Longitudinal screening for depression and anxiety in prostate cancer (PC) and association with disease and treatment factors. *First Author: Risa Liang Wong, Department of Medicine, Division of Hematology/Oncology, University of Pittsburgh, Pittsburgh, PA*

Background: Untreated depression and anxiety are associated with worse outcomes in patients with cancer. Despite recommendations for longitudinal screening, many patients are only assessed at the start of care. Men with PC often experience many phases of disease or treatment over a span of years, and androgen deprivation therapy (ADT) is associated with mood changes and depression. How depressive or anxiety symptoms fluctuate in men with PC, influenced by disease and treatment factors, is not well-described. **Methods:** Men with ≥1 Urology or Medical Oncology clinic visit for PC in the prior 6 months were emailed the PHQ-9 and GAD-7 depression and anxiety screening tools every 60 days; a score of ≥10 (moderate to severe symptoms) on either was considered a positive screen. Baseline characteristics and disease/treatment changes (PSA, radiographic, or biopsy progression, treatment change or start, or discontinuation of treatment due to lack of efficacy or toxicity) were collected by survey and chart review. We report early findings of factors associated with a positive screen or change in screening status with χ^2 and forward stepwise binary logistic regression (model inputs: receipt of ADT or disease/treatment change during study, and variables previously associated with depression or anxiety: age, race, marital status, education, income, history of psychiatric disorder, use of psychoactive medication, time since diagnosis, and localized, biochemically recurrent, or metastatic disease). **Results:** From 6/2021-12/2021, 201 men enrolled. At baseline, 50.7% had localized, 18.9% biochemically recurrent, and 30.3% metastatic disease; 40.8% were on ADT; 30.8% had a history of psychiatric disorder (22.9% depression, 19.9% anxiety, 9.0% other); and 24.9% were on psychoactive medication (19.9% antidepressant, 8.5% anxiolytic, 2.0% antipsychotic). 184 men completed at least 2 screens with mean follow-up 6.5 months (SD 1.3). 32 men (15.9%) screened positive at least once (15.4% PHQ-9, 4.5% GAD-7), of which half (N = 16) initially screened negative and later positive. Changing from a negative to positive screen was more likely when a disease/treatment change occurred during the study (18.3% vs 4.5%, p = 0.003). A higher proportion of men on ADT screened positive, especially if newly started during the study or in the 60 days preceding (35.7% new ADT vs 24.7% continuing ADT vs 8.0% no ADT, p = 0.002). In fully adjusted multivariable analyses, factors associated with a positive screen were history of psychiatric disorder (OR 6.3, 95% CI 2.6-15.4, p < 0.001), receipt of ADT (OR 3.8, 95% CI 1.5-9.5, p = 0.005), and lower income bracket (OR 1.7, 95% CI 1.3-2.5, p = 0.002). **Conclusions:** Longitudinal screening for depression and anxiety in PC identifies men who initially screen negative. Symptoms are associated with ADT and disease or treatment changes, which may inform optimal screening practices. Piflufolastat F 18-PET/CT in patients with prostate cancer: An analysis of OSPREY (cohorts A and B) standardized uptake value (SUV) results stratified by PSA and Gleason score. *First Author: Michael A. Gorin, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: The OSPREY clinical trial was a phase 2/3 prospective study of prostate specific membrane antigen (PSMA) PET/CT using piflufolastat F 18. Piflufolastat F 18 (aka ^{18}F-DCFPyL or PyL) is a novel PSMA-targeting radiopharmaceutical approved for imaging of PCa pts both at initial staging and for disease recurrence. Here we describe SUV results by biopsy status, baseline PSA levels, and Gleason score (GS). **Methods:** Piflufolastat F 18-PET/CT was evaluated in men with NCCN high-risk PCa scheduled to undergo radical prostatectomy with pelvic lymphadenectomy (RP-PLND) (Cohort A) and men with radiologically suspected recurrent/metastatic PCa (Cohort B). A single IV dose of 9 mCi (333 MBq) of piflufolastat F 18 was administered followed by PET/CT acquisition 1-2 hours later. Piflufolastat F 18 uptake in various lesion locations as defined by maximum and peak SUV (SUVmax, SUVpeak) were determined by three blinded, independent central readers for each tissue (e.g., bone, lymph nodes (LN), soft tissue). To measure SUVs, the reader placed a volume of interest (VOI) on each identified lesion. SUVmax was defined as the maximum single-voxel SUV within the VOI. SUVpeak within the VOI was defined as the average SUV within a fixed-sized VOI (1 cm diameter sphere), representing the cluster with the highest average SUV. **Results:** 345 men underwent piflufolastat F 18-PET/CT. Cohort B (n = 93evaluable) SUVmax and SUVpeak were significantly higher for biopsy positive (+)(one biopsy lesion/pt) when compared to biopsy negative (-) lesions from bone and LN. SUVpeak for biopsied bone and LN (Cohort B) appeared to increase with rising baseline PSA. In high-risk PCa pts, SUVpeak for prostate (Cohort A; n = 252 evaluable) increased with baseline PSA and were highest for GS 9-10 (Table). **Conclusions:** Piflufolastat F 18-PET/CT uptake was significantly higher in biopsy + lesions and increased with baseline PSA. Prostate SUVpeak was highest for GS 9-10. Clinical trial information: NCT02981368. Research Sponsor: Progenics Pharmaceuticals, a Lantheus company.

Long-term outcomes and genetic predictors of response to metastasis-directed therapy versus observation in oligometastatic castration-sensitive prostate cancer: A pooled analysis of the STOMP and ORIOLE trials. *First Author: Mathew Pierre Deek, Rutgers Cancer Institute, Baltimore, NJ*

Background: Prospective reports suggest metastasis directed therapy (MDT) in oligometastatic castration sensitive prostate cancer (omCSPC) is associated with improved treatment outcomes. Here we present long term outcomes of the phase II STOMP and ORIOLE trials and assess the ability of a high-risk (HiRi) mutational signature to provide prognostic and predictive information regarding MDT response. **Methods:** Patients with omCSPC (< 3 lesions) enrolled on STOMP (n = 62) and ORIOLE (n = 54) randomized to MDT or observation were pooled. The primary endpoint was progression-free survival (PFS) defined as either PSA or radiographic progression, initiation of androgen deprivation, or death. Secondary endpoint was radiographic PFS (rPFS) defined as radiographic progression or death. Both were calculated using the Kaplan-Meier method and stratified by treatment group. Next generation sequencing (NGS) was performed to identify a HiRi mutational signature defined as pathogenic mutations within *ATM*, *BRCA1/2*, *Rb1*, or *TP53*. Cox proportional hazards regressions were fit to calculate hazard ratios (HR) and assess the prognostic and predictive values of HiRi mutational status. **Results:** Median follow-up was 52.5 months. Median PFS was prolonged with MDT (11.9 months) compared to observation (5.9 months) with a pooled HR of 0.44 (95% CI, 0.29 – 0.66, p-value < 0.001). MDT was associated with PSA decrease in a majority of patients (84%) as compared to the observation group (41%). On NGS, the incidence of a pathogenic mutation in a HiRi gene was 24.3%. HiRi mutation was prognostic for PFS – in those without a HiRi mutation median PFS was 11.9 months compared to 5.9 months in those with a HiRi mutation (HR of 1.74, p = 0.06). HiRi mutation was also prognostic for rPFS – those without a high-risk mutation experienced median rPFS of 22.6 months compared to 10.0 months in those with a high-risk mutation (HR 2.62, p < 0.01). Tumors without a HiRi mutation treated with MDT experienced the longest PFS (13.4 months) while those with a HiRi randomized to observation experienced the shortest PFS (2.8 months). Stratifying by both treatment arms and HiRi status appeared to show a differential benefit to MDT, with those with HiRi mutations experiencing a larger relative magnitude of benefit to treatment: (HiRi mutation: HR of 0.05, p < 0.01; no HiRi mutation: HR of 0.42, p = 0.01; p interaction, 0.12) suggesting a HiRi mutational status can provide information regarding differential response to treatment. **Conclusions:** Long-term outcomes from the only two randomized trials in omCSPC suggest a sustained benefit to MDT over observation. A HiRi mutational signature appears prognostic for outcomes in omCSPC and those with HiRi might have a relatively larger magnitude of response to MDT. Future studies are needed to optimize patient selection. Clinical trial information: NCT02680587. Research Sponsor: Prostate cancer foundation.

Chromosomal instability (CIN) in circulating tumor cells (CTC) predicts for taxane sensitivity in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Niamh M. Keegan, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Few clinically validated biomarkers can inform therapy (tx) sequencing in mCRPC. Previously, we credentialed a biomarker of CIN in individual CTCs using phenotypic identification of cells with ≥9 large scale transitions (LSTs) and classification of CIN as high when detected in ≥3 CTC/mL (CIN3+). CIN3+ was associated with shorter radiographic progression survival (rPFS) and overall survival (OS) following taxane (T) or androgen receptor signaling inhibitor (ARSi) tx in mCRPC. Similarly, high CIN defined as ≥1 CTC/mL with ≥9 LSTs (CIN1+) predicts worse rPFS and OS following ARSi. Here, we explored if CIN1+ or CIN3+ predicted differential outcomes in pts on-tx with T or ARSi for mCRPC. **Methods:** We analyzed 208 banked CTC samples from 173 mCRPC pts collected within 30 days prior to starting a new tx with either T (n=88) or ARSi (n=120) in 2012-2017. CTCs were detected using Epic Sciences platform and CIN defined using the phenotypic classifier (PMID 32816908). Retrospective clinical annotation was completed for OS, defined as time from index tx start date to death, and rPFS, defined as index date to date of new or/and increasing lesion size in on-tx radiology report or death. Associations with rPFS and OS were studied according to samples' CIN1+ and CIN3+ status. T vs. ARSi comparisons were adjusted using Cox models that incorporated pre-tx covariates, i.e. prior T or ARSi txs, total CTC count, presence of visceral disease, and prognostic lab values. **Results:** The median (range) follow-up from tx start to date of death or last follow-up was 7 (5-9) years. There were 53/120 (44%) pts starting ARSi that had prior ARSi txs and 41/88 (46%) pts starting taxane that had prior taxane txs. CTCs were detected in 184 (88%) samples, CIN1+ in 73 (35%; 64% pre-T, 36% pre-ARSi), and CIN3+ in 47 (22%; 60% pre-T,40% pre-ARSi). Compared to CIN1+, model results (Table) suggest that CIN3+ predicts a longer rPFS (p<0.01), and possibly OS (p=0.05), with T therapy. Compared to CIN1-, CIN3- also predicts a longer OS with ARSi therapy (p=0.04). **Conclusions:** CIN3+ CTC may be a more discriminating predictive biomarker than CIN1+ to help guide selection of T or ARSi tx in pts with mCRPC. Adequately powered prospective studies are planned. Research Sponsor: U.S. National Institutes of Health.

Circulating tumour cells (CTCs) and PSMA PET correlates in the phase I PRINCE trial of ^{177}Lu-PSMA-617 plus pembrolizumab for metastatic castration resistant prostate cancer (mCRPC). *First Author: Anis Hamid, Eastern Health and University of Melbourne, Melbourne, Australia*

Background: The Phase I PRINCE trial (NCT03658447) is evaluating the efficacy of ^{177}Lu-PSMA-617 plus pembrolizumab for mCRPC. The utility of serial monitoring of CTCs and PET as biomarkers of prognosis and clinical benefit of ^{177}Lu-PSMA-617-based therapy remains unknown. **Methods:** 36 of 37 pts with high PSMA expression on PSMA PET underwent serial CTC collections in conjunction with PSMA PET at baseline, every 12 weeks for 48 weeks and every 24 weeks thereafter. CK+, CD45- CTCs were enumerated from 3ml of blood and stained for PSMA (Epic Sciences platform). Associations between PSMA+ CTC counts, PET molecular tumor volume (MTV), total lesional activity (TLA; MTVxSUVmean) were assessed by Spearman correlation. Cox models assessed the association of CTC and PSMA PET parameters with radiographic progression-free survival (rPFS) and PSA PFS. A subset of pre-treatment CTCs underwent single cell low-pass whole genome sequencing to characterize copy number aberrations. **Results:** 32/36 pt (89%) had detectable CTCs (median 7, range 0-514) with 23 (64%) being PSMA+ (median 1, range 0-224) at baseline. At w12, 23/33 (70%) had CTCs detected with 10 (30%) being PSMA+. Baseline PSMA+ CTC count and MTV were moderately correlated (r_s= 0.57, p < 0.001). Of 22 evaluable pts with baseline PSMA+ CTC, 18 (82%) showed decrease by w12 with clearance in 13. This paralleled reductions in MTV (-18% med relative change, IQR: -57 to -1) and TLA (-48% med relative change, IQR: -77 to -28). Total CTC and PSMA+ CTC counts at baseline, and PET parameters were not associated with PSA PFS or rPFS. Clearance of PSMA+ CTC by w12 (13/22 pts) was associated with improved rPFS (med NR vs 3.0 mos, HR 0.23, 95%CI 0.07-0.74, p = 0.007) and PSA PFS (med 11.2 vs 3.5 mos, HR 0.28, 95%CI 0.11-0.73, p = 0.006). Persisting PSMA-neg CTCs at w12 trended to worse rPFS (med 4.1 vs 12.3 mos, p = 0.11) and PSA PFS (med 5.1 vs 12.3 mos, p = 0.07). Of pts not progressing by w12, decrease in PSA (HR 0.83 per 10% decrease, 95%CI 0.74-0.93, p < 0.001), MTV (HR 0.85 per 10% decrease, 95%CI 0.75-0.96, p = 0.008), MTV > 30% decrease (HR 0.30, 95% CI 0.08-1.08, p = 0.05) and TLA (HR 0.88 per 10% decrease, 95%CI 0.78-1.00, p = 0.04) associated with improved rPFS beyond w12. Pre-treatment CTCs (18 pts) exhibited genomic heterogeneity and frequent loss of *PTEN*, *TP53* and *RB1*. Pts with compound *TP53* and *RB1* loss at baseline nonetheless had PSMA+ CTCs in high proportion (med 91.3% of total CTCs). **Conclusions:** PSMA PET-positive mCRPC is associated with high rates of PSMA+ CTCs which decline with ^{177}Lu-PSMA-617 plus pembrolizumab in parallel with PSMA MTV/TLA. Despite imaging suitability for therapy, CTCs had heterogenous PSMA expression and genomic alterations associated with aggressive disease. Early changes in PSMA+ CTCs and MTV/TLA were associated with outcomes and may aid in determining clinical activity of LuPSMA-based therapy. Research Sponsor: None.

Impact of PSMA PET/CT on prostate cancer salvage radiotherapy management: Results from the prospective randomized phase 3 trial [PSMA SRT NCT03582774]. *First Author: Wesley R Armstrong, Ahmanson Translational Theranostics Division, University of California, Los Angeles, CA*

Background: The purpose of the randomized PSMA SRT trial is to compare the success rate of salvage radiation therapy (SRT) for recurrence of prostate cancer (PCa) after radical prostatectomy (RP) with (intervention arm) and without (control arm) planning based on PSMA PET/CT. Here we report the secondary endpoint of the trial: impact of PSMA PET/CT on the treatment plan. **Methods:** This is a Randomized, controlled, prospective, open label, phase 3 clinical trial with institutional funding. 193 patients were randomized to proceed with standard SRT with any conventional imaging aside from PSMA PET/CT (control arm) or undergo a 68Ga-PSMA-11 PET/CT scan prior to SRT (investigational arm). The following information was collected on case-report forms before randomization (intended SRT plan) and after treatment: Radiation field region (prostate fossa (PF), pelvic lymph node (PLN)), total dose, dose per fraction, duration, ADT use and duration, PSMA influence on target volume, or other (free-text). Changes between SRT plan before randomization and delivered treatment were classified as Major, Minor or No Change. Major change: change of ADT duration ≥3 months, change of standard RT volumes (PF and PLN), target volume delineation beyond standard RT field, simultaneous-integrated boost (SIB) beyond standard RT fields, and initiation of advanced systemic therapy (novel ADT agents, chemotherapy). Minor change: SIB within standard RT fields. Fisher exact test was used to compare prevalence of events between study arms. **Results:** Enrollment is complete. 193 patients enrolled from 09.06.2018 to 8.17.2020: 90 and 103 randomized to the control group and PSMA group. Median Time from RP to enrollment and median PSA was 20.3 months (IQR 1.4–245) and 0.3 ng/ml (IQR 0.2-10.3), and 28.3 months (IQR 1.2–21) and 0.23 ng/ml (IQR 0.1-29.9), respectively. The control arm had 13 dropouts (17%) while the intervention had one (1%). PSMA was positive in 38/102 (38%): 12/102 (12%) outside of pelvis, and 20/102 (20%) in PLNs . Pre-randomization RT plan and Delivered RT plan were available in 193/193 (100%), (77/90 control (86%) and 102/103 PSMA (99%), (p = 0.0004)respectively. There were 0/77 (0%) and 7/102 (7%) minor changes in the control and PSMA groups (p = 0.02). There were 17/77 (22%) and 45/102 (44%), major changes (p = 0.004); 32/45 (71%) were PSMA-related. Treatment escalation occurred in 7/17 (41%) and 36/52 (69%) (p = 0.048), and de-escalation in 10/17 (59%) and 10/52 (19%) (p = 0.004). Nine/102 patients (9%) received advanced systemic therapy in relation to PSMA findings whereas only 1/77 (1%) patient in the control received advanced therapy (p = 0.044). **Conclusions:** In this prospective randomized phase 3 study, proportion of major changes between the pre-randomization SRT plan and the delivered RT plan was 44% in the PSMA intervention group and 22% in the conventional imaging control group. Clinical trial information: NCT03582774. Research Sponsor: None.

Genomic alterations and evolution in patients with prostate cancer with histologic evidence of neuroendocrine differentiation. *First Author: Ethan Barnett, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The incidence of transformation to neuroendocrine prostate cancer (NEPC) has increased in castration resistant prostate cancer (CRPC) in parallel with treatment advances inhibiting androgen receptor signaling. The current understanding is that this occurs in ~10-20% of CRPC cases. Missing is a determination of the timing of molecular events that drive the process. **Methods**: Under an IRB-approved protocol, retrospective annotation of all MSK-reviewed pathology reports was conducted for 1447 prostate cancer patients with MSK-IMPACT sequencing data. For patients with pathologically confirmed NEPC, the date of the first sample with unequivocally reported NEPC (described as "neuroendocrine carcinoma" or as having "neuroendocrine differentiation" or "neuroendocrine features") was recorded. Patients with early signs of histologic transformation not specifically reported as NEPC (double negative prostate cancer or rare/focal staining for NE markers) were analyzed separately. Sequencing results were described by castration-status at collection (CRPC vs castration-sensitive) and, if applicable, the relationship to NEPC diagnosis (i.e. pre- vs post-NEPC). Genomic enrichment analysis was used to identify differentially altered genes between groups. **Results**: In total, 95 (6.6%) patients had pathologically confirmed NEPC during their disease course, from whom 150 samples with sequencing results were available: including 18 patients with matched pre- and post-NEPC samples. CRPC samples from patients with NEPC (n = 70) were significantly enriched for *RB1* alterations (50% vs 12%, $p < 10^{-10}$, $q < 10^{-10}$). *AR* alterations were significantly enriched in CRPC samples from patients without NEPC (n = 380) (63% vs 21%, $p < 10^{-10}$, $q < 1.27*10^{-8}$). Further, alterations in numerous genes including *TP53*, *AMER1*, *ARID5B*, *YAP1*, *SOX2*, and *NKX2*.1 were enriched in NEPC patients at the 95% confidence interval (CI) without correction for repeat testing. Matched pre- and post-NEPC samples demonstrated that *TP53* alterations in post-NEPC samples are detected in the majority of pre-NEPC samples (8 of 10 patients), but *RB1* alterations in post-NEPC samples are detected in a minority of pre-NEPC samples (1 of 8 patients). 54 (3.7%) patients had evidence of early histologic transformation. CRPC samples from these patients (n = 29) were enriched for mutations in *RB1*, *MAP2K2*, *MUTYH,* and *CTNNB1* at the 95% CI without correction. *FOXA1* mutations were enriched in patients without transformation. **Conclusions**: *RB1*, consistent with previous findings, is enriched in NEPC. The inability to detect *RB1* alterations in pre-NEPC samples supports divergent evolution, although technical limits of tissue panel sequencing make it difficult to rule out the presence of sub-clonal alterations. Further study of additional genes which contribute to histologic transformation and the development of NEPC is warranted. Research Sponsor: None.

18F-FluorThanatrace (18F-FTT) positron emission tomography (PET/CT) in prostate cancer measures in vivo PARP-1 expression and is associated with adverse clinicopathologic features. *First Author: Neil Taunk, Penn Medicine Abramson Cancer Center, Philadelphia, PA*

Background: We performed the first clinical trial to evaluate expression of PARP-1, the target of PARP-inhibitors (PARPi), in prostate cancer (PC) using 18F-FluorThanatrace (18F-FTT), a novel radiopharmaceutical that selectively measures PARP-1 expression with PET/CT. Approvals for PARPi in metastatic castrate resistant prostate cancer (mCRPC) have improved clinical outcomes in men with homologous recombination deficient (HRD) associated PC. Patient selection using genetic biomarkers such as HRD and PARP-1 IHC are insufficient PARPi biomarkers. We report the first trial of assessment of PARP-1 expression in men with prostate cancer. **Methods:** Men with localized PC with planned prostatectomy were included. Patients were required to have 2+ biopsy cores with > 50% involvement, OR > 1cm dominant prostate lesion on MRI. Men received a single pre-operative [18F]FTT scan. [18F]FTT is. Patients received a single injection of 8-12 mCi [18F]FTT and underwent 60 minutes dynamic scanning and static scan at 90 minutes post-injection. Ex vivo IHC, autoradiography, and germline/somatic genomic testing was performed after surgical removal. The study was approved by the University of Pennsylvania IRB (UPCC #13817, ClinicalTrials.gov, NCT03334500). **Results:** 30 men consented for participation (29 with presurgical MRI) from 6/2019 to 12/2020. Mean PSA was 9.8 ng/mL (range 2.35 – 60). Gleason Grade (GG) groups included: GG 1 (n = 1), GG 2 (n = 10), GG 3 (n = 5), GG 4 (n = 7), and GG 5 (n = 7). Stages included: pT2 (n = 12), pT3a (n = 10), pT3b (n = 8). Two patients had pN1 disease (cN0 by MRI). Mean injected dose was 10.32 mCi (range 7.52 – 11.62). There were no serious adverse events noted for any patient. Of patients with presurgical MRI, a range of uptake on the PET/CT correlated to the dominant lesion on MRI. The mean and median SUVMax of all lesions was 3.52 and 3.46, respectively (range 1.03 – 6.56). Both patients cN0 on MRI, had those nodes identified on the [18F]FTT scan. SUVMax was significantly associated with increasing Gleason Grade group Rs = 0.37298, p (2-tailed) = 0.04. SUVMax was significantly associated with Decipher scores (GenomeDx Biosciences, San Diego, CA) Rs = 0.63077, p (2-tailed) = 0.02. Ex vivo IHC showed PARP1 localization to the dominant region on the MRI. Ex vivo autoradiography using [I125]KX1, a FTT analogue, and correlation to genomic HRD (DDR aberrations and HRD scores) is underway. **Conclusions:** [18F]FTT detects *in vivo* PARP-1 expression in prostate cancer and SUVMax is associated with higher Gleason Grade groups and Decipher scores, This tracer may be used as an imaging biomarker for PARP-1 expression in men with prostate cancer, the target of PARPi. A follow-up study to assess change in [18F]FTT uptake before and after administration of PARPi in men with mCRPC is underway to test [18F]FTT as a biomarker PARPi (UPCC #08821). Clinical trial information: NCT03334500. Research Sponsor: None.

Need for organ preservation in postchemotherapy retroperitoneal lymph node dissection (PC-RPLND). *First Author: Tim Nestler, Department of Urology, University Hospital Cologne, Cologne, Germany*

Background: The aim ofPC-RPLND for advanced nonseminomatous germ cell tumors is to resect all remaining metastatic tissue. So far, the resection of adjacent visceral or vascular organs is also commonly performed to achieve complete resection of the residual mass. To determine the possibility of more organ preservation, we aimed to analyze the pathohistology of patients with adjunctive surgery as the frequency of metastatic involvement in those organs with teratoma or vital cancer is currently unknown. **Methods:** We reviewed a cohort of 1204 patients who underwent PC-RPLND between 2008 and 2021 as a 2-center study and identified 242 (20.1%) cases of adjunctive surgery during PC-RPLND. We analysed the pathohistological presence of germ cell tumor elements in the resected organs: viable tumor (V), teratoma (T) or necrosis / fibrosis (N). Surgery associated complications were reported according to the Clavien-Dindo classification. Outcomes of subgroups were compared by using log-rank test. **Results:** V, T and N were present in 54 (22%), 94 (39%) and 94 (39%) of all patients with adjunct resected organs. In 242 patients, 325 adjunct organs were resected with 66 (27.3%) of these patients receiving a resection of multiple organs. The kidney was the most often resected organ (n = 77; V: 29% T: 39% N: 32%), followed by V. Cava (n = 67; V: 25% T: 36%, N: 39%) and partial liver resections (n = 50; V: 16%, T: 30%, N: 54%). Postoperative complications occurred in 30% of which 22% were Clavien grade III-V, showing no significant differences between V, T and N; p = 0.093. 27% of all patients suffered from a relapse during a median follow-up of 22 months [0-180]. Patients with T or V in the resected specimens had a significantly reduced 5-year RFS compared to patients with only N (39%, 81%, p < 0.001). **Conclusions:** This study shows tremendous need for more organ preservation as 40% of all resections of adjunct organs are oncologically unnecessary due to the presence of N only in the pathological specimens. Therefore, in case of doubt, we should increase intraoperative frozen section to avoid oncologically unnecessary adjunctive surgeries, especially nephrectomies and vascular resections. Additionally, serological or image-based means for a more accurate presurgical workup are required to spare patients with N from PC-RPLND in general. Research Sponsor: None.

Salvage high-dose chemotherapy (HDCT) for relapsed primary mediastinal nonseminomatous germ-cell tumors (PMNSGCT). *First Author: Fadi Taza, Division of Hematology and Oncology, Indiana University Simon Cancer Center, Indianapolis, IN*

Background: Patients with PMNSGCT have high relapse rates after first-line therapy. Historical outcomes in this subset with standard-dose salvage chemotherapy or HDCT+bone marrow transplant (BMT) have been poor. The use of peripheral-blood stem-cell transplant (PBSCT) has allowed for more rapid engraftment and the ability to start the 2nd course 3-4 weeks after the 1st course of HDCT. We report survival outcomes of salvage HDCT+PBSCT in relapsed PMNSGCT. **Methods:** Between 2004-January 2021, 32 pts with relapsed PMNSGCT were treated with HDCT+PBSCTx2 utilizing our institutional regimen: carboplatin 700 mg/m2 + etoposide 750 mg/m2, for 3 consecutive days, followed by PBSCT. Median time between cycle1 day1 to cycle2 day1 was 3.2 wks (range, 2.6-4.6). Kaplan-Meier methods were used for progression-free (PFS) and overall survival (OS) analysis. **Results:** Median age was 30. At the start of HDCT, median AFP was 192 (range, 4-17130) and hCG 1.5 (range, 0.6-15711). First-line therapy was standard germ cell tumor chemotherapy such as bleomycin-etoposide-cisplatin (BEP) or etoposide-ifosfamide-cisplatin (VIP). HDCT was 2nd line in (26, 81.3%) and 3rd line in (6, 18.8%). Eighteen (56.3%) pts had platinum-refractory disease defined as progression within 4 weeks of 1st line chemo. Twenty-three (72%) patients had extra mediastinal metastases (mets) at the start of HDCT. Metastatic sites included pulmonary (17), lymph nodes (2), liver (3), bone (2), brain (1). Median follow-up time from start of HDCT was 1 yr (range, 0.02-14.1). Twenty-six (81%) pts completed both cycles, while 6 (19%) completed only one cycle due to toxicity or progression. The estimated 2-yr PFS was 30.7 (95% CI, 15.8-46.9) and 2-yr OS was 35.2 (95% CI, 18.9-51.9). At the most recent follow-up, 9 (28%) pts were continuously no evidence of disease (NED), including 2 pts who had surgical resection of teratoma following HDCT. Median follow-up from the start of HDCT for the NED pts was 4.6 yrs (range, 1-14.1). Five of the NED pts had extra mediastinal mets, and 2 had platinum-refractory disease. Among the 9 NED pts, HDCT was 2nd line in 7 (77.8%) and 3rd line in 2 (22.2%). These results compare favorably to historical data with standard-dose chemotherapy or HDCT+BMT in relapsed primary mediastinal GCT with salvage rates < 10% (Hartmann et al., JCO 19:1641-1648, 2001). Grade ≥3 toxicity, as previously described in our study (Adra et al., JCO 35:1096-1102, 2017), occurred in 8 (25%) pts. There were two treatment-related deaths. **Conclusions:** HDCT+PBSCT is a safe and effective salvage therapy in pts with relapsed PMNSGCT with curative potential. In our opinion, these complicated patients are best managed at tertiary centers with expertise in medical oncology, stem cell transplantation, and thoracic surgical oncology. Research Sponsor: None.

Epigenetic age acceleration in U.S. testicular cancer survivors (TCS). *First Author: Yinan Zheng, Northwestern University, Chicago, IL*

Background: Given the young age at diagnosis and effective therapies (cisplatin-based chemotherapy and/or surgical approaches), most TCS gain many decades of life. Attention has been drawn to the potential downsides of these treatment successes, including the accelerated development of age-related diseases. Previous studies have suggested that cytotoxic treatment and carcinogenesis are associated with epigenetic changes, leading to premature biological aging processes. **Methods:** We recruited 24 TCS managed with surgical approaches alone and 24 cisplatin-treated TCS (all also treated with surgical removal of the cancerous testis) and who had histologic/serological germ cell tumor diagnosis before 55 years, and were disease-free at routine follow up. We also included 310 cancer-free race- and age-matched (+/- 5 years) males from a normative cohort, i.e., the Coronary Artery Risk Development in Young Adults (CARDIA) Study. We undertook genome-wide interrogation of blood DNA methylation (DNAm) using the Illumina Infinium Methylation EPIC BeadChip (EPIC array). We quantified aging using DNAm GrimAge, a validated, composite biomarker consisting of DNAm surrogate biomarkers of seven plasma proteins associated with various age-related conditions plus a DNAm surrogate of smoking pack-years. The comparison analysis was adjusted for age, race, smoking status, blood cell type proportions estimated using DNA methylation batch effect, and other laboratory-related technical factors. **Results:** The median chronological age of TCS was 28 years (range 19-64) with 25% smokers. Compared to their chronological age, TCS managed with surgical approaches alone had a mean GrimAge of 39.4 years (i.e., 9.2 years older, paired t-test P = 0.001), and cisplatin-treated TCS had a mean GrimAge of 45.2 years (i.e., 14.9 years older, paired t-test P < 0.001). Compared to the matched CARDIA controls, TCS managed with surgical approaches alone were on average 3.0 years epigenetically older (P = 0.093), and cisplatin-treated TCS were on average 11.2 years epigenetically older (P < 0.001), suggesting an increasing trend with treatment burden (P-trend < 0.001). **Conclusions:** Our data showed a faster epigenetic aging process in TCS. Consistent with previous studies, our data is in line with the hypothesis that TC cytotoxic treatment may induce premature aging. Although TCS managed with surgical approaches alone had no exposure to cytotoxic drugs, their epigenetic age may also be accelerated due to TC development and/or risk factors that contributed to it as well as post-therapy factors. Research Sponsor: U.S. National Institutes of Health.

Management of residual nonretroperitoneal disease in nonseminomatous germ-cell tumors (NSGCT). *First Author: Jennifer King, Indiana University School of Medicine, Indianapolis, IN*

Background: The management of NSGCT patients (pts) with post-chemotherapy residual non-retroperitoneal disease (RP) remains unsettled. Decisions for surveillance vs surgical resection are commonly steered by pathology from retroperitoneal lymph node dissection (RPLND). Data is limited in pts who do not require RPLND (normal or normalized RP post-chemo). **Methods:** The prospectively maintained Indiana University testicular cancer database was queried for pts with metastatic NSGCT who completed first-line chemotherapy and had residual extra-RP disease without residual RP disease. Pts with post-chemo non-RP surgical resection were included. **Results:** 134 pts met eligibility. Median age at diagnosis was 28.6 (range, 16.2-51.5). Primary tumor predominant histology was embryonal (35.1%), mixed (25.4%), seminoma (2.2%), yolk sac (9.7%), choriocarcinoma (15.7%), teratoma (11.2%). 76 pts (56.7%) had teratoma in the primary tumor. Metastatic sites at diagnosis were RP (15.7%), mediastinal LN (8.2%), lung (28.4%), liver (11.2%), bone (6.7%), brain (21.6%). Those with RP mets at diagnosis had normalization of RP nodes after chemo. IGCCCG risk was good in 57, intermediate in 21, and poor in 56 pts. Median pre-chemo AFP was 66 (0.9-467,000). hCG was 960.5 (0.5-1,300,000). First-line chemo was BEPX4 in 68, BEPx3 in 29, EPX4 in 10, VIPX4 in 9, and other in 18 pts. All pts had surgical resection of non-RP disease. None had RPLND. 84 pts had lung nodule resection, 16 had mediastinal LN, 8 had cervical LN, 5 had liver, 6 had bone, and 20 had brain met resection. Of the 76 pts with teratomatous elements in the orchiectomy, 41 (53.9%) had teratoma and 24 (31.6%) had non-teratoma GCT in post-chemo non-RP surgical specimens. Of the 58 pts without teratoma in the orchiectomy, 9 (15.5%) had teratoma and 34 (58.6%) had non-teratoma GCT in the non-RP surgical resection specimens. Teratoma in the orchiectomy was a predictor of non-RP teratoma (Fisher's exact test P<0.0001). **Conclusions:** The presence of teratoma in orchiectomy predicts teratoma in residual post-chemo non-RP disease in pts who do not undergo RPLND. The absence of teratoma in orchiectomy should not preclude resection of residual non-RP disease given a subset of patients had persistent GCT. Research Sponsor: None.

Identifying germline genetic alterations or environmental factors associated with bilateral germ cell tumor (GCT). *First Author: Jack Patrick Gleeson, University College Cork, Cork, Ireland*

Background: Germline genomic alterations and/or environmental factors are proposed as critical to GCT development given the significant rates of bilateral and familial cases. A number of low-moderate risk loci for GCT have been identified (Litchfield, Eur Urol 2018 & Pluta, Nat Comm 2021), predominantly by analysing unilateral GCT, with a polygenic heritability model proffered. We postulate bilateral GCT represents an extreme phenotype with higher frequency of loss of function germline genomic alterations and/or pre-disposing environmental exposures. **Methods:** Bilateral GCT pts who consented to a prospective clinically annotated GCT DNA registry were included for analysis. The registry integrates self-reported questionnaires on environmental exposures, relevant medical history and germline whole exome sequencing (WES). Pathogenicity of variants identified by WES were classified using the algorithm Pathogenicity of Mutation Analyzer (PathoMAN) [Ravichandran, Genet Med 2019]. Aggregated WES results were curated to identify disruptive or deleterious variants affecting the same genes as the most significant individual variants in the Litchfield series. A < 1% minor allele frequency threshold was set for candidate variants, likely benign/benign variants were excluded. **Results:** Of 43 bilateral cases with germline WES results, median age at first diagnosis was 32.1 years (range 18-73), 9 tumors were synchronous and 34 metachronous with median interval between diagnosis of 76.4 months for metachronous cases. Tumor histology was seminoma in 52 and nonseminoma in 34. 39 of 43 (91%) pts completed questionnaires with 35 (90%) reporting White race, 2 Hispanic/Latino, 1 Asian, and 1 Peruvian. 13 (33%) reported prior smoking, 21 (54%) prior marijuana use, and 6 (15%) other illicit drug use. 6 (15%) pts reported undescended testis and 1 (3%) hypospadias. 24/43 (45%) patients harbored ≥1 variant within 15 Litchfield genes (60%). 43 distinct variants were identified: 33 (77%) nonsynonymous missense alterations, 7 (16%) intron variants, 1 inframe deletion in *STH3TC1*, and 1 initiator and 1 stop codon variant in *DEFB132*, which plays a role in binding spermatozoa. Multiple bilateral patients harbored variants in *MPDZ* (n = 7), *EHBP1L1* (n = 6), *SKIV2L* (n = 5), *FAM160A2* (n = 3), *ADAMTS18* (n = 3), *JMJD4* (n = 3), *ABCC4* (n = 3), *R3HCC1* (n = 2), *MLXIP* (n = 2) and *VPS16* (n = 2). **Conclusions:** In this bilateral GCT cohort, we identified several alterations in candidate susceptibility genes from the Litchfield series, whereas no convincing causative recurrent environmental exposures were observed. Our results support a polygenic model of GCT pathogenesis and show that analyzing enriched cohorts such as bilateral GCT may aid understanding of GCT pathogenesis. Additional analysis of the specific variants is required to further assess pathogenicity, elucidate their role and association with bilateral GCT. Prognostic significance of raised serum tumor markers (STM) after 2 cycles of chemotherapy in men with intermediate- and poor-risk non-seminomatous testicular germ cell tumors (NSGCT) treated at a single-centre in India. *First Author: Ankur Nandan Varshney, All India Institute of Medical Science (AIIMS), New Delhi, India*

Background: Testicular GCT is a rare malignancy, with excellent outcomes. However, approximately one-fourth of intermediate risk and half of the patients with poor risk disease succumb to recurrent GCT. We looked at the prognostic significance of raised serum tumor markers after 2 cycles of chemotherapy in patients with poor risk GCT. **Methods:** This is a chart-review based retrospective analysis of patients with intermediate and poor risk NSGCT diagnosed and treated at a tertiary care centre in New Delhi, India from 2015-2021. Risk categories were defined as per the International Germ Cell Cancer Collaborative Group. Multivariable Cox regression models were constructed to analyse the prognostic impact of normal STM at the end of second cycle of chemotherapy on overall survival (OS) and relapse free survival (RFS), while adjusted for measured confounders. **Results:** A total of 312 patients were identified with testicular NSGCT, of whom 109 were intermediate (n = 48, 44%) and poor risk (n = 61, 56%). The median age at diagnosis was 27 (interquartile range, 21-34) years. ECOG PS of patients was 0-1 in 51% and 2-4 in 49%, and poor risk patients were more likely to have a poor ECOG PS at diagnosis (70% vs 30%, P < 0.001). First-line chemotherapy was BEP in 86% patients and VIP in the remaining 14%, and surgery for residual disease was performed in 22%. Overall, 35% patients had normal STM after 2 cycles of chemotherapy, and patients with intermediate risk were likely to achieve normal STM at this time-point (50% vs 23%). At a median follow-up of 62 months, the 5-year RFS rate was 62% (poor risk 52% and intermediate risk 78%), and OS rate was 68% (58% and 80%, respectively). Men with normal STM after 2 cycles chemotherapy had a better RFS (hazard ratio [HR], 0.70; 95% confidence interval 0.48-0.81; P < 0.001) and OS (HR,0.82; 95% CI 0.61-0.99; P = 0.04). After adjusting for risk category, and ECOG PS in a multivariable Cox regression model, patients with normal STM at the end of 2 cycles of chemo continued to have better outcomes (adjusted HR for RFS, 0.78; 95% CI, 0.77-0.89; P = 0.03, and adjusted HR for OS, 0.92; 95% CI,0.81-0.99; P = 0.05). Intermediate risk NSGCT and good ECOG PS also predicted better RFS and OS. **Conclusions:** Patients with NSGCT whose STMs do not normalize after 2 cycles of chemotherapy have worse RFS and OS compared to those with normal STM at this time-point. Further clinical trials will be needed to study the role of escalation or switch of chemotherapy in this subset of population. Research Sponsor: None.

