected tumors, preventing the development of a prognostic score to better optimize patient's management. **Methods**: This is a retrospective analysis of clinicopathological features from patients diagnosed with a localized PEComa, within all centers from the French Sarcoma network and one center in Belgium. We analyzed 12 clinicopathological factors in a Cox proportional hazard framework to derive a multivariate prognostic risk model for progression-free survival (PFS). We built the PEComa PROgnostic score (PEC-PRO) ranging from 0 to 5, based on the coefficients of the multivariate model. Three different prognostic groups were identified: low risk (score = 0), intermediate risk (score = 1) and high risk (score ≥2). **Results**: Ninety-three patients were analyzed with a median follow-up of 46 months (range, 3-253). At diagnosis, the median age was 54 years (range, 13-84), with female predominance (72%). Most common primary locations were uterus (n = 15;16%) and kidney (n = 15;16%). Median tumor size was 6.2 cm (range, 0.8-30). Among patients with reported surgical margins, 64 (73%) and 23 (27%) had R0 and R1-2 margins, respectively. The median PFS was 26 months (IC95, 2.9-124.4), with 1- and 5-year overall survival (OS) rates of 95.7% and 69.9%, respectively, while the median OS was not reached. Using univariate analyses, male gender, primary tumor size > 5 cm, high nuclear grade and cellularity, high mitotic rate > 1/50 HPF, necrosis, vascular invasion, nodal invasion, and R1-2 margins were associated with a shorter PFS. Among those, male gender (HR = 2.88; IC95 1.12-7.411, p = 0.03), vascular invasion (HR = 3.14; IC95 1.10-8.96, p = 0.034), necrosis (HR = 3.93; IC95 1.35-11.47, p = 0.015), and R1-2 margins (HR 4.47; IC95 1.60-12.46, p = 0.007) remained associated with PFS in the multivariate analysis and were included in the multivariate model. Median PFS in patients with high PEC-PRO score was 16 months as compared to 104 months and not reached for patients with intermediate and low PEC-PRO scores, respectively (p < 0.001). We also confirmed the prognostic relevance of the PEC-PRO score in terms of OS. **Conclusions**: Using a weighted combination of clinicopathological features, the PEC-PRO score reliably predicts the post-operative recurrence risk in patients with localized PEComas. It has the potential to better improve follow-up strategies and personalize adjuvant treatments. The findings of this retrospective analysis require validation in a prospective trial. Research Sponsor: None.

Which angiosarcoma subtypes may benefit from immunotherapy? *First Author: Stefan G van Ravensteijn, Department of Medical Oncology Radboud University Medical Centre, Nijmegen, Netherlands*

Background: Angiosarcomas (AS) are aggressive mesenchymal tumors arising from cells with endothelial properties. They include de novo primary AS (pAS), and secondary AS (sAS) due to prior radiotherapy, UV exposure or chronic lymphedema. Treatment options are limited and their prognosis is poor. Development of new treatment strategies is difficult due to the heterogeneity and rarity of AS. We hypothesize that immunological and genomic profiles are significantly different between pAS and sAS and may result in different immune checkpoint inhibition (ICI) based treatment strategies. **Methods:** Tumor samples from AS patients were retrospectively collected. Patients were categorized as pAS or sAS. Lymphocytes were analyzed using multiplex immunohistochemistry on tissue microarrays. Genomic profiling was performed in a selected subgroup with "TruSight Oncology 500", a Next Generation Sequencing panel containing 523 cancer related genes. **Results:** Immunological data were analyzed from 257 AS patients. The cohort comprised 80 pAS patients and 177 sAS patients. The median density of CD3+ T cells was 250 cells/mm^2 in pAS vs 452 cells/mm^2 in sAS (p< 0.001). Median CD4+ T helper cell density was 128 cells/mm^2 in pAS vs 246 cells/mm^2 in secondary AS (p< 0.001). The median density of CD8+ cytotoxic T cells was 85 cells/mm^2 in pAS vs 111 cells/mm^2 in sAS (p= 0.057). Density of FoxP3+ T regulatory cells was higher in sAS (median 42 cells/mm^2) compared to pAS (median 23 cells/mm^2) (p< 0.001). The median count of CD20+ B cells in pAS was 24 cells/mm^2 compared to 32 cells/mm^2 in sAS (p= 0.533). Genomic analysis was performed on tumor DNA from 51 patients (25 pAS and 26 sAS). Median tumor mutational burden (TMB) was 3.2 (range 0.8-11.9) mutations per megabase (mut/Mb) in pAS vs 3.9 (range 0.0-99.6) in sAS (p= 0.485). No microsatellite instability was detected. A pathogenic mutation, gene amplification or gene loss was identified in 82% of all patients (n = 42, 70% of pAS vs 100% of sAS (p< 0.01)). In 36 patients (71%) at least one (likely) pathogenic mutation was detected (54% pAS vs 88% sAS, (p= 0.013)). In 20 patients (39%) mutations in the DNA damage response (DDR) pathway were detected (12% pAS vs 68% sAS (p< 0.01)). The most frequently found mutated genes were *TP53* (10%), *BRAF* (6%), *ERCC4* (6%), *PTPRD* (6%), *WETD2* (6%) and *SETD2* (6%). Amplifications were found in 49% (n = 25) of all patients (15% pAS vs 84% sAS, (p< 0,01)). *MYC* amplifications were most common and were detected in 15% of pAS and 68% of sAS. Immune profiles of the 51 genomically characterized patients are currently under further investigation. **Conclusions:** We showed a clear distinction in immunological and genomic profiles between pAS and sAS. The potential benefit of ICI seems to be most promising in sAS with a T cell inflamed tumor microenvironment, frequent MYC amplifications, DDR mutations, and high mutational load, while in pAS boosting strategies to enhance susceptibility to ICI might be interesting for further investigation. Research Sponsor: Sarcoma Foundation of America.

11573 **Poster Session**

Five-year results of a phase 2 trial using ipilimumab (I), nivolumab (N), and trabectedin (T) for previously untreated advanced soft tissue sarcoma (NCT03138161). *First Author: Erlinda Maria Gordon, Sarcoma Oncology Research Center, Santa Monica, CA*

Background: Understanding the bifunctional role that the immune system plays in tumor eradication vs growth promotion is critical in the design and timing of tumoricidal and immunologic therapies for sarcomas. Hypothesis: Immune checkpoint inhibitors that promote sustained T cell activation would be most effective when given as first line therapy, together with a tumoricidal agent. **Methods:** Eligible patients for this Phase 2 study are males or females ≥ 18 years of age with locally advanced unresectable or metastatic soft tissue sarcoma, previously untreated, with measurable disease by RECIST v1.1. Treatment protocol: (I) mg/kg i.v. q 12 wks, (N) 3 mg/kg i.v. q 2 wks, (T) 1.2 mg/m2 CIV q 3 wks. Treatment Outcome Parameters: (1) Best objective response rate by RECIST v1.1, (2) Progression-free survival (PFS), (3) Overall survival (OS), and (4) Incidence of treatment-related adverse events. **Results:** Ninety-nine patients were enrolled. Efficacy analysis (n = 88): There were 8CR (1 surgical CR), 11PR, 58SD, 11PD. Overall response rate was 21.6%, Disease Control Rate, 87.5%. The median PFS was 7 (range:1-44) months, median OS, 14 (range: 1-46) months. Grade 3 TRAEs include fatigue (n = 8), adrenal insufficiency (n = 1), dehydration (n = 1), hyponatremia (n = 2), increased AST (n = 8), increased ALT (n = 24), increased ALP (n = 2), port site infection (n = 2), psoriasis exacerbation (n = 1), anemia (n = 9), thrombocytopenia (n = 2), and neutropenia (n = 5). Grade 4 TRAES include anemia (n = 1), neutropenia (n = 1), thrombocytopenia (n = 2), increased AST (n = 2), increased ALT (n = 2), and increased CPK (n = 2). Grade 5 TRAES include rhabdomyolysis (n = 1). There was no incidence of alopecia nor cardiac toxicity reported. **Conclusions:** Taken together, these data indicate that first-line combinatorial therapy with Ipilimumab, Nivolumab, and Trabectedin (1) may be more effective than standard first line therapy (doxorubicin/ifosfamide/mesna), and (2) is safer than standard first line therapy for advanced soft tissue sarcoma. Clinical trial information: NCT03138161. Research Sponsor: None.

***nab*-Sirolimus for patients with advanced malignant PEComa with or without prior mTOR inhibitors: Biomarker results from AMPECT and an expanded access program.** *First Author: Mark Andrew Dickson, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Malignant perivascular epithelioid cell tumor (PEComa) is a rare and aggressive sarcoma. *nab*-Sirolimus is an albumin-bound intravenous (IV) mTOR inhibitor (mTORi) approved for the treatment of adult patients with locally advanced unresectable or metastatic malignant PEComa. The AMPECT trial (NCT02494570) was the first prospective study in advanced malignant PEComa. In exploratory biomarker analyses, *TSC1* or *TSC2* alterations were associated with response. We report data from the final analysis of AMPECT patients, who were naïve to mTORi, and in patients with malignant PEComa with prior mTORi exposure treated with *nab*-sirolimus in an expanded access program (EAP) (NCT03817515). **Methods:** In AMPECT, patients with malignant PEComa naïve to mTORi received *nab*-sirolimus (100 mg/m^2 IV days 1 and 8 of every 21-day cycle) until progression or unacceptable toxicity. The primary endpoint was ORR by independent radiology review. Other endpoints included duration of response (DOR) and disease control rate (DCR), defined as complete response (CR), partial response (PR), or stable disease (SD) at ≥12 weeks. In the EAP, patients with malignant PEComa and prior mTORi exposure received the same dose of *nab*-sirolimus as in AMPECT. Responses and DCR were evaluated post hoc via electronic medical record review. Genetic profiling, including *TSC1* or *TSC2* status, was assessed in both protocols, but no specific mutation criteria were required for enrollment. **Results:** Data include 47 total efficacy-evaluable patients, 31 in AMPECT and 16 with malignant PEComa and prior mTORi exposure treated in the EAP from July 2019–July 2021. Prior mTORi on the EAP included sirolimus, everolimus, temsirolimus, or sapanisertib; 12 patients had exposure to 1 prior mTORi and 4 to ≥2 prior mTORi, and 50% had had progressive disease as best response on mTORi. In AMPECT, ORR was 39% (12/31 patients), and DCR was 71%. Median DOR was not reached after 3 years of follow-up. On the EAP, 4/16 patients (25%) achieved PR (DOR range: 1.3+–25.2+ months, 3 ongoing), and 8/16 (50%) had SD as best response; the DCR was 63% (10/16). Of patients with known *TSC1* or *TSC2* inactivating alterations in the combined datasets (n = 23), 57% had a response (AMPECT, 64%; EAP, 44%). There were no Grade 4 or 5 treatment-related adverse events on either protocol **Conclusions:** *nab*-Sirolimus provided durable responses in mTORi-naïve patients with malignant PEComa and clinical benefit in an expanded access protocol for patients with malignant PEComa with prior mTORi therapy. Although AMPECT and the EAP cannot be directly compared, response rates showed similar trends regardless of prior mTORi exposure and in patients with *TSC1* or *TSC2* alterations. Based on the emerging biomarker results, a tissue-agnostic study in patients with *TSC1* and *TSC2* alterations has been initiated (NCT05103358). Clinical trial information: NCT02494570, NCT03817515. Research Sponsor: AADi Bioscience.

Trabectedin in advanced retroperitoneal well differentiated/dedifferentiated liposarcoma and leiomyosarcoma (TRAVELL): Results of a phase 2 study from Italian sarcoma group (ISG). *First Author: Roberta Sanfilippo, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy*

Background: To further explore the activity of T as second/further line treatment in retroperitoneal leiomyosarcoma (LMS) and well differentiated/dedifferentiated liposarcoma (LPS). The primary endpoint of the study was the growth modulation rate (GMR) defined as the ratio between the time to progression under T (TTP) and during previous chemotherapy treatment (TTP-1). The secondary end-points were objective response rate as per RECIST and PFS. **Methods:** This was a multicenter, single-arm Phase 2 study, conducted in 20 Italian centers. Patients with locally relapsed or metastatic disease, already treated with one or more previous systemic treatments with anthracyclines and/or ifosfamide, were enrolled. T was administered at a dose of 1.3-1.5 mg/mq with a top dose of 2.6 mg per cycle. T was administered as a 24h continuous infusion until progressive disease, major toxicity, patient's intolerance or medical decision. As per protocol, patients were considered responders if the GMR was > 1.33, non-responders if < 0.75 and neither if 0.76-1.32. Eighty evaluable patients were needed to detect an odds of trabectedin response ≥ 2.5, corresponding to 71.4% of patients with a GMR > 1.33 (80% power, one-sided alpha 2.5%). **Results:** From August 2014 to February 2019, 104 patients were registered and 91 were evaluable for the primary endpoint (32 pts with LMS and 59 with LPS). Overall, the median number of cycles received was 6.0 (q1-q3 3.0-12.0), the main reason for treatment discontinuation was disease progression in 72% of patients, followed by medical decision (8%). The median TTP was 6.0 months (6.2 and 6.0 for LMS and LPS), while the median TTP-1 was 7.5 months (8.1 and 6.4 for LMS and LPS). Thirty three patients (52% 95%CI: 36-58, p = 0.674, odds of response = 1.1) had a GMR > 1.33 (LMS: 46%, 95%CI 26-67,odds = 0.85; LPS 56%, 95%CI 40-72, odds = 1.3).Overall, response rate (CR+PR) was 16% (24% for LMS and 12% for LPS). Overall, in LPS we observed 15/47 patients with GMR < 0.5 and 15/47 with GMR > 2. Among LMS patients, 9/26 had a GMR < 0.5 and 10/26 > 2. Between LPS six patients had a GMR > 5. Previous treatment had been based on anthracyclines and/or ifosfamide in 85% of patients (91% in LPS population). **Conclusions:** While the primary end point of the study was not met, we noticed a subgroup of patients with a markedly discrepant TTP with T in comparison to previous therapy (GMR < 0.5 or > 2, the latter including some pts with a long TTP with T). Efforts are ongoing to assess the pathologic counterparts of such discrepancies. T seems to be selectively active in poorly understood subgroups, with a pattern of activity distinct from other available agents. Clinical trial information: 2012-005428-14. Research Sponsor: Pharmamar, Italian sarcoma Group.

Genetic abnormalities and aberrant expression of genes involved in chromosome segregation and mitosis in patients with chromosomally unstable malignant soft tissue tumors haboring extensive somatic loss-of-heterozygosity (LOH). *First Author: Katsuhito Takahashi, Kameda Medical Center, Center for Multidisciplinary Treatment of Sarcoma, Department of Sarcoma Medicine, Kamogawa, Japan*

Background: Malignant soft tissue tumor is a rare cancer with few therapeutic options. Recent genomic analysis of soft tissue sarcoma (STS) revealed a high degree of chromosomal instability (CIN) including genome-wide copy number alteration, aneuploidy, whole genome doubling and chromothripsis. In STS patients, we observed extensive somatic LOH, a hallmark of CIN, which is haploid of germline mutations/variants in cancer-related genes. CIN of STS genome implicates abnormalities in chromosome segregation and mitosis. So far, studies on this issue, however, have not been reported in STS patients. **Methods:** We recruited 155 patients with metastatic/recurrent malignant soft tissue tumors (135 female and 20 male, mean age 51 at analysis, 100 LMS, 19 LPS, 4 ESS, 3 UPS, 3 AS, 3 MPT, 3 GIST and others) with information of familial cancer burden. Whole exome sequencing and analysis were performed in both blood and tumor samples as described in 2018ASCO. KIF18A expression was assessed by immunohistochemistry. **Results:** Patients with tumors harboring less than 33% somatic LOH in a total of somatic and LOH mutations/variants in 595 COSMIC genes (n = 54) have a better prognosis than those (34-66%, n = 49, 67-100%, n = 52) with tumors harboring more LOH genes (5-year OS; 71% vs 52% or 46%, p = 0.0299, p = 0.0117, respectively). Neither TMB nor MSI status was associated with LOH. Of the genes involved in chromosome segregation and mitosis, we found that a family of ARHGAP genes which play a role in the spindle assembly and Aurora A kinase activation was frequently mutated in both tumor and germline genomes (n = 81 in a total of 155). Damaging ARHGAP mutations/variants in tumors are correlated with higher LOH values (54±3.4%, n = 81 vs. 39±3.3%, n = 74. mean±SE, p = 0.0021) and poor prognosis of patients (5-year OS; 58% n = 81 vs. 41% n = 74, p = 0.0098). We also found that elevated and robust expression of a mitotic kinesin KIF18A in tumors harboring higher LOH and/or damaging ARHGAP mutations/variants (n = 12) but not in lower LOH tumors without ARHGAP mutations/variants (n = 4). **Conclusions:** This study, for the first time, demonstrates that genetic abnormalities and aberrant expression of genes involved in chromosome segregation and mitosis in patients with malignant soft tissue tumors. The results reveal a novel target of drug discovery for incurable STS because CIN tumor cells are shown to be particularly vulnerable to KIF18A inhibition, while somatic, diploid cells are not. Research Sponsor: Promotion fund for genomic medicine of rare cancers by Japan Sarcoma Association, Research Grant from Osaka Foundation for the Prevention of Cancer and Cardiovascular Diseases.

Efficacy and safety of eribulin in the treatment of advanced adult soft tissue sarcoma (STS): First real-world data in Chinese population. *First Author: Xi Guo, Department of Medical Oncology, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Eribulin has shown efficacy in STS, especially for the L-type sarcomas, including liposarcoma (LPS) and leiomyosarcoma (LMS). We investigated the efficacy and safety of eribulin in the treatment of advanced adult STS in Chinese population. **Methods:** The study retrospectively analyzed data from patients diagnosed as advanced STS and received eribulin monotherapy or combination regimens in the Department of Oncology, Zhongshan Hospital affiliated to Fudan University from January 2020 to February 2021. Primary endpoint was objective response rate (ORR) by RECIST v1.1. Secondary endpoints included disease control rate (DCR), progress-free survival (PFS) and treatment-related adverse events (TRAE) by CTCAE v5.0. **Results:** A total of 40 patients who received at least two doses of eribulin and underwent at least one post-baseline response assessment were included in analysis. The mean age was 48 years. 82.5% (33/40) had L-type sarcomas, and 17.5% (7/40) had non-L-type sarcomas. Overall, 25% (10/40) of patients received eribulin alone; and 75% (30/40) received combination regimens. Drugs used with eribulin included gemcitabine, tyrosine kinase inhibitors (TKIs), anti-PD-1 antibodies, or TKIs plus anti-PD-1 antibodies. For the 40 patients, the ORR was 27.5% (11/40) and the DCR was 60% (24/40). The ORR for myxoid liposarcoma was especially encouraging: 54.5% (6/11) and the DCR was 72.7% (8/11). 10 patients received the combined therapy of anti-PD-1 antibodies, TKIs, and eribulin and showed a likely better ORR of 30% (3/10) and DCR of 70% (7/10). After a median follow-up time of 12.57 months (IQR, 8.43-16.30), the median PFS was 4.13 months (95% CI, 2.17-8.40). 10 out of 33 (30.3%) patients with L-type sarcomas had achieved PR and the median PFS was 2.67 months, 1 out of 7 (14.3%) patients with non-L-type sarcomas had achieved PR and the median PFS is 4.45 months. Common TRAEs were bone marrow suppression (42.5%), hypertriglyceridemia (25%), fatigue (10%), hypertension (7.5%). No treatment-related death happened. Logistic regression analysis of the multiple factors influencing ORR revealed no difference between taxane-treated and taxane-naïve patient groups. **Conclusions:** This study presents the first real-world data on the use of eribulin in STS in Chinese population. Eribulin monotherapy or combination therapy were likely more effective in this population, as well-tolerated as with Study 309, especially in treating liposarcoma. Eribulin used in combination with TKI and anti-PD-1 antibody showed potential efficacy in STSs. Further clinical exploration of front-line eribulin monotherapy and combination strategies in this setting is warranted. Research Sponsor: None.

Clinical markers of immunotherapy outcomes in sarcoma. *First Author: Marium Husain, The Ohio State University Medical Center, Columbus, OH*

Background: Despite immunotherapy's promise in oncology, its use for sarcoma remains challenging. There are no sarcoma-specific biomarkers for immune checkpoint inhibitors (ICI). Previously, we reported our institutional experience highlighting ICI activity in 29 patients with sarcoma. In this updated study, we further explore responses to ICI based on ICI regimen and other covariates to identify significant clinical factors in sarcoma outcomes. **Methods:** Patients in the Ohio State University Sarcoma clinics were enrolled in the Sarcoma Retrospective ICI database from January 1, 2015 through November 1, 2021. Data included treatment regimen (single agent ICI or ICI+combination) along with covariates: stage, age, gender, histology, change in neutrophil-to-lymphocyte ratio (NLR), number of cycles of ICI and immune-related adverse events (irAE). ICI+combination was further categorized into ICI+chemotherapy, ICI+radiation, ICI+surgery or ICI+multiple (more than 2 modalities). Statistical analysis included log rank tests and proportional hazard regression. The primary objective was to evaluate overall survival (OS) and progression-free survival (PFS). **Results:** One hundred and thirty-five patients met inclusion criteria. We demonstrated improved OS in patients treated with ICI+combination ($p = 0.014$, median 64 weeks), but no effect on PFS ($p = 0.471$, median 31 weeks). Whether patients had received single agent or combination ICI, those who received more than 3 cycles of ICI had an improved OS and PFS ($p < 0.05$ for both). Patients who received single-agent ICI and whose change in NLR was less than 5 had an improved OS ($p = 0.002$); this was not seen in patients who received ICI+combination therapy ($p = 0.441$). Patients who had a documented irAE of dermatitis had improved OS but only in the ICI+combination cohort ($p = 0.021$). There were no differences in OS based on age, gender, histology or sub-categories of ICI+combination. This was not the case for PFS; patients who received any ICI regimen and were younger than 70 had a worse PFS ($p = 0.036$). Patients who developed an irAE, specifically colitis ($p = 0.009$), hepatitis ($p = 0.048$) and dermatitis ($p = 0.003$) had an improved PFS. There were no differences in PFS based on ICI regimen (or subcategories of ICI+combination), gender, histology, change in NLR or grade of irAE. Our ICI cohort results are consistent with historical data from our previous study. Further, irAEs are similar to historical data. **Conclusions:** This retrospective study demonstrates that ICI+combination therapy can improve OS in sarcoma. This is consistent with our prior results of ICI in sarcoma. Benefits in OS/PFS were seen in patients who received more than 3 cycles of ICI and developed certain irAE. These results can direct the optimal duration of ICI therapy. Those with decreased change in NLR also had improved OS, demonstrating a potential prognostic biomarker. Further studies are needed to validate our findings. Research Sponsor: None.

The emerging fifth epidemiologic subtype of Kaposi sarcoma in HIV-negative men who have sex with men at a tertiary care center in NYC from 2000 to 2021. *First Author: Ayana E Morales, Weill Cornell Medical College, New York, NY*

Background: Kaposi sarcoma (KS) is a vascular tumor caused by human herpesvirus 8, also known as Kaposi sarcoma herpesvirus. There are 4 widely accepted distinct epidemiologic subtypes of KS: classic, endemic, iatrogenic, and epidemic (HIV-associated) forms. An emerging 5th subtype is increasingly recognized: non-epidemic KS in men who have sex with men (MSM) who are HIV-negative and have no other known causes for immunodeficiency. **Objectives:** To characterize a cohort of non-epidemic KS seen at the Sarcoma Medical Oncology or Dermatology Clinics at Memorial Sloan Kettering Cancer Center in New York City from 2000 to 2021 to identify risk factors, presentation, treatment course, and prognosis of these patients. **Methods:** Following IRB approval, a retrospective observational study was performed. Eligible patients were identified through the Electronic Health Records (EHR). The patients were characterized based on age at presentation, sex, gender identity, comorbidities, coinfections, and treatments and outcomes amongst other factors. Study data were collected and managed using REDCap electronic data capture tools. **Results:** Seventy-two patients were identified. The median age at time of diagnosis was 58 (range: 32-83). At initial diagnosis, 46% (33/72) of patients underwent observation, 50% (36/72) received localized treatment (i.e. excision, cryotherapy or topical therapy), and 4% (3/72) received systemic treatment with chemotherapy. The median duration of follow-up was 22 months. In follow-up, 43% (31/72) of patients had progression of disease requiring recurrent treatment: 24% (17/72) received localized treatment while 18% (13/72) received chemotherapy. Patients who received chemotherapy, predominantly pegylated liposomal doxorubicin, received treatment for a median duration of 13 months (range: 2-72 months). By the end of the follow-up period, 7 patients had died, of which 2 deaths were attributed to KS. During follow up, 10% (7/72) of patients were diagnosed with a lymphoproliferative disorder. **Conclusions:** This study is the largest yet, to our knowledge, to characterize the non-epidemic KS subtype in HIV-negative MSM. It is important to recognize this KS subtype to identify these individuals, who despite not having HIV are at increased risk for KS. Accurate recognition of this subtype may also allay patient concerns regarding overall prognosis, given that the majority of these patients present with indolent disease and have favorable outcomes compared to the epidemic variant of KS. Additional research is needed to understand the potential increased risk of lymphoproliferative disorders. Research Sponsor: U.S. National Institutes of Health.

DNA damage response pathways in synovial sarcoma. *First Author: Priscila Barreto Coelho, University of Miami Miller School of Medicine/Sylvester Comprehensive Cancer Center, Miami, FL*

Background: Synovial sarcomas (SS) harbor a specific, balanced, reciprocal translocation t(X;18) leading to the oncogenic SS18-SSX fusion. Defective DNA damage response (DDR) is a hallmark of cancer leading to genomic instability and is associated with chemosensitivity. Efforts have been made to identify a genetic signature that predicts SS progression, treatment response, and survival in order to identify more accessible and effective treatments. This investigation explores the role of DDR in pathogenesis of SS. **Methods:** Patients with the diagnosis of SS from 2013 to 2021 within the Caris Life Science database were included in the study. A combination of NGS of DNA and RNA at a CLIA-certified laboratory (Caris Life Sciences, Phoenix, AZ) was performed on archival tumors. Homologous recombination deficiency (HRD) scores were calculated as a composite of loss of heterozygosity, telomeric allelic imbalance, and large-scale transitions, using a positive threshold of 42. This study was approved by the University of Miami (UM)-Sylvester IRB and all the data collected was de-identified. **Results:** A total of 120 patients were identified with 49 of these patients from UM-Sylvester. Mean age of diagnosis on the sample was 46 years old (range of 15-86) and 45.8% were female. Among the 49 patients from UM-Sylvester, mean age was 60 years old (range of 35-84), 28 patients had a gene alteration identified (57%) and 6 of them a homologous recombination deficiency (HRD) gene (12%). A total of 63 different genes were identified with the most common *TP53* (49%), *LOH* (12.2%), *ATRX* (10.2%) and *RB1* (6.1%). Other HRD genes identified were *MLH1* (4%) and *CHEK2* (4%). There was no correlation identified between the age (15-65 vs elderly $\geqslant$ 65 years) or the gender (female vs male) and the presence of a mutated DDR ($p = 0.615$; $p = 0.091$ respectively). Within the entire Caris database ($N = 120$), we identified 11 patients ($N = 120$, 9%) whose tumor tested positive for any DDR gene alteration. The most common were *ATM* (2.6%), followed by *ATRX* (1.6%) and *CHEK2* (0.9%). The median HRD score was 22 within the sample. **Conclusions:** We report here the most common genes altered on molecular profile for a large cohort of SS samples. The prevalence of predicted pathogenic DDR gene mutation carriers in our cohort (9%) suggests that constitutional defects in this pathway may be associated with SS. We found higher rates of positive DDR on the UM-Sylvester cohort, and this could be associated with specifics of our population, given high frequency of Hispanic patients. Work is ongoing to associate our findings with race, ethnicity, survival and response to treatments. Work is ongoing to associate our findings with race, ethnicity, survival and response to treatments. These correlations will be reported in the final abstract. Cytotoxic therapy remains gold standard for metastatic SS, but better understanding of the molecular profile can pave way for further options, including targeted therapy and immunotherapy. Research Sponsor: None.

Efficacy of liposomal doxorubicin in patients with intra- and extra-abdominal desmoid fibromatosis. *First Author: Rodney Dixon Dorand, Vanderbilt University Medical Center, Nashville, TN*

Background: Desmoid tumors (DT) or aggressive fibromatosis are rare growths of fibroblastic connective tissue that can be locally aggressive but without metastatic potential. Most cases are sporadic, but 5-20% of cases are associated with Familial adenomatous polyposis (FAP). Despite numerous systemic options, optimal choice is unclear, and there is a paucity of studies comparing efficacy based on tumor site. Liposomal doxorubicin (LD) can be an appealing option for DT patients (pts) given its favorable schedule and toxicity profile. In this study, we compared outcomes in pts with intra-abdominal (IA) and extra-abdominal (EA) DT who received LD. **Methods:** We identified pts with DT who were treated with LD between 1/2010 - and 2/2022 at two sarcoma centers. Tumor and pt characteristics and outcomes were clinically (symptom improvement) and radiologically (RECIST 1.1) assessed. **Results:** 40 pts with DT treated with LD were identified; 58% female and 42% male. Pt characteristics and outcomes are summarized in Table 1. Primary tumor site was IA in 21 (53%) pts. FAP was present more commonly in pts with IA vs EA DT, 8/21 (43%) and 4/19 (21%), respectively. In the IA cohort, LD was given as first (15/21, 71%), second (10%) or third (19%) line therapy. LD was used more commonly as a later line in the EA cohort with 16%, 52%, 16%, and 16% receiving it in first, second, third, and fourth lines, respectively. 37 pts were evaluable for response. Response rate in the IA cohort treated in first-line was 50% (8 of 16) and 10 of 12 evaluable pts had symptomatic improvement. No first-line responses were seen in the EA cohort. As later lines of therapy, 7/12 pts had disease control in the second line, 6/8 pts in the third line, and 1/2 pts in the fourth line with LD in the IA cohort. 1 patient had fourth line response to LD in the EA cohort. Disease control rate with LD was 72.5% across all pts. Reasons for early discontinuation of LD included progression or lack of symptom improvement (20%), allergic reaction (12.5%), adverse effects (7.5%), or infection (2.5%). No acute or long-term cardiotoxicity was reported. 2 pts had no signs of recurrence or symptoms at follow-up, 33 pts were alive with symptomatic DT, 1 patient died from disease, and 3 were lost to follow-up. **Conclusions:** In our study, LD provided tumor response, disease control, and symptomatic improvement regardless of location or prior therapy, with responses most frequently seen in IA DT in first line setting. Further studies should include comparison of efficacy, adverse effects, and patient-reported outcomes while accounting for tumor location and line of therapy. Research Sponsor: U.S. National Institutes of Health.

	All Cases	IA	EA

TPS11582 **Poster Session**

A randomized, placebo-controlled, phase 2 trial of INBRX-109 in unresectable or metastatic conventional chondrosarcoma. *First Author: Sant P. Chawla, Sarcoma Oncology Research Center, Santa Monica, CA*

Background: Chondrosarcomas (CS) are the third most common type of primary bone cancer after myeloma and osteosarcoma. Conventional CS represent 85–90% of all cases and are typically treated with surgical resection. However, there are no approved systemic treatment options for patients with unresectable or metastatic conventional CS, and outcomes remain poor. INBRX-109 is a precision-engineered, tetravalent death receptor 5 (DR5) agonist antibody designed to overcome the limitations of earlier-generation agonists and exploit the tumor-specific cell death induced by DR5 activation. DR5 is one of two pro-apoptotic receptors for the trimeric tumor necrosis factor-related apoptosis-inducing ligand (TRAIL). Early clinical activity of INBRX-109 was observed in an ongoing phase 1 trial and warrants further investigation. INBRX-109 has been granted an FDA fast-track designation for conventional CS. **Methods:** This is a multicenter, randomized, blinded, placebo-controlled phase 2 study in patients with unresectable or metastatic conventional CS, measurable disease by RECIST 1.1, and radiologic disease progression within 6 months prior to screening. Any number of prior lines of therapy are allowed, except for prior DR5 agonists. Patients must be ≥18 years of age and have an ECOG performance status of 0/1 and have archival or fresh tissue available. Approximately 201 patients will be randomized (2:1) to INBRX-109 (3 mg/kg intravenously, every 21 days) or placebo, stratified by histologic grade (Grade 1/2 vs 3), isocitrate dehydrogenase (IDH)1 R132/IDH2 R172 status (wildtype vs mutation), and line of systemic therapy (none vs prior). Treatment will continue until disease progression/unacceptable toxicity. Patients treated with a placebo will have the option to cross over to INBRX-109 upon disease progression. The primary endpoint is progression-free survival (PFS) by independent radiology review. Secondary endpoints are overall survival, PFS by investigator assessment, quality of life, overall response rate, duration of response, disease control rate, safety, pharmacokinetics, and immunogenicity. Adverse events will be recorded and graded by NCI CTCAE Version 5.0. Median PFS of 7.0 months is projected for INBRX-109 and 4.0 months for placebo (corresponding hazard ratio of 0.571); INBRX-109 will be declared superior if the 1-sided p-value from the stratified log-rank test is <0.025. More than 50 sites are planned across the US/Europe. The study is actively enrolling. Clinical trial information: NCT04950075. Research Sponsor: Inhibrx, Inc, La Jolla, CA, USA.

TPS11583 **Poster Session**

Phase 2 study to evaluate palbociclib in combination with irinotecan and temozolomide in pediatric patients with recurrent or refractory Ewing sarcoma. *First Author: Theodore Willis Laetsch, Children's Hospital of Philadelphia, University of Pennsylvania, Philadelphia, PA*

Background: Palbociclib (PD-0332991) is a highly selective, reversible, small molecule inhibitor of cyclin-dependent kinases (CDK) 4 and 6, administered orally. Functional dependence of Ewing Sarcoma (EWS) cell lines and tumor xenografts on Cyclin D1/CDK4 via genetic knockdown has shown both Cyclin D1 and CDK4 as critical dependencies for EWS cell line proliferation. The phase 1 portion of the study established the recommended Phase 2 dose (RP2D) with two chemotherapy backbones in children with solid tumors. The Phase 2 portion of the study now enrolls patients with EWS. The primary objective of this portion of the study is to determine whether the addition of palbociclib to irinotecan (IRN) and temozolomide (TMZ) will prolong event-free survival (EFS) of pediatric and young adult patients with recurrent or refractory EWS. **Methods:** Patients with recurrent or refractory EWS are randomized 2:1 to receive either palbociclib in combination with IRN and TMZ or IRN and TMZ alone. Randomization is stratified by type and time of disease recurrence (primary refractory or 1st recurrence <2 years vs. 1st recurrence ≥2 years or 2nd or greater recurrence). The primary efficacy endpoint is EFS per investigator assessment. Secondary efficacy endpoints include objective response, progression-free survival and overall survival. An interim futility analysis will be conducted to allow for early stopping of the study due to futility/no signal of activity based on the primary endpoint of EFS. Safety and planned interim efficacy data will be assessed by an Independent Data Monitoring Committee (DMC). Key eligibility criteria include: recurrent or refractory EWS with evaluable disease, no known bone marrow metastases, histopathological confirmation of EWSR1-ETS or FUS-ETS rearrangement or availability of formalin fixed paraffin embedded (FFPE) tumor tissue sample for central testing, age ≥2 and <21 years at the time of study entry. Treatment intervention: Patients randomized to palbociclib with IRN and TMZ treatment arm will receive palbociclib at the RP2D of 75 mg/m^2 orally (either as a capsule or oral solution) once daily on Days 1-14 of each 21-day treatment cycle. TMZ will be administered orally once daily at 100 mg/m^2 on Days 1-5 (intravenously (IV) if patient cannot swallow the TMZ capsule). IRN will be administered IV at 50 mg/m^2 on Days 1-5. Patients randomized to the chemotherapy only treatment arm will receive IRN and TMZ at the same doses on Days 1-5 of the 21-day treatment cycle. Treatment will continue until disease progression, patient and/or legal guardian refusal, unacceptable toxicity, or up to 24 months of treatment, whichever occurs first. The Phase 2 enrolment has been initiated and 1/75 patients has been enrolled as of Jan 2022. Clinical trial information: NCT03709680. Research Sponsor: Pfizer Inc.

TPS11584 **Poster Session**

A phase 1/2 dose-escalation and dose-expansion study of ZN-c3 in combination with gemcitabine in adult and pediatric subjects with relapsed or refractory osteosarcoma. *First Author: Viswatej Avutu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Osteosarcoma (OS) is the most common primary bone malignancy of childhood and adolescence with 5-year survival rates of 65-70% for localized disease and < 30% for de novo metastatic disease or recurrent disease. Pooled analysis of previous phase 2 trials by the Children's Oncology Group has determined a 4-month event-free survival (EFS) of 12%. The Wee1 kinase helps regulate DNA damage repair at the G2-M checkpoint. In the presence of DNA damage, the Wee1 kinase is activated, arresting cells in the G2 phase and preventing entry into the M phase. Inhibition of the Wee1 kinase abrogates the G2-M checkpoint, forcing cancer cells to undergo unscheduled mitosis even in the presence of DNA damage, leading to mitotic catastrophe. However, the Wee1 kinase is often upregulated in OS, preserving the G2-M checkpoint and allowing tumor growth and metastases. Additionally, up to 90% of OS tumors have alterations in p53, a critical protein in the regulation of the G1-S checkpoint, especially in relapsed or refractory cases. With a dysfunctional G1-S checkpoint, cancer cells further rely on G2-M checkpoint to repair DNA damage and preserve genomic integrity. Prior studies have demonstrated that pharmacologic inhibition of the Wee1 kinase produced cell death in OS cell lines and patient-derived xenografts. While p53 mutational status appeared to modulate efficacy of the Wee1 kinase inhibitor, activity was observed in p53 wild type, mutant and null cell lines. Combination therapy studies have also been performed, demonstrating potential synergism with gemcitabine. As expected, by precipitating DNA damage, susceptibility to inhibition of the G2-M checkpoint is further increased. **Methods:** NCT04833582 is an ongoing, open label, multicenter, phase 1/2 clinical trial to evaluate the activity of ZN-c3, an oral Wee1 inhibitor, in combination with gemcitabine in subjects ≥12 years and ≥40 kg, with relapsed, refractory OS. Subjects are dosed once daily, continuously with ZN-c3 and receive gemcitabine 1000 mg/m^2 on days 1 and 8 of 21-day cycles. Up to 18 subjects are expected to enroll in the phase 1 portion based on a typical 3 + 3 escalation design; ~60 subjects will be enrolled in the phase 2 portion, consisting of three stages: futility, promising clinical activity, and improved precision for clinical activity. The first two stages follow a Simon two-stage optimal design with 30 subjects, to differentiate an EFS rate at 18 weeks between 12% and 36% (which may be considered a more suitable endpoint for OS, compared with radiographic response). Tumor and skin punch biopsies are incorporated into the trial to identify potential biomarkers of treatment response. Subjects must be able to swallow oral tablets and have measurable disease by RECIST v1.1; prior exposure to gemcitabine is allowed. Global enrollment began August 1, 2021, and is ongoing. Clinical trial information: NCT04833582. Research Sponsor: Zentalis Pharmaceuticals.

TPS11585 **Poster Session**

REGOMAIN: A randomized, placebo-controlled, double-blinded, multicenter, comparative phase II study of the efficacy of regorafenib as maintenance treatment in patients (pts) with high-grade bone sarcomas (HGBS) at diagnosis or relapse and without complete remission after standard treatment. *First Author: Mehdi Brahmi, Centre Léon-Bérard, Lyon, France*

Background: Primary metastatic osteosarcoma (OS) patients are treated with a curative intent following the same principles of non-metastatic OS, while the treatment of recurrent OS is primarily surgical in the case of isolated lung metastases. When complete removal of all metastases cannot be achieved, the prognosis remains poor, with a median Progression-Free Survival (PFS) between 3 to 8 months, and therefore there is a clinical need to reduce the risk of progression after the initial treatment sequence. The REGOBONE study reported a significant PFS benefit of regorafenib (REG) compared to placebo (in osteosarcomas: median PFS: 16.4 *versus* 4.1 weeks) and a manageable safety profile in patients with histologically confirmed HGBS (i.e., osteosarcoma or other bone sarcomas with the exception of Ewing sarcomas, chondrosarcoma and chordoma). **Methods:** This multicenter trial is ongoing to study the efficacy and safety of maintenance REG in pts > = 16 years old with HGBS, without complete remission but with no progressive disease after standard treatment, either at diagnosis or at relapse. Sixty pts will be randomly allocated in a 1:1 ratio to receive either oral REG at a daily dose of 120mg or its matching placebo, continuously for a maximum of 12 months. Randomization is stratified according to the setting of the disease: initial diagnosis versus relapse. The primary objective is to compare the efficacy (PFS) between the 2 arms. The expected 4-month PFS rates are 30% in the control arm and 60% in the REGO arm (HR = 0.42). Fifty-two events will provide 87% power to show significant improvement in PFS, using a 2-sided log-rank test at a 5% level. Secondary endpoints include Overall Response Rate (ORR), Disease Control Rate (DCR), Time to Treatment Failure (TTF), Overall Survival (OS), Quality of Life (QoL), and safety profile. Radiological endpoints will be evaluated using the RECIST 1.1 with tumor assessments every 2 months (first 6 months) and then every 3 months. Translational objectives will identify predictive biomarkers for efficacy of REG as maintenance therapy. Pts of the control arm who experience disease progression may switch to receive open label REG. As of Feb 1st, 2022, 3 patients have been randomized. 14 sites of the French Sarcoma Group will participate. An amendment is being implemented to lower the age limit (12 years old) and to expand tumor types to other HGBS (Ewing sarcomas, chondrosarcomas, Undifferentiated Pleomorphic Sarcomas, Leiomyosarcomas and angiosarcomas). Clinical trial information: NCT04698785. Research Sponsor: Programme Hospitalier de Recherche Clinique.

TPS11586 **Poster Session**

A phase II/III, randomized, open-label, multicenter study of BI 907828 compared to doxorubicin in the first-line treatment of patients with advanced dedifferentiated liposarcoma (DDLPS): Brightline-1. *First Author: Patrick Schöffski, Department of General Medical Oncology, Leuven Cancer Institute, University Hospitals Leuven, Leuven, Belgium*

Background: The standard of care in the first-line treatment of patients (pts) with unresectable/metastatic DDLPS is doxorubicin, despite only moderate efficacy and many associated adverse events (AEs). BI 907828 is a mouse double minute 2 (MDM2)–p53 antagonist that binds to MDM2 and blocks its interaction with p53, leading to p53 stabilization, *TP53* target gene induction, cell-cycle arrest and apoptosis in *TP53* wild-type tumor cells. In a Phase I study, BI 907828 monotherapy demonstrated a manageable safety profile and preliminary signs of efficacy, particularly in pts with DDLPS (Gounder et al, ESMO 2021). **Methods:** NCT05218499 is a Phase II/III, randomized, open-label, international, multicenter study (~125 sites) that aims to evaluate whether BI 907828 is superior to doxorubicin in the first-line treatment of advanced/metastatic DDLPS. In the Phase II part, ≤180 pts will be randomized 1:1:1 to receive BI 907828 30 mg or 45 mg orally every 3 weeks (q3w), or doxorubicin 75 mg/m^2 intravenously q3w to a maximum cumulative dose of 450 mg/m^2. Main inclusion criteria include: ≥18 years of age; histologically proven advanced/metastatic, unresectable DDLPS; positive MDM2 immunohistochemistry or amplification; ≥1 measurable target lesion (RECIST v1.1); and ECOG PS 0/1. Exclusion criteria include a known *TP53* gene mutation and prior systemic therapy for liposarcoma. In the experimental arm, treatment will continue until disease progression, unacceptable AEs, or consent withdrawal. Pts who receive doxorubicin may cross-over to receive BI 907828 after confirmed progressive disease. The primary endpoint is progression-free survival (PFS; based on blinded independent central review), defined as the time from randomization to tumor progression (RECIST v1.1) or death from any cause, whichever occurs first. Secondary endpoints are objective response (OR), duration of OR, overall survival, disease control, and pt-reported health-related quality of life. In Phase II, an interim analysis (based on the totality of safety and PK/PD data) will be used to select the optimal BI 907828 dose. Subsequently, an interim futility analysis will be performed after ~56 PFS events using a log-rank test stratified by the extent of disease (locally advanced vs metastatic). If the selected BI 907828 dose passes the futility boundary, the trial will proceed to Phase III. In the Phase III part, ≥120 additional pts will be randomized 1:1 to receive the selected BI 907828 dose or doxorubicin. The primary PFS analysis will be performed after ~92 and ~65 PFS events in pts enrolled before and after the interim futility analysis, respectively, using a weighted inverse normal method combining one-sided p-values from a stratified log-rank test. Enrollment is ongoing. Clinical trial information: NCT05218499. Research Sponsor: Boehringer Ingelheim.

TPS11587 **Poster Session**

A phase II study, with a safety lead-in, to evaluate ATX-101, a peptide drug targeting PCNA, in advanced dedifferentiated liposarcoma and leiomyosarcoma. *First Author: Sminu Bose, Columbia University Irving Medical Center, New York, NY*

Background: Soft tissue sarcoma (STS) is a heterogeneous malignancy of mesenchymal origin; leiomyosarcoma (LMS) and liposarcoma (LPS), two of the most common adult STS, are treated with first-line chemotherapy with objective response rates (ORRs) of 15-20%. There is an urgent need for novel therapeutics. ATX-101 is a small peptide comprised of a novel human AlkB homolog 2 proliferating cell nuclear antigen (PCNA) interacting motif termed APIM coupled to cellular and nuclear delivery domains. Via APIM, PCNA interacts with many cellular proteins important in the cellular stress and DNA damage responses, as well as intracellular signaling, apoptosis, metabolism, and anti-tumor immunity. In preclinical studies, ATX-101 demonstrated single-agent activity and potentiated other cytotoxic and targeted agents across multiple cancer models *in vitro* and *in vivo*, including LMS and LPS. In a phase I safety and pharmacokinetic study in solid tumors, ATX-101 was well tolerated and demonstrated prolonged disease stabilization in patients (pts) with heavily pretreated malignancies. This study will evaluate preliminary efficacy and further establish the safety profile of ATX-101 in advanced LMS and LPS. **Methods:** This is a single-arm, open-label, Simon 2-stage, phase II clinical trial of ATX-101 in pts with advanced LMS and LPS. Eligible pts have ECOG PS ≤2, progression on ≥1 prior line of therapy and disease measurable by RECIST v1.1 and amenable to image-guided biopsy. Pts receive ATX-101 60 mg/m2 IV weekly in continuous 21-day cycles. The 1° endpoint is progression free rate at 12 weeks (PFR12). A Simon 2-stage design is used to evaluate for improvement in PFR12 of ≤ 30% (null hypothesis) versus ≥ 55% (alternative hypothesis). The design calls for 34 pts with a safety lead-in among the first 10 pts enrolled. If 15/34 meet the PFR12 endpoint, the treatment is promising. This design yields 85% power and 1-sided type I error of 5%. 2° endpoints include progression free survival, ORR, and safety. 10 pts undergo tumor biopsies pre-treatment and during cycle 2. Tissue is used for correlative analysis interrogating ATX-101's effects on the immune microenvironment through multiplex immunohistochemistry, DNA damage response through whole exome sequencing/RNAseq to evaluate for alterations in HR pathway component genes, and intracellular signaling pathways by Western blot for AKT/mTOR components. The study opened to accrual 12/2021. Clinical trial information: NCT05116683. Research Sponsor: APIM Therapeutics.

TPS11588 **Poster Session**

A pilot study of lenvatinib plus pembrolizumab in patients with advanced sarcoma. *First Author: Sujana Movva, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: New treatment options are needed for sarcomas. Pazopanib is the only targeted agent approved for multiple soft tissue sarcoma (STS) subtypes with a response rate of 6% and a PFS of 4.6 months. Immunotherapy has a limited role in STS, as the SARC028 study of pembrolizumab demonstrated an overall response rate of 18%, with the highest response rate seen in the undifferentiated pleomorphic sarcoma (UPS) cohort at 23%. Lenvatinib is an oral, multi-tyrosine kinase inhibitor approved for the treatment of multiple cancer types including progressive, radioiodine-refractory thyroid cancer and unresectable hepatocellular carcinoma with inhibitory activity against the receptor tyrosine kinases VEGFR 1-3, FGFR 1-3, KIT, PDGFR alpha/beta, and RET. Early outcomes with the combination of lenvatinib and pembrolizumab suggest that this regimen could be broadly superior to PD-1 targeting alone for several tumor types as high rates of objective response have been noted. The rationale for this study is based on preclinical work demonstrating the immunosuppressive effects of VEGF in the tumor immune microenvironment including inhibition of dendritic cell maturation, recruitment of immunosuppressive Tregs, MDSCs and TAMs and up-regulation of PD-1 on CD8+ cells. **Methods:** This is a pilot study evaluating the efficacy of lenvatinib and pembrolizumab in the treatment of select metastatic and/or unresectable sarcomas. Patients will be enrolled in one of five cohorts: Cohort A: leiomyosarcoma; Cohort B: UPS; Cohort C: vascular sarcomas (including angiosarcoma and epithelioid hemangioendothelioma); Cohort D: synovial sarcoma and malignant peripheral nerve sheath tumor; and Cohort E: bone sarcomas (limited to osteosarcoma and chondrosarcoma). Eligible patients should have had at least one prior therapy for unresectable and/or metastatic disease, but no more than three prior lines of therapy. Prior treatment with angiogenesis inhibitors or immunotherapy is excluded. Archival tissue is required for eligibility. Patients enrolled in the study will be treated initially with a 2 week run-in of lenvatinib 20 mg orally daily which will be continued daily thereafter. Subsequently, they will start pembrolizumab 200 mg intravenously every 21 days. The primary endpoint for each cohort is best overall response rate documented by RECIST v1.1 Criteria at 27 weeks. A sample size of 10 patients is planned for each of the five histological cohorts. If 2 or more confirmed responses are observed among the 10 patients in an arm, the drug combination will be considered positive and worthy of further investigation for that arm. Secondary endpoints are PFS, OS, duration of response and safety/tolerability of the combination. On-treatment biopsy and blood samples will be required for correlative assessments. Accrual in all cohorts is ongoing. Clinical trial information: NCT04784247. Research Sponsor: Parker Institute, Sarcoma Foundation of America, Linn Fund, Witherwax, EHE Foundation.

TPS11589 **Poster Session**

MANTRA: A randomized, multicenter, phase 3 study of the MDM2 inhibitor milademetan versus trabectedin in patients with de-differentiated liposarcomas. *First Author: Mrinal M. Gounder, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: Murine double minute 2 (MDM2) is a negative regulator of tumor suppressor protein p53. MDM2 induces degradation of p53 and promotes tumorigenesis. *MDM2* amplification occurs in many cancers but is documented in up to 100% of well-differentiated or dedifferentiated liposarcomas (WD/DDLPS) [Cancer Genome Atlas Research Network. Cell 2017]. Inhibition of the MDM2-p53 interaction is a promising therapeutic approach to restore p53 tumor suppressor activity in WD/DDLPS. Milademetan (RAIN-32) is a small-molecule MDM2 inhibitor that inhibits the MDM2-p53 interaction and restores p53 function at nanomolar concentrations. In a phase 1 study, milademetan showed promising efficacy in 53 patients with WD/DDLPS when administered on an intermittent schedule (260 mg QD on Days 1–3 and 15–17 on a 28-day cycle), with a median progression-free survival (PFS) of 7.4 months [Gounder et al. AACR-NCI-EORTC 2020]. WD/DDLS are relatively resistant to chemotherapy, and systemic treatment options for patients with advanced disease are limited. MANTRA (RAIN-3201) is a randomized, multicenter, open-label, phase 3 registration study designed to evaluate the efficacy and safety of milademetan versus trabectedin in patients with unresectable or metastatic DDLPS with disease progression on ≥ 1 prior systemic therapies. **Methods:** Eligible patients are ≥ 18 years of age with histologically confirmed unresectable and/or metastatic DDLPS, with or without a WD component, who have received ≥ 1 prior systemic therapies, including ≥ 1 anthracycline-based regimen, with radiographic evidence of progression by RECIST v1.1 within 6 months before study entry. Prior treatment with trabectedin or an MDM2 inhibitor is not permitted. Patients will be randomly assigned (1:1) to receive milademetan (260 mg once daily orally Days 1–3 and 15–17 on a 28-day cycle) or trabectedin (1.5 mg/m^2 as a 24-hour intravenous infusion every 3 weeks). Randomization is stratified by Eastern Cooperative Oncology Group performance status (0 or 1) and number of prior treatments for WD/DDLPS (≤ 2 or > 2). Tumor response will be evaluated by RECIST v1.1 at Weeks 8, 16, 24, and 32, and then every 12 weeks. Primary endpoint: PFS by blinded independent central review. Secondary endpoints: overall survival; disease control rate; objective response rate; duration of response; PFS by investigator assessment; safety; health-related quality of life. Exploratory endpoints: molecular markers in peripheral blood and/or tumor tissue; milademetan pharmacokinetics. To demonstrate a 3-month increase in PFS (from 3 to 6 months) corresponding to a hazard ratio of 0.5, approximately 160 patients will be required to observe 105 events with 93.9% power and 2-sided significance level of 5%. Clinical trial information: NCT04979442. Research Sponsor: Rain Therapeutics, Inc.

TPS11590 **Poster Session**

MOTION: A randomized, phase 3, placebo-controlled, double-blind study of vimseltinib (DCC-3014) for the treatment of tenosynovial giant cell tumor. *First Author: William D. Tap, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Tenosynovial giant cell tumor (TGCT) is a rare, locally aggressive neoplasm that occurs in the synovium of joints, bursae, or tendon sheaths. TGCT is caused by upregulation of the colony-stimulating factor 1 (CSF1) gene, resulting in aberrant CSF1 expression and the recruitment of CSF1 receptor (R)-dependent inflammatory cells. Resection is the primary treatment, but nonsurgical treatment options are necessary for patients with symptomatic TGCT not amenable to surgical resection. Vimseltinib is an oral switch control TKI specifically designed to selectively and potently inhibit CSF1R. In a Phase 1/2 study in patients with TGCT, vimseltinib showed encouraging antitumor activity with an overall objective response rate (ORR) of 42% in the cohort receiving 30 mg twice weekly (recommended phase 2 dose; Gelderblom et al, ESMO 2021 Poster). Vimseltinib was also well tolerated, and the majority of the common (≥15%) treatment-emergent adverse events (TEAEs) were Grades 1–2. Among these common TEAEs, the only Grade 3–4 event in the Phase 2, twice-weekly, 30-mg cohort was increased blood creatine phosphokinase (CPK); however, this elevated CPK was not associated with any symptoms (Gelderblom et al, ESMO 2021 Poster). Phase 1/2 efficacy and safety data support further development of vimseltinib; here, we describe the ongoing Phase 3 study for patients with TGCT not amenable to surgical resection. **Methods:** MOTION (NCT05059262) is a Phase 3, randomized, placebo-controlled, double-blind study that aims to evaluate the efficacy and safety of vimseltinib for the treatment of TGCT not amenable to surgical resection. Participants must be at least 18 years of age and have histologically confirmed and symptomatic TGCT for which surgical resection will potentially cause worsening functional limitation or severe morbidity. Prior CSF1R therapy is not permitted (previous imatinib and nilotinib is allowed). In Part 1 of the study, eligible participants will be randomized 2:1 to receive either vimseltinib 30 mg twice a week or matched placebo for 24 weeks. The primary outcome measure is ORR assessed by central read using Response Evaluation Criteria in Solid Tumors version 1.1 at 25 weeks. Secondary outcome measures include ORR per tumor volume score, range of motion, and patient-reported outcomes. Participants assigned to placebo in Part 1 will have the option to receive vimseltinib in Part 2, a long-term treatment phase in which participants will receive open-label vimseltinib. This international study plans to randomize 120 participants and is currently enrolling. Clinical trial information: NCT05059262. Research Sponsor: Deciphera Pharmaceuticals, LLC.

TPS11591 **Poster Session**

ARST2031: A study to compare early use of vinorelbine and maintenance therapy for patients with high risk rhabdomyosarcoma. *First Author: Wendy A Allen-Rhoades, Mayo Clinic, Rochester, MN*

Background: Patients with high-risk rhabdomyosarcoma (HR-RMS) continue to have poor outcomes with 3-year event free survival (EFS) rates of 30% or less despite chemotherapy dose intensification on recent cooperative group RMS trials. Vinorelbine (VINO) has demonstrated clinical activity in RMS patients with relapsed/refractory disease and shown to provide a survival benefit when given with oral cyclophosphamide as maintenance chemotherapy for a select group of patients that achieved first complete remission. **Methods:** ARST2031 is a randomized Phase 3 trial with the primary aim to compare event-free survival (EFS) of patients with HR-RMS treated with vincristine, dactinomycin and cyclophosphamide (VAC) followed by maintenance with vinorelbine and oral cyclophosphamide (VINO-CPO) or vinorelbine, dactinomycin and cyclophosphamide (VINO-AC) followed by maintenance with VINO-CPO. Patients are stratified by histology and randomly assigned to VAC followed by VINO-CPO maintenance or VINO-AC followed by VINO-CPO maintenance. To be eligible, patients must be ≤ 50 years of age at the time of enrollment with newly diagnosed RMS except adult-type pleomorphic, based upon institutional histopathologic classification. All patients must have Stage 4 disease and patients diagnosed with embryonal RMS (ERMS) must be ≥ 10 years of age. Patients with malignant cytology in cerebrospinal fluid, intra-parenchymal brain metastases, or diffuse leptomeningeal disease are excluded. The study was activated on September 13, 2021 and is anticipated to enroll approximately 4 patients per month. The planned sample size is 100 patients, with approximately 50 patients randomized to each arm. Safety and feasibility of VINO-AC will be assessed in the first 8 patients prior to randomization. The study will have power of 0.8 to detect a hazard ratio of 0.61 (74 events in total) when the one-sided Type I error rate is 0.10, with 30 months of accrual and 2 years of follow-up. The hazard ratio of 0.61 was determined by assuming piecewise exponential distributions and specifying the 2-year EFS of 46% vs. 28% and long-term EFS of 32% vs. 16%, based on prior outcome data. Biospecimens will be collected and banked for future use. Clinical trial information: NCT04994132. Research Sponsor: U.S. National Institutes of Health.

TPS11592 **Poster Session**

A phase 1b lead-in to a randomized phase 2 trial of lurbinectedin plus doxorubicin in leiomyosarcoma (LMS). *First Author: Gregory Michael Cote, MGH, Boston, MA*

Background: Single agent or combination chemotherapy regimens, typically including doxorubicin or gemcitabine, represent standard of care options for first- and second-line therapy in patients (pts) with metastatic LMS. However, response rates (ORR) and progression-free (PFS)/overall survival (OS) remain poor. Lurbinectedin (PharmaMar S.A. and Jazz Pharmaceuticals) uniquely binds DNA, inducing DNA double strand breaks leading to apoptosis and delaying progression through phase S/G2 of the cell cycle. Lurbinectedin is a novel structural analog of trabectedin with improved toxicity profile, potency, and pharmacokinetics. In a prior pilot study, we showed that the combination of lurbinectedin and doxorubicin (L+D) was safe, with early signs of clinical activity, particularly in LMS. Thus, we designed this investigator-initiated/investigator-sponsored phase 1b lead-in to optimize doses of L+D, to be followed by a randomized (1:1) phase 2 study of L+D versus doxorubicin monotherapy in anthracycline-naïve LMS. **Methods:** Pts age > 18 years with locally advanced or metastatic, unresectable LMS (non-GIST soft-tissue sarcoma histologies allowed in Phase 1b), without prior anthracycline or lurbinectedin/trabectedin, ECOG PS < 3, measurable disease by RECIST 1.1, and normal organ function, are eligible. Phase 1b dosing will include a fixed dose of lurbinectedin and two dose levels of doxorubicin. The Phase 1b lead-in follows a standard 3+3 design where dose escalation will occur if 0/3 or 1/6 patients experience a dose-limiting toxicity (DLT). Tumor assessments are conducted every two cycles. Once the recommended phase 2 dose (RP2D) is confirmed, Phase 2 will be initiated. Fifty pts will be randomized 1:1 including doxorubicin +/- lurbinectedin. Randomization will be stratified by uterine v. non-uterine origin of LMS. Pts progressing on single agent doxorubicin will be allowed to cross over to lurbinectedin monotherapy. The Phase 2 primary endpoint is PFS. Secondary endpoints include disease control rate, ORR, OS, PFS2 (for doxorubicin monotherapy patients who cross to lurbinectedin monotherapy). Archival tumor, germline DNA, and ctDNA will be collected for correlative studies exploring genomic markers of sensitivity/resistance. We will provide respective point estimate along with 90% confidence interval for each of the arms. Log-rank test will be performed to test the difference in survival (both PFS and OS) between groups. Regression analyses of survival data will be based on the Cox proportional hazards model. The first pt in dose-level 1 of the Phase 1b lead-in was enrolled in February 2022. Clinical trial information: NCT05099666. Research Sponsor: Jazz Pharmaceuticals.

TPS11593 **Poster Session**

TTI-621-03: A phase I/II study of TTI-621 in combination with doxorubicin in patients with unresectable or metastatic high-grade leiomyosarcoma (LMS). *First Author: Sant P. Chawla, Sarcoma Oncology Research Center, Santa Monica, CA*

Background: Doxorubicin is a standard of care agent for patients with advanced soft tissue sarcoma, with a response rate of around 15%, progression-free survival of 5-7 months and cumulative cardiac toxicity that limits its use. TTI-621 is a recombinant soluble fusion protein that combines the N-terminal portion of human SIRPα (the binding domain for CD47) with the Fc region of human IgG1, generating a decoy receptor for CD47 on the surface of tumor cells that both over-rides CD47-mediated inhibition of phagocytosis and provides a pro-phagocytic stimulation. Many solid tumors express high levels of CD47 which is associated with poor prognosis, thought to be the result of CD47-mediated inhibition of macrophage phagocytosis and escape of immune-mediated clearance. Interruption of the CD47-SIRPα signaling pathway using monoclonal antibodies to CD47 has shown anti-tumor activity in animal models and in some early clinical trials. The combination of doxorubicin with CD47-targeted antibodies results in enhanced anti-tumor activity and increased macrophage-mediated cell killing in animal models and macrophage-mediated phagocytosis of cancer cell lines *in vitro*, suggesting that combining TTI-621 with doxorubicin might be more effective than doxorubicin alone in tumor types that express CD47 and have high numbers of macrophages, such as LMS. Thus, a Phase 1/2 study was initiated to evaluate this combination in patients with advanced soft tissue sarcoma, including LMS. **Methods:** TTI-621-03 is a Phase 1/2, open-label study of TTI-621 in combination with doxorubicin in patients with anthracycline-naïve disease. The Phase 1 dose escalation evaluates doses of TTI-621 (0.2 to 2.0 mg/kg) in combination with doxorubicin at 75 mg/m^2 in patients with high-grade soft tissue sarcomas. Expansion cohorts will evaluate TTI-621 (0.2 and 2.0 mg/kg) with doxorubicin in patients with LMS, with pathology confirmed at a central laboratory. The primary goals of this study are evaluation of safety of TTI-621 administered in combination with standard-of-care doxorubicin and to further evaluate clinical activity (ORR, PFS, OS), safety, PK and patient-reported quality of life in the LMS subpopulation. The dose escalation portion of the study has been completed without DLT. Enrollment to the expansion portion of the study is underway. Clinical trial information: NCT04996004. Research Sponsor: Trillium Therapeutics Inc, a Pfizer Company.

TPS11594 **Poster Session**

A phase II multi-arm study to test the efficacy of oleclumab and durvalumab in specific sarcoma subtypes. *First Author: Neeta Somaiah, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Anti-PD 1/PD-L1 blockade alone or in combination with anti-CTLA4 have yielded suboptimal results in most sarcoma subtypes. CD73, an ectonucleotidase, catalyzes the rate-limiting step for adenosine production in the extracellular space, which then aids tumors in evading immune recognition and destruction. Oleclumab, a monoclonal antibody (mAb) selectively binds and inhibits the activity of CD73, and preclinical data suggests additive activity with durvalumab, a mAb that blocks PD-L1. We designed a trial combining oleclumab and durvalumab in certain sarcoma subtypes, selected based on modest activity with anti-PDL-1 and intense staining with CD73 in the tumor microenvironment. **Methods:** This phase 2 study (NCT04668300) is enrolling patients with age ≥18 years with recurrent/metastatic angiosarcoma (cohort 1) or dedifferentiated liposarcoma (DLPS) (cohort 2) and ≥12 years with recurrent/metastatic osteosarcoma (cohort 3), who have received at least one prior systemic therapy but are checkpoint inhibitor naïve and have measurable disease. Each treatment cycle is 28 days with oleclumab administered at 3000 mg i.v. every 2 weeks x 5 doses, and then every 4 weeks and durvalumab administered at 1500 mg i.v every 4 weeks. Tumor assessments are based on RECIST 1.1 and immune-related response criteria (irRC) and performed at baseline, and every 8 weeks after start of therapy, with an additional scan at 12 weeks for confirmation of response. Planned sample size is ≤ 25 pts in each arm. The primary efficacy endpoint for cohorts 1 and 2 is response rate (RR) at 4 months (per RECIST 1.1). The primary efficacy endpoint for cohort 3 is event free survival (EFS) rate at 4 months. If there is a high probability that the RR4 months is unlikely to be at least 20% for cohorts 1 and 2 or the EFS4 months is unlikely to be at least 40% for cohort 3 then the accrual of the corresponding cohort will be halted. The cohorts will be monitored separately for both futility and toxicity in groups of 5 after a minimum of 10 patients have been enrolled in each cohort. Secondary endpoints for the study include safety, best RR by RECIST and irRC, median PFS, and OS. Core needle biopsies and blood samples are collected at baseline and early on-treatment (week 6). Fresh flow cytometry is being performed to assess changes in T-cell activation, proliferation, and function and CD73 expression in the membrane and cytoplasm is being assessed by immunohistochemistry. Localization of tumor-infiltrating lymphocytes and engagement of the PD-1/PDL1 axis is being assessed using multiplex immunofluorescence staining. As of Jan 30th, 2022, twenty-two patients have initiated study treatment, 3 in cohort 1, 12 in cohort 2, and 7 in cohort 3. Clinical trial information: NCT04668300. Research Sponsor: Astra-Zeneca.

TPS11595 **Poster Session**

Phase 1/2 study of devimistat in combination with hydroxychloroquine (HCQ) in patients with relapsed or refractory (R/R) clear cell sarcoma (CCS). *First Author: Mark Agulnik, Northwestern University, Feinberg School of Medicine, Chicago, IL*

Background: CCS of the soft tissues is a rare and aggressive subtype of sarcoma that often starts in the tendons of the arms or legs. It is molecularly characterized by t(12;22)(q13;q12) translocation, resulting in EWSR1-ATF1 or EWSR1-CREB1 gene fusion. Despite reports of occasional responses to systemic therapies, currently available therapies have shown limited efficacy in advanced CCS. Therefore, there is a significant unmet medical need for more active agents in CCS. Devimistat is a stable intermediate of a lipoate analog that inhibits pyruvate dehydrogenase and α-ketoglutarate dehydrogenase enzymes of the tricarboxylic acid (TCA) cycle preferentially within the mitochondria of cancer cells. Devimistat induces autophagy in cancer cells. In a metastatic mouse model of CCS, treatment with devimistat in combination with chloroquine significantly suppressed tumor growth (Egawa et al, 2018). Based on this data, we hypothesized that inhibition of autophagy with HCQ may sensitize cancer cells to devimistat with increased efficacy and acceptable toxicity. Given its expected synergy, we have initiated a single-arm phase I/II prospective, multicenter, open-label, non-randomized study to evaluate maximally tolerated dose (MTD), safety, and efficacy of devimistat in combination with HCQ in patients with R/R CCS. **Methods:** In the phase 1 portion of the study, patients with R/R CCS and other fusion-positive R/R sarcomas will be enrolled and a standard 3+3 design will be followed to evaluate toxicity, MTD, and recommended phase 2 dose. There will be two patient groups based on weight, and dose escalation will be conducted separately for each group. Starting dose of HCQ will be 5mg/kg PO BID for patients < 45 kg and 200 mg PO BID for patients ≥45 kg on days 1 through 5 of every 28 days. The first dose of HCQ each day will be followed 2 hours later by 1,000 mg/m^2 devimistat (for patients < 45 kg) and 2,000 mg/m^2 of devimistat (for patients ≥ 45 kg) administered over 2 hours. A maximum of 36 patients will be enrolled for the phase I portion, 18 for each patient group. In the phase 2 portion of the study, only relapsed or refractory CCS patients will be enrolled, and the response rate will be determined using RECIST 1.1. In phase 2, pharmacokinetics, duration of response, clinical benefit rate, progression-free survival, overall survival, safety, and patient-reported outcomes will also be assessed. This portion of the study will utilize Simon's admissible two-stage design with 29 patients. This study started enrolling participants in November 2021 and has dosed six patients to date. The first two dose-escalation cohorts for patients ≥45 kg have been completed without DLT and the third dose level will be opening shortly. Clinical trial information: NCT04593758. Research Sponsor: Rafael Pharmaceuticals.

12000 **Oral Abstract Session**

Impact of acetaminophen on the efficacy of immunotherapy in patients with cancer. *First Author: Alban Bessede, ImmuSmol, Bordeaux, France*

Background: Pain is the most common symptom experienced by patients with advanced cancer. Acetaminophen (APAP, commonly known as paracetamol) alone or in combination with a weak opioid, such as codeine or tramadol, is usually considered as the first-line strategy to manage mild-to-moderate pain in this setting. Although generally considered to be safe, several evidences suggest that APAP may have negative immunomodulatory effects. Randomized studies have shown that APAP use is associated with blunted vaccine immune responses. Given its potential to impair vaccine effectiveness, the World Health Organization stated in 2015 that administration of APAP before or at the time of vaccination is not recommended. This study aimed to assess APAP impact on efficacy of immunotherapy in patients with cancer. **Methods:** Exposure to APAP was assessed by plasma analysis and was correlated with clinical outcome in three independent cohorts of patients with advanced cancer who were treated with immune checkpoint blockers (ICB): the CheckMate 025 trial, n = 297 (NCT01668784, sponsor: Bristol Myers Squibb), the institutional biomarker program BIP n = 34 (NCT02534649, sponsor: Institut Bergonié, Bordeaux, France) and the institutional biomarker program PREMIS n = 297 (NCT03984318, sponsor: Gustave Roussy, Villejuif, France). APAP immunomodulatory effects were evaluated on a pre-clinical tumor model (MC38) and on human peripheral blood mononuclear cells (PBMCs) from healthy donors. **Results:** Detectable plasma APAP levels at treatment onset was associated with a significantly worse clinical outcome in ICB-treated cancer patients (HR for progression-free survival : 1.43, 95% CI 1.07–1.91, p = 0.015; HR for overall survival: 1.78 95% CI 1.18–2.68, p = 0.006), independently of other prognostic factors (age, performance status, number of previous lines of treatment, tumor type, number of metastatic sites, presence of liver metastases, LDH levels). APAP significantly reduced ICB efficacy in the pre-clinical MC38 model, as well as the production of PD1 blockade-related interferon-γ secretion by human PBMCs. Moreover, reduction of ICB efficacy *in vivo* was associated with significantly increased tumor infiltration by regulatory T cells (Tregs). Administration of APAP over 24 h induced a significant expansion of peripheral Tregs in healthy individuals. In addition, interleukin-10, a crucial mediator of Treg-induced immune suppression, was significantly upregulated upon treatment with ICB in cancer patients taking APAP. **Conclusions:** This study provides strong preclinical and clinical evidence of the role of APAP as a potential suppressor of antitumor immunity. Hence, APAP should be used with caution in patients treated with ICB. Research Sponsor: None.

12001 **Oral Abstract Session**

Correlation of psychological distress with quality of life and efficacy of immune checkpoint inhibitors in patients with newly diagnosed stage IIIB-IV NSCLC. *First Author: Fang Wu, Department of Oncology, The Second Xiangya Hospital, Central South University, Changsha, China*

Background: Psychological distress is common among cancer patients and leads to activation of the hypothalamic-pituitary-adrenal (HPA) axis and sympathetic nervous system (SNS) and continuous production of distress hormones, which may contribute to a highly immunosuppressive tumor microenvironment (TME). Meanwhile, preclinical studies have shown that psychological distress could undermine cancer therapies. Therefore, we investigate the prevalence of psychological distress in non-small-cell lung cancer (NSCLC) patients, identify its impact on quality of life (QoL) and efficacy of immune checkpoint inhibitors (ICIs), and explore the possible neuro-endocrinological mechanisms. **Methods:** Patients with newly diagnosed stage IIIB-IV NSCLC received ICIs as first-line treatment were included. The assessments of psychological distress including depression and anxiety symptoms were measured using the Patient Health Questionnaire-9 (PHQ-9) and Generalized Anxiety Disorder-7 (GAD-7), respectively. The QoL was measured by Short Form Health Survey 36 (SF-36). Stress hormones including serum cortisol, adrenocorticotropic hormone (ACTH), plasma epinephrine (Epi), and norepinephrine (NE) were determined by ELISA kit before treatment. Objective response rates (ORR) and Median progression-free (PFS) were estimated using the Chi-square test, Kaplan-Meier, and Cox regression method. **Results:** 77 NSCLC patients with a mean age of 60.9 years were enrolled. Stage distribution included 50 (64.9%) stage IIIB/C and 27 (35.1%) stage IV. 44(57.1%) patients were present psychological distress. Psychological distress was associated with poorer QoL (P<0.001). The median follow-up time was 16.2 months. Compared with non-psychological distress patients, psychological distress patients had a significant lower ORR (35.9% vs 63.64%; *P*=0.033) and shorter PFS (median 12.63 vs 14.60 months; 95% CI: 0.36 to 1.98; *P*=0.026). Moreover, psychological distress was the only independent predictor for PFS (HR:2.71, 95%CI: 1.06~6.90; *P*=0.037) in multivariate Cox regression analyses. The patients with psychological distress had higher levels of serum cortisol (*P*=0.040) and plasma Epi (*P*=0.023). Additionally, the serum cortisol (*P*=0.043) and plasma Epi (*P*=0.025) concentrations were associated with inferior ICIs response. **Conclusions:** Psychological distress is common within stage IIIB-IV NSCLC patients. Patients with psychological distress are associated with worse QoL and inferior outcomes to ICIs and discover the potential mechanisms of neuro-endocrinological hormones in resistance to ICIs therapy. Research Sponsor: Beijing Xisike Clinical Oncologic Research Foundation (Grant No. Y-BMS2019-100), Beijing Xisike Clinical Oncology Research Foundation (Grant No. Y-HS202102-0130).

12002 **Oral Abstract Session**

Impact of age and frailty on acute care use during immune checkpoint inhibitor (ICI) treatment: A population-based study. *First Author: Lawson Eng, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: ICIs are a common therapeutic option across solid tumors. However, older adults were poorly represented in clinical trials evaluating ICIs, especially those who are very old or frail. Although ICIs are better tolerated than chemotherapy, some patients develop immune related adverse events (irAEs) that may require hospitalization. We performed a population-level retrospective cohort study to evaluate the impact of age and frailty among older adults on acute care use and irAE related hospitalizations. **Methods:** We used administrative data deterministically linked across databases to identify a cohort of cancer patients > 65 years of age receiving ICIs from June 2012 to October 2018 in Ontario, Canada and obtained data on socio-demographic and clinical covariates, and acute care utilization. Acute care use was defined as an emergency department visit or hospitalization from initiation to 120 days after the last ICI dose; hospitalizations were classified as irAE related based on ICD-10 codes. Frailty was assessed using the McIsaac Frailty Index. Multivariable competing risk analyses with Fine Gray subdistribution hazards evaluated the impact of age and frailty on both acute care use and irAE hospitalizations adjusted for sex, rurality, BMI, autoimmune history, hospitalization within 60 days prior to starting ICI and comorbidity score. **Results:** Among 2737 patients, median age 73 (18% age > 80, 50% age 70-79); 43% received Nivolumab, 41% Pembrolizumab and 13% Ipilimumab; 53% had lung cancer, 34% melanoma. 70% were robust, 26% pre-frail and 4% frail. Most patients (1962; 72%) had an acute care episode during the window, while 212 (8%) had an irAE hospitalization. Older age was associated with reduced risk of being hospitalized due to an irAE when measured as a continuous variable (aHR 0.97 per year [0.95-0.99] p = 0.01). Older adults, age > 80 years were also less likely to be hospitalized due to an irAE (age 70-79 vs 65-69, aHR 0.92 [0.66-1.27] p = 0.61, age > 80 vs 65-69, aHR 0.63 [0.39-1.01] p = 0.05). Age was not associated with acute care use as a continuous or categorical variable. Increasing frailty was associated with increased risk of acute care use during ICI treatment (pre-frail vs robust, aHR 1.20 [1.07-1.36] p = 0.003; frail vs robust, aHR 1.45 [1.12-1.86] p = 0.004) but was not associated with irAE hospitalizations. When evaluating both age and frailty in the same model, the identified associations remained significant. **Conclusions:** Among older adults receiving ICIs, age was not associated with acute care use but may be associated with reduced risk of experiencing an irAE related hospitalization. In contrast, frailty was associated with risk of acute care use but was not associated with risk of an irAE related hospitalization. Age and frailty may need to be considered independently when evaluating their use as potential factors influencing toxicity risk among older adults receiving ICIs. Bacterial decolonization to prevent acute radiation dermatitis: A randomized controlled trial. *First Author: Yana Kost, Department of Medicine, Division of Dermatology, Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

12004 **Oral Abstract Session**

A phase III, randomized, sham-controlled trial of acupuncture for treatment of radiation-induced xerostomia (RIX) in patients with head and neck cancer: Wake Forest NCI Community Oncology Research Program Research Base (WF NCORP RB) trial WF-97115. *First Author: Lorenzo Cohen, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The majority of head/neck (HN) patients who undergo radiotherapy develop RIX. Unfortunately, existing treatments are of limited benefit and have side effects. Initial small studies suggest acupuncture may treat chronic RIX. A multicenter, phase III, randomized, sham-controlled trial (NCT02589938) was conducted to compare true acupuncture (TA) with sham acupuncture (SA) and wait list control (WLC) group in treating chronic RIX. **Methods:** HN patients with chronic RIX at least 12 months post-RT were recruited through the WF NCORP RB network (2UG1CA189824). Patients must have received bilateral radiation therapy with subsequent grade 2 or 3 xerostomia per modified RTOG scale, with no history of xerostomia or other illness known to affect salivation prior to HN XRT. All patients received standard oral hygiene and were randomized to TA, SA, or WLC. Patients in TA and SA were treated 2 times per week for 4 weeks. Those experiencing a marginal response (10-19 point decrease on the Xerostomia questionnaire (XQ)) received another 4 weeks of the respective treatment. Patients who had no response (increase in XQ score or decrease of < 10 points from baseline), partial response (20 or more point decrease in XQ score from baseline), or complete response (XQ score = 0) did not receive further treatment. Patient outcomes including XQ and FACT-HN were collected at baseline, 4, 8, and 12 weeks; the primary endpoint was XQ at 4 weeks. A sample size of 80 per group (240 total), had 80% power to detect a difference of 10 points between groups, assuming two-sided alpha = 0.013 and 20% attrition. Analysis of covariance adjusted for baseline XQ and Bonferroni corrections for pairwise comparisons. **Results:** 258 from 33 different practices participated. Average age was 65 years, 78% male, and 67% had AJCC stage IV a,b disease. At week 4, there was a group main effect on the XQ (P = 0.02) revealing significant between group differences between TA and WLC (51.1 vs 56.8, P = 0.008), with marginal between group difference between TA and SA (51.1 vs 54.5, P = 0.066) and no difference between SA and WLC (P = 0.36). A similar pattern was seen at week 8 (TA = 48.3, SA = 50.8, WLC = 54.8; only TA vs WLC significant, P = 0.012) and 12 (TA = 48.6, SA = 49.3.8, WLC = 54.6; TA vs WLC, P = 0.02; SA vs WLC, P = 0.04; TA vs SA, P = 0.79). Incidence of clinically significant RIX (XQ scores > 30) followed a similar pattern. The FACT-HN at week 12 revealed statistically and clinically significant group differences for the total score and several subscales between TA vs SA and WLC with no differences between SA and WLC. Completer and mediation analyses will be presented. **Conclusions:** True acupuncture was more effective in treating chronic RIX and improving QOL one or more years after the end of XRT than sham acupuncture or standard oral hygiene. Clinical trial information: NCT02589938. Research Sponsor: U.S. National Institutes of Health.

12005 **Oral Abstract Session**

Evaluating risk for second primary cancers by radiotherapy technique in prostate cancer survivors. *First Author: Kishan Pithadia, NCI - DCEG, Rockville, MD*

Background: Radiotherapy-related adverse effects such as the development of subsequent neoplasms cause significant morbidity among prostate cancer survivors. Advances in radiotherapy techniques, including intensity-modulated radiation therapy (IMRT) and proton beam radiotherapy (PBRT), have aimed to reduce exposure to adjacent healthy tissues to reduce adverse effects. Initial reports based on small sample sizes and limited follow up (through 2011) have suggested reduced risks for subsequent colon and rectal cancers following IMRT compared to 3D conformal radiotherapy (CRT) for prostate cancer patients, but not for subsequent bladder cancer. We sought to extend previous reports with larger sample size and longer follow up. **Methods:** We conducted a retrospective cohort study within the linked database of Surveillance, Epidemiology and End Results (SEER) cancer registries and Medicare claims. The cohort included men diagnosed with first primary non-metastatic prostate cancer at ages 66-84 during 2002-2011; received initial IMRT, PBRT, or CRT; and survived without developing a second primary cancer ≥5 years after diagnosis (follow up through 2016). Cox regression models estimated risks of second primary solid tumors after IMRT and PBRT vs CRT, adjusting for age at prostate cancer diagnosis, tumor grade, race, Charlson comorbidity score, and receipt of initial prostate cancer therapy. **Results:** The cohort (median follow-up = 8.4 years) included 51,020 patients, of whom 19,536 received CRT alone, 29,868 received IMRT without PBRT, and 1,616 received PBRT. Compared to patients who received CRT (n = 1,348, 7.0%), both IMRT (n = 1,289, 4.3%; hazard ratio [HR] = 0.87; 95% confidence interval [CI], 0.80-0.95) and PBRT (n = 83, 5.1%; HR = 0.77; 95% CI 0.62-0.97) showed a decrease in risk of developing any second solid malignancy. In analyses by second cancer type, risks of colon cancer (HR = 0.70; 95%CI, 0.52-0.94) and bladder cancer (HR = 0.79; 95%CI, 0.65-0.97) were significantly lower after IMRT than CRT, whereas no association was observed for anorectal cancers (HR = 1.00; 95%CI, 0.65-1.53). Further investigation by time since prostate cancer diagnosis revealed a time-dependent decrease after IMRT compared to CRT in risk for bladder cancer (HRs = 0.94, 0.87, 0.61 for 5-7.4, 7.5-9.9, and 10+ years respectively) and anorectal cancer (HRs = 1.22, 0.97, 0.78), whereas the opposite trend was observed for colon cancer (HRs = 0.70, 0.68, 1.05). **Conclusions:** In this large cohort with increased follow-up time compared with previous reports, we observed reduced risk of colon and bladder cancer with IMRT overall, as well as time-dependent patterns for bladder and anorectal cancer that were consistent with improved tumor targeting. Further research is needed with larger sample sizes to evaluate long-term effects after PBRT. Our study supports the value of quantifying adverse effects as radiotherapy techniques evolve. Research Sponsor: U.S. National Institutes of Health.

12006 **Oral Abstract Session**

Open-labeled placebo for the treatment of cancer-related-fatigue in patients with advanced cancer: Results of a randomized controlled trial. *First Author: Sriram Yennu, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Despite the high frequency of cancer related fatigue (CRF) in patients with advanced cancer (PAdC), there are no effective pharmacological treatments. Our group previously found that the placebo response was 56% among PAdC participating in CRF trials. There are no clinical trials using open label placebo for CRF in PAdC. The purpose of this study was to determine the effects of open labeled placebo (OLP) compared to waitlist control (WLC) in reducing CRF in PAdC using Functional Assessment of Chronic Illness Therapy-Fatigue subscale (FACIT-F). **Methods:** In this randomized controlled trial, PAdC with fatigue ≥ 4/10 on ESAS were randomized to OLP one tablet twice a day or WLC for seven days (primary end point). After week 1 in patients of both arms received placebo for 3 weeks. Changes in FACIT-F from baseline to Day 8 (primary outcome), and changes after 21 days of placebo in both arms were assessed. Secondary outcomes included quality of life (QOL)[FACT-G], fatigue dimensions(MFSI-SF), depression(CES-D), and Fatigue cluster(ESAS fatigue, pain, and depression). **Results:** 82/90(91%) patients were evaluable. The adherence to placebo [mean%(SD)], was 93.6(18.6), and 88.1(20.2) at Day 8 and Day 29 respectively in OLP arm, and 89.9 (73) at Day 29 in WLC arm. The mean(SD) FACIT-F change at day 8 was 6.6 (7.6) after OLP, 2.1 (9.4) after WLC (p = 0.016). On days 15 and 29, when all patients received OLP, there was significant improvement of CRF but not difference between arms. FACT-G Total Score, FACT-G EWB, ESAS Fatigue, and Fatigue cluster score, all showed significant evidence of reduced CRF in the OLP arm on Day 8 of the study (p = 0.002, 0.030, 0.029, and 0.044, respectively). There was no significant difference in adverse events between the two groups. **Conclusions:** Open labeled placebo was efficacious in reducing CRF, fatigue cluster, and QOL in fatigued advanced cancer patients at the end of one week. The improvement in fatigue was maintained for 4 weeks. Further studies of this intervention are justified. Clinical trial information: NCT03927885. Research Sponsor: None.

Randomized trial of diet and exercise on chemotherapy completion in women with breast cancer: The Lifestyle, Exercise, and Nutrition Early After Diagnosis (LEANer) study. *First Author: Tara B. Sanft, Yale School of Medicine, New Haven, CT*

Background: In observational studies, 25%-55% of women with breast cancer (BC) do not complete chemotherapy as initially prescribed, primarily due to toxicity. Relative dose intensity (RDI) is an integrated measure of chemotherapy dose delays and reductions and is associated with cancer mortality. Physical activity (PA) and diet may reduce treatment toxicity, but less is known about their effect on RDI. We conducted a randomized trial of a diet and PA intervention on RDI (primary endpoint) in women with newly diagnosed BC initiating chemotherapy. **Methods:** 173 women with Stage I-III BC were randomized to usual care (UC, n = 86) or a yearlong, 16-session, in-person or telephone-administered diet and PA intervention (n = 87) delivered by registered dietitians. Dates, doses and reason for dose-adjustments/delays of chemotherapy were abstracted from electronic medical records or obtained from treating oncologists. T-tests and Chi-square tests were used to examine the effect of the intervention vs. UC on RDI. **Results:** Participants were 53±11 years old, had a body mass index of 29.7+6.8 kg/m^2, 51% had stage I BC and 22% were under-represented minorities. 27 different chemotherapy regimens were prescribed. Participants randomized to intervention completed 94% of counseling sessions during chemotherapy and had statistically significant improvements in PA and diet compared to UC. Average continuous RDI was unexpectedly high in both groups, with 93%+14% of prescribed chemotherapy completed (p = 0.92). However, 17% and 15% of intervention and UC participants, respectively, had < 85% RDI (p = 0.70) and more than one-third had at least one toxicity-associated dose reduction and/or delay (> 7 days) for at least one chemotherapy drug (39% intervention and 37% UC, p = 0.80). In posthoc analyses, there was a benefit of the intervention on chemotherapy completion compared to UC in the 74 women receiving neoadjuvant chemotherapy (RDI: 95% intervention vs. 90% UC, p = 0.05). Among intervention women, a dose-response effect was seen with participants who achieved more PA and better diet quality via the Healthy Eating Index (above median) experiencing higher RDI vs participants who were below the median for PA and/or diet quality (97% vs 90% RDI, p = 0.05). **Conclusions:** A primarily telephone-based diet and PA intervention led to improved diet and PA, but did not improve RDI compared to UC. However, a dose-response effect of the intervention was observed with higher PA and diet associated with higher RDI. Future analyses will examine intervention effects on secondary endpoints of endocrine therapy adherence and patient-reported outcomes when all women reach the 1-year timepoint (end of intervention). Further study of diet and PA interventions in patients receiving neoadjuvant chemotherapy are necessary. Clinical trial information: NCT03314688. A randomized control trial to determine necessary intervention elements to achieve optimal symptom outcomes for a remote symptom management system. *First Author: Kathi Mooney, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Interventions to improve patient-reported cancer symptom outcomes (PROs) are often multicomponent. In order to scale efficacious interventions, it is important to know if all components are needed to achieve the greatest benefit. We deconstructed the Symptom Care at Home (SCH) monitoring and management system, a multicomponent intervention found to be highly efficacious in reducing symptom burden for patients at home. SCH remotely monitors daily PROs, provides tailored automated self-management coaching based on the severity pattern reported for 11 monitored symptoms and alerts a nurse practitioner (NP) of poorly controlled moderate to severe symptoms. The NP follows up to intensify symptom care utilizing the SCH decision support system based on national guidelines. **Methods:** A 5 group randomized controlled design was utilized with 755 participants assigned to PRO assessment plus: Gp 1, (N = 143) automated self-management coaching, Gp 2, (N = 144) automated self-management coaching plus an activity tracker, Gp 3, (N = 147) NP follow up without decision support, Gp 4, (N = 154) NP follow up utilizing decision support or Gp 5, (N = 167) automated coaching plus NP follow up utilizing decision support- the complete SCH intervention. The primary outcome was maximum likelihood estimation of overall symptom severity over the duration of study participation (62 day median). **Results:** Patients were recruited from sites in Utah and Georgia. The majority of patients were female (60.3%), married (59.9%), 60.7% Caucasian and 34.9% Black, with a mean age of 59.4 years and Stage 3 or 4 cancer (65.7%). Most common diagnoses included breast (17.1%), lung (13.9%), colorectal (12.9%), pancreatic (8.6%) and ovarian (8.4%). Adherence rate for daily symptom reports was 73.8% with no differences between groups. 84.2% of patients reported one or more moderate or severe symptoms- most commonly fatigue (70.1%), pain (64.8%) and trouble sleeping (56.0%). Group 5- the complete SCH intervention had significantly greater symptom relief than any other group (Gp 5 vs Gp 1 or Gp 2 automated coaching both $p < .001$; Gp 5 vs Gp3 NP without decision support $p = .039$; Gp 5 vs Gp 4 NP with decision support $p = .017$). The two NP groups did not differ significantly but were significantly better than either automated coaching groups. The two automated coaching groups did not differ significantly from one another. **Conclusions:** PRO assessment with automated coaching and NP decision-supported follow-up for moderate to severe symptoms achieved better symptom reduction than the individual components. Better symptom relief can be obtained for patients at home through a synergistic, multicomponent intervention that combines a tailored symptom coaching component with notification and follow up by clinicians when symptoms rise to moderate or severe levels- both components contribute to better outcomes. Clinical trial information: NCT02779725. Research Sponsor: U.S. National Institutes of Health.

Association between an electronic health record (EHR)–embedded frailty index and survival among older adults receiving cancer chemotherapy. *First Author: Heidi D. Klepin, Wake Forest Baptist Comprehensive Cancer Center, Winston Salem, NC*

Background: Innovative strategies to facilitate rapid frailty screening are critically needed to enhance personalized oncology care among vulnerable older patients. An electronic frailty index (eFI) holds promise as a passive measure of frailty. The eFI was initially designed for primary care. The objective of this study was to establish feasibility, estimate prevalence of frailty, and evaluate the predictive value of the eFI for overall survival (OS) among older adults with cancer planned to receive chemotherapy. **Methods:** Consecutive patients (N = 509) aged 65+ with newly diagnosed lung, colorectal or breast cancer treated with chemotherapy were identified from our cancer registry between 2017 and 2020. Calculation of the eFI requires at least two ambulatory visits over a 2-year period and utilizes demographic information, vital signs, smoking status, ICD-10 diagnosis codes, select outpatient laboratory measurements, and functional information (if available from Medicare Annual Wellness Visits) during the 2 years prior to diagnosis. Frailty status is categorized as fit (eFI $\leq$0.10), pre-frail (0.10 < eFI$\leq$0.21), and frail (eFI > 0.21) based on the proportion of deficits present over the total number evaluated (score range 0-1). Non-calculable scores indicate insufficient historical primary care data within two years prior to cancer diagnosis. OS was estimated by eFI category using Kaplan Meier curves and compared using log rank testing. Cox proportional hazards models evaluated the adjusted association between eFI categories and mortality. **Results:** The cohort included 509 adults (median age 72.2 yrs, 55% female, 83.5% white, 13.4% black, 45.8% stage 4) with lung (N = 312), colorectal (N = 111) and breast (N = 86) cancer. Distribution of eFI categories at diagnosis were fit (25.9%), pre-frail (41.1%), frail (17.3 %) and not calculable (15.7%). The proportion of patients categorized as "fit" differed by disease type (19.9% lung, 30.6% colorectal, 41.9% breast, $p < 0.0001$). In univariate analyses, eFI frailty category was associated with OS (median OS for fit, pre-frail, frail and not calculable were > 54, 25, 19 and 10 months respectively, $p < 0.0001$.). Adjusting for age, gender, race, stage, and cancer type, the hazard of death was higher for pre-frail (Hazard Ratio, [HR] 1.7, 95% Confidence Interval [CI] 1.2-2.4), frail (HR 2.3, 95% CI 1.5-3.4) and not calculable eFI categories (HR 2.8, 95% CI 1.8-4.2) compared to fit patients. **Conclusions:** Calculating an EHR embedded eFI at the time of diagnosis among older adults treated with chemotherapy was feasible and identified nearly one-fifth of patients as frail. eFI-defined frailty status was associated with survival, with poorer survival among the most frail supporting eFI validity. The eFI is a promising scalable tool to efficiently conduct frailty screening in oncology clinical practice. Research Sponsor: U.S. National Institutes of Health.

12010 **Clinical Science Symposium**

Preliminary findings of implementing the G8 screening tool in an academic cancer center. *First Author: Kuang-Yi Wen, Thomas Jefferson University, Philadelphia, PA*

Background: Older patients often experience more toxicity from cancer treatments due to their functional age and co-morbidities. The G8 is a geriatric screening tool designed to identify patients who are appropriate for a comprehensive geriatric assessment (CGA) which will inform and optimize oncology therapeutic decision making, reduce toxicities and improve outcomes. Using a nurse-led assessment approach, we have implemented an EMR embedded G8 tool across our cancer center since June 2020. We aim to describe the characteristics of those patients who scored abnormal ($\leq$ 14) on the G8. **Methods:** The demographic and clinical characteristics were collected from the EMR for those who were $\geq$ 65 and have completed the G8 screening tool from June 2020 to Jan 2022. Summary statistics such as means, standard deviations and proportions were reported. Comparisons of various endpoints between dichotomized ($\leq$ 14 vs. > 14) G8 scores were performed using pairwise two-sample t-test, pairwise proportion test, Fisher's exact test and/or Pearson's chi-squared test. Selected stakeholders were elicited for their perspectives on the implementation process. **Results:** 544 patients age $\geq$ 65 completed G8 screening with a mean score of 13.4 ($\pm$ 2.3). The mean age was 75.2 ($\pm$ 7.0), and 55.7% were females and 78.3% were non-Hispanic White. The most frequent cancer type was breast cancer (21.3%), followed by lung/respiratory cancer (18.2%), and GI cancer (15.8%). The percentage of patients appropriate for a CGA (based on an abnormal G8 score) was 59% (n = 332), of which only 10% (n = 31) were referred. A spearman correlation of 0.4 ($p < 0.001$) between G8 scores and age was obtained. A statistically significant association between ECOG and G8 groups was found, but not for any comorbidities. The prevalence of current/former smoking and extreme polypharmacy (> 10) is significantly higher in the G8 abnormal group. Implementation process evaluation found new patients with cancer overwhelmed with information, a lack of patient education and provider engagement, and an unstandardized referral process to CGA, were barriers for CGA referral. **Conclusions:** The G8 is an effective tool identifying patients appropriate for a CGA. An EMR embedded G8 steadily improved the G8 utilization uptake but not referral for CGA at our institution. To further improve awareness, utilization and referral, we are redesigning a hybrid workflow integrating patient-mediated MyChart implementation and nurse navigator engagement. EPIC enhancements are being designed to inform the oncologist of the patient's G8 score, CGA referral status and the final CGA report. Research Sponsor: U.S. National Institutes of Health.

A decision curve analysis of the clinical usefulness of a two-step frailty assessment strategy in older patients with prostate, breast, colorectal, or lung cancer. *First Author: Adolfo Gonzalez Serrano, Université Paris Est Créteil, INSERM, IMRB, Créteil, Cedex, France*

Background: Geriatric Assessment (GA) is recommended to assess the health status and select the most appropriate cancer treatment in older patients. However, GA is resource- and time-consuming. Thus, a two-step approach using frailty screening has been recommended. We aimed to evaluate the usefulness of frailty screening over GA for identifying unfit individuals who need GA and reducing unnecessary GA in fit individuals in a population of older outpatients with cancer. **Methods:** We analyzed patients age 70 and older with prostate, breast, colorectal, or lung cancer included in the multicenter, prospective ELCAPA cohort study (NCT02884375) between February 2007 and December 2019. All patients had a GA at inclusion. GA was the reference test. We defined unfit patients as those having at least one abnormal score in the following domains: functional status, mobility, comorbidity, cognition, mental health status, nutrition, and polypharmacy. We defined unfit patients according to the G8 and modified G8 scores using the recommended cut-offs ($\leq$ 14 out of 17 points and $\geq$ 6 out of 35 points, respectively). We calculated each screening tool's sensitivity, specificity, and positive and negative predictive values. We used decision curve analysis to estimate the net benefit (the percentage of patients found to be unfit) of screening over GA. We assessed the avoided unnecessary GAs for each screening tool (reducing unnecessary GA in fit patients without decreasing the number of unfit patients undergoing [necessary] GA). We calculated these estimates across different threshold probabilities corresponding to the value of missing an unfit patient compared to exposing a fit patient to an unnecessary GA. A probability of 0.33 indicated that missing an unfit patient was two times worse than referring a fit patient to an unnecessary GA. A probability of 0.50 indicated that missing an unfit patient was the same as exposing a fit patient to an unnecessary GA. **Results:** We analyzed 1,648 patients with prostate (15%), breast (52%), colorectal (22%), or lung cancer (11%). The median age was 81 years, 559 patients (34%) had metastatic disease, and 1,428 patients (87%) were unfit. The sensitivity (95% CI) and specificity were 85% (84-87) and 59% (57-61) for the G8 score, and 86% (84-87) and 60% (58-63) for the modified G8 score. With a threshold probability of 0.33, the net benefit was 0.71 for the G8 score, 0.72 for the modified G8 score, and 0.80 for GA. With a threshold probability of 0.50, the net benefit was 0.68 for the G8 score, 0.69 for the modified G8 score, and 0.73 for GA. We did not observe a reduction in unnecessary GA of screening tools over GA. **Conclusions:** Frailty screening tools showed good diagnostic performances. However, our findings suggest that the GA-for-all strategy provides the higher clinical benefit in older patients with cancer. Research Sponsor: RINC4, EUR-LIVE Graduate School of Research "Life Trajectories and Health Vulnerability".

Rural-urban disparities in Geriatric Assessment (GA) impairments and mortality among older adults with cancer: Results from the Cancer and Aging Resilience Evaluation (CARE) Registry. *First Author: Mackenzie Fowler, University of Alabama at Birmingham, Birmingham, AL*

Background: Rural-urban disparities persist in cancer incidence and mortality, despite improvement in cancer screening and treatment. Older adults are at increased risk for cancer, represent the majority of cancer cases, and are more likely to reside in rural areas than younger adults are. GAs are recommended in clinical management of older adults with cancer, in part to identify aging-related impairments predictive of adverse outcomes; few studies have explored rural-urban disparities in GA impairments and mortality among older patients with cancer. **Methods:** We included 937 older adults (≥60y) from the CARE registry recently diagnosed with cancer who underwent GA at their first pre-chemotherapy visit to the UAB oncology clinic. Rural-urban status using Rural-Urban Commuting Area (RUCA) codes, classified the cohort by residence in metropolitan, micropolitan, and rural/small town areas. We included self-rated performance status (PS) (≥2 on Eastern Cooperative Oncology Group PS), instrumental activities of daily living (IADL) [≥1 impairment], physical and mental health-related quality of life (HRQoL) [t-score < 40 on PROMIS 10-item Global Health], and overall survival as outcomes. Logistic regression evaluated the association between rural-urban status and each outcome (except overall survival, where we used Cox regression analyses). Micropolitan residence was chosen as the reference category due to similar high risk in both rural and urban areas. **Results:** Median age at study participation was 69.0y (Interquartile range: 64.0-74.0); 12.4% resided in rural, 14.8% in micropolitan and 72.8% in urban areas; 22.5% were diagnosed with colorectal cancer, 19.0% with pancreatic, and 12.4% with hepatobiliary; 74.7% were Stage III/IV. Participants in rural areas were more likely to be white and less educated. After adjustment for age, sex, race, education and cancer type/stage, rural residence was associated with increased odds of impaired PS (OR = 1.93, 95% CI: 1.10-3.40), limitations in IADLs (OR = 1.79, 95% CI: 1.03-3.10), and impaired physical HRQoL (OR = 1.84, 95% CI: 1.05-3.22) compared to micropolitan residence. Urban residence was not significantly associated with any GA outcomes compared to micropolitan residence. Rural residence was associated with higher hazard of death compared to micropolitan residence (HR = 1.88, 95% CI: 1.09-3.24) as well as urban residence (HR = 1.67, 95% CI: 1.13-2.45). **Conclusions:** Among older adults with newly diagnosed cancer, rural residence was associated with impaired PS, limitations in IADLs, impaired physical HRQoL, and reduced overall survival. Implementation of routine GA among older adults in rural areas may aid in early identification and intervention on GA impairments to improve cancer outcomes. Effectiveness of Active Living After Cancer (ALAC), a community-based physical activity program for underserved cancer survivors and their caregivers. *First Author: Scherezade K. Mama, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Physical activity (PA) improves physical functioning and quality of life in cancer survivors, yet few cancer survivors meet recommendations of ≥150 minutes/week of moderate intensity PA. Active Living After Cancer (ALAC) is a community-based program to improve the quality of life of cancer survivors by promoting PA and providing navigation services for survivorship issues. This study evaluates the impact of ALAC on PA, physical functioning, and quality of life in underserved cancer survivors who participated with and without a caregiver. **Methods:** Cancer survivors were recruited through community organizations to participate in ALAC, which consists of 12 weekly sessions, with or without a caregiver. Participants completed assessments of PA (Godin Leisure Time Exercise Questionnaire), physical functioning (30-sec sit-to-stand test), and quality of life (PROMIS physical and mental health) at baseline and follow-up. Paired samples t-tests were used to assess changes in physical activity, physical functioning and quality of life in cancer survivors and general linear models were used to compare changes between cancer survivors who participated with vs. without a caregiver. **Results:** Cancer survivors (N = 539; M age = 61.0±11.3 years) were mostly women (92.4%), Hispanic (57.3%) or non-Hispanic Black (21.5%), and medically underserved (85.3%). Most were breast cancer survivors (69.4%), diagnosed with Stage 0-III cancer (91.5%), and participated in ALAC without a caregiver (N = 463, 85.9%). From baseline to follow-up, the percent of cancer survivors meeting PA recommendations increased from 30.3% to 59.6% (Δ = 27.8 score, t= 16.4, p< .001), and the number of sit-to-stand repetitions in a 30-second period increased from 12.4 to 14.3 (Δ = 2.1, t= 8.6, p< .001). Cancer survivors also reported significant improvements in physical (Δ = 0.6, t= 2.4, p= .015) and mental (Δ = 1.0, t= 3.7, p< .001) health-related quality of life. Cancer survivors who participated with a caregiver reported improvements in physical (Δ = 0.7) and mental (Δ = 1.2) health-related quality of life, whereas those who participated without a caregiver reported slight decreases in physical (Δ = -0.2) and mental (Δ = -0.2) health-related quality of life. However, group x time interactions were not statistically significant [physical $F(1,412)$ = 1.9, p= .168; mental $F(1,412)$ = 49.2, p= .061]. **Conclusions:** Results confirm the effectiveness of ALAC among medically underserved cancer survivors for increasing PA and physical function and suggest that quality of life improvements may be enhanced by participating with a caregiver. Thus, community-based programs should encourage participation with a caregiver when possible to further increase PA, improve cancer survivorship, and reduce cancer health disparities among underserved cancer survivors. Association of parental cancer and minor child's unmet economic needs in food, housing, and transportation. *First Author: Zhiyuan Zheng, American Cancer Society, Atlanta, GA*

Background: A cancer diagnosis is associated with substantial economic burden among cancer survivors and their families. Some families make sacrifices that adversely affect food, housing, and transportation to offset high out-of-pocket medical expenses. Cancer survivors with minor children may be particularly vulnerable to financial hardship, even years after diagnosis. However, little is known about the extent to which parental cancer affects minor children's food insecurity, unmet housing needs, and delayed medical care due to transportation barriers. **Methods:** The 2013 to 2018 National Health Interview Survey was used to identify minor children (ages 5-17 years) living in families with a parental cancer history (n = 812, representing 860,488 children) and children without a parental cancer history (n = 22,129, representing about 24.5 million children). Multivariable logistic regressions were used to compare family-level food insecurity, parent's worry about ability to pay monthly bills and housing costs, and delayed medical care for the child because of no transportation between minor children with and without a parental cancer history. All analyses adjusted for child-, parent-, and family-related characteristics, including child's age group, sex, and race/ethnicity; parent's age group, sex, race/ethnicity, health insurance coverage, number of comorbid conditions, and obesity status; family's structure (married/cohabiting parents versus single parent families), highest educational attainment in the family, and family income as a percentage of the federal poverty level. **Results:** About 3.4% of minor children were living in families with a parental cancer history. In adjusted analyses and compared to children whose parents did not report a history of cancer, children of cancer survivors were more likely to live in families that experience shortages in basic economic needs, such as food bought did not last 26.0% (95% confidence intervals[CI]: 22.3%-29.7%) vs 16.7% (95CI: 16.1%-17.3%), inability to afford balanced meals 16.9% (95CI: 13.8%-20.0%) vs 13.3% (95CI: 12.8%-13.8%), worry about paying monthly bills 44.8% (95CI: 40.6%-48.9%) vs 37.9% (95CI: 37.1%-38.7%), and worry about housing costs 35.7% (95CI: 31.9%-39.5%) vs 30.7% (95CI: 30.0%-31.5%). Moreover, children with a parental cancer history were more likely to experience delayed medical care due to lack of transportation than children without a parental cancer history 3.6% (95CI: 2.2%-4.9%) vs 1.6% (95CI: 1.4%-1.9%), all p < .05. **Conclusions:** Parental cancer is associated with greater likelihood of food insecurity, worse housing and other living conditions, and transportation barriers to medical care for minor children. Efforts to identify minor children with a parental cancer history and develop strategies to attenuate their unmet economic needs are warranted. Research Sponsor: None.

Bias reported by family caregivers of healthcare team support when assisting patients with cancer-related decision-making. *First Author: James Nicholas Dionne-Odom, University of Alabama at Birmingham, Birmingham, AL*

Background: Individuals receiving healthcare services often experience differential treatment based on their personal identity characteristics (e.g., age, race, gender), including in the context of shared decision making with clinicians. Yet, little is reported about the extent of bias experienced by family and friend caregivers from the clinician support they and patients receive when making cancer-related decisions. **Methods:** Analysis of data from a nationally-representative U.S. online survey conducted by CancerCare (2/2021-7/2021) of family caregivers of patients with cancer (N = 2,703). Bias experienced in decision support was assessed with the item: "Have you felt that the support you and the person with cancer have received for making cancer-related decisions by your doctor or healthcare team has been negatively affected by any of the following?" Check-all-that-apply response options included: age, race, language, education, political affiliation, body weight, insurance type or lack of insurance, income, religion, sexual orientation, and gender/sex. Chi-square was used to compare demographics and bias; regression analyses were used to identify relationships between bias and caregiver's psychological distress, measured by the GAD-2 and PHQ-2. **Results:** Out of 2,703 cancer caregiver respondents, 47.4% (n = 1,281) reported experiencing at least one type of bias when receiving healthcare team support for making cancer-related decisions, with body weight (24.7%), age (22.2%), and income level (19.9%) being the most commonly endorsed biases. Experiencing one or more types of bias differed by caregivers' age (p < .001; younger > older), gender (p < .001; male and transgender/gender nonconforming > females), race (p < .01; African American/Black and Alaskan Native, American Indian, Native Hawaiian, or Pacific Islander > White and Asian), ethnicity (p < .001; higher for Hispanic/Latino), education (p < .01; higher education > less education), and length of time providing care (p < .01; higher for longer time providing care). After covariate adjustment, the odds of having high anxiety (GAD-2 scores≥3) were 3 times higher for caregivers experiencing ≥1 types of bias compared to those experiencing none (adjusted OR, 3.12; 95% CI, 2.6-3.7); similarly, the odds of having high depression symptoms (PHQ-2 scores≥3) were also 3 times higher (adjusted OR, 3.29; 9% CI, 2.8-3.9). **Conclusions:** Half of caregivers involved in their care recipients' cancer-related decisions report bias in the decision support received from the healthcare team. Furthermore, experiencing bias was associated with increased odds of experiencing psychological distress. The pervasiveness of bias experienced by families involved in patients' cancer-related decisions suggests the priority need to critically evaluate and improve clinician decision support practices. Accounting for the high enrollment of African Americans in Winship Cancer Institute's myeloma clinical trials. *First Author: Tekiah McClary, Emory Healthcare, Winship Cancer Institute, Atlanta, GA*

Background: Multiple myeloma (MM) is twice as common in African Americans (AA) as in Whites, yet AA make up only 5% of multiple myeloma (MM) clinical trial participants nationwide. Multiple studies have attempted to identify the reasons why AA are underrepresented in clinical trials and have discovered that sociodemographic factors, a lack of understanding, mistrust of sponsors, and a variety of opportunity barriers all contribute to AA underrepresentation in clinical trials. At one cancer center, African Americans make up 33% of those enrolled in MM clinical trials. To begin to account for this success in enrolling AA in myeloma clinical trials, a survey was designed to determine whether the major barriers to AA clinical trial participation existed at this cancer center. **Methods:** The survey was open to any AA patient who had consented to a clinical trial. The Trust in Medical Research scale (TMR) developed by Hall et al., the Human Connection (THC) scale developed by Mack et al., and the Duke Intrinsic Religiosity Scale (DUREL) were the three main scales used in the survey. Adapted assessment questions from Advani et al were used to assess the importance of side effects in deciding to participate in clinical trials. **Results:** We offered the study to 76 patients and 80% (61/76) participated. The mean TMR score was 15.0 which is significantly greater than the 11.6 score observed for AAs at other institutions ($p < 0.001$). The mean human connection score was 57.7 which is significantly greater than the 54.6 observed in the population of the Mack study, which accrued mostly white participants ($p < 0.001$). The Pearson correlation coefficient between the TMR score and the human connection score is 0.37, indicating a significant positive correlation between human connection scores and trust scores (p-value = 0.002). The average score for the intrinsic religiosity section of the DUREL scale was 13 (score of 15 indicates high religiosity). The average score of importance of side effects was 8.574, significantly higher than the Advani AA response of 6.7 (p-value < 0.001). **Conclusions:** African Americans enrolled in clinical trials at the high enrolling cancer center had higher THC and TMR scale scores than reported nationally, both helping to facilitate trial enrollment. The high intrinsic religiosity score observed suggests that high religiosity had no impact on clinical trial participation, nor did concern about side effects. Furthermore, a high THC score was associated with a high trust score. Since this THC scale assesses whether participants believe their doctors listen carefully, care about them, offer hope, provide clear explanations, and so on, establishing a human connection may be one way to increase AA trust in providers, increase AA clinical trial enrollment and overcome other barriers. Strategies for implementing an ePRO-based symptom management program (eSyM) across six cancer centers. *First Author: Michael J. Hassett, Dana-Farber Cancer Institute, Boston, MA*

Background: Electronic patient-reported outcome (ePRO)-based symptom management can improve cancer care outcomes. However, implementation is challenging as it requires 1) tremendous technical resources to integrate ePROs into the electronic health record (EHR), 2) substantial buy-in from clinicians and patients, 3) between visit symptom management, and 4) institutional investment to support engagement. **Methods:** The SIMPRO Consortium developed and deployed eSyM, an EHR-integrated ePRO-based symptom management program for medical oncology and surgery patients, at 6 cancer centers between September 2019-March 2022. Site teams document new and changes to implementation strategies monthly using REDCap (data collection is ongoing). Strategies are itemized using the Expert Recommendations for Implementation Change (ERIC) list and mapped to the Consolidated Framework for Implementation Research (CFIR) list of barriers. The SIMPRO Coordinating Center (Dana-Farber) reviews all ERIC-CFIR classifications for consistency. **Results:** To date, 162 distinct strategies have been documented. On average, sites have implemented 23 strategies, 5 preparing for go-live and 18 remaining active beyond go-live. Preparation of clinical staff, training, and routine program evaluation are consistent high impact strategies. Other adaptive strategies have varied across sites, including various approaches to patient and provider engagement. Foundational strategies have been deployed by the coordinating center to support the multi-center initiative. **Conclusions:** Methodical deployment using theory-based implementation strategies may foster adoption of novel health care delivery systems by patients, clinicians, and institutions. Attention to the specific high-value strategies identified by the SIMPRO Consortium could support similar ePRO deployment at other institutions. Research Sponsor: U.S. National Institutes of Health.