Anti-EGFR antibody plus anti-PD-1 antibody and chemotherapy as a neoadjuvant regimen for patients with locally-advanced penile squamous cell carcinoma: A prospective, single-arm, single-center, phase II clinical trial. *First Author: Xin An, Department of Medical Oncology, Sun Yat-sen University Cancer Center; State Key Laboratory of Oncology in South China; Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

Background: Advanced penile squamous cell carcinoma (PSCC) is a rare disease with a poor prognosis. We performed a monocentric, Simon's two-stage phase II study to evaluate the efficacy and safety of PD-1 blockade plus anti-EGFR target therapy and chemotherapy as neoadjuvant therapy in patients with locally advanced PSCC. We previously reported promising results in the first stage. The enrollment of the second stage had been completed by January 2022, herein we reported the updated results. **Methods:** Patients with chemotherapy-naive, locally-advanced PSCC (cT4 or cTxN3M0) were enrolled. The neoadjuvant regimen consists of anti–PD-1 antibody toripalimab, anti–EGFR antibody nimotuzumab, and chemotherapy (albumin-bound paclitaxel plus cisplatin and ifosfamide). Curative surgery was performed following a maximum of four cycles of treatment. The primary endpoint is the pathological complete response (pCR) rate. Secondary endpoints include overall response rate (ORR), relapse-free survival (RFS), overall survival (OS), and treatment-related adverse events (TRAEs). **Results:** A total of 29 patients were enrolled in two stages, with a median age of 57 (range 31-71) years. Till January 2022, 21 patients had completed the neoadjuvant treatment, 17 (81%) achieved an objective response, (CR 5, PR 12), 2 had SD, and 2 showed PD. Among 18 patients who underwent radical surgery, 11 showed no residual tumor on histopathology, with a pCR rate of 61.1% (11/18). The median follow-up time was 10.6 months. Two patients with PD died from disease, and 2 patients who experienced disease relapsed after radical surgery, in which 1 with SD, and 1 with PR. No relapse was observed among patients with pCR. The survival data are still immature. No unexpected toxicities and treatment-related death were recorded. Five out of 21 (23.8%) patients experienced grade 3 or 4 TRAEs. Grade 3 neutropenia occurred in 3 (14.3%) patients with 10 used G-CSF prophylaxis. No febrile neutropenia occurred. Other grades 3 toxicities included 1 case of peripheral sensory neuropathy and 1 anemia. The most common grade 1/2 TRAEs were alopecia (100%), decreased appetite (85.7%), nausea (71.4%), peripheral sensory neuropathy (66.7%), anemia (66.7%), neutropenia (33.3%), and infusion-related reactions (28.6%). The most common immune-related adverse events (IRAEs) were grade 1/2 hypothyroidism (19.0%), and grade 1 hyperthyroidism (4.8%). No severe IRAEs including pneumonitis, colitis, and myocarditis were observed. **Conclusions:** The triple combination is a provoking safe and efficacious neoadjuvant regimen for patients with advanced PSCC. Clinical trial information: NCT04475016. Research Sponsor: None.

5038 **Poster Session**

Influence of darolutamide on cabazitaxel systemic exposure. *First Author: Stefan A.J. Buck, Erasmus MC Cancer Institute, Rotterdam, Netherlands*

Background: Taxane efficacy in metastatic castration-resistant prostate cancer (mCRPC) patients is limited due to resistance development. In preclinical models it has been shown that addition of the androgen receptor signalling inhibitor (ARSI) enzalutamide improves cabazitaxel efficacy. However, we have previously shown that the clinical utility of this combination is hampered by a strong CYP3A4 drug-drug interaction with enzalutamide, resulting in a 22% reduced cabazitaxel systemic exposure. Darolutamide has much weaker CYP3A4 inducing effects and therefore may affect cabazitaxel systemic exposure to a lesser extent. **Methods:** We investigated the influence of darolutamide on cabazitaxel plasma exposure. mCRPC patients were enrolled on cabazitaxel monotherapy (20 mg/m^2 Q3W) on day 1 and received concomitant darolutamide (600 mg b.i.d.) from day 2 onwards for maximal 12 weeks. During cabazitaxel infusion on day 1, and after 6 and 12 weeks of darolutamide treatment, we measured cabazitaxel systemic exposure via Area Under the Curve from 0 to 24 hours ($AUC_{0\text{-}24h}$). **Results:** Cabazitaxel systemic exposure in 18 patients after 6 weeks of darolutamide was not significantly different compared to prior to darolutamide treatment ($AUC_{0\text{-}24h}$: -4%; 95%CI -19 – +13%; $p = 0.58$). Also, after 12 weeks of darolutamide treatment, cabazitaxel systemic exposure was unaltered ($AUC_{0\text{-}24h}$: +4%; 95%CI -10 – +20%; $p = 0.54$). Darolutamide plasma concentrations were constant throughout the study (Table). **Conclusions:** From a pharmacokinetic perspective cabazitaxel and darolutamide can be safely combined in mCRPC patients. Our findings pave the way for testing the efficacy of this promising combination in an era of combination regimens for prostate cancer. Clinical trial information: NL8611. Research Sponsor: Bayer BV.

Pharmacokinetics of cabazitaxel and darolutamide.

	Area Under the Curve (ng*h/mL)	Cycle 1 (CV%)	Cycle 2 (CV%)	Cycle 3 (CV%)	Relative difference (%) (95% CI)	*p* value
6 weeks (n=18)	Cabazitaxel $AUC_{0\text{-}24h}$	173 (26)	165 (27)		-4 (-19 – +13)	0.58
	Darolutamide $AUC_{0\text{-}12h}$		39,175 (41)			
12 weeks (n=12)	Cabazitaxel $AUC_{0\text{-}24h}$	176 (24)		183 (28)	4 (-10 – +20)	0.54
	Darolutamide $AUC_{0\text{-}12h}$		36,549 (33)	40,517 (28)	11 (-2 – +25)	0.09

Candidate surrogate endpoints in advanced prostate cancer: Aggregate meta-analysis of 143 randomized trials. *First Author: Laila A Gharzai, Northwestern University, Chicago, IL*

Background: The Intermediate Clinical Endpoints (ICEs) in Cancer of the Prostate (ICECaP) working group identified metastasis-free survival as a valid surrogate endpoint for overall survival (OS) for patients with localized prostate cancer. No comparably validated surrogate endpoints for OS exist in advanced prostate cancer. **Methods**: In this meta-analysis, PubMed was searched for trials in advanced prostate cancer, defined as node positive (N1M0), metastatic castration-sensitive (mCSPC), non-metastatic (MOCRPC), or metastatic castration-resistant prostate cancer (mCRPC). Eligible randomized trials were required to report OS and ≥1 intermediate clinical endpoint (ICE). ICEs included biochemical-failure (BF), clinical failure (CF), BF-free survival (BFS), progression-free survival (PFS), radiographic PFS (radiographic +/- other study defined endpoints). Candidacy for surrogacy was assessed using the second condition of the meta-analytic approach, correlation of the treatment effect of the ICE and OS, using R^2 weighted by the inverse variance of the log ICE hazard ratio and defined as an $R^2 > 0.70$. **Results:** A total of 143 randomized trials (n = 75,601 patients) were included. No candidate endpoints met criteria for surrogacy; R^2 BF (n = 28,922) 0.42 (95%CI 0.18-0.64), BFS (n = 25,741) 0.57 (95%CI 0.37-0.73), CF (n = 22,616) 0.31 (95%CI 0.0075-0.56), PFS (n = 52,639) 0.50 (95%CI 0.35-0.63), and radiographic PFS (n = 52,548) 0.50 (95%CI 0.35-0.63). Within preplanned subgroups by castration sensitive or resistant disease, or by treatment type, neither BFS nor PFS met criteria for surrogacy. When assessing radiographically-defined progression (exclusive or with clinical progression), PFS for the overall group and by castration status did not meet criteria for surrogacy. Sensitivity analyses demonstrated that candidacy for surrogacy of all endpoints tested did not change over time. **Conclusions:** Our aggregate screening method for surrogate endpoints in advanced prostate cancer demonstrated commonly used clinical endpoints are not valid surrogate endpoints for OS, and further composite endpoint construction is necessary. Research Sponsor: Prostate Cancer Foundation, U.S. National Institutes of Health.

5040 **Poster Session**

Safety and survival outcomes in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) treated with lutetium-177–prostate-specific membrane antigen (^{177}Lu-PSMA) after radium-223 (^{223}Ra): Interim analysis of the RALU study. *First Author: Kambiz Rahbar, Department of Nuclear Medicine, University Hospital Münster, Münster, Germany*

Background: ^{223}Ra and ^{177}Lu-PSMA both prolong overall survival (OS) in different mCRPC settings. Previous data from the observational REASSURE (Sartor O, et al. 2021) and WARMTH (Ahmadzadehfar H, et al. 2021) studies suggested the feasibility of sequencing ^{223}Ra and ^{177}Lu-PSMA therapies. Here we used data from the observational, retrospective RALU study to further examine the safety and clinical outcomes of sequential ^{223}Ra/^{177}Lu-PSMA therapy in pts with mCRPC. **Methods:** This interim analysis investigated the baseline characteristics, safety (primary endpoint) and OS (secondary endpoint) in pts who received ^{177}Lu-PSMA after ^{223}Ra using retrospective data collected in German centers. **Results:** Data from 49 pts were available for this interim analysis. At baseline, before the start of ^{177}Lu-PSMA, 73% of pts were Eastern Cooperative Oncology Group performance status (ECOG PS) 1 and 27% ECOG PS 2. Visceral metastases were present in 31% of pts. Median prostate-specific antigen (PSA) and alkaline phosphatase (ALP) were 287 ng/ml and 142 U/L, respectively (Table). 70% of pts received ≥4 life-prolonging therapies prior to ^{177}Lu-PSMA, with abiraterone acetate (80%), enzalutamide (67%) and docetaxel (92%) being the most frequently used. 74% of pts received ≥5 ^{223}Ra injections. Pts received either PSMA-617 (67%) or PSMA I&T (33%): 65% of pts received 1–4 cycles and 33% received 5–6 cycles. Median duration of ^{177}Lu-PSMA therapy was 4.9 months (m) (0–57.1). Median time from the last ^{223}Ra dose to first ^{177}Lu-PSMA dose was 9.3 m (0.9–41.9). Any grade treatment-emergent adverse events (TEAEs) from the start of ^{177}Lu-PSMA therapy to 30 days of follow-up occurred in 91.8% of pts, and serious TEAEs in 20% of pts. Grade 3-4 hematologic laboratory abnormalities up to 90 days post-^{177}Lu-PSMA occurred in 34.7% of pts for anemia, 12.8% for thrombocytopenia and 2.0% for neutropenia. No grade 5 toxicities occurred. 39% of pts had ≥30% decline in PSA during ^{177}Lu-PSMA treatment. Median OS was 12.6 m (95% CI 8.8–16.1) from the start of ^{177}Lu-PSMA therapy. **Conclusions:** In this real-world retrospective analysis of selected pts with advanced mCRPC, the ^{223}Ra/^{177}Lu-PSMA treatment sequence was clinically feasible and well tolerated. Research Sponsor: Bayer.

Alkaline phosphatase (ALP) decline and overall survival (OS) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) treated with radium-223 (Ra-223) in the REASSURE study. *First Author: Nicholas D. James, The Institute of Cancer Research, London, United Kingdom*

Background: Ra-223 extends OS in pts with mCRPC. Predictive markers of response to Ra-223 are needed to help select pts who would benefit most from Ra-223 therapy. The ALSYMPCA study suggested a correlation between ALP decline and longer OS. Here, we evaluated whether ALP decline is associated with OS in the global real-world REASSURE study. **Methods:** Pts treated with Ra-223 were grouped by baseline ALP ≤147 U/L vs >147 U/L and any ALP decline vs no decline at week 12 from the first Ra-223 dose. The 147 U/L cut-off was selected based on the highest upper limit of normal for ALP from literature. Pts with a trend of decreasing ALP at closest value to week 12 between weeks 8 and 16 were included in the any decline group. Association of ALP decline with OS was assessed in the ≤147 U/L and >147 U/L groups separately. Median OS is provided with an unadjusted hazard ratio (HR) (95% confidence interval [CI]). Multivariate Cox models provided adjusted HRs (95% CI) for the association of ALP decline with OS. Some baseline covariates were not included in the models due to missing data. **Results:** 785 of 1465 pts had baseline ALP measurements, of whom 779 had week 12 ALP measurements: 443 had ≤147 U/L and 336 >147 U/L. In the ≤147 U/L group, median OS was 23.0 months (m) (95% CI 20.9–25.7) in pts with ALP decline (n=329) and 16.4 m (95% CI 14.1–20.4) in pts with no decline (n=114). In the >147 U/L group, median OS was 12.9 m (95% CI 11.7–14.3) in pts with ALP decline (n=295) and 8.1 m (95% CI 5.6–10.3) in pts with no decline (n=41). Comparison of unadjusted and adjusted HRs is shown in the Table. **Conclusions:** Pts with an ALP decline in first 12 weeks of Ra-223 treatment had longer OS. The effect of other baseline variables, including age, PSA, Hgb and prior treatments, provided adjustment but did not change this outcome. Research Sponsor: Bayer.

Outcome of patients with PSMA PET/CT screen failure by VISION criteria and treated with 177Lu-PSMA therapy: A multicenter retrospective analysis. *First Author: Masatoshi Hotta, University of California Los Angeles, Los Angeles, CA*

Background: The VISION trial showed that 177Lu-PSMA prolongs survival and improves the quality of life of patients with advanced mCRPC. It used PSMA-PET/CT to select patients for inclusion. The screen failure rate was "only" 12.6% (126/1003) and some have argued that the trial could have been positive even in an unselected population. It remains unknown whether the VISION-PET criteria were appropriate to stratify patients into likely responders versus non-responders to177Lu-PSMA. Here, we evaluated the outcome of patients who would have been excluded by the VISION-PET criteria and were nevertheless treated with 177Lu-PSMA. **Methods:** Patients treated with ≥1 cycle of 177Lu-PSMA between 11/2017 and 07/2021 (n = 74) who were registered in our institutional database and those enrolled in a multicenter dataset published previously (n = 230) (Gafita A, Lancet Oncol 2021) were retrospectively studied. One dual certified nuclear medicine and radiology reader reviewed baseline PSMA PET/CT studies and classified the patients as eligible (VISION-PET-E) or screen failure (VISION-PET-SF) based on the VISION-PET criteria: 1) absence of metastatic lesion(s) with uptake > liver background (i.e., low PSMA expression) or 2) presence of ≥ 1 metastatic lesion measurable by CT (≥ 1 cm for bone lesions with soft-tissue component (M1b) and solid/visceral organs lesions (M1c); ≥ 2.5 cm for lymph nodes lesions (N1-M1a)) with uptake ≤ liver background (i.e., PSMA-negative lesions). Outcome measures were PSA response rates (decline of ≥50% (PSA50RR), any decline (anyPSARR)), PSA-progression free-survival (PSA-PFS), and overall survival (OS). **Results:** 3/304 patients (1%) were excluded (lost to follow-up (n = 2), missing CT data (n = 1)). The median follow-up time was 22.5 (range: 2.1-62.3) months. 272/301 (90.4%) were VISION-PET-E, while 29/301 (9.6%) were VISION-PET-SF: 8/301 (2.7%) and 21/301 (7.0%) patients with low PSMA expression and PSMA-negative lesions, respectively. The VISION-PET-SF patients had worse PSA50RR (21% vs 50%; p = 0.005), anyPSARR (41% vs 71%; p = 0.003), median PSA PFS (2.1 months (95%CI: 1.1-3.3) vs. 4.1 (4.0-5.8); p = 0.023)), and tended to have a shorter OS (9.6 months (95%CI: 4.7-14.0) vs. 14.2 (12.6-15.9); p = 0.16) than the VISION-PET-E patients. **Conclusions:** VISION-PET-SF patients had worse outcomes than the VISION-PET-E patients. Our cohort only included patients who were eligible by each local site criteria. It did not include those 10-15% of patients who were excluded by local site assessment. Thus, 20-25% of the patients may be screen failures in unselected populations. Refinements in patient selection for 177Lu-PSMA are needed to optimize outcomes. Not characterizing target expression prior to PSMA-targeted treatment appears now non-ethical as a predictive whole-body imaging biomarker for response to PSMA-targeted therapies is available. Research Sponsor: None.

PSMA PET tumor-to-salivary glands ratio (PSG score) to predict response to Lu-177 PSMA radioligand therapy: An international multicenter retrospective study. *First Author: Masatoshi Hotta, University of California Los Angeles, Los Angeles, CA*

Background: PSMA-targeted radioligand therapy can improve the outcome of patients with advanced mCRPC. However, patients do not respond uniformly and a PSA decline of ≥50% (PSA50) was achieved only in 46% of the patients in the VISION trial. We hypothesized that using the parotid glands instead of the liver as the reference organ enables more selective stratification. The aim of this study was to test PSMA PET tumor-to-Salivary Glands ratio (PSG score) to predict outcomes after Lu-177 PSMA. **Methods:** This was an international multicenter retrospective study using the established dataset consisting of 270 men with mCRPC treated with Lu-177 PSMA (Gafita A, Lancet Oncol 2021). First, we assessed baseline PSMA PET quantitatively (qPSG score) to calculate the tumor-to-salivary gland ratio (qPSG = SUVmean whole-body-tumor / SUVmean parotid glands) using a semi-automatic segmentation software (qPSMA). Patients were divided into three groups: high (qPSG > 1.5), intermediate (qPSG = 0.5 - 1.5), and low (qPSG < 0.5). Second, we assessed the reproducibility and the predictive value of the PSG score visually (vPSG score) graded by ten nuclear medicine physicians. Each reader read the baseline PSMA PET 3D maximum intensity projection (MIP) images, and classified the patients into three groups: (high) most of the lesions (> 80%) show higher uptake than parotid glands; (intermediate) neither "low" nor "high"; (low) most of the lesions (> 80%) show lower uptake than parotid glands. In case of disagreement, a majority vote was used. Outcome measures were PSA-progression free-survival (PSA-PFS), overall survival (OS), and PSA50. **Results:** 237 men were analyzed after excluding 33 men whose parotid glands were out of the scan range. The number of the patients in the high, intermediate, and low groups were 56/237 (23.6%), 163 (68.8%), and 18 (7.6%) for qPSG score, and 106/237 (44.7%), 96 (40.5%), and 35 (14.8%) for vPSG score, respectively. The inter- and intra-readers reproducibility of the vPSG score showed substantial (Fleiss' weighted Kappa: 0.68) and almost perfect (Cohen's weighted Kappa (mean): 0.83) agreement, respectively. The median PSA-PFS of high, intermediate, and low groups were 7.2, 4.0, and 1.9 months (p < 0.001) for qPSG score and 6.7, 3.8, and 1.9 months (p < 0.001) for vPSG score, respectively. Higher PSA50 rate was observed in the high group followed by the intermediate and low groups (high vs intermediate vs low: [qPSG] 69.6% vs 38.7% vs 16.7%; [vPSG] 63.2% vs 33.3% vs 16.1%). The median OS was longer in the high group than in the intermediate + low (i.e., non-high) group by qPSG (15.0 vs. 11.7 months (p = 0.013)) and vPSG score (14.3 vs.11.0 months (p = 0.038)). **Conclusions:** The PSG score is a valuable predictive biomarker for response to Lu-177 PSMA. The vPSG score yielded substantial reproducibility and comparable predictive value to the qPSG score. Research Sponsor: None.

Progression patterns by types of metastatic spread, prostate-specific antigen (PSA), and clinical symptoms: Post-hoc analyses of ARAMIS. *First Author: Alicia K. Morgans, Dana-Farber Cancer Institute, Boston, MA*

Background: Darolutamide (DARO), a highly potent and structurally distinct androgen receptor inhibitor, prolonged metastasis-free survival by nearly 2 years and reduced the risk of death by 31% vs placebo (PBO) with a favorable tolerability profile in patients (pts) with nonmetastatic castration-resistant prostate cancer (nmCRPC) in ARAMIS. We present *post-hoc* analyses of ARAMIS to evaluate the association between metastatic progression with prostate-specific antigen (PSA) and clinical progression and to describe the distribution of metastatic progression between groups. **Methods:** Pts with nmCRPC were randomized 2:1 to DARO (n=955) or PBO (n=554) while continuing androgen-deprivation therapy. Descriptive analyses were performed using the primary data cutoff (Sept 3, 2018) for the double-blind period. Post-baseline metastases were based on central review of conventional radiographic imaging every 16 weeks. PSA and pain progression were defined per primary analysis (*N Engl J Med.* 2019;380:1235-46). **Results:** Metastatic progression was observed in 13.6% of DARO and 28.5% of PBO pts. Most pts had isolated progression as bone (DARO 46%, PBO 39%) or lymph node (32%; 40%) metastasis (Table). Pts with radiographic progression had shorter median time from initial diagnosis to study treatment (DARO 72.9, PBO 74.4 months) vs the overall ARAMIS population (86.2, 84.2 months). Of all pts with metastatic progression, baseline PSA levels (ng/mL) were similar in DARO (12.6) and PBO pts (15.1); DARO pts had lower median PSA before metastasis (16.7) vs PBO pts (48.0) and median absolute/relative PSA decrease from baseline of -0.7/-3.2% vs an increase for PBO pts of 29.5/181%. PSA progression before metastasis was observed in 55.6% (160/288) of pts, occurring in fewer DARO (45.4%) vs PBO pts (63.9%) (treatment difference 18.5%; nominal 95% CI 6.5%–30.6%). The median time between PSA progression and metastasis was 7.0 months with DARO vs 5.6 months with PBO. Pain progression before metastatic progression was rare and similar between groups (DARO 16.9%, PBO 17.7%). **Conclusions:** DARO significantly reduced risk of metastatic progression and improved overall survival vs PBO without changing the pattern of metastatic progression. Many pts with nmCRPC experienced metastatic progression without PSA progression, and pain progression was rare. These results support the use of imaging with PSA monitoring to properly identify disease progression in pts with nmCRPC. Clinical trial information: TBC. Research Sponsor: Bayer AG and Orion Pharma.

Molecular correlates of high B7-H3-expressing metastatic castrate-resistant prostate cancers (mCRPC) via exome, transcriptome, and epigenome analyses. *First Author: Xiaolei Shi, University of Minnesota, Minneapolis, MN*

Background: mCRPC is a lethal condition with limited effective treatment options. B7-H3, a transmembrane protein of the B7 checkpoint superfamily is overexpressed in prostate cancer (PC) and is associated with poor prognosis. While several novel approaches target B7-H3 in prostate cancer, lack of knowledge about the molecular features and regulatory mechanisms of B7-H3 expression in mCRPC prevents the optimal design of these interventions. We aimed to characterize B7-H3 in mCRPC with the purpose to reveal the roles of B7-H3 in mCRPC pathogenesis, and stratify the patient population optimal for B7-H3–targeted therapies. **Methods:** We conducted bioinformatic interrogations at genome-scale on whole-exome and whole-transcriptome sequencing (WES, WTS) data from SU2C/PCF (n = 209, mCRPC), SUWC (n = 101, mCRPC) and GTEx (n = 246, benign prostate tissue). We developed and utilized novel machine learning (ML) algorithms to examine the association of B7-H3 with other key PC pathways. We examined the genetic and epigenetic regulation of B7-H3 by CHIP-seq. We also performed single-cell mRNA sequencing (scRNA-seq) analysis on one patient before and after treatment with the AR inhibitor, enzalutamide. We utilized both Gene Set Enrichment Analysis (GSEA) and our ML approaches to identify enriched signaling pathways in high B7-H3–expressing mCRPC. **Results:** Expression of B7-H3 was significantly elevated in mCRPC compared to benign prostate tissues, and was distinctive from other B7 family members. High B7-H3 expression was significantly associated with ERG fusions, AR-V7 variant, and increased FOXA1 and androgen receptor (AR) mRNA expression. At gene-level analysis, our ML algorithm suggested that B7-H3 shared similar gene networks as AR and its co-regulators, HOXB13, and FOXA1. CHIP-seq analysis revealed that the distal enhancers of B7-H3 in mCRPC were hyperactive (based on enhanced H3K27Ac marks) relative to primary tumors. Notably, these B7-H3 enhancers were bound by HOXB13, FOXA1 and AR in mCRPC samples. Our scRNA-seq analysis of one patient resistant to enzalutamide showed increased number of B7-H3-expressing cells. Based on integrated GSEA and ML analyses on WTS data, B7-H3 was positively associated with TGF-beta signaling, an enzalutamide resistance pathway. **Conclusions:** In mCRPC, we found B7-H3 overexpression as compared to other B7 family members. The association of B7-H3-high expression and certain genomic alterations may stratify mCRPC patients for B7-H3–targeted therapy. Further, B7-H3 exhibited regulation by AR, HOXB13 and FOXA1, at the B7-H3 enhancers. The activating epigenetic modification at the distal enhancers represents another potential marker to examine B7-H3 expression in tumors. Altogether, our study indicates that B7-H3 is a critical target in mCRPC patients, including those resistant to enzalutamide. Research Sponsor: U.S. National Institutes of Health.

Predictors of overall survival among Black South African men treated with androgen-deprivation therapy for metastatic prostate cancer. *First Author: Yoanna S Pumpalova, Columbia University Irving Medical Center, New York, NY*

Background: Men in sub-Saharan Africa (SSA) are disproportionately affected by prostate cancer (PCa), and many have metastatic disease (mPCA) at presentation. In SSA, androgen deprivation therapy (ADT) is the first-line treatment for mPCa, and often the only available therapy. Treatment failure and death is common. We identified predictors of overall survival (OS) in Black South African (SA) men with mPCa on ADT. **Methods:** We performed a retrospective analysis of prospectively gathered data from men diagnosed with mPCA (3/22/2016 - 10/30/2020) at Chris Hani Baragwanath Hospital in Johannesburg, which was also a study site for the concurrent Men of African Descent and Carcinoma of the Prostate study. We included men with mPCA treated with ADT (received at least 1 dose of luteinizing hormone-releasing hormone agonist and/or had surgical castration), who had ≥1 PSA level drawn ≥12 weeks after ADT start. OS was defined from ADT start to death. PSA progression (PSA-P) definition was adapted from PCWG 3. Cox regression models were used to identify predictors of OS. PSA-P was treated as a time-dependent covariate. **Results:** Of 200 men with mPCa, we excluded 6 who did not receive ADT and 41 without sufficient data for PSA-P analysis. Of 153 men, 26.8% were <65 years old and 12% had a family history of PCa. Median PSA at diagnosis was 71.5 ng/mL (interquartile range (IQR) 20.7-432.6), median alkaline phosphatase level (ALP) 108 IU/L (79-224) and median hemoglobin (Hb) 13 g/dL (IQR 10-15). Median PSA nadir was 2.8 ng/mL (IQR 0.55-17.93). The rate of PSA-P at 1- and 2-years was 12.1% [95%CI 5.9-17.8] and 37.5% [95%CI 26.1-47.2]. The median follow-up was 2.75 years, and the 3-year OS was 61.9% [95%CI 52.7-72.6]. Cox proportional hazard ratio (HR) models of risk factors for OS are shown in Table 1. PSA-P was a strong predictor of OS. Men with PSA nadir >4ng/mL after ADT start had a HR for death of 3.77 [1.86-7.62]. Men with ALP >150 IU/L and those with Hb <13.5g/dL at diagnosis were also at higher risk for death (HR 3.09 [1.64-5.83] and HR 2.00 [1.28-6.56] respectively). **Conclusions:** Among Black men in SA treated with ADT for mPCA, PSA-P strongly predicts OS. In this cohort, high ALP and anemia at diagnosis, and PSA nadir >4ng/mL after ADT start are associated with higher risk for death. These factors can be used identify high risk men with mPCA, for whom early treatment escalation to chemotherapy should be considered. Research Sponsor: U.S. National Institutes of Health, Conquer Cancer Foundation of the American Society of Clinical Oncology, U01-CA184374, P30 CA13696.

Tolerability of [^{177}Lu]Lu-PSMA-617 by treatment exposure in patients with metastatic castration-resistant prostate cancer (mCRPC): A VISION study subgroup analysis. *First Author: Scott T. Tagawa, Weill Cornell Medicine, New York, NY*

Background: In the phase 3 VISION study, lutetium (^{177}Lu) vipivotide tetraxetan ([^{177}Lu]Lu-PSMA-617; ^{177}Lu-PSMA-617) + protocol-permitted standard of care (SoC) improved clinical benefit and was generally well tolerated despite a higher rate of adverse events (AEs) than SoC alone. Here we assess AE incidence by exposure to ^{177}Lu-PSMA-617. **Methods:** VISION was an international, open-label study of ^{177}Lu-PSMA-617 in adults with PSMA-positive mCRPC previously treated with ≥ 1 androgen receptor pathway inhibitor and 1–2 taxane regimens. Patients received ^{177}Lu-PSMA-617 (7.4 GBq every 6 weeks, ≤ 6 cycles) + SoC or SoC alone. rPFS and OS were primary endpoints; safety was a secondary endpoint. AE analysis by exposure to ^{177}Lu-PSMA-617 was carried out in pre-specified subgroups. ^{177}Lu-PSMA-617 cycle duration was generally ~6 weeks and cycle 6 duration was until the earliest date of subsequent treatment, and date of last administration of randomized treatment (including SoC) + 30 days. The cycle of onset in which an AE first occurred in a patient at maximum grade was assessed. **Results:** The median duration of cycle of onset for cycles 1 to 5 was 6 weeks; for cycle 6, it was 26.6 weeks (Table). Of the 529 patients in the ^{177}Lu-PSMA-617 group, 240 (45.4%) received ≤ 4 cycles and 289 (54.6%) received 5–6 cycles of treatment. In patients who received ≤ 4 or 5–6 cycles, 234 (97.5%) and 285 (98.6%) treatment-emergent AEs (TEAEs); 100 (41.7%) and 92 (31.8%) serious TEAEs; 205 (85.4%) and 246 (85.1%) treatment-related AEs; and 13 (5.4%) and 6 (2.1%) fatal TEAEs, respectively, were observed. Number of TEAEs and serious TEAEs by cycle of onset are shown in the Table. **Conclusions:** Over 50% of patients with mCRPC received 5–6 cycles of ^{177}Lu-PSMA-617. For cycles 1–5, TEAEs occurred at every cycle, with similar frequency. More TEAEs were observed in cycle 6, reflecting its longer median duration than other cycles. Clinical trial information: NCT03511664. Research Sponsor: Advanced Accelerator Applications, a Novartis Company.

A phase 1/2 multicenter investigator-initiated trial of DKN-01 as monotherapy or in combination with docetaxel for the treatment of metastatic castration-resistant prostate cancer (mCRPC). *First Author: David R Wise, Laura & Isaac Perlmutter Cancer Center at NYU Langone Health, New York, NY*

Background: Dickkopf-1 (DKK1) is a secreted Wnt signaling modulator that is upregulated in prostate cancers with low androgen receptor (AR) expression and co-occurring mutations in Wnt signaling family genes. DKN-01, a potent humanized monoclonal antibody (IgG4) with neutralizing activity against DKK1, delays prostate cancer growth in pre-clinical DKK1-expressing models in an NK cell dependent manner. These data provided the rationale for a prospective clinical trial testing DKN-01 in patients with mCRPC and elevated DKK1. Here, we report the safety and efficacy results of the phase 1 dose escalation cohorts. **Methods:** This is an investigator-initiated parallel-arm non-randomized phase 1/2 clinical trial testing DKN-01 alone or in combination with docetaxel 75 mg/m^2 for men with mCRPC who progressed on ≥1 AR signaling inhibitor. Eligible patients who had progressed on or were intolerant of docetaxel were assigned to the monotherapy cohort whereas taxane-naïve patients were assigned to the DKN-01 plus docetaxel combination cohort. DKK1 status was determined by RNA in-situ expression. The primary endpoint of the phase 1 dose escalation cohorts was safety, characterized by dose-limiting toxicity (DLT). A secondary endpoint of the study was to correlate anti-tumor activity, DKK1 expression (cutoff H-score ≥ 1), and clinical evidence of aggressive variant prostate cancer (AVPC). **Results:** 13 pts were enrolled in the completed phase 1 portion of this study – 7 patients in the monotherapy cohort and 6 patients in the combination cohort. No DLTs were observed at DKN-01 300mg or 600mg dose levels as monotherapy or in combination with docetaxel. No treatment-related serious adverse events occurred in either cohort. A best overall response of stable disease occurred in 2 out of 7 patients in the monotherapy cohort. In the combination cohort, all 5 evaluable patients had a partial response (PR) – 3 confirmed and 2 unconfirmed. All evaluable combination patients had ≥ 50% reduction in either PSA or CEA. Confirmed PRs in the combination cohort were observed in both DKK1 low (DKK1 H-score < 1) and high expressing tumors (H-score ≥1), including in 2 out of 3 patients with AVPC. **Conclusions:** DKN-01 600mg was well tolerated and selected as the recommended phase 2 dose as monotherapy and in combination with docetaxel. DKN-01 in combination with docetaxel showed promising clinical activity in prostate cancers regardless of DKK1 expression and was particularly promising in patients with AVPC. Further accrual into the phase 2 portion of this study is ongoing alongside preclinical and correlative studies aiming to investigate the mechanism of action of this combination therapeutic strategy. Clinical trial information: NCT03837353. Research Sponsor: Leap Therapeutics, Other Foundation.

Final analysis of the phase 1b/2 study of sabizabulin in men with metastatic castration-resistant prostate cancer who progressed on an androgen receptor targeting agent. *First Author: Mark Christopher Markowski, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: Sabizabulin is a novel oral cytoskeleton disruptor being developed for use in metastatic castration resistant prostate cancer (mCRPC). A Phase 1b/2 clinical study was conducted to establish the maximum tolerated dose (MTD) and evaluate the preliminary efficacy in men with mCRPC resistant to androgen receptor targeting agents. **Methods:** The Phase 1b portion of the study in 39 men utilized escalating and expanding dose and duration. The Phase 2 portion studied 41 men with mCRPC at the recommended Phase 2 dose of 63 mg daily. Efficacy was assessed by bone/CT scans. A final analysis of the safety and efficacy data including the primary endpoint, the median progression-free survival was conducted. **Results:** Although the MTD was not reached in the Phase 1b, the recommended Phase 2 dose was set at 63 mg/day to maximize GI tolerability. The most common adverse events (> 10% frequency) at the 63 mg oral daily dosing (combined Phase 1b/2 data) were predominantly Grade 1-2. Grade ≥3 events included diarrhea (7.4%), fatigue (5.6%) and ALT/AST elevations (5.6% and 3.7%, respectively). Neurotoxicity and neutropenia were not observed. Preliminary efficacy data in patients treated with ≥1 continuous cycle (21 days) of 63 mg or higher (n = 55) included an objective response rate of 6/29 (20.7%) in patients with measurable disease (1 complete, 5 partial). 14/48 (29.2%) of the patients had PSA declines. The Kaplan-Meier median radiographic progression-free survival was estimated to be 11.4 months (95% C.I. 29.63-65.79) (n = 55). Durable responses lasting > 2.75 years were observed with 14.5% (8/55) demonstrating a response greater than 12 months. **Conclusions:** This clinical trial demonstrated that chronic oral daily dosing of sabizabulin has a favorable safety profile with significant preliminary cytotoxic and cytostatic antitumor activity. These data support the ongoing Phase 3 VERACITY trial of sabizabulin in men with mCRPC who have progressed on an androgen receptor targeting agent. Clinical trial information: NCT03752099. Olaparib plus abiraterone as first-line therapy in men with metastatic castration-resistant prostate cancer: Pharmacokinetics data from the PROpel trial. *First Author: Andrew J. Armstrong, Duke University Medical Center, Durham, NC*

Background: PROpel (NCT03732820) is a double-blind, Phase III trial of abiraterone + olaparib vs abiraterone + placebo as first-line treatment in patients with metastatic castration-resistant prostate cancer (mCRPC). Here we report results from the pharmacokinetics (PK) analysis of patients in PROpel. **Methods:** Patients were randomized 1:1 to receive abiraterone (1000 mg qd) plus prednisone/prednisolone with either olaparib (full monotherapy dose: 300 mg bid) or placebo. Eligible patients were biomarker unselected with confirmed prostate adenocarcinoma and castration-resistant metastatic disease. They had not received prior chemotherapy or next-generation hormonal agents (NHAs) for mCRPC. PK sampling was performed in a subset of patients. Concentrations of olaparib and abiraterone, and its active metabolite Δ4-abiraterone, were measured at steady state predose, at 30 min, 2 h, 3 h, 5 h, and 8 h postdose. The data underwent noncompartmental analysis to evaluate the effect of olaparib on abiraterone PK. The PK of olaparib in the presence of abiraterone was also compared with olaparib PK from other monotherapy studies to evaluate the effect of abiraterone on olaparib PK. **Results:** The PK analysis included 66 patients from the olaparib + abiraterone arm and 58 patients from the placebo + abiraterone arm. Olaparib absorption was rapid, with median $t_{max,ss}$ of 2 h. Absorption of abiraterone was rapid in both treatment groups, with median $t_{max,ss}$ observed between 2.00 and 2.04 h. The steady state exposure of olaparib in the presence of abiraterone, based on AUC_{ss}, $C_{max,ss}$ and $C_{min,ss}$, was similar to observations for patients receiving olaparib 300 mg bid monotherapy in other Phase III studies, with values of 39.3 μg·h/mL, 6.3 μg/mL, and 1.0 μg/mL, respectively. Steady state exposures for abiraterone were similar between the two treatment arms (abiraterone + placebo: $AUC_{(0\text{-}8)}$ = 339.5 ng·h/mL, $C_{max,ss}$ = 105.4 ng/mL, $C_{min,ss}$ = 8.5 ng/mL; abiraterone + olaparib: $AUC_{(0\text{-}8)}$ = 393.7 ng·h/mL, $C_{max,ss}$ = 112.6 ng/mL, $C_{min,ss}$ = 7.7 ng/mL), and PK data for the abiraterone + olaparib arm were similar to those reported in the literature for abiraterone monotherapy. **Conclusions:** Combination treatment of olaparib (full monotherapy dose: 300 mg bid) and abiraterone (1000 mg qd) in patients with mCRPC had no clinically significant effect on the PK profiles of either drug. The steady state exposures for abiraterone were similar between the two treatment arms, indicating that co-administration with olaparib 300 mg bid has no effect on the PK of abiraterone. In line with previous Phase II trial data, results from PROpel confirmed that there were no relevant PK based drugdrug-interactions between olaparib and abiraterone. Clinical trial information: NCT03732820. Research Sponsor: AstraZeneca as part of an alliance between AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ.