Strategy Type	ERIC Category	CFIR Domain (Construct)	Example
High-Impact (Universal)	Develop & implement quality monitoring tools	Process (reflect & evaluate)	Automated reports to capture usage rates
	Conduct educational meetings	Process (engage)	Training sessions with clinicians
	Purposefully reexamine the implementation	Characteristics of individuals (knowledge & beliefs about the intervention)	Meetings with stakeholders
Adaptive (Site-Specific)	Prepare patients to be active participants	Process (execute)	Phone calls, portal messages, and/or in-person approaches to assist patients
Foundational (Consortium-Wide)	Obtain & use patient/consumer feedback	Intervention characteristics (adaptability)	Modify questionnaires & alerts
	Create a learning collaborative	Outer setting (cosmopolitanism)	Monthly consortium meetings
	Assess for readiness; identify facilitators & barriers	Inner setting (implementation climate)	Stakeholder assessments pre and post go-live

Psychological mobile app for patients with acute myeloid leukemia (AML): A randomized clinical trial. *First Author: Areej El-Jawahri, Massachusetts General Hospital, Boston, MA*

Background: Patients with AML experience substantial decline in their quality of life (QOL) and mood during their hospitalization for intensive chemotherapy. Yet, few interventions have been developed to enhance patient-reported outcomes during treatment. **Methods:** We conducted a randomized trial of a psychological mobile app (DREAMLAND) for patients with a new diagnosis of AML receiving intensive chemotherapy at Massachusetts General Hospital and Dana-Farber Cancer Institute. Patients were randomly assigned to DREAMLAND or usual care. DREAMLAND was tailored to the AML trajectory and included four required modules focused on 1) supportive psychotherapy to help patients deal with the initial shock of diagnosis; 2) psychoeducation to manage illness expectations; 3) psychosocial skill-building to promote effective coping; and 4) self-care. The primary endpoint was feasibility defined as at least 60% of eligible patients enrolling, and 60% of those enrolled completing at least 60% of the required modules. We assessed patient QOL (Functional-Assessment-of-Cancer-Therapy-Leukemia), psychological distress (Hospital-Anxiety-and-Depression-Scale [HADS] and Patient-Health-Questionnaire-9 [PHQ-9]), symptom burden (Edmonton-Symptom-Assessment-Scale), and self-efficacy (Cancer Self-Efficacy Scale) at baseline and day +20 post chemotherapy. We used ANCOVA to assess the effect of DREAMLAND on outcomes. **Results:** We enrolled 66.7% (60/90) of eligible patients and 62.1% completed ≥ 75% of intervention modules. At day +20 after intensive chemotherapy, patients randomized to DREAMLAND reported improved QOL (132.06 vs. 110.72, P = 0.001), lower anxiety (3.54 vs. 5.64, P = 0.010) and depression (HADS: 4.76 vs. 6.29, P = 0.121; PHQ-9: 4.62 vs. 8.35, P < 0.001) symptoms, and improved symptom burden (24.89 vs. 40.60, P = 0.007) and self-efficacy (151.84 vs. 135.43, P = 0.004) compared to the usual care group. **Conclusions:** A psychological mobile app for patients newly diagnosed with AML is feasible to integrate during hospitalization for intensive chemotherapy and may improve QOL, mood, symptom burden, and self-efficacy. Clinical trial information: NCT03372291. Research Sponsor: National Palliative Care Research Center.

Efficacy of a password-protected, pill-dispensing device with mail return capacity to enhance disposal of unused opioids after cancer surgery. *First Author: Jacob C. Cogan, Columbia University Medical Center, New York, NY*

Background: Opioid misuse is a public health crisis. Initial opioid exposures often occur post-operatively, and 10% of opioid-naïve patients who undergo cancer surgery subsequently become long-term opioid users. It has been shown that 70% of opioids prescribed post-operatively go unused, but only 9% of unused pills are disposed of appropriately, which increases the risk of unintended use. We evaluated the impact of an inexpensive, password-protected pill-dispensing device with mail return capacity on disposal of unused pills after cancer surgery. **Methods:** We conducted a prospective, proof-of-concept pilot study among adult patients scheduled for major cancer-related surgery. Enrolled patients received opioid prescriptions in a pill-dispensing device (Addinex) from a specialty pharmacy. The mechanical device linked to a smartphone app, which provided passwords on a prescriber-defined schedule. Patients were able to enter unique passwords into the device to receive their pills if the prescribed time had elapsed. The smartphone app provided clinical guidance based on patient-reported pain levels, and suggested tapering strategies. Patients were instructed to return the device in a DEA-approved mailer when opioid use was no longer required for acute pain control. Unused pills were destroyed upon receipt. The primary objective was to determine the feasibility of device return, defined as > 50% within 6 weeks. We also explored total pill use and return, patterns of device use and patient satisfaction. **Results:** We enrolled 30 patients between October 2020 and December 2021. The median age was 46 (range 29–72). Surgical procedures included abdominal hysterectomy (13), mastectomy and reconstruction (10), and soft tissue tumor resections (7). Overall, the majority of participants (n = 24, 80%) returned the device, and more than half (n = 17, 57%) returned the device within 6 weeks of surgery. There were 19 patients who obtained opioids from the device. Among these patients, the majority were satisfied with the device (n = 14, 74%); felt the benefits of the device justified the added steps involved (n = 14, 74%); and would sign up to receive opioids in the device again (n = 13, 68%). The other 11 patients used no opioids. None of these non-users reported any opioid requirements for pain control, and all but one (n = 10, 91%) returned the device and unused pills. In total, 567 opioids were prescribed, and 170 (30%) were used. Of the 397 excess pills, 332 (84% of unused pills, 59% of all pills prescribed) were returned by mail. **Conclusions:** We found that use of an inexpensive pill-dispensing device with mail return capacity was a feasible and effective strategy to enhance disposal of unused post-operative opioids. Interestingly, a substantial number of prescribed pills were unused. This system also improves confidence with indicated opioid use while reducing diversion. PEARL: A randomised phase 3 trial of palliative care early in advanced lung cancers (ALTG/TOGA 13/008). *First Author: Linda R. Mileshkin, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Early referral to palliative care was associated with improved health-related quality of life (HRQL) and overall survival (OS) in a US phase 3 trial in lung cancer patients (pts). International studies in mixed cancer types have reported conflicting results. PEARL aimed to determine whether early referral to palliative care would improve HRQL, OS, and resource use in Australian pts with recently diagnosed, advanced thoracic cancers. **Methods:** Eligible participants (pts) in this unblinded, multi-centre, randomised, phase 3 trial had advanced thoracic cancers diagnosed within 60 days, and the ability to complete patient-rated outcome measures (PROMS). Pts were randomly allocated to early referral to palliative care (ER) or referral at clinician's discretion (DR). All pts received standard oncological care. PROMS were completed at baseline, every 3-4 weeks for 6 months, then 6-8 weekly. The primary objective was to determine the frequency of sustained, substantial improvements in HRQL, defined as a 5-point improvement in the FACT-L Trial Outcome Index (TOI) maintained for at least 2 consecutive assessments. Secondary outcomes included OS, documentation of advanced care plan (ACP), PROM scores at 12 weeks, anxiety/depression (PROMIS-ED), lung cancer symptoms (FACT-L), global HRQL (ICECAP-SCM), carer-satisfaction and burden, and understanding of illness and prognosis. The accrual target of 200 gave 80% power (alpha 0.05) to detect an absolute improvement of 20% in the proportion of pts achieving the primary endpoint. **Results:** 113 pts and 78 carers were recruited when the trial closed for slow accrual. Pt characteristics were well balanced: 88 (75%) had NSCLC, 18 (16%) small cell and 7 (6%) mesothelioma. Median age was 69 (IQR 62-74), 63 (56%) were male; systemic anti-cancer therapy ongoing or planned in 88 (78%). Median follow-up was 30 months. First consultations with a palliative care specialist within 60 days of diagnosis occurred in more pts assigned ER vs DR (57% vs 3.5%). Sustained substantial improvements in FACT-L TOI were reported by similar numbers of pts assigned ER vs DR: 33% vs 32%, p = 0.9. OS was similar among those assigned ER versus DR (median 12 vs 18.4 months, p = 0.11). A similar % had a written advanced care plan at death: 15/40 (39%) vs 15/33 (47%). We found no important differences between arms in global HRQL (ICECAP-SCM), depression/anxiety (PROMIS-ED), lung cancer symptoms (FACT-L), carer satisfaction (FAMCARE-2), carer burden (CRA), or understanding of illness by carers or pts. **Conclusions:** Early referral to palliative care, compared with discretionary referral, did not improve important outcomes for Australian thoracic cancer pts or carers. Our findings suggest that the palliative care needs of such pts were addressed equally well by delayed referral when clinically indicated, resulting in reduced burden for resource-limited specialist palliative services. Clinical trial information: ACTRN12617000166370. Research Sponsor: Cancer Australia 1101882_Mileshkin.

Bereavement practices of gynecologic oncologists: Physician and care team practices compared to caregiver needs. *First Author: Lauren E. Harrison, University of Connecticut Health Center, Farmington, CT*

Background: Gynecologic cancers account for over 34,000 deaths in the United States annually. Family-centered care is beneficial to the family unit and patient throughout the illness course. Research is lacking regarding how physicians should approach family members or other caregivers after a patient dies. We aimed to assess how gynecologic oncologists are currently practicing and compare that to family members' needs during the bereavement period. **Methods:** We devised a set of paired surveys that were distributed to the Society for Gynecologic Oncology and to patient families. Families were recruited using social media, publicizing in local organizations, and advertising in University of Connecticut campus-wide emails. Likert-scale style questions with responses ranging from "1" to "10" were used to assess opinions on aspects of bereavement care and reported as means. Differences in means were assessed using ANOVA and T-tests and considered to be statistically significant if the P-value was < 0.05. **Results:** We received completed surveys from 129 physicians and 17 caregivers from different families. 48% of physicians reported contacting patient families, and, similarly, 47% of family members reported receiving contact from physicians. Physicians had a mean 6.21/10 confidence level (where 10 is maximum confidence) in providing bereavement care, while families reported 5.76/10 confidence in their physician's ability to provide bereavement support ($P = 0.493$). Factors that influenced physicians confidence in providing bereavement support were undergoing formal training in bereavement (6.84/10 vs 5.14/10 for physicians who had not been trained, $P < 0.001$) and being in practice for more than 11 years (5.65/10 for ≤10 years in practice, 7.05 for ≥11 years, P = 0.001). Physicians who contacted patients personally had a higher confidence level (6.98/10) in providing bereavement support compared with those who did not contact families (5.51/10, $P < 0.001$). Family members were nearly unanimous in reporting a desire for physicians to contact them personally (16/17), and stated that a phone call (56%) or a sympathy card (38%) were their preferred methods of contact. **Conclusions:** Our study suggests that although families appreciate contact from physicians after their loss, physicians do not have a high level of confidence in providing this support. Physicians who undergo bereavement training and who reached out after patients had died have higher confidence levels in interacting with family members. Based on these results, formal bereavement training should be incorporated into gynecologic oncology fellowships in order to increase the comfort levels and likelihood of gynecologic oncologists reaching out to families after a patient has died. Oral minoxidil for the treatment of late alopecia in cancer survivors. *First Author: Alyce Mei-Shiuan Kuo, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Late alopecia is defined as incomplete hair regrowth > 6 months following cytotoxic chemotherapy or from initiation of endocrine therapy. It has been reported in up to 25-30% of cancer survivors and is associated with decreased quality of life and reduced dose intensity of cancer therapies. Minoxidil is an aminopyridine potassium channel opener, resulting in vasodilation and premature entry of resting hair follicles into the anagen (growth) phase and increase in hair follicle size. This study aims to assess clinical outcomes and adverse events of oral minoxidil for the treatment of cancer therapy-related late alopecia. **Methods:** We retrospectively assessed all women with late alopecia treated with oral minoxidil (1.25 mg daily) evaluated at an oncodermatology referral program between 1/2018-5/2021. Outcomes were assessed by standardized photography (4 views) and trichoscopy (HairMetrix, Canfield Scientific, Inc.). Trichoscopy recorded hair density (hair count/cm^2) and hair thickness (shaft diameter) at uniform frontal and occipital target areas (12 and 36 cm midline from the glabella, respectively). Adverse events were recorded and graded using CTCAE v5.0. Descriptive statistics were used to summarize the patient demographics and clinical characteristics. Changes in trichoscopy measurements from baseline to follow-up were estimated using paired t-tests. **Results:** Two hundred and sixteen patients (mean age 57.8±13.7) were included for analysis. Thirty-one (14%) received chemotherapy alone, 65 (30%) endocrine monotherapy, and 120 (56%) chemotherapy followed by endocrine therapy. The majority of patients (n = 170, 79.1%) had a history of breast cancer. Standardized photography assessments (n = 119) after a median of 105 days (IQR = 70) on oral minoxidil revealed clinical improvement in 88 (74%). Trichoscopy assessments (n = 42) after a median of 91 days (IQR = 126) demonstrated increased frontal hair density (124.2 vs 153.2 hairs/cm^2, p = 0.008) and occipital hair density (100.3 vs 123.5 hairs/cm^2, p = 0.004). There was no statistically significant difference in average frontal or occipital hair thickness (69.3 vs 67.3 μm, p = 0.22, and 70.3 vs 69.9 μm, p = 0.84, respectively). No patients reported discontinuation of oral minoxidil due to adverse effects. **Conclusions:** Oral minoxidil may benefit both frontal and occipital late alopecia in cancer survivors treated with cytotoxic and/or endocrine therapy. This regimen was well tolerated by patients. Prospective, controlled studies are needed to confirm these observations. Research Sponsor: None.

12023 **Poster Discussion Session**

Vitamin D insufficiency as a peripheral neuropathy risk factor in white and black patients in SWOG 0221. *First Author: Ciao-Sin Chelsea Chen, University of Michigan, Ann Arbor, MI*

Background: Peripheral neuropathy (PN) is a treatment-limiting toxicity of paclitaxel. Black patients have higher rates of PN and vitamin D insufficiency, and our prior work suggests vitamin D insufficiency increases risk of paclitaxel-induced PN. The objective of this study was to validate that patients with vitamin D insufficiency have higher risk of paclitaxel-induced PN and investigate whether this explains racial disparities in PN risk. **Methods:** This retrospective validation study was conducted in the phase III SWOG 0221 (NCT00070564) trial comparing paclitaxel-containing chemotherapy regimens for early-stage breast cancer. Pre-treatment 25-hydroxy-vitamin D was quantified in cryopreserved serum. Males and patients who received less than a third of the paclitaxel treatment were excluded. The association between vitamin D insufficiency (≤20 ng/mL) and grade 3+ sensory PN was tested via logistic regression and then adjusted for self-reported race, age, paclitaxel schedule (QW vs Q2W), and body mass index. **Results:** Of the 1,116 female patients in the analysis, 169 (15.1%) experienced PN and 376 (33.7%) had vitamin D insufficiency. Vitamin D insufficiency was associated with higher PN risk (19.4% vs 13.0%, OR = 1.62, p = 0.005, Data Table). The association was borderline significant (OR = 1.44, p = 0.056) after adjustment for black race (OR = 2.41, p = 0.001), paclitaxel schedule (OR = 2.22, p < 0.001), and age (OR = 1.03, p = 0.005). Compared with white patients (n = 943), black patients (n = 99) had more prevalent vitamin D insufficiency (77.8% vs 28.6%, OR = 8.72, p < 0.001) and increased PN risk (29.3% vs 13.5%, OR = 2.66, p < 0.001); adjusting for vitamin D insufficiency decreased but did not eliminate the higher PN risk in black patients (OR = 2.23, p = 0.002). **Conclusions:** Vitamin D insufficiency increases risk of paclitaxel-induced PN and partially explains the higher risk of PN in black patients. Prospective trials are needed to test whether vitamin D supplementation lessens PN and reduces disparities in treatment outcomes. Research Sponsor: American Cancer Society, University of Michigan Rogel Cancer Center.

	Univariate Odds Ratio [95% Confidence Interval]	p-value	Multivariable Odds Ratio [95% Confidence Interval]	p-value
Vitamin D – Insufficient (n = 376) vs Sufficient (n = 740)	1.62 [1.16, 2.25]	**0.005**	1.44 [0.99, 2.08]	0.056
Race - Black (n = 99) vs White (n = 943)	2.66 [1.64, 4.23]	**< 0.001**	2.41 [1.43, 4.02]	**0.001**
Race - Asian (n = 32) vs White (n = 943)	1.48 [0.54, 3.45]	0.395	1.60 [0.58, 3.79]	0.322
Race - Other (n = 42) vs White (n = 943)	1.29 [0.51, 2.79]	0.555	1.34 [0.53, 2.95]	0.499
Paclitaxel Schedule - Q2W (n = 530) vs QW (n = 586)	2.20 [1.58, 3.11]	**< 0.001**	2.22 [1.58, 3.15]	**< 0.001**

12024 **Poster Discussion Session**

Differences in clinician and patient assessment of baseline neuropathy in patients receiving taxane-based chemotherapy enrolled to SWOG S1714 (NCT# 03939481). *First Author: Meghna S. Trivedi, Columbia University Irving Medical Center, New York, NY*

Background: Chemotherapy induced peripheral neuropathy (CIPN) can lead to treatment dose reduction or discontinuation and significantly impact quality of life and functional status. Clinical trials have historically excluded patients with pre-existing neuropathy. Thus, it is unknown how many patients start treatment with baseline neuropathy as well as the impact on the trajectory of neuropathy symptoms. There are several patient- and clinician-based methods to assess CIPN; however, there is no consensus on the best method to evaluate CIPN or whether clinician versus patient assessment differs at baseline. **Methods:** In SWOG 1714, we enrolled patients ≥ 18 years of age with Stage I-III non-small cell lung, breast, or ovarian/fallopian tube/peritoneal cancer starting treatment with a taxane. Patients with baseline neuropathy were eligible. Neuropathy was assessed with patient-reported outcomes (PROs), including the European Organization for Research and Treatment of Cancer QLQ-CIPN20 (CIPN-20) and the PRO version of the Common Terminology criteria for Adverse Events (PRO-CTCAE) for severity of and interference caused by numbness and tingling, and the clinician-assessed National Cancer Institute (NCI)-CTCAE Grading Scale Version 5.0 for nervous system disorders. **Results:** Of 1336 patients enrolled on S1714, 1322 (99.0%) were eligible. The median age was 55.7 years (range 23.9-85.5) and 98.9% were female. The cohort was racially/ethnically diverse with 73.6% White, 11.3% Black, 4.6% Asian, and 10.5% Other and 10.5% Hispanic/Latino. Most of the patients enrolled had breast cancer (91%) and 67 patients (5.1%) reported having a neurological condition. Paclitaxel was administered to 60.2% and docetaxel to 39.8% and 98.5% planned to start treatment with full dose of taxane. Based on clinician assessment with NCI-CTCAE, 87.6% of patients at baseline had Grade 0 peripheral sensory neuropathy, 10.2% Grade 1, 2.0% Grade 2, and 0.2% Grade 3. The mean baseline CIPN-20 sensory subscore (range 0-100, higher number indicating greater severity) was 5.68 (standard deviation 10.41). Using the PRO-CTCAE for severity of numbness and tingling, 75.4% reported no baseline symptoms, 18.2% "mild", 4.8% "moderate", 1.1% "severe", and 0.5% "very severe" symptoms. With respect to interference of numbness and tingling with daily activities, 88.5% reported "not at all", 8.3% "a little bit", 2.0% "somewhat", 0.9% "quite a bit", and 0.3% "very much". **Conclusions:** In this diverse cohort of predominantly breast cancer patients, there was limited evidence of significant pre-existing neuropathy. Clinician assessments of neuropathy may underestimate the symptoms of patients, emphasizing the importance of PROs in evaluating symptoms, particularly when baseline symptom is an exclusion criterion for clinical trials. Influence of decision support persons on breast cancer treatment decisions among Latinas. *First Author: Krystal A Morales, University of Michigan, Ann Arbor, MI*

Background: Prior studies suggest that decision support persons (DSPs) involvement in breast cancer promotes greater deliberation and decision quality. Despite having the highest level of involvement, Latinx DSPs report the lowest satisfaction with their involvement. The reasons for this remain unknown. We examined the treatment decision-making experiences of Latinx DSPs, their influence on treatment deliberation, subjective decision quality (SDQ), and treatment received. **Methods:** Women with newly diagnosed early-stage breast cancer as reported to the Surveillance, Epidemiology, and End Results (SEER) registries of Georgia and Los Angeles County in 2014-2015 were surveyed. Participants identified the DSPs who played a key role in treatment decisions, who were also surveyed. We examined: (1) bivariate associations of DSP characteristics (e.g type, age, race/ethnicity, education, acculturation level) with DSP-reported level of engagement (informed about decisions, involvement (extent and satisfaction), and aware of patient preferences), (2) DSP engagement with patient-reported SDQ and treatment deliberation using multivariable linear regression with standardized scales (3), and treatment received by DSPs preferred treatment. **Results:** 2502 patients (68%) and 1203 eligible DSPs (70%) responded, resulting in 1,173 dyads, 292 where the patient identified as Latina, and 881 as non-Latina. Among Latina dyads, 78%, 17%, and 5% DSPs identified as Latinx, White, and Asian/Black/Other, respectively. Latinx DSPs within Latina/Latinx dyads were younger, had lower educational attainment and acculturation when compared to other dyads. The proportion of married/partnered status was not different across dyads, but the key DSP for the Latina-Latinx dyads was more often a daughter (37%), over a husband/partner (21%), compared to the other dyads. Latinx DSPs reported being more informed (adjusted mean 4.26, p = 0.058) compared to the other dyads, and being more informed was positively associated with higher patient SDQ (adjusted mean difference 0.176, p = 0.034), despite no difference in treatment deliberation. Overall, Latinx DSP had a higher preference for mastectomy, especially with reconstruction when compared to non-Latinx (40% vs 28%). Overall, 27% of Latinas (vs 13% non-Latina) underwent lumpectomy despite their DSP's preference for mastectomy. **Conclusions:** These findings reveal that the key DSP for many married Latinas is often a daughter over spouse/partner. Our results suggest that including daughter/DSPs in treatment decisions and tailoring strategies to meet their information needs may positively impact Latina SDQ. Potential areas of improvement include surgical options preferences, where notable discrepancy was seen between Latinas and non-Latinas. Awareness of these differences can minimize treatment regret, improve decision quality, and ultimately outcomes in Latinas. Research Sponsor: National Cancer Institute and American Cancer Society.

Patients with cancer symptom and physical function reporting by caregivers as predictors of adverse clinical outcomes. *First Author: Elad Neeman, Hematology/Oncology Fellowship Program, Kaiser Permanente, San Francisco, CA*

Background: Informal caregivers are essential partners in the delivery of cancer care, and often can accurately identify and report symptoms and physical function of the patients they care for. We assessed whether such reporting by caregivers is predictive of adverse patient outcomes. **Methods:** In this prospective study, adult solid cancer patients on active intravenous systemic therapies and their informal caregivers were recruited from 18 Kaiser Permanente Northern California cancer centers. Using a study mobile app (TOGETHERCare), caregivers completed weekly surveys for 4 weeks, which were based on normalized NIH-PROMIS scores to report patients' physical function and PRO-CTCAE to report patients' symptoms. Patients' adverse clinical outcomes were abstracted from the medical record and included: emergency department (ED) visits or hospitalizations, grade 3-4 adverse events (AEs), and treatment delays, up to 1 month following the 4-week study period, as well as mortality and hospice referrals up to 6 months following the study period. Simple univariate logistic regressions were used to correlate caregiver reports (either at baseline or most proximal preceding an adverse outcome) with mortality and hospice referrals, and quasi-Poisson regressions were used for the other adverse outcome measures. **Results:** Fifty-four patient-caregiver dyads were enrolled, and 52 were included in this analysis. A third of patients had breast cancer and almost 75% had stage 3 or 4 disease. Caregivers predominantly identified as male (61.5%), spouse/partner (76.9%), and non-Hispanic White (63.5%). At least one adverse outcome was experienced by 36.5% of the patients. Caregiver-reported PRO-CTCAE consistently predicted ED/hospitalizations and mortality, and caregiver-reported PROMIS scores predicted hospice referrals (see Table). **Conclusions:** The results suggest that caregiver reporting of patients' symptoms and physical function could help provide early predictions of adverse patient outcomes. Financial stress and burden among caregivers of cancer survivors in the United States. *First Author: Nicholas Theodoropoulos, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: United States caregivers perform annual services equating to nearly $500 billion, with three-quarters of family caregivers utilizing personal funds. Nearly a third of all caregivers of cancer survivors report using all or most of their savings to contribute to the cost of cancer care. Prior studies indicate the duration of caregiving is associated with an increase in caregiving burden. This study aims to further describe the financial stress and burden in relation to caregiving duration for people who provide care to cancer survivors. **Methods:** A retrospective cross-sectional study was conducted using the 2015 and 2020 National Alliance for Caregiving and American Association of Retired Persons survey data. Multivariable logistic regressions were used to examine differences in reporting financial stress between various racial/ethnic groups while adjusting for education, income, and employment. **Results:** A total of 2,998 caregivers were included, where 208 of them were caring for cancer patients. Caregivers of cancer patients who provided care > 21 hours/week were statistically more likely to be less educated, lower income, single, and unemployed compared to those who provided < 21 hours/week. Caregiving for > 21 hours/week compared to < 21 hours/week is associated with being more likely to report communicating with healthcare professionals about a recipient's care (87.7% vs. 75.9%; p = 0.038). It is borderline significant that caregivers who provided care for > 21 hours/week were more likely to advocate for recipients (68.7% vs. 56.8%; p = 0.086) and monitor condition severity to adjust care needs (84.9% vs. 70.7%; p = 0.100). After controlling for confounders (education, income, and employment), Non-Hispanic Black (odds ratio (OR) = 1.30; 95% CI: 1.02-1.65), Hispanic (OR = 1.39; 95% CI: 1.02-1.89), and Asian (OR = 1.51; 95% CI: 1.02-2.24) cancer caregivers had increased odds of reporting increased financial stress compared to Non-Hispanic White caregivers. **Conclusions:** Longer duration of caregiving to cancer survivors is associated with a greater burden for caregivers. Financial stress disparities related to caregiving exist between racial/ethnic groups, with non-white caregivers being more likely to report increased financial strain. Special financial programs are needed to assist caregivers of cancer survivors, a growing but understudied population. Research Sponsor: None.

Medical assistance in dying (MAiD) in patients with cancer. *First Author: Sara Moore, The Ottawa Hospital Cancer Centre, Ottawa, ON, Canada*

Background: Medical assistance in dying (MAiD) was legalized in Canada in 2016. Cancer accounts for 60-70% of MAiD cases, though little is known about the demographic profile, cancer diagnoses, and treatments received in patients with cancer who pursue MAiD. We reviewed all patients with cancer who underwent MAiD through a large regional MAiD program, in order to better understand this population and identify gaps in the current system of care delivery. **Methods:** All patients with cancer who received MAiD through the Champlain Regional MAiD Network (CRMN) from June 1 2016 – November 30 2020 were reviewed. The CRMN provides the majority of MAiD services covering a population of 1.3 million in Eastern Ontario. Baseline demographic factors, diagnostic information, and treatment details were collected by retrospective review. The primary endpoint was the proportion of patients with an oncology consultation prior to MAiD. **Results:** During the study period, 255 patients with cancer underwent MAiD. Baseline characteristics included: median age at death 71 (range 31-100), 51% male, 56% married/common-law. The most prevalent solid tumors were gastrointestinal [GI] (n = 77, 30%), lung (n = 47, 18%), and genitourinary [GU] (n = 35, 14%). Most patients (n = 201, 79%) had metastatic disease at the time of MAiD. Of those without metastatic disease at time of death, common tumor sites included central nervous system (42%) and head and neck (23%). The majority of patients (n = 229, 89%) had seen an oncology specialist prior to MAiD; 226 (88%) had seen a systemic oncologist (medical, hematologic, or gynecologic oncologist), and 189 (69%) a radiation oncologist. Seventy-three percent of patients were followed by a systemic oncologist within 90 days of MAiD, and 44% within 30 days of MAiD. At least one line of systemic therapy was received by 159 (62%) patients, 138 (54%) received radiotherapy, and 61 (24%) best supportive care alone. Median time from last systemic therapy to MAiD was 85 days, and from last radiation therapy to MAiD was 137 days. Palliative care assessed at least 213 patients (84% [8% unknown]). Common reasons for pursuing MAiD included disease-related symptoms (33%), fear of future suffering or disability (19%), and ability to control the time and manner of death (17%). Among 26 patients who had not seen an oncologist, median age was 84 (range 61-100), 77% male, 42% GI primary / 19% GU / 15% lung. Most had seen a palliative care specialist (n = 23, 88%), and in the remaining 3 patients palliative care involvement was unknown. **Conclusions:** MAiD is a relatively new option for patients with cancer in Canada. The vast majority of patients with cancer who pursue MAiD are diagnosed with advanced/incurable disease, and most have met with an oncology specialist. As cancer treatments become more effective and more tolerable, collaboration between oncologists and MAiD providers is required to ensure patients are well informed of treatment options prior to MAiD. Research Sponsor: None.

Prognostic impact of systemic anti-cancer therapy on patients with advanced cancer at end of life: Analysis of a multicenter prospective cohort study using propensity score methods. *First Author: Shuji Hiramoto, Peace Home Care Clinic, Otsu, Japan*

Background: Prognosis is said to worsen when systemic anti-cancer therapy (SACT) is administered until a patient's end of life (EOL) and professional palliative care is delayed. However, the prognostic impact of SACT at EOL is unclear. **Methods:** In this preplanned secondary analysis of a multicenter, prospective East Asian cross-cultural collaborative cohort study, consecutive patients with advanced cancer admitted to palliative care units between January and December 2017 were divided into four groups: patients who had and had not received SACT (SACT vs. non-SACT) and patients whose last administration of SACT was before or within 1 month of study enrolment (non-1M SACT vs. 1M SACT). The primary endpoint was difference in survival time from a palliative performance scale (PPS) of < 20 to death between the SACT and non-SACT groups, and the 1M SACT and non-1M SACT groups. The analysis was adjusted for age; sex; primary cancer site; metastatic site; comorbidity (Charlson comorbidity index); and history of radiotherapy, smoking, and psychiatric disorders. Weighting for inverse probability of treatment was applied. A secondary endpoint was to identify EOL symptom and care factors prognostic for survival time using a Cox proportional hazards model. **Results:** The 1396 study patients (712 men, 684 women; median age: 73 years) came from 21 institutions throughout Japan. Primary tumor sites were upper gastrointestinal (471 patients), lower gastrointestinal (193 patients), lung (241 patients), breast (93 patients), urologic (101 patients), gynecologic (82 patients), head and neck (56 patients), central nervous system (25 patients), and hematologic (39 patients). Metastatic sites were liver (554 patients), lung (522 patients), bone (373 patients), and brain (199 patients). The SACT, non-SACT, 1M SACT, and non-1M SACT groups consisted of 853, 539, 126, and 1270 patients, respectively. Survival time was significantly shorter in the SACT group (6.83 days, p = 0.03) than in the non-SACT group (9.01 days). No significant difference between the 1M SACT group (7.57 days) and the non-1M SACT group (7.36 days) was evident. Prognostic factors were use of opioids (HR 1.289), antipsychotics (HR 0.787), and anxiolytics (HR 0.867); infusion of more than 1 L daily (HR 0.727); and apnea (HR 0.874), dyspnea (HR 1.874), nausea (HR 0.612), fatigue (HR 1.284), and ascites (HR 1.236). **Conclusions:** Prognosis was shorter for patients with a history of SACT than for those without a history of SACT at EOL. However, SACT at EOL was not a prognostic factor. This information is useful in advance care planning for selecting and explaining treatment at EOL to patients and their families. Research Sponsor: Hospice Palliative Care Japan.

The impact of primary palliative care on advance care planning in advanced cancer. *First Author: Michael Cohen, UPMC Cancer Center - Magee-Womens Hospital, Pittsburgh, PA*

Background: Palliative care specialists are experts in conducting advance care planning (ACP), but are a limited resource. We sought to determine the impact of a nurse-led primary palliative care intervention on ACP completion among patients with advanced cancer. **Methods:** We performed a secondary analysis of a cluster randomized controlled trial looking at the impact of nurse-based primary palliative care at community cancer centers. In the parent trial, patients with advanced cancer received either monthly primary palliative care visits with trained nurses within their cancer center or usual care. Nurses in the intervention arm received special training in addressing symptom management and ACP. ACP uptake was assessed at enrollment and 3 months later via validated questionnaire in the forms of an end-of-life conversation (EOLC) with one's oncologist or completion of an advance directive (AD). The present analyses were restricted to patients without ACP at baseline. Multivariable logistic regression tested differences in ACP uptake by treatment arm when adjusting for age, religious importance, education, time with current oncologist, and ECOG. **Results:** Of 672 patients enrolled, 182/336 in the intervention arm and 196/336 in usual care lacked an EOLC at baseline and completed three-month assessments. Of those, 82/182 (45.1%) in the intervention arm and 29/196 (14.8%) in the usual care arm reported having an EOLC at three months (Table). Similarly, 111/336 in the intervention arm and 105/336 in usual care lacked an AD at baseline and completed the three-month assessments. Of those, 48/111 (43.2%) in the intervention arm and 19/105 (18.1%) in usual care completed an AD over the study period (Table). For both types of ACP, the treatment effect suggested increased uptake of new ACP in the intervention arm after controlling for variables known to be associated with ACP (Table) **Conclusions:** Nurse-led primary palliative care increased the uptake of ACP among patients with advanced cancer. Training oncology nurses embedded within community cancer centers may represent a feasible mechanism to improve access to primary palliative care and uptake of advance care planning. Clinical trial information: NCT02712229. Research Sponsor: U.S. National Institutes of Health, Other Government Agency.

Odds of ACP with an oncology nurse-led primary palliative care intervention.

EOL Conversation	Odds Ratio	95% CI	P-Value
Unadjusted	4.72	(2.89, 7.71)	<0.001
Adjusted	5.28	(3.10, 8.97)	<0.001
Advance Directive			
Unadjusted	3.45	(1.85, 6.43)	<0.001
Adjusted	3.68	(1.89, 7.16)	<0.001

Adjusted for age, religious importance, education, time with current oncologist, and ECOG.

Quality of end-of-life care for patients with multiple myeloma: A 12-year analysis of a population-based cohort. *First Author: Ghulam Rehman Mohyuddin, University of Utah, Salt Lake City, UT*

Background: Despite treatment advances, multiple myeloma (MM) remains a significant source of morbidity and mortality. The end of life for patients with MM has not previously been examined within the context of a population-based cohort in a publicly funded health system. **Methods:** We retrospectively analyzed patients with death attributable to MM between 2006-2018 using ICES linked databases in the public health care system in Ontario, Canada. Aggressive care was defined as two or more emergency department visits in the last 30 days before death, at least two new hospitalizations within 30 days of death, or an ICU admission within 30 days of death. Supportive care was defined as physician house call 2 weeks before death, or a palliative nursing or personal support visit at home in last 30 days before death. Multivariable logistic regression models were used to assess for factors predisposing to aggressive or supportive care. Patients were stratified based on receipt of autologous stem cell transplant (ASCT). **Results:** In total, 5095 patients were included (Table). Overall, 23.2% of patients received chemotherapy in last two weeks of life and 55.6% of patients died in the hospital. Most patients were admitted to hospital within the last 30 days of life (73.4%:ASCT cohort, 61.4%:non-ASCT cohort). A minority received aggressive care at end of life (28.3%:ASCT cohort, 20.4%:non-ASCT cohort), and a majority received supportive care at end of life (65.4%:ASCT cohort, 61.5%:non-ASCT cohort). Multivariate regression models showed that patients ≥ 80 years (compared to 60-69) were less likely to receive aggressive care (OR=0.54, 95% CI=0.42-0.68), and those with residence in smaller size community of < 10,000 were more likely to receive aggressive care (OR=1.89, 95% CI=1.5-2.4). Supportive care was significantly less likely to be received by patients (OR=0.72, 95% CI= 0.59 to 0.88) and more likely to be received by patients aged 18-49 (OR=1.9, 95% CI=1.2-3.1). Neighbourhoods with lowest income quintiles (OR=0.65, 95% CI=0.53-0.78) were less likely to receive supportive care. When trended over time, patients receiving supportive care at end of life increased (56.0% in 2006 to 70.3% in 2018). **Conclusions:** We demonstrate that despite improvements over time, a substantial number of patients with MM experience aggressive care and hospitalizations at the end of life. Despite this being a publicly funded system, disparities in end-of-life care based on age, income and area of residence are present. Research Sponsor: Canadian Cancer Society Research Institute via the Canadian Centre for Applied Research in Cancer Control (grant No. 2015-703549).

Death with dignity utilization among patients with thoracic, head, and neck cancer. *First Author: Natalie F. Uy, University of Washington, Seattle, WA*

Background: Death with Dignity (DWD) legislation, which took effect in 2009 in Washington state, allows terminally ill patients (pts) to self-administer physician-prescribed, life-ending medication. Thoracic, head and neck cancer (THN) pts are among the top cancer types requesting DWD; however, data describing this group are limited. **Methods:** This retrospective chart review, conducted at Seattle Cancer Care Alliance/University of Washington and Fred Hutch, collected demographics, disease, treatment, support services and steps of the DWD process. We tested the association between disease characteristics of interest and DWD completion using Fisher's Exact test. **Results:** Between Jan 2014 and October 2020, 498 pts inquired about DWD, and 108 (22%) were THN pts. Among THN pts, 51 (47%) only initiated the DWD request process, 35 (33%) only completed the DWD request process, and 22 (20%) completed the DWD request and self-administered the medication. Pts were white (n=90, 83%), male (n=64, 59%), primarily English speaking (n=103, 95%), nonreligious (n=69, 64%), single/divorced/non-partnered (n=55, 51%), and insured (n=103, 95%). Median age at request was 68 years (range 35-88). The table details THN DWD utilization. At time of DWD request, the median time from diagnosis was 14 months (range=0.2-242.7), and 62 (57%) had received ≥2 lines of therapy. Among 78 (72%) pts who received systemic therapy, 51 (65%) were ≥30 days from last therapy to time of death. Within 30 days prior to DWD request, 30 (28%), 25 (23%), and 7 (7%) pts saw social work, palliative care, and spiritual health respectively, and 35 (32%) were hospice-enrolled. Stage IV at diagnosis had higher rates of DWD medication use (p=0.05). There was no significant correlation between DWD medication use and primary site, ECOG score at request, insurance type, mental health diagnosis, use of depression/anxiety or pain medications, or hospice enrollment during DWD process. **Conclusions:** THN pts requesting DWD were predominantly white, nonreligious, insured males. Pts with advanced stage at diagnosis were more likely to use DWD medication. There was a higher proportion of DWD medication use with poorer performance status, and no association between use of depression/anxiety, pain medications, or utilization of supportive care services and DWD medication usage. Future research should investigate DWD utilization among THN pts in multiple centers and states to evaluate these patterns. Research Sponsor: This research was supported by Biostatistics, shared resource of the Fred Hutch/University of Washington Cancer Consortium (P30 CA015704).

Cancer doesn't know what day of the week it is: Temporal trends in day of death, 2000-2017. *First Author: Kanan Shah, NYU Grossman School of Medicine, New York, NY*

Background: Improving end-of-life care is an opportunity to reduce trauma for both patients and caregivers. Studies support the existence of a psychosomatic phenomenon known as the "holiday effect," allowing critically ill patients to enter a bargaining phase and postpone death until a given event. We hypothesized that there may be a temporal trend as patients with cancer attempt to delay death until the arrival of family on weekends or the passage of a holiday. **Methods:** All deaths due to malignant neoplasms (ICD C00-C97) from 2000-2017 were collected from the National Center for Health Statistics. Outcomes were the days of week and months of year that death occurred. Weekend mortality was defined as death on Friday, Saturday, or Sunday. Holiday mortality was defined as death in December or January. Chi-squared tests were performed to determine differences in deaths by day or month. Logistic regression examined associations between day or month of death and age, education, race/ethnicity, location of death, marital status, race, and sex. Statistical analyses were performed using SAS statistical software, version 9.4 (SAS Institute Inc). **Results:** 10,305,990 deaths due to cancer were recorded from 2000-2017. Deaths were not uniform across day of week or month of year ($p < 0.001$ each). Each year, rates of death increased progressively from Monday to Thursday, peaked on Friday and Saturday, and declined on Sunday. There was a relative 3.4% difference in death rate between the peak on Friday and nadir of deaths on Monday. Each year there was a consistent increase in deaths in December and January, with a nadir in February with a relative difference of 10.2%. Multivariate logistic regression assessed associations in weekend and holiday cancer death. Non-hospital death (home, nursing facility, hospice) was more likely to occur on the weekend (aOR from 1.03-1.05, $p \leq 0.01$ for all). Hispanic patients (aOR 1.01, $p = 0.001$) were more likely to die on weekends. Females (aOR 0.99, $p = 0.02$), those who were divorced (aOR 0.99, $p = 0.04$) and those with pancreatic cancer (aOR 0.99, $p = 0.01$) were less likely to die on weekends. Non-hospital death was less likely to occur on Holiday months (aOR from 0.95-0.96, $p \leq 0.01$ for all). Those > 75 were more likely to pass away in Holiday months compared to younger age groups (OR 1.02-1.03, $p < 0.05$ for both). Cancer type was associated with holiday mortality; those with breast or prostate cancer were more likely to pass away (OR 1.01, $p < 0.05$ for both) during the holidays compared to those with lung cancer. **Conclusions:** There is a human element to death. The unequal distributions of deaths due to cancer in this study are small but significant; they suggest a non-biological variation that precludes cancer mortality from being strictly date agnostic. Temporal trends in cancer death highlight an opportunity to improve end of life care and demonstrate how care should shift focus to what matters to patients including time with family. Geographic disparities in breast cancer mortality and place of death in the United States from 2003 to 2019. *First Author: Kelli Clemons, Medical College of Georgia, Augusta, GA*

Background: Breast cancer is the 2nd leading cause of cancer-related death in women with existing barriers in preventive services, access to treatment, and end-of-life care. There are unique sociopolitical challenges to rural healthcare with gaps in national health funding and hospice infrastructure. We investigated rural-urban disparities in age-adjusted mortality rates (AAMRs) and place of death in individuals dying from breast cancer. **Methods:** CDC WONDER database was utilized to analyze deaths from breast cancer from 2003 to 2019 using population classification per 2013 US Census: large metropolitan (≥1 million), small- or medium-sized metropolitan (50,000-999,999), and rural areas (< 50,000). We extracted AAMRs by geographic area, age, and race/ethnicity. We estimated annual percentage changes (APC) in AAMR using robust linear regression models of the log-scale AAMR, including population size as weights, and assessed differential changes over time by geographic area with interaction tests. We estimated the percent of all deaths occurring in medical, hospice, and nursing facilities, and home. Odds ratios (OR) for the association between each place of death and individual-level characteristics were calculated using logistic regression, adjusting for year of death. Differential changes in place of death over time by geographic region were assessed with interaction tests. **Results:** From 2003 to 2019, there were 676,532 breast cancer-related deaths (52.9% large metro, medium/small metro 30.3%, rural 16.8%). Total AAMR declined from 39.8 to 30.9 during this period with rural areas noting least improvement (APC -1.24, 95% CI [-1.39, -1.09], $p < 0.001$ for time trend) compared to large metropolitan (APC -1.74, 95% CI [-1.63, -1.46]). Non-Hispanic Black women had higher AAMRs among all racial/ethnic groups. Across all years, women in large metropolitan (OR 2.02, 95% CI [1.96, 2.07]) and medium/small metropolitan (OR 2.19, 95% CI [2.12, 2.25]) had higher odds of dying in a hospice facility compared to rural areas. Rural women died least often in a hospice facility (9.7% vs 14.5% large metropolitan vs 16.9% medium/small metropolitan in 2019), more often in a nursing facility (19.2% vs 12% large metropolitan vs 13.9% medium/small metropolitan) and slightly more often at home (44.6% vs 41.7% large metropolitan vs 43.4% medium/small metropolitan). Women in large metropolitan areas were most likely to die in a medical facility. **Conclusions:** Rural women with breast cancer experienced greater mortality and least annual improvement, with notable disparities in place of death. Our findings support interventions to improve access across cancer care continuum and congressional policy to urgently re-invest in cancer care access in rural areas. Research Sponsor: None.

Sociodemographic factors associated with end-of-life palliative care utilization in female breast cancer: A national inpatient database analysis. *First Author: Tien-Chan Hsieh, Danbury Hospital, Danbury, CT*

Background: Palliative care (PC) has been shown to improve end-of-life quality in cancer patients. Nevertheless, several studies suggest that PC utilization is associated with socioeconomic factors. Patients with breast cancer, the most common neoplasm in women in the U.S., has lower PC utilization than those with other malignancies. We aim to investigate any sociodemographic barriers that are associated with the inpatient PC utilization in female breast cancer in the U.S. at the end of life. **Methods:** We used the National Inpatient Sample database of Healthcare Cost and Utilization Project, an all-payer inpatient care database in the United States, with data years 2014-2019. The end-of-life case was defined as hospitalized at least three days and passed away. We included all adult women (age at least 18 years old and female gender in electronic health records). The breast cancer cases were identified with International Classification of Diseases (ICD) 9th or 10th edition within the top three diagnoses. PC consultation could be identified with the ICD procedure code. Comorbidities were controlled with Charlson Comorbidity Index. After univariable analysis, the factors that were statistically associated with PC utilization would subsequently be added to the multivariable logistic regression model. **Results:** Between the year 2014 to 2019, we identified a total of 2,226 adult female patients who had breast cancer as their top three diagnoses and were hospitalized at least three days before death. 217 (9.7%) cases were 40-49 years old; 441 (19.8%) cases were 50-59 years old; and 1,455 (65.4%) patients were at least age 60 or above. The top three racial groups were Caucasian 1,420 (63.8%), African American 418 (18.8%), and Hispanic 166 (7.5%). 1,267 (56.9%) of all the cases had PC consult. African American (adjusted odds ratio [aOR]: 0.75; $p < 0.005$) and Hispanic (aOR: 0.62; $p < 0.05$) were significantly associated with less PC utilization than the Caucasian reference group in multivariable regression model. Lower PC prevalence was also observed at rural hospitals and Midwest region. Higher income group and private insurance no longer showed statistically significant higher PC utilization after adjusted for other variables. **Conclusions:** In end-of-life hospitalization with breast cancer as primary diagnosis, racial and hospital resource factors were significantly associated with the PC utilization. Cultural difference could be associated with the lower PC prevalence since adjusting income and insurance types could not explain the disparities in PC utilization among different racial groups. Future study should investigate and address the disparities of PC utilization in female terminal breast cancer. Research Sponsor: None.

Comparative study of two cohorts of older adults with advanced cancer treated before and after implementation of a geriatric oncology service. *First Author: Tomohiro F. Nishijima, Geriatric Oncology Service/Medical Oncology, NHO (National Hospital Organization) Kyushu Cancer Center, Fukuoka, Japan*

Background: A comprehensive geriatric assessment (CGA) has been recommended by guidelines for older adults with cancer for whom chemotherapy is considered. As a quality assessment effort, we examined the effect of CGA conducted by a geriatric oncology service (GOS) in routine practice on clinical outcomes. **Methods:** This was a comparative study of two cohorts of consecutive patients aged ≥ 70 years with unresectable, locally advanced or metastatic cancer who were referred to medical oncology for first-line chemotherapy before (September 2015-August 2018) and after (September 2018-March 2021) the establishment of a GOS at a single institution in Japan. When the treating physician requested a consultation, the GOS conducted a CGA and provided recommendations for the oncologic treatment plan and geriatric interventions. We compared time to treatment failure (TTF) rates at 30, 60 and 90 days as well as 6-month overall survival (OS) rates between the two cohorts adjusting for potential confounders. TTF was defined as the time from start of first-line chemotherapy to discontinuation of first-line chemotherapy for any reason. **Results:** The study population consisted of 342 patients. Median age was 75 years (range: 70-95 years) and 85% had gastrointestinal tract cancer including gastroesophageal (43%) and colorectal (41%). Baseline characteristics of the patients treated before (n = 151) and after (n = 191) GOS implementation were similar with regard to age, sex, cancer type, and performance status. In the after GOS cohort, 82 patients (43%) received CGA before the treatment decision and oncologic treatment plans were changed after consultation in 49 patients (60%). For the majority of these patients, the treatment plan was adjusted to a less intensive option. Two hundred and eighty-two patients received chemotherapy (n = 128 before, n = 154 after GOS cohort) and 60 patients were treated with best supportive care only (n = 23 before, n = 37 after GOS cohort). More patients in the after GOS cohort were treated with reduced-intensity chemotherapy compared with those in the before GOS cohort (55% vs. 39%, P = 0.007). TTF event rates at 30 days (5.7% after vs. 14% before, P = 0.02), 60 days (13% after vs. 29% before, P = 0.001) and 90 days (26% after vs. 36% before, P = 0.06) were lower in the after GOS cohort compared to the before GOS cohort. Among patients receiving chemotherapy, significantly more patients were alive at 6 months in the after GOS cohort compared to the before GOS cohort (84% vs. 72%, P = 0.01). In all patients receiving CGA (n = 94), 219 interventions to address health problems were recommended and 97 interventions were conducted with an overall implementation rate of 44%. **Conclusions:** In this before-and-after quality assessment study, implementation of the GOS was associated with improved TTF and OS in older adults with advanced cancer receiving first-line chemotherapy. The impact of diabetes on the performance of skeletal muscle density (SMD) in screening for frailty: Findings from the Cancer and Aging Resilience Evaluation (CARE) Registry. *First Author: Sydney T Thai, Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: SMD is a marker of myosteatosis that can be obtained from routine computed tomography (CT) imaging and could be used to screen patients for further frailty evaluation. But diabetes (DM) is linked with myosteatosis in men and SMD utility for patients with DM is unknown. We assessed SMD performance as a frailty screening tool in older adults with primarily gastrointestinal cancer and compared performance in patients stratified by sex and DM. **Methods:** We analyzed CARE Registry patients at baseline, a sample with mostly late-stage, gastrointestinal malignancies. Frailty and DM were captured in the CARE tool, a patient-reported geriatric assessment. SMD was calculated from CT scans at L3 vertebrae. Analyses were run for each sex and by DM status. We used linear regression to assess crude associations of SMD and frailty score. SMD performance in classifying frail status (vs. non-frail) was analyzed with 1) area under the receiver operating characteristic curves (AUC) and confidence intervals (CIs); and 2) sensitivity and specificity for sex-specific SMD quartile cut-offs (Q1, median, Q3). Cut-off performance was compared between patients with DM vs. without using differences in sensitivity and specificity and CIs. CIs were estimated with 2,000 bootstrap replicates. **Results:** The analytic sample (N=874; 27% DM, 32% frail) was 39% female with median age 68 years. For each sex-DM subset, regression results had negative slopes indicating that low SMD was associated with higher frailty score. AUCs for women with and without DM were 0.57 (95% CI 0.45-0.69) and 0.62 (0.54-0.70). AUCs for men with and without DM were 0.68 (0.59-0.77) and 0.58 (0.52-0.65). Sex-stratified sensitivity and specificity results are below. Median cut-offs had both sensitivity and specificity >0.50; Q3 cut-offs had higher sensitivity but low specificity. **Conclusions:** SMD could be used to pre-screen older adults with and without DM for further clinical frailty assessment. With high-sensitivity cut-offs (Q3), 13% to 26% of frail patients could be missed. Compared to other groups, SMD pre-screening for men with DM may miss the fewest frail patients but would produce many false-positives. Research Sponsor: None.

Sex	SMD cut-off point, Houndsfield Units	Sensitivity [DM vs. No DM difference, 95% CI]	Specificity [DM vs. No DM difference, 95% CI]

Modified CARG score using data from the electronic health record to predict chemotherapy toxicity in older adults. *First Author: Jasmine L Martin, Geisinger Health Systems, Danville, PA*

Background: Older adults starting chemotherapy are at greater risk of toxicity compared with younger patients. Additional tools are needed to aid in management decisions for this population. The Cancer and Aging Research Group (CARG) chemotherapy toxicity calculator is one such tool, which stratifies older adults into high, intermediate, or low risk for chemotherapy toxicity (Hurria, A., Mohile, S., Tew, W. P., & et al. (2016). Validation of a prediction tool for chemotherapy toxicity in older adults with cancer. *Journal of Clinical Oncology*, *34*(20), 2366–2371. https://doi.org/10.1200/jco.2015.65.4327). This tool relies on a face-to-face encounter to ask questions, e.g. "How is your hearing?" or "Can you take your own medicines?" in addition to lab values such as hemoglobin and creatinine clearance. We modified the CARG chemo toxicity calculator to include data points which could be pulled from the electronic health record (EHR) without the need for a face-to-face encounter to assess for an association with emergency department (ED) visits and hospital admissions. **Methods:** Retrospective data analysis was conducted using the EHR of patients over age 65 diagnosed with a solid tumor from 1/1/2019 to 12/31/2020 who started chemotherapy. A modified CARG score was calculated using age, cancer type, number of drugs, hemoglobin, creatinine clearance, and falls within the past 6 months. The remaining items needed to calculate the complete CARG score were excluded since they were not accessible in the EHR. We assessed ED visits leading to admission, ED visits leading to discharge, direct admissions, and the total of all 3 visit types for all patients. **Results:** A modified CARG score was calculated for 763 patients. Multiple models were evaluated and negative binomial distribution was found to be the best fitted for our data. For every one unit increase in our calculated score the number of ED visits which lead to hospital admission increased by 6% (p-value = 0.0156). Additionally, there was a 5% increase in combined ED visits, ED visits leading to admission, and direct admissions for every one unit increase in risk score (p-value = 0.0063). ED visits that did not lead to admission were found not to have an association with the risk score (p-value= 0.1263). (Table) **Conclusions:** A modified CARG score using data obtained from patients' EHR had a statistically significant association with increased ER visits that resulted in hospital admission and with the total of ED visits leading to admission, ED visits leading to discharge, direct admissions. Using these outcomes as a surrogate for toxicity, we deduce that a simple tool could be used to predict chemotherapy toxicity in older adults. Research Sponsor: Geisinger Cancer Institute.

Outcomes	Incidence Rate Ratio for Risk Score (95% CI)	p value
ER Visits	1.04 (0.99, 1.10)	0.1263
ER Visits that Lead to Admission	1.06 (1.01, 1.11)	0.0156
Direct Admissions	1.05 (0.99, 1.12)	0.0899
Total Visits	1.05 (1.01, 1.09)	0.0063

Improved overall survival of metastatic cancers in the United States across all age groups in the immunotherapy era: Implications for considering elderly patients (age ≥ 75) for immune checkpoint inhibitors (ICIs). *First Author: Yu-Wei Chen, Vanderbilt Ingram Cancer Center, Nashville, TN*

Background: ICIs have changed the treatment paradigm in many cancer histologies. Population-level data regarding the impact of ICIs on the contemporary US cancer patients is scarce. In addition, elderly patients were underrepresented in the landmark trials. **Methods:** Metastatic cancers (melanoma, lung cancer, kidney cancer, head and neck cancer, Hodgkin's lymphoma, and urothelial cancer) diagnosed between 2004-2018 were identified in the Surveillance, Epidemiology, and End Results (SEER) database. The year of the first FDA approved ICI in each cancer site was considered the commencement of the ICI era. The impact of metastatic cancers diagnosed in the ICI era was assessed in each age group (<65, 65-75, and ≥75) using multivariable Cox regression after adjustment for age, sex, race, household income and residence status (metropolitan vs non-metropolitan) **Results:** There were 363,191 patients with metastatic cancers included in the analysis [lung cancer: 68%, head and neck cancer: 14%, Hodgkin Lymphoma: 7%, kidney cancer: 7%, urothelial cancer: 3%, and melanoma: 2%): 60% were male and 73% were non-Hispanic White. The median age was 66 (interquartile range: 57-75). After baseline adjustments for sociodemographic factors, metastatic cancers diagnosed in the ICI era had improved overall survival except urothelial cancer (Table). Results of overall survival and cancer-specific survival were consistent across all age groups (<65, 65-75, and ≥75). Among patients with age ≥75, metastatic cancers diagnosed in the ICI era had improved overall survival in melanoma (AHR: 0.81, p-value<.0001), lung cancer (AHR:0.91, p-value<.0001), kidney cancer (AHR: 0.89, p-value: 0.0004), head and neck cancer (AHR:0.82, p-value<.0001), Hodgkin lymphoma (AHR: 0.75, p-value:0.003) but not in urothelial cancer. **Conclusions:** Metastatic cancers diagnosed in the ICI era had improved overall survival and cancer-specific survival including the subgroup of age ≥ 75. ICIs should not be withheld in elderly patients solely due to chronological age. Research Sponsor: U.S. National Institutes of Health.

The association between ICI era and overall survival in metastatic cancers.

		All-Cause Mortality (AHR, 95%)

Deficit Accumulation Frailty Index (DAFI) scores and acute myeloid leukemia outcomes. *First Author: Catherine Lai, University of Pennsylvania, Philadelphia, PA*

Background: Novel strategies are needed to assess frailty in the context of therapy decisions for older adults with acute myeloid leukemia (AML). Our objectives were to describe pre-treatment DAFI scores for older AML patients treated on clinical trials and explore their relationship with treatment outcomes. **Methods:** We conducted a exploratory analysis utilizing data from two clinical trials of adults aged ≥60 years with newly diagnosed AML (Alliance/CALGB 11001 [intensive therapy] and Alliance/CALGB 11002 [non-intensive therapy]). We included the subset of patients in each trial enrolled on geriatric assessment companion studies (Alliance/CALGB 361006, 361101). A DAFI score was calculated for each patient using 51 variables including demographic, geriatric assessment, and laboratory data derived from the geriatric assessment. Individuals with ≥90% items were included (consistent with other studies); DAFI scores ranged from 0 to 1 and were evaluated using established categories (0- <.2 [robust]; 0.2-<.35 [pre-frail]; 0.35+ [frail]) and as a continuous score. Associations between DAFI scores and toxicity and overall survival (OS) were evaluated with Fisher's exact-testing and Kaplan Meier/cox proportional hazards, respectively. **Results:** The median age was 68 years (range 61, 82) and 72 years (range 61, 92) for those getting intensive (N=31) and less intensive therapy (N= 75), respectively. Individuals in the intensive study had a median pre-treatment DAFI score of 0.15 (range 0.05, 0.31) and were all categorized as robust (75%) or pre-frail (25%). There was no significant difference in median OS (14.6 vs. 14.7 months) or non-hematological grade 3+ adverse events (AEs; 85% vs. 89%) between robust vs. pre-frail individuals in this trial, respectively. However, pre-frail adults experienced a trend towards greater grade 4 non-hematological toxicity than robust individuals (67% vs 26%, p=0.05). In the non-intensive trial, the median DAFI score was 0.24 (range 0.04, 0.48) and most individuals were pre-frail (49.3%) or frail (17.3%). Non-hematologic grade 3+ AEs did not vary by DAFI group, 88% robust, 95% pre-frail, and 77% frail (p=0.15). Median OS was 7.4, 10.8, and 6.3 months for robust, pre-frail, and frail respectively (p=0.17). Adjusting for age, each 0.1 increase in DAFI score was associated with increased mortality hazard (HR 1.8, 95% CI 1.0-3.2). **Conclusions:** DAFI score calculation provides a potential novel strategy for categorization of frailty in AML. In our assessment, higher DAFI scores were associated with toxicity during intensive induction and mortality in the less intensive setting. This method should be studied in larger samples randomized by treatment intensity. Support: UG1CA189823; Bayer Healthcare/Berlex (CALGB 11001); NCT01253070 (CALGB 11001). Clinical trial information: NCT01253070, NCT01420926. Research Sponsor: ALLIANCE studies.

General practitioner contacts, hospitalizations, and nursing home transfers in older patients up to three years after new cancer diagnosis: Results from a large data linkage cohort study. *First Author: Victoria Depoorter, KU Leuven, Leuven, Belgium*

Background: Long-term outcomes after cancer diagnosis in older persons are largely unexplored because of limited follow-up in clinical studies. By linking clinical data with population-based data, studying long-term outcomes in large cohorts becomes feasible. The current study aims to explore long-term outcomes in the care trajectory of older patients with cancer and to assess their association with baseline geriatric screening and assessment (GS/GA) results. **Methods:** A large cohort study of older patients with a new cancer diagnosis was set up by linking clinical, cancer registry and administrative health data based on a unique patient identifier. Clinical data were derived from a previously performed prospective multicentric Belgian study (2009-2015). Patients aged ≥ 70 years were screened with G8 followed by GA in case of an abnormal result (≤14/17). Tumor characteristics and vital status were derived from cancer registry data and long-term outcomes (general practitioner (GP) contacts, hospitalizations and nursing home transfers) from administrative health data. In patients that survived at least 3 months since inclusion, outcomes were assessed from the day after inclusion until 3 years after. Event rates were calculated using person-time at risk to allow for varying follow-up time. Patients were censored 3 months before death to exclude influence of end-of-life care. **Results:** After data linkage, 6,391 older patients with a new cancer diagnosis were available for this analysis. The median age was 77 (range: 70–100) and 59.8% was female. Diagnoses included solid (92.8%) and hematologic malignancies (7.2%). In the patients with a solid tumor, breast, colorectal and lung cancer were the most common and 20.1% of patients had stage IV. 64.3% of patients had an abnormal baseline G8 score. During the 3 year follow-up, 2,602 (40.7%) of the included patients died. In these 3 years, 5,985 (95.2%) patients had at least one contact with a GP and 4,634 (72.5%) had at least one new hospital admission (event rates in Table 1). Of the 3,724 patients living independently at inclusion and still alive after 3 years, 281 (7.5%) had been transferred to a nursing home and of those, 240 (85.4%) patients had an abnormal baseline G8 score. **Conclusions:** Older patients with an abnormal baseline G8 score have more GP contacts, hospital admissions and nursing home transfers in the 3 years following a new cancer diagnosis compared to patients with normal baseline G8 score. Baseline G8 could help identify patients at risk for higher long-term healthcare utilization. Research Sponsor: Kom op tegen Kanker (Stand up to Cancer).

Event rate per person-year for GP contacts and hospitalizations.

	All pts (n = 6,391)	Pts with normal G8 score (> 14/17) (n = 2,281)	Pts with abnormal G8 score (≤ 14/17) (n = 4,110)
GP contacts (n = 101 missing)	10.96	8.95	12.47

Functional decline in older breast cancer survivors treated with and without chemotherapy and non-cancer controls. *First Author: Jingran Ji, City of Hope National Medical Center, Duarte, CA*

Background: Although breast cancer and breast cancer chemotherapy (chemo) have been linked to accelerated functional decline, it is not well understood whether this decline is driven by cancer itself or the combination of cancer and chemo. Here, we compared the change in functional status over time in older breast cancer survivors treated with and without chemo and age-matched women without cancer. **Methods:** Women age ≥65 with non-metastatic breast cancer (n = 538; 441 treated with chemo and 97 without chemo) and n = 100 non-cancer controls were prospectively evaluated at two timepoints: ≤14 days pre-chemo (baseline) and ≤30 days post-chemo (or matched times for non-chemo and non-cancer controls). At each timepoint, functional status was measured using instrumental Activities of Daily Living (iADL) scores. The primary endpoint was the proportion of patients with a decline in functional status (Yes/No, yes defined as ≥2-point decrease [minimal meaningful difference] in iADL scores between timepoints). Baseline demographic, functional, and clinical characteristics were compared between survivors treated with and without chemo and non-cancer controls using *t* and chi-squared tests. Among the 441 women treated with chemo, univariate and multivariable logistic regression analyses were performed to determine baseline risk factors associated with chemo-induced functional decline. **Results:** 10% of older survivors treated with chemo experienced a clinically meaningful decline in function as compared to 3% in the non-chemo and 4% in non-cancer control groups (p = 0.017). Across the 3 groups, there were no differences in median age, race/ethnicity, education, number of comorbidities, or baseline functional status (iADL, ADL, Timed Up and Go [TUG]). Among the 441 older survivors treated with chemo, greater age, higher BMI, more comorbidity, lower ADL score, and longer TUG were significantly associated with functional decline univariately. After multivariable analyses, age ≥78 (26% declined, odds ratio [OR] = 3.67, 95% CI 1.60-8.43) and BMI > 30 (16% declined, OR = 2.11, 95% CI 1.02-4.38) remained significantly associated with functional decline. Patients who were both ≥78 years old and obese (BMI > 30) had the highest odds of developing functional decline post-chemo (41% declined, OR = 8.43, 95% CI 2.48-28.63). **Conclusions:** In this study, older breast cancer survivors treated with chemo had a 3-fold increased incidence of clinically meaningful decline in functional status as compared to age-matched survivors not treated with chemo and those without cancer. Although these findings need to be replicated in larger studies, our results raise the possibility that accelerated functional decline may be driven by cellular damage from cytotoxic chemo. Further research is warranted to understand the impact of cancer and its treatment on older adults' functional status and underlying aging processes. Clinical trial information: NCT01472094. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Validation of the Cancer and Aging Research Group (CARG) model to identify risks of chemotherapy toxicities in Asian older adults. *First Author: Jia Li Low, NUH, Singapore, Singapore*

Background: Older adults are at an increased risk of chemotherapy related toxicities. Identification of risk factors can facilitate oncologists in tailoring treatment, potentially mitigate the risk of chemotherapy toxicity and improve social economic outcomes. Tools like the Karnofsky Performance Status (KPS) and Geriatric Assessment (GA) are used in clinical practice to guide treatment decisions for older adults with cancer. The CARG model incorporating the GA and clinical variables was developed and validated to predict for grade 3-5 toxicities, although this has not yet been validated in Asians. **Methods:** Patients ≥70 years old with solid malignancies receiving chemotherapy at the National University Cancer Institute, Singapore were recruited between June 2017 and January 2018. The study aims to verify the application of the CARG model, KPS, GA and oncologists' estimate of toxicity in a multi-ethnic Asian population. The risks of chemotherapy toxicity were calculated using the CARG model (low risk: 0-5, medium risk: 6-9, high risk: ≥10). A GA including a physician rated KPS score (low risk: 90-100, medium risk:80, high risk: ≤70) and a timed up and go (TUG) test (low risk: ≤12s, high risk: > 12s) were performed for all patients. The attending oncologist (blinded to the CARG score) was asked to give an estimated likelihood (low/medium/high) of chemotoxicity. Chemotherapy related toxicities were captured by chart review based on the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE) version 5.0. The area under the receiver operating characteristic (ROC) curve and a univariate analysis of predictors of toxicity were calculated. **Results:** A total of 200 patients were included. Median age was 74 (range: 70-89). The ethnic makeup of the population consisted of Chinese (N = 177; 88.5%), Malay (N = 17; 8.5%), Indians (N = 4; 2%) and other ethnicities. Majority of patients were males (N = 110; 55%), had metastatic disease at diagnosis (N = 114; 57%) and had gastrointestinal cancers (N = 80; 40%). 75% (N = 150) had polychemotherapy and 55% (N = 110) received full dose chemotherapy. More than half of patients (68.5%) experienced G3-5 toxicities, with 65.5% requiring hospitalization. The CARG model predicted 22.5% of patients as low, 50.5% as medium and 27% as high risk of chemotoxicity. The area under ROC for the CARG model was 0.74 (95% CI, 0.67-0.82). A one-point increase in the CARG score was associated with a 15% increase in the odds of G3-5 toxicities. 84.5% of patients needed > 12s for the TUG test. The TUG score, KPS and oncologist's prediction of toxicity was predictive of an increased risk of G3-5 toxicities (p < 0.01). **Conclusions:** This study confirms the validity of the CARG predictive model in Asians and can streamline healthcare delivery in older adults. Development of a more robust predictive model incorporating the KPS and TUG into the CARG model could be considered. Adherence to oral treatments in elderly patients with advanced prostate cancer: The ADHERE study, a prospective trial of the Meet-URO network. *First Author: Pasquale Rescigno, Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Italy*

Background: Novel anti-androgen hormonal therapies (NAHTs) for advanced prostate cancer (PC) are mainly oral with an overall good toxicity profile and offer the convenience of home administration and reduced hospital footfalls. This imposes the burden of self-administration, often unsupervised, on a population of elderly patients overwhelmed by the assumption of many other concomitant medications. Therefore, lack of treatment adherence is becoming an increasingly social and health issue. **Methods:** In a prospective observational cohort study, metastatic castration-resistant PC (mCRPC) patients aged ≥70 years receiving abiraterone (ABI) or enzalutamide (ENZ) were enrolled in six Italian centres of the Meet-Uro network and monitored for their treatment adherence. Monitoring included pill counting, self-assessment questionnaire and clinical diaries at each clinical visit. Non-adherence rates were based on proportions of missed/prescribed pills ratios by pill counting as an overall estimate or the median of individual values. **Results:** Overall, 234 pts were recruited (median age: 78 years [73-82], 86 were treated with ABI and 148 with ENZ; 69% of the pts received NAHT in the pre-chemotherapy setting, while 24% in the post-chemo and 6% had the two treatments consecutively. Pts were monitored for adherence for a median time of seven cycles [IQR:4-12]. The two arms were well balanced for all baseline characteristics, besides steroids use (100% vs 9%, $p < 0.001$), as ABI requires steroids, and Charlson score, whose range was higher for ENZ pts than ABI pts (range 10-12 vs 8-11, $p = 0.028$). Overall, the percentage of non-adherence was higher for ABI than ENZ (5.2 vs 4.2 missed/prescribed pills, $p < 0.001$). After Bonferroni correction, geriatric G8 score correlated with non-adherence ($p = 0.004$, $r = 0.18$). Pts on ENZ tended to report missing pills more frequently than ABI pts, and the reason for non-adherence was forgetfulness (42% vs 17%, $p < 0.001$). A third of pts never completed the clinical diary given at each cycle. Overall survival (OS) within the study was 48.8 months. However, patients on ABI had a longer progression-free survival (PFS) compared to pts treated with ENZ (median PFS 28.4 [24.2-32.5] vs 23.1 [18.2-28.1] months, $p = 0.041$). **Conclusions:** Physicians tend to treat elderly and frailer people with ENZ. mCRPC patients on ENZ are more adherent to treatment, with forgetfulness being a potential barrier. Nevertheless, OS and PFS were consistent with those from ABI and ENZ pre-chemo registration studies, with ABI conferring a longer PFS in our study population. Research Sponsor: None.

Early patient-reported outcomes are a promising predictive factor of cancer progress and outcome in older patients: The *EPROFECY* study. *First Author: Carole Helissey, Clinical Research Unit, Military Hospital Begin, Saint-Mandé, France*

Background: Contrary to commonly-held beliefs, older patients (OPs, aged 70 or more) in oncology are compliant with the use of a telemonitoring digital platform. Such a tool allows the medical team to gain detailed knowledge of the tolerance profile of patients, and help monitor and maintain their quality of life, which is a particularly important goal for older patients. The EPROFECY study assesses the predictive power of the patient health status in the first month of treatment, evaluated with the digital telemonitoring platform Cureety, on survival. **Methods:** This prospective study was conducted at the Military Hospital Bégin on OPs. Patients were allowed to respond to a symptomatology questionnaire based on CTCAE v.5.0, personalized to their pathology and treatment. An algorithm evaluated the patient status based on reported adverse events: correct (A), compromised (B), to be monitored (C) and critical state (D). For A/B (good health status), the patient received therapeutic advice to help manage each of the reported adverse events. For C/D (poor health status), the patient was invited to call the hospital. To assess the early tolerance of patience to their treatments, we determined the health status in the 1st month after initiation of treatment, which was classified as "Good health" (GH, majority of A/B reports) or "Poor health" (PH, majority of C/D reports). The primary endpoint was to assess if the first-month tolerance is a predictive factor of progression free-survival (PFS). The secondary endpoint was to assess if the first-month tolerance is a predictive factor of overall survival (OS). **Results:** Sixty-one patients were enrolled between July 1st, 2020 and September 30th, 2021. The median age was 78.0 years (range 70.0 – 99.0), with 81% presenting a metastatic stage, and the most represented cancer being prostate cancer. The median follow-up was 8.2 months. Overall, 2299 ePRO were completed, 89% (n= 2036) corresponding to a "correct" or a "compromised" state and only 11% (n=263) corresponding to a state "to be monitored" or "critical". Based on the first month of questionnaires, 62% of the patients were classified in the GH group, and 38% in the PH group. The PFS ratio at 6 months was 64.6 % in GH vs 23.4 % in PH (HR = 0.1980, 95% CI = 0.04431–0.8845, p = 0.0339). The OS ratio at 6 months was 100% in GH versus 95.5 % in PH (HR: 0.69, 95 % CI = 0.06 – 8.29, p = 0.77). **Conclusions:** This is the first study that assesses the use of PRO-based tolerance as a predictive factor of treatment response in older individuals. We demonstrated here a significant 80% reduction in the risk of progression in OPs that exhibited a good first-month tolerance. This suggests that e-PRO follow-up might be an effective predictor of response and a tool to treatment plan. Research Sponsor: None.

New strategies for multimodal analgesia in patients with high-risk geriatric cancer in perioperative period. *First Author: Sergey V. Tumanyan, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation*

Background: Perioperative pain (POP) in high-risk geriatric patients with cancer (HRGCP) is an important issue. The purpose of this study was to optimize perioperative analgesia in HRGCP. **Methods:** This randomized study of the quality and effectiveness of perioperative analgesics included 115 HRGCP aged 64-88 years who underwent surgeries on the organs of the chest, abdomen and pelvis for various cancers. The patients were divided into 2 groups. Group 1 (n = 52): patient-controlled analgesia with morphine and nonsteroidal anti-inflammatory drugs (NSAIDs); group 2 (n = 63): ultrasound-guided bilateral transversus abdominis plane (TAP) block with ropivacaine. Intraoperative and perioperative analgesia was maintained with a continuous infusion of lidocaine, magnesium sulphate, microdoses of fentanyl and NSAIDs. Results and pain syndrome were assessed by monitoring the Efficacy Safety Score (ESS), personal and reactive anxiety, stress response (cortisol, insulin, lactate, glucose), rates of functional activity recovery, the need for opioid analgesics, frequency of postoperative nausea and vomiting (PONV). **Results:** Patients in group 2 showed a significant decrease in the perioperative need for opioid analgesics and significantly decreased POP. Analysis of variance of mean values revealed statistically lower scores of ESS, visual analogue scale and POP ($p < 0.05$) during the first 24 hours of perioperative period in group 2 compared with group 1. Patient-controlled analgesia showed analgesic effect in 88.5% ($p < 0.05$) cases. However, the effect was less pronounced, compared to multimodal analgesia, and did not reduce cognitive disorders. In group 2, opioid-sparing analgesic effect was 95.3% ($p < 0.05$). Multimodal analgesia reduced the stress response ($p < 0.05$) in perioperative period and did not cause cognitive dysfunction while reducing PONV episodes, unlike morphine. Despite the minimal doses of narcotic analgesics in group 2, multimodal analgesia provided safe analgesia and functional activity recovery in perioperative period with minimum negative effects of opioids. **Conclusions:** The strategy of multimodal analgesia based on a combination of intraoperative TAP block and infusions of lidocaine and microdoses of fentanyl can significantly improve the quality of analgesia in perioperative period. Locoregional therapy trends by frailty and life expectancy in older adults with T1N0 hormone receptor-positive breast cancer. *First Author: Christina Ahn Minami, Division of Breast Surgery, Department of Surgery, Brigham and Women's Hospital, Breast Oncology Program, Dana Farber/Brigham and Women's Cancer Center, Boston, MA*

Background: Women >70 years old with T1N0 hormone receptor-positive (HR+) breast cancer face complex locoregional therapy decisions, as breast surgery type, and omission of axillary surgery or radiation therapy (RT), do not impact overall survival. Although frailty status and life expectancy (LE) ideally factor into therapy decisions, their impact on decision-making is unclear. We sought to identify trends in, and factors associated with locoregional therapy type by frailty and LE, and to determine if therapy type was associated with cause of death. **Methods:** Women >70 years old with T1N0 HR+/HER2-negative breast cancer diagnosed 2010-2015 were identified in SEER-Medicare. Stratified by validated claims-based frailty (Kim et al) and LE (Tan et al) measures, trends in therapy (lumpectomy, lumpectomy + axillary surgery, lumpectomy + RT, mastectomy, lumpectomy + axillary surgery + RT, and mastectomy + axillary surgery, with the last two combinations deemed "more intense" therapy) were analyzed. Generalized linear mixed models were used to identify factors associated with therapy receipt (breast surgery type, axillary surgery, and RT) and, among the women who died in this cohort, to explore potential associations between local therapy received and cause of death. **Results:** Of the 16,188 women included, 21.8% were frail, 22.2% had a LE<5 years, but only 12.3% were both frail and had a LE<5 years. In frail women who had a LE < 5 years, more intense therapy regimens decreased significantly (lumpectomy + axillary surgery + RT: 27.5% to 17.3%, p<0.001; mastectomy + axillary surgery: 20.8% to 13.9%, p=0.02) over the study period. However, in 2015, 30% of frail women with a LE<5 years still underwent a more intense regimen. On multivariable analysis, frailty and LE<5 years were associated with a lower likelihood of axillary surgery (frailty: OR 0.65, 95% CI [0.57-0.73]; LE<5 years: OR 0.67, 95% CI [0.59-0.76]) and RT (frailty: OR 0.77, 95% CI [0.69-0.86]; LE<5 years: OR 0.73, 95% CI [0.65-0.83]), but not with breast surgery type. Of the 1868 women who died, 306 (16.4%) died of breast cancer and those undergoing more intense therapy were as likely to die of breast cancer vs other causes (Table). **Conclusions:** In older women with T1N0 HR+ disease, rates of more intense therapy are decreasing but 30% of frail women with a limited LE still underwent more intense therapy in the final study year. As therapy intensity does not affect breast cancer-specific mortality, appropriate de-escalation of locoregional therapy is needed. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Predictive factors of toxicity of immune checkpoint inhibitors (ICI) in older patients with lung cancer: The ToxImmune study. *First Author: Carole Helissey, Clinical Research Unit, Military Hospital Begin, Saint-Mandé, France*

Background: Immunotherapy (Im) improved the survival of patients with lung cancer. It may be responsible for adverse events impacting these patients' quality of life. We have few data on the tolerance of older cancer patients (OP) to immunotherapy. The Toximmune study aims to describe the safety of older lung cancer patients to Im and identify clinical, biological and radiological markers that can help to predict immune-related adverse events for OP. **Methods:** All patients aged 60 years and older who had received at least one dose of ICI between June 2015 and December 2020 and diagnosed with lung cancer were included. We collected patients' baseline demographic characteristics, biological blood markers and imaging by PET-scanner. All adverse events (AEs) and immune-related AEs (irAEs) were recorded (CTCAE V.5.0). **Results:** 49 patients were included, median age was 71 (range 61-97). The incidence of grade 2 and grade 3-4 was 34% and 6% respectively. The main irAEs reported were: asthenia in 51% patients after 13.5 months median delay (grade ≥2 in 22%),musculoskeletal disorders in 45% after 21 months median delay (grade ≥2 in 10%), pneumonitis in 37% after 21 months median delay (grade ≥2 in 10%), and colitis in 35% after 21 months median delay (grade ≥2 in 6%). Female sex, primitive tumor SUV max < 5, number of metastases ≥ 3, prior systemic therapy > 1, PLR < 250 were significantly associated with a risk of toxicity in univariate analysis ($p < 0.05$) We developed the ToxImmune score (0, 1, or ≥2) to predict the risk of having a grade ≥2 adverse event by adding the following risk factors: Primitive Tumor SUV < 5 = 1, Number of metastases ≥3 = 1, And L1 = 0 vs > L1 = 1. The incidence of grade ≥2 adverse events was 31%, 35% and 86% with ToxImmune scores 0, 1 and 2 respectively ($p = 0.032$). Median overall survival times (OS) & progression-free survival (PFS) were 21.8 & 21 months, 15.1 & 6.6 months, and 9.8 & 2.1 months for ToxImmune scores 0, 1 and ≥ 2 respectively ($p = 0.06$ & $p = 0.001$). There was significant association between the ToxImmune score and the risk of "progressive disease" at the first assessment of the disease: 16% for score = 0, 48% for score = 1, and 71% for score = 2, ($p = 0.01$). **Conclusions:** The quality of life is our goal for OP care. The ToxImmune score, which is based on objective clinical parameters, identifies OP with a significant higher risk of severe adverse events. Also, this score was significantly associated with patients' PFS risk of developing rapid tumor progression. It could be used in clinical practice to personalize toxicity surveillance in OP treated for lung cancer with immunotherapy. This score will be validated in larger prospective cohorts. Research Sponsor: None.

Geriatric assessment (GA) and the influence on the variability of treatment recommendations for elderly patients (pts) with gastrointestinal (GI) tumors. *First Author: Moritz Buettelmann, Technical University Carl Gustav Carus, Dresden, Germany*

Background: GA is recommended to guide therapy for elderly cancer pts. To assess whether GA results influence the recommended treatment and the inter-oncologist variability of treatment recommendations, we conducted a case-vignette-based study in medical oncologists (MOs). **Methods:** MOs were asked to give medical treatment recommendations for GI cancer pts in three steps: (1) based on tumor findings alone to simulate the guideline recommendation for a "50-year-old standard patient (pat.) without comorbidities", (2) for the same tumor situation in an elderly pat. according to the medical history, comorbidities, lab values and a short video simulating the clinical consultation situation and (3) after in addition the results of a full GA were disclosed (Barthel index, Cumulative Illness Rating Scale, G8, Geriatric Depression Scale, Mini Mental Status Examination, Mini-Nutritional-Assessment [MNA], Time Get Up and Go, EORTC-QLQ30 and stair climb test - each with short interpretation aid). Each MO voted for 2-4 randomly allocated pts out of a pool of 10 pts with mean age 78.5 years. A slider (like a visual analogue scale) was used to express the grade of recommendation for several treatment options per patient. The means and variances for each treatment option were calculated and compared for analysis. **Results:** Seventy German MOs had given 164 treatment recommendations that were substantially different for elderly compared to younger pts. The recommendations had a significantly higher variance for elderly pts than for the "standard" pts ($p < 0.0001$) indicating a lower inter-oncologist agreement regarding the treatment recommendations in elderly pts. MOs with > 6 years working experience as specialist had no lower variance in their recommendations. There was a non-significant trend towards a lower variance if the MOs were based at outpatient units of hospitals (compared to MOs working with in-patients or as private oncologists) and for MOs working at larger hospitals (> 800 beds) compared to those based at smaller ones. The knowledge on the full GA results had marginal influence on the treatment recommendations itself or its variance, only ($p = 0.92$). In the survey, the geriatric tools were rated more than two times higher as being meaningful (53%) and useful (49%) than they were used in clinical practice (19%). The most used tool in the routine care for geriatric pts was the MNA (30%). **Conclusions:** There is a large variability regarding the "optimal" treatment in geriatric pts without meaningful improvement with larger working experience. Although the recommended therapeutic regime varied in elderly pts and the MOs rated the GA results as "useful", the GA results did not influence the individual recommendations or its variance, and GA is rarely used in daily practice indicating that more research on an effective implementation into the clinical practice is needed. Research Sponsor: None.

Factors associated with the evaluation of geriatric assessment (GA) domains by oncology specialists in Mexico. *First Author: Haydee Cristina Verduzco-Aguirre, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, DF, Mexico*

Background: Use of GA by oncology specialists is low in Mexico, with some of the domains of the GA more frequently assessed than others in everyday practice. We aimed to explore factors associated to the evaluation of individual GA domains by Mexican cancer care providers. **Methods:** Secondary analysis of a mixed-methods study which consisted of an online cross-sectional survey of Mexican oncology specialists and follow-up interviews on the use of GA in cancer care. We performed multiple logistic regression analyses with frequency of evaluation of specific GA domains as the dependent variable (dichotomized as never/sometimes vs most of the time/always). Independent variables included age, gender, medical specialty, and practice size of the survey respondent, presence of a geriatrician in main practice site, and perceived confidence in managing common situations in older adults relevant for each GA domain (dichotomized as not at all/mildly vs very/completely). A p-value of < 0.05 was considered significant in each model. **Results:** Of 196 survey respondents, 62% were male, 50% surgical oncologists, 51% took care of > 10 patients per day, and 61.7% had access to a geriatrician at their main practice site. Frequently (most of the time/always) evaluated domains included: comorbidities (94.4%), daily function (72.9%), nutrition (67.3%), cognition (54.1%), depression (42.9%) and falls (42.3%). Self-perceived confidence in managing dementia (OR 2.72; 95% CI 1.42-5.51, $p = 0.008$) and being a surgical oncologist (OR 2.80; 95% CI 1.29-5.72, $p = 0.003$) were associated with increased evaluation of cognition. For nutrition, only self-perceived confidence in nutritional evaluation was associated (OR 3.86; 95% CI 2.0-7.46, $p < 0.001$). For comorbidities, self-perceived confidence in managing osteoporosis (OR 5.61; 95% CI 1.03-30.4, $p = 0.046$). For falls, significant factors included age (OR 1.04; 95% CI 1.01-1.07, $p = 0.004$), practice size (OR 0.46; 95% CI 0.23-0.91, $p = 0.026$), and self-perceived confidence in evaluation and prevention of falls (OR 6.31; 95% CI 3.19-12.46, $p < 0.001$). Age (OR 1.03; 95% CI 1.01-1.06, $p = 0.011$) and self-perceived confidence in managing depression (OR 2.52; 95% CI 1.33-4.78, $p = 0.005$) were associated with evaluation of depression. For daily function, no variables were significantly associated. Follow-up interviews showed quality and appropriateness of evaluations may not be ideal, such as asking only about orientation and level of consciousness when evaluating cognition. **Conclusions:** Self-perceived confidence in evaluating and managing common situations in older adults is associated with the evaluation of GA domains as part of everyday practice among cancer care providers in Mexico. This analysis supports the use of educational interventions to boost knowledge and confidence regarding the proper use of validated GA tools among oncology specialists. Nurse navigator–initiated geriatric assessments in hematology/oncology clinics. *First Author: John L. Shaia, Permanente Medical Group, San Francisco, CA*

Background: As the number of older adults with cancer continues to grow, there is an urgent and unmet need to implement geriatric assessments and toxicity screening tools (G8 and CARG toxicity tool) for patients 65 and older with a cancer diagnosis in real-world settings. Studies of these tools show completion rates of 20-35% when administered by a physician. To determine if nurse navigators could increase completion rates, we implemented a pilot in seven community cancer centers within an integrated health system. **Methods:** A pilot project of G8 and CARG toxicity tool implementation was completed at seven community cancer centers from May 1,2021 to December 31,2021 in patients age ≥ 65 years, with solid or malignant hematologic cancer diagnosis. G8 was administered at seven sites and CARG was assessed in addition to G8 on solid tumor patients undergoing chemotherapy at four of the seven sites. Referrals to nutrition, audiology, physical therapy, psychiatry, and neurology were sent by nurse navigators based on assessment results. **Results:** The total number of eligible patients for G8 was 1372, with 1082 (78.9 %) successfully completing assessment, and the total number of eligible patients for CARG toxicity tool was 563 with 516 (91.6%) successfully completing assessment. The median age of patients completing assessment was 74 years old (range 65-100) and 52% were female. The cohort included Asian / Pacific Islanders (23%), Black (15%), Hispanic White (8%), and Non-Hispanic Whites (51%). Most common cancers included genitourinary cancer (18%), breast cancer (17%), upper GI cancer (15%), and thoracic cancer (13%). The assessments resulted in referrals to multiple services including nutrition (193 referrals), audiology (30), physical therapy (18), psychiatry (5), and neurology (5). **Conclusions:** Nurse navigators can successfully implement G8 and CARG toxicity tool in hematology-oncology clinics in a broad range of cancer types at a high rate with resultant referrals to multiple supportive services in real-world settings. Research Sponsor: None.

Remote geriatric assessment program for older patients starting new chemotherapy treatment in Brazil. *First Author: Cristiane Decat Bergerot, Centro de Cancer de Brasilia, Instituto Unity de Ensino e Pesquisa, Brasilia, Brazil*

Background: Older cancer patients in developing countries face considerable challenges in obtaining access to specialized medical attention, often due to a lack of human resources and healthcare infrastructure. This study sought to explore the benefit of a remote, validated geriatric assessment (GA) program for older patients starting chemotherapy in Brazil. **Methods:** Older adults (65+ years) beginning a new chemotherapy treatment regimen in Brazil were recruited. Through telehealth, patients were assessed with GA before starting chemotherapy treatment for any type of solid cancer and at a follow-up visit (3 months after enrollment). GA results were discussed by a multidisciplinary team (e.g., geriatrician, psychologist, nutritionist) and recommendations were determined. Outcome measures included chemo toxicity scores (CARG, scale 0-19), physical symptoms (FACT-G, scale 0-108) and activities of daily living (IADL, scale 0-5 for men and 0-8 for women, or scale 0-1 for IADL ratio). Descriptive statistics were generated, and paired t-tests were used to evaluate the change in these measures over time. **Results:** A total of 51 older patients from 5 different Brazilian states (Amazonas, Distrito Federal, Espirito Santo, Pernambuco and Rio Grande do Sul) have been enrolled to date. The mean distance from a patients' home to their place of cancer treatment was 21 miles (range: 3-101 miles). Participants had a mean age of 76.5 years (SD = 7.6) and were predominantly female (57%), white (57%), married (61%), and had a high school degree or more (65%). Patients were mostly diagnosed with gastrointestinal (39%) or gynecological (20%) cancers; 55% of patients were diagnosed with a stage IV disease. The majority of patients (80%) were referred to appropriate remote services based on the GA; including geriatricians (41%), nutritionists (39%) and/or psychologist (16%). At the time of abstract submission, data from 34 complete cases were available for longitudinal analysis, in which we observed a decrease in chemo toxicity scores (M_1= 6.65, M_2= 5.88, p = 0.035) and an improvement in FACTG (M_1= 92.94, M_2= 98.53, p < 0.001). The improvement in IADL ratio was not significant (M_1= 0.79, M_2= 0.85, p = 0.069). **Conclusions:** This novel, ongoing study is, to our knowledge, the first to implement a remote GA program in Brazil. Our preliminary findings suggest that a remote GA program, with appropriate referrals to specialists, may increase the reach of supportive services and improve cancer care in developing countries. Association of polypharmacy and potential drug-drug interactions with adverse outcomes in older adults with advanced cancer receiving systemic treatment. *First Author: Mostafa Refaat Mohamed, University of Rochester James Wilmot Cancer Institute, Rochester, NY*

Background: Polypharmacy (PP) is common in older adults starting cancer treatment and associated with increased risk of potential drug-drug interactions (PDI). PP and PDI may affect treatment-related outcomes in older patients. This study evaluates the association of PP and PDI with systemic treatment adverse outcomes in older adults with advanced cancer. **Methods:** This secondary analysis of prospectively collected data from the GAP 70+ Trial (NCT02054741; PI: Mohile) enrolled patients aged 70+ with advanced (i.e. incurable) cancer; had ≥1 geriatric assessment domain impairment; and planned to start a new chemotherapy regimen or another regimen with high risk of toxicity. PP was assessed prior to initiation of treatment and defined as concurrent use of ≥8 medications (meds). PDI among all drugs were reviewed prior to initiation of treatment using Lexi-Interact® Online with category D and X considered "major PDI". Study outcomes were assessed within 3 months of treatment initiation and included: 1) total number of Grade ≥2 toxicities according to National Cancer Institute Common Toxicity Criteria; 2) total number of Grade ≥3 toxicities; and 3) early treatment discontinuation due to toxicity. Multivariable linear and logistic regression models were used to examine the association of PP and PDI with treatment adverse-outcomes adjusted for age, gender, cancer type, comorbidity, physical function, social support, and study arm. **Results:** Among 718 participants, the mean age was 77 (range 70-96); 43% were females; and 57% had lung or gastrointestinal cancers. The median number of meds was 5 (range 0-24); 28% received ≥8 concurrent meds; and 25% had ≥1 major PDI. The mean number of Grade ≥2 toxicities for patients with PP was 9.8 versus 7.7 in patients without PP (adjusted β=1.87, standard error [SE]=0.71, P<0.01). The mean number of Grade ≥3 toxicities for patients with PP was 2.9 versus 2.2 in patients without PP (adjusted β=0.59, SE=0.29, P=0.04). Patients with ≥1 major PDI had 59% higher odds of early treatment discontinuation versus those without major PDI (adjusted odds ratio 1.59, 95% confidence interval=1.03-2.46, P=0.03). There was no significant association between PP and early treatment discontinuation. Major PDI were not significantly associated with toxicity (Ps>0.05). **Conclusions:** In a cohort of vulnerable older adults with advanced cancer, PP and PDI are associated with increased risk of systemic treatment adverse outcomes. Providing meaningful screening and interventional tools to optimize medication use may improve treatment outcomes in these patients. Funding:UG1-CA18996, U01CA233167. Prevalence of frailty for middle-aged and older adults starting a new line of systemic cancer treatment: Is age just a number? *First Author: Mackenzi Pergolotti, The University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Frailty is associated with adverse outcomes and increased risk of mortality for older adults (>60 years) with cancer. Geriatric assessment (GA) has gained popularity in routine cancer care as a clinical tool to screen for frailty in older adults starting a new line of cancer treatment, and to guide clinical decision making during systemic therapy. Emerging research indicates GA may also be useful to identify frailty in middle-aged adults (40-60 years) with cancer, but more research is needed. In this study, we used GA data to compare the prevalence of frailty between middle-aged and older adults starting a new line of systemic cancer treatment. **Methods:** Participants included adult patients with cancer due to begin a new line of systemic therapy at a multi-office community-based oncology private practice and enrolled in a clinical trial (NCT04852575). At baseline, participants completed an online version of the Cancer and Aging Resilience Evaluation (CARE) — a patient-reported GA adapted from the Cancer and Aging Research Group. Frailty score was constructed using a 44-item deficit accumulation method and categorized as frail (>0.35), pre-frail (0.2-0.35) or robust (0-0.2) using published cutoffs. We grouped participants by age, middle-aged (40-60 years) or older-aged (>60 years), then used independent t-test and chi-squared statistic to compare frailty scores (continuous) prevalence of frailty (categorical) between groups. Hypothesis testing was two sided and the level of significance was 0.05. **Results:** Participants (n=96) were predominantly female (62%), Caucasian (68%) and beginning first line systemic therapy (69%) for either newly diagnosed cancer or new recurrence of disease; median time since diagnosis was 1 month. Common cancer types included: breast (34%), gastrointestinal (23%), hematologic (15%) and lung (12%). Disease stage was predominantly stage 3 (28%) or stage 4 (38%). When comparing middle-aged (n=31, M_{age} = 54.74 ± 4.79, range = 41.23 – 59.98 years) vs. older adult -groups (n=65, M_{age} = 70.27 ± 5.91, range = 60.64 – 84.29 years), there was no significant difference in mean frailty score (p = 0.22) or the proportion categorized as frail vs. pre-frail vs. robust (p = 0.32); see Table. Stage of disease and prevalence of common cancer types was similar between age groups (p>.05). **Conclusions:** In our cohort, middle and older aged patients who completed patient-report GA had similar prevalence of frailty before starting systemic therapy. Using the GA as a functional-age assessment to detect frailty for adults of varied ages could allow for earlier intervention aimed at impacting tolerance to therapy. Clinical trial information: NCT04852575. Research Sponsor: None.

Frailty scores and categorization for middle- vs. older-aged.

	Frailty score, *M* ± SD	% Frail	% Pre-frail	% Robust	Between-group difference
Middle-aged	0.22 ± 0.10 (0.07 – 0.54)	8.2%	36.7%	55.1%	p>.05
Older adult	0.24 ± 0.10 (0.13 – 0.59)	14.3%	40.8%	44.9%	

12055 **Poster Session**

Using G8 and carg toxicity score to predict emergency room (ER) visits, hospitalizations, and mortality in older patients with newly diagnosed cancer. *First Author: Amit Arora, Kaiser Permanente, Fremont, CA*

Background: ASCO and NCCN guidelines recommends Geriatric Screening (G8) and CARG chemotherapy toxicity tool assessment for all older patient before receiving chemotherapy as high risk G8 (< 14) and CARG (≥10) are associated with increased chemotherapy toxicities. We conducted a pilot to understand predictors of high risk G8/CARG and if high risk G8/CARG can predict ER/hospitalization and mortality in community-based Oncology clinics in Kaiser Permanente Northern California. **Methods:** G8 and CARG were administered to all patients ≥65 years with newly diagnosed cancer from 5/1/21 to 12/31/21. Patients were followed for at least 30 days after assessment for ER/hospitalization and mortality. The median follow-up days from referral to ER/hospitalization was 96 days (range 0-273 days). Chi-Square tests were applied for G8/CARG risk category with demographic and utilization variables. Cox proportional-hazards models were performed to see the association between G8/CARG score and days from referral to ER/hospitalization, and days from referral to death, adjusted for age, sex, race, and cancer type. **Results:** During this pilot 1082 patients (52% female) completed G8, and 516 patients (57% female) completed CARG. Percentage of patients with high risk G8/CARG increased with each decade (G8: < 70 yrs (58%), 70-79 (63%), 80-89 (90%), ≥ 90 (100%); p < 0.001); (CARG: < 70 yrs (19%), 70-79 (43%), 80-89 (65%), 90 and above (81%); p < 0.001). More men than women had high risk CARG (48% vs. 39%, p = 0.012). Ethnicity was not associated with high risk G8 / CARG. Upper GI cancers (UGI) were associated with highest proportion of patients with high risk G8 (88%) and CARG (58%) whereas breast cancer (BC) had the lowest proportion of patients with high risk G8 (46%) and CARG (14%); p < 0.001. In the adjusted G8 model for ER/hospitalization, high risk G8 vs low risk (HR 1.58, CI 1.23-2.03, p = 0.0003) was related to ER/hospitalization. In the adjusted CARG model for ER/ hospitalization, high risk CARG vs low risk (HR 2.42, CI 1.37-4.29, p = 0.0024) and medium risk CARG vs low risk (HR 2.17, CI 1.23-3.83, p = 0.0074) were related to ER/hospitalization. In the adjusted G8 model for mortality, high risk G8 vs low risk (HR 4.52, CI 2.28-8.97, p < 0.0001) were related to mortality. In the adjusted CARG model for mortality, high risk CARG vs low risk (HR 3.92, CI 1.21-12.74, p = 0.023) and medium risk CARG vs low risk (HR 1.59, CI 0.48-5.33, p = 0.45) were related to mortality. **Conclusions:** This community-based pilot shows that increasing age is associated with high risk G8 / CARG. G8 and CARG assessment at the time of initial cancer diagnosis can predict early ER/hospitalization and mortality in older adults with cancer and should be included as a part of initial assessment. Research Sponsor: None.

Remote symptom monitoring (RSM) during treatment for metastatic prostate cancer (mPC) in older men: Feasibility and efficacy. *First Author: Shabbir M.H. Alibhai, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Emerging data support multiple benefits of RSM during chemotherapy to improve outcomes. These studies do not focus on older adults and do not include non-chemotherapy strategies. mPC represents a major burden in older men. Although both chemotherapy and androgen receptor axis-targeted therapies (ARATs) prolong survival, toxicities are substantial and increased in older men. Understanding the feasibility of RSM and key symptoms experienced by men with mPC on treatment is crucial to designing appropriate supportive care interventions. We aimed to assess RSM feasibility and understand key symptoms during treatment with chemotherapy or an ARAT among older men. **Methods:** Older adults aged 65+ starting chemotherapy, an ARAT, or Radium-223 for mPC were enrolled in a prospective observational multicentre study. Participants completed the Edmonton Symptom Assessment Scale (ESAS) on weekdays online or by phone. Weekly detailed questionnaires assessed mood, anxiety, fatigue, insomnia, and pain. Notifications were sent to the clinical oncology team with severe symptoms (ESAS 7 or higher). Study duration was the first treatment cycle (~3-4 weeks). Feasibility data were analyzed descriptively. Linear mixed effects models examined symptoms over time and by cohort. Clinician responses were assessed descriptively. **Results:** A total of 90 men were included (mean age 76.5y, 48% ARAT, 38% chemotherapy, and 14% Radium-223, 42% frail by Vulnerable Elders Survey-13 cutoff of 3+). Approximately half the patients preferred phone-based RSM. Patients provided RSM responses in 1,874 of approximately 2,000 (94%) instances. In the combined cohort, the most common symptoms of moderate to severe intensity (ESAS 4 or higher) occurring at least once were poor well-being (66%), fatigue (62%), reduced appetite (56%), insomnia (54%), and pain (46%). Symptom patterns were similar between chemotherapy and ARAT groups. Moderate to severe symptoms were more common and lasted longer among frail than non-frail men. Symptoms tended to remain stable or improve over the course of 3-4 weeks of RSM. 89% of participants were satisfied or very satisfied with RSM, although daily reporting was reported by several as burdensome. 45% had severe symptoms from RSM leading to informing the oncology care team, 79% of whom were followed up by a nurse or physician, and 12% of treatments were modified. **Conclusions:** RSM is feasible, acceptable to older adults, and identifies clinically relevant symptoms, but accommodation needs to be made for phone and the optimal frequency of RSM needs to be established. Poor well-being, fatigue, reduced appetite, and insomnia occurred in over half of participants. Longer-term follow up will be important. Research Sponsor: Prostate Cancer Canada.

Using CT-based body composition metrics and frailty index in predicting survival among older adults with cancer. *First Author: Smith Giri, University of Alabama at Birmingham, Birmingham, AL*

Background: Older adults with cancer are at an increased risk of treatment related toxicities and excess mortality during cancer treatment. While altered body composition and frailty are associated with worse survival among older adults with cancer, no prior study has examined their combined influence on survival prediction. **Methods:** Prospective study of older adults (≥60 years) undergoing geriatric assessment (GA) at initial visit with a medical oncologist at UAB from 9/2017-07/2021 with available abdominal computed tomography (CT) within 60 days of GA. Using multi-slice CT images from T12 to L5 level, volumetric skeletal muscle (SMV), visceral (VATV) and subcutaneous (SATV) adipose tissues, and skeletal muscle density (SMD), were derived. Sex-specific z-scores for each measure were determined. A 44-item frailty index was obtained, using the deficit accumulation model. Overall survival (OS) was defined as time from GA to death or last follow-up (11/8/2021). Kaplan-Meier estimates of survival rates were compared using log-rank statistics. Multivariable cox regression models were used to predict OS in a random sub-sample (1:1 split of training:validation set), sequentially adding frailty and each body composition measure and assessing improvement with likelihood ratio tests and Harrel's C statistic. **Results:** 815 patients were included (median age 68 years, 61% men, and 75% non-Hispanic Whites. 73% had gastrointestinal malignancies (stage III, 25%, stage, IV 48%). 32% were frail, 31% pre-frail. There was a weak negative correlation between height-adjusted SMV and frailty (r = -0.16), particularly among men (r -0.24). Over a median follow-up of 25.7 months (range 0.3-49.6 months), 268 patients (33%) died. The 2-year survival rate was 75.9%, 68.5% and 52.2% among robust, pre-frail and frail (log-rank p < .001), respectively. In multivariable models adjusted for age, sex, race, cancer type and cancer stage, being frail (vs robust) (Hazards Ratio, HR = 2.32; 95%CI: 1.69-3.2; $p < .001$) and higher skeletal muscle volume (HR = 0.85; 95%CI: 0.72-0.99; $p = 0.04$, per SD increment) were independently associated with OS. Adding body composition and frailty to clinical variables led to significant improvement in prediction (Harrel's C increased from 0.69 to 0.74). In the validation set, discrimination was similar (Harrel's C = 0.72) and plots suggested good model calibration. **Conclusions:** CT-based body composition metrics and frailty are independent predictors of OS among older adults with cancer and improve survival prediction compared to routine clinical risk factors. Research Sponsor: None.

Complementary and alternative medicine use and recommendations for discontinuation of supplements in an integrative oncology clinic. *First Author: Stacy D. D'Andre, Mayo Clinic, Rochester, MN*

Background: It is well established that many patients with cancer are taking dietary supplements (DS) and alternative medicines and often do not disclose such to their care teams. There is potential for harm in several ways: 1) interactions with their medications that may increase side effects, 2) interactions with their treatment that may lead to decreased efficacy, 3) direct toxicity from the supplement 4) financial toxicity. We have recently started a new Integrative Oncology service to help counsel patients about improving lifestyle factors and assist patients with safe and evidence-based integrative treatments and supplements. **Methods:** Patient data (N=100) were collected prospectively from an Integrative Oncology Clinic. The number and type of DS were documented. Using the Natural Medicines Database (NMD), we determined whether supplements interacted with the patients' other medications or cancer therapies. We calculated the percentage of patients in which a recommendation for discontinuation of DS was recommended, along with the supporting reasons. We calculated the most common DS being taken and other alternative therapies beyond supplements. **Results:** Ninety-one percent of patients took DS, with an average of 5.5 per patient (range 0-20). The most common DS patients reported taking (%): Vit D (52), Vit C (41), Multivitamin (34), probiotic (27), B Vitamins (26), Ca (20), zinc (20), fish oil (18), cannabis (18), mushrooms (18), turmeric (17), magnesium (15), melatonin (14), biotin (11), coq10 (7), iron (8), VIT E (5), and glucosamine (5). Eighty-nine percent of patients using DS were on active cancer therapy. In thirty-five percent of patients, we recommended stopping some of their DS or other therapies. Number of patients using alternative therapies beyond DS: IV Vitamin C (5), Rick Simpson oil (high dose THC) (4), extreme diets (4), mistletoe (2), re-purposed meds (2); and one each was using hyperbaric O2, ozone, homeopathic, ayurvedic, insulin-potentiated chemo, miracle mineral cure, chelation, low dose naltrexone **Conclusions:** Cancer patients both on and off active treatment are using large numbers of DS with potential for adverse effects and/or decreasing efficacy of treatments. This study highlights the prevalence of DS and alternative medicine usage in cancer patients referred to an integrative oncology clinic and demonstrates the need for counseling about safe supplement use; in 35% of patients, discontinuation of DS was recommended. Research Sponsor: None.

Reasons for recommending discontinuation of supplements.

Reason for Recommending D/C supplement	%
Potential for toxicity (ex. bleeding, known toxicity, excess vitamins)	46
Potential to decrease the efficacy of treatment (ex. antioxidants, excess B12, iron)	37
Interaction with medications or cancer treatment (per NMD)	17

12059 **Poster Session**

Impact of circuit, interval-based exercise on insulin resistance and adiponectin among minority cancer survivors. *First Author: Cameron N. Christopher, Dana-Farber Cancer Institute, Boston, MA*

Background: Hispanic and Black adults have a heightened risk of metabolic syndrome compared to non-Hispanic white adults, increasing the risk of cardiovascular disease, diabetes, and co-morbid outcomes. Further, Hispanic and Black adults are more likely to be sedentary and obese than non-Hispanic white adults, leading to an increased risk of insulin resistance and poor metabolic health. Exercise improves cardiometabolic health, including insulin sensitivity and adiponectin, however few studies have focused on minority cancer survivors. The aim of our (NCT03284346) was to determine whether a 4-month circuit-based aerobic and resistance exercise intervention can improve insulin resistance and adiponectin levels in breast, prostate, and colorectal Hispanic and Black cancer survivors. **Methods:** Overweight or obese (BMI > 25.0 kg/m2), sedentary breast, prostate or colorectal cancer survivors who self-identified as Hispanic or Black were randomized to exercise (n = 30) or usual care (n = 10). Survivors in the 4-month supervised exercise intervention participated in a thrice weekly, circuit, interval-based moderate-vigorous aerobic (65-85% of VO_{2max}) and resistance (65-85% of 1-repetition maximum). Insulin resistance, assessed by Homeostasis Model of Assessment (HOMA-IR), and adiponectin levels were collected at baseline and post-intervention from fasting blood sample collection. Repeated-measures analysis of variance and t-tests were performed to assess within- and between-group differences. **Results:** The study sample was 66 ± 10.4 years old, Hispanic (55%), Black (45%), overweight (78%), and female (60%). Adherence to the intervention was 90% and post-intervention outcome measures were available on 100% of participants. Post-intervention, insulin resistance (within group mean difference: -3.2, p < 0.01; between group mean difference: -4.5, p < 0.01) and adiponectin levels (6.1 ug/mg, p < 0.01; 8.6 ug/mg, p < 0.01) significantly improved in the exercise group when compared to baseline and to usual care, respectively. **Conclusions:** A circuit, interval-based aerobic and resistance exercise intervention improved insulin resistance and adiponectin levels in breast, prostate, and colorectal minority cancer survivors. Accessible exercise interventions for minority cancer survivors may be effective to mitigate metabolic dysregulation and co-morbid conditions in survivorship and support cardiometabolic health. Clinical trial information: NCT03284346. Research Sponsor: Donations to the Dieli-Conwright Laboratory (patients donated money who had participated in previous studies).

Symptom monitoring with patient-reported outcomes using a web app with alerting algorithms among patients with lung cancer (SYMPRO-Lung). *First Author: Annemarie Becker, Amsterdam University Medical Centers, Amsterdam, Netherlands*

Background: The use of patient reported outcomes (PROs) to monitor symptoms during and after cancer treatment can improve symptom management, health-related quality of life (HRQoL), and overall survival, especially when linked to an alert system. Previous studies used alerts to the health care provider (HCP), but will this also work when patients receive the alerts? The aim is to compare a reactive (patient receives alert) and an active (HCP receives alert) method of PRO symptom monitoring on symptom incidence and management during the first 15 weeks of treatment. **Methods:** SYMPRO-Lung is a Dutch multicenter stepped wedge RCT performed among lung cancer (LC) patients to monitor symptoms, using a PRO-CTCAE LC subset . The NCI scoring algorithm assessed the symptom severity. If symptoms exceeded a predefined threshold an alert was sent by email to the HCP (active arm) or to the patient (reactive arm). Differences between both study arms in baseline characteristics, symptom incidence and management, were assessed using chi-square tests. **Results:** In total, 244 patients (active arm n = 155, 64%, reactive arm n = 89, 37%) completed 2412 symptom checklists during the first 15 weeks of treatment, with a mean of 10 per patient (pp) (SD 4.3). A total of 673 alerts (28%) were triggered, with a mean of 3 (SD 2.1) pp in both arms. The top 3 symptoms that caused the app to send an alert were fatigue (n = 231, 19%), pain (n = 188, 16%), and constipation (n = 144, 12%). Decreased appetite, diarrhea, and nausea were significantly higher in the reactive arm compared to the active arm (see table). For 313 alerts (74%), telephone contact with a HCP was the only intervention needed. 57 Alerts (13%) were discussed during a planned outpatient's consultation in the week of the alert. For 39 alerts (9%) the patients were referred to another specialty (see table). However, 'no need to follow-up' (FU) was requested after 237 alerts (35%). For all symptoms, the no FU request was significantly higher in the reactive arm (n = 135, 32% vs n = 102, 40%), compared to the active arm (p-values between 0.02 and < 0.001). **Conclusions:** In both arms an average of 3 alerts pp were triggered. In the reactive arm, significantly more patients chose not to contact their HCP compared to the active arm. Future research needs to unravel the underlying mechanisms and the potential consequences of this observed difference between study arms. Clinical trial information: Trial NL7897. Research Sponsor: Roche, Other Foundation.

No. of symptoms that caused an alert with a sign. difference	Total n (%)	Active n (%)	Reactive n (%)	*p*-Value
Decreased appetite	108 (8.9)	57 (7.8)	51 (10.5)	.025
Diarrhea	79 (6.5)	39 (5.3)	40 (8.2)	.011
Nausea	64 (5.3)	29 (4.0)	35 (7.2)	.003

Evaluation of social connectedness, loneliness, and anxiety among cancer survivors during the 2020-2021 winter surge of COVID-19 pandemic. *First Author: Hermine Poghosyan, Cancer Outcomes, Public Policy, and Effectiveness Research (COPPER) Center, Yale University, New Haven, CT*

Background: Limited research is available about cancer survivors' level of stress, social connectedness and loneliness during the COVID-19 that can put them at increased risk for poor physical and mental health. We estimated relative decreased rate of social connectedness and increased rates of loneliness/sadness and stress/anxiety among cancer survivors during the 2020-2021 winter surge of COVID-19 and investigated whether decreased social connectedness is associated with increased feelings of loneliness/sadness and stress/anxiety. **Methods:** This cross-sectional study used data from Medicare Current Beneficiary Survey COVID-19 Winter 2021 Supplement, nationally representative phone survey of Medicare beneficiaries living in community, conducted in March-April 2021. We included 1,836 respondents who self-reported cancer history (other than skin cancer). Outcomes were self-reported feelings of loneliness/sadness and stress/anxiety over the past 4 months. The independent variable was social connectedness defined as feeling less socially connected to family/friends over the past 4 months. We used weighted descriptive statistics and multivariable logistic regression adjusting for self-reported socio-demographics (age, sex, race, income), region, metropolitan residency, Medicaid eligibility, living alone, depression, having access to internet and health care. We applied sample weights to account for complex survey design with results generalizable to 9.5 million cancer survivors. **Results:** Out of 9505626 cancer survivors, 6.8% self-reported as Black, 7.1% Hispanic, 80.4% White, 59% women, 42.7% reported decreased social connectedness, 20.3% increased feeling of loneliness/sadness, and 40.0% increased feeling of stress/anxiety in the past 4 months. Women had higher rates of reporting increased feelings of loneliness/sadness (12.0% vs. 26.1%, P = < .001), stress/anxiety (30.0% vs. 46.6%, P = < .001), and decreased social connectedness (38.7% vs. 45.5% P = .028) than men in the past 4 months. Among self-reported racial and ethnic groups, Hispanics had the highest rates of reporting increased feelings of loneliness/sadness (31.2% vs. 20.5% of Whites vs. 10.2% of Blacks, P = .008) and stress/anxiety (54.0% vs. 39.4% of Whites vs. 31.2% of Blacks, P = .034). No statistically significant difference was found in social connectedness by self-reported race and ethnicity. Survivors who reported decreased social connectedness had higher odds of feeling more lonely/sad (adjusted OR = 3.67, 95%CI 2.85-4.72, P = < .001) and more stressed/anxious (adjusted OR = 2.63, 95%CI 2.1- 3.26, p = < .001) over the past 4 months. **Conclusions:** Increased feelings of loneliness/sadness and anxiety/stress in the past 4 months were prevalent among cancer survivors. Also, almost half of them reported decreased social connectedness at the end of the second year of COVID-19. Research Sponsor: None.