On-treatment plasma ctDNA fraction and treatment outcomes in metastatic castration-resistant prostate cancer. *First Author: Sofie H. Tolmeijer, Department of Medical Oncology, Radboud Institute of Molecular Sciences, Radboud University Medical Center, Nijmegen, Netherlands*

Background: Androgen receptor pathway inhibitors (ARPI) are standard of care for treatment-naive metastatic castration-resistant prostate cancer (mCRPC), but primary or rapidly acquired resistance is common. Early identification of resistant disease is critical for improving management strategies. We investigated whether on-treatment changes in plasma ctDNA fraction (ctDNA%; the proportion of cell-free DNA that is tumor-derived) associate with ARPI treatment outcomes. **Methods:** We collected serial plasma cell-free DNA from 81 patients with mCRPC: at baseline and following 4 weeks of treatment during two prospective multi-center observational studies (NCT02426333; NCT02471469). CtDNA% was calculated by integrating deep targeted and shallow whole-genome sequencing. Samples were dichotomized at above and below 1%, and designated as high or low ctDNA%, respectively. Outcome measurements were radiographic and/or clinical progression-free survival (rcPFS) and overall survival (OS). Non-durable responses were defined as rcPFS < 6 months, excluding patients with PSA progression alone (n = 3) or treatment cessation for toxicity (n = 4). **Results:** Median follow-up was 27.4 months (IQR 17.7-34.9). CtDNA% was high in 47/81 (58%) patients at baseline and 29/81 (36%) patients at 4 weeks. The median ctDNA% for patients with high ctDNA was 15.0% (IQR 4.9-43.8%) at baseline and 5.0% (IQR 2.0-20.6%) at 4 weeks. High baseline ctDNA% was prognostic for rcPFS and OS (Table). RcPFS and OS was shortest for patients that retained high ctDNA% at 4 weeks. However, patients converting from high to low ctDNA% at 4 weeks did not experience different outcomes to patients with low ctDNA at both timepoints. ctDNA% associations with rcPFS and OS were independent of established clinical prognostic factors. 23/27 (85%) patients experiencing non-durable responses had high ctDNA% at baseline and 4 weeks. Only 3/47 patients (6%) experiencing durable responses had high ctDNA% at both timepoints. Sensitivity and specificity for predicting non-durable response was 85% and 94%, respectively. **Conclusions:** Early changes in ctDNA% are strongly linked to duration of first-line ARPI treatment benefit in mCRPC and may have utility for informing clinical trials testing early therapy switches in patients unlikely to experience durable disease responses. Clinical trial information: NCT02426333; NCT02471469. Phase I/II study of the selective PI3Kβ inhibitor GSK2636771 in combination with pembrolizumab in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) and PTEN loss. *First Author: Ecaterina Elena Dumbrava, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PTEN loss activates the PI3K/AKT signaling pathway, contributes to an immunosuppressive tumor microenvironment, resistance to androgen deprivation therapy and poor clinical outcome in pts with mCRPC. Treatment with anti-PD1 antibodies improves survival in many cancers, but efforts to harness its benefit in mCRPC have been unsuccessful. In preclinical PTEN loss models, selective PI3Kβ inhibitor enhanced survival and the frequency of intratumoral T cells. We hypothesized that the combination of PI3Kβ inhibitor and anti-PD-1 antibody is safe and promotes antitumor activity. To test this, we conducted a phase I/II study (NCT01458067) of PI3Kβ inh GSK2636771 and pembrolizumab in pts with solid tumors (including melanoma and mCRPC) with PTEN loss. We report the results from a cohort of pts with mCRPC and PTEN loss. **Methods:** The phase I primary objective was to determine the safety, tolerability, and recommended phase II dose (RP2D) of GSK2636771 + pembrolizumab using a 3+3 design. Pembrolizumab was given at 200 mg IV Q3W and dose escalation started at 300mg orally daily of GSK2636771 for 21 days cycle. The phase II primary objective was to evaluate the efficacy of the combination using RECIST 1.1. Secondary objectives were to evaluate PK and PD effects in tumor and blood. Tumoral PTEN loss was defined by loss of protein expression by IHC or by presence of an inactivating mutation identified by next-generation sequencing (NGS). **Results:** A total of 12 pts with mCRPC and PTEN loss were enrolled (2 pts in the dose escalation and 10 pts in the dose expansion cohorts). Median age was 67 years (range 55-80) and pts had a median of 4 lines of prior therapies with 83% of pts receiving prior taxane-based chemotherapy. The RP2D was identified at 200mg PO QD of GSK2636771 + pembrolizumab 200mg IV Q3W. Most treatment-related adverse events were grade (G) 1-2 with the most common being diarrhea (33%) and rash (42%). A total of 4 pts had G3 rash, including 2 pts with G3 immune-related bullous pemphigoid. Dose-limiting toxicities in pts with mCRPC included G3 hypophosphatemia and G3 rash. Treatment was discontinued because of G3 toxicity in 1 pt and 42% of pts required a dose reduction of GSK2636771. Among 11 evaluable pts at 200mg daily of GSK2636771, partial response (PR) was achieved in 2 pts (-56% and -59% as compared to baseline, per RECIST1.1), which was associated with ongoing progression free survival (PFS) > 12 months (24.1 and 13.6 months, respectively) and PSA > 50% reduction as compared to baseline. In addition, a pt with tumor reduction of 18% per RECIST1.1 has remained on treatment for 15.8 months. **Conclusions:** GSK2636771 plus pembrolizumab had an acceptable safety and tolerability profile. The combination showed promising preliminary antitumor activity and durable responses in a heavily pretreated population of pts with mCRPC. Clinical trial information: NCT01458067. Research Sponsor: Merck, GSK, Melanoma SPORE.

Characterization and impact of canonical Wnt Signaling Pathway (WSP) alterations on outcomes of metastatic prostate cancer. *First Author: Rana R. McKay, University of California San Diego Health, La Jolla, CA*

Background: Recurrent alterations in the WSP have been identified in patients with advanced prostate cancer. Aberrant Wnt signaling has been implicated in disease progression and hormonal resistance in prostate cancer. We utilized a multi-institutional real-world dataset to characterize molecular alterations in the canonical WSP in men with prostate cancer, and correlate that with overall survival (OS). **Methods:** Prostate cancer patients who underwent tissue-based DNA and RNA sequencing utilizing a commercially available CLIA-certified assay (Caris Life Sciences) were investigated. Next generation sequencing (NGS)/ whole exome (WES) and transcriptome sequencing (WTS) was performed on prostate cancer tissue derived from prostatic and/or metastatic sites. Patients with somatic activating mutations in *CTNNB*, pathogenic fusions in *RSPO2*, or inactivating mutations in *APC* or *RNF43* were characterized as having aberrant canonical Wnt signaling (WSP-MT). A subset analysis was conducted in metastatic prostate cancer (mPCa) samples with microsatellite stable (MSS) tumors excluding RNF43 (G569fs*) mutations. Comparative analyses were done using Fisher-Exact or X^2 tests, and significance was determined by adjusted p value using Benjamini-Hochberg correction (q < 0.05). OS was obtained from insurance claims data and calculated using Kaplan-Meier estimates. Enriched mRNA transcripts were identified as those with an adjusted p value < 0.001, logFC > 1.5, and (-)log10 FDR > 20. **Results:** Overall, 21.8% (n = 715/3283) of samples were classified as WSP-MT, of which 297 (41.5%) were from primary tumor samples and 418 (58.5%) were from metastatic sites. WSP-MT were highest in metastases to CNS (54.5%, n = 12/22), liver (43.8%, n = 91/208) and lung (42.3%, n = 91/208). Compared to WSP wild-type, WSP-MT tumors had a greater frequency of dMMR/MSI-H status (18% vs. 2%, q < 0.001). In the subset of mPCa, MSS tumors (WSP-MT excluding RNF43 (G569fs*) mutations, n = 318; WSP wild-type n = 951), WSP-MT were enriched for mutations in SPOP (14.3% vs. 6.9%, q = 0.004). In these tumors, WSP-MT samples were most enriched for mRNA expression of CST1, NKD1, AXIN2, and ZNRF3 (all known canonical WSP activators). OS was inferior in mPCa WSP-MT patients compared to WSP wild-type (HR 0.49, 95% CI 0.37-0.64, p < 0.0001). Relative to WSP wild-type cases, OS was shorter from time of enzalutamide/abiraterone/apalutamide start (HR 0.25, 95% CI 0.15-0.43, p = 0.0001), and from first-line taxane chemotherapy (HR 0.47, 95% CI 0.21-1.02, p = 0.052) in pts with WSP-MT. **Conclusions:** Canonical WSP alterations are enriched in metastatic tumors, with highest prevalence in visceral (CNS, liver, lung) metastases. Clinical outcomes in WSP-mutant cancers are inferior with both hormonal and chemotherapies, heralding an urgent need to develop novel therapeutic strategies for such patients. Research Sponsor: None.

Biallelic loss of TP53, PTEN, and RB1 in association to aggressive clinical features and poor outcomes in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Corinne Maurice-Dror, BC Cancer, Vancouver, BC, Canada*

Background: Deleterious alterations in tumor suppressor genes (TSGs) *TP53, RB1*, and *PTEN* are potential markers of small cell neuroendocrine prostate cancer (SCNP), and androgen receptor pathway inhibitor (ARPI) resistance. We examined the outcomes and clinical features of mCRPC patients (pts) harboring biallelic loss in 0, 1, 2 or all 3 TSGs. **Methods:** We identified 210 consecutive mCRPC pts providing ≥1 plasma cell-free DNA sample with ≥20% circulating tumor DNA fraction (ctDNA%) during their mCRPC disease course. ctDNA% ≥20% enabled sensitive characterization of biallelic TSG loss (including by homozygous deletions and mutation plus somatic loss-of-heterozygosity; LOH). Patient records were reviewed for baseline characteristics, SCNP histology, and presence of liver metastases. We investigated associations between TSG loss and the following clinical outcomes: PSA response (PSA decline ≥50% (PSA50 RR)), progression free survival (PFS) on 1L therapy, and overall survival (OS) from 1L therapy. **Results:** Median follow-up was 16.5 months (range: 0.4-112.4) and OS event rate was 95%. Median age at 1L mCRPC was 71 years (range: 48-98). Most pts were ECOG PS 0-1 (79%) and 13% had liver metastases. 91% received ARPI for 1L mCRPC and 7% received ARPI for castration-sensitive disease. *TP53* was primarily inactivated by somatic mutation plus LOH (90%), whereas *RB1* (71%) and *PTEN* (86%) were more commonly inactivated by homozygous deletions. Compared to pts without evidence of biallelic TSG loss, pts with loss of 3 TSGs were significantly enriched for *de-novo* M1 disease (86 vs. 60%, p=0.05) and liver metastases (28.5 vs. 6.8%, p<0.05). Ten pts (4.7%) had histologically confirmed SCNP and provided ctDNA at time of SCNP diagnosis. Of these, 7 (70%) had biallelic loss of ≥2 TSGs. For all pts receiving 1L therapy, loss of ≥1 TSG(s) was associated with decreased OS (HR: 1.86, 95% CI: 1.40-2.48, p<0.01) and PFS (HR:1.74, 95% CI 1.29-2.34, p<0.01) compared to pts with no biallelic TSG loss. Furthermore, a cumulative increase in the number of TSGs lost was associated with an incremental reduction in OS and PFS (Table). **Conclusions:** In a cohort enriched for poor prognosis (i.e. high ctDNA%), cumulative loss of TSGs is associated with aggressive disease features and poor clinical outcomes. These patients may benefit from alternative treatment intensification strategies. Research Sponsor: BC Cancer Foundation, Prostate Cancer Foundation.

Activation of the AKT pathway and outcomes in patients (pts) treated with or without ipatasertib (ipat) in metastatic castration-resistant prostate cancer (mCRPC): Next-generation sequencing (NGS) data from the phase III IPATential150 trial. *First Author: Christopher Sweeney, Dana-Farber Cancer Institute, Boston, MA*

Background: Ipat + abiraterone (abi) significantly reduced the risk of radiographic disease progression vs placebo (pbo) + abi in pts with mCRPC and PTEN loss tumors by immunohistochemistry (IHC; HR, 0.77; 95% CI: 0.61, 0.98; P=0.034) but not in ITT pts (HR, 0.84; 95% CI: 0.71, 0.99; P=0.043; Sweeney Lancet 2021). A greater risk reduction was seen in pts with *PTEN* loss by NGS (HR, 0.65; 95% CI: 0.45, 0.95). We describe the efficacy and safety of pbo + abi vs ipat + abi at the second interim analysis (IA) of overall survival (OS) and explore the impact of AKT pathway alterations. **Methods:** Pts with mCRPC were randomized 1:1 to ipat (400 mg/d) + abi (1000 mg/d) + prednisone (5 mg bid) or pbo + abi + prednisone. Coprimary endpoints were investigator-assessed radiographic progression-free survival by Prostate Cancer Working Group 3 (PCWG3) criteria in pts with PTEN loss tumors by IHC (PTEN loss in ≥50% of tumor cells) and in ITT pts. Secondary endpoints in both populations included OS, objective response rate (ORR) per RECIST 1.1 and PCWG3 and time to pain progression (TPP). Ad hoc analyses assessed pts with *PIK3CA*/*AKT1*/*PTEN* alterations by NGS vs wildtype (WT). **Results:** Median follow-up was 31 mo (cutoff: 2021 Sept 30). In PTEN loss by IHC pts, median OS was 35.8 mo (n=261) with pbo + abi and 36.8 mo (n=260) with ipat + abi (HR: 0.95; 95% CI: 0.74, 1.21; P=0.665); in ITT pts, median OS was 36.7 mo (n=554) with pbo + abi and 40.3 mo (n=547) with ipat + abi (HR: 0.90; 95% CI: 0.76, 1.07). With longer follow-up, the safety profile was consistent with that of the primary analysis. In the full NGS evaluable population (n=743), ipat + abi was associated with better outcomes in pts with *PIK3CA*/*AKT1*/*PTEN* alterations (Table). Among pts with *PTEN* loss tumors by NGS (205 of the evaluable 518 pts), median OS was 29.8 mo (n=102) with pbo + abi and 35.8 mo (n=103) with ipat + abi (unstratified HR: 0.82; 95% CI: 0.56, 1.19). **Conclusions:** At the second IA, no significant improvement in OS was observed with ipat + abi in pts with PTEN loss by IHC. Exploratory analyses in pts with *PIK3CA*/*AKT1*/*PTEN* alterations by NGS suggest that these patients have poorer prognosis but may derive greater benefit from ipat + abi. Clinical trial information: NCT03072238. Research Sponsor: F. Hoffmann La-Roche Ltd.

Impact of activating androgen receptor (AR) mutations on AR sensitivity to alternative ligands and response to ODM-208, a selective, first-in-class CYP11A1 inhibitor, in patients with advanced metastatic castration-resistant prostate cancer (mCRPC). *First Author: Alice Bernard-Tessier, Institut Gustave Roussy, Villejuif, France*

Background: Activating AR mutations ensure a continued AR activation by non-androgen steroid ligands, e.g. progesterone and glucocorticoids. CYP11A1 is the only enzyme that catalyzes the conversion of cholesterol to pregnenolone, from which all steroid hormones (glucocorticoids, mineralocorticoids, and sex steroids) are subsequently derived. ODM-208, an oral, selective inhibitor of CYP11A1, is being evaluated for safety and efficacy as a treatment of mCRPC in the ongoing CYPIDES phase I/II trial in men previously treated with both novel hormonal therapies and taxanes (ClinicalTrials.gov identifier: NCT03436485). Preliminary phase 1 results were previously reported (Fizazi K et al., ASCO GU 2022). Here we confirm that the in-vitro sensitivity of common AR mutations to ODM-208 treatment is mirrored in patient response in CYPIDES phase 1. **Methods:** ODM-208 was administered at daily doses between 6-150 mg (phase 2 dose: 10 mg) with dexamethasone and fludrocortisone, resulting in maximal suppression in all measured steroids at all doses. AR ligand-binding domain (LBD) mutations (L702H, V716M, W742L, W742C, H875Y, F877L, T878A, T878S, M896T, M896V) were assessed using a BEAMing assay (Sysmex Inostics) from plasma circulating cell-free DNA (cfDNA) collected before the first dose of ODM-208. The activation of wild-type (wt) and LBD mutated AR with various ligands was also studied in vitro using a luciferase reporter assay in AR negative PC3 cells. **Results:** 17 of 44 patients had at least one AR activating mutation, the most frequent being L702H (n = 11), T878A (n = 10), and H875Y (n = 6). Eleven out of the 16 evaluable patients (68%) with an AR LBD mutation achieved ≥50% reduction in serum PSA compared with 2 out of the 24 evaluable patients (8%) without an AR LBD mutation (P < .0001). The in vitro sensitivity of each of these common AR mutations to a variety of non-androgenic steroids will be presented, along with detailed PSA responses, duration of responses, and safety in mCRPC patients bearing the same mutations. **Conclusions:** AR activating mutations may permit continued hormone dependence in mCRPC, related to actions of non-androgenic steroid hormones. Treatment with ODM-208 blocked all steroid hormone production and resulted in frequent ≥50% PSA reductions in this group of heavily pretreated mCRPC pts with various AR LBD mutations, some being long-lasting. cfDNA AR mutations are a promising predictive biomarker for ODM-208 efficacy. Dexamethasone did not activate mutated ARs, supporting its selection for glucocorticoid replacement therapy in combination with ODM-208. Clinical trial information: NCT03436485. Transcriptional profiling of matched biopsies reveals molecular determinants of enzalutamide resistance. *First Author: Thomas Westbrook, University of Michigan, Ann Arbor, MI*

Background: Castration-resistant prostate cancer (CRPC) is the lethal form of the disease. One of the principal therapies in CRPC is the potent androgen receptor (AR) signaling inhibitor enzalutamide (enza). Most patients benefit from enza, but disease progression is nearly universal. A variety of resistance mechanisms have been described by comparing enza-naïve and enza-resistant tumors. However, these results are largely from different groups of patients and do not provide information on the changes induced by enza within a given patient. Lineage plasticity—most commonly-exemplified by loss of AR signaling and switch from a luminal to an alternate differentiation program—is a particularly aggressive resistance mechanism. Importantly, lineage plasticity appears to be increasing in incidence since more widespread use of potent AR signaling inhibitors such as enza. To improve our understanding of resistance mechanisms induced by enza treatment, we analyzed the transcriptomes of matched metastatic CRPC patient biopsies obtained prior to treatment and at the time of disease progression. **Methods:** All biopsies were obtained as part of the Stand Up 2 Cancer/Prostate Cancer Foundation-funded West Coast Dream Team, a prospective, IRB-approved protocol focused on understanding the biology of metastatic CRPC. We identified 21 patients for whom matched tumor biopsies with RNA-seq were available prior to starting treatment with enza and at the time of progression while still taking enza. **Results:** Our RNA-seq analysis demonstrates that the majority of progression tumors cluster with their baseline pair, suggesting that enza does not markedly change the tumor transcriptome in most cases. Three of 21 patients showed evidence of lineage plasticity at progression by gene expression analysis. By analyzing the RNA-seq data, we identified pathways linked to stemness that were more activated in baseline tumors from patients whose progression tumors underwent lineage plasticity. Furthermore, we identified a gene signature enriched in these baseline tumors that was associated with risk of lineage plasticity after enza treatment. We determined that high expression of this signature was strongly associated with poor survival from the time of AR signaling inhibitor treatment in independent patient samples, suggesting this signature is linked to poor patient outcome. **Conclusions:** Enza-resistant tumors are heterogeneous. Most tumors do not undergo significant transcriptional changes at progression vs. baseline. Matching recent reports, approximately 15% of tumors underwent lineage plasticity upon progression. Our work implicates a gene program that may predispose tumors to enza-induced lineage plasticity. Finally, the gene signature we identified may be a marker of lineage plasticity risk and tumor aggressiveness in CRPC prior to the initiation of AR signaling inhibitor therapy. DynAMo: A dynamic allocation modular sequential trial of approved and promising therapies in men with metastatic CRPC. *First Author: Paul Vincent Viscuse, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Response to androgen signaling inhibitors is highly variable and dictates prognosis in castration resistant prostate cancer (CRPC). The development of effective combinations for CRPC has been hampered by the absence of biomarkers to identify its distinct biological subsets, obligating the homogeneous application of therapies to a heterogeneous disease in clinical trials. We previously defined the *aggressive variant prostate cancers* as a framework for the study of those with poor responses to androgen signaling inhibitors (dubbed 'androgen indifferent') and observed improved outcomes in this subset when carboplatin was added to cabazitaxel (CABCARB). In contrast, results of prospective trials suggested that anti-CTLA-4 therapy may benefit patients with androgen responsive disease. We hypothesized that said combinations applied to subsets defined by early marker declines to androgen ablation would improve overall survival (OS) over historical data in unselected CRPC. **Methods:** In an open-label, phase II trial (NCT02703623), men with mCRPC received abiraterone and apalutamide (ABIpAPA; *Mod 1*). At week 8, patients had either a 'satisfactory' (S) decline in PSA (≥ 50% from baseline) and CTC (≤5/7.5mL) or 'unsatisfactory' (US). S patients (*Mod 2)* were randomized to continue ABIpAPA alone (*2A*) or with up to 4 cycles of ipilimumab (IPI, *2B*). US patients (*Mod 3)* continued ABIpAPA with up to 10 cycles of CABCARB. Thereafter patients continued ABIpAPA until progression. OS was calculated from entry into *Mod 2* or *3*. Based on historical data, the estimated median OS for men in *Mod 2* and *Mod 3* were 36 and 16 months respectively. **Results:** 195 men with CRPC were enrolled between May 2016 and August 2019. 128 (67%) were allocated to S of which 64 each were randomized to receive IPI vs. not. 3 went off study during *Mod 1* without clinical decline. Of 64 patients allocated to US, 59 were treated with CABCARB on study. Men in US were more likely to have had *de novo* metastasis (33% vs 59%, p < 0.001), RECIST measurable disease (23% vs 42%, p = 0.01), and liver metastases (3% vs 13%, p = 0.01). Differences in baseline circulating markers between the groups are shown in Table 1. Serious adverse events were reported for 3 (4.7%), 21 (33%), and 6 (10.2%) patients for M*od 2A, 2B,* and *3* respectively. One death due to neutropenic sepsis occurred in *Mod 3*. At a median follow-up of 48 months, the median (95% CI) OS in *Mod2A* was 44.3 (38.1, 47.7) months, 41.4 (33.3 months, not reached) in *Mod 2B*, and 18.7 (14.3, 36.3) months in *Mod 3*. **Conclusions:** These data substantiate the impact of underlying biology on CRPC patient outcomes and the urgent need for biomarkers that can enable the development of therapies specific to each subset. Correlative studies to identify said biomarkers will be presented. Clinical trial information: NCT02703623. Research Sponsor: Janssen, BMS, Sanofi.

Health-related quality of life (HRQoL) and pain in the MAGNITUDE study of niraparib (NIRA) with abiraterone acetate and prednisone (AAP) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) and homologous recombination repair (HRR) gene alterations. *First Author: Dana E. Rathkopf, Memorial Sloan Kettering Cancer Center and Weill Cornell Medicine, New York, NY*

Background: Results from the international, randomized, double-blind, phase 3 MAGNITUDE study demonstrated that NIRA + AAP improved radiographic progression-free survival, time to cytotoxic chemotherapy, and time to symptomatic progression, with manageable toxicity in pts with mCRPC and HRR alterations (9-gene panel). Here, we report HRQoL and pain in MAGNITUDE. **Methods**: Eligible pts with mCRPC and HRR alterations were randomized 1:1 to NIRA + AAP or placebo (PBO) + AAP orally daily in 28-day cycles. Pts had ECOG status ≤1 and a Brief Pain Inventory–Short Form (BPI-SF) worst pain score ≤3 in prescreening. HRQoL assessments on day 1 of specified cycles included Functional Assessment of Cancer Therapy–Prostate (FACT-P) and BPI-SF. Changes from baseline were compared between treatment arms using repeated measures analysis. Proportional hazards regression models were used to compare time to deterioration (TTD) in worst pain intensity between arms. **Results**: Compliance for FACT-P and BPI-SF was > 80%. Most pts maintained low pain levels over time. Repeated measures analyses showed no clinically meaningful differences in pain over time or between arms. Median TTD in pain intensity was not reached in either arm. At the 25th percentile, there was a trend toward longer TTD in pain intensity with NIRA + AAP vs PBO + AAP (11.1 vs 10.1 mo; HR, 0.87; 95% CI, 0.61-1.24). HRQoL was maintained with NIRA + AAP, with no clinically meaningful differences in FACT-P total score over time or between arms. There was a trend toward greater worsening in early cycles on FACT-P physical wellbeing with NIRA + AAP vs PBO + AAP, driven by events within the known safety profile of NIRA + AAP (worsening of side effect bother, lack of energy, and nausea); however, overall, most pts reported minimal side effect burden (Table). **Conclusions**: In MAGNITUDE, most pts maintained low pain levels and positive HRQoL over time, with no clinically meaningful differences between treatment arms, further supporting the use of NIRA + AAP in pts with mCRPC and HRR alterations. Side effect burden was perceived as low in both arms. Although more pts on NIRA+AAP reported worsening side effects, the symptoms were generally perceived as mild. Clinical trial information: NCT03748641. Research Sponsor: Janssen Research & Development, LLC.

	Change from baseline				Response of "not at all" or "a little bit" on respective items across cycles	
	Improved/stable		Worsened			
FACT-P item median (range), %	NIRA + AAP	PBO + AAP	NIRA + AAP	PBO + AAP	NIRA + AAP	PBO + AAP

Comparing pretest video genetic education for prostate cancer patients: Do patients need assistance? *First Author: Samantha Greenberg, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: Expanded germline genetic testing recommendations for individuals with prostate cancer (PCa) have resulted in increased demand for pre-test genetic education. As a result, alternative service delivery models in genetic counseling (GC) have been suggested. Previous research has shown no difference in genetic testing uptake when video genetic education (VGE) is used rather than face-to-face counseling. However, data is limited when evaluating how VGE is delivered to patients. This study aimed to evaluate the impact of pre-test VGE on genetic testing uptake when facilitated by a GC assistant or self-completed by the patient. **Methods:** PCa patients referred for GC were contacted for pre-test VGE. Patients were randomized to undergo VGE with a GC assistant via Zoom (assistant-led) or perform VGE on their own via email instructions (patient-led). Assistant-led VGE was scheduled via standard of care, and patient-led VGE involved electronic and phone contact. In both arms, pre-test VGE included administrating family history collection via electronic software and viewing of informational genetics video. VGE completion and genetic testing uptake was the primary outcome measured for all participants. Initial pilot data was presented previously. This analysis represents the entire study period outcome. Data analysis used t-test, Fisher's exact and chi square. **Results:** From 10/1/2020-12/31/2021, 266 PCa patients were referred. In total, 254 were randomized, with 130 in the assistant-led intervention and 124 randomized to the patient-led arm. Technological limitations, loss to follow up, and procedural withdrawals resulted in 41 (31.5%) patients in the assistant-led arm and 65 (52.4%) in the self-led arm. The primary reason for discontinuing the process was lack of patient response to contact to schedule their genetics visit (n = 109, 35 patient-led, 74 assistant-led). There was significantly more loss to follow up in the assistant-led arm versus the self-led arm (p < 0.001). Of those who completed VGE, the median age was 66 years, with no difference between the two arms (p = 0.66). Participants primary identified as white (n = 96, 91%) and non-Hispanic (n = 100, 94%). There was no difference in uptake of genetic testing (p = 0.09) between patient and assistant led VGE. **Conclusions:** A randomized intervention suggests no difference in genetic testing uptake when pre-test VGE occurs with an assistant or is patient-led. Analyses of satisfaction, decision conflict, and knowledge are needed to evaluate if patient-led VGE is a suitable alternative to GC. Loss to follow up given standard of care scheduling approaches for assistant-led VGE suggests pre-test VGE may be better delivered during oncology visits. Additional evaluation of the facilitators and barriers, in addition to larger multi-center studies, are required to consider patient-led pre-test VGE as a primary method of pretesting genetic education. Epidemiology and racial differences of prostate cancer clinical states. *First Author: Shannon R. Stock, Department of Surgery, Durham Veterans Affairs Health Care System, Durham, NC*

Background: There is a lack of data on the incidence rates (IRs) and racial differences in advanced prostate cancer (PC) clinical states. This is the first study to evaluate PC IRs among Black and White men in the Veterans Affairs Healthcare System (VAHCS) in the following clinical states: non-metastatic hormone-sensitive PC (nmHSPC); de novo metastatic HSPC (mHSPC); non-metastatic castration-resistant PC (nmCRPC); metastatic CRPC (mCRPC). **Methods:** This retrospective cohort study included adult Black and White men who were active users of the VAHCS, having ≥ two visits at VA centers over any 18-month interval during the study period (2012-2019). PC was identified by ≥ two ICD codes for PC on separate dates. Metastatic status was identified by an algorithm of ICD codes and common treatments for metastatic PC. Castrate resistant status was determined based on rising PSA during periods of continuous androgen deprivation therapy. Annual IRs for each clinical state and rate ratios (RR) for race were standardized using age and race-specific population estimates from the U.S. Census. The joinpoint regression software 4.9.0.0 was used to evaluate trends and identify change points in IRs over time. **Results:** 2019 IRs (per 100K person-years) and 95% confidence intervals among Black and White men respectively by clinical state were 453.0 (441.2, 464.7) and 205.3 (201.5, 209.1) (nmHSPC); 33.7 (30.4, 37.0) and 15.1 (14.1, 16.0) (mHSPC); 23.4 (21.0, 25.9) and 8.5 (7.8, 9.1) (nmCRPC); and 49.1 (45.5, 52.8) and 19.4 (18.4, 20.3) (mCRPC). The RR for all clinical states was significantly higher for Black vs. White men (all p < 0.0001): 2.2 (nmHSPC and mHSPC), 2.8 (nmCRPC), and 2.5 (mCRPC). Although IRs varied over time, these RRs were consistent across time. Trends in IRs over time were also consistent by race. From 2012, the IRs for nmHSPC declined to a nadir in 2016 (annual percent change (APC) -9.1%) and then increased through 2019 (APC = 3.1%). IRs for mHSPC increased throughout the study period (APC = 10.6%). IRs for nmCRPC decreased from 2012 to a nadir in 2014 (APC = -9.3%) and then increased through 2019 (APC = 3.8%). IRs for mCRPC increased from 2012 to 2016 (APC = 7.7%) and then leveled off through 2019 (APC = -0.2%). **Conclusions:** Our findings provide novel and comprehensive data on IRs across prostate cancer clinical states by race and over time within the VAHCS. Despite the VAHCS providing an environment of relatively equal access to care, Black men experience a disproportionate burden of PC with IRs over 2-fold higher for all clinical states relative to White men. This highlights that resolving access to care alone is unlikely to fully eliminate PC racial differences and that there are other multifactorial issues to address. The temporal trends for nmHSPC observed in our study, including the nadir in 2016, are consistent with the timing of the 2012 US Preventive Services Task Force guidelines advising against PSA screening and the subsequent draft reversal in 2017. Association of *RB1* mutational status with overall genomic landscape in neuroendocrine prostate cancer (NEPC). *First Author: Petros Grivas, University of Washington and Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: NEPC is a high-grade aggressive form of prostate cancer. We queried whether *RB1* mutation status would impact the genomic features of NEPC in *RB1* mutated vs non-mutated cases. **Methods:** From a series of 13,496 cases of clinically advanced PC, we identified 415 cases (3.1%) with a diagnosis of small cell PC or NEPC as determined by the submitting physician. They were sequenced using a hybrid capture-based FDA-approved clinical genomic profiling (CGP) assay to detect all classes of genomic alterations (GA). Tumor mutational burden (TMB) was determined on 0.8 Mbp of sequenced DNA and microsatellite instability (MSI) was determined on 95 loci. PD-L1 expression was determined by IHC (Dako 22C3) with low tumor cell positive staining 1-49% and high staining ≥50% expression. **Results:** 253 (61%) of NEPC feature GA in *RB1* (RB1 mut+). This contrasts with a 5.8% frequency of *RB1* GA in the non-NEPC (P < .0001). The *RB1* mut+ NEPC featured a slightly greater number of pathogenic GA/tumor than the *RB1* mut- NEPC (5.1 vs 4.2). Age and *TMPRSS2-ERG* fusion frequency were similar between the groups. *RB1* Mut- NEPC was associated with significantly higher amplifications (amp) and total GA in *AR* compared to *RB1* mut+ NEPC. *RB1* mut+ NEPC featured significantly greater frequency of *PTEN* GA. GA frequencies in targetable kinases and DNA repair GA including *BRCA1/2* and *ATM* linked to PARP inhibitor (PARPi) response were similar in both groups. For potential immune-oncology (IO) biomarkers, *RB1* Mut+ NEPC featured significantly greater frequency of positive PD-L1 expression and lower frequencies of *MDM2* and *CDK12* GA. *CD274* (*PD-L1*) amplification, MSI-high status and cases with TMB ≥10 mut/Mb were uncommon in both groups. gLOH was higher in RB1 mut+ than *RB1* mut- (P = .005). There were more cases of non-European ancestry in the *RB1* mut- group. APC I1307K mut were found in 3/162 (1.9%) *RB1* mut- NEPC only. **Conclusions:** In NEPC, the presence of *RB1* mutation is associated with various GA that may have clinical relevance. Further study of *RB1* status as a guide in trial designs on therapy selection for men with NEPC appears warranted. Research Sponsor: Foundation Medicine Inc.

NEPC	RB1 mut+ (253 cases)	RB1 mut- (162 cases)	P Value
AR	5.1%	14.2%	0.002
TP53	68.0%	58.0%	0.02
PTEN	43.1%	25.9%	0.0004
PIK3CA	5.5%	4.9%	NS
gLOH	10.91%	9.08%	.005
MSI High/TMB≥10mut/Mb	1.6%	1.9%	NS
TMB≥10/20 mut/Mb	8.6%/3.0%	6.0%/2.0%	NS
PD-L1 Low/High Positive	28.6%/4.7% (64 cases)	6%/4.1% (49 cases)	0.003

Overall survival (OS) and biomarker results from combat: A phase 2 study of bipolar androgen therapy (BAT) plus nivolumab for patients with metastatic castrate-resistant prostate cancer (mCRPC). *First Author: Mark Christopher Markowski, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD*

Background: During BAT, intramuscular (IM) administration of testosterone (T) results in rapid cycling of serum T from supraphysiologic to near-castrate levels in men with mCRPC. In a retrospective study, clinical responses to immune checkpoint blockade (ICB) in mCRPC patients (pts) previously treated with BAT were observed. Here, we report the OS and biomarker results of a Phase 2 study in mCRPC pts treated with BAT in combination with nivolumab (COMBAT; NCT03554317). **Methods:** This was a multi-center, single arm, open label Phase 2 study in mCRPC pts who received T cypionate 400mg IM (BAT) every 28 days plus nivolumab 480mg IV every 28 days. Pts initially received BAT alone for a 12-week period, prior to the addition of nivolumab. Eligible pts were those with asymptomatic mCRPC who had soft tissue metastases amenable to biopsy, and who progressed on at least one prior novel AR targeted therapy (and up to one prior chemo for mCRPC). The primary endpoint was confirmed PSA_{50} response. OS and radiographic progression free survival (rPFS) were key secondary endpoints. All pts underwent baseline metastatic biopsies, and 24 had a second biopsy after 12 weeks of BAT. Semi-quantitative IHC (for AR, Ki67, MYC, PTEN, TP53, RB1) was performed on 24 paired biopsies, of which 15 pairs were also evaluable for RNA (whole transcriptome) sequencing. **Results:** 45 pts were enrolled. As previously reported, the PSA_{50} response was 40% (18/45, 95% CI: 26-56%, P=0.02 against the 25% null hypothesis), and median rPFS was 5.6 (95% CI: 4.4–6.0) months. After a median follow-up of 17.8 months, the median OS was 27.8 (95%% CI: 17.6–NR) months. In 24 pts with paired biopsies prior to administration of nivolumab, BAT significantly decreased median MYC (P=0.046) and Ki-67 (P=0.030) expression by IHC. 71% (17/24) of pts had any decrease in MYC following BAT, with 29% (7/24) having a >50% decrease. A >50% MYC protein decline was associated with longer rPFS (HR 0.33, 95%CI 0.14–0.78, P=0.005) and a nonsignificant association towards longer OS (HR 0.78, 95%CI 0.24–2.48, P=0.679). MYC protein and mRNA levels were tightly intercorrelated (r=0.65, P<0.001). Both rPFS and OS were numerically longer in pts with >50% declines in MYC mRNA levels (P>0.1 for both). **Conclusions:** BAT combined with nivolumab led to a median overall survival of >2 years in heavily pretreated mCRPC pts. BAT attenuated MYC expression, correlating with better outcomes. Clinical trial information: NCT03554317. Research Sponsor: Bristol Myers Squibb, Other Foundation, Other Government Agency.