Prevalence of pain symptoms among U.S. adult cancer survivors. *First Author: Xinwen Hu, Washington University School of Medicine, St. Louis, MO*

Background: Pain symptoms are common in cancer survivors. The life expectancy of US cancer survivors continues to raise. To date, the comprehensive pattern of pain symptoms in US cancer survivors by cancer history remains unknown. **Methods:** Data on pain symptoms and correlates were derived from a nationally representative sample of cancer survivors (n = 55,716, weighted population = 17,352,886) in the 1997-2018 National Health Interview Survey. Individuals who answered "yes" to the questions "During the past three months, did you have headache/facial/neck/low back pain/low back pain radiating to the leg" were considered as having pain symptoms at respective anatomical regions. The US national prevalence of pain overall and by anatomical regions were estimated. Correlates of pain symptoms were examined using multivariable logistic regression. **Results:** The prevalence of overall pain symptoms was persistently high (48.5%, 95% CI: 48.0-49.0) in cancer survivors from 1997-2018 (P for trend = .58), driven by low back (37.6%, 95% CI: 37.1-38.0) and neck pain (20.9%, 95% CI: 20.5-21.3), and was leading in survivors of bone (63.1%, 95% CI: 57.9-68.4), soft tissue (58.1%, 95% CI: 50.6-65.6), and brain (58.2%, 95% CI: 52.3-64.0) cancers. Considerable pain symptoms were reported by survivors of commonly diagnosed cancers: lung (48.5%), breast (46.7%), colon (52.2%) and prostate (38.4%) cancers. The prevalence of pain is higher in females (52.9%) than males (42.6%) across all anatomical regions (OR, 1.50 [95% CI, 1.38-1.63]), particularly headache (19.8% vs. 8.6%) and facial pain (8.6% vs. 3.9%). Of note, females with reproductive system cancers, cervical (66.3%), uterine (60.0%) and ovarian (59.4%) cancers, have a higher prevalence in all types of pain than those with other cancers. Cancer survivors aged ≥65 years were less likely to report pain symptoms than younger survivors (OR, 0.71 [95% CI, 0.64-0.79]). Despite no racial disparity in the prevalence of overall pain, Non-Hispanic Blacks (18.6%, 95% CI: 17.2-20.0) and Hispanics (21.2%, 95% CI: 19.5-22.9) were more likely to report headache than Non-Hispanic Whites (14.4%, 95% CI: 14.0-14.8). A higher prevalence of pain symptoms was consistently observed in cancer survivors with low income, smoking history, low physical activity levels, diabetes, and cardiovascular diseases (all $P < .05$). Age at cancer diagnosis (P for trend < .001), but not the time since, affected pain symptoms. Cancer survivors diagnosed at age 0-14 (53.0%, 95% CI: 49.1-56.9) and 15-39 years (58.6%, 95% CI: 57.5-59.7) had a significantly higher prevalence of pain across all anatomical regions than those at ≥40 years (45.5%, 95% CI: 44.9-46.1). **Conclusions:** Half of US cancer survivors experienced pain symptoms, driven by low back and neck pain. Higher prevalence of pain was noted in cancer survivors with younger age, female sex, low income and suboptimal lifestyle behaviors, calling for adequate pain management in cancer survivorship. Sacubitril-valsartan improves longitudinal strain and ejection fraction in preclinical models treated with anthracyclines through NLRP3, MyD88 pathways resulting in a reduction of myocardial IL-1β, IL-6, TNF-α and growth factors. *First Author: Nicola Maurea, Istituto Nazionale per lo Studio e la Cura dei Tumori "Fondazione G. Pascale"-IRCCS, Naples, Division of Cardiology, Naples, Italy*

Background: Doxorubicin-mediated adverse cardiovascular events are among the leading causes of morbidity and mortality in breast cancer patients. Sacubitril-valsartan (LCZ 696) is a combination drug, made up of neprilysin inhibitor sacubitril and angiotensin II receptor blocker valsartan, used for the treatment of heart failure in patients with a reduced ejection fraction. We hypothesized that LCZ 696, administered during doxorubicin, could improve cardiac function and cardiac inflammation in preclinical models. **Methods:** Human fetal cardiomyocytes (HFC cell line) were exposed to subclinical concentration of doxorubicin (200 nM) alone or in combination with LCZ-696 (100 mM) for 72 h. After the incubation period, we performed the following tests: cell viability, apoptosis and necrosis; expression of malondialdehyde and 4-hydroxynonenal and concentration of intracellular Ca2+. Moreover, pro-inflammatory studied were also performed (activation of NLRP3 inflammasome; expression of TLR4/MyD88; mTORC1 Fox01/3a; NF-κB). C57Bl/6 mice were untreated (Sham, n = 6) or treated for 10 days with doxorubicin i.p at 2.17 mg/kg (DOXO, n = 6), LCZ-696 at 60 mg/kg (LCZ, n = 6) or doxorubicin combined to LCZ-696 (DOXO-LCZ, n = 6). Ejection fraction, radial and longitudinal strain were analyzed through transthoracic echocardiography (Vevo 2100). Cardiac tissue expression of NLRP3 inflammasome, Myd88, NF-kB and 13 chemokines (IL-1α, IL-1β, IL-2, IL-4, IL-6, IL-10, IL-12, IL17-α, IL-18, IFN-γ, TNF-α, G-CSF, and GM-CSF) were quantified. **Results:** LCZ-696 exerts cardioprotective effects, enhancing cell viability of 48-54.6% compared to only doxorubicin-treated cells (p < 0,001 for all); LCZ 696 decreased NLRP3, MyD88 and NF-kB expression in cardiac cells. In preclinical study, LCZ 696 improved significantly the EF and prevented the reduction of radial and longitudinal strain after 10 days of treatment with doxorubicin. A reduced expression of NLRP3, MyD88 and NF-kB in cardiac tissues was seen in DOXO-LCZ group compared to DOXO mice (p < 0.001). Cardiac expression of IL-1β, IL-6, TNF-α, G-CSF and GM-CSF were significantly reduced after treatment with LCZ-696 indicating anti-inflammatory properties. **Conclusions:** LCZ-696 exerts direct beneficial effects in cardiomyocytes exposed to doxorubicin. In preclinical models, LCZ-696 reduced inflammation and cytokine expression involved in doxorubicin-mediated cardiotoxicity. Research Sponsor: Ricerca Corrente.

Performance of the 2021 CKD-EPI equations without a race coefficient in a multi-racial population of adults with solid tumors: A prospective cross-sectional study. *First Author: Veronica Torres Costa E Silva, Instituto do Cancer do Estado de São Paulo, São Paulo, Brazil*

Background: We previously showed that estimated glomerular filtration rate (eGFR) based on serum creatinine (Scr)(eGFRcr) using the 2009 CKD-EPI equation performed better than Cockroft-Gault equation (CG) in solid tumor patients in Brazil (Onco-GFR Study). In that study, eGFR based on Scr and cystatin C (Scys)(eGFRcr-cys) using the 2012 CKD-EPI was the most accurate equation and suitable for use as a confirmatory test. The CKD-EPI 2009 eGFRcr and 2012 eGFRcr-cys equations include a term for race (Black vs. non-Black). The 2021 CKD-EPI eGFRcr and eGFRcr-cys equations do not include race and are now recommended in the US, but have not been assessed in a multi-racial population or in cancer patients. The aim of this study is to evaluate the performance of the 2021 CKD-EPI equations in the Onco-GFR Study. **Methods:** Measured GFR (mGFR) was determined using the plasma clearance of ^{51}Cr-EDTA. Scr and Scys assays were traceable to international standards. **Results:** A group of 1,200 patients recruited between April 2015 and September 2017 were included for analysis. Patients were 58.8±13.2 years, 50.8% male. Race distribution was Black participants 12.8% and non-Black participants 81.2%. Mean (SD) mGFR was 78.5±21.7 ml/min/1.73 m^2. For eGFRcr, the overestimation of mGFR was larger for the 2021 vs. 2009 equation -10.0 vs. 8.1 ml/min/1.73m^2, resulting in lesser accuracy 1-P30 of 22.3 vs. 19.1, but still more accurate than CG equation (1-P30 of 24.9, P = 0.05). For eGFRcr-cys, the overestimation of mGFR was larger for the 2021 vs. 2012 equation (-4.1 vs. -2.0 ml/min/1.73m^2). eGFRcr-cys using the 2021 equation was more accurate than eGFRcr using the 2021 equation and eGFRcys using the 2012 equation (1-P30 9.8 vs. 22.3 and 12.3, p-values < 0.001 and 0.01, respectively) (Table). **Conclusions:** 2021 CKD-EPI eGFRcr equation race performed better than CG. 2021 CKD-EPI eGFRcr-cys performed better than 2021 eGFRcr and 2012 eGFRcys equations. Removing race from eGFR equations represents an advance and should be incorporated in cancer care. Research Sponsor: Fundação de Amparo à Pesquisa do Estado de São Paulo.

Filtration marker (eGFR)	Equation and Year	Median bias (eGFR - mGFR) (ml/min/1.73 m2)	Precision IQR (ml/min/1.73 m2)	Accuracy (1-P_{30}) (%)	RMSE

Development of breast cancer after thyroid cancer and trends over time. *First Author: Kriti Ahuja, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL*

Background: Thyroid cancer occurs early in adulthood and is thrice as common in women. Further, 1 of 8 women in the U.S develop breast cancer, usually later in life. We are studying the development of breast cancer after thyroid cancer in women within the US. **Methods:** The Incidence – SEER Research Data, 18 registries, Nov 2020 Sub (2000-2018) database was queried with SEER*Stat 8.3.9.2 for thyroid cancer in females and subsequent breast cancer. Further, the MP-SIR function of SEER*Stat 8.3.9.2 was applied to evaluate the Incidence – SEER Research Data, 18 Registries (excl AK), Nov 2020 Sub (2000-2018) for risk of developing breast cancer after thyroid cancer in females in terms of SIR (Standardized Incidence Ratio) and Excess Risk, stratified by age categories. **Results:** From 2000 to 2018, 151654 cases of thyroid cancer were diagnosed in 150787 women, most of which were papillary adenocarcinoma, NOS (50.2%) and papillary carcinoma, follicular variant (26.8%). About 64% cases occurred in Non-Hispanic Whites (NHW) and 60% of all cases developed from ages 30 to 60 (~ 20% per decade). There was a considerable rise in incidence over the years, from > 4000 cases in year 2000 to > 9500 cases in 2018, with percentage change (PC) of 122.3%, and Annual Percentage change (APC) of 4.6% (CI 3.6-5.7, p < 0.05) across all age groups, highest in 60-69 age group (APC 7.5; CI 6-9.1, p < 0.05). At follow-up, 3300 cases of primary breast cancer were diagnosed in 3062 women of the above population. Infiltrating duct carcinoma, NOS constituted 70.5% cases, followed by lobular carcinoma, NOS at 10%. About 4 out of 5 breast tumors were ER positive (82.6%). NHW constituted > 70% cases and >50% cases occurred in age group 50-69 (approximately 25% per decade). We found an overall increasing trend in frequency of breast cancer after thyroid cancer with APC 14.1 (CI 11.9-16.3, p < 0.05). MP-SIR function in Incidence – SEER Research Data, 18 Registries (excl AK), Nov 2020 Sub (2000-2018) indicated that 3005 women developed breast cancer after thyroid cancer (consistent with the above data as it has latency criteria of 2 months and excludes AK). Overall, an increased risk of developing breast cancer after thyroid cancer was found, with SIR 1.21 (CI 1.16-1.25, p < 0.05) and Excess risk 4.88 across all age categories, highest at 1 year following diagnosis of thyroid cancer with SIR 1.29 (CI 1.15-1.44, p < 0.05) and excess risk 5.91. Among different age categories, SIR was highest for ages ≥70 at 1.32 (CI 1.2-1.45, p < 0.05) with excess risk 13.45. **Conclusions:** Women with thyroid cancer are at increased risk for subsequent primary breast cancers (usually ER+), with an overall increasing trend from 2000 to 2018. As we continue to make progress in the diagnosis and treatment of thyroid cancer in women, it is important to be cognizant of their increased risk for developing a subsequent primary and possible significance in terms of breast cancer screening. Retrospective analysis of healthcare disparities in Philadelphia chromosome-positive ALL: A single-institution experience of a large metropolitan area. *First Author: Ian Michael Bouligny, VCU Massey Cancer Center, Richmond, VA*

Background: Philadelphia chromosome-positive (Ph+) ALL is an aggressive hematological neoplasm with a dismal prognosis. Hematopoietic stem cell transplant (HSCT) remains the standard of care for those reaching complete remission due to high relapse rates with conventional therapy alone. We have previously demonstrated findings concerning for imbalanced outcomes among racial groups in AML. In the era of TKIs targeting BCR-ABL1 in combination with conventional therapy, it is unclear whether trends noted in AML are also seen in Ph+ ALL. Thus, the purpose of this study was to investigate the impact of healthcare disparities on outcomes in Ph+ ALL with regards to access to care, response rates, toxicities, and overall outcomes. **Methods:** We retrospectively analyzed 59 patients with Ph+ B-ALL treated at our institution with TKIs +/- chemoimmunotherapy during January 2015 to January 2021. Baseline patient demographics were obtained, including insurance type, performance status at diagnosis, cytogenetic and molecular profiling, dates and doses of induction, toxicity, response, MRD analysis, and HSCT access and outcomes. Race was determined by patient self-report as recorded in the electronic medical record. **Results:** We divided 58 patients (one excluded as race was unknown) into two cohorts: 23 (39.7%) patients that identified as minorities, including African American, Hispanic/Latino, and Asian, and 35 (60.3%) identifying as White. There were no differences in baseline characteristics including age (p = .367), sex (p = .788), ECOG at diagnosis (p = .438), Charlson Comorbidity Index scores (p = .551), or presence of additional poor-prognostic mutations (p > .999). Despite this, minorities were significantly more likely to be treated with lower-intensity regimens compared to non-minorities (p = .022). Achievement of CR by MRD was approaching statistical significance favoring the non-minority cohort (60.0% versus 27.3%, p = .055). Receipt of HSCT numerically favored the non-minority cohort, approaching statistical significance (54.3% versus 26.1%, p = .056). At a median follow-up time of 3.3 y., the median OS was not reached between the two groups and there was no difference in survival between the two groups (p = .662). **Conclusions:** Despite similar patient-related characteristics, minority populations are more likely to be treated with lower-intensity strategies, concerning for bias in regimen selection. Achievement of CR by MRD and receipt of HSCT appeared to be numerically lower in the minority cohort. While there appeared to be no difference between the two cohorts with regards to survival during the follow-up period, it is unclear if this would be maintained with longer follow-up. These findings highlight the need for ongoing vigilance regarding physician biases and increasing the need for improving access to curative treatment for all patients. Research Sponsor: None.

Lymphedema therapy referral is associated with improved understanding of lymphedema prevention among breast cancer survivors. *First Author: Madelyn Klugman, NewYork Presbyterian-Weill Cornell, New York, NY*

Background: Lymphedema is common among breast cancer survivors (BCS) and negatively affects quality of life. There are modifiable factors to reduce lymphedema risk and exacerbation; it is unknown how aware survivors are of these factors. We hypothesized referral to lymphedema therapy (LT) to be associated with improved lymphedema knowledge. **Methods:** BCS were approached during follow-up visits at an NCI-designated cancer center between 2014-2015 and asked to complete an anonymous survey. Eligibility criteria: age ≥18, English-speaking, > 6 months post-surgery, no cancer recurrence, no prior or subsequent second cancer. Surveys included 10 true/false questions to assess beliefs of common lymphedema misconceptions and questions about sociodemographics, cancer treatment, and prior LT referral. Charts were reviewed to determine history of axillary lymph node dissection (ALND) or sentinel node biopsy (SLNB). Multivariable logistic regression assessed the relationship between prior LT referral and correctly answering questions about lymphedema misconceptions. **Results:** Of 209 participants, 67% identified as non-Latinx white, 13% Black, 10% Latinx and 8% Asian. 53 (25%) had been referred to LT. Those who had SLNB were less frequently referred to LT [15 (14%)] than those who had ALND [38 (39%)]. There were 5 lymphedema knowledge questions with < 80% correct responses (Table). Those previously referred to LT more often correctly answered the questions about weight gain and using the arm on an airplane than those not referred (chi-2: $p < 0.01$ and $p < 0.01$), but they were less likely to answer correctly about carrying > 10 lbs or strenuous activity at work ($p < 0.01$ and $p = 0.02$, respectively) (Table). These associations remained in multivariable analyses, other than strenuous work activity (Table). **Conclusions:** We identified several misconceptions regarding lymphedema among BCS. LT referral is a potential opportunity to debunk common misunderstandings regarding lymphedema risk reduction; providers should have a low threshold to refer patients. Lymphedema therapists teach progressive exercise strategies, which may have inadvertently caused participants to think they should avoid carrying objects > 10 lbs. Research Sponsor: American Cancer Society, Conquer Cancer Foundation of the American Society of Clinical Oncology, U.S. National Institutes of Health.

Multivariable analysis* of lymphedema therapy referral with correctly answering lymphedema questions.

Question (answer)	% correct	% correct (referred to LT)	% correct (not referred)	Odds ratio	95% confidence interval
Avoid using arm on affected side for strenuous activity at work (F)	48	33	52	0.52	0.24-1.11
Avoid using arm on affected side to carry > 10lbs (F)	49	32	54	0.37	0.17-0.80
Weight gain can increase risk of lymphedema (T)	55	73	49	3.63	1.66-7.96
Exercise arm on airplane (T)	63	80	58	2.65	1.15-6.13
Avoid using arm on affected side to lift weights (F)	75	76	74	0.85	0.36-2.01

*Adjusted for age, race/ethnicity, education, axillary surgery (ALND vs. SLNB), radiation therapy.

Cardiovascular disease in testicular cancer survivors: Identification of risk factors and impact on quality of life. *First Author: Sjoukje Lubberts, Department of Medical Oncology, University Medical Center Groningen, Groningen, Netherlands*

Background: Testicular cancer (TC) treatment has been associated with cardiovascular disease (CVD) development. To facilitate development of preventive strategies, this study assessed risk factors associated with CVD in TC survivors. **Methods:** Incidence of coronary artery disease, myocardial infarction and heart failure was assessed in a multicenter cohort comprising 4,748 TC survivors treated at ages of 12-50 years between 1976-2007. Patients who developed CVD and a random sample from the cohort received a questionnaire on cardiovascular risk factors (CVRF) and quality of life (QoL, measured with SF-36). A subgroup (n=304) of responders in the cohort additionally underwent clinical evaluation of CVRF. **Results:** After a median follow-up of 16 years, 272 patients developed CVD. Compared to orchidectomy only, platinum-based chemotherapy was associated with increased CVD risk (Hazard Ratio (HR) 1.8, 95% Confidence Interval(CI) 1.3-2.5). CVD risk was increased among patients who were obese or a smoker at diagnosis (HR 4.7, 95%CI 2.4-9.3 and HR 1.5, 95%CI 1.1-2.2, respectively) and patients with Raynaud's phenomenon (HR 1.9, 95%CI 1.1-3.6) or a family history of CVD (HR 2.7, 95%CI 1.6-4.5). TC survivors with CVD reported inferior QoL on physical domains (table). In TC survivors who underwent clinical evaluation for CVRF (median age at assessment 51 years), 86% had dyslipidemia, 50% hypertension and 35% metabolic syndrome, irrespective of treatment. **Conclusions:** TC survivors treated with platinum-based chemotherapy, who were obese or smoking at diagnosis, had family history of CVD and who developed Raynaud's phenomenon are at risk to develop CVD, which affects QoL. Many TC survivors carry undetected CVRF. We advocate early lifestyle adjustments and lifelong follow-up with low-threshold treatment of CVRF, especially in obese and smoking patients treated with platinum-based chemotherapy. Research Sponsor: Dutch Cancer Society.

Quality of life in TC survivors with or without CVD. (The SF-36 scale scores are presented as mean with standard error. *:corrected for age at completion of questionnaire, using linear regression.)

Time for paying attention to fluoropyrimidine-associated cardiotoxicity: A pooled data analysis for epidemiology based on 60537 cases. *First Author: Yajie Lu, Xijing Hospital, Air Force Medical University of PLA, Xi'an, China*

Background: With the rise of cardio-oncology discipline, treatment-related cardiotoxicity has become a growing concern. However, fluoropyrimidine induced cardiotoxicity has been underestimated for a long time. The aim of this study was to comprehensively investigate the incidence and profiles of the cardiotoxicity associated with fluoropyrimidine using a pooled data meta-analysis. **Methods:** A systematic literature review was performed using PubMed, Embase, Medline, Web of Science, Cochrane library databases and clinical trials on studies published between the establishment of each database and March 31, 2021, investigating fluoropyrimidine associated cardiotoxicity (FAC). The main outcome was pooled incidence of FAC, and the secondary outcome were specific treatment-related cardiac AEs. Random-effects or fixed-effects modeling was used for analyses according to the heterogeneity assessed by Cochran's Q test. Subgroup analysis and meta-regression were conducted to explore the source of heterogeneity, and the incidence of FAC was compared among different clinical characteristics. The protocol was registered in PROSPERO (No. CRD42021282155). **Results:** Two hundred and six studies involving 60537 patients were included in this meta-analysis, covering 31 countries or regions in the world. The pooled incidence of FAC was 5.18% (95% CI 4.32%-6.10%) for all grade and 1.5% (95% CI 1.09%-1.96%) for grade 3 or higher. A total of 0.29% of patients died from severe cardiotoxicity. Cardiac ischemia and arrhythmia were the two most common cardiac AEs, occurring in 2.31% (95% CI 1.70%-3.00%) and 1.69% (95% CI 1.08%-2.42%) of patients, respectively. ECG alterations occurred in 5.85% (95% CI 3.4%-8.9%) of patients, indicating asymptomatic ECG alterations in a subset of the population. The incidence of cardiotoxicity varied among different regions, gender, cancer types and treatment regimens. Studies conducted in Asia outlined a significant higher pooled incidence of FAC than in Europe ($\chi 2 = 4.47$, $p = 0.03$) and America ($\chi 2 = 4.49$, $p = 0.03$). Female population had a lower pooled incidence than general population ($\chi 2 = 9.90$, $p = 0.01$). The highest pooled incidence was observed in esophagus cancer (10.53%, 95% CI 5.8%-16.35%), and the lowest occurred in breast cancer (3.66%, 95% CI 2.4%-5.12%). In addition, combination therapy, high cumulative dose, anthracycline addition, and pre-existing cardiac disorder significantly increased the risk of FAC ($p < 0.05$). No obvious publication bias was detected by funnel plots and Egger's test ($p < 0.05$), and the stability of our results was confirmed by the sensitivity analysis. **Conclusions:** FAC is not a rare condition during treatment containing fluoropyrimidines. Our results provide comprehensive global data on epidemiology of FAC, potentially representing an important reference on cancer management in clinical practice. Research Sponsor: None.

12072 **Poster Session**

Randomized trial of atorvastatin during and following receipt of doxorubicin for breast cancer and lymphoma (WF-98213). *First Author: William Gregory Hundley, Virginia Commonwealth University, Richmond, VA*

Background: Statins taken for cardiovascular (CV) indications by breast cancer (BC) and lymphoma survivors during doxorubicin (DOX) treatment may attenuate left ventricular ejection fraction (LVEF) decline, but statin impact among these survivors with no CV indications is unknown. **Methods:** In 279 patients from 31 cancer centers, we conducted a double blind, placebo-controlled, 24-month randomized trial of 40mg/day atorvastatin among those receiving DOX for BC or lymphoma. At pretreatment, six and 24 months after initiating DOX for BC or lymphoma, we assessed LV volumes, strain, mass, and LVEF (via cardiac magnetic resonance), cognitive function and serum markers of inflammation. Using a linear model adjusted for pretreatment measures, our primary analysis assessed change in LVEF over time by randomization group. **Results:** Participants were aged 49±12 years; 92% women, 83% white race. The mean pooled LVEF decline from pretreatment to 24 months was 62.2±6.0% to 57.6±6.3% ($p < 0.001$). Adjusting for pretreatment LVEF, 24-month declines in LVEF averaged 3.5±0.5% and 3.3±0.5% respectively for placebo vs statins ($p = 0.83$). Both randomized groups were similar for: incidence of > 10% change in LVEF, LV strain, LV mass, cognition and inflammation biomarkers, including among those > 90% study drug compliant ($p > 0.05$ for all). **Conclusions:** In BC and lymphoma survivors with no existing indication for statin therapy, prospective statin administration does not appear to impact LVEF declines two years after doxorubicin. Clinical trial information: NCT01988571. Research Sponsor: U.S. National Institutes of Health.

Measure	Group	Baseline	6 Month	24 Month	p-value, Change from Baseline to 24 Month
Ejection Fraction (%)	Statin	62.6 (61.5 – 63.8)	57.5 (56.3 – 58.7)	57.8 (56.5 – 59.1)	p < 0.001
	Placebo	61.8 (60.6 – 63.0)	57.5 (56.4 – 58.7)	57.4 (56.1 – 58.6

Analysis of incidence/mortality/cost for thrombotic events in hospitalized patients with lung cancer using the National Inpatient Sample database. *First Author: Kuldeepsinh Atodaria, Abington Jefferson Health, Abington, PA*

Background: Thrombotic events are a common complication of lung cancer. We performed a retrospective analysis of an inpatient adult population (age ≥18) using the National Inpatient Sample (NIS) database from the years 2003-2014. **Methods:** The analysis was performed on the NIS database, using IBM SPSS Statistics 28.0.0.0 software. The cases for lung cancer were selected based on ICD-9(International Classification of Disease) codes for lung cancer. The cases were weighted by Weight to discharges in the universe. These cases were checked for a diagnosis of acute lower extremity Deep Vein thrombosis (DVT) and acute Pulmonary Embolism (PE) again using ICD-9 codes. Chi square tests were utilized to check the significance of association between mortality and DVT/PE. Independent T-tests were utilized to check the association of cost of hospitalization and length of stay with DVT/PE. **Results:** There were a total of 4,940,262 cases (53.0% male) of lung cancer from the years 2003-2014. 112,569 (2.3%) cases had a diagnosis of acute lower extremity DVT, and 164,208 (3.3%) cases had a diagnosis of acute PE. Overall, death for lung cancer cases was 516,070(10.5%). Death rate in patients with DVT was 12.4%(frequency = 13,943). DVT and death during hospitalization were positively associated, X^2 (1, N = 4,936,702) = 578.792, $p < .001$. Rate of death for PE was 15.5% (25,360). PE and death during hospitalization were positively associated as well, X^2 (1, N = 4,936,702) = 4540.012, p .000. DVT was associated with a prolonged length of stay (M = 8.66 days, SD = 8.8.624), compared to cases without DVT (M = 6.42 days, SD = 6.42), t(4,940,122) = 115.02, p = .000. DVT was also associated with increased total charges of hospitalization (M = $ 62,950, SD = 85,105), compared to cases without DVT (M = $ 41,764, SD = 55,410), t(4,864,517) = 124.09, p = .000. PE was associated with a prolonged length of stay (M = 8.01 days, SD = 8.13), compared to cases without PE (M = 6.42 days, SD = 6.41), t(4,940,122) = 97.89, p = .000. PE was also associated with increased total charges of hospitalization (M = $ 56,161, SD = 76,585), compared to cases without PE (M = $ 41,772, SD = 55,468), t(4,864,517) = 100.85, p = .000. **Conclusions:** DVT and PE are common complications of Lung Cancer. They are associated with increased mortality in these patients. DVT increases the mean LOS by 2.24 days, and mean charges by $21,186. PE increases the mean LOS by 1.59 days, and the mean charges by $14,389. Prevention of DVT and PE could help bring down the mortality, LOS and charges of hospitalization. This data provides support to the usage of prophylactic anticoagulation in patients with lung cancer as shown in recent trails with Direct Acting Oral Anticoagulants(DOACs), and further study of DVT/PE in Lung cancer patients would be warranted. The association of early integrated rehabilitation and moderate or severe fatigue in 600 patients with breast cancer: A comparison between the intervention group and control group in a prospective study. *First Author: Nikola Besic, Institute of Oncology Ljubljana, Ljubljana, Slovenia*

Background: Fatigue after breast cancer treatment is a major health problem that is very difficult to treat. Our aim was to determine whether the early introduction of focused rehabilitation from the start of the cancer treatment is associated with the frequency of fatigue in breast cancer patients. **Methods:** The subjects of our prospective study were 600 female breast cancer patients (26-65 (mean 52) years of age), who participated in the pilot study on the individualized integrated rehabilitation of breast cancer patients in 2019-2022 and were followed for at least six months. The control group included 300 patients and the intervention group 300 patients. The patients completed three questionnaires (EORTC QLQ - C30, B23 and NCCN): before and six months after the beginning of cancer treatment. The control group obtained the same rehabilitation as was offered to all breast cancer patients in our hospital before the start of our study. The multidisciplinary rehabilitation team reviewed the documentation of all the patients from the intervention group before six months after the beginning of treatment and recommended appropriate interventions according to the patient's problems. The integrated rehabilitation coordinator referred patients for additional treatments in compliance with the institute's new clinical pathway (psychologist, general practitioner, nutritional treatment, physical rehabilitation, kinesiologist-guided online exercises, gynaecologist, analgesia, vocational rehabilitation). Data on the patients' demographics, disease extent, cancer treatment and complaints reported in questionnaires were collected. This data and the frequency of fatigue six months after the beginning of treatment in both groups of patients were analysed using the chi-square and ANOVA test. **Results:** There were no differences between the control and the intervention group of patients in terms of age, education, disease extent, surgical procedures, systemic cancer treatment, or radiotherapy. There were no differences between the groups in the prevalence of fatigue before the start of treatment. Before the cancer treatment, 50% of the patients in both groups reported fatigue, while moderate or severe fatigue was reported in the intervention and control groups in 9% and 10% ($p = 0.69$), respectively. Six months after the beginning of cancer treatment, fatigue was reported in the intervention and control groups in 66% and 70% ($p = 0.38$), respectively. However, moderate or severe fatigue were reported in the intervention and control groups in 17% and 26% ($p = 0.02$), respectively. **Conclusions:** Early integrated rehabilitation is associated with a lower prevalence of moderate or severe fatigue in breast cancer patients in comparison to the control group six months after the beginning of cancer treatment. Racial differences in cardiovascular disease mortality among cancer survivors. *First Author: Hyuna Sung, American Cancer Society, Atlanta, GA*

Background: Cancer survivors have an elevated risk of death from cardiovascular disease (CVD). Whether the risk differs by race/ethnicity and cancer type has not been fully explored in the U.S. **Methods:** Data from survivors of top 23 cancers diagnosed at ages 20 to 64 years during 2000-2018 were obtained from 17 Surveillance, Epidemiology, and End Results registries. Risks for CVD death among survivors relative to the general population were calculated using standardized mortality ratios (SMRs) in each racial/ethnic group: Non-Hispanic White (NHW), Non-Hispanic Black (NHB), Hispanic, Non-Hispanic Asian or Pacific Islander (API), and Non-Hispanic American Indian (AI). Among survivors, the risks were compared by race/ethnicity using cause-specific proportional hazards models for competing risks, controlling for year of diagnosis, age at diagnosis, sex, stage (when appropriate), and the first course of treatment receipt (surgery, radiotherapy, chemotherapy). **Results:** Among 2,806,515 survivors (NHW, 68%; NHB, 13%; Hispanic, 12%; API, 7%; AI, 0.5%), 57,883 CVD deaths occurred during 6.4 person-years of mean follow-up (32 per 10,000). Cancer survivors overall were at increased risk of CVD death compared to their general population counterpart with an SMR of 1.76 among API (95% CI = 1.69-1.84; 8.7 excess deaths per 10,000), 1.49 among AI (95% CI = 1.33-1.68; 11.9 excess deaths per 10,000), 1.46 among Hispanic (95% CI = 1.41-1.50; 7.4 excess deaths per 10,000), 1.30 among NHB (95% CI = 1281-1.33; 14.9 excess deaths per 10,000), and 1.13 among NHW (95% CI = 1.12-1.14; 3.4 excess deaths per 10,000) survivors. Compared with NHW survivors, the adjusted hazard of CVD death was statistically significantly higher among NHB survivors for 23/23 cancers and among AI survivors for 9/18 cancers but was statistically significantly lower among Hispanic survivors for 5/23 cancers and among API survivors for 10/23 cancers, with no significant difference otherwise. The highest hazards ratios (HRs) were among NHB survivors of melanoma (HR = 3.19, 95% CI = 2.11-4.83); breast (HR = 2.73, 95% CI = 2.57-2.89); pancreatic (HR = 2.63, 95% CI = 2.19-3.16); and testicular (HR = 2.59, 95% CI = 1.62-4.14) cancers, whereas the lowest HRs were among API survivors of head and neck (HR = 0.53, 95% CI = 0.44-0.63) and cervical (HR = 0.57, 95% CI = 0.41-0.80) cancers and Hispanic survivors of cervical cancer (HR = 0.59, 95% CI = 0.46-0.75). **Conclusions:** The risk of CVD death differs considerably among cancer survivors by race/ethnicity and cancer types, highlighting the need for targeted prevention and surveillance in primary care. Future studies are needed to identify factors that contribute to this variation in order to inform efforts towards mitigating risk. Research Sponsor: None.

SNP-SNP interactions and a 4-locus model for prediction the risk of anthracycline-mediated cardiotoxicity in patients with breast cancer. *First Author: Dmitry Yu. Gvaldin, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation*

Background: Numerous pharmacogenetic studies have identified genetic polymorphisms (SNPs) associated with an increased risk of anthracycline-mediated cardiotoxicity (AMC). The purpose was to search for SNP-SNP interactions associated with the risk of cardiotoxic manifestations caused by anthracycline therapy in breast cancer patients. **Methods:** The study included 256 Caucasian patients (median age - 55 years) with a diagnosis of breast cancer with normal cardiovascular system parameters at baseline, who were treated with anthracyclines in 2019-2020. For SNP genotyping of c.4544G > A rs8187710 (ABCC2), c.1744C > T rs11549465 (*HIF1A*), g.22125504G > C rs1333049 (*CDKN2A/B*) and c.214T > C rs4673 (*CYBA*). DNA was extracted from blood by using DNA-sorb-B (AmpliSens, Russia). HRM-PCR was performed on a CFX96 amplifier (Bio-Rad, USA). The presence of polymorphism was confirmed by the Sanger method on a Genetic Analyzer 3500 (ABI, USA). **Results:** During the follow-up period 21 (8.2%) patients developed signs of subacute (changes developed within several weeks after the last course of therapy) or early chronic anthracycline mediated cardiotoxicity (changes developed within a year after completion of anthracycline therapy). Using the multifactorial dimension reduction method. We obtained a 4-locus model of SNP-SNP interactions c.4544G > A rs8187710 (*ABCC2*) x g.22125504G > C rs1333049 (*CDKN2A/B*) x c.214T > C rs4673 (*CYBA*) x g.23708527G > A rs28714259 which has high prognostic properties. The specificity of the test based on the 4-locus model was 68%, the sensitivity was 100%, and the overall accuracy was 71%. The results of the analysis of SNP-SNP interactions indicate the greatest contribution of rs4673 and rs28714259 to the predisposition to AMC. The first ones yet into antagonistic interactions with rs28714259, rs1333049 and rs11549465, the second with rs8187710, rs11549465 and rs4673. On the contrary rs11549465 and rs1333049 contribute to a synergistic effect. **Conclusions:** The 4-locus model discovered in this study can form the basis of prognostic tests that predict early the risks of developing AMC in cancer patients, which in the future allow to personalize and select the most optimal treatment regimen. Polymorphism rs4673 and plasma paraoxonase 1 level for prediction and early diagnosis of anthracycline-mediated cardiotoxicity in patients with breast cancer. *First Author: Dmitry Yu. Gvaldin, National Medical Research Centre for Oncology, Rostov-on-Don, Russian Federation*

Background: Anthracyclines are highly effective chemotherapeutic agents, used for a wide variety of malignancies. Despite their antitumor efficacy there is a risk of cardiotoxic manifestations that reduce the time and quality of life of patients. The purpose was to study the effectiveness of molecular genetic tests based on rs4673 *CYBA* genotyping (c.242C > T) and measurement of plasma paraoxonase 1 (PON1) level in patients with breast cancer (BC) for predicting and diagnosing anthracycline-mediated cardiotoxicity (AMC). **Methods:** The study included 256 Caucasian patients (median age - 55 years) with a diagnosis of breast cancer normal cardiovascular system parameters at baseline, who were treated with anthracyclines in 2019-2020. For rs4673 genotyping, DNA was extracted from the blood by using DNA-sorb-B (AmpliSens, Russia). HRM-PCR was performed on a CFX96 amplifier (Bio-Rad, USA). The presence of polymorphism was confirmed by the Sanger method on a Genetic Analyzer 3500 (ABI, USA). The concentration of PON1 in blood plasma was measured at baseline and after 4 course of chemotherapy with anthracyclines using ELISA kits (Cloud-Clone Corp., China/USA). **Results:** During the follow-up period 21 (8.2%) patients developed signs of subacute (changes developed within several weeks after the last course of therapy) or early chronic AMC (changes developed within a year after completion of anthracycline therapy). In the group of patients without AMC the frequency of the minor allele rs4673 (c.214C > T *CYBA*) was 0.38, the frequency of genotypes C/C was 0.4, C/T - 0.43, and T/T - 0.17. The risk of AMC increased by 6.49 times in the presence of the rs4673 polymorphic allele (p = 0.002). The area under the ROC curve of the test based on rs4673 genotyping was 71.9%. The concentration of PON1 after the 4 courses of chemotherapy increased by 19.57% in the group of patients without cardiotoxic manifestations (p = 0.018) and in the group of patients with AMC by 20.23% (p = 0.007) as compared to the initial level. Besides, after 4 courses of chemotherapy the PON1 level was higher in patients with AMC by 25.08% (p = 0.026) than in patients without cardiovascular complications. The sensitivity of the test based on the measurement of the PON1 level in the blood plasma after 4 courses of chemotherapy was 100%, the specificity was 70.8% with a cut-off value of 2.9 ng/ml. **Conclusions:** This study has showed that genotyping of patients for the rs4673 polymorphism allows pre-stratification of the risk group white determination of the PON1 level in blood plasma after 4 courses of chemotherapy gives the opportunity to identify patients with AMC and promptly correct the chosen treatment. Research Sponsor: None.

CT scan versus bioelectrical impedance spectrometry sarcopenia assessment to predict chemotherapy toxicity in early breast cancer. *First Author: Gabriel Aleixo, Cleveland Clinic Foundation, Cleveland, OH*

Background: There is growing literature on the impact of the progressive loss of skeletal muscle known as sarcopenia in women with early breast cancer (EBC). Imaging techniques such as Computed Tomography (CT) scans are the most studied methods to detect sarcopenia in patients with cancer; however, most patients with EBC do not require routine CT scans. Bioelectrical impedance spectrometry (BIS) is a method that does not expose patients to radiation and provides measurements to assess sarcopenia instantaneously. The extent to which BIS-assessed sarcopenia correlates with CT-assessed sarcopenia is uncertain. It is also unclear whether sarcopenia detected with either method can be associated with chemotherapy tolerance To address these questions, we evaluated the correlation between CT and BIS sarcopenia and associations of sarcopenia by each method with chemotherapy related outcomes in patients with EBC. **Methods:** This retrospective study identified patients with EBC who received chemotherapy (ACT, TC, TH, THP), underwent BIS analyses (ImpediMed) at any point between diagnosis and treatment completion and also received a CT abdomen including L3 level. Axial CT L3 segments were analyzed using Slice-O-Matic software. CT L3, and BIS generated the Skeletal Muscle (SM). Skeletal Muscle Index (SMI) was then calculated to assess for sarcopenia: BIS SMI= (SM in kg)/ (patient height, m2) and CT L3 SMI (SM cm2/ height m2). Patients were divided into normal SMI, and sarcopenia (if BIS was used SMI <6.75 kg/m2 and if CT SMI <40 cm2/m2). Patient medical records were reviewed for patient characteristics, grade 3 and 4 toxicity, including neuropathy symptoms, chemotherapy dose reductions, early treatment discontinuation or need for hospitalization during chemotherapy treatment. Spearman's rank coefficient was used to assess the correlation between CT SMI and BIS SMI. Multivariable logistic regression was used to associate sarcopenia with outcomes, controlling for age and BMI. **Results:** 361 patients received chemotherapy, underwent BIS; of those 171 had L3 CT scans. The correlation between L3 CT SMI and BIS SMI was r= 0.64 p<0.0001. In the multivariable model, sarcopenia assessed by L3 CT scan was associated with chemotherapy dose reduction (CI 0.04-0.60 p=0.01) and neuropathy (CI 0.10-0.95 P=0.04) but not with grade 3 or 4 chemotherapy toxicity (CI 0.13-1.09 p=0.07), early treatment discontinuation (p=0.3) or hospitalization (p=0.60). Sarcopenia assessed by BIS was associated with grade 3 or 4 chemotherapy toxicity (CI 0.2-0.83 p=0.01), neuropathy (CI 0.1-0.51 p=0.0003), early treatment discontinuation (OR 0.26 CI 0.11-0.80 p=0.001), and hospitalization (CI 0.12-0.68 p=0.004). **Conclusions:** There is a strong correlation between L3 CT scan and BIS screened sarcopenia in patients with EBC. Sarcopenia detected with either CT L3 or BIS is associated with worse chemotherapy tolerance. Research Sponsor: HONORS award from American Society of Hematology.

Change in telomere length and cardiovascular risk in testicular cancer survivors. *First Author: Ellen L.D. Volders, Department of Medical Oncology, University Medical Center Groningen, Groningen, Netherlands*

Background: Testicular cancer (TC) survivors cured with chemotherapy (CT) are prone to develop cardiovascular events, as part of an early aging phenotype. Telomere shortening could be a mechanism contributing to these events and their risk factors. **Methods:** In a prospectively followed cohort of patients with disseminated TC who received cisplatin containing CT (Lubberts et al., Eur J Cancer 2016), mean absolute leukocyte telomere length (TL) was measured using qPCR before and one year after start of cisplatin containing CT. Cardiovascular risk factors, including development of the metabolic syndrome (according to the NCEP ATP III definition) and hypogonadism (LH >10 U/L or testosterone < 10 nmol/L or use of testosterone suppletion), were assessed before and up to 5 years after CT. Shortening of TL was defined as a decrease of >33% after one year compared to baseline; short TL was defined as <5 kilobase (kb) pair (=P25). Data are presented as median (range). For comparisons, a Mann-Whitney U or Chi-Square test was applied. **Results:** 55 out of 73 patients of the initial cohort were evaluable for this analysis. CT regimens consisted of 3xBEP (n=41), 4x BEP (n=11), 4xEP (n=3). At baseline, patients with a BMI > 30 kg/m2 (n=12) had a shorter TL (4.9 (2.2-13.4) vs. 6.3 kb (3.1-12.9), p= .045); there was no difference in age. For the whole group, TL did not change one year after CT compared to baseline (5.7 (2.2-13.4) vs. 5.8 kb (1.6-19.2), p=.335). Patients with TL shortening after 1 year (n=7) showed a significant increase in diastolic blood pressure (p=.007) and triglycerides (p=.003), compared to those with unchanged TL (table). TL shortening after 1 year or short TL at baseline (n=7+11) are not significant predictors for newly developed metabolic syndrome (25 vs. 21%; p=.777), nor hypogonadism (38 vs. 17%; p=.120) after 5 years, compared to the others. **Conclusions:** A small subset of TC patients treated with cisplatin containing CT showed shortening of TL 1 year after treatment. This shortening is associated with a rise in diastolic blood pressure and triglycerides. Short or shortening of telomeres are not predictive for development of the metabolic syndrome or hypogonadism. Research Sponsor: Dutch Cancer Society.

Impact of adverse health outcomes (AHOs) on self-reported physical and mental health in U.S. testicular cancer survivors (TCS). *First Author: Paul C. Dinh, Indiana University School of Medicine, Indianapolis, IN*

Background: No study has systematically evaluated the impact of AHOs on PROMIS-validated measures of physical and mental health in TCS. Patient-reported outcomes are increasingly recognized as crucial in TCS follow-up, given their young age at diagnosis and high cure rates. **Methods:** Eligible TCS (age < 60 yr at diagnosis, given first-line cisplatin-based chemotherapy (CHEM)) completed comprehensive health surveys, prescription drug usage, and PROMIS global physical health and global mental health measures. PROMIS scores were compared to US subpopulation norms for similar-age men. 2017-2018 NHANES data were compared with select survey responses. Linear regression examined the relationship between individual AHOs (pain, obesity, cisplatin-induced peripheral neuropathy (CIPN)), cisplatin-related AHOs (CIPN, hearing loss, vertigo, tinnitus, renal disease), cardiovascular (CVD) AHOs (7 AHO), and all AHOs taken together (24 AHOs), with PROMIS global physical and mental health measures. Regression models were adjusted for age, cisplatin dose, time since CHEM, education, income, smoking, and alcohol. **Results:** Among 213 TCS (median age at evaluation: 46 yr; IQR: 38-52 yr; median time since CHEM completion: 10.6 yr; IQR: 6.8-16.6 yr), the most common AHOs were tinnitus (60%), self-reported hearing loss (60%), CIPN (55%), and Raynaud Phenomenon (43%). The median number of AHOs was 5 (IQR: 3-7), and 12% of TCS had ≥10 AHOs. Only 1.4% of TCS had no AHOs. Compared to NHANES men without cancer, controlling for age, education, and race, fewer TCS currently smoked (3% vs. 22%; P< .001) and fewer were obese (31% vs. 43%, P= .026) but alcohol intake was comparable. However, TCS had significantly lower physical (mean: 48.5 vs. 51.2, P< .001) and mental health (mean: 48.4 vs. 50.8, P< .001) than US men. Increasing numbers of AHOs were significantly associated with decreasing physical (P< .001) and mental health (P< .001) after adjustment. The magnitude of effect was strongest for the number of cisplatin-related AHOs with both physical (β: -1.3; 95% CI: -1.9, -0.7; P< .001) and mental health (β: -1.3; 95% CI: -2.1, -0.4; P= .003) after adjustment. In individual AHO adjusted models, CIPN (β: -1.8; 95% CI: -3.3, -0.4), pain (β: -5.0; 95% CI: -6.8, -3.2) and obesity (β: -2.7; 95% CI: -4.3, -1.1) were significantly associated with decreased physical health. Only pain (β: -5.9; 95% CI: -8.4, -3.4) and CIPN (β: -2.0; 95% CI: -4.0, -0.1), but not obesity, were associated with decreased mental health. **Conclusions:** At a median of 11 years after CHEM completion, 50% of TCS have ≥5 AHOs, and over 1 in 10 have ≥10 AHOs. AHO following cisplatin chemotherapy have major deleterious impacts on patient-reported measures of physical and mental health. Future survivorship research should focus on developing preventive and interventional strategies to care for TCS most vulnerable for impaired physical and mental health after CHEM. Research Sponsor: U.S. National Institutes of Health.

Effects of exercise during adjuvant chemotherapy for breast cancer on long-term cardiotoxicity. *First Author: Willeke Naaktgeboren, UMC Utrecht, Utrecht, Netherlands*

Background: A common conception is that exercise training is cardioprotective for patients with breast cancer receiving adjuvant chemotherapy, but evidence to support this assertion is limited. This study aims to evaluate the effect of exercise training during adjuvant chemotherapy for breast cancer on long-term structural and functional cardiac outcomes. **Methods:** This is a follow-up study of two previously performed randomized studies in breast cancer patients; the PACT (N = 204) and PACES (N = 230) study. Cardiac outcomes, including extracellular volume fraction (ECV), left ventricular ejection fraction (LVEF) on cardiac MRI and global longitudinal strain (GLS) on echocardiography, were evaluated in patients allocated to moderate-to high-intensity exercise and non-exercise controls using linear and logistic regression models, adjusted for relevant confounders. Additionally, we explored the influence of self-reported PA during chemotherapy on cardiac outcomes, regardless of treatment allocation. **Results:** In total, 185 breast cancer survivors were included (mean age 58.9±7.8 years, mean time since treatment 8.5±1.1 years). Mean ECV was 25.3±2.5 in the control group and 24.6±2.8 in the exercise group. Mean LVEF was borderline normal in both (54.6±4.9 and 53.0±7.8) with an LVEF < 50% of 17.1% and 27.8% in control and exercise group, respectively. Compared to control, no significant effect of exercise during chemotherapy on ECV (β = -0.61, 95%CI: -1.55;0.32) or on abnormal ECV (OR = 0.80, 95%CI: 0.26;2.45) was found. Native T1 was statistically significantly lower in the exercise group compared to control (β = -16.75%CI: -31.5 ;-1.93). The odds of having an abnormal native T1 appeared lower in the exercise group (OR 0.58, 95%CI: 0.28;1.17). We found no benefit of exercise for LVEF or GLS (β = -1.82, 95%CI: -4.06;0.42 and β = 0.21, 95%CI: -0.87;1.28), nor on the likelihood of having an abnormal LVEF or GLS (OR = 1.78, 95%CI: 0.79;4.16); OR = 1.21, 95%CI: 0.56;2.63), respectively. Higher self-reported physical activity levels during chemotherapy tended to be associated with better cardiac outcomes. **Conclusions:** Exercise training during chemotherapy was not associated with long-term cardioprotection in patients with early-stage breast cancer. The high prevalence of cardiac abnormalities years post-chemotherapy suggests the need to include cardiac assessment in long-term follow-up programs for breast cancer survivors and calls for more research on cardioprotective measures during adjuvant chemotherapy, including alternative exercise dosing regimens and pharmacological adjuncts. Clinical trial information: NTR7247. Research Sponsor: KWF/Alpe, 10325 / 2016-1.

Thromboembolism (TE) and association with survival in patients (pts) with melanoma receiving chemo– or immunotherapy. *First Author: Tamara A. Sussman, Dana-Farber Cancer Institute, Boston, MA*

Background: Emerging reports suggest high rates of venous thromboembolism (VTE) and arterial thromboembolism (ATE) with immune checkpoint inhibitors (ICI) in pts with melanoma, but it is unclear whether these are truly increased compared to older systemic therapy approaches. We assessed the incidence of TE in melanoma pts on ICI, cytokine therapy (CY), and chemotherapy (chemo), and evaluated its impact on survival. **Methods:** We conducted a cohort study using the SEER-Medicare database to evaluate rates of TE in pts with melanoma treated from 2008-2019 with ICI (ipilimumab, nivolumab, pembrolizumab), CY (IL2, IFN), and/or chemo (antineoplastic agents, BRAF/MEK inhibitors) within two years of treatment initiation. TE including VTE events of deep venous thrombosis, pulmonary embolism, and ATE of MI, ischemic stroke, and transient ischemic attack were identified by at least two outpatient claims or one inpatient claim. Overall survival (OS) from treatment start was analyzed by time-varying Cox analysis. **Results:** The cohort comprised 13,124 pts with median age 75 (24-101) years and 68% male. Of these, 14.8% received ICI, 48.9% chemo, 1.7% CY, 31.8% chemo+ICI, and 2.8% chemo+CY. At treatment start, comorbidities included 72% of pts with hypertension, 33% cerebrovascular disease, 17% atrial fibrillation, 7.3% history of VTE, and 13.0% history of ATE. Overall, 11.4% were on anticoagulation and 5.2% on antiplatelet agents. Incidence rates of ATE and VTE after treatment start are shown (Table). VTE was highest at 3 months after starting therapy with 19.6 events per 100 person-years in those receiving chemo+ICI, 17.1 events with chemo, 15.4 events with ICI, 10.1 events with chemo+CY, and 7.7 events with CY. In multivariable analysis, VTE and ATE were associated with worse OS compared to patients without (HR 2.77 [95%CI, 2.50-3.08], and HR 2.53 [95%CI, 2.23-2.86], respectively). **Conclusions:** Systemic therapy with ICI and chemo, especially when exposed to both sequentially or concurrently, demonstrates a high incidence of TE in pts with melanoma. TE is associated with substantial worsening of survival. TE rates are not substantially increased with ICI in comparison to chemo. Further studies are needed to identify benefit of thromboprophylaxis. Research Sponsor: Sondra and Stephen Hardis Endowed Chair to Dr Khorana.

Adverse health outcomes (AHO) in testis cancer survivors (TCS) following high-dose chemotherapy (HDCT) and autologous stem cell transplant. *First Author: Meagan Elizabeth Miller, Indiana University School of Medicine, Indianapolis, IN*

Background: Patients with relapsed/refractory germ cell tumors are often cured with tandem platinum-based HDCT followed by autologous stem cell transplant in the ≥2nd line treatment setting. A comprehensive assessment of long-term AHO (adverse health outcomes) in TCS cured with HDCT has not been previously described. **Methods:** Testis cancer survivors (TCS) at least 1 year after HDCT and treated at Indiana University were eligible. TCS were asked to complete a comprehensive, well validated survey regarding 19 different AHO. TCS demographics, disease characteristics, treatment received, and AHO were collected. **Results:** From 2/2021-1/2022, 118 eligible TCS were invited. 70 TCS completed the survey (59.3% completion rate). TCS received HDCT followed by autologous stem cell transplant in the 2nd (91.4%), 3rd (7.1%) or 4th line (1.4%) setting. At the time of survey completion, 93% of respondents were at least two years from HDCT (range 1.6-16.2 y) with a median age of 42 y (range 24.8-66.6 y). Median age at the time of original germ cell tumor diagnosis was 32 y (range 17.4-56.8 y). TCS reported a median of 3 AHO with 37% of participants reporting 5 or more AHO. 90% of participants reported tinnitus, 91% experienced hearing impairment, and 52% required the use of hearing aids. Additionally, 46% TCS noted peripheral neuropathy and 26% reported problems with balance/vertigo/dizziness. Prevalence of kidney disease was 10%, and 24% TCS experienced erectile dysfunction. In regards to physical activity, 47% of participants were not participating in vigorous physical activity (defined as > 6 mets/week). 16% TCS reported use of medications to treat anxiety and/or depression, and 19% required testosterone replacement therapy. The prevalence of hypertension, coronary artery disease, Raynaud phenomenon, hypercholesterolemia, diabetes, and thyroid disease were 13%, 1%, 17%, 12%, 4%, and 6% respectively. **Conclusions:** Despite the high cure rate of HDCT, TCS report a substantial burden of morbidity with the majority experiencing ototoxicity, and with half of the TCS requiring hearing aids. Special attention to these AHO and efforts to develop ototoxicity prevention approaches are urgently needed for this patient population. Research Sponsor: None.