Reasons for oncologist and urologist treatment choice in metastatic castration-sensitive prostate cancer (mCSPC): A physician survey linked to patient chart reviews in the United States. *First Author: Stephen J. Freedland, Division of Urology, Department of Surgery, Cedars-Sinai Medical Center and Department of Surgery, Durham Veterans Affairs Health Care System, Durham, NC*

Background: Based on level 1 evidence of overall survival, ASCO/NCCN/AUA guidelines uniformly recommend novel hormonal therapy (NHT) or chemotherapy (CHT) added to androgen deprivation therapy (ADT) as standard of care in mCSPC. However, real-world evidence across US healthcare systems suggests most patients receive ADT +/- first generation non-steroidal antiandrogens (NSAA). Reasons behind the lack of treatment intensification (TI) in mCSPC have not been studied. **Methods:** Data from medical charts of patients initiating mCSPC treatment from Jul '18-Nov '21 were retrospectively extracted from multiple US academic/community practices. Oncologists and urologists who treated these patients were surveyed to provide reasons for treatment choices including prostate specific antigen (PSA) goals and explicit reasons for not prescribing NHT. Descriptive statistics (Fishers exact tests) were used to compare outcomes between groups; p-values for odds ratios (OR) were generated via Wald test. **Results:** 65 oncologists and 42 urologists provided data on 621 patients. Median age at initial mCSPC treatment start was 68.0 years, 58% were White, 25% Black, 84% had de novo metastases, 30% had high-volume disease including 22% with visceral metastases, and 83% had ECOG PS score ≤1. In the first-line (1L) setting, most mCSPC patients received ADT±NSAA alone (69%), while TI rates with ADT+NHT (26%) or ADT+CHT (4%) were low. An additional 27% (n = 166/621) received subsequent TI while still castration-sensitive. According to the physician survey, the top 5 reasons why their patients did not receive initial NHT were perceptions about: drug tolerability (38%), lack of clinical trial evidence of overall survival improvement (31%), lack of reimbursement (26%), patient financial constraints (20%), and questions about sequencing NHTs earlier vs later in disease (21%). Regarding treatment goals for PSA response, physicians more frequently reported a relative (%) reduction than an absolute PSA reduction (85% vs 51%). Oncologists considered a median PSA reduction of 50% (IQR 25-75) adequate vs 75% (IQR 50-90) among urologists. Urologists had higher rates of TI at 1L and/or subsequent treatment in patients who were still castration-sensitive (p < 0.01). Physicians who aimed for deeper PSA reduction of 75-100% were more likely (OR = 1.63; p = 0.034) to provide TI in 1L compared with physicians with less aggressive PSA goals (0-49%). **Conclusions:** To our knowledge, this is the first study identifying reasons for underutilization of intensified treatment in mCSPC. While survey results suggest perceptions of tolerability and lack of efficacy and financial considerations affect NHT use, in practice, non-guideline driven PSA reduction goals are associated with low rates of TI. These results demonstrate the need for further medical education. Research Sponsor: Pfizer and Astellas Pharma.

Genomic aberrations associated with overall survival (OS) in metastatic castration-sensitive prostate cancer (mCSPC) treated with apalutamide (APA) or placebo (PBO) plus androgen deprivation therapy (ADT) in TITAN. *First Author: Neeraj Agarwal, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: TITAN, a phase 3 PBO-controlled study in patients (pts) with mCSPC, showed APA + ADT improved radiographic progression-free survival and OS vs PBO + ADT. In this exploratory analysis, we report the relationships between biomarkers and OS in TITAN. **Methods:** Circulating tumor (ct)DNA and genomic aberrations in 17 PC-related genes, including androgen receptor (AR), were assessed at baseline (BL; 114 pts) and end of study treatment (EOST; 129 pts) using next-generation sequencing. ctDNA was assessed qualitatively; genomic aberrations were assessed within ctDNA-positive samples as inactivation (heterozygous/homozygous deletion or single nucleotide variant [SNV]) or activation (amplification or SNV). Associations of detected ctDNA/aberrations at BL or EOST with OS, and biomarkers at EOST with OS on subsequent therapies, were evaluated using univariate or multivariate analyses and Cox proportional hazards model; results were stratified by treatment arm. **Results:** Among pts from both treatment groups, 36% had detectable ctDNA, of which 27% had any genomic *AR* aberration and 24% had *AR* gene amplification at BL; prevalence of these biomarkers increased significantly from BL to EOST (Table). The most prevalent non-AR aberrations at BL (*TP53*, homologous recombination repair [HRR] pathway, *PTEN, RB1*, and *PIK3CA* genes) increased at EOST but not significantly (Table). Among assessed aberrations, presence of ctDNA or any *AR* genomic aberrations at BL (HR, 1.9 or 6.7; all p < 0.05) and any *AR* genomic aberrations or PI3K pathway activation at EOST (1.7, p < 0.05 or 2.2, p < 0.001) was significantly associated with poor OS in multivariate analyses from both treatment groups. In univariate analyses of pts who received subsequent therapy (chemotherapy: 106; hormonal therapy: 161), worse OS was associated only with *PIK3CA* activation, PI3K pathway activation, or *TP53* inactivation at EOST (3.7, p < 0.05; 2.4, p < 0.05; 3.0, p < 0.01, respectively) in chemo-treated pts. A small sample size in some biomarker subgroups limits interpretation. **Conclusions:** These hypothesis-generating data from TITAN show that presence of ctDNA or select AR and non-AR biomarkers at BL or EOST were associated with poor OS. The predictive value of these biomarkers for survival in mCSPC needs further confirmation. Clinical trial information: NCT02489318. Research Sponsor: Janssen Research & Development.

Feasibility of a novel wrist-worn thermal device for management of vasomotor symptoms in patients with prostate cancer. *First Author: Alicia K. Morgans, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Vasomotor symptoms (VMS), or hot flashes, are a common side effect of androgen deprivation therapy (ADT) for prostate cancer (PCa). VMS negatively impact sleep, fatigue, and quality of life (QOL) in PCa survivors. There are few nonpharmacological treatments for VMS. The Embr Wave is a wearable thermal device that applies cooling to thermoreceptors on the inside of the wrist and has been associated with patient reported decreases in hot flash interference in women. We performed a single-arm feasibility study evaluating the Embr Wave for management of VMS in PCa survivors. **Methods:** 57 PCa survivors reporting bothersome hot flashes were enrolled and instructed to use the device as needed for VMS during the 4-week study. The primary outcome was device usage recorded by the device (minutes and sessions). Additional outcomes included the change in patient reported Hot Flash Related Daily Interference Scale (HFRDIS, range 0-10) and Patient Reported Outcomes Measurement Information System Sleep Disturbance 4a (PROMIS SD, range 0-100) and Sleep Related Impairment 8a (PROMIS SRI, range 0-100). Study procedures were conducted remotely using a virtual clinical trial management platform. **Results:** The study was conducted from May to Dec 2021 in the US. 44 men completed the study; 39 had retrievable usage data. Median age was 66 (range 57-78) years and median 3 (1-23) years since PCa diagnosis. The most common hormonal treatments were leuprolide (n=22), abiraterone (n=13), and enzalutamide (n=6). Baseline scores indicated moderate hot flash interference and mild sleep disturbance (Table). Mean±SD (median) usage of the Embr device was 3.2±2.5 (2.3) hours and 7.6±3.6 (7.5) sessions per day. 26 (67%) participants reported using the device 7 days/nights each week. Improvements were observed in HFRDIS, PROMIS SD, and PROMIS SRI scores (Table). There were also improvements in subjective ratings of hot flash frequency, duration, interference with daily life/sleep, bothersomeness and control (all p<0.01). The majority (69%) of participants reported that the device was effective at helping them manage hot flashes. No adverse events were reported. **Conclusions:** Results of this study support the feasibility of use of the thermal device for management of bothersome hot flashes in PCa survivors. Future randomized controlled studies are warranted to evaluate patient reported outcomes related to frequency and severity of VMS, sleep quality, fatigue, and overall QOL, in addition to defining the potential utility of the Embr thermal device in PCa survivors experiencing VMS. Clinical trial information: NCT04892914. Research Sponsor: Embr Labs.

Measure	Baseline	Week 4	Change
HFRDIS, mean [95% CI]	4.3 [3.7, 4.9]	3.2 [2.6, 3.8]	-1.1 [-1.6, -0.6] p<0.001
PROMIS SD T-score, mean [95% CI]	56 [54, 58]	50 [48, 53]	-6.0 [-8.0, -4.0] p<0.001

A pilot trial of neoantigen DNA vaccine in combination with nivolumab/ipilimumab and prostvac in metastatic hormone-sensitive prostate cancer (mHSPC). *First Author: Koral Shah, Washington University School of Medicine, Saint Louis, MO*

Background: Treatment with immune checkpoint blockade (ICB) alone results in suboptimal response rates in prostate cancer. Prostvac-VF Tricom is a therapeutic vaccine that incorporates DNA for the shared self-antigen PSA. Personalized neoantigen vaccines based on specific mutated epitopes may have the ability to overcome immunoresistance seen with self-antigens. Even in low mutational burden tumors like prostate cancer, T cell responses against neoantigens have been correlated with favorable clinical outcomes. Thus, we hypothesized that the combination of shared antigen and neoantigen vaccines with dual ICB will induce robust immune responses and improve clinical outcomes. **Methods:** This Phase I clinical trial (NCT03532217) enrolled patients from 2018-2021. Eligible patients had histologically confirmed high risk mHSPC, must have completed a course of docetaxel and received continuous androgen deprivation therapy. Patients were treated with Prostvac-VF in combination with ipilimumab/nivolumab within 60 days of the last docetaxel dose. Then, patients were continued on monthly nivolumab with their personalized neoantigen vaccine administered via intramuscular electroporation. The primary objectives of this study were to assess the feasibility, safety/tolerability, and immune responses of this combination strategy. Key secondary objectives include failure free survival, milestone overall survival (OS), PSA responses, and radiographic progression free survival. **Results:** Nineteen patients were enrolled and treated on trial, and feasibility was shown with 15 (79%) receiving neoantigen vaccines. Four patients did not receive neoantigen vaccines (2 for progressive disease, 2 for ICB toxicity). Treatment was well-tolerated with only 2 (2.4%) grade 3 treatment related adverse events (TRAEs) of colitis, and no grade 4+ TRAEs. The common grade 1-2 TRAEs were diarrhea (10%), injection site reactions (10%), rash (7.4%), and fatigue (6%). Median follow-up to date is 22.6 (11.3-39.6) months, with median OS not yet reached and 2 year milestone OS of 75%. Six (31.5%) patients had PSA progression per PCWG2 criteria while on treatment, with the median time to PSA progression not yet reached for the total population. Increases in activation/co-stimulatory/co-inhibitory seen after treatment with Prostvac/ICB, suggest immune priming. Sample collection is complete and immune correlative analyses are ongoing. Final safety/tolerability and preliminary correlative and clinical outcomes will be reported. **Conclusions:** This is the first clinical trial evaluating the use of personalized neoantigen vaccines in a combination immunotherapeutic approach in mHSPC patients. Clinical trial information: NCT03532217. Research Sponsor: Prostate Cancer Foundation, Other Foundation.

Clinical outcomes and safety of enzalutamide (ENZA) plus androgen-deprivation therapy (ADT) in metastatic hormone-sensitive prostate cancer (mHSPC) in patients aged < 75 and ≥ 75 years: ARCHES post hoc analysis. *First Author: Russell Zelig Szmulewitz, The University of Chicago, Chicago, IL*

Background: Patients with metastatic prostate cancer aged ≥75 years have a poorer prognosis compared with younger patients. In ARCHES (NCT02677896), ENZA + ADT improved radiographic progression-free survival (rPFS), overall survival (OS), and other key secondary endpoints vs. placebo (PBO) + ADT in patients with mHSPC. Final OS results confirmed a long-term survival benefit with ENZA + ADT. This *post hoc* analysis of ARCHES data investigated OS and other clinical outcomes in patients aged <75 and ≥75 years. **Methods**: Patients with mHSPC (n=1150) were randomized 1:1 to ENZA (160 mg/day) + ADT or PBO + ADT, stratified by disease volume and prior docetaxel use. Subgroup analysis was performed in patients aged <75 and ≥75 years. Efficacy and safety outcomes were compared across treatment arms. **Results**: Of the ARCHES population, 339 patients (29.5%) were aged ≥75 years (ENZA + ADT, n=170; PBO + ADT, n=169); PBO patients crossing over to ENZA were aged: <75 years, n=133; ≥75 years, n=47. Some differences in baseline characteristics were observed between age groups, such as higher prior docetaxel use in patients aged <75 years (ENZA + ADT, 21.0%; PBO + ADT, 20.4%) vs. those aged ≥75 years (ENZA + ADT, 10.6%; PBO + ADT, 11.2%). When compared to PBO + ADT, ENZA + ADT improved OS and other secondary efficacy endpoints in both age groups without evidence of statistical heterogeneity (Table); however, 95% confidence intervals for OS and rPFS hazard ratios spanned 1 in the older age group. The safety profile of treatment arms was generally similar in both age groups, with a higher incidence of falls, cognitive impairment, and cardiovascular events among elderly patients receiving ENZA + ADT vs. PBO + ADT. **Conclusions**: This *post hoc* analysis of ARCHES data demonstrated that ENZA + ADT provides clinical benefit and is generally well-tolerated in patients with mHSPC aged ≥75 years, supporting the therapeutic role of ENZA in these patients. Clinical trial information: NCT02677896. Research Sponsor: Astellas Pharma Inc. and Pfizer Inc.

Defining more precisely the effects of docetaxel plus ADT for men with mHSPC: Meta-analysis of individual participant data from randomized trials. *First Author: Claire Vale, MRC Clinical Trials Unit at UCL, London, United Kingdom*

Background: Adding docetaxel to androgen deprivation therapy(ADT) improves survival in metastatic, hormone-sensitive prostate cancer (mHSPC), but uncertainty remains about who benefits most. To investigate this thoroughly and reliably, the STOPCAP M1 collaborationconducted a meta-analysis of individual participant data (IPD) from relevant trials. **Methods:** Methods were included in a registered protocol (CRD42019140591). Updated IPD from the GETUG-15, CHAARTED and STAMPEDE trials were harmonised and checked. The main outcomes were overall survival (OS), progression-free survival (PFS) and failure-free survival (FFS). Overall pooled effects were estimated using intention-to-treat, 2-stage, fixed-effect meta-analysis, adjusted for age, PSA, Gleason sum score, performance status, and timing of metastatic disease (missing covariate values imputed), with 1-stage and random-effects sensitivity analyses. We assessed subgroup effects using 2-stage, fixed-effect meta-analysis of within-trial interactions, adjusted for the same covariates. We based these on PFS to maximise power, and OS whenever interactions were found. To explore multiple subgroup interactions, and to derive subgroup-specific absolute treatment effects, we used 1-stage, flexible parametric modelling and standardisation. **Results:** We obtained IPD for all 2261 men randomised, with median FU of 6 years (all patients). There were clear relative benefits of docetaxel on OS (HR = 0.79, 95% CI 0.70 to 0.88, p<0.0001), PFS (HR = 0.70, 95% CI 0.63 to 0.77, p<0.0001) and FFS (HR = 0.64, 95% CI 0.58 to 0.71, p<0.0001). With evidence of non-proportional hazards, we also estimated 5-year absolute differences: OS 10% (95% CI 6 to 15%), PFS 9% (95% CI 5 to 13%) and FFS 9% (95% CI 6 to 12%). The relative effect of docetaxel on PFS differed by volume of metastases (interaction p=0.027; *high volume* HR = 0.60, 95% CI 0.52 to 0.68; *low volume* HR = 0.78, 95% CI 0.64 to 0.94), and timing of metastatic disease (interaction p=0.077; *synchronous* HR = 0.67, 95% CI 0.60 to 0.75; *metachronous* HR = 0.89, 95% CI 0.67 to 1.18). OS results were similar. When metastatic disease volume and timing were combined, docetaxel appeared to improve PFS and OS for all men, except those with low volume, metachronous disease (Table). **Conclusions:** This IPD meta-analysis provides the most detailed assessment of the effects of docetaxel for mHSPC, and suggests that men with low volume, metachronous disease should be managed differently to those with other types of metastatic disease. Research Sponsor: Prostate Cancer UK; UK Medical Research Council.

Volume & timing of metastatic disease	Absolute effect (95% CI) at 5 years I Change from baseline			
	PFS		OS	
High volume, synchronous	10% (6 to 14%)	10 → 20%	11% (6 to 16%)	25 → 36%
High volume, metachronous	10% (-2 to 22%)	20 → 30%	8% (-6 to 23%)	35 → 43%
Low volume, synchronous	7% (0 to 14%)	40 → 47%	6% (-1 to 13%)	55 → 61%
Low volume, metachronous	-3% (-14 to 9%)	50 → 47%	-1% (-12 to 10%)	70 → 69%

Bone biomarkers and overall survival (OS) in men with advanced hormone-sensitive prostate cancer (HSPC): Results from SWOG S1216, a phase III trial of ADT +/- orteronel.

First Author: Primo "Lucky" N. Lara, University of California, Sacramento, CA

Background: Circulating bone biomarkers (BB) are strongly prognostic for OS in castration-resistant PC (CRPC). We prospectively evaluated BB in men with HSPC in S1216, a trial that established new OS benchmarks. We sought to identify patient (pt) subsets with differential OS outcomes as defined by BB. **Methods:** Markers of bone resorption [CTx;PYD] & formation [CICP;BAP] were assessed. Pts were randomly divided into training (1/3) & validation (2/3) sets. In the training set, recursive partitioning of OS was used to identify the ideal dichotomous cutpoint for each BB & for a combination of biomarker split points to define prognostic groups. In the validation set, Cox PH models were used to assess impact of BB on OS, adjusted for pt & tumor characteristics. Adjusted odds ratios for 3-year OS based on BB & baseline clinical factors were developed using logistic regression to estimate receiver operating characteristic (ROC) curves. **Results:** Of 1,279 men, 949 had baseline BB. Median age–68y; median PSA-28 ng/dL; Gleason>7: 60%; Zubrod PS 0/1-97%. Values of BB at the median & at cutpoints maximized for OS were identified. For 3 of the BB, the cutpoint was at the ~85th %ile; for PYD it was at the median. Recursive partitioning algorithms applied to the training set identified 4 groups with differential OS based on a dichotomous split of CTx in combination with additional CICP splits within each group. Hazard ratios (HR) for OS based on elevated BBs are shown. ROC analysis showed that only BAP & PYD had significantly higher AUC(0.73;0.74) compared to AUC of baseline clinical factors(0.71) w/ p=0.02 and 0.03 respectively. There was no evidence of BB x treatment interaction (all p>=0.2). **Conclusions:** In men initiating ADT for HSPC, elevated BB are strongly prognostic for worse OS. BB levels alone & in combination with pt/tumor characteristics identify unique subsets of men with high probability of being alive at 3 years from ADT initiation. These results validate the clinical value of BB in the HSPC state, extending BB utility beyond CRPC. Clinical trial information: NCT01809691. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Pharmaceutical/Biotech Company.

Radiographic progression in the absence of prostate-specific antigen (PSA) progression in patients with metastatic hormone-sensitive prostate cancer (mHSPC): Post hoc analysis of ARCHES.

First Author: Andrew J. Armstrong, Duke Cancer Institute Center for Prostate and Urologic Cancers, Duke University School of Medicine, Durham, NC

Background: Enzalutamide (ENZA) + androgen deprivation therapy (ADT) significantly reduced the risk of radiographic progression and increased overall survival in men with mHSPC, regardless of baseline PSA levels (ARCHES; NCT02677896). This *post hoc* analysis investigated concordance between PSA progression and radiographic progression in patients with mHSPC. **Methods:** Patients with mHSPC (n=1150) were randomized 1:1 to ENZA (160 mg/day) + ADT or placebo (PBO) + ADT. The concordance between radiographic progression and PSA progression, as defined by Prostate Cancer Clinical Trials Working Group 2 (PCWG2) criteria, and between any rise in PSA above nadir was assessed. **Results:** In total, 267/1150 patients in ARCHES had radiographic progression (ENZA + ADT, n=79; PBO + ADT, n=188). At radiographic progression, the median (range) PSA for ENZA + ADT-treated patients was 2.25 ng/mL (0–1062.3 ng/mL) and 17.47 ng/mL (0–1779.5 ng/mL) for PBO + ADT-treated patients. Most patients (67%) treated with ENZA + ADT did not have PCWG2-defined PSA progression at radiographic progression, compared with 57% of those treated with PBO + ADT (Table). The median absolute and percentage rise in PSA from nadir to radiographic progression was 0.77 ng/mL and 200%, respectively, with ENZA + ADT compared with 12.23 ng/mL and 367%, respectively, with PBO + ADT. **Conclusions:** In this *post hoc* analysis of ARCHES, we found frequent discordance between radiographic progression and PSA progression by PCWG2 criteria or any PSA rise over nadir in patients with mHSPC treated with ENZA + ADT. Thus, regular imaging is recommended to detect radiographic progression among patients treated with potent androgen receptor pathway inhibitors, such as ENZA + ADT, as serial PSA monitoring alone may not be sufficient to detect radiographic progression in many patients. Clinical trial information: NCT02677896. Research Sponsor: Astellas Pharma Inc., Pfizer Inc.

Concordance of radiographic progression and increasing PSA.

n (%)	ENZA + ADT (n=79)	PBO + ADT (n=188)
PSA progression[a] at time of radiographic progression[b]		
Yes	26 (32.9)	108 (57.4)
No	53 (67.1)	80 (42.6)
Any rise in PSA from nadir at time of radiographic progression[b]		
Yes	52 (65.8)	160 (85.1)
No	27 (34.2)	28 (14.9)

[a]PSA progression is defined as a ≥25% increase and an absolute increase of ≥2 ng/mL above the nadir, confirmed by a second consecutive value at least 3 weeks later; [b]Radiographic progression was assessed by independent central review or death (defined as death from any cause within 24 weeks from study drug discontinuation), whichever occurred first.

Efficacy and safety of relugolix in men with advanced prostate cancer based on baseline body mass index (BMI): A subgroup analysis from the randomized, phase 3 HERO study versus leuprolide (LEU).

First Author: Fred Saad, University of Montréal Health Center, Montréal, QC, Canada

Background: BMI has been correlated with adverse prostate cancer outcomes, such as risk of biochemical failure, mortality and androgen deprivation therapy complications. Relugolix is a FDA-approved, once-daily oral GnRH receptor antagonist that has demonstrated superior continuous suppression of testosterone (T) to castrate levels through Week 48 compared to LEU (96.7% vs 88.8%, respectively; Shore N, NEJM 2020;382:2187) in men with advanced prostate cancer (APC). This HERO subgroup analysis looks at the impact of baseline BMI on efficacy and safety. **Methods:** HERO was a phase 3 randomized, open-label study to evaluate relugolix vs LEU in 930 men with APC. This analysis looked at all men enrolled and treated in the HERO study divided by baseline BMI (BMI subgroups: <25.0 [underweight and healthy weight]; 25.0 – 29.9 [overweight]; and >29.9 [obese]). Assessments included sustained T suppression to castrate levels (<50 ng/dL) from Day 29 through 48 weeks, early T suppression to castrate levels (Day 4 and Day 15), prostate specific antigen (PSA) response (>50% decrease from baseline) at Day 15 with confirmation at Day 29, and profound castration rate (<20 ng/dL) at Day 15. T recovery subset analysis was not included due to low patient numbers. All analyses performed were descriptive. **Results:** Of the 930 men (relugolix:622; LEU:308) treated in HERO, 287 (30.9%) men had BMI <25, 424 (45.6%) were 25 – 29.9, 219 (23.5%) were >29.9. Sustained castration rates through 48 weeks were higher for the relugolix group than the LEU group and results for select key secondary endpoints were generally consistent across BMI categories, although PSA response proportions were lower in obese patients (table). No differences were noted in the incidence or types of adverse events within treatment groups in the subgroups analyzed. **Conclusions:** In this HERO study subgroup analysis, relugolix demonstrated greater continuous T suppression than LEU regardless of baseline BMI. Although higher BMI has been associated with poorer outcomes, we did not observe a similar trend with T responses. A numerically lower PSA response was seen in obese patients. Additional research with longer follow-up is warranted. Clinical trial information: NCT03085095. Research Sponsor: Myovant Sciences GmbH, in collaboration with Pfizer, Inc.

Prevalence of DNA damage repair (DDR) alterations in patients with metastatic hormone-sensitive prostate cancer (mHSPC) receiving enzalutamide (ENZA) or placebo (PBO) plus androgen deprivation therapy (ADT): ARCHES post hoc analysis.

First Author: Arun Azad, Peter MacCallum Cancer Centre, Melbourne, VIC, Australia

Background: DDR alterations are associated with poorer prognosis, including shorter overall survival (OS), in patients with mHSPC. In ARCHES (NCT02677896), patients with mHSPC treated with ENZA + ADT had a reduced risk of radiographic progression or death and improved OS versus PBO + ADT. This *post hoc* analysis assessed the prevalence of DDR alterations and associated baseline characteristics in patients with mHSPC in ARCHES. **Methods**: Patients with mHSPC (n=1150) were randomized 1:1 to ENZA (160 mg/day) + ADT or PBO + ADT. Germline DDR alteration testing was performed in blood using Ambry Genetics CustomNext-Cancer panel; 16 DDR-related genes were reported in the subset of patients who consented to participate in a pharmacogenomic study (n=664; Table). Descriptive analyses of baseline demographics and disease characteristics by DDR status were performed. **Results**: Of 664 patient samples tested, 652 were evaluable for analysis (ENZA + ADT, n=326; PBO + ADT, n=326). Baseline characteristics of these patients were similar to the ARCHES intent-to-treat population. The prevalence of DDR+ patients was lower than expected (n=34/652, 5.2%; Table). Of DDR+ patients, 13 (38.2%) had low-volume disease, compared with 228 (36.9%) of DDR– patients. High-volume disease was present in 21 (61.8%) DDR+ and 390 (63.1%) DDR– patients. Of DDR+ patients, 6 (17.6%) had localized disease at initial diagnosis (M0), compared with 145 (23.5%) DDR– patients. *De novo* metastatic disease at initial diagnosis (M1) was present in 28 (82.4%) DDR+ patients and 465 (75.2%) DDR– patients. Of DDR+ patients, 29 (85.3%) were from Europe, four (11.8%) were from North America, and one (2.9%) was from the Asia-Pacific region. **Conclusions**: This *post hoc* analysis found a lower prevalence of DDR alterations in patients with mHSPC in ARCHES, compared with the 7–12% previously reported in patients with metastatic castration-resistant prostate cancer (Lozano et al. *Br J Cancer* 2021; Pritchard et al. *N Engl J Med* 2016). We did not identify differences in baseline disease characteristics based on DDR status. Clinical trial information: NCT02677896. Research Sponsor: Astellas Pharma Inc. and Pfizer Inc.

A phase 1b adaptive androgen deprivation therapy trial in metastatic castration sensitive prostate cancer. *First Author: Jingsong Zhang, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Despite early utilization of new hormonal agents (NHA, abiraterone, enzalutamide and apalutamide) in metastatic castration sensitive prostate cancer (mCSPC), increasingly more men are dying from prostate cancer. While continued development of new drugs is needed, we propose improved survival of metastatic prostate cancer can be obtained through tumor evolution informed treatment strategies. Compared to the conventional treat until progression paradigm, our previous study (NCT02415621) in metastatic castration resistant prostate cancer reported that on and off abiraterone therapy adapted to individual's PSA response dynamics can provide better cancer control with less abiraterone usage (Zhang et al, Nat Commun. 2017). Here we present the first interim analysis of our adpative therapy trial in mCSPC with a median follow up of 21 months. **Methods:** Men with asymptomatic mCSPC and no liver metastasis were enrolled after achieved > 75% PSA decline with 12 - 16 weeks of luteinizing hormone-releasing hormone (LHRH) analog, and 8 - 12 weeks of NHA. Both treatments were stopped after enrollment. PSA and testosterone levels were measured every 6 weeks, CT and bone scan were performed every 18 weeks while on study. Treatment will be restarted if subjects develop PSA or radiographic progression per prostate cancer working group 3 criteria. If the testosterone level (T) is > 100 ng/dl, LHRH analog will be restarted. If the T is between 50 and 100 ng/dl, NHA will be restarted. If the T is below 50, combined therapy with LHRH analog and NHA will be restarted. Treatment will be discontinued after achieving 50% or more PSA decline. For patients who restarted therapy for radiographic progression, partial response or stable disease needs to be documented on the post treatment scans along with PSA response prior to stopping therapy. The primary objective is feasibility, which is measured by percentage of patients who remain on study without on treatment disease progression at 12 months from first dose of LHRH analog for mCSPC. **Results:** 16 evaluable patients were enrolled between April 2019 and June 2021. Five of the 16 patients had high risk mCSPC based on the LATITUDE trial criteria. The median follow up was 21 months at the data cut off in January 2022. Only one patient was off study due to imaging progression at 27.6 months from first dose of LHRH analog for mCSPC. Three of the 16 patients developed on treatment PSA progression at month 12.3 and 15.2, and 20.5. Given none of the first 14 enrolled patients developed disease progression at 12 months, the study has already met its primary objective of feasibility. **Conclusions:** It is feasible to use individual's PSA response and testosterone level to guide intermittent therapy with LHRH analog and NHA in mCSPC. The study is ongoing to collect data on secondary endpoints of median time to PSA progression and median time to radiographic progression. Clinical trial information: NCT 03511196. Research Sponsor: Moffitt Cancer Center, Clinical Trial innovation award.

5076 **Poster Session**

Survival analysis of the randomized phase II trial to investigate androgen signaling inhibitors with or without androgen deprivation therapy (ADT) for castration-sensitive prostate cancer: LACOG 0415. *First Author: Fernando Cotait Maluf, Hospital Beneficência Portuguesa de São Paulo, Hospital Israelita Albert Einstein, Latin American Cooperative Oncology Group (LACOG), São Paulo, Brazil*

Background: LACOG 0415 is a phase II, open-label, clinical trial evaluating ADT-free alternatives for advanced castration sensitive prostate cancer (CSPC). **Methods:** Patients with locally advanced, high-risk biochemical recurrence or metastatic CSPC were randomized (1:1:1) to receive ADT with abiraterone acetate plus prednisone (ADT+AAP), apalutamide alone (APA), or apalutamide with AAP (APA+AAP). The primary endpoint of the trial was the proportion of patients who achieved PSA≤0.2 ng/mL level at week 25. Patients without disease-progression and with clinical benefit after week 25 were allowed to maintain treatment at the discretion of physicians. Herein, we presented the outcomes of 2 year-overall survival (2y-OS) and time-to-treatment failure (TTF). The time-to-event endpoint was estimated by Kaplan-Meier method and compared by stratified log-rank test. **Results:** 128 patients were randomized to the ADT+AAP (n = 42), APA (n = 42), and APA+AAP (n = 44) arms. At week 25, PSA≤0.2 ng/mL was observed in 75.6% (95%CI 59.7%-87.6%), 60.0% (95%CI 43.3%-75.1%), and 79.5% (95%CI 63.5%-90.7%) of patients in the ADT+AAP, APA, and APA+AAP arms, respectively. 110 patients continued treatment after week 25. At the 2-year visit, 80 (62.5%) patients remained on the study medication. Median TTF was 24.0 months (95%CI 23.3 - 24.0) with ADT+AAP, 24.0 months (95%CI not estimated) with APA, and 24.0 months (95%CI 13.0-24.0) with APA+AAP. The main reasons for treatment discontinuation were disease progression (n = 8, 6.3%), toxicity (n = 10, 7.8%), death (n = 6, 4.7%), withdrawal (n = 4, 3.1%), and other (n = 19, 14.8%). The estimated proportion of patients who were alive at 2 years (2y-OS rate) was 92.5% (95%CI 84.3-100) with ADT+AAP, 87.9% (95%CI 77.9-97.8) with APA, and 92.7% (95%CI 84.8-100) with APA+AAP (p = 0.5926). 2y-OS was 92.9% (95% CI 85.3 - 96.2) in patients with PSA ≤ 0.2 ng/mL at week 25, while 2y-OS was 85.0% (95% CI 72.9-97.1) in patients with PSA > 0.2 ng/mL at week 25 (p = 0.1250). **Conclusions:** Patients with advanced CSPC treated with ADT+AAP, APA, or APA+AAP had high rates of PSA response and favorable 2y-OS. PSA ≤ 0.2 ng/mL at week 25 seems to be a surrogate prognostic predictor of OS in advanced CSPC. In the overall sample, patients with PSA ≤ 0.2 ng/mL at week 25 had higher 2y-OS rate than those with PSA > 0.2 ng/mL at week 25 (92.9% vs. 85.0%), however without statistical significance. Clinical trial information: NCT02867020. Research Sponsor: Janssen-Cilag.

Estrogen receptor β and *TMPRSS2-ERG* expression association with clinical outcomes in metastatic hormone-sensitive prostate cancer. *First Author: Caterina Aversa, Medical Oncology Department, Hospital Clínic, Barcelona, Spain, Barcelona, Spain*

Background: *TMPRSS2-ERG* fusion has been associated with estrogen receptor (ER) signalling in prostate cancer (PC). The isoform beta of ER (ERβ), encoded by ESR2, is considered anti-proliferative and tumor-suppressive. In preclinical studies, ESR2 has shown an inhibitory role towards *TMPRSS2-ERG*, resulting in decreased proliferation and tumor regression. In this clinical series, we sought to investigate the correlation between *TMPRSS2-ERG* and ESR2 expression and its impact on clinical outcomes in a cohort of patients (pts) with metastatic hormone-sensitive PC (mHSPC). **Methods:** This is a multicenter retrospective biomarker study. *TMPRSS2-ERG* and ESR2 were tested in total mRNA from FFPE tumor samples by nCounter platform (Nanostring Technologies). *TMPRSS2-ERG* and ESR2 expression were correlated with castration-resistant PC free survival (CRPC-FS) and overall survival (OS) by Kaplan Meier and multivariate Cox modeling. R (v.3.6.3) software was used for statistical analysis. **Results:** 218 mHSPC pts were included: 125 received androgen deprivation therapy (ADT) with Docetaxel and 93 ADT alone. Median age was 66.4 years (range 46.3-84.6), 75.7% (*N*= 165) presented with *de novo* mHSPC, 15.1% (*N*= 33) had visceral metastasis and 68.3% (*N*= 149) had high volume disease. Median follow-up was 38.8 months (m) (range 6.7-223.5) and 189 pts (86.7%) developed CRPC. Five pts were excluded due to lack of follow-up. Median time to CRPC was 18.8 m (95% CI 15.8-20.5) and median OS was 48.8 m (95% CI 43.2-59.1). Pts were grouped according to *TMPRSS2-ERG* fusion detection in TE positive (TE+) (*N*= 108, 49.5%) and TE negative (TE-) (*N*= 110, 50.5%) and according to ESR2 expression levels segregated into tertiles in ESR2 high (ESR2+) (*N*= 74, 33.9%) or ESR2 low-mid (ESR2-) (*N*= 144, 66.1%). TE+ status was associated to higher ESR2 levels (*P*= 0.03). The TE+/ESR2+ group showed longer CRPC-FS and OS, compared with the other groups, as shown in the table. TE+/ESR2 expression was independently associated with longer CRPC-FS (HR 0.3, 95% CI 0.2-0.5, *P*< 0.001) and OS (HR 0.3, 95% CI 0.2-0.5, *P*< 0.001). Moreover, a significant interaction between treatment (ADT vs ADT+Docetaxel) and TE+/ESR2+ status related to CRPC-FS was found (HR: 0.38, *P*= 0.014), suggesting that TE+/ESR2+ pts may benefit more from ADT than from the combination of ADT+Docetaxel. **Conclusions:** Our study suggests a protective role of ESR2 within a subgroup of mHSPC pts characterized by *TMPRSS2-ERG* fusion, which warrants further investigation of ESR2 as a prognostic factor, for treatment selection and as a potential pathway for targeted treatment in PC. Association of prostate-specific antigen (PSA) response and overall survival (OS) in patients with metastatic hormone-sensitive prostate cancer (mHSPC) from the phase 3 ARASENS trial. *First Author: Fred Saad, University of Montréal Health Center, Montréal, QC, Canada*

Background: Reductions in PSA level have been associated with improved OS in patients (pts) with mHSPC. In ARASENS (NCT02799602), darolutamide (DARO) + androgen-deprivation therapy (ADT) in combination with docetaxel significantly reduced the risk of death by 32.5% (hazard ratio [HR] 0.675; 95% confidence interval [CI] 0.568–0.801; *P*< 0.0001) vs ADT + docetaxel in pts with mHSPC. We report the association between PSA response and OS from ARASENS. **Methods:** Pts with mHSPC were randomized 1:1 to DARO 600 mg twice daily or matching PBO + ADT and docetaxel. Serum PSA was measured at screening and every 12 weeks. Exploratory analyses included time to PSA progression (≥25% increase from PSA nadir [lowest or at study entry] and PSA increase ≥2 ng/mL ≥12 weeks from nadir [both confirmed by a second value ≥3 weeks later]) and undetectable PSA (< 0.2 ng/mL for 2 samples ≥3 weeks apart) at 24, 36, and 52 weeks and any time during treatment. Comparisons between treatment groups were performed using the Cochran-Mantel Haenszel test stratified by randomization stratification factors (metastatic spread according to TNM classification and alkaline phosphatase levels at study entry). Post hoc landmark analyses evaluated the association between undetectable PSA at weeks 24 and 36 and OS for the overall population. **Results:** Of 1306 randomized pts, 1305 were included in the full analysis set (DARO 651; PBO 654), both with ADT and docetaxel. Median (range) PSA levels at study entry were 30.3 (0.0–9219.0) and 24.2 (0.0–11,947.0) ng/mL, respectively. DARO significantly prolonged time to PSA progression (HR 0.255; 95% CI 0.208–0.313; *P*< 0.0001). Undetectable PSA was achieved in more pts receiving DARO (48.7%) vs PBO (23.9%) at 24 weeks, and the rate continued to increase at 36 and 52 weeks in the DARO group to 57.1% and 60.2%, respectively, vs minimal change in the PBO group (25.1% and 26.1%). Undetectable PSA levels at any time were achieved in 67.3% in the DARO group and 28.6% in the PBO group. A treatment difference in undetectable PSA based on non-overlapping 95% CIs was observed at all time points. For the overall population, OS was improved for pts who achieved undetectable PSA levels vs those who did not at 24 weeks (HR 0.398; 95% CI 0.321–0.493) and 36 weeks (HR 0.351; 95% CI 0.284–0.434). Additional baseline and safety data by PSA level will be reported. **Conclusions:** The combination of DARO + ADT and docetaxel significantly prolonged the time to PSA progression and more pts receiving DARO vs PBO achieved undetectable PSA levels, reflecting strong PSA response over time. In pts with mHSPC, achievement of undetectable PSA at 24 and 36 weeks was associated with improved OS, with risk of death reduced by 60% and 65%, respectively, vs those who did not achieve undetectable PSA at 24 and 36 weeks. Clinical trial information: NCT02799602. Research Sponsor: Bayer AG and Orion Pharma.