Impact of anti-HER2 therapy alone and in association with weekly paclitaxel on the ovarian reserve of young women with HER2-positive early breast cancer: Biomarker analysis of the NeoALTTO trial. *First Author: Matteo Lambertini, IRCCS Ospedale Policlinico San Martino-University of Genova, Genoa, Italy*

Background: The potential gonadotoxicity of anti-HER2 agents remains largely unknown and limited conflicting evidence exists for taxanes. Anti-Mullerian hormone (AMH) is an established biomarker of ovarian reserve; its measurement during systemic therapies may aid in indicating gonadotoxicity, in the diagnosis and prediction of primary ovarian insufficiency (POI). The present analysis explored for the first time the impact of anti-HER2 therapy alone and then combined with weekly paclitaxel on ovarian reserve measured by AMH levels in breast cancer (BC) patients not previously exposed to anthracycline and cyclophosphamide. **Methods:** This biomarker analysis of the NeoALTTO (NCT00553358) randomized phase III neoadjuvant trial included premenopausal women aged ≤45 years at diagnosis of HER2-positive early BC with available frozen serum samples at baseline (i.e. before administering any anticancer treatment), at week 2 (i.e. "biological window" of anti-HER2 therapy alone) and/or at the time of surgery (i.e. after completion of paclitaxel plus anti-HER2 therapy and before starting adjuvant chemotherapy). Central AMH testing was performed with the Roche Elecsysâ AMH Plus assay (LoD = 0.01 ng/ml). AMH levels during anti-HER2 therapy alone and then combined with paclitaxel were assessed as a measure of treatment acute gonadotoxicity. The impact of different anti-HER2 agents, patients' age, and baseline AMH levels on treatment gonadotoxicity were also investigated. **Results:** The present analysis included 130 patients with a median age of 38 years (IQR: 33-42 years). AMH values at the 3 time points differed significantly from each other ($p < 0.001$). At baseline, median AMH levels were 1.29 ng/mL (IQR 0.56 – 2.62 ng/mL). At week 2, a small but significant reduction in AMH levels was observed (median value: 1.10 ng/mL, IQR 0.45 – 2.09 ng/mL, $p < 0.001$). At surgery, there was a larger significant decline in AMH levels (median value: 0.01 ng/mL, IQR 0.01 – 0.03 ng/mL, $p < 0.001$). There was no significant difference between treatment arms (trastuzumab vs. lapatinib vs. trastuzumab plus lapatinib) in the degree of reduction in AMH levels at week 2 ($p = 0.763$) and at surgery ($p = 0.700$). Age and pre-treatment ovarian reserve had a major influence on treatment-induced gonadotoxicity risk, with older age and lower AMH levels at diagnosis being associated with a greater negative impact. **Conclusions:** This biomarker analysis of the NeoALTTO trial showed for the first time that anti-HER2 therapies alone had limited gonadotoxicity but the addition of weekly paclitaxel resulted in marked AMH decline which likely has implications for subsequent ovarian function and fertility. These data highlight the importance of oncofertility counselling among all premenopausal women with HER2-positive BC receiving systemic anticancer treatments. Clinical trial information: NCT00553358. Open-label, phase 2 study of roxadustat for treatment of anemia in patients receiving chemotherapy for non-myeloid malignancies. *First Author: John A. Glaspy, University of California Los Angeles School of Medicine, Los Angeles, CA*

Background: Anemia is prevalent in patients (pts) receiving myelosuppressive chemotherapy (> 60%) and exacerbated by repeated treatment cycles due to cytotoxic agent accumulation. Chemotherapy-induced anemia (CIA) management options are suboptimal. We evaluated the efficacy and safety of roxadustat in pts with anemia receiving myelosuppressive chemotherapy. **Methods:** This open-label, single-arm, proof-of-concept Phase 2 study included pts with mostly advanced, non-myeloid malignancies and CIA (hemoglobin [Hb] ≤10 g/dL) who had not received red blood cell (RBC) transfusion or erythropoietin-stimulating agents within 4 weeks of enrollment. Patients were treated with oral roxadustat for ≤16 weeks. The primary efficacy endpoint was maximum mean change in Hb within 16 weeks of baseline without RBC transfusion in pts who had received ≥1 dose of roxadustat and who had a baseline and ≥1 post-dose Hb assessment. Hb response and safety data were preliminarily assessed in pts receiving a starting dose of 2.0 mg/kg thrice weekly (TIW) for 4 weeks: doses of 100, 150, and 200 mg were given to pts weighing < 70, 70–100, and > 100 kg, respectively. Following a review of data from these pts, dose was increased to 2.5 mg/kg—150, 200, and 250 mg TIW to pts weighing < 70, 70–100, and > 100 kg, respectively—and adjusted every 4 weeks from Week 5 based on Hb response. **Results:** Patients were assigned to 2.0 mg/kg (n = 31) and 2.5 mg/kg (n = 61) starting doses, and 89 were assessed for efficacy. The maximum mean Hb change from baseline without RBC transfusion was 2.47±1.51 g/dL and 2.52±1.54 g/dL in the 2.0 mg/kg and 2.5 mg/kg cohorts, respectively. Hb increased by ≥1.5 g/dL in 73% of pts and ≥2.0 g/dL in 61% of pts. Median time to ≥2.0 g/dL Hb increase was 71.0 days. Both cohorts had higher proportions of pts with a Hb increase of ≥1, ≥1.5, or ≥2 g/dL at Week 16 compared with baseline. Median time to ≥1 and ≥2 g/dL Hb increase was shorter in pts who started on 2.5 mg/kg compared with 2.0 mg/kg doses (≥1 g/dL: 30 vs 44; ≥2 g/dL 57 vs 105, respectively). Fewer pts required an RBC transfusion (Week 5 to end of treatment) when starting on 2.5 mg/kg compared with 2.0 mg/kg doses (10.2% vs 20.0%). Subgroup analyses based on major tumor and baseline chemotherapy types demonstrated efficacy of roxadustat at both starting doses. The overall safety profile observed was consistent with the patient population under study. Overall, 92% of pts experienced an adverse event (AE). Most AEs were consistent with the underlying malignancies and chemotherapy regimens used. The incidence of deep vein thrombosis was 15.2% (n = 14) and pulmonary embolism was 9.8% (n = 9). There were 17 deaths (18.5%) during the study; none were attributed to roxadustat, and most were associated with disease progression. **Conclusions:** Roxadustat increased Hb in CIA regardless of tumor type and chemotherapy regimen. These data support additional clinical study. Clinical trial information: NCT04076943. Research Sponsor: FibroGen, Inc.

Cancer diagnosis, cancer treatment, and association with cardiovascular disease in older adults: Results from ASPREE. *First Author: Jaidyn Muhandiramge, School of Public Health and Preventive Medicine, Monash University, Melbourne, VIC, Australia*

Background: New treatments and early detection measures have led to declines in cancer mortality rates and a growing population of cancer survivors at risk of short- and long-term effects of cancer and cancer treatment (C&CT), including cardiovascular disease (CVD). Although shared risk factors may contribute, several C&CT-related mechanisms including inflammation, treatment-related cardiotoxicity, and coagulation disorders may play a role. There are several studies exploring the link between C&CT and CVD; however, many do not examine risk stratified by cancer type or disease extent, nor investigate the impact of different treatment modalities. **Methods:** This analysis utilized data from the ASPirin in Reducing Events in the Elderly (ASPREE) trial, an international, multi-center, double-blinded randomized controlled trial that investigated the benefits and risks of aspirin in healthy older people. Multivariate time-dependent Cox regression models (adjusted for clinically significant factors including age, gender, smoking, and metabolic disease) were used to investigate the impact of C&CT on myocardial infarction, stroke, hospitalization for heart failure, and a composite endpoint combining these. Crude incidence rates were estimated using a competing risks regression model. Subgroup analysis was performed by metastatic status, cancer type, and treatment modality. **Results:** Of the 19,114 ASPREE participants (56% female; median age 75.1 years; median follow up 4.7 years), 1,933 received a post-randomisation cancer diagnosis. Participants with cancer had a greater rate and risk of CVD than those without cancer (15.3 per 1000 person-years (/1000pyrs] vs 10.5/1000pyrs, respectively; Hazard Ratio [HR] = 1.70, 95% Confidence Interval [CI] 1.32-2.10). The greatest increase in risk was seen for hospitalization for heart failure (HR 2.00, 1.18-3.38, 95% CI 1.18-3.38), although increases in risk were also seen for myocardial infarction, all-stroke, and ischaemic stroke. In subgroup analysis by cancer type, blood cancer (HR 2.33, 95% CI 1.25-4.36), lung cancer (HR 2.76, 95% CI 1.23-6.19), and melanoma (HR 1.97, 95% CI 1.02-3.82) were associated with an increased risk of composite CVD. 'Any cancer treatment' conferred increased risk of hospitalisation for heart failure (HR 1.78, 95% CI 1.15-2.75), although individual treatment modalities, including cytotoxic chemotherapy, targeted therapy, and radiotherapy conferred increased risks of various cardiovascular outcomes. **Conclusions:** Our findings indicate that both cancer and anti-cancer treatment confer risk for CVD in the elderly, the magnitude of which varied depending on cancer type and treatment modality. Given the implications of cardiovascular events for quality of life and mortality, these results support the integration of CVD screening and management into routine care for cancer survivors. Trajectory of aging following diagnosis of cancer. *First Author: Morgan Simons, NYU Grossman School of Medicine, New York, NY*

Background: Aging is a nebulous concept with several definitions, but they all generally include physical and cognitive decline in function as a key component. We hypothesized that following cancer diagnosis, patients decline in physical and cognitive function would correspond with accelerated and/or accentuated aging trajectories. The magnitude of the functional changes could inform strategies to minimize impact of cancer diagnosis on trajectory of aging. **Methods:** We analyzed 32,935 participants >50 years enrolled between 1995-2018 in the Health and Retirement Study (HRS), a population-based, biennial longitudinal health interview survey of older adults in the United States. We assessed the changes in physical and cognitive function among cancer patients controlling for their pre-cancer trajectories and comparing it with aged population with no cancer diagnosis as control. The primary outcomes were change in physical function (Activities of Daily Living (ADL) and Instrumental Activities of Daily Living (IADL): range 0–11) and global cognitive function (Telephone Interview for Cognitive Status (TICS): range 0–27). The secondary outcome was change in self-rated health (SRH: range 1-5). We estimated the effect of acute change based on the immediate post-cancer outcome measurements compared to the trajectories before cancer; and the long-term effect as the per-year change in outcome decline post cancer compared to aging of cancer-free respondents adjusting covariates by linear mixed models. **Results:** 5,101 developed incident cancer: 1,514 in the 50-64 age group, 1,901 in the 65-74 age group, and 1,686 in the 75+ age group. 27,834 participants were cancer-free throughout. Cancer was associated with acute declines in physical function (0.06 [0.01– 0.10] and 0.25 [0.14– 0.36] points), cognitive function (0.22 [0.04–0.39] and 0.24 [0.01– 0.46] points), and SRH (0.19 [0.14–0.23] and 0.22 [0.12–0.33] points) for age of onset groups 50- and 75+ respectively. Moreover, participants with cancer demonstrated accelerated decline in physical function (0.02 [0.01–0.03], and 0.06 [0.05–0.07] points per year faster for 50-74 and 75+ age-of-onset groups respectively) compared to cancer-free participants, but not in cognitive and SRH. Lung, colorectal & breast cancer were associated with the highest acute and accelerated decline in functions, while prostate cancer was associated with moderate and insignificant decline. **Conclusions:** Using 24 years of nationally representative longitudinal data, this study provides, for the first time, evidence for the heterogeneous aging trajectories of cancer patients across varying age-of-onset and cancer types. Our results supported an accelerated aging trajectory of physical function with increased acceleration with increasing age-of-onset compared to the non-cancer population. It also provides evidence for accentuated aging trajectories of cognitive function and self-rated health. Research Sponsor: None.

Associations between DNA methylation age and chronic health conditions in survivors of childhood leukemia and CNS tumor. *First Author: Maria Monica Gramatges, Baylor College of Medicine and Dan L. Duncan Comprehensive Cancer Center, Houston, TX*

Background: Survivors of childhood cancer are at risk for treatment related morbidities, including an early onset of chronic health conditions (CHC). Survivors are at risk for epigenetic age acceleration (EAA), i.e. when DNA methylation (DNAm)-predicted age exceeds chronologic age. EAA has been associated with treatment exposures and incidence of cardiometabolic, pulmonary, and neurologic CHC. We characterized the burden of CHCs in survivors of acute lymphoblastic leukemia (ALL) and central nervous system (CNS) tumors, two of the most common childhood cancers, and determined the association between EAA, cancer diagnosis, and burden of CHC. **Methods:** We included survivors of CNS tumor or ALL diagnosed at Texas Children's Hospital (TCH) between 1992-2013, who were seen at least once in the TCH Long-Term Survivor Clinic. Demographics, diagnosis, treatment data and date of onset and type of CHC were abstracted from the electronic health record. All CHCs required subspecialty care, were present for at least 1 year, and were classified by system into one of 8 categories. Germline samples were obtained at an average of 10.5 years after diagnosis, and at an average age of 15.9 years of age. Samples were analyzed by Illumina MethylationEPIC BeadChip array on an iScan System in the Baylor College of Medicine (BCM) Laboratory for Translational Genomics. Methylation data were processed using *minfi*, normalized with *noob*, and EAA estimated using the Horvath calculator. The relationship between EAA, diagnosis, and CHCs was determined by multivariable linear regression. **Results:** Endocrine (65%), neuropsychiatric (78%), and sensory/motor (73%) CHCs were common in the CNS tumor group (n = 77). Metabolic (22%) and neuropsychiatric (59%) CHCs were common in the ALL group (n = 268). Survivors of CNS tumor had an earlier time of CHC onset, were more likely to have endocrine and sensory motor outcomes, and less likely to have metabolic outcomes vs. ALL survivors. On average, both survivor groups had EAA: 3.3 years (range: -12.2-15.5 years) for 138 ALL survivors and 4.4 years (range: -0.9-10.9 years) for 38 CNS tumor survivors, but EAA did not differ between diagnoses after adjustment for RT (p = 0.75). For CNS tumor survivors, EAA was 0.8 years greater for each system affected by CHC (beta = 0.8, p = 0.043) after adjustment for RT. For ALL survivors, EAA was not associated with CHCs (p = 0.33), but was associated with RT (p = 0.007). **Conclusions:** CHCs are prevalent in survivors of childhood ALL and CNS tumors, with patterns that differ by cancer diagnosis. In this cohort of relatively young 5 year + survivors of ALL and CNS tumor, all survivors had similar EAA but demonstrated cancer diagnosis-specific differences in associations between EAA, RT and burden of CHC. Association of metabolic risk factors with breast cancer survival in a population-based cohort. *First Author: Elizabeth Feliciano, Kaiser Permanente Division of Research, Oakland, CA*

Background: Metabolic abnormalities may impact breast cancer prognosis, but research has been limited by small samples and assessment of laboratory values at a single time point, often prior to cancer diagnosis and treatment. In a population based cohort, we utilized time-updated laboratory values and adjusted for cancer treatment to assess the association between metabolic risk factors (glucose, high-density lipoprotein (HDL), low-density lipoprotein (LDL), triglycerides) and breast cancer survival. **Methods:** 13,434 women diagnosed with stage I-III breast cancer from 2005-15 at Kaiser Permanente were included. All outpatient fasting glucose, HDL, LDL, and triglyceride values from diagnosis through 2019 or death were extracted from electronic medical records. Lab values were updated a median of 5 times between 1-7 years post-diagnosis. Risk of breast cancer-specific mortality was evaluated with Cox proportional hazards models adjusted for metabolic labs, demographics, body mass index, and diabetes, and then for dyslipidemia and anti-hypertensive medications, tumor characteristics (stage, ER and HER2 receptor status) and cancer treatment (use of chemotherapy, and tamoxifen v. aromatase inhibitors). **Results:** Mean (SD) age at diagnosis was 62.3 (11.8) years. Over median follow-up of 9 years, 2,876 patients died (1,080 of breast cancer). Patients with low HDL (≤45 vs. >45 mg/dL) had higher breast cancer-specific mortality (HR, 1.87; 95% CI, 1.62-2.16); high levels of glucose, triglycerides, and LDL were not associated. The increased risk associated with low HDL persisted after adjusting for tumor characteristics, cancer treatment, and medications. **Conclusions:** Low HDL evaluated over time after cancer diagnosis is associated with higher breast cancer mortality independent of cancer treatments and changes in other metabolic risk factors. Cholesterol may play a role in breast cancer due to its role in cell membrane structure, signaling pathways, and steroid hormone synthesis. Future studies should address whether pharmacologic or lifestyle treatment of lipids after breast cancer diagnosis can optimize survival outcomes. Research Sponsor: U.S. National Institutes of Health.

Quantification of methylation-specific cardiomyocyte cell-free DNA as an early marker of cardiotoxicity in patients with breast cancer receiving anthracyclines and trastuzumab. *First Author: Zachary Ray Moore, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: There is currently no way to reliably predict which patients undergoing therapy for breast cancer will develop cardiotoxicity. An early biomarker of cardiotoxicity could provide opportunity for intervention prior to the appearance of gross abnormalities on echocardiogram (ECHO). A droplet digital PCR (ddPCR) assay for circulating cell-free DNA (cfDNA) can detect cfDNA released from dying cardiomyocytes with high sensitivity by differentiating cfDNA of cardiomyocyte origin based on the pattern of methylation specific to the cell type. Circulating cfDNA of cardiac origin was tested as an early biomarker of toxicity in patients who underwent breast cancer treatment while closely monitoring cardiac function in a prospective clinical trial. **Methods:** A cardiomyocyte methylation-specific quantitative ddPCR assay was tested in plasma samples from 29 patients who were part of a larger prospectively enrolled cohort of women who received anthracyclines and trastuzumab for HER2-positive breast cancer. Blood samples were tested from prior to doxorubicin and cyclophosphamide (AC) chemotherapy, two months later after completing AC and prior to trastuzumab, and every 3 months to 12 months post-treatment. Patients were assessed for clinical cardiotoxicity, defined as heart failure (NYHA class III/IV) or significant EF decline (> = 10% to below 53% or > = 16%) until completion of cancer therapy. The maximum detected level of cardiac cfDNA (copies per 500 μL plasma) was compared between those who experienced cardiotoxicity and those who did not by two-sided T-tests. Results are reported as mean +/- standard deviation. **Results:** At baseline, cardiac cfDNA levels were low (mean 1.1 +/- 2.4 copies). Of 29 patients, five developed clinical cardiotoxicity. The maximum number of cfDNA copies at any time point was elevated in patients who experienced cardiotoxicity compared to those who did not (mean of 20.6 +/- 7.3 copies versus 9.3 +/- 9.8 copies, p = 0.0216). Of the patients with cardiotoxicity, elevated cfDNA of greater than 10 copies was detected an average of 3.6 +/- 2.5 months prior to the onset of clinical cardiotoxicity. **Conclusions:** Methylation specific cardiac cfDNA shows promise as an early indicator of cardiotoxicity in patients treated with anthracyclines in this pilot study. A previously reported analysis in the levels of seven other biomarkers including high-sensitivity troponin I and NT-proBNP pre- versus post-treatment in the full cohort of 80 patients did not show any statistically significant associations with the development of cardiotoxicity, suggesting that cardiac cfDNA may be uniquely informative. Clinical trial information: NCT02177175. Research Sponsor: Chanel Endowment for Survivorship Research Grant, MSKCC Imaging and Radiation Sciences Program.

Racial disparity in breast cancer survivorship: Results of a qualitative research study to identify themes from a series national healthcare provider live virtual forums. *First Author: Jill M. Binkley, TurningPoint Breast Cancer Rehabilitation, Atlanta, GA*

Background: Significant disparity exists in the diagnosis, treatment, and survivorship outcomes among Black breast cancer (BC) survivors. Unmet physical and emotional needs in BC survivors are well documented, but there is mounting evidence that Black BC survivors have more significant survivorship issues and a greater burden of illness than White counterparts. Barriers to rehabilitation and recovery care exist for all BC survivors; however, they are magnified in Black BC survivors due to systemic racism, healthcare provider bias and discrimination, lack of culturally relevant care models, and socio-economic barriers. There is limited literature on lived personal and professional experiences of racial disparity in BC survivorship. **Methods:** The purpose of this qualitative research was to document patient, clinician and researchers' perceptions surrounding contributing factors, lived experiences, and potential solutions to racial disparity in BC survivorship against the contextual background of reported inequities. A narrative approach was utilized to identify themes from a series of four virtual healthcare provider forums that explored lived personal and professional experiences, issues and potential solutions surrounding racial disparity in BC survivorship from October 2020-September 2021. The forums included perspectives of patients, healthcare providers, researchers, and stakeholders in the BC field. The total live and online views for all four forums was 2,093. An independent thematic analysis was performed by the investigators, all of whom have emic perspectives with respect to race and/or breast cancer. **Results:** Three main themes were independently identified by study investigators: 1. societal and cultural contributing factors contributing to racial disparity in BC survivorship, 2. contribution of healthcare providers and systems to racial disparity in BC survivorship and 3. models of care and research considerations that would reduce racial disparity. These themes were widely echoed by forum participants throughout the series. With respect to solutions, widespread implementation of navigation models and the *Prospective Model of Rehabilitation for Women with Breast Cancer* that address physical and psychosocial treatment side effects would reduce disparity. The importance of the inclusion of voices of Black BC survivors in community-based participatory research aimed at reducing survivorship disparity is critical. **Conclusions:** The findings provide compelling documentation of lived personal and professional experiences of racial disparity in BC survivorship. These issues have been described in the literature for nearly two decades. Potential solutions exist and must be enacted immediately to ensure equitable survivorship outcomes for Black individuals following a BC diagnosis. Long-term outcomes of adrenal insufficiency (AI) due to anti–PD(L)-1 immune checkpoint inhibitors (ICI) among patients with cancer. *First Author: Ben Nguyen, SUNY Downstate Medical Center, Brooklyn, NY*

Background: Endocrine immune-related adverse events (irAEs) to anti-PD-(L)1 ICI, including hypophysitis, autoimmune insulin-dependent diabetes mellites (ICI-DM), and primary adrenal insufficiency (AI), are rare but often associated with long term co-morbidities. AI from anti-PD-(L)1 ICI without CTLA-4 blockade is not well characterized in the literature. Long term outcomes for AI including need for replacement steroids and cortisol levels are unknown. **Methods:** We performed a single center retrospective analysis of patients treated with ICI including anti-programmed cell death protein-1 (Anti-PD-1: nivolumab or pembrolizumab), anti-programmed death-ligand-1 (anti-PD-L1: atezolizumab or cemiplimab) and diagnosed with ICI induced AI by a board-certified endocrinologist from 1/1/2011 to 12/31/2021. Patients treated with anti-CTLA-4 based therapy were not included. Patient baseline characteristics, presenting symptoms at the time of AI diagnosis, and treatment with corticosteroids were obtained by chart review. Baseline labs were collected at the time of AI and during routine patient follow-up. Descriptive statistics are reported for the cohort. **Results:** Twenty-nine patients were identified, 27 diagnosed with secondary and 2 diagnosed with primary AI. The median age was 63 (range 39-84), 18 (62%) males and 11 (38%) females, 14 (48%) receiving anti-PD(L)-1 monotherapy and 22 receiving anti-PD(L)-1 combination therapy either with chemotherapy (7, 24%), targeted therapy (6, 21%) or other/investigational therapy (2, 7%). The common tumor types were 6 renal cell carcinoma, 4 urothelial carcinoma, 4 melanoma, 15 others. The common presenting symptoms were 26 (90%) with fatigue,16 (55%) weakness, 11 (38%) nausea/vomiting, 4 (14%) headaches and 2 (7%) arthralgias. The common concomitant irAEs were 16 (55%) hypothyroidism, 8 (28%) acute kidney injury, 7 (24%) colitis, 6 (21%) joint pain, 3 (10%) pneumonitis & dermatitis. Eleven (38%) patients were treated with high dose steroids. Median follow-up time for survivors in the cohort was 24 months (range 7-68). Median cortisol level at time of AI diagnosis was 1.1 (IQR 0.9, 2.7; n = 27) and 1.8 (IQR 0.6, 6.4; n = 10) at last follow-up (median lab follow-up 39 months, range 29-58); 7 of 10 patients with available data had cortisol < 5.0 at last follow-up. For secondary AI patients, median ACTH at time of diagnosis was 2.3 (IQR 2.0, 5.0; n = 21) and 2.0 (IQR 2.0, 7.2; n = 7) at last follow-up. Twenty-two of 23 patients with available data continued replacement steroids at last follow-up. **Conclusions:** AI associated with anti-PD(L)-1 ICI is primarily secondary. Cortisol and ACTH levels remain low even during long-term follow-up. Most patients need long-term replacement steroids. Systemic and comprehensive follow-up for patients who develop AI due to anti-PD(L)-1 ICI is needed to confirm these findings. Research Sponsor: None.

Hair Safe Study: Effects of scalp cooling on hair preservation and hair regrowth in breast cancer therapy—A prospective interventional study. *First Author: Christine Brunner, Department of Obstetrics and Gynecology, Medical University of Innsbruck, Innsbruck, Austria*

Background: Chemotherapy (CT) is a frequent and well established treatment in women with breast and gynecological tumors. Alopecia is one of the most common side effects of CT seriously impairing patient quality of life and body image. While other CT associated side effects can be controlled by supportive treatment strategy, adequate preventive measures for alopecia have been lacking. New evidence supports the efficacy of scalp cooling for alopecia prevention during CT. The aim of this study was to investigate preventive scalp cooling (SC) for chemotherapy-induced-alopecia in breast cancer patients undergoing standard adjuvant or palliative chemotherapy. We also analysed the impact of SC on hair regrowth after chemotherapy-induced-alopecia. **Methods:** This was a non-randomized, 2-arm interventional study conducted at the Department of Obstetrics and Gynecology, Medical University Innsbruck. Breast cancer patients receiving any chemotherapy associated with alopecia (i.e. taxane or anthracycline-based chemotherapy) were allocated either to an intervention group receiving SC or to a control group (no SC). SC during chemotherapy was applied by the Paxman scalp cooling system. The primary endpoint was hair preservation (HP) which was assessed by experts and patients using the CTCAE score and analysed during and after completion of chemotherapy. The secondary endpoint was hair regrowth (HR) after 3 and 6 to 9 months post chemotherapy. **Results:** The study population included 128 patients. The majority, namely 88 (69%) patients were assigned to the intervention group (CAP) and received SC, 40 patients were allocated to the control group (NCAP). HP was significantly higher in the group receiving SC than in the NCAP by patients' self-evaluation (24% vs. 0%; P = 0.001) and experts' assessment (72% vs. 0%, P ≤ 0.001). HR was comparable between both groups. Using the patients' evaluation 50% of patients with taxane monotherapy had a grade 1 alopecia compared to 17% of patients with an anthracycline-taxane CT (50% vs 17%, P = 0.018). Drop-out rate was 13% in CAP and 5% in NCAP group. Main reasons for drop-out were hair loss and patients' requests. **Conclusions:** Our study demonstrates that SCsignificantly reduced or avoided chemotherapy-induced-alopecia in breast cancer patients undergoing chemotherapy, especially in patients who received taxane-monotherapy. SC was a safe procedure without severe adverse events. Therefore, SC can be highly beneficial for patients receiving specific chemotherapy and the option should be made available to as many patients as possible. No significant effect was noted regarding regrowth after chemotherapy in the SC group. Research Sponsor: None.

Predictive value of baseline patient-rated treatment bother for early anastrozole discontinuation in a racially diverse cohort: Results from ECOG-ACRIN E1Z11. *First Author: Fengmin Zhao, Dana–Farber Cancer Institute, Malden, MA*

Background: The Functional Assessment of Cancer Therapy patient-reported outcomes (PRO) item GP5 ("I am bothered by side effects of treatment") estimates treatment tolerability. We aimed to extend our previous finding that GP5 predicts early aromatase inhibitor (AI) discontinuation (E1Z03, 96% White) in the racially diverse E1Z11 trial cohort. **Methods:** E1Z11 was coordinated by the ECOG-ACRIN NCI Community Oncology Research Program (NCORP) Research Base. Postmenopausal women initiating anastrozole per clinical care for ER+ stage I-III breast cancer with a pain score 0-3/10 and no rheumatologic comorbidities were eligible. Accrual of a racially diverse cohort of 1,000 women, including Black and Asian women, was planned. GP5 was administered prior to initiating anastrozole (trial baseline) and at 3, 6, 9 and 12 months. GP5 was scored on a 5-point Likert scale from 0 (not at all) to 4 (very much) and dichotomized as no/little treatment bother (0/1) or moderate/high treatment bother (2-4), consistent with previous analyses. A univariate Cox proportional hazards model estimated baseline GP5's association with treatment duration via hazard ratio (HR). Early treatment discontinuation status was defined as treatment duration < 12 months with discontinuation not attributed to disease progression or death (n = 4), consistent with previous analyses. **Results:** 1,046 women enrolled from 6/2013-10/2018 (640 White, 201 Black, 205 Asian), including 590 (56%) from NCORP Community or Minority/Underserved Sites. Approximately 10% (100/987 with GP5 data) reported moderate/high treatment bother prior to initiating anastrozole. Anastrozole discontinuation rate at 1-year was 26.2% overall; it was lower among women with no/little treatment bother (25.7%, GP5 = 0-1) compared to moderate/high treatment bother prior to initiating anastrozole (34.7%, GP5 = 2-4; HR = 1.50, 95% confidence interval [CI]:1.04-2.15, p = 0.027). Subgroup analyses by racial cohort showed a similar predictive effect of GP5 in the White (n = 606, HR = 1.76, 95% CI: 1.12-2.77, p = 0.014) and Black (n = 184, HR = 1.85, 95% CI: 0.92-3.71, p = 0.079) cohorts, but not in the Asian cohort (n = 197, HR = 0.40, 95% CI: 0.10-1.62, p = 0.20). **Conclusions:** Moderate/high treatment bother prior to starting anastrozole was observed in 10% of patients and associated with a higher risk of early discontinuation, except in Asian patients. Our findings support the presence of a treatment tolerability threshold which can be compromised by pre-treatment burden. Treatment tolerability may also be influenced by cultural and genetic factors, which will be explored in further analysis of genetic and PRO data. Clinical trial information: NCT01824836. Research Sponsor: U.S. National Institutes of Health.

Associations between diet quality and chronic health conditions (CHCs) in adult survivors of childhood cancer in the St. Jude Lifetime Cohort Study (SJLIFE). *First Author: Emily R Finch, St. Jude Children's Research Hospital, Memphis, TN*

Background: Survivors of childhood cancer are at increased risk for early development of CHCs, including metabolic syndrome (MetS), low bone mineral density (LBMD), and gastrointestinal (GI) disease. Dietary modification is often recommended for prevention and/or treatment of these CHCs in non-cancer populations. However, associations between diet quality and severity of CHCs in adult survivors of childhood cancer are not well known. **Methods:** Adult survivors (≥10 years post-diagnosis) of childhood cancer who completed a clinical evaluation and Block Food Frequency Questionnaire were included. Diet quality was estimated using the Mediterranean diet score (aMED), with scores ranging from 0 to 9 (increased scores represent higher adherence to diet). CHCs were graded (modified CTCAE) and classified as "low" (grade ≤1 for LBMD and GI; grade ≤2 for MetS) or "high" (grade 2-4 for LBMD and GI; grade 3-4 for MetS). A multivariable linear regression model was used to estimate the mean aMED score by "low" or "high" disease category, with adjustment for age at evaluation, sex, race, education, total energy intake, adjusted BMI, physical activity, smoking, and alcohol consumption. **Results:** 2,822 survivors of childhood cancer (52.4% male, 83.1% non-Hispanic white) were included. The most prevalent diagnosis was acute lymphoblastic leukemia (34.1%). Time from primary diagnosis was 24.2±8.5 years and age at recruitment was 32.5±8.7 years. Lower adherence to aMED diet was associated with "high" MetS and LBMD, but not GI disease. See the Table for aMED multivariate-adjusted diet quality scores by CHC. **Conclusions:** In this cross-sectional analysis, MetS and LBMD were associated with poor adherence to the aMED diet. Although longitudinal investigation of associations between diet quality and CHCs in survivors of childhood cancer are needed to determine causal association between diet quality and CHCs in childhood cancer survivors, dietary interventions in early or late cancer survivors may help prevent development or progression of specific treatment related chronic conditions. Research Sponsor: U.S. National Institutes of Health, American Lebanese Syrian Associated Charities.

Multivariate-adjusted aMED diet quality scores by dichotomized CHC category in adult survivors of childhood cancer.

Chronic Health Conditions	Low Disease Category Adjusted Mean Diet Score (95% CI)	High Disease Category Adjusted Mean Diet Score (95% CI)	p-value
MetS	4.21 (4.13-4.30)	4.07 (3.94-4.20)	***0.002***
LBMD	4.22 (4.12-4.25)	3.98 (3.77-4.19)	***<0.0001***
GI	4.17 (4.09-4.24)	4.16 (4.03-4.30)	0.82

Physical performance limitations and participation restrictions among cancer survivors: A population-based study from NHANES data 2015-2018. *First Author: Samantha A. Myers, University of British Columbia, Vancouver, BC, Canada*

Background: Anti-cancer therapies have improved survival outcomes in cancer survivors; however, therapy-related toxicities may impact organ structure and function and interfere with physical performance and participation in life roles. This analysis aimed to estimate the prevalence of physical performance limitations (PL) and participation restrictions (PR) among recent (< 5 years since diagnosis), and long-term (≥ 5 years) cancer survivors. **Methods:** Data from the 2015-2018 National Health and Nutrition Examination Survey (NHANES) were analyzed using multivariable logistic regression, accounting for age, sex, race, and income, and incorporating survey sampling methodology. Odds ratios compared proportions of PL and PR among 663 (weighted population estimate 14,319,219) recent and 341 (weighted population estimate 7,261,088) long-term survivors, and 10,284 (weighted population estimate 215,042,155) persons with no reported cancer history. Two-sided two sample z-tests were used to compare proportions to a previous publication of data from 1999-2002 NHANES data. **Results:** Physical performance limitations were 1.5-1.7 times (63% vs 29%) and PR 1.5-1.6 times (38% vs 18%) more prevalent in cancer survivors than in those with no cancer history. Long-term cancer diagnosis was associated with increased prevalence of PL and PR, particularly in survivors aged 20-39 years. Proportions increased by 7% for PL and by 10% for PR compared to 1999-2002 values (p-values <0.001). **Conclusions:** Over 60% of cancer survivors reported PL and nearly 40% reported PR. Despite an interim increase in evidence of the benefits of exercise to manage therapy-related toxicities, these values are a significant increase when compared to 1999-2002 NHANES data. Targeted education for providers and exercise interventions aimed to improve physical function and performance in early cancer survivors should be considered to address the physical sequelae from anti-cancer therapies. Research Sponsor: None.

Associations between age, cancer history and physical performance limitations (PL) and participation restrictions (PR) reported among adult participants in NHANES 2015-2018.

The safety and efficacy of psilocybin therapy in patients with cancer and major depressive disorder. *First Author: Manish Agrawal, Associates in Oncology, Rockville, MD*

Background: More than 17 million people in the U.S. live with cancer and up to 25% of them have major depression. Depression leads to lower treatment adherence, reduced quality of life, and higher rates of mortality in cancer. Yet, interventions used to treat depression in patients with cancer have limited success. Prior trials using psilocybin to treat anxiety and depression associated with cancer suggested improvements in psychological distress. However, treatment in a homogenous psychiatric sample has yet to be investigated. Further, psilocybin has not been given in groups, and in a setting conducive to the "whole person" approach to treatment. This trial built upon previous studies and tested the safety, feasibility, and efficacy of psilocybin therapy in cancer patients diagnosed with major depressive disorder (MDD), with the novel use of group treatment in a cancer center setting. **Methods:** Phase II, single-center, open label trial, where 30 patients received a dose of 25 mg of psilocybin. Inclusion criteria: 1) age ≥ 18 years, 2) met criteria for MDD, 3) a Hamilton Depression Rating Scale score ≥ 18 at baseline, 4) diagnosis of a malignant neoplasm. Patients who had curative treatment for cancer as well as those with advanced metastatic disease were included. Patients were divided into cohorts and they received 1 group preparation session, simultaneous administration of psilocybin, and 2 group integration sessions. Therapeutic care was also provided before, during, and after the session using the 1:1 model of psychological support. The primary outcome measures for safety were adverse events, vital signs, ECGs, blood tests, and suicidality scores (C-SSRS). The secondary and exploratory outcome measures consisted of 15 assessments conducted at baseline and post-treatment at day 1, week 1, week 3, and week 8 to determine the efficacy of treatment. **Results:** A total of 30 patients were enrolled over the course of only 8 months with an attrition rate of 0%. All completed the trial with no serious adverse events. Beyond high tolerability of the treatment, we also found a clinically meaningful change in depressive symptoms. After a single administration of psilocybin therapy, the average score on the Montgomery Asberg Depression Rating Scale (MADRS) dropped by 19.1 points (95% CI, 22.3 to 16.0, p < 0.0001). A sustained response rate (a decrease of ≥ 50% in the MADRS score from baseline to week 8) was seen by 24 patients. 50% of patients showed complete remission of depression symptoms (a MADRS score < 10) one week after treatment, which was sustained for up to 8 weeks. **Conclusions:** This study adds to the growing body of psilocybin research with promising results showing the safety, feasibility, and efficacy of simultaneous psilocybin treatment in patients with cancer with MDD. The value of group support for patients with cancer was also explored, with implications for increased scalability of psilocybin therapy in real-world settings. Clinical trial information: NCT04593563. Research Sponsor: COMPASS Pathways.

12099 **Poster Session**

An open-label, randomized, controlled trial to evaluate the efficacy of antihistamine premedication and infusion prolongation in prevention of hypersensitivity reaction to oxaliplatin. *First Author: Chalita Lagampan, Division of Medical Oncology, Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*

Background: Hypersensitivity reaction (HSR) is a common toxicity in patients receiving repeated oxaliplatin. Oxaliplatin induced HSR could be severe and results in treatment discontinuation. There is no standard recommendation for prevention of oxaliplatin induced HSR. **Methods:** We conducted a prospective, single center, open-label, randomized controlled trial comparing the standard premedication and 2-hour infusion protocol to the additional antihistamine premedication, intravenous chlorpheniramine, and 3-hour infusion protocol. After three months of chemotherapy, the randomization was done at 5thand 7th cycles of 3-week and 2-week oxaliplatin based regimens, respectively. The primary endpoint was the incidence of HSR. **Results:** From July 2020 to March 2021, a total of 160 patients underwent randomization (80 patients in both intervention and control groups). After 11 months follow-up, all patients had completed planned treatment cycles. HSRs occurred in 1 (1.3 %) and 10 (12.5%) patients in intervention and control groups, respectively, p = 0.005). There were 6 (7.5%) patients with more than grade 1 HSRs in control groups, but none in intervention group. In the intervention group, one patient with HSR experienced grade 1 erythema and palpitation. There is no report of significant adverse event from anti-histamine premedication or oxaliplatin infusion prolongation. **Conclusions:** Additional antihistamine premedication and infusion prolongation started in 2nd half of treatment course can significantly reduced HSR incidence in patients receiving oxaliplatin. Clinical trial information: TCTR20210506001. Research Sponsor: None.

Interim analysis of a single-center, single-arm, prospective phase 2 study to evaluate the efficacy and safety of benralizumab for alpelisib rash in metastatic PIK3CA-mutant, hormone receptor–positive breast cancer. *First Author: Mario E. Lacouture, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Rash associated with increased peripheral eosinophils develops in approximately 50% of metastatic breast cancer patients receiving alpelisib. Antihistamines and corticosteroids have limited benefit. Refractory rash may lead to decreased dose intensity and affect clinical outcome. Benralizumab is an anti-IL-5Rα chimeric monoclonal antibody that depletes peripheral eosinophils and has demonstrated benefit in eosinophilic asthma and hypereosinophilic syndrome. We investigate the efficacy and safety of benralizumab for the treatment of alpelisib rash. **Methods:** We performed a single-center, single-arm, prospective phase 2 study to evaluate the efficacy and safety of benralizumab in cancer patients who developed CTCAE grade 2/3 skin events resulting from immunotherapy or targeted therapies with absolute blood eosinophil counts of ≥300/mcl. While remaining on culprit drugs, patients were treated with benralizumab 30mg once every 4 weeks for the first 3 doses followed by once every 8 weeks for 3 additional doses (approved dosing for eosinophilic asthma). Primary endpoint was clinical response measured as reduction in CTCAE grade 2/3 skin event to grade ≤1 by week 4. Secondary endpoints were patient quality of life (QoL) measured by skindex16, safety data, need for supportive oral corticosteroids, and changes in cytokines and eosinophil biomarkers. This interim analysis focuses on patients with PIK3CA-mutant metastatic breast cancer receiving alpelisib. **Results:** Between September 16th 2020 and January 1st 2022, we enrolled 10 metastatic breast cancer patients with grade 2/3 rash attributed to alpelisib (5 pts with G3). All patients had a reduction of rash to grade ≤1 (n = 10, p < 0.0001), and a decrease in peripheral absolute eosinophils (mean 500/mcl to 0, p < 0.0001). Of these, 6 patients had been on prophylactic oral antihistamines and 2 had oral steroid coadministration. QoL significantly improved (Skindex16 mean score 58 to 16, p = 0.0001) and eosinophils in skin histology decreased per HPF (mean 6.25 to 0.25, n = 8, p = 0.2) by week 4. An increase in IL-5 > 600% and reduction IL-6 and TNF-α > 50% were reported by week 4 and 8. Grade 1/2 mucositis in 4 patients were reported as adverse events. **Conclusions:** Our findings suggest that benralizumab is safe and effective for the treatment of grade 2/3 rash with eosinophilia related to alpelisib in patients with breast cancer. A reduction in rash severity was evidenced in all patients, along with improved QoL. Larger controlled studies are in development to evaluate the efficacy of benralizumab for the prevention of alpelisib rash. Clinical trial information: NCT04552288. Research Sponsor: U.S. National Institutes of Health.

Racial differences in interest and use of integrative medicine among patients with breast cancer. *First Author: Jori Sheade, University of Chicago Medical Center, Chicago, IL*

Background: Breast cancer treatment can be associated with side effects (SEs) that negatively impact quality of life. While some SEs can be treated with medications, such interventions come with additional SEs. Acupuncture, massage, meditation, music therapy and yoga have received ASCO endorsement for the management of therapy-related SEs. Many patients are interested in integrative services, but little is known about racial differences in interest and use of integrative services among patients with breast cancer. **Methods:** Breast cancer patients enrolled in the Chicago Multiethnic Epidemiologic Cohort study were sent a survey regarding their interest and use of five integrative services: acupuncture, massage, meditation, music therapy and yoga. Participants were asked how interested they would be in these services if offered, using a five-point Likert scale. Prior use was self-reported. Proportional odds were modeled for "interest" and binary logistic regression was modeled for "self-reported use." Adjusted odds ratios (aOR) and 95% confidence intervals (CI) were calculated, controlling for age, education, marital status, household income, insurance, Carlson comorbidity index, molecular subtype and stage. **Results:** 1,300 patients responded to the survey, 928 White and 285 Black. Compared with White patients in this cohort, Black patients were less educated, had a lower household income, were more likely enrolled in Medicaid/Medicare, and had a greater Carlson comorbidity index. Over 97% of patients had stage 0-III breast cancer. While there was no difference in interest in acupuncture between Black and White patients (aOR 1.1, 95% CI 0.8-1.7), Black patients were significantly more interested in the use of massage (aOR 1.9, 95% CI 1.3-2.8), meditation (aOR 2.0, 95% CI 1.4-3.0), music therapy (aOR 2.7, 95% CI 1.8-4.0) and yoga (aOR 2.1, 95% CI 1.4-3.1). Black patients were significantly less likely than Whites to report acupuncture use (aOR 0.5, 95% CI 0.3-0.8); but there were no racial differences in self-reported use of massage (aOR 0.8, 95% CI 0.5-1.3), meditation (aOR 0.8, 95% CI 0.5-1.4), music therapy (aOR 1.7, 95% CI 0.8-3.3) and yoga (aOR 0.7, 95% CI 0.4-1.2). **Conclusions:** Black patients with breast cancer expressed more interest in integrative services than their White counterparts; there were no racial differences in self-reported use of integrative services except an increased use of acupuncture among White patients. A breast program focused on equity should provide access to these resources for all patients. Interest and self-reported use of integrative services among patients with breast cancer, by race. Research Sponsor: None.

	Interested or very interested		Self-reported use	
	White (n=928), %	Black (n=285), %	White (n=928), %	Black (n=285), %

Race differences in patient-reported symptoms and adherence to adjuvant endocrine therapy among women with early-stage, hormone receptor-positive breast cancer. *First Author: Xin Hu, Emory University, Rollins School of Public Health, Atlanta, GA*

Background: Low rates of adherence to adjuvant endocrine therapy (AET) is a significant clinical problem. Symptom burden is a key barrier to adherence, but less is known about how changes in symptom burden affects adherence. Moreover, whether higher symptom burden in racial minorities explains their lower rates of adherence, has been relatively unexamined. We used longitudinal data to address these gaps in knowledge. **Methods:** Using electronic medical records linked with patient-reported data, Medicare and Medicaid claims, we identified women with early-stage, hormone receptor-positive breast cancer who initiated AET from a large cancer center in 08/2007-12/2015, had continuous insurance coverage and ≥1 symptom report before and during AET. Patient-reported symptoms were collected using a tablet-based platform [ConcertAI]. A total of 49 physical symptoms and 11 mental health symptoms were evaluated and classified into 7 physical and 2 mental clusters based on previous literature and clinical expertise. For each cluster, we counted the number of symptoms with moderate severity (≥3 points) at baseline, and with ≥3-point increase during 1-year follow-up. Adherence was defined as the percent of days covered by AET during the 1-year follow-up. We compared Black and White patients' symptoms at baseline and changes during the therapy, and conducted multivariable regression for patients' adherence adjusting for race, symptom measures, sociodemographic and clinical characteristics. **Results:** Black women (n = 168) were diagnosed at a younger age, with more advanced stage, and lived in areas with lower socioeconomic status than White women (n = 391, $p < .05$). Adherence to AET in the first year was 78.8% for Black and 82.3% for White women ($p = .16$). Black women experienced higher severity in most symptom clusters at baseline and during the follow-up than White women ($p < .05$). Neuropsychologic, Vasomotor, Musculoskeletal, Cardiorespiratory, Distress and Despair symptom clusters both at baseline and their increases during the follow-up were associated with 1.2 to 2.6 percentage points (ppt, $p < .05$) decreases in adherence. This means, each additional count of moderate severity symptoms in these clusters would decrease 4 to 9 days on AET. After adjusting for distress and despair symptoms, Black women had a 6.5 ppt higher adherence rate than White ($p < .05$). **Conclusions:** Black women had higher symptom burden at baseline and during the first year of AET. Both physical and mental health symptoms at baseline and the changes during therapy were associated with lower adherence. However, Black women had non-significantly lower rates of adherence despite the higher symptom burden due to unmeasured factors that offset the impact of symptom severity. Better symptom management could improve AET adherence and potentially reduce racial disparities in cancer outcomes. Research Sponsor: U.S. National Institutes of Health.

Efficacy and safety of dexamethasone-based mouthwash to prevent chemotherapy-induced stomatitis in women with breast cancer: A multicenter, open-label, randomized phase II study. *First Author: Shigeto Maeda, National Hospital Organization Nagasaki Medical Center, Omura, Japan*

Background: Stomatitis, a frequent adverse event in patients undergoing chemotherapy, can lead to pain, ulcers, bleeding, and malnutrition due to reduced oral intake, which not only deteriorates quality of life but may also result in dose reduction or interruption of chemotherapy. However, there is currently no standard approach for preventing chemotherapy-induced stomatitis. Therefore, this study aimed to assess the efficacy and safety of a dexamethasone-based mouthwash for preventing chemotherapy-induced stomatitis in patients with early breast cancer. **Methods:** We conducted a multicenter, randomized, controlled phase II trial. Patients with early-stage breast cancer scheduled for epirubicin and cyclophosphamide (EC) or docetaxel and cyclophosphamide (TC) therapies were allocated in a 1:1 ratio to the intervention and control groups. The sample size was set to 120 cases based on the following assumptions: stomatitis incidence of 50% in the control group and 30% in the intervention group, alpha error of 0.2, one-sided power of 0.9, and dropout proportion of 10%. The intervention group received chemotherapy, oral care, and a dexamethasone-based mouthwash (10 mL, 0.1 mg/mL; swish for 2 min and spit, 4 times daily for 9 weeks), and the control group received chemotherapy and oral care. The primary endpoint was the incidence of stomatitis that was compared between the two groups. **Results:** There were 60 patients in the control group and 61 in the intervention group. One patient in the control group and two in the study group withdrew consent; one patient in the control group was excluded because of discontinuation of the first cycle of chemotherapy and unavailability of data related to the incidence of stomatitis. Finally, the data of 58 patients in the control group and 59 in the intervention group were analyzed. There were no differences in age and chemotherapy regimens between the groups. The incidence of stomatitis was 55% in the control group and 38% in the intervention group (risk ratio 0.68; 80% confidence interval, 0.52 – 0.88; p = 0.052). The grade of stomatitis (0/1/2/3) was significantly lower in the study group (intervention group vs. control group: 37/13/7/2 vs. 26/16/7/9, p = 0.03). There were no differences in the duration of stomatitis between the groups. Moreover, the percentage of patients who adhered to the mouthwash regimen was 87% (range, 14% – 100%). There were no significant differences in the occurrence of other adverse events between the groups, and only one case of oral candidiasis was observed in the intervention group. **Conclusions:** Dexamethasone-based mouthwash safely reduced the incidence and severity of stomatitis in patients receiving chemotherapy (EC/TC) for early breast cancer. Clinical trial information: UMIN000030489. Research Sponsor: None.

Efficacy of olanzapine, netupitant, and palonosetron in controlling nausea and vomiting associated with highly emetogenic chemotherapy in patients with breast cancer (OLNEPA). *First Author: Camilla Vieira de Reboucas, Faculdade de Medicina do ABC, Santo André, Brazil*

Background: Chemotherapy induced nausea and vomiting (CINV) is a highly prevalent adverse event[1,2] that can result in decreased quality of life, dose reduction and interruptions of treatment.[3] Four drug protocol including Olanzapine, 5-hydroxytryptamine type 3 receptor (5HT3) antagonist, a neurokinin 1 receptor (NK1) antagonist and dexamethasone is the current standard of care for highly emetogenic chemotherapy (HEC) [2,4-6]. Corticosteroids are associated with side effects like insomnia and weight gain. To our knowledge, total Dexamethasone omission has not been addressed previously. **Methods:** This is a prospective single arm phase II study designed to evaluate the efficacy of Olanzapine, Netupitant and Palonosetron in controlling nausea and vomiting induced by highly emetogenic chemotherapy. Eligible patients were women with histologic confirmed breast cancer, planned to start treatment with Doxorubicin and Cyclophosphamide. Exclusion criteria included use of opioids or antipsychotic medications, medical condition that could potentially cause vomiting or inability to take oral medications. Patients were assigned to take Olanzapine 5mg QD, days 1 – 5, Netupitant 300mg and Palonosetron 0.5mg on day one. No corticosteroid use was allowed. The null hypothesis considered that the scheme containing Olanzapine, Netupitant and Palonosetron could not effectively control nausea. Based on a previous phase III study with Olanzapine (Navari *et al.*), we set the control of nausea at 20% and the expected control rate at 40% for the present study. To reach 5% (two-sided) significance and 80% statistical power, we calculated that a minimum sample size of 50 patients was required, assuming a 5% dropout rate. We used the one-sample T-test of proportion to analyze the data, based on intent-to-treat (ITT) The primary endpoint was complete control of nausea in the first 5 days after chemotherapy administration. Secondary endpoints were complete emesis control (no emesis, no use of rescue medication) and complete control (no emesis, no rescue and no nausea) **Results:** Fifty patients were enrolled from January 2020 to December 2021. The median age was 47.6 years-old (range: 29 – 78 years) and 48 patients (96%) received chemotherapy with curative intent. For the primary endpoint, complete nausea control rate was 46% (IC 32 – 59%) and p < 0.0001. The emesis control rate was 68% (IC 55 – 80%) and overall control rate was 46% (IC 32 – 59%). One patient dropped out for dizziness and drowsiness following administration of Olanzapine. **Conclusions:** Omitting Dexamethasone for highly emetogenic chemotherapy is feasible and showed similar control of nausea and vomiting compared to standard four-drug protocol. This could be a potential prophylactic regimen of choice for patients who have a contraindication for Dexamethasone use. Clinical trial information: NCT04669132. Research Sponsor: None.

Using the consolidated framework for implementation research to evaluate facilitators and barriers to early outpatient specialty palliative care in patients with advanced cancer. *First Author: Rachel E Rosenblum, Division of Hematology & Oncology, University of Pittsburgh Medical Center, Pittsburgh, PA*

Background: Prior studies have shown that integration of early outpatient specialty palliative care (OSPC) with oncologic care improves patient's symptom burden and quality of life. As a result, the American Society of Clinical Oncology (ASCO) recommends that OSPC be offered within 8 weeks of diagnosis of an advanced solid malignancy. Over the past decade, there has been an increase in the availability of OSPC services, particularly at National Cancer Institute (NCI)-designated cancer centers; however, the majority of OSPC referrals still occur late in the disease course. The aim of this study was to evaluate the facilitators and barriers to implementation of early OSPC. **Methods:** To assess the contextual determinants of early OSPC implementation, we developed a survey based on constructs from the Consolidated Framework for Implementation Research (CFIR), an implementation meta-framework. Using input from subject-matter experts, we tailored the survey to include a total of 18 relevant constructs from the 5 CFIR domains. The survey was distributed to the ambulatory palliative care (PC) clinical leader at NCI-designated cancer centers. The survey assessed each CFIR construct using a 5-point Likert Scale, where +2 represented the strongest facilitators, and -2 represented the strongest barriers. We inquired about respondent sociodemographics and OSPC clinic characteristics and used descriptive statistics to summarize responses to survey items. **Results:** Survey responses were collected between 12/15/21 and 1/18/22. Of the 63 NCI-designated cancer centers invited to participate, 40 (63%) completed the survey, while 3 (5%) did not due to not having an ambulatory program. All respondents were physicians. Half of the OSPC clinics were established for more than 10 years, and the majority (75%) provided care to more than 300 distinct outpatients annually. The most commonly agreed upon facilitators (Likert score = 1 or 2) to early OSPC included PC clinicians' awareness of the ASCO recommendation for early OSPC (100%), informal communication between PC and oncology clinicians (100%), PC clinicians' belief that OSPC improves the quality of oncology care (100%) and access to telemedicine (93%). The most commonly agreed upon barriers (Likert score = -1 or -2) included inadequate number of OSPC providers (73%) and lack of performance metric goals relating to early OSPC set by PC leadership (65%). **Conclusions:** Although OSPC clinics at NCI-designated cancer centers have grown over the last ten years, the utilization of early OSPC is impacted by the implementing institution's resource availability, interdepartmental communication, stakeholder beliefs, and leadership engagement. Future studies should compare the barriers and facilitators of early OSPC identified by PC clinicians and oncologists to inform implementation strategies. Phase 2, randomized, double-blind trial of EC-18 versus placebo to mitigate the development and time course of oral mucositis from concomitant chemoradiation for head and neck cancer. *First Author: Christina Henson, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: Oral mucositis (OM) is a debilitating side effect of concomitant chemoradiotherapy (CRT) for head and neck cancer (HNC). EC-18 may effectively mitigate OM by minimizing the CRT-induced innate immune response. This Phase II, 2-stage trial evaluated safety, tolerability, and efficacy of EC-18 in reducing the duration, incidence, and trajectory of severe OM (SOM) in HNC patients. **Methods:** Patients (n = 105) with pathologically confirmed oral cavity, oropharynx, hypopharynx, or nasopharynx squamous cell cancers who received intensity-modulated radiation therapy (IMRT; with ≥ 55 Gy on ≥ 2 oral sites) and weekly or tri-weekly cisplatin were studied. In Stage 1, 24 patients were randomized (n = 6 per arm) to receive 500, 1000, or 2000 mg of EC-18, or placebo. Following independent Data Safety Monitoring Board review, 81 patients in Stage 2 received EC-18 2000 mg (n = 41) or placebo (n = 40) throughout CRT. WHO OM grade was assessed twice weekly during IMRT and then once weekly for up to 6 weeks post-IMRT. The primary efficacy endpoint was duration of SOM during the active and short-term follow-up (STFU) periods in the compliant per-protocol population (PP). Much of Stage 2 was conducted during peak periods of the COVID-19 pandemic which measurably impacted patient compliance relative to test medication dosing and planned radiation. Consequently, to assess efficacy most accurately, the PP population was analyzed (with at least 4 weeks of study drug dosing, minimum cumulative radiation of 55 Gy, 80% study drug compliance in the first 28 days of dosing, and without using not-allowed-therapy). **Results:** Patient demographics and baseline characteristics were balanced between groups. Adverse events (AEs) were comparable amongst cohorts without drug-related severe AEs. In the PP, the median duration of SOM from baseline through STFU was 0 day in the EC-18 group (n = 22) *v* 13.5 days in the placebo group (n = 20). SOM incidence through STFU (45.5% *v* 70%) and opioid use (time to onset: 32.3 *v* 26.0 days; and duration: 32.8 *v* 37.5 days) favored EC-18 *v* placebo. Results of the covariates analyses suggested that EC-18 favorably impacted SOM incidence in patients who experienced SOM treated with weekly low-dose cisplatin (n = 26; 37.5% *v* placebo 70.0%) and HPV+ tumors (n = 29; 35.3% *v* placebo 66.7%; Table). One-year long-term follow-up for tumor outcomes is ongoing. **Conclusions:** EC-18 safely mitigated the development and the time course of SOM in CRT-treated HNC patients. In addition, EC-18 may provide substantial benefits to subpopulations of HPV^+ HNC patients treated with low dose cisplatin. Clinical trial information: NCT03200340. Research Sponsor: None.

Incidence of SOM through STFU for the selected PP subgroups who experienced SOM.

PP Subgroups	EC-18	Placebo
All PP	45.5% (10/22)	70.0% (14/20)
Weekly Cisplatin	37.5% (6/16)	70.0% (7/10)
HPV^+	35.3% (6/17)*	66.7% (8/12)

*One unknown HPV status.

Olanzapine with or without an NK-1 receptor antagonist for preventing chemotherapy-induced nausea and vomiting in patients receiving highly emetogenic chemotherapy: A phase III randomized, double-blind, placebo-controlled trial (ALLIANCE A221602). *First Author: Rudolph M. Navari, Simon Williamson Clinic, Birmingham, AL*

Background: Chemotherapy-induced nausea and vomiting (CINV), a major adverse effect of cancer treatment, can attenuate life quality. Multiple international antiemetic guidelines have recommended a 4-drug regimen (corticosteroid, 5-HT3 receptor antagonist, NK-1 receptor antagonist, and the antipsychotic medication olanzapine) for decreasing highly emetogenic CINV. This raised a question regarding whether antiemetic therapy regimens for highly emetogenic chemotherapy could be de-intensified, decreasing cost and side effects from anti-emetogenic agents. **Methods:** Study A221602 was developed to compare two olanzapine-containing antiemetic regimens, one with the use of an NK-1 receptor antagonist (aprepitant or fosaprepitant) and one without. Patients (pts) received intravenous highly emetogenic chemotherapy as either 1) cisplatin, given on one day, at a dose of ≥ 70 mg/m2, with or without other chemotherapy agent(s) or 2) doxorubicin (60 mg/m2) plus cyclophosphamide (600 mg/m2) on one day. Pts in both arms received 1) a 5-HT_3 receptor antagonist (palonosetron 0.25 mg IV or ondansetron 8-16 mg IV or 16-24 mg PO,) on day one, 2) dexamethasone (12 mg PO, day one followed by 8 mg PO, days 2-4), and 3) olanzapine (10 mg/day PO, days 1 to 4). On Day 1, all agents were given prior to chemotherapy, with the exception that olanzapine could be taken prior to chemotherapy or at bedtime. Additionally, pts were randomized to receive an NK-1 receptor antagonist (fosaprepitant 150 mg IV or aprepitant 130 mg IV; 346 pts) or a matching placebo (344 pts). The primary objective was to compare the proportion of patients with no nausea for 5 days following receipt of their chemotherapy between the two study arms. **Results:** While there was no suggestion of outcome differences on day 1 between the two study arms, fewer pts (7.4%; upper limit of the 95% confidence interval was 13.5%) without NK-1 receptor antagonists were without nausea for the complete 5-day study period. **Conclusions:** Per the study design, created to exclude a 10% benefit for NK-1 receptor antagonists, the results did not provide sufficient evidence to reject the hypothesis that the 4-drug regimen was superior to the protocol 3-drug regimen (p=0.24). Support: UG1CA189823; Clinical trial information: NCT03578081. Research Sponsor: U.S. National Institutes of Health.