Effect of docetaxel (D) use on survival outcomes in patients with metastatic castration-sensitive prostate cancer (mCSPC) treated with novel hormonal therapies (NHTs): A meta-analysis. *First Author: Deniz Can Guven, Hacettepe University Cancer Institute, Department of Medical Oncology, Ankara, Turkey*

Background: ARASENS and PEACE-1 trials have shown that the addition of NHTs to D + androgen deprivation therapy (ADT) improves overall survival (OS) outcomes in mCSPC. However, whether a true synergism is present with using NHT+ADT+D is unknown due to the lack of a trial testing the efficacy of adding D to the NHT+ADT backbone. Our objective was to evaluate the survival outcomes with NHTs according to D use in mCSPC. **Methods:** The literature search was done from PubMed and Embase databases to identify published studies until February 12th, 2022 for meta-analysis. The MeSH search terms were "castration-sensitive prostate cancer" OR "hormone-sensitive prostate cancer" OR "hormone-naïve prostate cancer" AND "abiraterone" OR "apalutamide" OR "enzalutamide" OR "darolutamide". The target outcome measures were progression-free survival (PFS) and OS. Generic inverse-variance method with a fixed-effects model was used, with hazard ratios with 95% two-sided confidence intervals (CI) as the principal summary measure (Review Manager software, version 5.3, The Nordic Cochrane Center, The Cochrane Collaboration, Copenhagen, Denmark). P values below 0.05 were considered statistically significant. **Results:** The literature search retrieved a total of 2565 records. Six phase III studies encompassing 6701 patients evaluating survival outcomes with NHTs in mCSPC (TITAN, ARCHES, ENZAMET, LATITUDE, STAMPEDE Abi- M1, and PEACE-1) were included after filtering of the available records. Results summarized in below table. In the combined analysis, the addition of NHTs to standard of care (SOC) improved PFS and OS. PFS benefit with NHTs was similar in studies (or study subgroups) with or without D use. However the relative OS benefit with a NHT was higher in studies (or study subgroups) without D than studies permitting D (concurrent or sequential). **Conclusions:** In this meta-analysis, the PFS and OS benefit with NHT in mCSPC was observed independent of D use. A randomized phase III study comparing D+NHT+ADT with NHT+ADT is needed to evaluate the contribution of D to survival outcomes in patients with mCSPC receiving treatment with NHT+ADT. Research Sponsor: None.

Summary results of PFS and OS benefit with NHT + ADT regardless of D use and without or with D.

	PFS HR (95% CI, p-value)	OS HR (95% CI, p-value)
NHT+SOC vs SOC (SOC: ADT or ADT+D)	0.49 (0.45-0.53, <0.001)	0.68 (0.63-0.73, <0.001)
NHT+ADT vs ADT	0.49 (0.45-0.53, <0.001)	0.62 (0.57-0.68, <0.001)
NHT+ADT+D vs ADT+D (sequential or concurrent)	0.49 (0.42-0.58, <0.001)	0.81 (0.67-0.96, 0.020)

Transcriptomic profiling of patients (pts) with de-novo metastatic castration-sensitive prostate cancer (DN-mCSPC) versus those with mCSPC that have relapsed from prior localized therapy (PLT-mCSPC). *First Author: Nicolas Sayegh, Huntsman Cancer Institute-University of Utah Health Care, Salt Lake City, UT*

Background: Pts with DN-mCSPC have been reported to experience worse prognosis and outcomes compared to those with PLT-mCSPC. We hypothesized that gene expression profiling of pre-treatment primary prostate tumors from PLT-mCSPC pts would be distinct from those with DN-mCSPC. **Methods:** Eligibility criteria: histologically confirmed mCSPC and available RNAseq profiling performed by a CLIA certified lab using primary prostate biopsies collected prior to start of treatment. Pts were categorized into two cohorts: PLT-mCSPC versus DN-mCSPC. The DEseq2 pipeline was used to analyze differentially expressed genes between the groups. The data included the Log2 fold change, Wald-Test p-values, and Benjamini-Hochberg adjusted p-values for each differentially expressed gene. These results were subjected to Gene Set Enrichment software analysis (GSEA) in order to identify pathways enriched in each cohort. All bioinformatic analysis was undertaken using R v4.2. **Results:** Ninety-seven (97) patients met eligibility (52 PLT, 45 *de novo*). Characteristics of the overall eligible pts: median age = 65, median baseline PSA = 12.6, Gleason score ≥8 = 71%, and high volume of disease = ~30%. Differential expression and pathway enrichment between cohorts: upregulation of cell-cycle signaling pathways (G2-M checkpoint, E2F) in pts with DN-mCSPC, and upregulation of androgen signaling and immune pathways (inflammatory response, NFKB-mediated TNF-alfa signaling) in pts with PLT-mCSPC (Table). **Conclusions:** These hypothesis-generating data, upon external validation, may provide the rationale for personalized therapy in men with mCSPC, such as the use of CDK4/6 inhibitors in addition to standard of care intensified ADT in men with DN-mCSPC. Research Sponsor: None.

Gene set enrichment scores contrast PLT versus *de novo* pts.

PATHWAY	NORMALIZED ENRICHMENT SCORE (NES)	P-value	P-adjust	Q-values
E2F TARGETS	-2.19	2.99E-10	1.50E-08	1.13E-08
G2M CHECKPOINT	-1.81	6.06E-06	1.01E-04	7.65E-05
ANDROGEN RESPONSE	1.57	0.006003	0.03335	0.02528
INFLAMMATORY RESPONSE	1.60	4.98E-04	0.004976	0.003771
TNFA SIGNALING VIA NFKB	2.08	8.43E-10	2.11E-08	1.60E-08

NES: positive values favor upregulation of PLT pts, negative values favor upregulation of de novo pts.

5081 **Poster Session**

Eight-year survival rates by baseline prognostic groups in patients with metastatic hormone-sensitive prostate cancer (mHSPC): An analysis from the ECOG-ACRIN 3805 (CHAARTED) trial. *First Author: Abhishek Tripathi, Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: To date there is no prospective survival data beyond 5 years for patients treated with ADT with or without docetaxel (D) when analyzed by well-defined baseline prognostic risk groups and treatment arms. In this updated analysis of the CHAARTED trial, we report the 8-year survival rate based on disease volume and metachronous vs. *de novo* metastatic disease status with ADT without or with docetaxel. **Methods:** An updated survival sweep was conducted in February 2022. Patients were prospectively identified by the state of metastatic disease as metachronous (prior local therapy) vs. *de novo* and low volume (LV) vs. high volume (HV; visceral and/or ≥4 bone metastases with one lesion beyond the vertebral bodies or pelvis) disease. Overall survival (OS) was defined as time from randomization to death or date last known alive and calculated using the Kaplan-Meier method. **Results:** Of the 790 patients randomized (last patient enrolled December 2012), 238 patients were still alive with a median follow up of 9.7 years for patients still alive. Median OS in the overall population was 60.4 and 47.2 mos in the ADT+ D and ADT arms respectively (Table; HR: 0.77; 95% CI: 0.65, 0.92; p=0.004). ADT+ D was associated with significantly higher 8-yr OS rate (28.5%) compared to ADT arm (15.4%; HR: 0.67; 95% CI: 0.53, 0.84; p=0.0005) in the *de novo* HV group (n=421). Notably, the 8-yr OS rates were almost doubled for patients with HV disease with early docetaxel (16% vs.30.2%, p<.0001) and this was seen in patients with both *de novo* and metachronous HV mHSPC. **Conclusions:** In this long-term updated analysis, ADT+D continued to demonstrate significantly improved OS in the overall population and this is still most clearly evident in patients with *de novo* HV mHSPC. Our findings highlight the role of baseline prognostic risk groups in predicting longer term survival and benefits from treatment intensification. Clinical trial information: NCT00309985. Research Sponsor: U.S. National Institutes of Health, Supported in part by a grant from the National Cancer Institute, National Institutes of Health, Department of Health and Human Services, and by grants (CA180820, CA180794, CA180795, CA180802, CA180799, CA180790, CA180853, CA189829, CA180801, CA180888, CA31946, and CA180821) from the Public Health Service. Sanofi provided the docetaxel and a grant to ECOG-ACRIN.

A randomized phase Ib/II study of intermittent androgen deprivation therapy plus nivolumab with or without interleukin-8 blockade in men with hormone-sensitive prostate cancer (MAGIC-8). *First Author: Matthew Dallos, Columbia University, New York, NY*

Background: Immunotherapy has limited efficacy in castration-resistant prostate cancer. Androgen deprivation therapy (ADT) has significant immunomodulatory effects and initially induces a complex immune infiltrate before castration-resistance develops. However, ADT also recruits immunosuppressive myeloid cells to the tumor microenvironment by increasing interleukin-8 (IL-8). We conducted a phase Ib/II clinical trial of immunotherapy plus ADT in men with recurrent castration-sensitive prostate cancer (CSPC). We hypothesized that anti-PD-1 (nivolumab) +/- anti-IL-8 (BMS-986253) given at the time of castration could induce anti-tumor immune responses and decrease disease progression. **Methods:** MAGIC-8 was a multicenter, phase Ib/II study evaluating nivolumab +/- BMS-986253 combined with a short course of degarelix acetate in patients with recurrent CSPC and rapid PSA doubling time (≤ 12 mos). In the Phase Ib portion, patients were treated with nivolumab (480mg Q4W) for 8 wks followed by nivolumab plus degarelix for an additional 16 wks. In the phase II portion, patients were randomized 1:2 to nivolumab + degarelix (Arm A) versus nivolumab + BMS-986253 (2400mg Q2W) + degarelix (Arm B). The primary endpoints were PSA recurrence at 10 mos following randomization and safety. Key secondary endpoints included biochemical recurrence-free survival (bPFS), time to recovery of testosterone (> 150ng/dl), and bPFS after recovery of testosterone. **Results:** Between October 16, 2019 and March 9, 2021, 59 patients were enrolled. The first 15 patients were treated on Arm A followed by 1:2 randomization to Arm A (N = 15) versus Arm B (N = 29). Median follow up was 11.6 mos at the data cutoff (1/24/22). Patients treated on Arm A had a significantly lower rate of PSA relapse (17.39%) at 10 mos compared to historical controls (p = < 0.001), including a subgroup of patients (6.67%) with recovery of testosterone and no PSA relapse at > 2 years of follow up. Median time-to-recovery of testosterone was 12.7 mos, median bPFS was 14.0 mos and median bPFS after recovery of testosterone was 5.5 mos. In Arm B, there was no difference in PSA relapse at 10 mos (35%, p = 0.09), median time-to-recovery of testosterone, median bPFS and median bPFS after recovery of testosterone compared to historical controls. Treatment in both arms was well tolerated with a lower rate of grade 3-4 treatment-related adverse events in Arm B compared to Arm A (3.5% vs 12.9%). **Conclusions:** A short course of ADT plus nivolumab may decrease the rate of PSA relapse and lead to durable long-term responses after recovery of testosterone in a subset of patients. These data support further evaluation of combining nivolumab with ADT in CSPC. Although the addition of BMS-986253 did not improve rate of PSA relapse, we observed significantly less toxicity with the addition of IL-8 inhibition. Clinical trial information: NCT03689699. Research Sponsor: Bristol-Myers Squibb, Other Foundation.

Indirect comparisons of triplet therapy as compared to novel hormonal therapy doublets in patients with metastatic castration sensitive prostate cancer. *First Author: Syed Arsalan Ahmed Naqvi, Mayo Clinic, Phoenix, AZ*

Background: ARASENS and PEACE-1 trials suggests treatment intensification with novel hormonal therapy (NHT) in addition to androgen deprivation therapy (ADT) and docetaxel (DOC) provides survival benefit as compared to DOC+ADT in patients with metastatic castration sensitive prostate cancer (mCSPC). However, the performance of triplet therapy as compared to NHT+ADT remains unexplored. **Methods:** MEDLINE, EMBASE and recent conference proceedings were searched to include phase III trials evaluating triplet therapy in patients with mCSPC and reporting treatment effects in subgroup of patients with and without docetaxel. Outcomes included overall survival (OS) and radiographic progression free survival (rPFS). Precomputed hazard ratios (HRs) and confidence intervals (CIs) from non-randomized subgroup comparisons were pooled after logarithmic transformation using inverse-variance weighting approach. A DerSimonian-Laird random-effects meta-analysis was then performed to assess subgroup differences. Interaction between subgroups was assessed using P-value of heterogeneity. Mixed treatment comparisons were computed using a fixed-effect model within the frequentist framework using subgroup effect estimates from eligible trials. **Results:** This meta-analysis included five clinical trials (ARASENS, PEACE-1, ENZAMET, ARCHES and TITAN) with a total of 5804 patients (docetaxel: 2836; no docetaxel: 2836). Subgroup analysis showed statistically significant difference between treatment effects in patients who received docetaxel (NHT + DOC + ADT; HR: 0.74; 95% CI: 0.66-0.84; I^2: 0%) and those who did not (NHT + ADT; HR: 0.61; 95% CI: 0.53-0.70; I^2: 0%) for OS (p-value of interaction: 0.04). However, no statistically significant interaction was observed in terms of rPFS (p-value: 0.46). Mixed treatment comparisons showed improved OS with NHT + DOC + ADT (HR: 0.74; 95% CI: 0.66-0.84) as compared to DOC + ADT, but not when compared to NHT + ADT (HR: 0.97; 95% CI: 0.78-1.20). NHT + ADT significantly improved OS compared to DOC + ADT (HR: 0.77; 95% CI: 0.64-0.92). Consistently, significant rPFS improvement was observed with NHT + DOC + ADT when compared DOC + ADT (HR: 0.49; 95% CI: 0.42-0.57) but not when compared to NHT + ADT (HR: 0.82; 0.65-1.04). NHT + ADT was observed to improve rPFS compared to DOC + ADT (HR: 0.60; 95% CI: 0.50-0.72). **Conclusions:** This exploratory and hypothesis generating analysis suggests that addition of docetaxel (triplet therapy) may not delay progression or prolong survival compared to NHT-based doublets. These findings provide direction for future clinical trials in this space and suggest an equipoise to the question of how triplet regimens compare with NHT-doublets. The results should be interpreted with caution as this analysis does not account for potential confounding relationships such as volume of disease. Research Sponsor: None.

5084 **Poster Session**

Patient (pt) population and radiation therapy (RT) type in the long-term phase 3 double-blind, placebo (PBO)-controlled ATLAS study of apalutamide (APA) added to androgen deprivation therapy (ADT) in high-risk localized or locally advanced prostate cancer (HRLPC). *First Author: Howard M. Sandler, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: Current management of HRLPC includes long-term ADT with primary RT. Despite definitive primary treatment, these pts have a high risk of metastasis and death. The phase 3 ATLAS study (NCT02531516) is investigating whether treatment intensification with the addition of APA to neoadjuvant and adjuvant treatment with gonadotropin-releasing hormone agonist (GnRHa) and external beam radiation therapy (EBRT) will improve metastasis-free survival (MFS) in high-risk pts. Here we describe (1) the distribution of baseline characteristics in this high-risk pt population and (2) the application of different RT regimens reflecting recent international guidelines and clinical practice changes for pts with HRLPC. **Methods:** Eligible HRLPC pts (Gleason score [GS] ≥ 8 or 7 and prostate-specific antigen [PSA] ≥ 20 ng/mL and stage ≥ cT2c), with ECOG PS 0/1 and Charlson Comorbidity Index (CCI) ≤ 3 are stratified by GS, pelvic nodal status, use of brachytherapy boost, and region; pts are randomized 1:1 to APA or PBO plus GnRHa for 30 (28-d) treatment cycles. Study treatment is applied neoadjuvant/concurrent to RT with APA 240 mg/d vs bicalutamide 50 mg/d for 4 cycles; another 26 cycles are completed adjuvantly after RT with APA 240 mg/d vs PBO. Primary end point is MFS (time from randomization to first distant metastasis on CT/MRI/bone scan by independent central review blinded to treatment or death from any cause). Imaging is conducted at baseline and q6m from biochemical failure until MFS. The protocol has been amended to include PET imaging (PSMA, fluciclovine, or choline). **Results:** Pts (N = 1503) were randomized at 266 sites in 24 countries in North America, Latin America, Europe, and Asia. The study is fully enrolled, but ongoing. Baseline characteristics for the total population: median age, 67 yrs; ECOG PS 0/1; 89%/11%; tumor classification at study entry: high-risk, 66%/very high–risk, 34%; median PSA, 6.3 ng/mL; cT2, 44%/cT3, 50%; cN1, 13%. In 90% of ATLAS pts, RT used was standard EBRT to prostate/pelvis over 6-8 weeks (cumulative 78-81 Gy); in 10%, recent hypofractionation schedules (per CHHiP or NRG/RTOG 0415) were applied (20x3 Gy/d or 28x2.5 Gy/d). 5.6% of pts had EBRT combined with brachytherapy (per ASCENDE-RT). **Conclusions:** Baseline characteristics of the ATLAS study population are reflective of pts with high- and very high–risk features and pelvic nodal involvement undergoing primary RT in clinical practice. The RT schedules applied reflect recent evidence and guideline changes for the use of hypofractionation in this pt population. ATLAS is an example of how RT can be included in phase 3 trials of HRLPC, in combination with next-generation androgen receptor inhibitors (eg, APA). Clinical trial information: NCT02531516. Randomized phase II trial of neoadjuvant androgen deprivation therapy plus abiraterone and apalutamide for patients with high-risk localized prostate cancer: Pathologic response and PSMA imaging correlates. *First Author: Diogo Assed Bastos, Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil*

Background: Patients (pts) with high-risk localized prostate cancer (HRLPC) have a significant risk of disease recurrence and metastasis after radical prostatectomy (RP). Neoadjuvant therapy remains investigational but there may be a role for the next-generation androgen signaling inhibitors. We sought to evaluate pathologic and imaging response after the intense neoadjuvant approach. **Methods:** This is a phase II investigator-initiated randomized trial of 3-month neoadjuvant therapy with goserelin (androgen deprivation therapy, ADT) + abiraterone acetate and prednisone (AAP arm) or AAP + apalutamide (A-APA arm) before RP for pts with HRLPC (Gleason ≥ 8 and/or cT3N0-1 and/or PSA ≥ 20 ng/mL). The primary endpoint was the rate of pathologic complete response (pCR) or minimal residual disease (MRD, tumor ≤ 0.5 cm). The secondary endpoints were safety, rate of residual cancer burden ≤0.25 cm^3 (RCB = tumor volume x cellularity), Gallium 68 prostate-specific membrane antigen (PSMA) positron emission tomography (PET)/magnetic resonance correlates and rate of biochemical relapse (BR). **Results:** Sixty-two pts were randomized to A-APA (N = 31) or AAP (N = 31). Median age was 65 (range 47-77) years. NCCN risk groups included high-risk disease in 19%, very high-risk in 76% and regional (N1) disease in 5% (79% cT3, 65% Gleason 8-10, 57% PSA ≥ 20 ng/mL). Outcomes after intense neoadjuvant ADT are described in the Table. There was no statistically significant difference between study arms regarding pCR/MRD or RCB ≤ 0.25 cm^3 rates. Patients with complete PSMA-PET response (psmaCR) demonstrated a RCB ≤ 0.25 cm^3 rate of 50% compared to 7.5% in pts without a psmaCR (P= 0.001). The rate of BR was 14% for pts with RCB ≤ 0.25 cm^3 versus 38% in pts with RCB > 0.25 cm^3 (P= 0.118). At current median follow-up of 2.6 years, all patients with both psmaCR and RCB ≤ 0.25cm^3 (N = 11, 18%) are free of BR. There were 2 grade (G) 5 adverse events (AEs) in the AAP arm (pulmonary embolism and sudden death, both after surgery). Nine (14.5%) pts (6 in A-APA; 3 in AAP) experienced G3-4 treatment-related AEs. The most common G3-4 AEs were hypertension (11.3%), AST/ALT elevations (3.2%) and skin rash (1.6%). **Conclusions:** No difference in pCR or MRD was observed between arms. Although pCR or MRD after intense neoadjuvant ADT was infrequent, a significant proportion of pts achieved a favorable pathologic response with RCB ≤ 0.25 cm^3. PSMA-PET response is a potential surrogate for pathologic response. Clinical trial information: NCT02789878. Research Sponsor: Janssen.

Outcomes after intense ADT.

	A-APA (N = 31)	AAP (N = 31)	*P* value
Complete PSMA response	15 (48%)	7 (23%)	0.034

Comparative healthcare research outcomes of novel Surgery in prostate cancer (IP4-CHRONOS): Pilot RCT assessing feasibility of randomization for focal therapy in localized prostate cancer. *First Author: Deepika Reddy, Imperial College London, London, United Kingdom*

Background: Randomised comparative data is lacking for focal therapy in localised prostate cancer. Imperial Prostate 4 CHRONOS (IP4- CHRONOS) is an RCT designed to reflect patient and physician equipoise to maximise acceptance to randomisation. **Methods:** Patients and physicians could opt for CHRONOS-A or CHRONOS-B. CHRONOS-A randomised between focal therapy (HIFU/cryotherapy) and radical therapy (radiation/prostatectomy). Using a multi-arm-multistage design, CHRONOS-B randomised between focal and focal combined with neoadjuvant medication (3 months of either finasteride or bicalutamide). We report the pilot phase outcomes on feasibility of randomisation. IP4-CHRONOS had ethics committee approval and was registered (ISRCTN17796995). **Results:** Due to impact of COVID-19, the target for CHRONOS-A was modified from 60 to 36; 36 patients were randomised over 24 months from 7 sites (Nov/2019-Nov/2021). CHRONOS-B randomised 64 patients over 14 months across 6 sites (Dec/2019-Feb/2021). Median (IQR) age and PSA (ng/ml) for CHRONOS-A were 69 (65-72) years and 6 (5-7) and for 66 (60.5-70) years and 6 (4-7) for CHRONOS-B, respectively. 34/36 (94%) and 60/64 (94%) had ISUP Grade Group > / = 2, respectively. 4/18 (22%) randomised to radical in CHRONOS-A withdrew consent; 1/22 (5%) randomised to focal withdrew. In CHRONOS-B, only 1/21 (5%) randomised to focal alone, and another randomised to focal with neoadjuvant bicalutamide withdrew. A qualitative recruitment intervention partially improved accrual to CHRONOS-A. **Conclusions:** IP4-CHRONOS evaluated patient and physician equipoise regarding focal therapy. Randomising between focal and radical therapy is not feasible due to strong patient preferences. A multi-arm, multi-stage RCT investigating the role of neoadjuvant agents combined with focal therapy is feasible. Clinical trial information: 17796995. Research Sponsor: Prostate Cancer UK.

Diagnosed with advanced prostate cancer: A population-based cohort from national oncology practices. *First Author: Simon P. Kim, University of Colorado Cancer Center Anschutz Medical Campus, Denver, CO*

Background: Clinical trials can provide access to novel systemic agents and possible improved survival for men diagnosed with regional and metastatic prostate cancer. Although clinical trials should be accessible to all patient populations, racial disparities to enrollment of clinical trials and its outcomes remain an important unknown outcome. Herein, we sought to elucidate the racial disparities in clinical trial enrollment and survival amongst advanced prostate cancer patients from a large community-based medical oncology consortium. **Methods:** Using CancerLinQ, we identified all patients who were diagnosed with regional (N1+) and/or metastatic (M1) prostate cancer from 2011 – 2021. Enrollment into a clinical trial and overall survival constituted the primary outcomes in this study. Multivariable logistic regression and Cox proportional hazard regression were used to identify covariates associated with each outcome. **Results:** Amongst the 160,888 patients with regional/metastatic prostate cancer, only 1.5% patients were enrolled in a clinical trial (n = 2,368). On multivariable analysis, patients with worse ECOG performance status were associated with lowers odds of clinical trial enrollment ($p < 0.001$). Relative to white patients, African-American men (AAM) also had lower odds of clinical trial enrollment (OR: 0.67; $p < 0.001$). For the entire cohort, clinical trial enrollment correlated with higher survival (HR: 1.19; $p < 001$) and lower survival for AAM men (HR: 0.85; $p < 0.001$) compared to white men after adjusting for other covariates. In the subgroup analysis of patients enrolled in clinical trials, AAM demonstrated similar survival to white patients (HR: 0.96, $p = 0.95$). **Conclusions:** Although African-American men with regional/metastatic prostate cancer face barriers to clinical trial enrollment, racial disparities in survival appear to resolve for patients who enroll in clinical trials. Increased attention is needed to address barriers to communication and access to clinical trials. Research Sponsor: Schramm Foundation.

Predictive value of extra-prostatic disease detection by pre-operative PSMA-PET for biochemical recurrence-free survival in patients treated with radical prostatectomy: Follow-up analysis of a multicenter prospective phase 3 imaging trial. *First Author: Loic Djaileb, UCLA Ahmanson Translational Theranostics Division, Los Angeles, CA*

Background: To assess the predictive value of pre-operative PSMA-PET staging for biochemical recurrence (BCR) free-survival (BCR-FS) in patients treated with radical prostatectomy (RP) and pelvic lymph node dissection (PLND) with intermediate-risk (IR) to high-risk (HR) prostate cancer (PCa) included in the prospective trial used for the FDA approval of 68Ga-PSMA-11. **Methods:** This is a post-hoc follow-up study of the efficacy analysis cohort included in the multicenter prospective phase 3 imaging trial (n = 764; NCT03368547, NCT02611882, NCT02919111) which assessed the diagnostic accuracy of ^{68}Ga-PSMA-11 PET for pelvic nodal metastasis detection prior to RP and PLND in patients with IR and HR PCa. Each PSMA-PET scan was read by three blinded independent readers. Readers assessed the presence of PCa (positive vs negative) by region: prostate bed (T), pelvic lymph nodes (N), extra-pelvic lymph nodes (M1a) bone (M1b) and visceral (M1c). A centralized per-region majority rule was used in case of disagreement. The surgical pathology report was used to assess the presence of pelvic lymph node metastasis by histopathology (pN0 vs pN1). The patients were followed up for biochemical progression after RP by the local investigators using electronic medical records. BCR was defined by a prostate-specific antigen (PSA) level > 0.2 ng/ml after RP or an initiation of PCa specific adjuvant/salvage therapy. Pairwise comparisons using Log-Rank test was performed to evaluate BCR-FS between the pre-operative PSMA scan reads (N0M0 vs. N+ and/or M+) and the histopathology status (pN0 vs. pN1). **Results:** From December 2015 to December 2019, a total of 764 patients were enrolled in the trial. 277/764 (36%) underwent RP after PSMA-PET. Clinical follow-up was obtained in 240/277 (87%) patients. The median age was 67 years (interquartile range, 61-71 years). The median follow-up time from RP was 21.4 months (IQR: 8.80 - 31.53). One hundred BCR events (41%) were observed, and 98/240 patients underwent salvage therapy or other treatment (40.6%). The BCR-FS was 24.3 (IQR: 7.8 - 48.8) in the whole cohort. 160/240 (66%), 28/240 (11.6%), 39/240 (16%), 13/240 (5.4%) patients were pN0/PSMA- (N0 and M0), pN+/PSMA+ (N+ and/or M+), pN+/PSMA-, and pN0/PSMA+, respectively. BCR-FS was higher in PSMA- than in PSMA+ patients (33 vs 7.3 months; $p < 0.0001$). BCR-FS was higher in pN0/PSMA- than in patients pN+/PSMA-, pN0/PSMA+ and pN+/PSMA+: 46 months vs 12.3, 11.7, and 3, respectively ($p < 0.001$). BCR-FS did not significantly differ between pN0/PSMA+ and pN+/PSMA- (11.7 vs 12.3; $p = 0.64$). **Conclusions:** PSMA PET staging information is predictive of BCR-FS after RP. Patients with extra-prostatic disease detected by pre-operative PSMA-PET scan have a high risk of biochemical relapse. Clinical trial information: NCT03368547. Research Sponsor: None.

Salvage radiotherapy guided by functional imaging for macroscopic local recurrence following radical prostatectomy: A multicentric retrospective study. *First Author: Nicolas Benziane Ouaritini, Institut Bergonié, Bordeaux, France*

Background: For prostate cancer (Pca), salvage radiotherapy (sRT) with or without androgen deprivation therapy (ADT) is currently the only curative treatment option in case of post-radical prostatectomy (RP) biochemical relapse (BR). Functional imaging techniques have shown that macroscopic recurrence (MR) in the prostate bed (PB) are frequent. In this study, we aimed to assess efficacy and safety of sRT in patients with MR inside the PB proven by functional imaging. **Methods:** A multicenter retrospective study was conducted in 16 European centers. Patients were included if they displayed BR after RP for Pca, with MR only in the PB proven by functional imaging. All patients had to be eligible for sRT. The overall population was divided along 4 groups according to the delivered treatment: dose escalation on MR (A), dose escalation on PB (B), double dose escalation MR+PB (C), no dose escalation (D). The primary endpoint was progression-free survival (PFS). Secondary outcomes included the metastasis-free survival (MFS), biochemical PFS (bPFS) and overall survival (OS). Grade ≥2 genito-urinary (GU) and gastro-intestinal (GI) acute and late toxicities were collected. **Results:** Between January 2000 and December 2019, 363 patients with isolated MR after RP for Pca were treated by sRT. The median pre-sRT PSA level was 0.63ng/mL (range, 0.2-23.6). At the time of BR, 266 (73%) patients presented MR in the PB proven by magnetic resonance imaging, and 110 (30%) by positron emission tomography. The median follow-up was 53.6 months (range, 47.52; 58.32). The 5-year PFS and MFS were 70% (95%CI [63.8-75.4]) and 83.7% (95%CI [78.4-87.8]), respectively. Grade ≥2 GU and GI late toxicities were found in 43 (12%) and 11 (3%) patients, respectively. A 5-year PFS benefit was highlighted for groups A, B and C (313 patients) when the MR dose was ≥72Gy: 72,8% (95%CI 64.6-79.4) versus 60.3% (95%CI 48,4-70,3), $p = 0.03$. **Conclusions:** In a modern series integrating functional imaging data, we confirmed that sRT is effective in the event of MR inside the PB, with an acceptable toxicity profile. In addition, with the help of functional imaging, we found that dose escalated ≥ 72 Gy on the MR had a significant impact on PFS. Prospective data should further investigate the correlation between MR-targeted dose escalation and PFS. Research Sponsor: None.

Recurrence, metastasis, and survival after radical prostatectomy in the era of advanced treatments. *First Author: Kristian D. Stensland, Dow Division of Health Services Research, Department of Urology, University of Michigan Medical School, Ann Arbor, MI*

Background: Accurate survival estimates after prostatectomy are critical for patient counseling, treatment decisions, and trial design. Prior prostate cancer natural history studies may not reflect contemporary outcomes and often lack key endpoints (e.g. incident metastases). For these reasons, we explored population-based recurrence and survival following radical prostatectomy. **Methods:** We conducted a retrospective study of men with localized prostate cancer treated with radical prostatectomy from 2005-2015 with follow up through 2019 in the Veterans Health Administration. We excluded men with adjuvant radiation or hormonal therapy and defined biochemical recurrence (BCR) as a PSA ≥0.2 ng/mL. We used a validated natural language processing encoded dataset to identify incident metastatic disease. We then estimated actuarial time from surgery to BCR, BCR to metastatic disease, and metastatic disease to death using Kaplan-Meier methods. **Results:** Of 22,033 men post-prostatectomy, 5,963 (27%) developed BCR, with 5- and 10-year BCR estimates of 21% and 29% (Table). Of 5,963 men with BCR, 678 (11%) developed metastasis, with 5- and 10-year metastasis-free survival from time of BCR of 91% and 77%. Of these 678 men with metastases, 235 died (35%), with 5- and 10-year overall survival of 61% and 47%. Median actuarial overall survival from incident metastatic disease was 8.8 years. **Conclusions:** On average, we found a man undergoing radical prostatectomy for localized prostate cancer can expect about a 1 in 4 chance of biochemical recurrence. Of men with BCR, we identified a 1 in 10 chance of developing metastases, surviving nearly 9 years after incident metastasis. Both metastasis-free survival after biochemical recurrence and overall survival after developing metastasis appear to have lengthened consistent with a long natural history after prostate cancer surgery. Novel advanced prostate cancer treatments may help explain these findings, though their optimal use warrants further study especially as advanced imaging techniques to characterize recurrence increase. Research Sponsor: U.S. National Cancer Institute.

National cohort of radical prostatectomy patients (n=22,033).

Characteristics	
Age at diagnosis (mean, (SD))	61.7 (6.2) years
Follow-up time (months, median, IQR)	111.3 (37.6) months
TNM stage

Methylated DNA markers in urine aid in the selective identification of patients with prostate cancer as well as clinically significant pathology. *First Author: Paras Shah, Mayo Clinic, Rochester, MN*

Background: Controversy surrounding prostate-specific antigen (PSA) based screening for prostate cancer (PCa) highlights the need for non-invasive assays that better discriminate patients with and without clinically significant prostate cancer (csPCa). Such distinction avoids overtreatment in patients with absent or indolent disease while capturing pathology that would derive benefit from intervention. We analyzed the presence of specific methylated DNA markers (MDMs) within urine samples of patients with biopsy proven PCa and assessed the ability to discriminate these patients from healthy controls with no clinical suspicion for PCa. **Methods**: 24 healthy volunteers with no clinical suspicion for PCa were age-matched to 24 patients with biopsy-confirmed disease across all Gleason scores. Urine collected from subjects was centrifuged with the cell-free supernatant analyzed in a blinded fashion for methylation signal within specific DNA sequences across 14 genes (*HES5, ZNF655, ITPRIPL1, MAX.chr3.193, SLCO3A1, CHST11, SERPINB9, WNT3A, KCNB2, GAS6, AKR1B1, MAX.chr3.727, GRASP, ST6GALNAC2*) by target enrichment long-probe quantitative-amplified signal assays. A patient was considered to have a positive MDM panel if any individual marker exceeded the corresponding100% specificity cut-off value (overall MDM panel specificity of 100%). MDM panel positivity was used to evaluate the sensitivity for distinguishing patients with PCa (any Gleason score) from controls as well as discriminate csPCa cancers from PCa Gleason 6. **Results:** Median age of healthy controls and PCa patients was 70 years (IQR 67-72) and 65 years (IQR 61-71), respectively. Median PSA was 6.4 (IQR 4.9-9.0) among PCa patients, including median PSA of 5 (IQR 4.0-6.1) for Gleason 6, and 7.8 (IQR 5.1-9.2) for Gleason ≥7 disease. Gleason 6, Gleason 7, and Gleason 8+ cancer was noted in 8, 10, and 6 patients, respectively. Utilizing an overall specificity cut-off of 100% for discriminating normal controls from PCa cases across the MDM panel revealed an overall sensitivity of 83% (95% CI: 63-95%) for detection of PCa (6 of 8 Gleason 6, 9 of 10 Gleason 7, 5 of 6 Gleason 8+) and 88% (95% CI: 62-98%) for csPCa (Gleason ≥ 7). When considering a 100% specificity threshold for controls and Gleason 6 patients, the sensitivity the MDM panel was 69% (95% CI: 41-89%) for csPCa (6 of 10 Gleason 7, 5 of 6 Gleason 8+). **Conclusions:** We describe a panel of 14 MDMs within urine that offer high specificity and sensitivity for detection of prostate cancers as well as selective identification of clinically significant disease states. Prospective comparison between urine MDMs and PSA blood testing is necessary to discern the differential clinical impact of each screening methodology. Research Sponsor: Exact sciences.

Is there a role for surgery after chemotherapy in recurrent/metastatic adrenal cortical cancer (ACC)? *First Author: Esmail Mutahar Al-Ezzi, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada*

Background: ACC is a rare endocrine malignancy. Patients with metastatic disease at diagnosis are often treated palliatively with systemic therapy. It is unclear if neoadjuvant cytoreduction with chemotherapy can render metastatic or previously resected but locally recurrent patients become surgical candidates and impact overall survival (OS). **Methods:** A retrospective single institution review (2002-2019) of metastatic ACC patients was performed. Descriptive statistics were used and OS was estimated by Kaplan-Meier method. **Results:** Out of 84 patients with metastatic ACC [30 (20.7%) upfront and 54 (37.2%) after definitive therapy], 51 received systemic therapy with mitotane and etoposide-doxorubicin-cisplatin (EDP) as standard 1st line regimen and varied subsequent lines of therapy. Two patients were excluded as they were lost to follow-up. Among the included 49 patients, 29 were females (59.2%) and 26 patients (53.1%) had functional tumors at baseline. Out of 33 patients who had information available on tumor grade, 26 (78.8%) were high grade. Nine pts (18.4%) underwent surgery after receiving systemic therapy (eight after EDP in first line and one after pembrolizumab in third line). These patients were younger (median age 39 years compared to 52.5 years for those receiving only chemotherapy), had locally recurrent disease (all nine patients) with four having evidence of progressive liver metastasis. Median number of EDP cycles delivered before surgery was 4 (range 3-7). The patient who underwent surgery after pembrolizumab received nine cycles of preoperative pembrolizumab. Five pts (55.5%) had partial response, three (33.3%) had disease progression and one (11.1%) had stable disease prior to surgery. Patients underwent surgery after a mean interval of 3.1 months (m) (1.1-5.1) after systemic therapy. Six patients had no evidence of disease (NED) (five with disease limited to adrenal bed) after surgery. Eight out of nine patients recurred after surgery with a median time of 6.1 m (4.4-7.8). The median OS for the entire cohort was 26 m (95% CI 22.3-35.2). This was not significantly better for patients undergoing surgery [median OS 31.2 m (95% CI 21.4-63.3) vs 24.7 m (95% CI 17.7-35.2) p = 0.48]. Patients rendered NED after surgery had numerically better OS than those with residual disease or those receiving only chemotherapy [median OS 39.6 m (24.8.-NR), vs 23.5 m (21.4-NR) vs 24.7 m (17.7-35.2), p = 0.271]. Higher Ki-67 predicted for inferior OS in the entire cohort with no effect of age, gender, tumor grade or functional status. **Conclusions:** Attempting to downstage patients with metastatic or locally recurrence with systemic therapy does not seem to prolong OS in patients with ACC. Selected patients with limited disease burden, who can be rendered disease free by surgery, may be suitable for this approach. Research Sponsor: None.

TPS5093 **Poster Session**

Camrelizumab combined with TIP (paclitaxel+cisplatin+ifosfamide) as neoadjuvant treatment of locally advanced penile cancer before lymphadenectomy: An exploratory, phase II study. *First Author: Yongsheng Chen, Harbin Medical University Cancer Hospital, Harbin, China*

Background: Penile squamous cell carcinoma (PSCC) is a highly aggressive disease that accounts for 95% of penile cancers and is characterized by a high risk of early locoregional spread and morbidity with subsequent potential for distant dissemination. The lymph node invasion is one of the most important factor that affects the prognosis of PSCC. Penile cancer patients with uninvolved inguinal lymph nodes had a 5-year survival rate of 66% compared with 27% for those with involvement, and penile cancer with the pelvic lymph node involvement have a worse 5-year survival rate that is typically less than 10%. Therefore, this study aims to reduce small lesions to reach the radical lymphadenectomy by camrelizumab combined with TIP in the neoadjuvant treatment of PSCC. **Methods:** In this single-arm, prospective, phase II study, 34 patients with histological or cytological diagnosis of locally advanced PSCC (TX, N2-N3, M0), ECOG performance score of 0-1, planned to be recruited. Enrolled patients with inguinal and/or pelvic lymph node metastasis (positive percutaneous lymph node biopsy) after primary tumor resection of penile cancer were treated with combined therapy including camrelizumab (200 mg, iv, Q3W), paclitaxel (175 mg/m^2, iv, Q3W), cisplatin (25 mg/m^2, iv, Q3W) and ifosfamide (1200 mg/m^2, iv, Q3W) for a total of 4 cycles. The primary endpoint is the rate of pathologic complete response (pCR). Secondary endpoints are event-free survival, overall survival, objective response rate, disease control rate and safety. On the basis of a threshold pCR rate of 13.6%, targeting an expected pCR of 34% and assuming 12 months follow-up, 80% power and a one-sided $\alpha = 0.05$, this design requires 34 evaluable patients to be accrued over 3 years. Clinical trial information: ChiECRCT20210503. Research Sponsor: None.

TPS5094 **Poster Session**

A phase II trial of cemiplimab alone or in combination with standard of care chemotherapy in locally advanced or metastatic penile carcinoma (EPIC Trial). *First Author: Emily Renninson, University Hospitals Bristol and Weston NHS FT, Bristol, United Kingdom*

Background: Penile cancer (PC) is rare but its incidence is increasing, with an increase of 21% over the last decade. The rarity of this cancer means a paucity of large prospective clinical trial data to guide the management of locally advanced/metastatic penile cancer (la/mPC). Cisplatin containing combination chemotherapy regimens are widely regarded as the standard of care (SOC) in this setting. However, with response rates of about 50% there is a need to further improve treatment outcomes. PDL1 is upregulated in 40–60% of PC cases and is correlated with poor prognosis making a case for immunotherapy as a treatment for la/mPC. Currently there are ongoing clinical trials exploring immunotherapy on penile carcinoma, however, none of these trials are looking at the combination of immunotherapy and chemotherapy. The novel immune checkpoint inhibitor cemiplimab has been approved for locally advanced and metastatic cutaneous squamous cell carcinoma (mcSCC). In view of this, we sought to evaluate the benefit and safety of cemiplimab alone, or, in combination with SOC chemotherapy in patients with la/mPC. **Methods:** This is a non-randomised, open label, two arm phase II multicentre trial of single agent cemiplimab versus cemiplimab + SOC chemotherapy in la/mPC, choice of arm decided by the investigator site based on chemotherapy eligibility. Eligibility includes patients with la/mPC who are candidates for immunotherapy +/- SOC chemotherapy (local UK centre choice of cisplatin/5FU or TPF or TIP regimes). 47 patients will be recruited from 10 UK centres: 29 patients into ARM 1 who will receive 4 cycles of cemiplimab 350mg IV q3 weekly + SOC chemotherapy, followed by single agent cemiplimab x 30 cycles (24 months total). 18 patients into ARM 2 who will receive single agent cemiplimab 350mg IV q3 weekly, up to 34 cycles (24 months total). The primary endpoint is clinical benefit rate (CBR) of cemiplimab: objective response rate (ORR) plus stable disease as assessed radiologically (RECIST 1.1) post cycle 4 in patients with la/mPC. Secondary end-points include safety, tolerability, CBR at 1, 2 and 3 years, ORR, progression-free survival, overall survival and assessment of patient health status and quality of life using the patient reported outcome measures EQ-5D-5L and EORTC QLQ-C30. Each arm will be analysed separately as a Fleming A'Hern study $\alpha = 0.05$ + power $(1\text{-}\beta) = 0.8$. Arm 1 assumes 25% meeting the clinical end point is a poor treatment (p0 = 0.25) and 50% is a good treatment (p1 = 0.5). Arm 2 assumes 5% meeting the clinical end point is a poor treatment (p0 = 0.05) and 25% is a good treatment (p1 = 0.25). To date, 4 patients have been recruited from 2 centres with the aim to open all UK centres to recruitment by June 2022. The EPIC trial is NCRN badged. Clinical trial information: 95561634. Research Sponsor: Sanofi.

TPS5095 **Poster Session**

ETCTN 10437: A single-arm phase II study of bone-targeted sn-117m-DTPA in symptomatic castration-resistant prostate cancer with skeletal metastases. *First Author: Zin Myint, University of Kentucky, Lexington, KY*

Background: Most patients with metastatic castration resistant prostate cancer (mCRPC) develop bone metastases with debilitating pain that is itself associated with shorter survival. Several bone-seeking radionuclides have been developed for palliation of metastatic bone pain. To date, radium-223 dichloride is the first and only approved targeted alpha therapy for mCRPC; the major dose limitation is bone marrow toxicity with modest pain relief. Sn-117m-diethylenetriaminepentaacetic acid (DPTA), is a complex of a radioisotope of tin with DTPA. It emits a low-energy conversion electron and also yields a gamma emission. Sn-117m-DPTA localizes selectively in bone, and the limited range (0.2-0.3 mm) of its conversion electrons resulting in deeper tissue penetration with less radiation effects on bone marrow as compared to radium-223 dichloride. Srivastava et al. (1998) reported in a phase I/II study of patients with painful bone metastases from a variety of solid tumors, 45% of patients obtained reduction of pain by at least 50%, and 30% had complete relief of pain for more than two weeks after one injection. Thus, Sn-117m-DTPA has high palliative efficacy with little significant toxicity. Additional evaluation of this agent in mCRPC patients is urgently required. **Methods:** The study is a phase 2 single-arm clinical trial of Sn-117m-DPTA (20 mCi/70Kg or 0.28 mCi/kg) intravenously every 8 weeks for two injections for patients with mCRPC metastatic to at least two bone sites with at least one clinically meaningful pain site at baseline. Re-treatment with additional two cycles is allowed if patients meet re-treatment criteria. Key eligibility criteria include 1) refractory mCRPC patients who progressed on any lines of therapies 2) self-reported bone pain (≥4 on an 11-point pain intensity scale), and 3) must be on either regular pain medication or have undergone palliative radiation for bone pain within 12 weeks prior to starting study treatment. Key exclusion criteria include 1) visceral metastases and 2) malignant lymphadenopathy exceeding 3cm in short-axis diameter. Twenty-five patients will be enrolled with a primary objective to assess the efficacy of Sn-117m-DTPA on sustained pain response; defined as 1) achieving pain index ≤3 index within a 12-week period and 2) maintaining pain index ≤3 over a 16-week period. Secondary endpoints include patient reported outcomes, adverse events, progression-free survival and overall survival. Correlative aims include assessing blood (systemic inflammatory markers) and tissue biomarkers (gene sequencing and polo-like kinase-1) for association with clinical benefit. An interim analysis will be performed to assess efficacy after 10 patients become evaluable. The study began enrolling patients in December 2021 and is ongoing. Clinical trial information: NCT04616547. Research Sponsor: ETCTN UM1 grant.

TPS5096 **Poster Session**

TALAPRO-3: A phase 3, double-blind, randomized study of enzalutamide (ENZA) plus talazoparib (TALA) versus placebo plus ENZA in patients with DDR gene–mutated, metastatic castration-sensitive prostate cancer (mCSPC). *First Author: Neeraj Agarwal, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT*

Background: TALA is a poly(ADP-ribose) polymerase inhibitor (PARPi) approved as monotherapy for germline *BRCA1/2*-mutated HER2-negative advanced breast cancer. Clinical efficacy in metastatic castration-resistant prostate cancers (mCRPC) with alterations in DNA damage response (DDR) genes involved directly or indirectly in homologous recombination repair (HRR) has been demonstrated with some PARPi. Phase 3 study findings (de Bono et al. *N Engl J Med*, 2020;382:2091-2102) resulted in the approval of olaparib for mCRPC. ENZA is an androgen receptor (AR) inhibitor and established therapy for mCSPC. Since PARP activity has been shown to support AR function, PARP inhibition may increase sensitivity to AR-directed therapies. In addition, AR blockade downregulates HRR gene regulation, which has been hypothesized to induce a "*BRCA*ness" phenotype. A Phase 2 study of TALA monotherapy (TALAPRO-1) demonstrated robust antitumor activity in men with heavily pretreated, HRR-mutated mCRPC. The Phase 3, double-blind, randomized trial TALAPRO-3 (NCT04821622) herein presented will compare the combination of TALA plus ENZA vs placebo plus ENZA in men with mCSPC with DDR/HRR alterations. **Methods:** Approximately 550 patients with mCSPC harboring DDR/HRR alterations will be randomized to TALA (0.5 mg once daily) plus ENZA (160 mg once daily) or placebo (once daily) plus ENZA (160 mg once daily). Patients will be stratified according to de novo mCSPC vs relapsed mCSPC, high-volume disease vs low-volume disease, where high-volume disease is defined as the presence of visceral metastases or ≥4 bone lesions with ≥1 beyond the vertebral bodies and pelvis and BRCA vs non-BRCA mutational status. Key eligibility criteria include age ≥18 years; histological diagnosis of prostate cancer; alterations in at least one of 12 DDR/HRR genes known to sensitize patients to PARPi (*ATM*, *ATR*, *BRCA1*, *BRCA2*, *CDK12*, *CHEK2*, *FANCA*, *MLH1*, *MRE11A*, *NBN*, *PALB2*, *RAD51C*); and metastatic disease (no brain metastases). Primary endpoint is rPFS (time to radiographic progression in soft tissue per RECIST 1.1 or in bone per PCWG3 criteria by investigator, or death). Secondary endpoints include overall survival, safety, and patient-reported outcomes. Patient recruitment is planned at approximately 285 sites in 27 countries, including the US and Europe, South America, South Africa, and Asia-Pacific. This study was approved by an Institutional Review Board. Clinical trial information: NCT04821622. Research Sponsor: Pfizer.

TPS5097 **Poster Session**

A phase 2, multicenter, parallel-group, open-label study of vudalimab (XmAb20717), a PD-1 x CTLA-4 bispecific antibody, alone or in combination with chemotherapy or targeted therapy in patients with molecularly defined subtypes of metastatic castration-resistant prostate cancer. *First Author: Mark N. Stein, Division of Hematology and Oncology, Herbert Irving Comprehensive Cancer Center, Columbia University Irving Medical Center, New York, NY*

Background: Although immune checkpoint inhibitor (ICI) monotherapy has shown limited clinical benefit in patients with metastatic castration-resistant prostate cancer (mCRPC), better outcomes have been observed with combination anti-PD-1/CTLA-4 therapy. In addition, whereas response rates are low in unselected mCRPC populations, tumors with selected molecular characteristics, including those associated with aggressive variant disease, CDK12 inactivation, and microsatellite instability high (MSI-H) status, have shown increased sensitivity to ICIs. Finally, altering the tumor microenvironment to promote antitumor immunity by combining ICIs with chemotherapy or targeted agents also has potential to increase clinical benefit. Vudalimab (XmAb20717) is a humanized bispecific monoclonal antibody that simultaneously targets PD-1 and CTLA-4 and binds preferentially to PD-1/CTLA-4 dual-positive cells. In a Phase 1 study, vudalimab monotherapy was generally well-tolerated and associated with complete and partial responses in patients with multiple tumor types, including mCRPC. This Phase 2 study is designed to evaluate the safety and antitumor activity of vudalimab in combination with other anticancer agents or alone in subgroups of mCRPC patients with and without specific tumor molecular subtypes. **Methods:** This multicenter, open-label study is being conducted at approximately 20 sites in the United States. Patients with mCRPC that progressed following treatment with ≥ 2 prior lines of anticancer therapy are enrolled into the following parallel cohorts based on the presence or absence of molecular abnormalities from prior sequencing of metastatic tumor: aggressive variant (Cohort 1), homologous recombination deficient or CDK12 mutation positive PARP inhibitor progressor (Cohort 2) or PARP inhibitor naïve (Cohort 3), MSI-H or mismatch repair deficient (Cohort 4), and no targetable mutation (Cohort 5). All patients will receive vudalimab 10 mg/kg intravenously every 2 weeks. Cohorts 1, 2, and 5 (n = 20 each) also will receive carboplatin AUC 4 + cabazitaxel 20 mg/m^2 (or docetaxel 60 mg/m^2, if not received prior) every 3 weeks; Cohort 3 (n = 20) also will receive olaparib 300 mg 2x/day; and Cohort 4 (n = 5) will receive vudalimab monotherapy. The primary objective is to evaluate the safety/tolerability of treatment based on adverse events. Secondary objectives include evaluating objective response (RECIST 1.1, as modified by PCWG3), radiographic progression-free survival, and PSA response. Exploratory objectives include assessing pharmacodynamic activity in peripheral blood and tumor, and correlations of response with cohort-specific molecular tumor characteristics. Enrollment has been initiated. Clinical trial information: NCT05005728. Research Sponsor: Xencor, Inc.

TPS5098 **Poster Session**

A phase Ia/Ib study of talazoparib in combination with tazemetostat in metastatic castration-resistant prostate cancer (mCRPC). *First Author: Atish Dipankar Choudhury, Dana-Farber Cancer Institute, Boston, MA*

Background: Enhancer of zeste homolog 2 (EZH2) is frequently overexpressed in metastatic castration-resistant prostate cancer (mCRPC), and is linked to lineage plasticity and therapy resistance. In pre-clinical studies, EZH2 directly regulates DNA damage repair (DDR) gene expression, and pharmacologic inhibition of EZH2 sensitizes prostate cancer cells to genotoxic stress as induced by poly-ADP ribose polymerase (PARP) inhibition. The PARP inhibitor talazoparib and EZH2 inhibitor tazemetostat are currently under study in mCRPC, and we are conducting a Phase 1 clinical trial of the combination. **Methods:** Phase 1a of the study will define the recommended phase 2 dose (RP2D) and Phase 1b will better assess safety and preliminary clinical activity of the combination at the RP2D. Eligible patients must have progressive disease after at least one secondary hormonal therapy and taxane-based chemotherapy (or felt not to be more appropriate for taxane), have disease evaluable for response (PSA ≥ 2 ng/ml or measurable disease by RECIST 1.1) and have a metastatic lesion amenable to biopsy adequate for next generation sequencing. In Phase 1a (n = 9-18), the starting doses are talazoparib 0.75 mg daily and tazemetostat 600 mg BID, with dose escalation/de-escalation of both agents by up to 2 dose levels [DLs] based on a 3+3 design. The RP2D is the maximum tolerated dose (MTD) or DL +2 (talazoparib 1 mg daily + tazemetostat 800 mg BID) if the MTD is not reached. After 6 patients are treated at the RP2D, phase 1b will enroll an additional 20 patients to an expansion cohort. The primary endpoint of safety and tolerability is based on incidence of dose-limiting toxicities [DLTs] and incidence and grade of adverse events [AEs] by CTCAE version 5.0. For the secondary endpoint of overall response rate (ORR; defined as PSA reduction by ≥ 50% OR radiographic response by RECIST 1.1), with a sample size of 26 (6 patients from dose escalation and 20 from expansion), we deem talazoparib+tazemetostat effective if ORR is ≥ 5/26 (19%). The probability of concluding that the treatment strategy effective is 0.11 if its true response rate is 10% and at least 0.93 if the true response rate exceeds 30%. Mandatory pre-treatment and on-treatment (8-week) biopsies will undergo targeted genetic sequencing, transcriptomic profiling, ChIP (Chromatin ImmunoPrecipitation)-seq, and immunohistochemistry (IHC) for DDR and differentiation markers; blood specimens will undergo circulating cell-free DNA and circulating tumor cell profiling – these studies will nominate possible predictive biomarkers for therapeutic response and serve as pharmacodynamic markers of combined PARP and EZH2 inhibition. The goal of this study is to expand treatment options in mCRPC through a novel approach to exploit EZH2 as a therapeutic target through co-targeting the DDR response. Enrollment began in July 2021. Clinical trial information: NCT04846478. Research Sponsor: Pfizer, Other Foundation, Pharmaceutical/Biotech Company.

TPS5099 **Poster Session**

Trial in progress: Durvalumab and olaparib for the treatment of prostate cancer in men predicted to have a high neoantigen load. *First Author: Alexandra Sokolova, Oregon Health and Science University Knight Cancer Institute, Portland, OR*

Background: Approximately 30% of patients (pts) treated with definitive surgical and/or radiation therapy for localized prostate adenocarcinoma develop biochemical recurrence (BCR). The optimal time to initiate androgen deprivation therapy (ADT) for such patients is controversial and depends on patient and provider preference, absolute PSA value, and PSA doubling time (PSADT), which has been associated with time to metastasis. Because the time from BCR to metastasis can be long in many cases, strategies allowing pts to avoid ADT while extending metastasis-free survival are desirable. Prior studies have shown that a high tumor neoantigen load correlates with response to anti-PD(L)1. We hypothesized that PARP inhibitor-induced genomic instability may sensitize tumors to anti-PD(L)1 through: i) increasing mutational burden and subsequent tumor neoantigen formation, and/or ii) through activation of other immunogenic pathways (e.g. the STING pathway). This trial investigates an ADT-sparing approach for men predicted to have high neoantigen load and who have BCR prostate cancer. **Methods:** This is a phase 2 clinical trial testing durvalumab (1500 mg IV every 4 weeks) and olaparib (300 mg PO twice a day) (one cycle = 4 weeks) in men with BCR (PSADT≤10 months) whose tumors are predicted to have high neoantigen load based on: biallelic *CDK12* mutations (Cohort A), mismatch repair deficiency (MMRd)/high microsatellite instability (MSI-H) (Cohort B), or loss of function mutations in homologous recombination repair (HRR) genes (Cohort C). Cohorts A and B will receive 3 cycles of durvalumab followed by 3 cycles of the combination of durvalumab and olaparib. Given the proven efficacy of olaparib in prostate cancer patient whose tumors posses an HRR gene mutation, Cohort C will receive 6 full cycles of the combination. Ten patients will be enrolled in each cohort (total n = 30) at two collaborating sites. This study was designed to provide preliminary efficacy data across eligible cohorts, with a primary objective of estimating the proportion of pts with an undetectable PSA at 12 months within each cohort. Secondary objectives include safety, proportion of patients with ≥50% decline in PSA from baseline and quality of life measures. Correlative studies will assess blood and tissue molecular biomarkers for association with outcomes. The study is open with two patients enrolled at the time of abstract submission. Clinical trial information: NCT04336943. Research Sponsor: Astra Zeneca.

TPS5100 **Poster Session**

Phase I/II study of ^{225}Ac-J591 plus ^{177}Lu-PSMA-I&T for progressive metastatic castration-resistant prostate cancer. *First Author: Jones T. Nauseef, New York-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY*

Background: PSMA is overexpressed by most prostate cancers and can be successfully targeted by both antibodies (mAb) and small molecule ligands (SML), each with overlapping and distinct binding sites, kinetics, and biodistributions [Kratochwil Sem Nuc Med 2019]. mAbs are larger, with longer circulating times resulting in greater exposure to bone marrow, but lesser access to PSMA expression on luminal tissue (*e.g.* salivary glands, small bowel, and kidney). In contrast, SMLs are rapidly excreted via kidneys and readily diffuse to all PSMA-expressing sites. Toxicities of 177Lu vary with these differences in biodistribution (*e.g.* more hematologic toxicity with mAb, more xerostomia and nausea with SML, $p < 0.001$)[Niaz AUA 2020]. Alpha emitting isotopes have shorter ranges but high potency compared to beta emitters which have longer ranges, but lower linear energy transfer. In preclinical models, the combination of mAb plus SML has demonstrated additive binding in LNCaP, CWR22Rv1, and PC3/PSMA PC cell lines, and synergistic uptake of 177Lu-mAb plus 177Lu-SML in xenograft models. We developed a phase I/II study to test our hypothesis that concomitant mAb and SML targeting, plus the combination of alpha (225Ac) and beta emitters (177Lu), may offer complementary benefits in a safe and effective manner. **Methods:** Key eligibility criteria include progressive mCRPC (PCWG3), at least 1 prior AR pathway inhibitor and taxane chemotherapy (or ineligible/refused), and adequate organ function and performance status. PSMA PET/CT must have at least 1 lesion with SUVmax > liver SUV. Prior PSMA-based therapy with radioisotopes is not allowed. 177Lu-PSMA-I&T (PNT2002) will be administered as in the phase III SPLASH study (6.8 GBq q8w for up to 2 doses). The phase I includes up to two dose-escalation cohorts of concurrent 225Ac-J591 (30 & 40 KBq/Kg q8w x2) in a modified 3+3 schema. All subjects undergo 177Lu SPECT on Day 8 after each dose. The primary objective of the Phase I study is to determine the dose-limiting toxicity and recommended phase II dose (RP2D) for this combination. Primary objective of the Phase II study is to assess the proportion of patients with > 50% PSA decline after treatment. Secondary objectives include radiographic response rate (PCWG3-modified RECIST 1.1), biochemical and radiographic progression-free survival, overall survival, safety (CTCAE 5.0), CTC count changes and conversions, and patient-reported outcomes (FACT-P, BPI-SF, EQ-5D). Exploratory objectives include pre- and post-treatment PSMA-based imaging changes, effects of PSMA radionuclides on the microbiome, relationship between genomic alterations and response, and relationship between PSMA PET/CT results and outcome. The phase I was activated at Weill Cornell Medicine in May 2021. Following determination of the RP2D, a multicenter phase II is planned at Prostate Cancer Clinical Trials Consortium (PCCTC) in 2022. Clinical trial information: 04886986. Research Sponsor: Weill Cornell Medicine, Pharmaceutical/Biotech Company, U.S. National Institutes of Health.

TPS5101 **Poster Session**

A phase 1 study of AMG 509 in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Daniel Costin Danila, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Six-transmembrane epithelial antigen of prostate 1 (STEAP1) is overexpressed on the surface of prostate cancer cells with low or no expression on normal tissue. AMG 509 is a bispecific XmAb 2+1 T-cell engager that simultaneously binds to STEAP1 on tumor cells and the CD3 complex on T cells resulting in T-cell mediated lysis of STEAP1-expressing cells. AMG 509 demonstrated significant antitumor activity in preclinical prostate cancer models. **Methods:** This 4-part, first-in-human study will evaluate AMG 509 in pts with mCRPC previously treated with novel hormonal therapy (NHT) and will assess the safety, tolerability, pharmacokinetics (PK), and efficacy of AMG 509 to establish the maximum tolerated dose (MTD) and/or the recommended phase 2 dose (RP2D). Part 1 is currently enrolling pts previously treated with NHT and up to 2 prior taxanes. As of 31 January 2022, 60 of up to 110 pts have been enrolled for treatment with intravenous (IV) AMG 509 with initial inpatient dosing followed by outpatient treatment. Part 2 will evaluate subcutaneous dosing of AMG 509 in the same patient population as in Part 1. Part 3 will explore AMG 509 IV dosing in chemotherapy-naïve pts who have been treated previously with one NHT and will provide additional data on the safety, PK, efficacy, pharmacodynamics, and correlative biomarkers at the MTD or RP2D determined in Part 1. Part 4 will evaluate the combination of AMG 509 with abiraterone (Part 4A) or enzalutamide (Part 4B) in pts previously treated with one NHT and up to 1 prior taxane for castration-sensitive disease. Primary outcome measures include dose-limiting toxicities, treatment-emergent and treatment-related adverse events, and change in clinical and laboratory parameters. Key secondary outcome measures include PK, objective response per RECIST 1.1, prostate-specific antigen response, progression-free survival, and overall survival. Key inclusion criteria are men ≥18 years of age with pathologically confirmed mCRPC, refractoriness to NHT, evidence of progressive disease, and ECOG performance status of 0–1. Key exclusion criteria are pure small cell or neuroendocrine carcinoma of the prostate, untreated CNS metastases or leptomeningeal disease, recent anticancer therapy or immunotherapy within 4 weeks of start of first dose not including luteinizing hormone-releasing hormone/gonadotropin-releasing hormone analogue (agonist/antagonist) therapy, radiation therapy, and a history of or current autoimmune disease or any disease requiring chronic immunosuppressive therapy. The trial is being carried out in investigative sites in North America, Australia, Asia, and Europe. The study opened in January 2020 and is recruiting pts for the dose exploration phase of Part 1; parts 2 and 4 are open for enrollment. Part 3 will be initiated once the MTD and/or RP2D have been determined in Part 1. Clinical trial information: NCT04221542. Research Sponsor: Amgen Inc.

TPS5102 **Poster Session**

Phase 3 VERACITY clinical study of sabizabulin in men with metastatic castration-resistant prostate cancer who have progressed on an androgen receptor targeting agent. *First Author: Robert Dreicer, University of Virginia Cancer Center, Charlottesville, VA*

Background: Sabizabulin is a first-in-class, oral agent that inhibits microtubule polymerization disrupting the cytoskeleton and arresting cellular proliferation. A Phase 1b/2 clinical study was conducted to establish the MTD and evaluate the preliminary efficacy in men with metastatic castrate resistant prostate cancer (mCRPC) who progressed on at least one androgen receptor targeting agent (ARTA). The most common AEs reported were mild to moderate diarrhea, fatigue, nausea, and vomiting with no clinically relevant neurotoxicity or neutropenia. In the Phase 1b/2, the median radiographic progression free survival for the 63mg dose (n = 55) was 11.4 months (range 6-36+ months) in the Phase 1b portion including responses > 2.75 years. The Phase 3 reformulation which had improved bioavailability is 32mg PO qd. **Methods:** VERACITY is an ongoing Phase 3 multicenter, randomized, active-control study designed to evaluate sabizabulin in the treatment of mCRPC who have progressed on at least one ARTA. Patients on the study will be chemotherapy naive. Subjects (n = 245) are being randomized in a 2:1 ratio to receive sabizabulin (32 mg/d oral) or active control (alternative ARTA) and will remain on study until radiographic progression-free survival (rPFS). Randomization will be stratified by: measurable disease vs bone-only disease and by prior exposure to ARTA (progressed on one vs more than one prior ARTA). The primary efficacy endpoint of the study is median rPFS. Secondary endpoints include: objective response rate (ORR), duration of objective response, overall survival and time to intravenous (IV) chemotherapy. The Phase 3, VERACITY registration clinical trial is current ongoing in approximately 45 clinical sites with enrollment anticipated to be completed in 2022 and with unblinded results presented in 2023 Based upon the Phase 1b/2 clinical trial, sabizabulin daily chronic oral dosing has a favorable safety profile, is feasible to administer chronically, and has significant and durable antitumor activity. mCRPC that has progressed following ARTAs and prior to taxane chemotherapy, remains an urgent unmet medical need for patients with advanced disease. Sabizabulin is an exciting first-in-class agent that may add to the armamentarium for the treatment of mCRPC following progression on ARTA's. Clinical trial information: NCT04844749. Research Sponsor: Veru Inc.

TPS5103 **Poster Session**

DASL-HiCaP: Darolutamide augments standard therapy for localized very high-risk cancer of the prostate (ANZUP1801)—A randomized phase 3, double-blind, placebo-controlled trial of adding darolutamide to androgen deprivation therapy and definitive or salvage radiation. *First Author: Tamim Niazi, Jewish General Hospital, McGill University, Montréal, QC, Canada*

Background: Radiation therapy (RT), plus androgen deprivation therapy (ADT) with a luteinizing hormone releasing hormone analog (LHRHA), is standard of care for men with very high-risk localized prostate cancer (PC), or with very high-risk features and persistent PSA after radical prostatectomy (RP). Despite this, incurable distant metastases develop within 5 years in 15% of men with very high-risk features. Darolutamide is a structurally distinct oral androgen receptor antagonist with low blood-brain-barrier penetration, a demonstrated favorable safety profile, and low potential for drug-drug interactions. Our aim is to determine the efficacy of adding darolutamide to ADT and RT in the setting of either primary definitive therapy, or salvage therapy for very high-risk PC. **Methods:** This study is a randomized (1:1), phase 3, placebo-controlled, double-blind trial for men planned for RT who have very high-risk localized PC on conventional imaging; or very high-risk features with PSA persistence or rise within one year following RP. The trial is stratified by: RP; use of adjuvant docetaxel; pelvic nodal involvement. 1100 participants will be randomized to darolutamide 600 mg or placebo twice daily for 96 weeks. Participants will receive LHRHA for 96 weeks, plus RT starting week 8-24 from randomization. Participants are allowed nonsteroidal antiandrogen in addition to LHRHA for up to 90 days prior to randomization. Early treatment with up to 6 cycles of docetaxel completed at least 4 weeks prior to RT is permitted. The primary endpoint is metastasis-free survival (ICECaP-validated), with secondary endpoints overall survival, PC-specific survival, PSA-progression free survival, time to subsequent hormonal therapy, time to castration-resistance, frequency and severity of adverse events, health related quality of life, fear of recurrence. Tertiary endpoints include incremental cost-effectiveness, and identification of prognostic and/or predictive biomarkers of treatment response, safety, and resistance to study treatment. Clinical trial information: NCT04136353. Research Sponsor: Bayer, Other Government Agency, ANZUP.

TPS5104 **Poster Session**

Phase 1 study of JNJ-69086420, an actinium-225-labeled antibody targeting human kallikrein-2, for advanced prostate cancer. *First Author: Michael J. Morris, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Radioligand therapy for metastatic castration resistant prostate cancer (mCRPC) has been shown to prolong survival, delay disease progression, and improve quality of life, raising hopes that these gains will be amplified with even more cancer-specific targets and more powerful radioligands. Human kallikrein-related peptidase 2 (hK2) is a tumor-associated member of the kallikrein family that shares significant homology to prostate-specific antigen and is minimally expressed in normal non-prostate tissues. JNJ-69086420 (JNJ-420; ^{225}Ac-DOTA-h11B6 [1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid]), is a first-in-class radioimmunotherapy targeted to hK2 antigen. In a phase 0 study of [^{111}In]-DOTA-h11B6, patients with mCRPC (progressed on standard therapies), treatment with a single dose of [^{111}In]-DOTA-h11B6 (2 mg) with/without 8 mg h11B6, demonstrated safety, good tumor localization, nominal normal-organ uptake, and no difference in pharmacokinetics (PK) between 2 and 10 mg antibody mass (Morris *et al. J Clin Oncol.* 2021 39:6 suppl, 122). We have initiated the first-in-human study to assess the safety, PK, pharmacodynamic (PD), and clinical activity of Ac-225 radiolabeled JNJ-420, to determine its recommended phase 2 dose (RP2D) in adults with advanced PC. **Methods:** This open-label, multicenter, phase 1 study will recruit approximately 50 men (aged ≥18 years) with advanced PC across dose escalation (Part 1) and expansion (Part 2) parts. Key eligibility criteria: mCRPC with histologic confirmation of adenocarcinoma, Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1, adequate organ function based on hematology and serum chemistry, and 1 or more prior novel androgen receptor-targeted therapies (prior chemotherapy acceptable). Key exclusion criteria: prior treatment with radium/strontium/samarium/radioconjugate therapy, superscan findings as protocol defined, active central nervous system metastases. In Part 1, men will receive intravenous (IV) injection of 50 μCi/ 2 mg JNJ-420 (once every 8 weeks) with one or multiple doses; escalation of dose levels to be based on dose limiting toxicities (DLTs) evaluation, until RP2D identification. In Part 2, JNJ-420 is to be given at one of the RP2D(s) determined in Part 1. Primary endpoint is safety (incidence and severity [grading per NCI-CTCAE V5.0] of AEs including DLTs). Secondary endpoints include prostate specific antigen response rate, overall response rate (PCWG3 modified RECIST 1.1 criteria), PK, PD, immunogenicity, and biomarker analyses. Enrollment began in Dec 2020; as of 10 Feb 2022, 4 sites have been initiated and 23 patients enrolled; currently, dose escalation is ongoing. Clinical trial information: NCT04644770. Research Sponsor: Janssen Research & Development, LLC.

TPS5105 **Poster Session**

A phase 1/2 study of REGN4336, a PSMAxCD3 bispecific antibody, alone and in combination with cemiplimab in patients with metastatic castration-resistant prostate cancer. *First Author: William Kevin Kelly, Thomas Jefferson University, Philadelphia, PA*

Background: Prostate cancer is the leading cause of new cancer diagnoses and the second most common cause of cancer-related death in American men. Prognosis is especially poor for men with metastatic castration resistant prostate cancer (mCRPC). Prostate-specific membrane antigen (PSMA) is highly expressed on malignant prostate tissue but shows limited expression on normal tissue. As such, PSMA is an excellent research target for treatment of mCRPC. REGN4336 is a PSMAxCD3 bispecific antibody designed to facilitate T-cell–mediated killing of PSMA-expressing tumor cells. In preclinical models, REGN4336 demonstrated strong PSMA-dependent antitumor activity that was dose-dependent. Preclinical data also support clinical research into the combination of REGN4336 with cemiplimab (anti–programmed cell death-1) for treating mCRPC. **Methods:** This is an open-label, Phase 1/2, first-in-human, multicenter dose-escalation study with dose expansion evaluating safety, tolerability, pharmacokinetics (PK), and antitumor activity of REGN4336 administered subcutaneously alone and in combination with intravenous cemiplimab in patients with mCRPC (NCT05125016). Patients must have received at least two prior lines of systemic therapy approved for metastatic and/or castration-resistant disease including a second-generation anti-androgen therapy. In this study, REGN4336 as monotherapy is administered weekly but may be extended to once every 3 weeks following identification of the minimal pharmacologically active dose. REGN4336 in combination with cemiplimab (350 mg) will be administered once every 3 weeks after a 4-week REGN4336 monotherapy lead-in cycle. Study therapies are administered until disease progression, intolerable adverse events, withdrawal of consent, or study withdrawal criterion is met. The primary objectives in dose escalation are to evaluate the safety, tolerability, PK, and recommended phase 2 dosing regimen (RP2DR) of REGN4336 alone and in-combination with cemiplimab. Expansion cohort(s) will be enrolled once RP2DRs have been determined. During the expansion phase, the primary objective is to assess clinical activity, as measured by objective response rate with REGN4336 alone or in combination with cemiplimab per modified Prostate Cancer Working Group 3 criteria. At selected sites, PSMA positron emission tomography/computed tomography scans will be performed at predefined timepoints on study. This study is currently open to enrollment. Clinical trial information: NCT03088540. Research Sponsor: Regeneron Pharmaceuticals, Inc.

TPS5106 **Poster Session**

Phase 1b study of bavdegalutamide, an androgen receptor PROTAC degrader, combined with abiraterone in patients with metastatic prostate cancer. *First Author: Neal D. Shore, Carolina Urologic Research Center, Myrtle Beach, SC*

Background: Bavdegalutamide (ARV-110) is a novel, oral PROteolysis TArgeting Chimera (PROTAC) protein degrader that targets wild-type androgen receptor (AR) and clinically relevant mutants. Bavdegalutamide demonstrated tumor growth inhibition in multiple xenograft models (eg, AR gene amplification, AR mutation, enzalutamide resistance, and enzalutamide insensitivity). In a phase 1/2 study (NCT03888612), bavdegalutamide showed clinical activity in patients with metastatic castration-resistant prostate cancer (mCRPC) who had previously received 1–2 prior novel hormonal agents (eg, abiraterone and/or enzalutamide), including heavily pretreated patients. Abiraterone is approved, in combination with a corticosteroid, to treat patients with mCRPC or with high-risk castration-sensitive prostate cancer (CSPC). Up to a third of patients treated with abiraterone develop primary resistance to this drug and nearly all patients experience disease progression. Here we describe a phase 1b study that will evaluate the combination of bavdegalutamide with abiraterone at the initiation of progression on abiraterone (prostate-specific antigen [PSA] progression without radiographic progression) to test if the addition of bavdegalutamide will overcome resistance to abiraterone and re-establish the AR pathway blockade in patients with prostate cancer. **Methods:** Eligible patients are men ≥18 years of age with histologically, pathologically, or cytologically confirmed adenocarcinoma of the prostate and Eastern Cooperative Oncology Group performance status of 0 or 1. Patients must be receiving ongoing treatment with stable doses of abiraterone and a concomitant corticosteroid for mCRPC or CSPC and have PSA progression ≥16 weeks after initiation of abiraterone, ≥2 rising PSA values measured ≥1 week apart, and no radiographic evidence of disease progression while receiving abiraterone. Ongoing androgen deprivation therapy with a gonadotropin-releasing hormone analogue or inhibitor or orchiectomy is required. Prior treatment with enzalutamide, apalutamide, darolutamide, or experimental AR-directed therapies is not permitted. Bavdegalutamide, abiraterone, and a corticosteroid will be administered daily in 28-day cycles. Primary objectives are to evaluate the safety and tolerability of bavdegalutamide plus abiraterone and determine the recommended phase 2 dose and schedule of this combination (based on the incidence of first-cycle dose-limiting toxicities and the frequency and severity of adverse events and laboratory abnormalities). Clinical trial information: NCT05177042. Research Sponsor: Arvinas Androgen Receptor, Inc.