A single-arm feasibility trial of memantine to prevent chemotherapy-related cognitive decline in patients with early breast cancer. *First Author: Zev Nakamura, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Up to 75% of patients with breast cancer report cognitive decline following chemotherapy. There is no standard of care prevention or treatment of cognitive problems in these patients. This trial (NCT04033419) examines the feasibility of using memantine to prevent cognitive decline during chemotherapy for breast cancer. **Methods:** We enrolled patients with stage I-III breast cancer scheduled to receive neo/adjuvant chemotherapy. Participants completed a cognitive battery (4 traditional neuropsychological measures and 3 computerized tests) and surveys of self-reported cognition (PROMIS Cognitive Function Short Form 8a) and other neuropsychiatric symptoms at pre-treatment (baseline) and 4 weeks after the last cycle of chemotherapy (post-assessment). Memantine (10 mg BID) was initiated within 1 week of starting chemotherapy and continued until the post-assessment. Adherence and adverse event (AE) monitoring occurred every 2-3 weeks during chemotherapy infusion visits. We used descriptive statistics to evaluate recruitment, retention, and tolerability, adherence, and acceptability of memantine. To evaluate objective cognition, we standardized individual measures using population-based data and averaged them to calculate composite scores of 1) global cognition; 2) attention, working memory, and executive function; and 3) learning and memory. Improvement or decline was defined as ≥ 0.5 SD change between the two assessments. For self-reported cognition, established cutpoints were used to define clinically meaningful change. **Results:** Of 154 eligible patients approached, 56 (36%) enrolled. Of 51 who completed the baseline assessment and started memantine, 44 (86%) completed the post-assessment; 2 remain active. Among evaluable participants, 92% reported taking ≥ 90% of scheduled doses. Only 36% self-reported cognitive decline, while no change was reported in 57% and improvement in 7%. Decline in objective cognitive domains was observed in 7 - 14% (see Table). There were 7 ≥ grade 3 AEs 2 were possibly related to memantine (diarrhea and hypokalemia). Only 3 participants expressed worry about memantine and only 2 felt that taking memantine disrupted their lives. **Conclusions:** Our findings suggest that memantine is a safe and feasible intervention for chemotherapy-related cognitive decline and may ameliorate cognitive loss. Randomized controlled trials are needed to determine its preliminary efficacy. Clinical trial information: NCT04033419. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Body weight (BW) response timing to anamorelin (ANAM) in advanced non–small cell lung cancer (NSCLC)–associated cachexia. *First Author: Richard J.E. Skipworth, Clinical Surgery, University of Edinburgh, Edinburgh, United Kingdom*

Background: BW loss and anorexia are key clinical manifestations of cancer cachexia, a multifactorial syndrome affecting around 80% of patients (pts) with advanced cancer. BW loss is associated with reduced tolerance and response to cancer therapy, and shorter survival. ANAM is a novel, oral selective ghrelin receptor agonist. In ROMANA 1 and 2 (NCT01387269, NCT01387282) studies in pts with NSCLC and cachexia, ANAM treatment significantly increased BW and improved anorexia symptoms and concerns compared with placebo (PBO), with rapid responses occurring at wk 3 and sustained at wk 6, 9, and 12. In this post-hoc analysis, we report the timing of BW responses to assess the effects of ANAM treatment at and beyond wk 3. **Methods:** In ROMANA 1 and 2, pts with advanced NSCLC and BMI <20 kg/m^2 or BW loss ≥5% in the past 6 mo received ANAM or PBO for 12 wk. BW responses were grouped on the basis of BW change from baseline (BW gain 0 to <5% or ≥5%, and BW loss); pts were classified according to the timing of first BW response as early responders (at wk 3), late responders (at wk 6, 9, or 12), and non-responders. Missing values were not imputed. Categorical variables are presented as number and percentages, with statistical comparisons performed using the chi-square test. **Results:** In total, 552 pts in the ANAM arm and 277 in PBO were included in the analysis for all time points; at wk 3/6/9/12, data were available for 534/520/461/412 pts in the ANAM arm and 270/262/229/206 in PBO. The non-cumulative rate of pts with BW gain ≥5% was significantly higher with ANAM compared with PBO at wk 3 (13 vs 6%, p=.0030), wk 6 (26 vs 8%, p<.0001), wk 9 (28 vs 9%, p<.0001), and wk 12 (31 vs 11%, p<.0001); conversely, the rate of BW loss was significantly lower with ANAM at all time points (p<.0001). There were no significant differences between ANAM and PBO in the rate of pts with BW gain 0 to <5% at wk 3, 6, 9, and 12 (p≥.0500). The timing of first occurrence of ≥5% BW gain response is shown in the table. The rates of early and late responders were significantly higher with ANAM compared with PBO, with 28% of ANAM-treated pts first responding beyond wk 3; a larger proportion of responses with ANAM were sustained over time. **Conclusions:** ANAM significantly increased the rates of ≥5% BW gain and reduced BW loss rates compared with PBO at all time points; the proportion of first responders at wk 3 and beyond wk 3 was higher with ANAM, with the most significant increase seen at wk 6. Continuing ANAM treatment beyond wk 3 results in a clinically significant benefit. Clinical trial information: NCT01387269, NCT01387282. Research Sponsor: Helsinn Healthcare SA.

First BW responses (≥5% BW gain from baseline).

Responder category	ANAM, n (%) N=552	PBO, n (%) N=277	p-value
Early responder (at wk 3)	71 (13)	17 (6)	.0030
Sustained response at wk 6, 9, and 12	41 (7)	7 (3)	.0044
Late responder (at wk 6, 9, or 12)	155 (28)	31 (11)	<.0001
Sustained response at wk 9 and 12	64 (12)	7 (3)	<.0001
At wk 6	92 (17)	13 (5)	<.0001

Intravenous amisulpride as rescue treatment of postoperative nausea and vomiting in patients undergoing oncologic surgical procedures. *First Author: Amber Elliott, Acacia Pharma, Amarillo, TX*

Background: Nausea and vomiting or retching after surgery can have significant adverse impacts, including increased length of stay, worse outcomes and patient dissatisfaction. Therefore, effective management remains a high priority. While more aggressive, multimodal prophylaxis has helped, options for treating those patients who fail are limited. Intravenous (IV) amisulpride has been shown to be safe and effective for the rescue treatment of Post-Operative Nausea and Vomiting (PONV) in a large, randomized, double-blind, placebo-controlled trial in a broad surgical population (Habib AS, Kranke P, Bergese SD, Chung F, et al. *Anesthesiology* 2019;130:203-212). We conducted a post-hoc analysis to investigate the safety and efficacy of amisulpride specifically in those patients undergoing oncologic surgery, predominantly excision of breast, gastrointestinal, or genitourinary malignancies. **Methods:** This subset analysis includes data from a randomized, double-blind, placebo-controlled, multicenter phase III trial of a single 10 mg dose of IV amisulpride as rescue treatment of PONV occurring in patients failing pre/peri-operative prophylaxis, generally with ondansetron and/or dexamethasone (Habib AS, Kranke P, Bergese SD, Chung F, et al. *Anesthesiology* 2019;130:203-212). The subset includes only those patients identified as undergoing surgery related to a specified malignancy or a mass considered likely to be malignant. The primary efficacy outcome was complete response (CR), defined as no emetic episodes (vomiting or retching) or administration of antiemetic rescue medication in the 24 hours after dosing. **Results:** In total, 465 patients were treated with either 10 mg amisulpride or placebo and 112 (56 in each group) underwent oncologic surgery. Of these, 43 (38%) underwent surgery for a pelvic tumor, 37 (33%) had breast or axillary surgery, 13 (12%) had colorectal, hepatic or pancreatic surgery and 19 (17%) underwent procedures for other malignancies, such as nephrectomy or thyroidectomy. The CR rate at 24 hours in the amisulpride group was 38%, compared to 23% with placebo. This was comparable with the success rates for the whole study population (42% vs 29%). The CR rate after 2 hours was 66% in the amisulpride group and 39% in the placebo group, also in line with the overall study results (70% vs 49%). Among those patients whose PONV occurred in the post-anesthesia care unit (PACU), the mean length of PACU stay from treatment to PACU discharge was 156 minutes in the amisulpride group and 230 minutes in the placebo group. Treatment-emergent adverse effects (TEAE) were comparable in nature and incidence between amisulpride and placebo. **Conclusions:** Amisulpride at 10 mg IV is safe and effective as rescue treatment for PONV in cancer patients undergoing surgery and is associated with a marked reduction in PACU length of stay. Research Sponsor: Acacia Pharma.

12112 **Poster Session**

Alleviating breathlessness in patients with cancer with dexamethasone (ABCD): A parallel-group, double-blind, randomized clinical trial (RCT). *First Author: David Hui, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Systemic corticosteroids are commonly prescribed for palliation of dyspnea in patients with cancer; however, evidence to support their use is limited. A small RCT suggested that dexamethasone may be efficacious. In this confirmatory RCT, we compared the effect of high dose dexamethasone and placebo on dyspnea in patients with cancer. **Methods:** This NCI-funded, multi-site, double-blind, parallel group RCT enrolled ambulatory patients with cancer, age ≥18, dyspnea ≥4/10 and randomly assigned them to receive dexamethasone 8 mg orally every 12 hours for 7 days followed by 4 mg orally every 12 hours for 7 days or matching placebo capsules. Permuted block randomization (block size = 6, 2:1) was conducted, stratified by baseline dyspnea and study site. Patients, research staff and clinicians were blinded. The primary outcome was change in average dyspnea intensity assessed with a 0-10 numeric rating scale (0 = none, 10 = worst) between baseline and day 7. Secondary outcomes included the Edmonton Symptom Assessment Scale (ESAS) and adverse effects (CTCAE v4.02). Intention-to-treat analysis was conducted with linear models to compare between groups. The planned sample size of 201 patients provided 80% power to detect a mean difference of 1.0 between treatment groups with a two-sided α of 5%, assuming a standard deviation of 2.0 and 15% attrition. (Clinicaltrials.gov NCT03367156). **Results:** Between 1/11/2017 and 4/23/2021, we enrolled 149 patients and 128 received the blinded study interventions (dexamethasone n = 85, placebo n = 43). Enrollment was terminated early by the Data Safety Monitoring Board when futility criterion was met in pre-planned interim analysis. The mean change in dyspnea NRS intensity between baseline and day 7 was -1.6 (95% CI -2, -1.2) in the dexamethasone group and -1.6 (95% CI -2.3, -0.9) in the placebo group, with no significant between-group difference (mean 0, 95% CI -0.8, 0.7; P = 0.91). Secondary analyses showed that the dexamethasone group had a significantly better ESAS appetite (mean difference -1.2, 95% CI -2.2, -0.1; P = 0.03) and well being (mean -1, 95% CI -1.8, -0.2; P = 0.02), and worse ESAS anxiety (mean 1.1, 95% CI 0.3, 1.9; P = 0.01) and depression (mean 0.9, 95% CI 0.1, 1.7; P = 0.02) compared to placebo. Similar magnitude of changes in dyspnea and ESAS symptoms were observed by day 14. Adverse effects were reported more frequently in the dexamethasone group (any grade): insomnia (38% v. 12%), neuropsychiatric symptoms (31% vs. 7%), infections (21% v. 12%), dyspepsia (26% v. 12%), edema (18% v. 9%), hiccups (12% v. 7%), flushing (9% v. 5%) and respiratory distress (6% v. 0%). More patients in the dexamethasone group required hospitalization within 30 d of last study medication (25% vs. 7%, P = 0.02). **Conclusions:** High dose dexamethasone did not improve dyspnea in patients with cancer more than placebo and was associated with more adverse events. Clinical trial information: NCT03367156. Research Sponsor: U.S. National Institutes of Health.

12113 **Poster Session**

Efficacy and safety of SER-109, an investigational microbiome therapeutic for recurrent *clostridioides difficile* infection: Data from ECOSPOR III, a phase 3 randomized trial. *First Author: Alla Paskovaty, Seres Therapeutics, Cambridge, MA*

Background: Patients with malignancies are at increased risk for recurrent *Clostridioides difficile* infection (rCDI) due to their immunosuppressed state and frequent exposure to antibiotics and chemotherapy. These factors disrupt the gut microbiome creating an environment conducive to *C. difficile* colonization. Patients with cancer have higher rates of rCDI and worse outcomes than those without malignancy. SER-109, an investigational microbiome therapeutic, was superior to placebo in reducing rCDI at 8 weeks compared with placebo (12% vs 40%, respectively) in ECOSPOR III, a Phase 3 randomized, double-blind trial of subjects with a history of rCDI [NEJM 2022; 386:220-9]. Here, we report secondary endpoints of rCDI rates at 4, 12 and 24 weeks. **Methods:** Adults with rCDI (≥3 episodes in 12 months) were screened at 56 US/Canadian sites. After standard-of-care antibiotics (vancomycin or fidaxomicin per investigator discretion), subjects were randomized 1:1 to SER-109 (4 capsules x 3 days) or matching placebo. The primary endpoint was rCDI (recurrent toxin + diarrhea requiring treatment) at 8 weeks; secondary endpoints included rCDI at 4, 12 and 24 weeks. Safety was evaluated through week 24. **Results:** 281 subjects were screened and 182 (intention-to-treat population; ITT) were randomized (59.9% female; mean age 65.5 years). The most common comorbidities were respiratory disease (36.3%) and cardiovascular disease (32.4%). A total of 28.6% and 18.1% had a history of immunocompromise and malignancy, respectively. Significantly fewer SER-109 vs. placebo treated subjects had rCDI posttreatment compared with placebo recipients at Weeks 4, 8, 12 and 24 (Table). The absolute risk reduction between placebo and SER-109 arms ranged from 22.1% to 28.3% across the 4 timepoints. The safety profile of SER-109 through week 24 was comparable to placebo. Most adverse events (AEs) were mild to moderate gastrointestinal occurrences. More placebo-treated vs SER-109-treated subjects experienced serious AEs through week 8, while comparable proportions of subjects in both arms reported serious AEs from 8 through 24 weeks. **Conclusions:** In this population of subjects with comorbidities, including malignancy and immunosuppression, SER-109 significantly reduced rCDI rates through week 24 with an observed safety profile comparable to placebo. Clinical trial information: NCT03183128. Research Sponsor: Seres Therapeutics.

Cumulative rCDI rates, relative risks, and rate differences at weeks 4, 8, 12 and 24.

Timepoint	SER-109 N=89	Placebo N=93	Relative Risk (95% CI)	Rate Difference
4 weeks, n (%)	10 (11.2)	31 (33.3)	0.35 (0.19-0.67)	-22.1
*8 weeks, n (%)	11 (12.4)	37 (39.8)	0.32 (0.18–0.58)	-27.4
12 weeks, n (%)	16 (18.0)	43 (46.2)	0.40 (0.24–0.65)	-28.3
24 weeks, n (%)	19 (21.3)	44 (47.3)	0.46 (0.30–0.73)	-26.0

*Week 8 was the primary efficacy endpoint. Weeks 4, 12 and 24 were secondary efficacy endpoints.

Patient-reported hope, quality of life (QOL), symptom burden, and coping mechanisms in early phase clinical trial participants. *First Author: Debra Lundquist, Massachusetts General Hospital, Boston, MA*

Background: Early phase clinical trials (EP-CTs) investigate novel treatment options in oncology, with recent advances in personalized therapy leading to improved outcomes and offering hope to patients with cancer. However, little research has sought to understand associations of patient-reported hope with QOL, symptom burden, and coping mechanisms in EP-CT participants. **Methods:** We prospectively enrolled consecutive adults with cancer participating in EP-CTs at Massachusetts General Hospital from 04/2021-01/2022. Participants completed baseline surveys prior to treatment initiation that assessed hope (Herth Hope Index [HHI], higher scores indicate greater hope), QOL (Functional Assessment of Cancer Therapy-General), symptom burden (physical: Edmonton Symptom Assessment System [ESAS]; psychological: Patient Health Questionnaire-4 [PHQ4]), and coping mechanisms (Brief COPE). We used independent samples t-test to test for mean differences between groups and regression models to explore associations of hope with patient characteristics as well as patient-reported QOL, symptom burden, and coping mechanisms. **Results:** Of 92 eligible patients, we enrolled 85 (enrollment rate 92.4%, median age = 61.4 years [range 54.7-68.9]; 56.5% female, and 95.3% metastatic cancer). Most common cancer types were gastrointestinal (41.2%), breast (21.2%), lung (7.1%), and gynecologic (7.1%). Patients had an average HHI score of 28.2 (range 12.0-36.0), with 32.9% reporting high levels of hope. We found that married patients had higher mean hope score compared with non-married patients (28.9 versus 26.1, p = 0.024), those with children had higher mean hope scores than those without (28.9 versus 25.9, p = 0.013), and those who had received 3 or more lines of prior therapy compared with 1-2 (29.3 versus 27.2, p = 0.045) had higher hope scores. We also found associations of hope with patients' QOL (B = 0.24, p < 0.001), symptom burden (ESAS-physical: B = -0.13, p = 0.001; PHQ4-depression: B = -2.26 p = < 0.001; PHQ4-anxiety: B = -0.94, p = 0.008), and coping (self-blame [B = -1.39, p = 0.003]; acceptance [B = 1.23, p = 0.002], denial [B = -1.09, p = 0.009], support [B = 1.06, p = 0.002], active [B = 0.73. p = 0.034], disengage [B = -3.24, p < 0.001]). **Conclusions:** In this prospective cohort study, we demonstrated that a substantial proportion of EP-CT participants had high baseline hope, and we identified several patient factors associated with their hope scores. We also found novel associations of higher hope scores with better QOL, lower symptom burden, and more adaptive coping mechanisms. Collectively, our findings highlight the potential for patient-reported hope to represent a key factor to consider when seeking to improve outcomes in EP-CT participants. Research Sponsor: None.

Implementation of electronic patient-reported outcomes in head and neck oncology at a comprehensive cancer center. *First Author: Nadine Jackson McCleary, Dana Farber Cancer Institute, Boston, MA*

Background: Monitoring electronic patient reported outcomes (ePROs) has demonstrated impact on quality of life and survival in oncology. Maintaining high response rates to ePRO measures is critical in routine care. We evaluate the routine care implementation of head and neck oncology (HNO)-focused ePROs and the impact of patient demographics and assignment method on response rate. **Methods:** Since October 2021, patients diagnosed with head and neck cancer (PHN) at Dana-Farber Cancer Institute (DFCI) have had the opportunity to respond to the EHR-integrated European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Head and Neck Module (EORTC QLQ-H&N43) at clinic visits, not to exceed every 30 days. PHN are also prompted at 7 and 14 days postoperative, regardless of clinic visit. HNO clinicians selected EORTC QLQ- H&N43 because of its actionable scores and limited overlap with cross-cutting ePRO tools at DFCI. Reviewed by Patient and Family Advisory Council members, PHN can respond to the questionnaire in English or Spanish via any internet-enabled device or tablet provided in clinic. Tablet assignment rates are sent via automated report to the HNO clinic manager. **Results:** Between October 2021 and January 2022, PHN responded to 64% of questionnaires for eligible clinic visits (1618/2535). Post-operatively, 65% of PHN responded to EORTC QLQ- H&N43 at least once within 28 days of surgery. Prompted at 7 and 14 days, PHN responded to 44% (133/300) of all post-operative questionnaires. Overall, PHN responded on their own device 50% of the time and on tablets in clinic 50% of the time. Response rates significantly associated with race, primary language, and age at clinic, but not post-operatively due to low sample size. PHN with a primary language other than English, older PHN, and PHN with races other than white responded less frequently, with the exception of Asian PHN in clinic who had the highest response rates. Clinician champions, EHR-integration, and a timely feedback loop to clinic managers facilitated response rates. **Conclusions:** Successful implementation of HNO ePROs is aided by clinical engagement and availability of real-time response rate data. ePRO response rate in HNO was found to be associated with race, primary language, age, and assignment method. Further work to focus on improving disparities within response rates and linking automatic interventions to scores is needed. Research Sponsor: None.

Risk assessment model potency to detect patients most likely to benefit from thromboprophylaxis: An application of the TARGET-TP score. *First Author: Kate Burbury, Department of Haematology, Peter MacCallum Cancer Centre & Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, Australia*

Background: Interventional trials applying risk models for targeted-thromboprophylaxis (TP) for ambulatory cancer patients have previously excluded low risk patients, preventing quantification of residual risk and unmet need. We compare potency and pragmatic application of risk models, to guide routine clinical utilisation. **Methods:** TARGET-TP, a three arm phase 3 randomized trial of TP, classified ambulatory lung and gastrointestinal cancer patients into high or low thromboembolism (TE) risk groups using an algorithm derived from fibrinogen and d-dimer levels. High risk patients (randomized arms) received enoxaparin or no TP. Low risk patients were enrolled as an observation arm. Risk model potency was assessed by comparing cumulative TE incidence at 180 days between the two arms not receiving enoxaparin. In this analysis, we also compared other risk models using published risk thresholds (Khorana Score (KS), PROTECHT, CONKO, CATS/MICA) using associations of predicted TE risk with observed TE events (cause specific Cox proportional hazards regression), sensitivity and specificity. **Results:** Among 328 patients, 200 (61%) were classified high TE risk using the TARGET-TP algorithm. Without TP, TE incidence was 23% among high risk and 8% low risk patients – compared to 8% in high risk enoxaparin treated patients. There was notable cohort migration, with individual patients reclassified between high- and low-risk across other risk. Up to 75% of TARGET-TP high risk patients were classified low risk by other models, and would not be considered for TP, potentially exposing substantive residual TE risk (75% low risk by CATS/MICA, 61% KS, 60% CONKO, 32% PROTECHT). Up to 57% of low risk patients were high risk by other models, potentially exposing unnecessarily to TP (57% high risk by PROTECHT, 27% KS, 26% CONKO, 5% CATS/MICA). Among 228 patients in TARGET-TP trial non-intervention arms: TE incidence and comparative risk (hazard ratio, HR) for high versus low TE risk were: TARGET-TP (23% high vs. 8% low, HR 3.33 [95%CI 1.58-6.99]), KS (17% vs. 13%, HR 1. 50 [95%CI 0.74-3.02]), PROTECHT (16% vs. 12%, HR 1.50 [95%CI 0.69-3.05]), CONKO (18% vs. 13%, HR 1.54 [95%CI 0.76-3.09]), CATS/MICA (26% vs. 12%, HR 2.72 [95%CI 1.26-5.86]). Sensitivity and specificity respectively: TARGET-TP 70%/61%, KS 39%/68%, PROTECHT 70%/37%, CONKO 39%/69%, CATS/MICA 27%/87%. **Conclusions:** Application of TE risk models demonstrated some ineffectual and if utilised to define TP eligibility, 4/5 would exclude patient cohorts with TE rates exceeding 10%. TARGET-TP was the only model to achieve both high sensitivity and specificity. This simple pragmatic model considers only d-dimer and fibrinogen, can be applied without complex calculations or nomograms, in real-time for any patient. Embedded outpatient palliative care for hematologic malignancies: Referral patterns and health care utilization. *First Author: Mazie Tsang, University of California San Francisco, San Francisco, CA*

Background: Patients with hematologic malignancies are less likely to receive outpatient palliative care (OPC) compared to patients with other cancer types. Little is known about the characteristics or health care utilization of patients with hematologic malignancies who are co-managed by OPC. In this study, we evaluated referral patterns and health care utilization of patients with hematologic malignancies who were seen in an embedded OPC clinic. **Methods:** We conducted a retrospective cohort study of patients who established care with an embedded OPC nurse practitioner from 3/2016 – 5/2020 at a quaternary academic medical center. We obtained information about patients' demographics, clinical characteristics, and reasons for referral to OPC from the electronic health record. Information about costs and health care utilization were provided by our finance team. For patients who were followed by OPC for at least 6 months, we used two-tailed t-tests to compare the number of hospitalizations and emergency department (ED) visits, as well as total costs, for the 6 months before and the 6 months after initiating OPC. This was approved by the UCSF IRB. **Results:** A total of 120 patients received OPC. Median age was 59 years (range 24-89), 48% were female, and 64% were Non-Hispanic White. Myeloma was the most common cancer (n = 50/120, 41.7%), followed by aggressive lymphoma (n = 21/120, 17.5%), and acute myeloid leukemia (n = 18/120, 15%). The primary reason for referral was for symptom management, such as pain (60%, n = 72/120), mood symptoms (12.5%, n = 15/120), and fatigue (7.5%, n = 9/120). Ten percent (n = 12/120) were referred for goals of care conversations prior to stem cell transplant (SCT). An advance directive was on file for 29% (n = 35/120) of patients, of which 34% (n = 12/35) were completed after OPC enrollment. Of the 38 patients who died, the median time from PC enrollment to death was 15.3 months, and 39% died on hospice. For the 65 patients who were followed by OPC for at least 6 months, the total number of inpatient hospitalizations, excluding SCT, went from 0.82 to 0.54 (p = 0.11) per person in the 6 months before compared to the 6 months after initiating OPC. ED visits went from 0.28 to 0.18 (p = 0.33). The total direct cost of inpatient hospitalizations, excluding SCT, decreased from $43,428 to $13,226 (p = 0.01), and the cost of ED visits went from $640 to $297 (p = 0.32) per person. **Conclusions:** There is an important role for embedded OPC for patients with hematologic malignancies, long before the end-of-life period, to manage symptoms and support decision-making. OPC is associated with a trend towards lower health care utilization and decreased hospitalization costs. Prospective studies are warranted to further explore the impact of OPC on symptoms and patient/caregiver experience, as well as to clarify how OPC impacts health care utilization. Efficacy of a nurse monitoring service at preventing disease- or therapy-related symptoms in patients receiving targeted therapy or immunotherapy. *First Author: Andrea Sbrana, Service of Pneumo-Oncology, Azienda Ospedaliera Universitaria Pisana, Pisa, Italy*

Background: The safety profile of Targeted therapies (TT) and immunotherapy (IT) may be underestimated and negatively affect the clinical outcome. **Methods:** A nationwide, randomized, open-label trial (NCT04726020) conducted among 29 Italian centers involved two cohorts of 223 adult patients (pts) with a solid tumor, receiving TT (group B, 119 pts) or IT (group C, 104 pts). Pts were randomized to receive a weekly nurse monitoring phone call, together with an educational leaflet with some practical advice about toxicities (experimental arm), or only the educational leaflet (control arm). In the experimental arm, pts received their monitoring phone call before their treatment began, then every week for up to 16 weeks of treatment were completed. The primary objective was the evaluation of the difference in toxicities according to patient-reported outcome (PRO)-CTCAE. **Results:** Both arms were comparable in terms of pts' characteristics (e.g. site of primary tumor, line of treatment). The adherence to the project (that is the completion of every expected call) was 62.1% in group B and 66.9% in group C. In group B, in the experimental arm, we found a higher number of pts without pain (53.7 vs 39.9%, p = 0.047); a trend of lower fatigue (29.2 vs 18%, p = 0.067) was also observed. In group C, a higher number of pts did not report fatigue (29.1 vs 17.5%, p = 0.043), shortness of breath (61.4 vs 38.5%, p = 0.002) or dry skin (72 vs 52.3%, p = 0.004). More pts also referred to be without pain (51.6 vs 38.8%, p = 0.065) and pruritus (75.9 vs 64.5%, p = 0.088), even if these difference were not statistically significant. **Conclusions:** The use of PRO assessment through active nurse monitoring might lead to a better tolerance of TT and IT with possible implications on pts' quality of life and ultimately on treatment outcome. In particular, in the IT group, several symptoms were prevented from occurring, thus encouraging a major effort to implement such active monitoring in this population. Clinical trial information: NCT04726020. Research Sponsor: None.

12119 **Poster Session**

Suicide risk among patients with cancer in the United States, 2000-2016. *First Author: Xuesong Han, American Cancer Society, Atlanta, GA*

Background: Individuals diagnosed with cancer have elevated suicide risk in the US, although little is known about risk associated with state of residence, health insurance coverage, or time since diagnosis by cancer types. This study used a recent national dataset to examine a wide range of patients' sociodemographic and clinical factors that may be associated with suicide risks. **Methods:** We identified patients diagnosed with cancer from 43 population-based state cancer registries in 2000-2016 with follow-up through Dec 31, 2016. Standardized Mortality Ratios (SMR) and 95% confidence intervals (95CI) were calculated by state of residence, attained age group, sex, and race/ethnicity to compare suicide risks in the cohort vs. the general US population. Hazard Ratios (HR) and 95CI from multivariable Cox proportional hazard models were derived to identify cancer-specific risk factors of suicide among the cohort, controlling for competing risks from other causes of death. **Results:** Among 16,771,397 patients, 7,972,782 (47.5%) died during the study period, and 20,792 (0.3%) from suicide. The overall SMR for suicide was 1.26 (95CI = 1.24-1.28), decreasing from 1.67 (95CI 1.47-1.88) in 2000 to 1.16 (95CI 1.11-1.21) in 2016. Patients from Alaska, Colorado and Idaho, those aged 65-69 years (SMR = 1.44, 95CI = 1.39-1.50), Hispanic patients (SMR = 1.48, 95CI = 1.38-1.58), those uninsured (SMR = 1.66, 95CI = 1.53-1.80) or insured with Medicaid (SMR = 1.72, 95CI = 1.61-1.84) or ≤64 years of age with Medicare (SMR = 1.94, 95CI = 1.80-2.07) had the highest suicide risks compared to the general population. Moreover, the highest suicide risk occurred within two years of diagnosis (SMR [95CI] = 7.19 [6.97-7.41], 5.60 [5.35-5.84] and 4.18 [4.03-4.33] for ≤5 months, 6-11 months, and 12-23 months after cancer diagnosis, respectively). In the first two years following diagnosis, the risk of suicide was higher in patients diagnosed with distant-stage than early-stage diseases (HR = 1.29, 95CI = 1.21-1.37), and in patients with more cancer types with poor prognoses and high symptom burdens, such as cancers of oral cavity & pharynx, esophagus, stomach, brain, lung and pancreas (HRs ranged 1.23-2.10 vs. colorectal cancer, all $P \leq 0.001$). After two years, patients diagnosed with cancers subject to long-term quality of life impairment, such as cancers of oral cavity & pharynx, female breast, bladder, and leukemia (HRs ranged 1.17-1.54 vs. colorectal cancer, all $P \leq 0.01$), had higher suicide risks. **Conclusions:** Suicide risk among patients diagnosed with cancer decreased during the past two decades but remained elevated compared to the general population. Different geographic, racial/ethnic, socioeconomic, and clinical factors, some of which are modifiable, contribute to increased suicide risk among patients diagnosed with cancer. Tailored social and psych-oncological interventions are warranted for suicide prevention in this vulnerable population. Research Sponsor: None.

Impact of cisplatin-induced hearing loss (CIHL) on patient-reported social and emotional functioning. *First Author: Victoria Sanchez, University of South Florida, Tampa, FL*

Background: Cisplatin is one of the most commonly used ototoxic drugs, but no study has quantified the handicap imposed by CIHL in U.S. adult-onset cancer survivors. Identification of survivors with high degrees of handicap and related risk factors is vital, as hearing loss (HL) in the general population is strongly related to adverse health outcomes, including cognitive decline, dementia, and poor mental health and social well-being. **Methods:** Eligible testicular cancer survivors (TCS) (age < 60 y at diagnosis, given first line cisplatin) completed comprehensive health surveys, including the validated 25-item Hearing Handicap Inventory for Adults (HHIA). HHIA quantifies emotional (13 items) and social difficulties (12 items) related to HL; for each scale (0-100%), based on their responses, TCS were grouped into 3 handicap levels: 0-16% (none/minimal), 17-42% (mild/moderate), and 43-100% (significant) following HHIA recommendations. A Spearman correlation evaluated the associations between increasing HL severity and HHIA group. The association between HL and reported cognitive dysfunction was evaluated by a logistic regression analysis adjusted for age, income, education, yrs since therapy, cisplatin dose, BMI, smoking, and hypertension, with results presented as OR[CI], p-value. **Results:** Among 213 TCS [median age at evaluation, 46 y (IQR: 38-52 y); median time since cisplatin completion, 10.6 y (IQR: 6.8-16.6 y)], CIHL was reported by 127 TCS (60%). Of TCS with CIHL, 31% reported some degree of related handicap (for total HHIA scale: 13% TCS and 18% TCS reporting mild/moderate and significant handicap, respectively). HL severity was significantly correlated with handicap level in all domains (social, $\rho = 0.85$, p < .001; emotional, $\rho = 0.72$, p < .001; and total, $\rho = 0.81$, p < .001). Cognitive dysfunction was more commonly reported by TCS with CIHL than TCS without (35% and 22%, p = .049). HL was a significant independent predictor of cognitive dysfunction, 2.20 [1.09-4.47], p = .028. Since many patients with HL in the general population report tinnitus (TINN), and TINN may suggest a worse HL phenotype, we additionally adjusted for TINN severity and found a significant independent association for TINN and cognitive dysfunction, 1.49 [1.05-2.11], p = 0.027. Despite these outcomes, only 10% of TCS with HL used hearing aids (n = 13). **Conclusions:** After cisplatin chemotherapy, 60% TCS report CIHL, and TCS with CIHL report poorer social and emotional function. One in 5 TCS with CIHL reported significant overall handicap. Despite these outcomes, the low prevalence of hearing aid use suggests a potential clinical intervention that could improve social and emotional well-being. If confirmed, the possible association between CIHL with TINN and cognitive dysfunction may be of particular interest, as the Lancet Commission on Dementia Prevention (2020) identified untreated HL as a key modifiable risk factor. Research Sponsor: National Cancer Institute.

12121 **Poster Session**

Machine learning model to predict mortality after discharge in hospitalized oncologic patients (pts) under active systemic therapy in the advanced setting: A multicenter cross-validation study. *First Author: Oriol Mirallas, Vall d'Hebron University Hospital and Institute of Oncology (VHIO), Barcelona, Spain*

Background: Prognostic factors for oncologic pts after surgery or curative systemic treatment have been described, including ECOG performance status, tumor staging and malnutrition. However, there is no solid evidence on which combination of variables best predicts mortality after hospitalization of metastatic cancer pts under active systemic treatment. **Methods:** Prospective multicentric study of pts hospitalized between 2020 and 2022 at the Oncology wards of Vall d'Hebron, Sant Pau and Mar Hospitals [PLANTOLOGY database] in Barcelona, Spain. Clinical factors such as ECOG, comorbidities, tumor characteristics, and laboratory results were collected at admission. Mental status (depression and anxiety) and QOL were assessed through the HADS and EORTC-QLQ30 questionnaires, respectively. Nutritional assessment was performed using the chair and hand grip tests. All variables were analyzed in uni- and multivariable regressions including a machine learning LASSO model to assess predictive discriminators of 30-day mortality after discharge. Missing data was imputed using Multivariate Imputation by Chained Equations. A bootstrap with 1000 iterations was used to validate the model and c-index. **Results:** Among 1,663 pts, 932 had advanced disease and were under oncologic treatment during the 6 months previous to urgent admission, our target population for model development and validation. Median age was 64 years, 51% had an ECOG > 1, median Charlson comorbidity index was 8 and 34% were under treatment in a clinical trial. The most frequent tumor types were lung (25%), colorectal (14%) and breast (12%) cancer. The most relevant factors associated with higher mortality at 30-day after discharge in LASSO model were high Charlson index, low neutrophil count, high LDH, poor ECOG status and progressive disease at admission (all p-values p < 0.05). The c-index corrected after bootstrap validation was 0.75. After adding the nutritional assessment, mental health status and QoL (subset of 606 with complete data), the predictive power of the model increased to a c-index corrected after bootstrap validation of 0.81. Our final prognostic model called the PRognostic Oncologic Plantology score (PROP) obtained a sensitivity of 0.75 and a specificity of 0.80 with an overall accuracy of 0.80. Only 10% of "low" PROP score pts (72% of the population) died within 30 days of discharge, as compared to 58% of early mortality in "high" PROP score pts. **Conclusions:** Our model, including clinical and analytical factors, predicts with accuracy the 30-day mortality of oncologic pts after discharge which is significantly improved with the addition of nutritional assessment and standardized questionnaires of QoL and mental status. The PROP score calculator will be built to help physicians adjust medical interventions for hospitalized cancer pts. Research Sponsor: None.

Self-reported efficacy and usage of cannabis among patients with cancer within the Minnesota Cannabis Program. *First Author: Dylan M. Zylla, HealthPartners Cancer Research Center, Minneapolis, MN*

Background: Patients with cancer are increasingly using cannabis to alleviate symptoms of pain, nausea, insomnia, and appetite loss. Despite the increased popularity of cannabis, little is known about the patterns of use in the cancer population, efficacy in treating symptoms outside of small clinical studies, and out-of-pocket expenses. We assessed self-reported efficacy and patterns of cannabis use from patients with cancer registered with the Minnesota Cannabis Program (MCP). **Methods:** We conducted an anonymous survey from December 2021-January 2022 of 797 individuals with cancer-associated pain, nausea/vomiting and/or anorexia currently enrolled in the MCP who had purchased a cannabis related product in the preceding three months. The mailed survey included questions about cancer history, cannabis use, and changes in symptoms. We conducted a descriptive analysis to describe patterns of use. **Results:** 225 individuals responded to the survey after a single mailing for a 28% response rate. 70% reported using cannabis at least once prior to cancer diagnosis. Respondents had diverse cancer diagnoses (breast (24%), lung (14%), colorectal (10%), prostate (9%)) and were more often female (52%), married, (71%), white (95%), and retired (40%) with a median age of 62.0. Most respondents (46%) had stage IV disease with the remaining 34% stage 1-3 (20% unknown). Household income varied across respondents with 10% reporting annual income <$20,000, 39% between $50-100k, and 33% with incomes ≥100k. 88% purchased at least one product with THC:CBD (tetrahydrocannabinol/cannabidiol) composition >1. Respondents reported that oral products were preferred to vaporizers (81% vs 45%) and 75% reported at least daily use. 27% reported monthly average out of pocket expenses for cannabis of $100-200; with 31% spending ≥$200/mo. The Table outlines perceived change in symptoms amongst users. **Conclusions:** Patients with cancer in the MCP with recent cannabis purchases predominantly use high THC:CBD products delivered via oral or vaporizer route on daily basis. While out of pocket costs for these products can be significant, many respondents report significant improvements in cancer related symptoms. Research Sponsor: U.S. National Institutes of Health.

Patient responses to the question of "How much do you think cannabis has worsened or improved your..... (symptom)."

Symptom*, n (%)	Worsened quite a bit	Somewhat worsened	No change	Somewhat improved	Improved quite a bit	Do not have symptom
Pain	0	1 (0.5)	21 (10.2)	68 (33.2)	102 (49.8)	13 (6.3)

Increasing the use of olanzapine in patients receiving chemotherapy in a community oncology practice. *First Author: Bindu Rani Potugari, Saint Joseph Mercy Health System, Ann Arbor, MI*

Background: The addition of olanzapine to high emetic risk chemotherapy regimens substantially improves nausea and vomiting within 24 hours and is recommended in the guidelines of both the American Society of Clinical Oncology (ASCO) and the National Comprehensive Cancer Network (NCCN). However, the uptake of olanzapine has been low in national and institutional settings. The purpose of this project was to increase guideline-concordant prescribing of olanzapine in eligible patients in a community oncology practice. **Methods:** We developed a multiphase program to address the barriers to the use of olanzapine in a community oncology practice. Patients' medical records (N = 423) were reviewed to collect baseline data. Motivational interviewing with prescribing clinicians elicited barriers to prescribing, reinforced clinical guidelines, and elicited and reinforced language that suggested a willingness to change prescribing patterns. Chemotherapy protocols were subsequently updated to include olanzapine for high emetic chemotherapy regimens, and prescriber and nurse education was provided by our pharmacists regarding the most recent ASCO and NCCN guidelines. A fellow-led educational session was provided to the infusion nursing team and care managers. At the end of a seven-month period, prescribing information was identified through a system-generated report followed by a medical record review for validation (N = 136) and was shared monthly with prescribing clinicians. **Results:** At baseline, the use of olanzapine was zero. Multiple barriers were identified regarding the use of olanzapine during motivational interviewing with clinicians, including lack of knowledge of the guidelines, belief that most patients do not require olanzapine, concerns about sedation with the previously recommended dose of 10 mg, and order sets that did not include olanzapine. After the interventions, there was a statistically significant increase in the use of olanzapine from 0% to 56% (p-value < 0.001). **Conclusions:** A combination of motivational interviewing, prescriber and nurse information support, and changes to the pre-populated order sets for chemotherapy antiemetics was highly successful in improving the uptake of guideline-concordant prescribing of antiemetics. This model of quality improvement, including motivation interview, may support quality improvement efforts across oncology. Research Sponsor: None.

Acupuncture for hot flashes in hormone receptor-positive breast cancer, a pooled analysis of individual patient data from parallel randomized trials. *First Author: Weidong Lu, Dana-Farber Cancer Institute, Boston, MA*

Background: Hot flashes are a common side effect of endocrine therapy in breast cancer patients (pts). In a coordinated multinational study, we evaluated the impact of acupuncture on hot flashes and related symptoms in hormone receptor-positive breast cancer pts undergoing adjuvant endocrine therapy in the USA, China, and South Korea. **Methods:** Parallel randomized trials were conducted at three sites: Dana-Farber Cancer Institute, USA; Jiangsu Hospital of Traditional Chinese Medicine, China; and Daegu Catholic University Medical Center, Republic of Korea, using the same inclusion/exclusion criteria, randomization, and measures. Breast cancer pts receiving adjuvant endocrine therapy and having ≥14 hot flashes per week were randomized equally to acupuncture (A) or usual care (UC); randomization was stratified by number of hot flashes per day (2-6 or 7+). Pts in arm A received a standardized acupuncture protocol twice per week for 10 weeks; pts in the UC arm received usual care. Symptoms were assessed at baseline and week 10. The primary endpoint was change in the Endocrine Symptom Subscale (ESS) of the Functional Assessment of Cancer Therapy-Endocrine Systems (FACT-ES). Secondary endpoints included changes in the FACT-Breast (FACT-B) and Daily Hot Flash Score (DHFS), a measure incorporating hot flash frequency and severity. Target enrollment was 160 pts (USA 80, China 40, Korea 40) providing 84% power to detect a clinically meaningful change in the ESS. Analyses were intention-to-treat. A pooled analysis of individual patient data was performed using linear models adjusted for site and baseline number of hot flashes. **Results:** Between Jan. 2019 and June 2021, 158 female pts with stage 0-III breast cancer were randomized from the USA (n=78), China (n=40), and South Korea (n=40). Median age was 48 years (range: 25 to 73). At baseline, pts reported similar numbers of hot flashes between study arms (6.2± 4.3 vs. 6.5± 3.8 per day). At week 10, pts in arm A reported statistically significant improvements in ESS score, FACT-B total score and DHFS compared with the UC arm (Table). The reduction in the DHFS from baseline in arm A was 53%. There were no serious adverse events. **Conclusions:** Acupuncture led to statistically and clinically meaningful improvements in hot flashes, endocrine symptoms, and breast cancer-specific quality of life in women undergoing adjuvant hormonal therapy for breast cancer in the USA, China and South Korea. Clinical trial information: NCT00797732, ChiCTR2100045888, KCT0003618. Research Sponsor: Comprehensive and Integrative Medicine Institute, South Korea.

Prevalence and perceptions of cannabis use among racially diverse patients with cancer pain: Results from a multi-site survey. *First Author: Brooke Worster, Thomas Jefferson University Hospital, Philadelphia, PA*

Background: While access to cannabis is prevalent among cancer patients[1], unknowns persist about real-time use, perceived effectiveness in cancer pain management and impact on other medication use, including opioids. Moreover, racial disparities in cancer pain management persist[2-3] with Black patients more likely to have undiagnosed pain.[4] Studies on the intersection of cannabis, opioids, race and cancer pain are needed. As part of an NCI-funded initiative, we assessed the perceived effectiveness of cannabis vs. opioids for pain control by race. **Methods:** A survey was created by three Mid-Atlantic, cancer centers to examine self-reported cannabis use and knowledge, barriers and perceptions about cannabis among cancer patients. All sites assessed common core questions and included additional questions assessing cannabis and opioid use. Patients were eligible to participate if they were treated for cancer within the prior year. Surveys were distributed both by mail and electronically via REDCap. Results are compared separately by site. **Results:** In all, 2,734 patients are included in this analysis. Rates of cannabis use since diagnosis ranged from 32-41% of respondents, with similar rates of use between gender and race. Patients under age 65 more frequently reported cannabis use. Across sites, only 7-8% of patients reported currently using opioids. A sizable number patients who use cannabis reported using cannabis instead of opioids to treat pain. Of those using cannabis, most felt that cannabis was better in managing their pain than opioids, with Black patients reporting this much more frequently than White patients across two sites (Site A 62.2% vs 43.2%, Site B 77.78 vs 48.96%, Site C 50.0% vs. 65.5%). The most common reasons patients reported using cannabis instead of opioids included the perception that: "cannabis is safer" (80-82%), "cannabis is less addictive" (70-73%), and "cannabis has fewer side effects" (68-74%). **Conclusions:** Cannabis is frequently used by cancer patients, with many reporting use instead of opioids for pain management. Of those using cannabis for pain management, a significant majority felt that it is more effective than opioids. Black patients report cannabis as more effective than opioids for pain control more frequently than other races. Given the ongoing under-treatment of cancer pain in Black patients, more data is needed to understand whether cannabis is an effective tool to reduce disparities in cancer pain management. Research Sponsor: U.S. National Institutes of Health.

Delayed versus immediate start of chemotherapy in asymptomatic patients with metastatic cancer: A systematic review and meta-analysis. *First Author: Simone Augustinus, Department of Surgery, Amsterdam Umc, University of Amsterdam, Cancer Center Amsterdam, Amsterdam, Netherlands*

Background: The number of asymptomatic patients diagnosed with metastatic cancer is increasing. This is mostly due to increased used of imaging, especially for screening and during follow-up. Traditionally, chemotherapy is started immediately in these patients, but some argue that withholding chemotherapy until symptoms occur may be beneficial for patients, especially in terms of quality of life. However, the impact on survival and quality of life is unknown. The aim of this study is to give an overview of delayed versus immediate chemotherapy in asymptomatic patients with metastatic cancer. **Methods:** We systematically searched PubMed, EMBASE (Ovid), and Cochrane for studies investigating the timing of start of chemotherapy in asymptomatic patients with metastatic cancer. Primary outcome was overall survival (OS). Secondary outcomes included quality of life (QOL) and toxicity. A meta-analysis was performed on OS, including all studies that compared direct versus delayed chemotherapy. Quality of life was described using the global health status derived from the EORTC-QLQ-C30 questionnaire evaluated in the studies. **Results:** Four randomized controlled trials and one retrospective study with overall 919 patients were included. The studies considered colorectal cancer (n = 3), ovarian cancer (n = 1), and gastric cancer (n = 1). The median OS varied from 11.9 to 25.7 months in the immediate treatment group versus 9.0 to 27.1 months in the delayed group. A pooled analysis demonstrated no significant differences in OS between the groups (pooled HR 1.05, 95% CI 0.90-1.22, p = 0.52). Quality of life was evaluated in three studies and suggested a better QOL in the delayed treatment group. In two studies including colorectal cancer patients the global health status in the immediate treatment group was lower at all time-points compared to the delayed treatment group, with no significant differences in any of the separate domains. In the study evaluating ovarian cancer patients, among others, the time median time spent in good global health score was lower in the immediate treatment group. Toxicity was compared between the two groups in one study, and this showed no significant differences. **Conclusions:** This systematic review with meta-analysis on timing of start of chemotherapy in asymptomatic patients with metastatic cancer suggests that a delayed start of chemotherapy, as compared to immediate start, does not result in worse OS, while it may better preserve QOL. Future randomized trials, with specific emphasis on quality adjusted life years are needed. Research Sponsor: None.

Impact of an augmented intelligence-based tool upon the timeliness of referrals to palliative care and hospice in patients with advanced cancer in the real-world setting. *First Author: Ajeet Gajra, State University of New York Upstate Medical University, Syracuse, NY*

Background: Timely integration of palliative care (PC) and hospice management for patients with advanced cancer requires informed clinical decision-making and expectation-setting to help patients realize their end-of-life (EOL) goals. Longer stay with hospice is a quality indicator in oncology care that requires earlier referral to PC and hospice. We have previously demonstrated that an augmented intelligence (AI) tool used to predict 30-day mortality can assist with an increase in referrals to PC and hospice. In this secondary analysis, we report on the impact of the AI tool on the timeliness of referral to PC and hospice prior to death. However, calculating days with hospice across multiple hospice providers and geographies can be challenging. Thus, we used a real-world (RW) measure of 14 to 90 days prior to death as a surrogate for timeliness for hospice and 90 to 180 days prior to death for a PC referral. **Methods:** Medical records of patients at a large community-based hematology/oncology practice in the Pacific Northwest who experienced a mortality event pre-deployment (January 2017 to April 2018) or post-deployment (May 2018 to June 2021) of the AI tool were electronically reviewed for evidence of a PC or hospice referral. Patients were included if the referral was between 14 to 90 days of the mortality event for hospice care or between 90 to 180 days prior to death for PC. Outcomes for additional timepoints (1-3 days and 4-13 days and >90 days) will be provided at the final presentation. Data were analyzed using a statistical process control chart. **Results:** Of the patients who experienced a mortality event, the following percentages had been referred pre- and post-deployment of the AI tool: PC 7.1% pre- and 15.0% post-deployment; hospice 11.5% pre- and 32.1% post-deployment. A system shift (≥6 points in a row steadily increasing or decreasing) occurred early after deployment, in June 2018. The overall improvements were 111.0% in PC referrals and 179.1% in hospice referrals within the respective timeframes. **Conclusions:** Deployment of an AI tool at a hematology/oncology practice substantially increased the proportions of patients referred to PC 90-180 days prior to death and hospice between 14 -90 days prior to death, suggesting a favorable impact on timeliness of referrals. If confirmed in additional studies, the AI-based tool can be utilized to integrate PC early in the management of patients with advanced cancer. Research Sponsor: None.

Proportion of patients with a palliative care (PC) or hospice referral prior to death.

Referral type	Time frame	Pre-deployment (January 2017 to April 2018)	Post-deployment (May 2018 to June 2021)	Overall Improvement
PC	90 to 180 days before death	7.1%	15.0%	111.0%
Hospice	14 to 90 days before death	11.5%	32.1%	179.1%

Major stressful events and risk of developing head/neck and pancreatic cancer. *First Author: Arthi Sridhar, The University of Texas Health Sciences Center at Houston, McGovern Medical School, Houston, TX*

Background: Major stressful life events have been shown to be associated with an increased risk of lung cancer, breast cancer and the development of various chronic illnesses. The stress response generated by our body results in a variety of physiological and metabolic changes which can affect the immune system, endocrine system and metabolism which has been shown to be associated with tumor progression. There is an indication that stress may need to be considered as a risk factor for malignancies. **Methods:** This is a matched case control study. The objective of this study was to determine if major stressful life events are associated with the incidence of head, neck, and pancreatic cancer (HNPC). Cases (CA) were HNPC patients diagnosed within the previous 12 months. Controls (CO) were patients without a prior history of malignancy and were matched with the cases by age and smoking status. Basic demographic data and medical information were collected from the patient's medical records. Data on major stressful life events were collected using the modified Holmes-Rahe stress scale, and the following variables: death of a spouse, death of a child/immediate family member, serious personal illness, divorce/separation, loss of a job, caring for ill family member, financial difficulties, relocation, stress at work, detention/incarceration and retirement. A total sample of 300 was needed (100 cases, 200 controls) to achieve at least 80% power to detect odds ratios (OR) of 2.00 or higher at 5% level of significance. **Results:** From January 2018 to August 2021, 278 patients were enrolled (CA = 77, CO = 201) matched for mean age (years) (CA = 63, CO = 64), median smoking exposure (years) (CA = 36, CO = 38). About 65% of patients in CA group and 49% of CO group were male and 54% and 46% of the CA and CO groups respectively were of white race. In a multivariable logistic regression analysis after controlling for potential confounding variables (including sex, age, race, education, marital status, smoking history), there was no difference in lifetime incidence of major stressful event between the cases and controls. However, patients with HNPC were significantly more likely to report a major stressful life event within past 5 years when compared to CO [OR = 2.59 (1.24, 5.44), p = 0.012]. **Conclusions:** Patients with head, neck and pancreatic cancers are significantly associated with having a major stressful life event within 5 years of their diagnosis. This study highlights the potential need to recognize stressful life events as risk factors for developing malignancies and consider incorporating early rehabilitative efforts for major life stressful events. Research Sponsor: None.

Effects of a yoga intervention on distress indicators among diverse women with gynecologic, gastrointestinal, and thoracic cancers. *First Author: Grace Ann Hanvey, University of Florida, Gainesville, FL*

Background: Depression, anxiety, and fear of cancer recurrence (FCR) constitute prevalent psychological concerns necessitating further attention in developing supportive care interventions for women with gynecologic, gastrointestinal, and thoracic cancers. Recent evidence indicates that such concerns may be especially severe among underserved women of color and women affected by low-socioeconomic status (SES). The purpose of the present study is to evaluate the magnitude of changes in depression, anxiety, and FCR associated with a mindfulness-based yoga intervention among a diverse sample of women with these cancers. A second aim is to identify how changes in these concerns may differ across sociodemographic groups. **Methods:** Women with gynecologic (n=86), gastrointestinal (n=17), or thoracic (n=20) cancers were enrolled in a group-based 10-week yoga intervention utilizing mindfulness meditation, relaxation, and gentle yoga. Prior to and following intervention, participants were administered assessments, including the Beck Depression Inventory – Second Edition (BDI-II) to measure depression, the State-Trait Anxiety Inventory (STAI) to assess anxiety, and the Fear of Cancer Recurrence Inventory (FCRI) to evaluate aspects of FCR. Mixed-linear models evaluated change in outcomes from pre- to post-intervention, with conditional models assessing the effects of age, race/ethnicity, and SES on change. Analyses were conducted prior to trial completion due to approaching accrual period termination. **Results:** The sample demonstrated a mean age of 58.46 (SD=10.82) and mean SES score of 3.98 (SD=1.55) using a 1 to 7 composite scale. Twenty-six percent of participants were of racial and/or ethnic minority status (n=32). Significant declines in total depressive symptoms, somatic depressive symptoms, state anxiety, and psychological distress due to FCR were observed across the sample. Higher SES was associated with significantly greater reductions in total depressive symptoms and affective depressive symptoms, specifically. Women of color experienced significantly greater declines in somatic symptoms compared to non-Hispanic White women. **Conclusions:** This mindfulness-based yoga intervention was associated with significant reductions in depressive symptoms, state anxiety, and psychological distress related to FCR among women with gynecologic, gastrointestinal, and thoracic cancers. Higher SES and underserved race/ethnicity status moderated some of these effects. Future research should explore the efficacy of this intervention among diverse women in a randomized clinical trial context. Clinical trial information: NCT03385577. Research Sponsor: University of Florida Health Cancer Center.

12130 **Poster Session**

Can personality feedback improve the process of self-management in cancer? Results from a randomized controlled trial. *First Author: Laura M Perry, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Although personality characteristics predict emotional and physical quality of life in cancer, personality assessments are rarely used to inform care. This study examined whether a personality feedback intervention improved three patient-reported outcomes underlying the process of cancer self-management: 1) self-awareness, 2) self-efficacy for managing symptoms, treatment/medication, and emotions, and 3) positive affect. **Methods:** A sample of 372 adults with a history of cancer participated in a single-session, pre-post randomized controlled trial via Qualtrics (Control n= 188, Intervention n= 184). The sample was recruited online through ResearchMatch.org and cancer social media sites. Participants completed a baseline survey of demographics, Big Five personality traits, and study outcomes using validated measures. Next, they were immediately randomized to receive either intervention or control materials, followed by a post-test of study outcomes. Intervention participants received a feedback report of their personality results and tailored self-management tips, while control participants received only a general description of the Big Five personality traits. Three general linear models tested between-group differences in changes from baseline to post-test on each outcome, while controlling for baseline scores and demographic and health characteristics. Significance thresholds for all coefficients across all three models were simultaneously adjusted for a false discovery rate of 15%. Intervention participants also responded to a 5-item acceptability scale. **Results:** Participants were mostly non-Latino/a White (91%), middle-to-older aged (M= 58.40, SD= 13.56), women (72%), and diagnosed with cancer an average of 6.06 years prior (SD= 3.91). Compared to controls, intervention participants experienced a greater increase on a composite measure of self-efficacy for illness self-management (d= 0.32, p= .002), as well as on the individual domain of self-efficacy for managing symptoms (d= 0.36, p< .001). Contrary to hypotheses, the intervention did not improve self-awareness or positive affect (ps ≥.132). Intervention participants rated the activity's acceptability a mean of 3.97 (SD= 0.68) on a scale from 1 to 5. **Conclusions:** This was the first study to demonstrate that a personality feedback intervention can improve self-efficacy in the context of managing a chronic illness. Findings call for follow-up studies to test whether these results translate into improved self-management behaviors and quality of life among individuals living with cancer. Clinical trial information: NCT04625439. Research Sponsor: None.