TPS5107 **Poster Session**

Alliance A031902 (CASPAR): A randomized, phase (ph) 3 trial of enzalutamide with rucaparib/placebo in first-line metastatic castration-resistant prostate cancer (mCRPC). *First Author: Arpit Rao, Dan L. Duncan Comprehensive Cancer Center, Baylor College of Medicine, Houston, TX*

Background: Despite a growing number of treatment options for first line mCRPC, approximately 40% of patients (pts) have radiographic progression within the first year. Androgen receptor (AR) signaling inhibition increases genomic instability with double-strand DNA breaks & co-inhibition of AR & PARP induces synthetic lethality in multiple preclinical models. Homologous recombination repair (HRR) gene aberrations do not appear to be necessary for this synergy as demonstrated in a ph 3 clinical trial of abiraterone & olaparib where this combination improved radiographic progression-free survival (rPFS) in HRR-wild-type pts compared with abiraterone alone. A ph 1b trial has since shown that enzalutamide plus rucaparib has acceptable safety profile & no significant drug-drug interactions (S-DDI). **Methods:** CASPAR/A031902 (NCT04455750) is a ph 3 study in which 984 pts will be randomized 1:1 to enzalutamide plus rucaparib or placebo. HRR gene aberration is not required for enrollment. All pts will undergo next-generation targeted-exome sequencing from archival tumor tissue (new biopsy only required if no archival tissue available). Treatment will be continued until disease progression & crossover is not allowed. Key eligibility criteria are age ≥ 18 years, ECOG PS 0-2, biopsy-proven prostate adenocarcinoma, progressive (PSA or radiographic) disease per Prostate Cancer Working Group 3 guidelines, measurable or nonmeasurable disease per RECIST 1.1, no prior treatment for mCRPC (prior docetaxel, abiraterone, darolutamide, or apalutamide in non-mCRPC setting is allowed), no significant uncontrolled comorbidity, & no medications with S-DDI with enzalutamide/rucaparib. Hierarchical co-primary endpoints are rPFS & overall survival (OS). The OS analysis will be undertaken as a primary endpoint if the rPFS endpoint is met. For a one-sided logrank test with a type 1 error rate equal to 0.025, the study has 90% power to detect a hazard ratio (HR) of 0.71 in rPFS (median rPFS of 15 & 21 months in control & combination arms, respectively) & 80% power to detect an HR of 0.80 in OS (median OS of 32 & 40 months, respectively). Key secondary endpoints are rPFS & OS in pts with *vs* without pathogenic *BRCA1*, *BRCA2*, or *PALB2* alterations; & differences in adverse events & quality of life (QOL) outcomes between the treatment arms. QOL assessments include Functional Assessment of Cancer Therapy–Prostate (FACT-P), Brief Pain Inventory Short Form (BPI-SF) & EQ-5D-5L. A key correlative endpoint is the sensitivity of ctDNA-based testing for alterations in HRR genes. Enrollment to CASPAR began in July 2021 & the study is available for participation to all US-NCTN sites with a projected enrollment of 3 years. Support: U10CA180821, U10CA180882, U24CA196171; U10CA180888. Clinical trial information: NCT04455750. Research Sponsor: U.S. National Institutes of Health, Clovis Oncology.

TPS5109 **Poster Session**

177Lu-DOTA-TLX591 safety, biodistribution and dosimetry study (ProstACT-SELECT). *First Author: Paola Antonini, Telix Pharmaceuticals, North Melbourne, Australia*

Background: The cell surface glycoprotein prostate-specific membrane antigen (PSMA) has proven to be an ideal therapeutic target in prostate cancer (PC) as it is highly expressed by malignant prostate cells .1,2 177Lu-DOTA-HuJ591-CHO (TLX591) is a radioimmunoconjugate comprised of the humanized IgG1 mAb rosopatamab, linked to the low energy beta-emitting radioisotope lutetium-177 (177Lu) via the bifunctional chelating agent DOTA-NHS ester. Chinese Hamster Ovary (CHO) cell line has been selected for the manufacture of the recombinant mAb. There is a strong rationale for investigation of TLX591 as a potential radioligand therapy for the treatment of PC, supported by previous clinical evidence of the safety of the antibody, as unconjugated and as a DOTA conjugate, and of the specificity of the antibody for PC tumors. 3,4,5,6. This multicenter Phase 1 radiomics study (ClinicalTrials.gov Identifier: NCT04786847) is designed to evaluate the safety, tolerability, biodistribution and dosimetry of TLX591 administered with best SoC to patients with PSMA-expressing, metastatic castration-resistant prostate cancer (mCRPC) progressing despite prior treatment with a novel androgen axis drug (NAAD). At the time of this abstract the study has commenced recruitment in Australia. This trial is sponsored by Telix Pharmaceuticals. **Methods:** The study will consist of 2 cohorts: Cohort 1: Five patients will be recruited for evaluation of biodistribution of TLX591 administered in combination with SoC. These patients will receive a single tracer (27 mCi) intravenous (IV) infusion of TLX591, and SPECT images and pharmacokinetic blood samples acquired at several time points until Day 13. A qualitative comparison of biodistribution of tracer level TLX591, as demonstrated by SPECT, with 68Ga-PSMA-11 on PET imaging will be performed to ensure equivalent (or improved) radiopharmaceutical tumour targeting. Dosimetry analysis will also be performed. If safety is confirmed by independent DSMB review, each individual patient in Cohort 1 will proceed 14 days following the initial tracer dose to a second administration of TLX591. SoC therapy will continue according to standard practice. Cohort 2: All further enrolled patients will receive two administrations of 76 mCi TLX591 for further evaluation of safety, tolerability and biodistribution, and efficacy in combination with SoC. 1. Research Sponsor: Telix Pharmaceuticals.

TPS5110 **Poster Session**

CCTG PR21: A randomized phase II study of [^{177}lu]lu-PSMA-617 verus docetaxel in patients with metastatic castration-resistant prostate cancer and PSMA-positive disease (NCT04663997). *First Author: Kim N. Chi, BC Cancer Agency, University of British Columbia, Vancouver, BC, Canada*

Background: [^{177}Lu]Lu-PSMA-617 improves outcome in men with metastatic, PSMA positive CRPC post androgen pathway inhibitor therapy and taxane chemotherapy compared to standard care (excluding chemotherapy, immunotherapy, radium-223 and investigational drugs; Sartor et al, NEJM 2021). The relative efficacy, adverse event experience and impact on QOL of [^{177}Lu]Lu-PSMA-617 compared to docetaxel chemotherapy in this patient population is unknown. We hypothesize that [^{177}Lu]Lu-PSMA-617 will improve radiographic PFS (rPFS) compared to docetaxel chemotherapy with a favourable safety and tolerability profile. **Methods:** CCTG PR21 is a Canadian Cancer Trials Group randomized phase II trial with a primary objective to compare rPFS between [^{177}Lu]Lu-PSMA-617 7.4 GBq (+/- 10%) IV q 6 weekly (maximum 6 cycles) versus docetaxel 75 mg/m^2 q 3 weekly (maximum 12 cycles). Secondary objectives are to compare the two arms with respect to: 6-month PFS rate (PCWG3 and RECIST 1.1), second rPFS after crossover to the alternate therapy, time to commencement of 3rd line systemic therapy, OS, PSA decline from baseline, clinical benefit rate and adverse events. Tertiary objectives include evaluation of QOL (FACT-P and EQ5D-5L), cost effectiveness, ctDNA and radiographic based prognostic and predictive biomarkers, dosimetry based approach to measurement of [^{177}Lu]Lu-PSMA-617 activity and creation of tissue and image biobanks. Key eligibility criteria include: mCRPC with PSMA positive disease using ^{18}F or ^{68}Ga radionuclide label, progression on ADT + ARPI therapy (using PSA, RECIST 1.1 or PCWG3 criteria) and adequate organ function. Statistical Design: Patients are allocated in 1:1 ratio to [^{177}Lu]Lu-PSMA-617 or docetaxel balanced for stratification factors of ECOG PS, LDH, visceral metastases, previous docetaxel in the castration sensitive setting > 1 year prior to enrollment as well as centre. Assuming a 6-month median rPFS for the control group, the detection of a hazard ratio (HR) of 0.67 with 80% power using a 1-sided 5% level test will require accrual of 200 participants in 24 months with 12-month follow-up to trigger the primary analysis. Conduct to Date: Study activation Dec 17 2020. Enrollment as of January 31 2022: 25. The DSMC last reviewed and recommended continuation of the trial in December 2021. Clinical trial information: NCT04663997. Research Sponsor: Canadian Cancer Society (Prostate Cancer Canada), AAA Novartis.

TPS5111 **Poster Session**

Open-label study of androgen receptor inhibition with darolutamide plus androgen-deprivation therapy (ADT) versus ADT in men with metastatic hormone-sensitive prostate cancer using an external control arm (ARASEC). *First Author: Neal D. Shore, Carolina Urologic Research Center, Myrtle Beach, SC*

Background: Darolutamide is a structurally distinct and highly potent androgen receptor inhibitor (ARI) that significantly improved metastasis-free survival by ~2 years and reduced the risk of death by 31% vs placebo in patients with nonmetastatic castration-resistant prostate cancer (CRPC). Darolutamide has a favorable safety and tolerability profile, with only ≤2% difference vs placebo for most adverse events (AEs) of interest (falls, fractures, hypertension, mental impairment). Fatigue was the only AE with > 10% incidence in the darolutamide arm (13.2%; placebo, 8.3%). Darolutamide has shown lower blood–brain barrier penetration than other ARIs in preclinical models (supported by human neuroimaging studies), which may lead to a lower risk of central nervous system-related AEs and has a low potential for drug–drug interactions. For patients with metastatic hormone-sensitive prostate cancer (mHSPC), the combination of darolutamide and ADT is expected to offer a favorable benefit–risk profile. ARASEC will evaluate the efficacy and safety of darolutamide plus ADT in mHSPC in the US (NCT05059236) and complement the data in the ongoing ARANOTE study (NCT04736199). **Methods:** ARASEC is a US-based, phase 2, open-label, single-arm study with an external control arm. Eligible patients will have confirmed adenocarcinoma of the prostate, radiologic evidence of metastatic disease by conventional imaging, and Eastern Cooperative Oncology Group performance status (ECOG PS) ≤2. Patients with mHSPC will receive darolutamide 600 mg twice daily plus ADT (luteinizing hormone-releasing hormone agonist/antagonist or orchiectomy). The control arm for ARASEC will be derived from the 393 patients with mHSPC treated with ADT alone in the CHAARTED trial. Patients in the active arm will be matched 1:1 to patients in the control arm using important baseline characteristics such as age, ECOG PS, extent of disease defined as low or high volume according to CHAARTED, and presence of bone and visceral metastases. Study duration was defined as the time from the first patient's first visit until either the event count threshold triggering the primary endpoint analysis has been met or all patients have been followed for ≥2 years after enrollment, whichever occurs later. The primary endpoint is progression-free survival (PFS), defined in CHAARTED as the time from enrollment to prostate-specific antigen (PSA) progression, clinical progression (including radiological or symptomatic progression or clinical deterioration), or death, whichever occurs first. Secondary endpoints are overall survival, radiographic PFS, time to CRPC, complete PSA response rate at 6 months, and safety. Patient recruitment is in progress. Clinical trial information: NCT05059236. Research Sponsor: Bayer AG and Orion Pharma.

TPS5112 **Poster Session**

Veterans affairs seamless phase II/III randomized trial of standard systemic therapy with or without PET-directed local therapy for oligorecurrent prostate cancer (VA STARPORT). *First Author: Abhishek A Solanki, Loyola University Chicago, Maywood, IL*

Background: Two diverging paradigms have been studied in recent years to improve the survival of men with recurrent metastatic prostate cancer (PCa). First, multiple recent phase II randomized trials have demonstrated improved long-term progression-free survival (PFS) with metastasis-directed therapy (MDT) in men with oligorecurrent PCa in the absence of systemic therapy. Yet, most patients receiving MDT for oligorecurrent PCa develop progression in new areas, arguing that systemic therapy is needed to treat occult metastases. The second approach that has recently been studied is whether escalating systemic therapy by adding novel androgen receptor axis targeted agents or chemotherapy improves outcomes in men with metastatic PCa. Multiple phase III randomized trials demonstrate that enhancing hormonal therapy with these therapeutic agents improves progression-free survival (PFS) and overall survival. Therefore, these agents have been integrated into today's standard systemic therapy (SST) for metastatic recurrence, and SST is the current NCCN guidelines standard of care for recurrent metastatic PCa. The primary goal of our study is to determine if adding PET-directed local therapy (PDLT) to SST improves disease control compared to SST alone in Veterans with oligorecurrent PCa. **Methods:** VA STARPORT is a phase II/III randomized trial open at 16 VA medical centers comparing SST with or without PDLT in Veterans with oligorecurrent PCa. Key eligibility criteria include prior localized PCa with biochemical recurrence after initial curative-intent local therapy and workup including any FDA-approved PCa PET/CT that reveals oligorecurrence in 1-5 metastatic lesions. The primary endpoint is castration-resistant prostate cancer-free survival (CRPC-free survival). Secondary endpoints include radiographic PFS, clinical PFS, freedom from index lesion progression, toxicity, quality of life, and prostate cancer-specific and overall survival. SST is delivered with an intent for indefinite SST using any NCCN guideline-concordant regimen in both arms. PDLT (Arm 2) consists of surgery or radiation to metastases and any present prostate/prostate bed local recurrence. Metastasis-directed radiation can consist of stereotactic body radiotherapy or elective nodal radiotherapy per clinician discretion from dose/fractionation options defined in the protocol. All participants undergo somatic tumor sequencing using the VA National Precision Oncology Program. Germline sequencing and tumor banking in a separate biorepository study is recommended. Assuming a hazard ratio of 0.60 for SST + PDLT vs SST, two-sided alpha = 0.05 and 90% power, a total of 464 participants will be randomized to generate 166 primary events (CRPC-free survival) by the end of the 48-month active study phase. The study began enrollment in August 2021. Clinical trial information: NCT04787744. Research Sponsor: Merit Review Award Number I01 CX002277 from the United States (U.S.) Department of Veterans Affairs Clinical Sciences R&D (CSRD) Service.

TPS5113 **Poster Session**

Focal radiation with pulsed systemic therapy of abiraterone, androgen deprivation therapy (ADT), olaparib towards castration-sensitive oligometastatic prostate cancer (FAALCON Trial). *First Author: Zachery R Reichert, University of Michigan, Ann Arbor, MI*

Background: Molecular imaging (i.e. PSMA directed agents) identifies metastatic prostate cancer at an earlier disease state than conventional imaging resulting in a new clinical entity within metastatic hormone-sensitive prostate cancer (mHSPC): molecular positive HSPC (mpHSPC). Historically, patients in this category with prior local therapy would have been classified as having a biochemical recurrence only, and observation was routine. Approaches to mpHSPC include observation or the use of focal and/or systemic therapies. Focal radiation for mpHSPC may delay the need for systemic therapy, yet many patients require further focal or systemic treatment. Androgen deprivation therapy (ADT) with abiraterone (abi) benefits men with high-risk localized disease and standard mHSPC. mpHSPC hypothetically resides somewhere between these two disease states. Finally, the inhibition of poly(ADP-ribose) polymerase (PARP) with olaparib plus abi shows promise in metastatic castration resistant prostate, suggesting this approach may be worthy of testing in earlier disease states. **Methods:** FAALCON is a single-site, phase 2 clinical trial testing olaparib with abi, ADT and radiation therapy in oligometastatic mpHSPC. Oligometastatic mpHSPC is defined as up to 5 radiation treatment sites (5 cm maximum size each) and must encompass all visible disease on the molecular scan. Patients must have had their prostate previously treated. The primary endpoint is the percentage of patients without treatment failure 24 months from study start. Treatment failure is defined as one of the following: new or progressive metastases on CT/MRI, new lesions on bone scan without alternate explanation, clinical progression, or a PSA doubling time under 6 months with an absolute final PSA over 1.5 ng/mL. Additional radiation therapy is deemed progression. Select secondary endpoints include time to any subsequent therapy, and percentage of patients with undetectable PSA with a recovered testosterone at multiple timepoints. Correlative work will analyze quality of life and prior prostatic tissue. ADT and abi (1000 mg daily) are given for 6 months, and radiation is completed by day 40. Olaparib (300 mg PO twice daily) is started 2 weeks after radiation completes and continues for the remaining ~5 months. After therapy completion, patients are monitored by PSA q3 months with imaging based on predetermined PSA cutoffs. Molecular imaging (PSMA-PET) may be offered on study. Historical disease control at 24 months is estimated at 40% from prior molecular guided radiation studies and intermittent ADT. With 80% power and a one-sided 5% type-I error, we can detect a hazard ratio of 0.5 (80% control rate) at 24 months with 26 patients. To account for dropout, 29 patients will be accrued. Clinical trial information: NCT04748042. Research Sponsor: AstraZeneca.

TPS5114 **Poster Session**

A phase III double blinded study of early intervention after radical prostatectomy with androgen deprivation therapy with darolutamide versus placebo in men at highest risk of prostate cancer metastasis by genomic stratification (ERADICATE). *First Author: Alicia K. Morgans, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA*

Background: Patients with high-risk scores by Decipher molecular testing after prostatectomy have a 5-year metastasis rate of 28% (Decipher 0.6-0.7) and 38% (Decipher > 0.7), likely due to micrometastatic disease. Clinical trials with intensified systemic treatment are warranted to increase cure rates and address this unmet need. Previous studies of adjuvant androgen deprivation therapy (ADT) in clinically identified high-risk disease have not demonstrated substantial benefit other than in men with lymph node positive disease. Darolutamide is a novel androgen receptor antagonist with demonstrated efficacy in improving metastasis-free survival (MFS) and overall survival (OS) in patients with non-metastatic castration-resistant prostate cancer, and OS in patients with metastatic hormone-sensitive prostate cancer (mHSPC). Whether treatment with ADT and darolutamide can increase MFS versus ADT plus placebo in the adjuvant setting for men with molecularly identified high-risk prostate cancer is unknown. **Methods:** Patients with CAPRA-S scores ≥3 and a PSA < 0.2 after radical prostatectomy undergo Decipher testing provided by the trial. Eligible patients with high-risk Decipher scores (> 0.6) will be randomized to treatment with ADT with darolutamide or placebo for 12 months. Patients are stratified by intent to deliver adjuvant radiation and by baseline PSA (undetectable vs detectable but < 0.2 ng/mL). The primary endpoint is MFS defined by novel PET or conventional imaging. With a sample size of 810 patients, the trial has 80% power with one-sided alpha = 0.025 to detect a HR of 0.60 for the experimental arm vs control arm for the primary endpoint. Secondary endpoints include recurrence-free survival, event-free survival, and quality of life (FACT-P, FACT-Cog, and FACIT-Fatigue), overall survival, and other disease-related outcomes. Trial was activated on December 9, 2020, and is currently enrolling patients. Clinical trial information: NCT04484818. Research Sponsor: CTEP - ECOG, Pharmaceutical/Biotech Company.

TPS5115 **Poster Session**

A phase I study of ADXS-504, a cancer type specific immunotherapy, for patients with biochemically recurrent prostate cancer. *First Author: Karie Runcie, Columbia University Medical Center, New York, NY*

Background: Roughly 20%-30% of prostate cancer patients experience biochemical recurrence (BCR), rising prostate-specific antigen (PSA) levels, after definitive therapy with radical prostatectomy (RP) or radiation therapy (RT). The optimal therapy and timing of treatment for BCR is unknown, however, for patients who are not eligible for salvage radiation, androgen deprivation therapy (ADT) is the standard first-line treatment. ADT is an effective therapy but has many acute and long-term toxicities. Novel strategies to reduce ADT exposure and prolong disease control are needed. ADXS-504 is a live attenuated *Listeria monocytogenes (Lm)*-based immunotherapy consisting of a truncated nonhemolytic fragment of listeriolysin O (tLLO) fused to a total of 24 tumor associated antigens (TAA). ADXS-504 was designed so that nearly 20% of patients with BCR cancer will express at least one of the targeted hotspot mutation peptide antigens and that >90% will express at least one of the TAAs targeted by the sequence-optimized TAA peptide antigens. By combining these shared, commonly expressed antigen targets into a single *Lm*-based immunotherapy, ADXS-504 provides the potential for a potent, disease-specific approach to treating patients with prostate cancer. In addition to the generation of antigen-specific T cell responses, treatment with *Lm*-based immunotherapies has been shown to reprogram the tumor microenvironment (TME), by reducing the frequencies and function of immunosuppressive regulatory T cells and myeloid-derived suppressor cells within the TME. A pre-clinical murine model showed that a proto-type Lm-construct could reduce the number of metastases after removal of the primary tumor by eliminating residual tumor cells. We hypothesize that ADXS-504 is safe and promotes anti-tumor immune responses that may delay or prevent the use of ADT in castration sensitive prostate cancer. **Methods:** This is an open-label dose-escalation phase I trial of ADXS-504 in patients with BCR of prostate cancer previously treated with RP or RT. The study will enroll up to 18 subjects with BCR with a PSA $\geq$ 0.3 and a PSADT $\geq$ 4 months without evidence of metastatic disease on traditional CT imaging and bone scans. ADXS-504 will be given by IV every 4 weeks level for 6 study treatments, followed by maintenance therapy given every 12 weeks for 4 doses for overall total of 10 doses of study treatment. DLTs will be evaluated over the first 28 days of treatment. PSA response, PSADT, and adverse events will be summarized. The Kaplan-Meier method will be used to estimate time to PSA progression and rPFS. Immunologic activity will be evaluated by ELISpot analysis, flow cytometry, and multiplex assays and blood samples will be collected for gene sequencing analysis. The study is currently open to enrollment. Clinical trial information: NCT05077098. Research Sponsor: Advaxis, Inc.

A randomized trial on pelvic lymph node dissection versus no lymph node dissection at radical prostatectomy: Report of a trial in progress. *First Author: Nicole Benfante, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The therapeutic benefit of pelvic lymph node dissection (PLND) in the surgical treatment of localized prostate cancer remains unproven. In this trial we aim to evaluate whether PLND reduces biochemical recurrence rates in clinically localized prostate cancer patients. We are presenting our experience in accrual during our first year of implementing this trial at Memorial Sloan Kettering Cancer Center. **Methods:** Patients without evidence of positive or suspicious pelvic lymph nodes on pre-operative imaging, and without prior pelvic radiation for prostate cancer are eligible. Following informed consent prior to radical prostatectomy, patients are enrolled onto the trial and surgeons are randomized using a cluster randomization. Surgeons are randomized to perform a PLND vs. no PLND for a 3-month period. Since our trial began accruing in July 2020, we have enrolled 366 patients (51 high risk, 286 intermediate risk, and 29 low risk) out of 996 eligible patients (37%) through January 2022. We have enrolled 168 patients in the PLND arm and 198 patients in the no PLND arm. Table 1 shows the breakdown of patient consent status in each risk group, by randomization assignment. At this stage in the accrual, we do not see evidence of consenting bias among PLND vs. no PLND randomization and risk group. We conclude that a single-center cluster randomized trial can accrue large numbers of patients in a short period of time, allowing for large scale trials to be completed. Currently, our trial is on track to complete accrual within our 5-year goal. Clinical trial information: NCT01407263. Research Sponsor: U.S. National Institutes of Health.

Consent status by risk group for PLND vs. no PLND randomization arms.

		Consented			Declined			Not Approached		
		High (N=51; 5.1%)	Intermediate (N=286; 29%)	Low (N=29; 2.9%)	High (N=29; 2.9%)	Intermediate (N=131; 13%)	Low (N=14; 1.4%)	High (N=113; 11%)	Intermediate (N=307; 31%)	Low (N=36; 3.6%)
No	PLND	25 (49%)	155 (54%)	18 (62%)	19 (66%)	70 (53%)	5 (36%)	58 (51%)	144 (47%)	20 (56%)

ATHENA–MONO (GOG-3020/ENGOT-ov45): A randomized, double-blind, phase 3 trial evaluating rucaparib monotherapy versus placebo as maintenance treatment following response to first-line platinum-based chemotherapy in ovarian cancer. *First Author: Bradley J. Monk, GOG Foundation, University of Arizona College of Medicine, Creighton University School of Medicine, Phoenix, AZ*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

5501 **Oral Abstract Session**

A phase I/II study of ruxolitinib with frontline neoadjuvant and post-surgical therapy in patients with advanced epithelial ovarian, Fallopian tube, or primary peritoneal cancer. *First Author: Charles N. Landen, Univ of Texas MD Anderson Cancer Ctr, Houston, TX*

Background: The Interleukin-6/JAK/STAT3 axis, via an increase in cancer stem-like cell (CSC) survival, is a reported driver of chemotherapy resistance. We hypothesized that addition of the JAK1/2 inhibitor ruxolitinib to standard chemotherapy would be tolerable and, by targeting therapy-resistant cells, improve the progression-free survival (PFS) of ovarian/fallopian tube/primary peritoneal carcinoma (OV/FT/PPC) patients treated in the up-front setting. **Methods:** Patients with OV/FT/PPC dispositioned to neoadjuvant chemotherapy were eligible for NRG-GY007 (NCT #02713386). In phase I, treatment was with dose-dense paclitaxel (P) 70 or 80 mg/m2 days 1, 8, and 15; carboplatin (C) AUC 5 or 6 day 1; and ruxolitinib (R) 15mg PO BID, every 21 days. In the absence of tumor progression or an inability to tolerate surgery, interval tumor reductive surgery (TRS) was required after cycle 3. After TRS, 3 additional cycles were administered, followed by maintenance ruxolitinib until progression, unacceptable toxicity, or voluntary withdrawal. In phase II, patients were randomized to dose-dense PC (arm 1) or dose-dense PC plus ruxolitinib (arm 2) at the phase I-defined dose of 15mg PO BID. After 3 cycles, TRS was performed, followed by another 3 cycles of the randomized regimen, without maintenance ruxolitinib. The primary phase II endpoint was progression-free survival (PFS). **Results:** 17 patients were enrolled in phase I. The MTD was P at 70, C at 5, and R at 15, which was chosen as the phase II dose. 130 patients were enrolled in phase II with a median follow-up of 24 months. There were five Grade 5 events in phase II, 2 in arm 1 and 3 in arm 2, with all except one being unrelated to therapy; a G5 febrile neutropenia in arm 2 was considered possibly related. In arm 2 there was potential trend towards higher grade 3-4 anemia (64% v 27% control), grade 3-4 neutropenia (53% v 37%), thromboembolic events (12.6% v 2.4%), and febrile neutropenia (6% v 0%). The HR for PFS was 0.702 (90% 1-sided CI = 0-0.89, log-rank p = 0.059). The median PFS in arm 1 was 11.6 versus 14.6 in arm 2. The overall survival HR = 0.785 (90% CI = 0.44 to 1.39, p = 0.70). There were no differences between rates of total gross resection. **Conclusions:** Ruxolitinib 15mg PO BID was well-tolerated with acceptable toxicity in combination with dose-dense PC. The primary endpoint of prolongation of PFS was achieved in the experimental arm. Further study of this combination can be considered. This trial also demonstrates the feasibility of early-phase randomized studies with novel agents and biospecimen collection in front line neoadjuvant treatment of ovarian cancer. Clinical trial information: 02713386. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

5502 **Oral Abstract Session**

Bevacizumab in first-line chemotherapy to improve the survival outcome for advanced ovarian clear cell carcinoma: A multicenter, retrospective analysis. *First Author: Toshiyuki Seki, Department of Obstetrics and Gynecology, Kashiwa Hospital, The Jikei University School of Medicine, Chiba, Kashiwa, Japan*

Background: Advanced ovarian clear cell carcinoma (ACCC, stage III/IV disease) is a rare tumor characterized by chemoresistance. Bevacizumab (Bev) was approved in November 2013 in Japan and became incorporated in the treatment of advanced ovarian cancer. However, the efficacy of Bev against ACCC remain unknown. We investigated the survival outcomes for ACCC, following first-line chemotherapy with or without Bev. **Methods:** Patients diagnosed with ACCC at seven institutions between 2008 and 2018 were enrolled in this study. Patients underwent cytoreductive surgery and taxane-carboplatin chemotherapy (78: triweekly regimen; 30: weekly regimen; 25: dose-dense regimen; 12: others) with or without concurrent and maintenance Bev (15 mg/kg/3 weeks). We compared the progression-free survival (PFS) and overall survival (OS) before (group A, n = 102) and after (group B, n = 43) Bev approval, using Kaplan–Meier method and Cox regression model. We excluded patients with poor performance status (PS) in group A, and patients who did not receive Bev due to poor PS or thrombosis in group B. **Results:** There was no significant difference between two groups in terms of age (p = 0.135) and initial CA125 level (p = 0.674). Thirteen (13%) and 11 (26%) patients had stage IV disease (p = 0.058) and 2 (3%) and 7 (16%) patients were of poor PS (PS ≥2) (p = 0.004) in group A and B, respectively (p = 0.058). More patients (29/43, 67%) in group B were achieved complete resection than in A group (52/102, 51%) (p = 0.068). The median cycle of Bev in B group was 16 (interquartile range: 6-21). The median follow-up time was 36 months. The median PFS increased from 12.5months in A group to 29.7 months in B group (log-rank test: p = 0.023, Wilcoxon test: p = 0.006). The median OS increased from 34.7 months in A group to 51.4 months in B group (log-rank test: p = 0.085, Wilcoxon test: p = 0.027). Multivariate analysis revealed that Bev use (Hazard ratio (HR): 0.54, p = 0.011; HR: 0.54, p = 0.019), PS <2 (HR: 0.33, p = 0.013; HR: 0.29, p = 0.006) and completeness of resection (HR: 0.38, p < 0.001; HR: 0.37, p <0.001) were independent prognostic factors for PFS and OS. **Conclusions:** Incorporating Bev in first-line chemotherapy may improve PFS in patients with ACCC. Research Sponsor: None.

Multivariable Cox proportional analysis of risk factors for progression-free survival and overall survival for advanced clear cell carcinoma.

		PFS			OS		
Variable		Hazard ratio	[95%CI]	*p* value	Hazard ratio	[95%CI]	*p* value

Pembrolizumab, maveropepimut-S, and low-dose cyclophosphamide in advanced epithelial ovarian cancer: Results from phase 1 and expansion cohort of PESCO trial. *First Author: Ana Veneziani, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Platinum-resistant ovarian cancer (PROC) continues to have a poor prognosis. Maveropepimut-S (MVP-S, namely DPX-Survivac) leverages the lipid-based DPX delivery platform to educate a specific and persistent T cell-based immune response to 5 HLA-restricted peptides from survivin, a cancer-related protein commonly upregulated in several cancers. MVP-S in combination with Pembrolizumab (Pemb) and low-dose Cyclophosphamide (CPA) is expected to enhance immune response. This trial aims to assess the safety and efficacy of this regimen in patients (pts) with PROC. **Methods:** Phase 1 escalation cohort allowed all PROC subtypes and comprised 2 dose levels (DL) of MVP-S with 1 initial dose 0.25 mL followed by boosters of 0.25 mL (DL1) or 0.5mL (DL2) SC q6w, combined with CPA (50 mg BID every other week) and Pemb (200 mg q3w). Dose escalation was performed using 3+3 design. Dose-limiting toxicities (DLT) were defined as G4 non-hematologic, ≥G3 persistent non-hematologic toxicity, laboratory value or febrile neutropenia; ≥G2 persistent injection site skin ulceration (> 1wk) or allergic/immune reactions by CTCAE v4.03. DL was considered safe if ≤1 DLT occurred in 6 pts until 21 days after initial and first boosting dose. Pts with high-grade serous (HGSOC) or endometrioid ovarian cancer were allowed in the Phase 2 expansion cohort (P2EC) and treated with the Recommended Phase 2 Dose (RP2D). Response was assessed every 6 wks. Activity in P2EC was defined as at least 2/10 partial response (PR) or stable disease (SD) for 12 wks according to RECIST 1.1. Primary endpoint is overall response rate (ORR), and secondary includes safety, PFS, and OS. Biopsies and blood draws were performed prior to and on treatment for genomic analysis, immune profiling and ctDNA. **Results:** Twenty-six pts were enrolled, 24 were evaluable for safety (8 DL1, 6 DL2, and 10 in P2EC). HGSOC represented 62% of phase I and 100% of P2EC. Median age was 61y (49-78). Pts received a median of 4 (1-7) prior lines of therapy. Median cycles of MVP-S were 2 (1-8). Toxicity G4/G3/G2 occurred in 1/3/7 pts of DL1 and 0/3/6 of DL2. G3/G2 immune-related AE (irAE) and injection site reactions (ISR) were observed in 1/1 and 1/3 pts treated at DL1, and in 1/0 and 2/2 pts at DL2, respectively. DL1 was selected as RP2D due to the occurrence of nephritis and ISR G3 at DL2. No AEs were qualified as DLT. On the P2EC, 5 G3 (1 irAE, 0 ISR) and 28 G2 (0 irAE, 3 ISR) toxicities were observed. At Phase 1, one pt with MSI-High clear cell subtype has ongoing CR after 26 mos of follow-up, 2 pts had PR and 6 SD.There were 1 PR and 3 SD on P2EC, of which 1 and 2, respectively, achieved response > 12wks. **Conclusions:** The combination of MVP-S, low-dose CPA, and Pemb was tolerable and met the efficacy endpoint in the expansion cohort in heavily treated PROC. Immuno-genomic correlative analyses are ongoing. Clinical trial information: NCT03029403. Research Sponsor: Merck and Immunovaccine, OICR (Ontario Institute for Cancer Research) and UHN (University Health Networking) sponsored.

Pembrolizumab + chemotherapy in patients with persistent, recurrent, or metastatic cervical cancer: Subgroup analysis of KEYNOTE-826. *First Author: Krishnansu Sujata Tewari, Obstetrics & Gynecology, University of California, Irvine, Orange, CA*

Background: In KEYNOTE-826 (NCT03635567),pembrolizumab (pembro) + chemotherapy (chemo) ± bevacizumab (bev) provided statistically significant, clinically meaningful PFS and OS improvements in patients with persistent, recurrent, or metastatic cervical cancer. In the present analysis of KEYNOTE-826, we assessed outcomes in several key patient subgroups. **Methods:** Eligible adult patients had persistent, recurrent, or metastatic squamous cell carcinoma, adenosquamous carcinoma, or adenocarcinoma of the cervix not previously treated with chemo and not amenable to curative treatment; measurable disease per RECIST v1.1; ECOG PS 0–1; and a tumor sample to determine PD-L1 status. Patients were randomized 1:1 to pembro 200 mg Q3W or placebo (pbo) for up to 35 cycles + chemo (paclitaxel 175 mg/m^2 + cisplatin 50 mg/m^2 or carboplatin AUC 5) ± bev 15 mg/kg. Dual primary endpoints are PFS by investigator assessment per RECIST v1.1 and OS in patients with PD-L1 CPS ≥1, all comers, and CPS ≥10. Treatment effects on PFS and OS were examined in patient subgroups defined by bev use (yes or no), histology (squamous or non-squamous [including adenocarcinoma and adenosquamous]), platinum use (carboplatin or cisplatin), and prior chemoradiation therapy (CRT). Hazard ratios (HR) and 95% CIs were based on a stratified Cox regression model. **Results:** 617 patients were randomized (pembro + chemo ± bev, n=308; pbo + chemo ± bev, n=309). At the May 3, 2021 data cutoff, median follow-up was 22 months. Pembro + chemo prolonged PFS and OS vs pbo + chemo in all subgroups evaluated in the all-comer population (Table). Similar benefits of pembro + chemo on PFS and OS were also seen in the protocol-specified CPS ≥1 and CPS ≥10 populations. **Conclusions:** Pembro + chemo ± bev prolonged PFS and OS vs pbo + chemo ± bev among the subgroups defined by bev use, histology, platinum use, and prior CRT and provided clinically meaningful benefits similar to the broader population of patients with persistent, recurrent, or metastatic cervical cancer. Clinical trial information: NCT03635567. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Tisotumab vedotin (TV) + pembrolizumab (pembro) in first-line (1L) recurrent or metastatic cervical cancer (r/mCC): Interim results of ENGOT Cx8/GOG 3024/innovaTV 205. *First Author: Domenica Lorusso, Fondazione Policlinico Gemelli IRCCS, Rome, Italy*

Background: TV monotherapy has received US accelerated approval for previously treated r/mCC with disease progression on or after chemotherapy based on clinically meaningful tumor response rate and duration of response (DOR) reported from the GOG-3023/ENGOT-cx6/innovaTV 204 study (Coleman et al., Lancet Onc. 2021). Recently, the recommended phase 2 dose (RP2D) and feasibility of TV + pembro, TV + carboplatin (carbo), and TV + bevacizumab in r/mCC were reported from the dose-escalation phase (Monk et al, IGCS 2021); interim safety and efficacy data from 2 dose-expansion cohorts, 1L TV + carbo and second-line/third-line (2L/3L) TV + pembro (Vergote et al, ESMO 2021) from the ENGOT-cx8/GOG-3024/innovaTV 205 (NCT03786081) study, were also reported. Here we report interim safety and efficacy results from a third dose-expansion cohort evaluating 1L TV + pembro in patients with r/mCC. **Methods:** Patients with r/mCC who had not received prior systemic therapy (excluding chemoradiation) for r/mCC were treated with the RP2D of TV 2.0 mg/kg + pembro 200 mg intravenously every 3 weeks. The primary endpoint was investigator-assessed confirmed objective response rate (ORR) per RECIST v1.1; secondary endpoints included DOR, progression-free survival (PFS), overall survival (OS), and safety. **Results:** 33 pts were treated with 1L TV + pembro (median 6 cycles). At data cutoff (July 1, 2021), median duration of exposure to TV + pembro was 5.1 mo (range 1-17) and median follow-up was 12.2 mo (range 1-17). Confirmed ORR among 32 evaluable patients was 41% (95% CI 24-59), with 3 (9%) complete responses and 10 (31%) partial responses. Median time to response was 1.4 mo (range 1.2-2.8); median DOR was not reached, with response ongoing in 7/13 patients. Median PFS was 5.3 mo (95% CI 4.0-12.2); median OS was not reached. The most common treatment-emergent AEs (TEAEs) were alopecia (61%), diarrhea (55%), epistaxis (49%), conjunctivitis (46%), and nausea (46%). Grade ≥3 TEAEs occurred in 67% of patients, the most common being anemia (12%); asthenia (9%); hypokalemia (9%); and increased alanine aminotransferase, decreased white blood cell count, dyspnea, and acute kidney injury (6% each). Three grade 5 TEAEs were reported of which one, disseminated intravascular coagulation, was considered treatment-related. Prespecified AEs of interest (grade 1-2/grade ≥3) with TV included ocular (58%/9%), peripheral neuropathy (45%/3%), and bleeding (61%/6%). Updated results with longer follow-up for this cohort and the 1L TV + carbo and 2L/3L TV + pembro cohorts will be provided at the meeting. **Conclusions:** TV + pembro demonstrated encouraging, durable antitumor activity with a manageable and acceptable safety profile as a 1L regimen for patients with r/mCC. This trial is ongoing and final analyses will be reported in the future. Clinical trial information: NCT03786081. Research Sponsor: Genmab A/S and Seagen Inc.