Association between unmet needs and utilization of emergency services among cancer survivors in Canada. *First Author: Megan Delisle, University of Ottawa, Ottawa, ON, Canada*

Background: In 2016, the Canadian Partnership Against Cancer distributed surveys to over 40,000 cancer survivors to understand their experiences transitioning from primary cancer treatment to follow-up cancer care. Previously reported results of this survey identified that cancer survivors had high rates of unmet physical, emotional and practical needs. This study describes the association between these unmet needs and emergency services (ES) utilization within the first three years after cancer treatment. **Methods:** 13,319 respondents returned the survey (response rate 33%). Respondents in this study have non-metastatic breast, hematologic, colorectal, melanoma or prostate cancer. The association between self-reported unmet needs and ES utilization was assessed using multivariable logistic regression. High ES utilization was defined as accessing ES more than three times per year during the first three years after active cancer treatment. **Results:** 8,911 participants are included in this analysis; 80.5% reported at least one unmet practical, physical, and emotional need (n=7169, Table). A total of 3.9% (n=344) reported high ES utilization. Unmet needs were a significant predictor of high ES utilization (OR 1.75 95% CI 1.14-2.68 p=0.01). Other significant predictors of high ES utilization on the multivariable analysis included: not being able to identify a healthcare provider in charge of follow-up cancer care (OR 2.73 95% CI 1.32-5.65 p=0.01), high oncologist utilization (OR 3.08 95% CI 2.28-4.15 p<0.01), high primary care provider utilization (OR 2.3 95% CI 1.76-3.0 p<0.01), having a chronic condition (OR 1.6 95% CI 1.19-2.07 p<0.01), having colorectal cancer (OR 2.12 95% CI 1.31-3.44 p<0.01), being enrolled in a clinical trial (OR 1.54 95% CI 1.11-2.16 p=0.01), and rating follow-up cancer care coordination as fair or poor (OR 1.39 95% CI 1.03-1.86 p=0.03). **Conclusions:** Unmet needs are associated with high ES utilization in the first three years after cancer treatment. A better understanding of the reasons for this association is required to develop approaches to reduce potentially preventable ES utilization and improve perceived care needs among cancer survivors. Research Sponsor: None.

Differences in unmet needs among high and low ES utilizers.

	High ES Utilizers % (n)	Low ES Utilizers % (n)	P-value
Unmet Practical Needs	53.2% (183)	31.8% (2723)	<0.01
Unmet Emotional Needs	78.5% (270)	63.8% (5465)	<0.01
Unmet Physical Needs	71.5% (246)	60.5% (5180)	<0.01

Sexual desire and satisfaction: Exploring gaps for the sexually inactive breast cancer survivor. *First Author: Hannah G. Peifer, Alpert Medical School of Brown University, Providence, RI*

Background: Sexual dysfunction is common among breast cancer survivors, but poorly characterized in sexually inactive women. We aim to better understand sexual desire in sexually inactive breast cancer survivors. **Methods:** We performed a cross-sectional survey of breast cancer survivors between 2014 and 2016. Women with a history of breast cancer were approached at a surveillance visit, offered enrollment, and signed consent. They completed the validated 19-question Female Sexual Function Index (FSFI) survey. The FSFI defines sexual inactivity as no sexual activity in the four weeks prior to survey completion. Fisher's exact test was used for categorical data analysis. Firth's bias-reduced logistic regression adjusted for age and menopausal status. **Results:** Of 585 respondents, 305 (53.1%) were age 40 to 59 and 241 (42.0%) were age 60 to 79 when surveyed. Four hundred and twenty-seven (73.0%) were post-menopausal and 285 (48.7%) were sexually inactive. Sexual inactivity was positively correlated with increasing age ($p < 0.001$) and not being in a current relationship ($p < 0.0001$). Four hundred and six (69.4%) respondents underwent lumpectomy and 179 (30.6%) underwent mastectomy with most having reconstruction, n = 129 (72.1%). Neither type of surgery or receipt of chemotherapy, endocrine therapy, or radiation were significantly different for sexually inactive and active respondents after controlling for age and menopausal status. 23.6% of sexually inactive respondents reported sexual desire half the time or more. 32.4% of sexually inactive respondents reported feeling sexual desire "a few times (less than half the time)" (versus 28.8% of sexually active respondents, $p = 0.005$) and 44% reported feeling sexual desire "almost never or never" (versus 8.0% of sexually active respondents, $p < 0.001$). 31.7% of sexually inactive respondents rated their degree of sexual desire as "low" (versus 25.0% of sexually active respondents, $p = 0.04$) and 40.9% rated it as "very low or none at all" (versus 7.0% of sexually active respondents, $p < 0.001$). 27.5% of sexually inactive respondents experienced moderately high sexual desire. Sexually inactive respondents were more likely to report being dissatisfied with their overall sexual life with 23.5% choosing the rating "moderately dissatisfied" (versus 8.8% of sexually active respondents, $p < 0.001$) and 28.1% choosing "very dissatisfied" (versus 5.8% of sexually active respondents, $p < 0.001$). **Conclusions:** Sexual inactivity is associated with lower rates of self-reported sexual desire and lower satisfaction with overall sexual life. However, nearly a quarter of sexually inactive respondents still reported significant sexual desire. This suggests patients classified as sexually inactive may not be content or indifferent to this lack of sexual activity or desire. Sexual inactivity in breast cancer survivors warrants intervention studies to improve sexual satisfaction. Research Sponsor: None.

Assessing Egyptian oncology patients' perceptions of treatment goals: A multicenter study. *First Author: Manar Hamed, Oncology Center of Mansoura University (OCMU), Mansoura, Egypt*

Background: Management of metastatic solid malignancies is generally focused on prolonging life along with improvement of quality of life. Hence palliative intent treatment. The understanding of the disease nature and its treatment intent is variable among patients and it's unclear what are the main contributing factors. Our study across multiple cancer centers in Egypt evaluated patients' understanding of whether their treatment was for curative or palliative purposes and sought to identify factors associated with understanding of treatment intent. **Methods:** This was a survey based study of 489 consecutive patients with stage IV solid tumor malignancies at four different cancer centers in Egypt. Patients were given a questionnaire, during a routine visit. Requested information included primary site of malignancy, stage, duration of treatment, whether they think the treatment is curative, and whether they think the treatment will help them live longer and/or relieve cancer-related symptoms. Patients also provided basic demographic information such as age, gender, marital status, area of residence and education level. Their answers regarding cancer type, stage and length of treatment were compared with their medical records. **Results:** Median age was 53 with 67% females. Of the 489 patients, 48% finished at least middle school education. The primary malignancies consisted of 35% breast, 19% gastrointestinal/liver, 9% genitourinary, 9% lung, 8% ovarian/uterine, 11% others. 57% of patients had been on treatment for at least 6months. 45% of patients didn't know they had a malignancy. 69% could not identify their disease stage, and only 19% of patients knew their cancer is stage 4. Only 11% of patients knew their treatment was not curative while 35% thought it was, and 53% did not know. Only 29% of patients believed their treatment would help them live longer and 62% believed the treatment would alleviate their symptoms. Younger patients were more aware of the Disease Nature (DN), however were less aware of the treatment intent (TI), compared to patients older than 60yo (P value 0.02). Urban residents answered more accurate DN questions compared to rural residents (P value 0.01), but both had similar limited understanding to TI (P value 0.2). Education level was the most consistent factor showing difference with higher level of education correlated with better understanding of DN and TI (P value 0.01). **Conclusions:** In our study, only 11% of patients receiving treatment with palliative intent reported understanding the intent was not curative. Factors influencing perception of treatment goals are many and include those specific to patients (education level), their cancers, and providers (educational materials). Ongoing studies will focus on identifying factors most strongly associated with a patient's perceived TI with development of a knowledge score. Research Sponsor: None.

The symbiosis of healthcare professionals and patients: Understanding the dynamics of long-term care relationships between healthcare professionals and patients in oncology. *First Author: Liam Il-Young Chung, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Chronic diseases are a significant source of physical, emotional, mental, and social distress to not only patients but also their friends and family. Healthcare professionals (HCPs) also share in the burden as they strive to provide the best possible care. In particular, cancer patients face great burden as they grapple with the uncertainty of their futures. Given the respective difficulties associated with cancer treatment, fostering a collaborative environment in which patients, caregivers, and HCPs mutually encourage each other becomes necessary to improve the quality of life of everyone involved. This study aims to investigate factors that influence a healthy long-term care relationship between patients and HCPs. **Methods:** This study is a qualitative analysis of HCPs' experiences with patients and their caregivers at a large metropolitan academic medical center. This study analyzed reflective essays written by HCPs as part of the Pacemakers initiative at the medical center, which seeks to empower HCPs, patients, and caregivers in creative ways along the management journey. The essays focused on HCPs' participation in meaningful experiences with patients and caregivers such as patient/caregiver award ceremonies celebrating their resilience and hope. A total of 22 essays (N = 22) were thematically analyzed by two independent coders to produce meaning-making codes and themes (italicized). **Results:** The presence of *support networks* (n = 10) was very important for the patients and caregivers. Conveying *solidarity* (n = 21) was also central in helping patients experience companionship and fellowship in their community with their medical team, family, and friends. It was also noted that *little means much* (n = 10); small acts of kindness showing genuine interest led to meaningful interactions that provided encouragement for the patients. *Compassion* (n = 19) and *patient-centeredness* (n = 17) were important in fostering a receptive environment in which patients and caregivers felt heard. Celebrating and honoring the patients' *resilience* (n = 10) made patients feel recognized, and this process of celebration was also found to bolster a *renewed sense of purpose for the HCPs* (n = 11). **Conclusions:** The results of this study highlight the importance of supporting patients and their caregivers holistically. Understanding and meeting this need through creative encouragement empowers not only the patients and caregivers but also the HCPs. Trust is built and patients are strengthened to pursue their health to the best of their abilities as HCPs show their deep care for their struggles and resiliency. This sacred experience of entrusting one's life to another builds the best environment for healing and recovery. This study shares a glimpse of how to best support patients as well as HCPs in long-term care relationships. Research Sponsor: None.

A comparative study of unmet information needs of patients with lymphoma and CLL: North America and Europe. *First Author: Olufunmilayo (Funmi) Bamigbola, Lymphoma Coalition, Mississauga, ON, Canada*

Background: Informed patients are consistently associated with better outcomes and overall patient experiences. However, there are still unknowns about the information needs of patients. This study uses the Lymphoma Coalition (LC) 2020 Global Patient Survey (GPS) on Lymphomas and CLL to describe the differences in the unmet information needs among patients with lymphoma and CLL in North America and Europe. **Methods:** Globally, 9,179 patients from 90+ countries took part in the LC 2020 GPS. The countries were grouped into regions, and the North American (NA) (n=1543) and European (EU) (n=4343) regions were used for this analysis (Table). The demographics of the regions were examined, and univariate, bivariate and multivariate analyses of questions relating to patients' information needs, were performed in IBM SPSS v27. **Results:** When compared, the regions differed significantly in patients' age distribution, lymphoma subtype, highest educational level completed, and area of residence. The top three areas of unmet information need for patients with lymphoma and CLL in both regions were: diagnosis and what it means, treatment options, and side effects from treatment. Compared to patients in the EU, patients in NA were 27% more likely to need more information about treatment options, 51% more likely to need more information about support for self-care, and 18% less likely to need more information about their diagnosis and what it means. These differences were statistically significant (Table). Patients from NA were 26% more likely to report that they had no informational needs compared to patients from EU (p=0.02) (Table). There was no significant difference between patients in both regions in their need for more information in the following areas: psychological support, support for their families, side effects from treatment and fertility (Table). **Conclusions:** Regardless of region, patients with lymphoma need more information about certain areas of their care than is currently provided. LC advocates for increased access to appropriate and adequate medical information for patients, and that this information be contextualized to the patient's needs. Research Sponsor: Pfizer Inc, AbbVie Corporation and Takeda Oncology.

Information needs of patients with lymphoma compared by regions.

Areas of informational needs	EU (%)	NA (%)	P-value	OR*· ** (95% CI)
Diagnosis and what it means	56%	51%	P=0.006	0.82 (0.71-0.95)
Treatment options	50%	61%	P=0.001	1.27 (1.01-1.46)
Support for self-care	14%	17%	P<0.001	1.51(1.24-1.84)
Psychological support/ counselling	26%	23%	P=0.27	1.10 (0.93-1.30)
Support for their family	12%	9%	P=0.06	1.26 (0.99-1.61)
Side effects from treatment	45%	38%	P=0.23	0.91 (0.79-1.06)
Fertility Have not needed more information	9% 11%	2% 16%	P=0.07 P=0.02	0.67 (0.43-1.04) 1.26 (1.03-1.55)

Vital best practices for antiracist patient engagement in AYA oncology research and advocacy: A Delphi study of BIPOC AYA experts. *First Author: Christabel K Cheung, 525 W. Redwood St., Baltimore, MD*

Background: In the thick of the ongoing global crises of the COVID-19 pandemic, uprisings against anti-Black racism and police brutality, and anti-Asian racism and violence, Black, indigenous, and people of color (BIPOC) adolescent and young adult (AYA) cancer patients may be particularly vulnerable and exploited. Whilst embroiled in sociopolitical complexity, BIPOC AYAs are increasingly called upon to contribute as patient advocates in AYA oncology research and advocacy. Researchers, clinicians, and advocates in AYA oncology must dismantle long-standing racism and create meaningful structural change. The purpose of this study is to derive vital best practices for implementing antiracist patient engagement in AYA oncology research and advocacy that are co-developed by BIPOC AYA cancer patients and oncology professionals. **Methods:** We utilized a modified Delphi technique with a panel of BIPOC AYA cancer patients (n = 32) to build consensus opinions on professional recommendations from a prior study (Cheung et al., 2021), and to generate antiracist best practices in patient engagement. The Delphi study was comprised of three consecutive and iterative survey rounds over the course of 8 months in 2021; participants were BIPOC AYAs diagnosed with cancer between ages 15-36 years. **Results:** Results detail best practices for the implementation of antiracist patient engagement across all research activities within the Patient-Centered Outcomes Research Institute's (PCORI) Framework for Patient Engagement. For example, BIPOC AYAs agreed with oncology professionals' high priority recommendation for including BIPOC AYAs at the highest levels of decision making in research topic selection. As such, a best practice is for researchers to ensure that such representatives not only hold BIPOC AYA identity, but also hold direct experience with the particular oncology diagnosis, issue, or other outcome of interest. Additionally, BIPOC AYAs concurred with oncology professionals' high priority for "transparency, honesty, and trust" as a core principle for best practices in patient engagement. They further explained that trustworthy relationships are especially important when collaborating with teens and young adults, who are developmentally just coming into their own. When describing successful experiences of inclusion, participants ranked "build collaborative relationships with BIPOC AYA communities and listen to patients not usually heard" and "recruit a diverse range of BIPOC patients and let them give actual input into the study" as the highest priority best practices. **Conclusions:** Findings from this study are instructional for AYA oncology researchers, clinicians, and advocates to prevent harmful tokenism and implement genuine antiracist inclusion to advance health equity. Future research should investigate best practices within unique clinical settings. Research Sponsor: University of Maryland School of Social Work, Competitive Innovative Research Award.

Understanding barriers and facilitators to clinical trial participation among Black patients with multiple myeloma. *First Author: Claire Saxton, Cancer Support Community, Washington, DC*

Background: Currently, Black patients make up 20% of people living with multiple myeloma, yet they represent only 6% of participants in clinical trials.[1] The underrepresentation of Black patients in clinical trials can contribute to outcome disparities thereby negatively impacting health equity in cancer treatment and outcomes.[2] This project examined attitudes towards clinical trials among Black multiple myeloma patients and caregivers. Findings will inform the development of programs aimed at increasing clinical trial participation in this population. **Methods:** In 2021, the Cancer Support Community conducted an online survey to gain insights on barriers, facilitators, and perceptions of clinical trials among Black multiple myeloma patients and caregivers/ care partners. Survey questions were informed by insights from prior focus groups. 94 patients and 101 caregivers were surveyed. **Results:** Most participants were male (62%) and African American (90%). 5% identified as African Caribbean and 5% as Black and Hispanic. The average age was 46 years. Just over half (51%) currently or previously participated in clinical trials. Of those who chose not to participate in a trial, the most common reasons were fear of side effects (46%) and fear of receiving a placebo (38%). Another barrier to participation reported was discomfort with being randomly assigned to a treatment (56%). Participants reported a significant level of distrust in medical research and doctors, saying that it was "very or somewhat likely" that doctors provide treatment as part of an experiment without patient consent (41%) and that they might be used as a "guinea pig" (25%). Of note, 57% of respondents said COVID had changed their attitude towards participating in clinical trials. 14 of 16 factors mentioned in our focus groups were affirmed by more than half of respondents as facilitating participation in a clinical trial. The top factors were: Understanding potential side effects (66%) My health care team speaks to me about trials (65%) Compensation offered for transportation, childcare, or time off work (62%) My family/community support my decision (61%). **Conclusions:** These findings are consistent with previous research which found that cancer patients reported the biggest attitudinal barriers to clinical trial participation were fear of side effects, distrust in medical research, and random assignment to clinical trial groups.[3] Our study highlights that Blacks and African Americans living with multiple myeloma value multifactorial efforts to increase clinical trial participation: logistical and financial interventions, patient/provider communication, and culturally sensitive support and education programs. These programs can also work to improve health equity by reducing barriers to overall care and encouraging Blacks and African Americans living with multiple myeloma to be active members of their health care team. TPS12138 **Poster Session**

Take charge during treatment: A planned exercise protocol to evaluate disparities and cardiovascular outcomes in Black and White patients with breast cancer undergoing treatment. *First Author: Mary C Hidde, Medical College of Wisconsin, Milwaukee, WI*

Background: Cardiotoxicity is a significant challenge associated with common first-line breast cancer (BC) chemotherapy (CTx) treatments including anthracyclines (AC) and targeted therapies, such as anti-Her-2 therapy. For targeted therapies, cardiac complications typically resolve once treatment is completed or stopped. For ACs, treatment may lead to permanent long term cardiac damage, and elevated risk for major adverse cardiovascular events (MACE). Black/African American (B/AA) women are at higher risk for AC-based cardiotoxicity compared to Non-Hispanic White (NHW) women. To date, most efforts have targeted managing and defining mechanisms of large vessels and cardiac damage. However, impaired microvascular function, a powerful but clinically underused predictor of future MACE, may also be implicated. Extensive evidence shows that exercise interventions reduce systemic inflammation and possibly MACE. However, few cardio-oncology studies have utilized exercise to mitigate cardiotoxicity, and none have quantified microvascular endothelial function. A further gap in cardio-oncology research is a paucity of studies focused on understanding and addressing disparities. This research project aims to 1) test the feasibility and efficacy of an exercise intervention designed to mitigate the effects of CTx, Take Charge during Treatment (TCT) and 2) examine the influence of socio-ecological factors on endothelial function in response to an exercise intervention. **Methods:** B/AA (n=50) and NHW (n=50) women diagnosed with non-metastatic BC, scheduled to receive AC and/or anti-HER-2 therapy, will be recruited and randomized to participate in the TCT intervention or usual care (NCT05223322). TCT is a virtual exercise coaching program with weekly coaching sessions, six of which include supervised exercise. Assessments to assess socio-ecologic and vascular outcomes are presented in the Table. Assessments will be completed prior to treatment (T1), after treatment completion (18-24 weeks, T2), and 12-months post treatment (T3). Clinical trial information: NCT05223322. Research Sponsor: American Heart Association.

TCT outcome measures.

Construct	Measurement Tool
Exercise Capacity	Maximal oxygen consumption (VO_2peak)
Interpersonal Socioecological Factors	Perceived Discrimination Scale, Brief Resilience Scale, Interpersonal Support Evaluation List, Neighborhood Social Cohesion Scale
Neighborhood Socioecological Factors	Contemporary and historical redlining, Local segregation, Racial composition, Social vulnerability index, Residential mobility, Urbanicity/rurality, Air pollution Walkability, Density of vegetation, % Tree canopy and landcover, Pharmacy access
Cardiovascular Outcomes	Pulse wave velocity, Brachial artery flow mediated dilation (FMD), *Ex-vivo* microvascular function
Gene Expression and Cytokine Profiling	PBMC and EC RNAseq, Inflammatory cytokine panel

Episodic future thinking: A behavioral intervention to promote weight loss in breast cancer survivors. *First Author: Jasmine S Sukumar, The Ohio State University Comprehensive Cancer Center, Division of Medical Oncology, Columbus, OH*

Background: Obesity at diagnosis is associated with an increase in breast cancer (BC) specific mortality. Behavioral interventions targeting obesity-related health choices offer a scalable approach to improve patient engagement in the community. Episodic Future Thinking (EFT) is a novel remotely delivered behavioral intervention which engages the science of prospection where participants mentally simulate positive, detailed, and personal events that can occur in the future. EFT targets a key behavioral economic measure – Delay Discounting (DD). As DD rate rises, an individual devalues future outcomes to a greater degree and has a higher bias for immediate gratification. EFT can decrease DD in obese patients, leading to improved diet quality and weight loss. However, valuation of the future may impact cancer survivors differently. Herein, we propose the first randomized Phase II trial evaluating adherence and changes in DD and body weight with 12-week remotely delivered EFT vs control in overweight or obese BC survivors. **Methods:** Eligible patients have a history of DCIS or stage 1 to 3 BC, BMI > 25 kg/m^2, have completed surgery, radiation, and chemotherapy, and are motivated to lose weight. They are randomized 1:1 to a 12-week EFT intervention or control (Episodic Recent Thinking; ERT). ERT is a validated control in which patients imagine events in the recent past. Randomization will be stratified by baseline DD rate. There is an optional 12 week follow up period where patients can continue to receive EFT or ERT cues. DD will be measured at baseline and every 4 weeks for 24 weeks. The primary endpoint is adherence, measured by percentage of thrice daily smartphone prompts participants open and attend to during the 12-week trial. Secondary endpoints are changes in body weight and DD rate at 12 and 24 weeks and change in PROs (PROMIS scales), insulin resistance (HOMA-IR), hs-CRP, and diet quality (HEI 2015) at 12 weeks from baseline. With 20 subjects per arm, the study has 80% power to detect deviation of 14 points from a target adherence rate of 80% using a 1 sample t-test. The primary endpoint is evaluable for all subjects, regardless of drop-out. Secondary endpoints will be evaluated using a linear mixed effects model. Hypothesis tests and confidence intervals will be two-sided at 5% significance/95% confidence level. Since trial activation in November 2021, 9 of the planned 46 patients are enrolled. Accrual is closely integrated with the dedicated Ohio State University Comprehensive Cancer Center Survivorship Program. This work is supported by the Alliance Cancer Control Program Pilot Award (5UG1CA189823-08). Clinical trial information: NCT05012176. Research Sponsor: U.S. National Institutes of Health.

Targeting adiposity and inflammation with movement to improve prognosis in breast cancer survivors (the AIM trial): Rationale, design, and methods. *First Author: Christina Marie Dieli-Conwright, Dana-Farber Cancer Institute, Boston, MA*

Background: Obesity is considered a leading modifiable contributor to breast cancer mortality worldwide due to its association with increased recurrence and decreased overall survival rate. A central mechanism by which obesity stimulates cancer progression is through chronic, low-grade inflammation in adipose tissue. Exercise has shown potential in improving inflammation but has not been implemented with breast cancer survivors. Our hypothesis is that exercise designed to target chronic inflammation and associated sarcopenic obesity will improve prognosis in obese breast cancer survivors. **Methods:** The AIM trial is a prospective, three-armed, phase II randomized controlled trial investigating the effects of a 16-week supervised circuit aerobic and resistance exercise (CARE) program compared to a traditional aerobic and resistance exercise (TARE) program, and attention control (AC) group, on adipose tissue inflammation in 300 breast cancer survivors. Main inclusion criteria are histologically confirmed breast cancer stage 0-III, completion of chemotherapy and/or radiation, sedentary, centrally obese, and free from musculoskeletal disorders. The primary endpoint is adipose tissue inflammation as assessed by core biopsy and blood draw; secondary endpoint is sarcopenic obesity; and exploratory endpoints are physical fitness and function and patient reported outcomes. Participants randomized to the exercise groups participate in three weekly supervised exercise sessions for 16-weeks. Participants randomized to the attention control group are offered the CARE intervention after the 16-week period of observation. Discussion: This is the first randomized controlled trial examining the effects of exercise on adipose tissue inflammation in obese, breast cancer survivors. Results will contribute to a better understanding of exercise modality on adipose tissue inflammation that can potentially improve patient prognosis. Clinical trial information: NCT03091842. Research Sponsor: U.S. National Institutes of Health.

TPS12141 **Poster Session**

Preventive effect of goshajinkigan against peripheral neuropathy induced by paclitaxel-containing chemotherapy: An open-label, randomized, phase II study. *First Author: Naoki Nakamura, Department of Respiratory Medicine, Okayama University Hospital, Okayama, Japan*

Background: Paclitaxel is a taxane agent that has been used as a standard treatment for various malignancies. However, taxanes, such as paclitaxel, unfortunately cause a high frequency of chemotherapy-induced peripheral neuropathy (CIPN) as a result of axonal damage (All grade; 70%) (Clin Cancer Res.1996), CIPN worsens patients' QOL and then lead to poor treatment compliance. Furthermore, there is no evidence for the prevention of CIPN. Goshajinkigan (GJG) is one of the Kampo medicine and it is approved in Japan for the treatment of numbness and has been commonly used for diabetic peripheral neuropathy. In addition, a non-clinical study has also shown the preventive effect of GJG against CIPN induced by paclitaxel (Molecular pain. 2014). To investigate if GJG indeed has a preventive effect for severe CIPN in patients receiving chemotherapy including paclitaxel, we started a two-arm randomized trial of GJG vs physician's choice of treatment for patients. **Methods:** Patients have to meet the followings: pathologically diagnosed with malignant tumor (regardless of cancer type) and scheduled to receive ≥4 courses of chemotherapy including carboplatin and paclitaxel (paclitaxel ≥150mg/m^2 every 3-4 weeks) as initial chemotherapy; age ≥20yrs; Performance Status of 0 or 1. The primary endpoint is set as a proportion of ≥G2 CIPN by CTCAE ver.5.0 by the end of 4 courses of chemotherapy. With stratification by cancer type and age, patients will be randomized centrally to receive GJG at the same time as chemotherapy (A), or to receive the physician's choice of treatment for pts if ≥G2 CIPN occurs without prophylaxis (B). Assuming that the incidence of ≥G2 CIPN would be 50% without prophylaxis and 20% with GJG prophylaxis, and assuming an 80% completion rate of four paclitaxel courses, the required sample size is 66 patients (1-β: 0.75, α: 0.1). The secondary endpoint includes time to the onset of CIPN G2, incidence rate and severity of CIPN at the end of each course, relative dose intensity of paclitaxel, adverse events other than CIPN. Enrollment began in 2022, and will be complete by 2025. Clinical trial information: 061210047. Research Sponsor: None.

TPS12142 **Poster Session**

Prospective study of biomarkers predictive of radiation-induced bladder toxicity in patients treated with radiotherapy for localized prostate cancer: RABBIO (Radiotoxicity Bladder BIOmarkers). *First Author: Carole Helissey, Clinical Research Unit, Military Hospital Begin, Saint-Mandé, France*

Background: Despite improvements in irradiation techniques, pelvic radiotherapy is responsible for acute and late adverse events in the bladder, defined as radiation cystitis (CysR). The early symptoms of bladder lesions secondary to pelvic irradiation are likely to occur during treatment or after radiotherapy in approximately 50% of irradiated patients. Acute radiation-related injuries are the first step of the fibrosis process. Fibrosis causes loss of bladder function and has a significant impact on the quality of life of the patients.The pathophysiology of CysR is not well understood, in particular because of the risks of complications caused by accessing the bladder tissue after irradiation, thereby limiting our ability to investigate this process and develop treatments. The main objective of our study is to assess the correlation of biologic biomarkers with the intensity of acute CysR and the quality of life of patients, evaluated with the digital telemonitoring platform Cureety. **Methods:** Patients with intermediate-risk localized prostate cancer and eligible for localized radiotherapy will be included. Inflammatory biomarkers will be analyzed on urine and blood samples before the initiation of radiotherapy, at week 4, 12 and 48 of irradiation, by quantitative methods such as the Multiplex Luminex assay, cytometry in flow and enzyme-linked immunosorbent assay ELISA. We will also characterize the gut and urinary microbiota in stool and urine samples using 16S rRNA sequencing technology. This is in order to assess the impact of the fecal and urinary microbiota in acute CysR. Between sample collection visits, patients will answer various questionnaires relating to the symptoms of radiation cystitis (IPSS), adverse events and quality of life (FACT-P), using the digital telemonitoring platform Cureety. Upon receipt of the questionnaires, an artificial intelligence algorithm will process the information and classify the patients according to the severity of symptoms and adverse reactions reported in accordance with CTCAE / IPSS. This will ultimately allow us to correlate urinary, blood and fecal biomarker levels with the severity of acute CysR symptoms and the quality of life reported by the patients. Conclusion: This prospective study is the first to explore the overexpression of inflammatory proteins in fluid biopsies from patients with symptoms of acute CysR. In addition, the 1-year post-treatment follow-up will allow us to predict which patients are at risk for late CysR and to stratify these patients towards radioprotective treatment. The results of this study will allow us to develop strategies to limit radiation damage to the bladder and improve the quality of life of patients. Clinical trial information: 2021A0319635. Research Sponsor: None.

TPS12143 **Poster Session**

Telehealth cognitive-behavioral therapy for cancer-related cognitive impairment: A model for remote clinical trial participation. *First Author: Robert J. Ferguson, University of Pittsburgh, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Cancer-related cognitive impairment (CRCI) can include persistent memory symptoms, and affects many cancer survivors. Memory and Attention Adaptation Training (MAAT) is an evidence-based cognitive behavioral therapy (CBT) that improves CRCI with demonstrated efficacy in telehealth delivery. MAAT consists of 8 weekly (45-minute) video visits. The aims of this study are to confirm MAAT telehealth efficacy in a phase III RCT (MAAT versus Supportive Therapy; ST) across large catchment areas of two comprehensive cancer centers. A secondary aim is to evaluate treatment-induced brain activation as assessed by functional MRI (fMRI) in a subset of participants. We present remote treatment and data capture methods of this open NCI-sponsored (R01CA244673) randomized clinical trial (NCT 04586530). These methods have high success in participant accrual despite COVID-19 pandemic conditions, and can be readily adopted to other clinical trials to enhance rural/underserved enrollment. **Methods:** We are enrolling 200 adult, stage I-III breast cancer survivors 1-5 years post-chemotherapy with cognitive complaints. Individuals with CNS disease, previous brain injury, dementia or psychiatric disorder are excluded. All study procedures are completed from the participant's home (except fMRI). Eligibility screening is a semi-structured phone interview followed by detailed informed consent online (Research Electronic Data Capture: REDCap) with staff phone guidance. Consented participants complete baseline brief phone-based neurocognitive assessment and validated patient-reported outcome measures (PROs) of cognition and quality of life via REDCap. Participants are randomized to MAAT or ST and assigned treating clinicians at respective cancer centers. All 8 visits are completed through secure telehealth platforms, followed by repeat phone/online assessment post-treatment and again at 6 months. Enrollment began in 3/2021. As of 1/2022 (9 months), 56 participants are enrolled (28% of the planned sample), 47 randomized (MAAT 24; ST 23), with 24 completing post-treatment assessments. If all assessments and treatment visits were in person, travel burden per participant is 968 miles/20.5 hours driven, and $542 (US 2021 Federal rate). Thus, study travel savings to date are $30,352. Participant feedback indicates telehealth makes participation possible, similar to previous MAAT research. The current RCT demonstrates utility, efficiency and cost-savings of telehealth and remote data capture technology in the conduct of cancer control research. Elements of methods described can also be adopted for cancer therapeutic trials. Comprehensive cancer centers, where most clinical trials are based, can enhance participation of remote and/or underserved populations that have higher rates of cancer, more disease burden and less opportunity for trial participation. Clinical trial information: NCT04586530. Research Sponsor: U.S. National Institutes of Health.

TPS12144 **Poster Session**

The RADIO trial: Randomized assessment of cisplatin dosing interval for ototoxicity with curative concurrent chemo-radiation for locally advanced head and neck squamous cell carcinoma. *First Author: Sara Kuruvilla, London Health Sciences Centre, London, ON, Canada*

Background: Patients with locally advanced squamous cell carcinoma of the head and neck (LASCCHN) receive curative chemoradiation (CRT) with Cisplatin, as a standard of care. A meta-analysis of 52 randomized trials comparing Low Dose (LD) and High Dose (HD) schedules demonstrated differing toxicity profiles but hearing effects were not rigorously studied. Hearing loss associated with HD Cisplatin can result in survivorship challenges. A local study suggested a protective effect for LD Cisplatin in relation to ototoxicity and pharmacogenomic markers, MATE1 and COMT, to be associated with risk for ototoxicity. We hypothesize that LD cisplatin is associated with reduced frequency of hearing loss when compared to the standard HD cisplatin in LASCCHN patients on CRT and that differences in MATE1/COMT can predict for cisplatin-related ototoxicity and be identified prior to treatment. Our goal is to develop an innovative personalized treatment pathway incorporating predictive pharmacogenomics markers to improve the tolerability and survivorship outcomes of curative CRT for LASCCHN. **Methods:** This is a prospective, open-label, randomized clinical trial. Following informed consent, eligible LASCCHN patients planned for primary CRT will be stratified by tumor p16 status and then randomized in 1:1 fashion to either concurrent LD Cisplatin (40mg/m2 every week) or HD cisplatin (100mg/m2 every 3 weeks). The primary outcome is to measure the change in incidence of CTCAE grade ≥2 hearing loss and hearing-related quality of life (QOL) at 1 year. As part of secondary and exploratory outcomes, differences in survival, loco-regional control, global QOL and other toxicities (e.g. nephrotoxicity, neurotoxicity) will be assessed. The relationship between MATE1 and COMT, as predictors for cisplatin-related ototoxicity will be evaluated. Cost-effectiveness analyses comparing the two regimens will be assessed. *Statistical plan:* Based on rates of CTCAE grade ≥2 hearing loss in an earlier study (Winquist et al., 2016), assuming a conservative rate of hearing loss, amongst treated patients, of 60% with HD cisplatin and 30% with LD cisplatin, a total sample size of 92 patients would achieve > 80% statistical power, (two-sided, alpha = 0.05 test of two proportions) to detect these differences. 100 patients would be targeted to accrual for an assumed 5% noncompliance rate. For hearing related QOL, a two-sided, alpha = 0.05, two-sample t-test with 50 patients per group would achieve > 80% statistical power to detect an effect size of 0.60 and > 95% power to detect an effect size of 0.75. All analyses will be based primarily on the intent-to-treat population. An arms-length data and safety monitoring committee (DSMC) will review safety data bi-annually. *Trial accrual status:* 60 participants have been accrued. Clinical trial information: NCT03649048. Research Sponsor: Academic Medical Organization of Southwestern Ontario, Medical Oncology Research Fund; Juravinski Cancer Center Foundation Grant.

TPS12145 **Poster Session**

A randomized phase III clinical trial of acupuncture for chemotherapy-induced peripheral neuropathy (CIPN) in cancer survivors. *First Author: Andee Dooley, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common and debilitating side effect in cancer survivors that can last long after completion of neurotoxic chemotherapy. Patients with CIPN often experience neuropathy symptoms such as pain, tingling, numbness, paresthesia, and dysesthesia, which can lead to significant functional decline and diminished quality of life (QoL). Our prior study showed that more than half of breast cancer survivors who received taxane-based chemotherapy experienced persistent peripheral neuropathy symptoms for a mean duration of 5.6 years after completing chemotherapy. This outcome highlights the importance of developing effective CIPN treatments to improve cancer survivors' QoL. Identifying nonpharmacological approaches to reduce CIPN symptoms and improve cancer survivors' outcomes is urgently needed. Acupuncture is a widely used, minimally invasive Traditional Chinese Medicine technique that has shown promising evidence as an effective and safe treatment for CIPN. We hypothesize that acupuncture may reduce CIPN pain and improve overall CIPN symptoms in cancer survivors. **Methods:** We are conducting a two-arm, parallel randomized clinical trial comparing electroacupunture (EA) versus sham acupuncture (SA) in cancer survivors at Memorial Sloan Kettering Cancer Center, New York, NY. The EA arm includes a total of ten sessions of EA over eight weeks using a standardized, semi-fixed protocol developed by our group based on the previously published pilot study (NCT03183037). The SA arm includes a sham technique that uses a combination of non-acupuncture points and a non-insertion procedure in ten sessions over eight weeks. The primary outcome of this study is the Brief Pain Inventory-Short Form (BPI-SF) average pain item. The secondary outcomes are quantitative sensory testing measures and additional patient-reported outcomes that include the BPI-SF pain interference subscale, Neuropathic Pain Scale (NPS), Functional Assessment of Cancer Therapy/Gynecologic Oncology Group-Neurotoxicity (FACT/GOG-Ntx), CIPN-20, PROMIS Global Health Scale, and Patients' Global Impression of Change (PGIC). The primary end point is week 12 and the secondary end point is week 24; treatment effects are assessed at baseline and at weeks 4, 8, 12, 18, and 24. Eligibility criteria includes: 1) Moderate-to-severe CIPN pain, defined by a score of 4 or greater on a 0–10 numeric rating scale; 2) completion of neurotoxic chemotherapy at least three months prior to enrollment; and 3) no changes in anti-neuropathy medications within three months of enrollment. We have accrued 30 participants as of February 2022, with a total accrual target of 250 participants. Accrual completion is anticipated by December 2024. Funding resource: NIH R37 CA248563. Clinical trial information: NCT04917796. Research Sponsor: U.S. National Institutes of Health.

TPS12146 **Poster Session**

A randomized phase III clinical trial of yoga for chemotherapy-induced peripheral neuropathy treatment. *First Author: Katherine Han, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common, painful, and debilitating side effect of many standard chemotherapy regimens. Patients with CIPN typically experience pain, paresthesia, and muscle weakness, and may exhibit significant functional decline and worsened quality of life. Our prior study showed more than half of breast cancer survivors experience persistent CIPN up to a mean duration of 5.6 years, which is associated with a doubled fall risk. Identifying nonpharmacological approaches to reduce CIPN symptoms and improve cancer survivors' outcomes is urgently needed. Yoga is a meditative movement therapy that that includes stretching, and flexibility and balance training. Our pilot study (NCT03292328) demonstrated that yoga reduced CIPN-related symptoms, and improved quality of life and functional reach scores compared to waitlist control. We hypothesize that yoga can reduce CIPN symptoms, improve function, and reduce the risk of falls. **Methods:** We are conducting a three-arm randomized education and usual care-controlled trial in cancer survivors with chronic CIPN pain at Memorial Sloan Kettering Cancer Center (MSK), New York, NY. Participants in the intervention arm will receive twice-weekly one-hour Hatha yoga classes virtually or in-person taught by MSK instructors, and practice yoga at home daily for eight weeks. Participants in the education control arm will receive one-hour virtual education classes twice per week taught by an MSK mind-body therapist for eight weeks. Participants in the usual care arm will continue their usual care for CIPN for eight weeks. The primary endpoint is the Brief Pain Inventory-Short Form (BPI-SF) average pain item at weeks 8 and 24. Secondary outcomes include the Neuropathic Pain Scale (NPS), Functional Assessment of Cancer Therapy/Gynecologic Oncology Group-Neurotoxicity (FACT/GOG-Ntx), Patient-Reported Outcomes Measurement Information System (PROMIS) Global Health outcome measure, Brief Fatigue Inventory (BFI), Insomnia Severity Index (ISI), Hospital Anxiety and Depression Scale (HADS), QLQ-CIPN-20, Functional Assessments, and quantitative sensory testing (QST) at weeks 0, 4, 8, 12, 18, and 24. Eligibility criteria included: 1) Moderate-to-severe CIPN pain, defined by a score of 4 or greater on a 0-10 numerical rating scale; 2) completion of neurotoxic chemotherapy at least three months prior; 3) no changes in anti-neuropathy medications within three months of enrollment; and 4) changes in balance and functionality. We have accrued five participants as of February 2022 with a total accrual target of 268 participants. We anticipate completing accrual in March 2025. Funding resource: NIH R01CA251470. Clinical trial information: NCT05121558. Research Sponsor: U.S. National Institutes of Health.

TPS12147 **Poster Session**

Immune-related adverse events and symptom burden in patients with melanoma receiving adjuvant immune checkpoint inhibitor. *First Author: Noha Abdel-Wahab, Assiut University Hospital, Faculty of Medicine, Assiut, Egypt*

Background: Adjuvant therapy with immune checkpoint inhibitors (ICIs) is approved for melanoma, but immune-related adverse events (irAEs) remain a challenge. Although acute toxicities are well defined, long-term AEs and impact on quality of life (QOL) are undetermined. Available data derived from clinical trials involve highly selected populations and do not reflect real world experience. Additionally, trials measure outcomes only at predetermined endpoints, and symptoms may vary throughout the course of therapy. Moreover, the pathogenesis of irAEs and symptoms remains poorly understood. We hypothesize that AEs and sustained inflammation induced by adjuvant ICIs increase symptom burden and negatively impact function and QOL in a subset of patients (pts), and elevated expression of pro-inflammatory cytokines and T cell signatures during therapy correlate with toxicity and symptom burden. Our preliminary data identified i) interleukin-6/Th-17 pathway as a possible mediator of irAEs, ii) immune reactivity and increases in inflammatory cytokines are associated with symptom burden in cancer survivors, and iii) prioritized 30 genetic markers conferring risk for irAEs in ICI-treated melanoma pts. **Methods:** This is a prospective longitudinal cohort study to evaluate potential toxicity/symptom burden and immune correlates in melanoma pts receiving adjuvant ICIs (NCT04990726). A total of 240 pts will be enrolled. Eligibility criteria: age ≥18 years (yrs), surgically resected stage II, III, or IV melanoma, initiating adjuvant nivolumab or pembrolizumab, no prior systemic therapy for melanoma, and no prior autoimmune diseases. Patients will be assessed at baseline (before ICI infusion) and every 3 months (mos) up to 2 yrs or until attrition or death. The primary endpoint is the incidence rate of any irAEs at 12 mos. Demographics, personal/family history, comorbidities, tumor history/stage, prior therapies, performance status, concurrent medications, and other factors that play a role in pts perceptions of disease are collected. At each visit, pts undergo a clinical evaluation to assess potential irAEs, new comorbidities, and tumor recurrence. Patient-reported outcomes of fatigue, depression, sleep disturbance, and QOL are collected at each visit to assess changes from baseline up to 2 yrs. In addition to standard methods of data collection at pre-specified times, we leverage mobile technology to capture symptoms and AEs in real time. Longitudinal blood samples will characterize pts immune signatures from baseline up to 2 yrs to evaluate their association with irAEs, symptom burden, and QOL, and to compare the genotype of pts with and without irAEs. To characterize the effect of adjuvant ICI on bone health, eligible pts are evaluated by whole body dual-energy X-ray absorptiometry at baseline and at 12 mos as an exploratory aim. The study is currently active, and 27 pts are enrolled. Clinical trial information: NCT04990726. Research Sponsor: U.S. National Institutes of Health, The University of Texas MD Anderson Cancer Center Institutional Research Grant, Division of Internal Medicine Developmental Funds, and Cancer Survivorship Seed fund.

Nurse AMIE: Addressing symptoms in rural patients with advanced cancer. *First Author: Cristina I. Truica, Penn State Health Milton S. Hershey Medical Center, Hershey, PA*

Background: Prior research has shown that monitoring symptoms in advanced cancer patients may provide a survival benefit. Monitoring is a labor-intensive process that requires nursing staff response and visiting a medical office. This may be more challenging in rural areas, given staffing challenges and distances traveled for care. Lower density of supportive care services has been documented in rural as compared to urban settings in Pennsylvania and West Virginia. We have developed a computer tablet-based supportive care program, called Nurse AMIE, and are investigating its use in symptom management among cancer survivors. Our hypothesis is that a tablet-based supportive care program can improve overall survival of advanced cancer patients in rural Pennsylvania and West Virginia. **Methods:** This randomized controlled trial will recruit 344 patients residing in a rural county or zip code (RUCC 4-9 or RUCA 4-10) in Pennsylvania or West Virginia, who receive treatment for stage III-IV cancer, are 18 years or older, ECOG 0-3, are fluent in written and spoken English, have sufficient vision/hearing to interact with a computer tablet and staff, and have a clinician-defined life expectancy of 6 months or more. Exclusion criteria: patients on active treatment or behavioral or supportive care trials, or with medical or psychiatric conditions that would impair ability to test study hypotheses. Patients will be randomized on a 1:1 basis to receive either Nurse AMIE or a binder with written supportive care materials. Intervention participants will be asked to log into Nurse AMIE daily, where they will interact with a nurse avatar and answer symptom questions (focusing on sleep, fatigue, pain, and distress). They will receive an empathic response to symptoms and be offered evidence based, guideline concordant self-care interventions to address symptoms (including exercise, nutrition, guided meditation, cognitive behavioral therapy videos, and soothing music). Once weekly, patients will answer 21 questions from the Pro-CTCAE survey. All symptom data will be loaded into a dashboard reviewed daily by study staff. Pain or distress scores of 7+ (out of 10) will be communicated to the care team through the EMR. The trial is powered to detect a 19% difference in overall survival at 2 years follow-up (based on Denis et al JAMA 2019). Secondary outcomes include incidence of chemotherapy toxicities, patient reported outcomes, and cost effectiveness. Enrollment is anticipated to start in March 2022. A community advisory board of 12 cancer patients and stakeholders meet on a quarterly basis to provide feedback on study activities (e.g., usability testing, adaptations, overall implementation) and ensure the project responds to the needs and preferences of rural cancer patients in Pennsylvania and West Virginia. NIH R01-CA254659. Clinical trial information: NCT05221606. Research Sponsor: U.S. National Institutes of Health.

TPS12149 **Poster Session**

Olanzapine versus fosaprepitant for prevention of chemotherapy induced nausea and vomiting in patients receiving carboplatin (AUC ≥ 4) containing chemotherapy regimen: A phase 3 randomized, double-blind, placebo-controlled trial. *First Author: Sneh Bhargave, Aiims, New Delhi, India*

Background: Chemotherapy-induced nausea and vomiting (CINV) is a common adverse effect affecting quality of life of patients of cancer undergoing chemotherapy. Carboplatin alone or in combination with various other chemotherapy drugs is one of the most commonly used drug in solid malignancies. It is categorised as a highly emetogenic drug in doses above AUC≥4 and multiple past studies revealed high CINV incidence. Current international antiemetic guidelines suggest NK1 receptor antagonist based triplet drugs as an effective regimen of CINV control in these patients. However, the nausea control rates are largely inadequate. Olanzapine, an atypical antipsychotic drug, is another drug that has shown significant activity in CINV control and is an integral part of current chemotherapy induced emesis and nausea prevention. However, robust comparative studies of olanzapine based triplets with NK1 based combination have been lacking. Hence we planned this study to compare efficacy of olanzapine containing triplet with NK1 receptor antagonist (fosaprepitant) based triplet drug combination in a phase 3 randomised study. **Methods:** This study is an investigator initiated phase 3 prospective randomised double blind placebo controlled trial comparing efficacy of olanzapine, 5HT3 receptor antagonist(ondansetron) and dexamethasone (experimental arm) against fosaprepitant, 5HT3 receptor antagonist(ondansetron) and dexamethasone (standard arm) for prevention of CINV among chemo-naïve patients (aged ≥18 years) receiving carboplatin (AUC ≥4) based chemotherapy regimen. Primary objective is to compare the number of patients with no nausea during overall periods (0-120 hours post-chemotherapy). Secondary objectives are to compare complete response (no emetic episodes and no use of rescue medication) in the acute(0-24 hr), delayed(25-120 hr),overall periods(0-120 hr) and to assess the frequency of rescue medication use. The other secondary objective includes assessment of adverse events in both the arms. Statistical Design: Planned accrual is total 214 patients including 10% drop out rate. It is a superiority design with an absolute improvement of 20% in the proportion of patients with no nausea from a baseline prevalence of 40% in the standard arm and two sided alpha of 5% as well as power of 80%. Conduct to date :Study activation : March 2021. Enrolment : 138 subjects. Clinical trial information: CTRI/2021/03/032165. Research Sponsor: None.

TPS12150 **Poster Session**

Optimizing supportive care for patients with metastatic lung cancer in the era of precision oncology. *First Author: Kelly Hsu, Massachusetts General Hospital, Boston, MA*

Background: Targeted therapy improves survival for patients with oncogene-driven non-small cell lung cancer (NSCLC). However, metastatic NSCLC remains incurable and patients often experience uncertainty about what to expect from their long and unpredictable illness trajectories. The aim of this trial is to pilot test a supportive care intervention that blends palliative care and survivorship for patients with metastatic oncogene-driven NSCLC. **Methods:** We will conduct a pilot randomized, controlled trial to evaluate the feasibility, acceptability and preliminary efficacy of a novel supportive care intervention for patients with metastatic oncogene-drive NSCLC. We will enroll 90 patients with a recent (within 6 months) diagnosis of metastatic NSCLC with a mutation in *EGFR*, *ALK*, *ROS1* or *RET* genes who are receiving targeted therapy. We will enroll the first ten patients in an open pilot and we will refine the intervention and study procedures based on pilot findings. We will randomize the remaining 80 patients 1:1 to the intervention or a usual care control. Participants randomized to the intervention arm will have four monthly visits with a palliative care clinician who has been trained to address the supportive care needs of patients with long illness trajectories. Sessions will cover 1) rapport building and baseline symptom and psychosocial assessment; 2) coping support and healthy lifestyle promotion; 3) cultivation of prognostic understanding; and 4) exploration of goals and values. Patients in both arms will complete surveys including secondary outcome measures at baseline, 12, and 20 weeks post-enrollment. The primary outcome of the study is feasibility of the palliative care intervention, defined as at least 60% enrollment among eligible patients and 75% completion of all four sessions and three surveys. We will also assess acceptability using measures of satisfaction and comfort with the intervention. We will evaluate the preliminary effects of this intervention on the following outcomes to inform a future large-scale efficacy trial: 1) distress related to prognostic uncertainty and 2) prognostic awareness (using the Prognostic Awareness Questionnaire: 34-item validated measure with items about likelihood of cure and impact of prognostic awareness on decisions, behaviors and mood); 3) confidence in chronic disease management using the Self-Efficacy of Management of Chronic Disease scale; and 4) documentation of discussions about goals and values in the medical record. We will analyze change within and between groups at 12 and 20 weeks using linear mixed models, controlling for baseline values and relevant demographic and clinical factors. Study accrual to the open pilot phase began in February 2022. Current enrollment: n = 0. Clinical trial information: NCT04900935. Research Sponsor: None.

Internet-delivered management of pain among cancer treatment survivors (IMPACTS WF-1901). *First Author: Megan Irby, Wake Forest School of Medicine, Clemmons, NC*

Background: Pain is a common symptom among cancer patients and often is inadequately treated. Treatment guidelines recommend patients have access to behavioral interventions that educate about pain and pain management. Pain coping skills training (PCST) accomplishes these goals through teaching cognitive and behavioral coping skills shown to reduce pain. When delivered in in-person, PCST can substantially improve chronic pain conditions. Yet, these interventions are underused due to myriad barriers (high costs, shortage of therapists, travel needs). There is a critical need for improved options to help reduce cancer-related pain and related impairment that should include evidence-based PCST interventions capable of overcoming access barriers. To address this need, we developed a web-based PCST program using a novel *expert systems* approach that retains critical features of in-person PCST in an automated program that requires no therapist. *PainTRAINER,* is an 8-week, interactive PCST program using tailoring algorithms, a knowledge database, and a virtual coach to guide development of essential skills for coping with chronic pain. **Methods:** With funding from the NIH HEAL Initiative, we have undertaken a randomized, prospective, comparative effectiveness trial through the Wake Forest NCI Community Oncology Research Program (NCORP) Research Base to determine the impact of *painTRAINER* on pain outcomes when compared to Enhanced Usual Care (EUC). Participants have a documented diagnosis of invasive cancer who are undergoing anticancer therapy or within 5 years of completing all cancer therapy. Participants must report cancer-related pain most days of the week of 4 or greater on the *PROMIS Pain Intensity Scale;* with pain of new onset or significantly exacerbated since cancer diagnosis. All participants receive usual care provided by their physician along with pain education materials. *PainTRAINER* arm participants have access to the *painTRAINER* program and a tutorial on how to use the program, and complete the *painTRAINER* modules on their own (1 session/week for 8 weeks). To enhance study access, patients without internet availability are provided a WiFi/cellular-enabled tablet during the intervention period. This trial examines short- and long-term outcomes measured immediately post-intervention and 3- and 6- months post-intervention. Primary outcomes are: pre- to post-intervention change in pain interference/severity. Secondary outcomes are: pain severity/interference at 3- and 6-month follow-up, opioid/analgesic use, health-related quality of life, and pain management self-efficacy. Qualitative interviews are conducted with a random sample of diverse participants who have completed the *painTRAINER,* and all who exit the study early, to subjectively assess experiences with pain and the clinical trial. Enrollment for this trial has begun (n = 36 of 456 patients enrolled) and is ongoing at 12 sites. Clinical trial information: NCT04462302. Research Sponsor: U.S. National Institutes of Health.

TPS12153 **Poster Session**

Use of the ORBIT model to refine and test a novel approach to exercise promotion for breast cancer survivors based on affect regulation. *First Author: Mary D. Chamberlin, Dartmouth-Hitchcock Medical Center, Lebanon, NH*

Background: Physical inactivity is a modifiable risk factor for breast cancer recurrence, but estimates suggest at least 50% of breast cancer survivors are insufficiently active. Guidelines specify all cancer survivors should avoid inactivity, and 90-minutes of moderate-vigorous physical activity (MVPA) per week is associated with clinically meaningful benefits (e.g., reduced cancer-related fatigue). Among the general population, how people feel during exercise (i.e., "affective response to exercise") predicts future exercise engagement. Past work shows prescribing affect-regulated exercise can increase MVPA among inactive adults; however, this strategy has yet to be tested with cancer survivors. The overarching goal of this trial-in-progress is to test the hypothesis that an affect-regulated exercise prescription (Affect-Rx) can promote clinically meaningful increases in MVPA among inactive breast cancer survivors. **Methods:** Design: The Obesity-Related Behavioral Intervention Trials (ORBIT) model was used to inform all choices about design and key research milestones for two sequential studies. Study 1 (Phase Ib) is a stakeholder-centered, single-arm pilot trial (NCT04903249). Study 2 (Phase IIa) is a randomized (2:1) proof-of-concept trial. In both studies, MVPA will be measured using waist-worn ActiGraph wGT3X-BT accelerometers for 10 days at baseline, 2-, 6- and 12-weeks follow-up. Participants also complete brief ecological momentary assessments (EMAs) of their feeling states (e.g., pain, fatigue) three times per day for the same 10-day data collection periods. Participants: >18 years or older, physically inactive, stage 0-III breast cancer survivors, with primary cancer-treatment completed within the last 5-years. Intervention: Both studies deliver the Affect-Rx prescription: Exercise at the highest pace that still feels good. The Control condition in Study 2 is a heart-rate regulated exercise prescription. Endpoints and Planned Analyses: The goal of Study 1 is to refine the study protocol for acceptability via participant interviews and objective indicators of acceptability (e.g., accelerometer wear-time). The primary milestone for Study 1 is a fixed protocol ready for testing in Study 2. The goal of Study 2 is to quantify the effect of Affect-Rx on MVPA at 12-weeks relative to Control. The primary milestone for Study 2 is clinically meaningful impact on MVPA operationalized as >50% participants completing 90-minutes of MVPA at the end of 12 weeks. The associations between daily variability in feeling states and MVPA will be analyzed using a mixed-effects, hierarchical regression modeling approach. Current Enrollment: Data collection for Study 1 are ongoing. To date, $N = 37$ women have enrolled in Study 1 and data collection is complete for $N = 13$ at week-12. We aim to collect complete data from at least $N = 20$ women in Study 1 and $N = 60$ women in Study 2. Clinical trial information: NCT04903249. Research Sponsor: U.S. National Institutes of Health, Other Government Agency.