5508 **Oral Abstract Session**

COVID-19 in patients with gynecologic cancer: A preliminary report from the COVID-19 and Cancer Consortium (CCC19). *First Author: Alicia Beeghly-Fadiel, Vanderbilt University Medical Center, Nashville, TN*

Background: Limited information exists regarding the severity of short-term outcomes among patients with gynecologic cancer who are infected with SARS-CoV-2. **Methods:** Patients with gynecologic cancer and laboratory confirmed SARS-CoV-2 infection were identified from the international CCC19 registry. We estimated odds ratios (OR) from ordinal logistic regression for associations with severity of COVID-19 outcomes, defined from least to most severe as hospitalization, intensive care unit (ICU) admittance, mechanical ventilation, and 30-day mortality. **Results:** Of 842 patients identified, 48% had endometrial cancer, 24% had ovarian cancer, 22% had cervical cancer, and 6% had dual primary/other gynecologic cancers. The majority were from the United States (86%), most were non-Hispanic White (46%), and the median age was 62 years (IQR 52-72). The majority were diagnosed with localized disease (68%); only 18 (2%) and 15 (2%) were fully or partially vaccinated, respectively. In the 3 months prior to COVID-19, 36% had any cancer treatment, with chemotherapy the most common (23%). When diagnosed with COVID-19, most patients were in remission (50%), while 37% had active disease, including 22% with metastatic disease. Most patients presented with typical COVID-19 symptoms (76%); few had a poor ECOG performance status (PS ≥2, 14%). Outcomes included hospitalization (50%), ICU admittance (12%), mechanical ventilation (8%), and death within 30 days of testing positive for SARS-CoV-2 (10%). In unadjusted models, increasing age (OR: 1.03 1.02-1.04) and Black race (OR 1.91, 1.31-2.77) were associated with increased severity of COVID-19 outcomes. Compared to patients in remission for ≥5 years, those with progressive disease had increased severity (OR 1.88, 1.25-2.82), while those in remission for < 5 years or with stable disease had decreased severity of COVID-19 outcomes (OR 0.55, 0.39-0.76). In multivariable models that included adjustment for age, race, and cancer status, additional factors associated with increased COVID-19 outcome severity included cardiac (OR 1.57, 1.13-2.19) and renal (OR 2.00, 1.33-3.00) comorbidities, an ECOG PS ≥2 (OR 5.15, 3.21-8.27), having pneumonia or pneumonitis (OR 4.08, 2.94-5.66), venous thromboembolism (OR 4.67, 2.49-8.75), sepsis (OR 14.2, 9.05-22.1), or a co-infection within ±2 weeks of SARS-CoV-2 (OR: 4.40, 2.91-6.65); asymptomatic SARS-CoV-2 infection was associated with decreased severity of outcomes (OR: 0.25, 0.16-0.38). The overall case fatality rate was 15.7%. **Conclusions:** Patients with gynecologic cancer experience significant morbidity and mortality related to infection with SARS-CoV-2. Age, race, cancer status, co-morbidities, and COVID-19 complications were associated with more severe COVID-19 outcomes, along the continuum from least to most, of hospitalization, ICU admittance, mechanical ventilation, and 30-day mortality. Research Sponsor: U.S. National Institutes of Health.

Dostarlimab in advanced/recurrent (AR) mismatch repair deficient/microsatellite instability–high or proficient/stable (dMMR/MSI-H or MMRp/MSS) endometrial cancer (EC): The GARNET study. *First Author: Ana Oaknin, Vall d'Hebron Institute of Oncology, Hospital Universitari Vall d'Hebron, and Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain*

Background: Dostarlimab is a programmed death 1 (PD-1) inhibitor approved in the U.S. as a monotherapy in patients (pts) with dMMR AR EC that has progressed on or after treatment with a platinum-containing regimen or dMMR solid tumors that have progressed on or after prior treatment, with no satisfactory alternative treatment options; and in the E.U. as a monotherapy in pts with dMMR/MSI-H AR EC that has progressed on or after treatment with a platinum-containing regimen. Here, we report on efficacy and safety in the 2 expansion cohorts of the GARNET trial that enrolled pts with EC. **Methods:** GARNET is a multicenter, open-label, single-arm phase 1 study. Pts were assigned to cohort A1 (dMMR/MSI-H EC) or cohort A2 (MMRp/MSS EC) based on local assessment. Pts received 500 mg of dostarlimab IV Q3W for 4 cycles, then 1,000 mg Q6W until disease progression, discontinuation, or withdrawal. The primary endpoints are ORR and DOR by blinded independent central review using RECIST v1.1. **Results:** For this third interim analysis, 153 dMMR/MSI-H and 161 MMRp/MSS pts were enrolled and dosed. Of these, 143 dMMR/MSI-H and 156 MMRp/MSS pts had measurable disease at baseline and ≥ 6 mo of follow-up and were included in the efficacy-evaluable population. ORRs were 45.5% (dMMR/MSI-H) and 15.4% (MMRp/MSS; Table). Median (m) DORs were not reached (NR; dMMR/MSI-H) and 19.4 mo (MMRp/MSS). Probability of PFS at 6, 9, and 12 mo was 49.5%, 48.0%, and 46.4% in dMMR/MSI-H EC and 35.8%, 31.3%, and 29.4% in MMRp/MSS EC, respectively. mOS was NR (dMMR/MSI-H) and 16.9 mo (MMRp/MSS). Overall, 27 pts (8.6%) discontinued treatment because of a treatment-related adverse event (TRAE; 13 dMMR/MSI-H, 14 MMRp/MSS). The majority of TRAEs were grade 1 or 2. The most common any-grade TRAEs were fatigue (56; 17.8%), diarrhea (46; 14.6%), and nausea (43; 13.7%). No deaths were attributed to dostarlimab in the EC cohorts. Hypothyroidism (12; 8%) was the most common any-grade immune-related TRAE. **Conclusions:** Dostarlimab demonstrated durable antitumor activity in both dMMR/MSI-H and MMRp/MSS AR EC. dMMR/MSI-H was associated with better outcomes: a higher response rate and longer PFS and OS. Safety was consistent with other PD-1 antibodies. Clinical trial information: NCT02715284. Research Sponsor: GlaxoSmithKline.

An open label, nonrandomized, multisite phase II trial combining bevacizumab, atezolizumab, and rucaparib for the treatment of previously treated recurrent and progressive endometrial cancer. *First Author: William Hampton Bradley, Froedtert and the Medical College of Wisconsin, Milwaukee, WI*

Background: Patients with metastatic recurrent endometrial cancer have limited effective therapies. Single agent pembrolizumab is utilized in mismatch repair deficient (MMRd) patients, while the combination of lenvatinib and pembrolizumab is now more commonly used in MMR intact patients who have progressed after chemotherapy combinations. This trial investigated a novel three drug regimen. **Methods:** Patients with recurrent endometrial cancer not amenable to curative intent surgery or radiation after one or two lines of therapy were eligible regardless of histology. This study is a multicenter, open-label, nonrandomized phase II trial. All subjects initially received the three-drug combination of rucaparib, bevacizumab, and atezolizumab. The primary goal of this trial was to estimate the overall response rate in these patients, and secondarily to estimate the progression-free and overall survival of patients treated with this triplet combination. Total enrollment was 30, with the first six subjects participated in a safety lead-in. Treatments until progression, toxicity, or clinician choice. Subjects could continue past progression if, in the estimate of the treating clinician and subject, clinical benefit was being provided. Subjects were eligible for analysis if they received at least one cycle and had one post-dose tumor assessment. The ORR assumption was 27% with a lower bound of 14%. **Results:** 30 subjects were enrolled between 07/2019 and 06/2021. Of these 26 were evaluable. Median follow up at cut off was 14.9 months. 23 subjects had clinical benefit, with 1 (4%) with CR, 9 (39%) with PR, and 13 (57%) with stable disease as best response. Overall median event-free (progression or death) was 5.3 (95% CI 2.7-7.9) months and overall survival 13.3 (95% CI NA) months at cut off. Median duration of therapy was 4.4 months (IQR 1.7-7.3), with 4 subjects remaining on study directed therapy at data cut off. Histology distribution was 50% serous, 20% endometrioid, and 13% carcinosarcoma. 19 pts were White, 8 African American, 2 identified as Asian, 1 unknown. In the MMR deficient patients, event-free probability was 11.9 months. Grade 3 or 4 treatment related adverse events occurred in 50% patients. **Conclusions:** To our knowledge, this trial represents the first use of a non-chemotherapy-based triplet therapy for recurrent endometrial cancer. The combination of rucaparib, bevacizumab, and atezolizumab may safely be used to treat recurrent/persistent endometrial cancer. This combination demonstrates clinically meaningful improvement in response, with acceptable toxicity. Enhanced response to therapy was seen in MMR deficient subjects. Clinical trial information: NCT03694262. Research Sponsor: Genentech and Clovis Oncology.

5511 **Clinical Science Symposium**

Randomized phase III study of maintenance selinexor versus placebo in endometrial cancer (ENGOT-EN5/GOG-3055/SIENDO): Impact of subgroup analysis and molecular classification. *First Author: Vicky Makker, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Endometrial cancers (ECs) are stratified into four molecular categories: wild type *TP53* with non-specific molecular profile typically with microsatellite stability (NSMP, p53wt/MSS), DNA polymerase ε exonuclease domain-mutated (POLEmut), microsatellite instability high (MSI) and *TP53* abnormal (p53abn). These are associated with specific prognoses. Selinexor (SEL) is a specific XPO1 inhibitor that leads to the nuclear retention and activation of tumor suppressor proteins (TSP) including p53. SEL showed improved progression-free survival (PFS) over placebo (PLB) in the stratification adjusted results of the ENGOT-EN5/GOG-3055/SIENDO study (NCT03555422; ESMO 2022). **Methods:** The SIENDO study is a prospective, multicenter, double-blind, placebo-controlled, phase 3 study of SEL (80 mg once weekly) vs. PLB (2:1 randomization) as maintenance therapy in 263 patients (pts) with advanced or recurrent EC after one line of taxane-platinum therapy with partial or complete remission. *TP53* mutations and MSI were assessed by centralized targeted sequencing and local immunohistochemistry. Classification was based on sequencing 648 genes on tumor samples from 172 pts (107 on SEL), assigned first by POLEmut, then MSI, then p53abn or p53wt (NSMP). Preliminary exploratory analyses based on molecular classification were prespecified in the trial. **Results:** The SIENDO study resulted in a median progression-free survival (PFS) of 5.7 months (SEL) vs. 3.8 months (PLB), with a stratification adjusted (eCRF) hazard ratio (HR) of 0.70 (p = .024; and a stratification non-adjusted (IRT) HR of 0.76 (p=0.063). Among the 172 patients who underwent molecular classification, those on SEL (107 pts) were classified as follows: 37 (35%) NSMP, 2 (2%) POLEmut, 18 (17%) MSI, and 50 (46%) p53abn. A similar distribution was seen in those on PLB (65 pts): 20 (31%) NSMP; 4 (6%) POLEmut; 8 (12%) MSI; 33 (51%) p53abn. Subgroup analysis of pts with *TP53*wt showed a PFS of 13.7 mo with SEL vs. 3.7 mo with PLB (HR 0.375; 95% CI, 0.210-0.670; nominal p = .0003) and pts with MSS/pMMR disease had a PFS of 6.9 mo with SEL vs. 5.4 with PLB (HR 0.593; 95% CI, 0.388-0.905, nominal p = .007). An analysis of patients with NSMP (p53wt, MSS) showed a substantial difference in PFS for SEL vs. PLB: medians NR and 3.71 months, respectively (HR 0.163; 95% CI, 0.060-0.444; nominal p < .0001). Analyses of the other 3 molecular categories did not show significant differences in PFS between SEL and PLB. Additional biomarker identification studies assessing tumor genetics and epigenetics are ongoing. **Conclusions:** SEL showed improved PFS over PLB in the SIENDO study based on the stratification adjusted analysis. As an indirect p53 activator, preliminary exploratory subgroup analyses of SEL showed improvement over PLB amongst the patients with TP53wt, MSS, and the NSMP EC comprising approximately 50% of patients with advanced/recurrent EC. Clinical trial information: NCT03555422. Research Sponsor: Karyopharm Therapeutics.

Mirvetuximab soravtansine (MIRV) in patients with platinum-resistant ovarian cancer with high folate receptor alpha (FRα) expression: Characterization of antitumor activity in the SORAYA study. *First Author: Ursula A. Matulonis, Dana-Farber Cancer Institute, Boston, MA*

Background: SORAYA is a global single arm phase 3 study evaluating MIRV in patients (pts) with FRα high platinum-resistant ovarian cancer (PROC). MIRV is an antibody drug conjugate comprising a FRα-binding antibody, cleavable linker, and maytansinoid DM4, a potent tubulin-targeting agent. In this study, MIRV demonstrated activity in a broad population of PROC, regardless of number of prior lines of therapy or prior PARPi (Matulonis, SGO 2022). Here we describe details of response to treatment important for clinical decision making. **Methods:** SORAYA enrolled PROC pts with high FRα expression by immunohistochemistry (Roche FOLR1 Assay ≥ 75% of cells with PS2+ staining intensity) who had received 1-3 prior therapies, including required prior bevacizumab. Pts received intravenous MIRV at 6 mg/kg, adjusted ideal body weight, on Day 1 of a 21-day cycle until disease progression or unacceptable toxicity. The primary endpoint was confirmed objective response rate (ORR) per RECIST v1.1 by investigator (INV) and the key secondary endpoint was duration of response (DOR); additional endpoints included time to response, CA-125 response, safety and tolerability. **Results:** 106 pts were enrolled; 51% had 3 prior lines; 48% had 1-2 prior lines of therapy; 48% received prior PARPi. ORR by INV was 32.4% (95% confidence interval [CI]: 23.6%, 42.2%), including five complete responses. Median time to response was 1.5 mos (range 1.0 to 5.6) and 71% of pts demonstrated tumor reduction. At the time of the protocol specified primary analysis (16 Nov 2021), the median DOR was 5.9 mos (95% CI: 5.6, 7.7). With 15 responders remaining on MIRV, the DOR continues to evolve. In the 86 response-evaluable patients for CA-125 (by Gynecologic Cancer Intergroup criteria), responses were observed in 46.5% (95% CI: 35.7, 57.6). Updated data will be presented including depth and duration of responses and impact of dose modifications. The most common treatment-related adverse events (TRAE; all grade, grade 3+) included blurred vision (41%, 6%), keratopathy (36%, 9%), and nausea (29%, 0%). TRAEs led to dose delays in 32%, dose reductions in 19%, and discontinuations in 7% of pts; one patient discontinued treatment due to an ocular event. The tolerability profile of MIRV consists of low-grade, reversible ocular and GI events, managed with dose modifications and supportive care. **Conclusions:** Treatment options for pts with PROC are limited. MIRV is the first biomarker-directed therapy demonstrating anti-tumor activity in pts with FRα high PROC. These results support the clinically meaningful impact MIRV has for pts with FRα high PROC, irrespective of prior therapies or dose modifications. Clinical trial information: NCT04209855. Research Sponsor: ImmunoGen.

5513 **Poster Discussion Session**

Safety and efficacy of MORAb-202 in patients (pts) with platinum-resistant ovarian cancer (PROC): Results from the expansion part of a phase 1 trial. *First Author: Shin Nishio, Department of Obstetrics and Gynecology, Kurume University School of Medicine, Fukuoka, Japan*

Background: MORAb-202 is an antibody-drug conjugate consisting of farletuzumab (an antibody that binds to folate receptor alpha [FRα]) paired with eribulin mesylate (a microtubule dynamics inhibitor) conjugated via a cathepsin-B–cleavable linker. The dose-escalation part of this phase 1 study confirmed antitumor activity in pts with ovarian cancer (Shimizu 2021, *CCR*); based on efficacy and safety, MORAb-202 0.9 mg/kg and 1.2 mg/kg Q3W were chosen as doses for the expansion part of this study in pts with PROC. **Methods:** The primary objective for the expansion part of this phase 1 study conducted in Japan was to define the safety and tolerability of MORAb-202. Secondary objectives included PK characterization and efficacy assessment (best overall response, objective response rate, progression-free survival, and overall survival). Eligible pts included those who had received ≤2 regimens of chemotherapy after diagnosis of PROC, had measurable disease per RECIST v1.1, and an ECOG PS of ≤1. Pts (except those with high grade serous histology) in the expansion phase were required to be FRα positive. The expansion phase began at the 0.9 mg/kg dose (Cohort 1); Cohort 2 (1.2 mg/kg) was initiated after safety assessment of Cohort 1 was completed. Tumor responses were assessed per RECIST v1.1 by investigator. **Results:** Twenty-four pts were treated in Cohort 1 and 21 pts were treated in Cohort 2. Grade ≥3 TEAEs occurred in 33.3% of pts in Cohort 1 and 28.6% of pts in Cohort 2. The most common TEAE was interstitial lung disease (ILD)/pneumonitis at both dose levels (Cohort 1: 37.5% [n=9; 8 with grade 1, 1 with grade 2]; Cohort 2: 66.7% [n=14; 6 with grade 1, 7 with grade 2, 1 with grade 3]). Other common TEAEs of any grade were nausea (25.0%; 33.3%), pyrexia (33.3%; 42.9%), malaise (16.7%; 28.6%), and headache (12.5%; 47.6%), in Cohorts 1 and 2, respectively. ORR was 25.0% and 52.4% in Cohorts 1 and 2, respectively (Table). Antitumor activity was observed across FRα-expression levels (<50% and ≥50%) and will be presented. **Conclusions:** In the PROC population, antitumor activity was seen with both the MORAb-202 0.9 mg/kg and 1.2 mg/kg doses. While pt numbers were small, efficacy was observed irrespective of FRα-expression levels. ILD/pneumonitis was the most common TEAE and was low grade in most pts. Dose optimization is ongoing to maximize the benefit/risk profile of MORAb-202. Clinical trial information: NCT03386942. Research Sponsor: Eisai Inc., Nutley, NJ, USA.

5514 **Poster Discussion Session**

A randomized phase II study of bevacizumab and weekly anetumab ravtansine or weekly paclitaxel in platinum-resistant or refractory ovarian cancer NCI trial#10150. *First Author: Stephanie Lheureux, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Mesothelin and its binder, antigen-CA125, are highly expressed in high grade serous and endometrioid ovarian cancers (HGOC) and, can inhibit paclitaxel-induced cell death. Anetumab ravtansine (AR) is a fully-human antibody directed at the mesothelin antigen, conjugated to a tubulin polymerization inhibitor. We assessed the safety and activity of the combination AR/bevacizumab (ARB) versus weekly paclitaxel/bevacizumab (PB) in patients (pts) with platinum resistant HGOC. **Methods:** An initial run-in phase I assessed the safety of ARB. After determination of the recommended phase 2 dose (RP2D), a multicenter 1:1 randomized phase 2 trial was designed to evaluate the progression free survival (PFS) in pts with platinum resistant/refractory HGOC. Pts were stratified by platinum resistant or refractory and prior bevacizumab (bev). Eligibility required measurable disease and mesothelin tested positive centrally on archival tissue by IHC. No limitation on the number of prior lines of therapy. A futility analysis was planned at 35 PFS events. The control arm was weekly intravenous paclitaxel 80mg/m^2 with bev 10mg/kg every 2 weeks. A CT was performed every 8 weeks for RECIST1.1 assessment. The toxicities were reported according to CTCAE version 5.1. NCT03587311. **Results:** 7 pts were enrolled in the run-in phase 1 and the RP2D determined as bev (10mg/kg) biweekly with AR (2.2mg/kg) weekly on a 28 day-cycle. In the phase 2, 57 pts were enrolled, 28 pts in the ARB and 29 pts in the control group. The positivity rate for mesothelin screening was 88%. Pts were heavily pre-treated, median prior lines of 3 (range (1-9) with 24 pts received prior bev (42%) and 13 pts were platinum refractory (7 in ARB and 6 in PB). At the time of 35 PFS events, one CR and 4 PR were observed (ORR = 18%) in the ARB arm, versus no CR and 16 PR in the weekly PB (ORR = 55%). The estimated median PFS was 5.3 (95% CI: 3.7-7.4) months for ARB and 9.6 (95% CI: 7.4-17.4) months for PB (HR = 1.7(95% CI: 0.9-3.4)). The median number of cycles were 4 (1, 29) and 8 (1, 19) respectively. The most common treatment-related AEs in the ARB arm were mostly grade 1/2 increase AST (71%) and ALT (64%), thrombocytopenia (61%), fatigue (57%), and peripheral neuropathy (46%). In the PB arm, the most common treatment-related AE were anemia (66%), neutropenia (59%), epistaxis (48%), fatigue (45%) and peripheral neuropathy (45%). **Conclusions:** At the time of futility analysis, weekly PB had better outcome than weekly ARB leading to the study termination. Molecular and blood analyses are on-going to assess potential biomarkers of response. This study highlights the importance of randomization in assessment of novel therapies and potential for re-challenge with bevacizumab. These data show that weekly PB is an effective regimen and can be considered as the control arm in platinum resistant HGOC. Clinical trial information: NCT03587311. Research Sponsor: U.S. National Institutes of Health.

5515 **Poster Discussion Session**

IGNITE: A phase II signal-seeking trial of adavosertib targeting recurrent high-grade, serous ovarian cancer with cyclin E1 overexpression with and without gene amplification. *First Author: George Au-Yeung, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Cyclin E1 gene amplification and protein over-expression is a marker of platinum resistance in high grade serous ovarian, fallopian tube or primary peritoneal cancer (HGSC), and may predict response to WEE1 inhibition. Adavosertib, a WEE1 inhibitor, has demonstrated activity in unselected women with recurrent ovarian and serous endometrial cancer. We aimed to evaluate the efficacy of adavosertib in women with recurrent platinum resistant HGSC with cyclin E1 over-expression, with and without gene amplification. **Methods:** IGNITE is a multicentre, phase 2 trial with 2 cohorts of women with recurrent platinum resistant HGSC. Tumors were assessed for cyclin E1 protein expression by IHC and *CCNE1* copy number by FISH. Patients were assigned to Cohort 1 if tumors were cyclin E1 over-expressed (H-score>50) and amplified (≥8 copies), and Cohort 2 if tumors were overexpressed and nonamplified. Patients with evaluable disease by RECIST v1.1 or GCIG CA-125 criteria were included. Adavosertib 300mg PO was given daily on days 1-5 and 8-12 of a 21-day cycle. The primary endpoint was investigator assessed clinical benefit (CB) defined as absence of progression for ≥ 18 weeks. Here we present the 18-week response data for the first 32 patients treated from Cohort 2, with a data cut-off of August 2021. **Results:** Between Jan-2020 and May-2021, 32 patients were accrued to Cohort 2. Median age was 62 years (range 42-77) and 84% had received ≥2 prior lines of chemotherapy. Median cyclin E1 IHC H-score was 120 and 28 patients (88%) had measurable disease by RECIST. Median number of cycles commenced was 8 (range 1-19). Overall response rate (ORR) was 53% and CB rate was 61% for all evaluable patients. Seventeen patients (53%) required a dose reduction, most commonly for neutropenia or fatigue. Seventeen patients experienced ≥Grade 3 treatment related adverse event, and 4 patients (15%) discontinued due to toxicity. **Conclusions:** The efficacy results in a biomarker-selected cohort of patients are promising with a higher response rate than reported in previous studies of adavosertib in unselected women with recurrent HGSC. Duration of response and progression free survival data will be presented as data matures. Clinical trial information: ACTRN12619001185156P. Research Sponsor: AstraZeneca.

Response	Response evaluable patients (n=32)	CA125 evaluable only patients (n=4)	RECIST measurable patients (n=28)
CR	2 (6%)	-	2 (7%)
PR	14 (44%)	-	14 (50%)
CA125 50% Response	1 (3%)	1 (25%)	-
SD	8 (25%)	-	8 (29%)
No CA-125 response and no PD	3 (9%)	3 (75%)	-
PD	4 (12%)	0 (0%)	4 (14%)
OR (CR/PR/CA-125 50% response)	17 (53% [35, 71])	1 (25% [0, 81%])	16 (57% [37, 76])
CB (No PD>18 weeks)[a]	19 (61% [42, 78])	1 (25% [0, 81%])	18 (67% [46, 83])

a - One patient had SD at week 7 and withdrew consent at week 15 when ceased treatment due to toxicity. This patient was considered not evaluable for clinical benefit and CB rate was calculated excluding this patient.

5516 **Poster Discussion Session**

Adavosertib in combination with carboplatin in advanced *TP53*-mutated platinum-resistant ovarian cancer. *First Author: Alaa Embaby, Department of Clinical Pharmacology, The Netherlands Cancer Institute, Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands*

Background: Ovarian cancer is globally the second most common cause of death among women with gynecologic malignancies. Despite high initial response rates, the overall prognosis of this patient population remains poor. The majority of advanced ovarian cancers will become platinum resistant defined by recurrence within six months after completion of platinum therapy. In the first part of the current phase II study, the combination of carboplatin and the Wee1 inhibitor adavosertib (AZD1775), showed to be safe and effective in patients with *TP53* mutated platinum resistant ovarian cancer. The aim of this additional cohort is to gain more information about the safety and efficacy of the combination and to explore predictive biomarkers for resistance and response to adavosertib. **Methods:** In this additional cohort 29 evaluable were treated with carboplatin AUC 5 mg/ ml·min and adavosertib 225 mg BID for 2.5 days in a 21-day cycle. The anti-tumor activity was assessed according to RECIST 1.1. Pre-, on- and post-treatment biopsies were obtained to explore genetic determinants of drug resistance and response to adavosertib. **Results:** A total of 32 patients with a median age of 62 years (39-77 years) were enrolled in this cohort. All patients had carboplatin/paclitaxel as first line therapy. Six patients received a second-line non-platinum containing regimen. Median platinum free interval was 5.8 months (range 1.7 – 11.9). Twenty-nine patients were evaluable for efficacy. Grade 1-2 bone marrow toxicity, nausea, vomiting and fatigue were the most common adverse events. Dose reductions of carboplatin and/or adavosertib were made in 15/29 evaluable patients (52%). Dose delays occurred in the majority of patients (76%), mostly due to neutropenia and thrombocytopenia. Twelve patients showed PR as best response, resulting in an ORR of 38% in the intention-to-treat population (95% CI 21%-56%). The median PFS was 5.6 months (range 1.1-32 months, 95% CI 4.2-7.0) and median duration of response was 5.3 months (95% CI 0.13-10.5). **Conclusions:** Adavosertib 225 mg BID for 2.5 days and carboplatin AUC 5 in a 21-day cycle could be safely combined and shows promising anti-tumor efficacy in patients with platinum resistant ovarian cancer. Bone marrow toxicity remains the most common reason for dose reductions and dose delays. Translational biomarker results (CCNE1 analysis as potential predictive marker for response and resistance and WGS) to better understand the anti-tumor activity of the combination are pending. Clinical trial information: NCT01164995. Research Sponsor: AstraZeneca.

5517 **Poster Discussion Session**

Efficacy and safety of lucitanib + nivolumab in patients with advanced gynecologic malignancies: Phase 2 results from the LIO-1 study (NCT04042116; ENGOT-GYN3/AGO/LIO). *First Author: Manish R. Patel, Drug Development Unit, Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, FL*

Background: LIO-1 is assessing the oral antiangiogenic, multikinase inhibitor lucitanib in combination with the programmed cell death receptor 1 (PD-1) inhibitor nivolumab. Individualized lucitanib dose titration is being explored to maximize lucitanib exposure and potential clinical benefit of the combination. Here, we present data from stage 1 of a Simon 2-stage design across 4 different types of advanced gynecologic cancers from the phase 2 part of LIO-1. **Methods:** Patients (pts) with advanced, recurrent, or metastatic endometrial cancer (EC, who received ≥1 prior platinum-based chemotherapy); cervical cancer (CC, who received ≥1 prior platinum-based chemotherapy ± bevacizumab); high-grade ovarian cancer (OC, who received ≥2 prior chemotherapies); or EC/OC with clear-cell histology (EOCC, who received ≥1 prior platinum-based chemotherapy + taxane) were enrolled. Prior PD-1 or programmed cell death ligand 1 (PD-L1) inhibitor treatment was excluded, except for up to 10 pts in the EC cohort. Pts received lucitanib at a starting dose of 6 mg once daily (QD), escalating to 8 mg QD and then 10 mg QD if safety-based titration criteria were met, plus intravenous nivolumab 480 mg every 28 days. The data cutoff was Jan 10, 2022. **Results:** Across cohorts, 100 pts were enrolled to stage 1; 27 (27%) remain on treatment. To date, 28 (28%) have escalated to lucitanib 8 mg, and 17 (17%) have escalated to the maximum dose of 10 mg. Confirmed responses per RECIST v1.1 have been reported in 5/22 (22.7%; 5 partial responses [PRs]) EC pts, 7/22 (31.8%; 2 complete responses [CRs], 5 PRs) CC pts, 4/33 (12.1%; 4 PRs) OC pts, and 5/23 (21.7%; 1 CR, 4 PRs) EOCC pts. Response duration ranges from 1.9+ to 13.1+ months. Of 5 pts with EC who received prior PD-1 inhibitor, there were 2 PRs, and 1 pt with ongoing stable disease of 7+ months. Grade ≥3 treatment-emergent adverse events (TEAEs) considered related to study treatment were reported in 43 (43%) pts, with hypertension the most frequent (n = 25 [25%]). Forty-six (46%) pts had a lucitanib-related TEAE that led to lucitanib interruption and 12 (12%) had one that led to lucitanib dose reduction. Eleven (11%) and 8 (8%) pts discontinued lucitanib and nivolumab, respectively, due to a treatment-related TEAE. Safety results were generally consistent across tumor cohorts. **Conclusions:** The combination of lucitanib + nivolumab is active in the treatment of advanced gynecological malignancies and has a manageable safety profile through effective dose titration. Stage 2 enrollment has continued in the CC cohort. Biomarker analysis is ongoing, and more mature efficacy and safety data will be presented at the meeting. Clinical trial information: NCT04042116. Research Sponsor: Clovis Oncology, Inc.

Real-world effectiveness of first-line maintenance olaparib in women with *BRCA*-mutated advanced ovarian cancer: U.S. retrospective cohort study. *First Author: Ramez Nassef Eskander, UC San Diego Moores Cancer Center, San Diego, CA*

Background: Following cytoreductive surgery and first-line (1L) platinum based chemotherapy, 70% of patients (pts) with newly diagnosed advanced ovarian cancer (AOC) experience relapse within 3 years. 1L maintenance treatment (tx) with olaparib monotherapy, a poly (ADP-ribose) polymerase inhibitor, extended progression free survival in pts with BRCA mutated (BRCAm) AOC in the SOLO-1 (NCT01844986) randomized controlled trial (RCT). We aimed to describe real world characteristics, tx patterns, and clinical outcomes of pts with newly diagnosed, BRCAm AOC. **Methods:** Data were collected from 457 pts via electronic case report forms in the US. Pt eligibility criteria were positive BRCAm test result between Jan-June 2019 (6 months post 1L olaparib FDA approval), newly diagnosed AOC (no maintenance tx prior to index), aged ≥18 years, no RCT enrollment, no active neoplasia, no prior tx for metastatic/stage IV cancer. Pt follow up was until July 2021. Kaplan-Meier (KM) estimation was used for time to event analysis using progression proxies: Time to subsequent therapy and discontinuation (or death for both) from initiation of 1L maintenance olaparib monotherapy. **Results:** Pt mean age (±SD) at index was 62 (±10) years, 64% of pts were white and 18% African American; further clinical characteristics are in the table. 95% of pts received ≥1 pharmacological tx. At 1L, 36% of pts (156/433) received maintenance tx after chemotherapy, with 64% of pts (277/433) receiving routine surveillance (no maintenance tx). Olaparib was the most common maintenance tx (67%, 105/156), with 67% of pts (70/105) prescribed olaparib monotherapy. At 24 months, the KM model estimated 91% of pts (95% confidence interval: 82, 96) would not progress to their subsequent therapy, with a median discontinuation of olaparib monotherapy of 25.0 (interquartile range [IQR]: 21.0, not estimable) months, over a median follow-up of 22.0 (IQR: 20.6, 24.0) months. **Conclusions:** This real world study complements SOLO-1 RCT data by demonstrating prolonged benefit of 1L olaparib in newly diagnosed pts with BRCAm AOC in terms of lower likelihood of progression (tx switch/death). To assess real world tx effectiveness globally, data collection across further eight countries is due to be completed in 2022. Research Sponsor: AstraZeneca and Merck Sharp & Dohme Corp, a subsidiary of Merck & Co, Inc, Kenilworth, NJ, USA, who are codeveloping olaparib.

Selected clinical characteristics of pts with newly diagnosed BRCAm AOC.

5519 **Poster Discussion Session**

Maintenance olaparib in patients (pts) with platinum-sensitive relapsed ovarian cancer (PSROC) by somatic (s) or germline (g) BRCA and other homologous recombination repair (HRR) gene mutation status: Overall survival (OS) results from the ORZORA study. *First Author: Sandro Pignata, Istituto Nazionale Tumori 'Fondazione G Pascale', IRCCS, Napoli, Italy*

Background: In the SOLO2 (NCT01874353) trial, maintenance olaparib provided clinically meaningful improvement in OS for PSROC pts with a gBRCA mutation (m) compared with placebo (median 51.7 vs 38.8 months [mo], respectively). The ORZORA trial (NCT02476968) assessed efficacy and safety of maintenance olaparib in PSROC pts with a BRCAm (s or g) or a non-BRCA HRRm. Median progression-free survival (18.0 mo, BRCAm; 16.4, non-BRCA HRRm) was reported at primary data cutoff (DCO). We report final OS analyses. **Methods:** We conducted an open-label, single-arm, multicenter study of PSROC pts in response to platinum-based chemotherapy (PBC) after ≥2 prior lines of PBC. Pts underwent prospective central screening for tumor BRCAm status (myChoice CDx, Myriad Genetic Laboratories, Inc.), then central gBRCAm testing (BRACAnalysis CDx, Myriad Genetic Laboratories, Inc.) to determine s or g status. An exploratory cohort comprised of pts with predefined non-BRCA HRRm (FoundationOne CDx, Foundation Medicine, Inc.). Pts received maintenance olaparib (400 mg bid; capsules) until progression. OS and time to second progression (PFS2) were secondary endpoints. **Results:** 181 pts were enrolled (BRCAm n = 145 [s, n = 55; g, n = 87; s/g status unknown, n = 3]; non-BRCA HRRm, n = 33; unassigned, n = 3). At DCO (June 25, 2021), median OS follow-up in censored pts was 42.6 mo in BRCAm and 39.3 mo in non-BRCA HRRm pts. OS and PFS2 are reported in the Table. PBC was received as a subsequent therapy by 33.1% BRCAm, 32.7% sBRCAm, 33.3% gBRCAm, and 45.5% non-BRCA HRRm pts. 177 pts received ≥1 dose of olaparib and were included in safety analyses; 6.2% of pts discontinued because of adverse events (AEs). 37.9% of pts reported grade ≥3 AEs, the most common being anemia (16.4%). Since primary DCO, one new primary malignancy and four myelodysplastic syndrome events occurred. **Conclusions:** In final OS analyses, maintenance olaparib capsules showed consistent clinical activity in BRCAm and sBRCAm PSROC pts. Exploratory analyses suggest similar activity in non-BRCA HRRm pts. No new safety signals were observed. Findings highlight that PSROC pts, beyond those with a gBRCAm, can benefit from maintenance olaparib. Clinical trial information: NCT02476968. Research Sponsor: This study was sponsored by AstraZeneca and is part of an alliance between AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Role of cytoreductive surgery for the second ovarian cancer relapse in patients previously treated with chemotherapy alone at first relapse: A subanalysis of the DESKTOP III trial. *First Author: Jalid Sehouli, Charité – Medical University of Berlin, Berlin, Germany*

Background: The DESKTOP III trial has demonstrated a significant survival benefit in AGO-score positive patients who underwent complete cytoreduction at 1st relapse compared to those treated with chemotherapy alone. The question whether eligible patients who missed the opportunity of potentially life prolonging surgery at 1st relapse would benefit from surgery at the time of their second relapse, remains open. **Methods:** Patients randomized in the standard, non-surgical arm of the DESKTOP III trial who underwent cytoreductive surgery at a subsequent relapse at investigator's discretion were separately analyzed. **Results:** The median progression-free survival (PFS) counted from randomization of 201 patients in the control arm of DESKTOP III was 14.0 months. 171 (85%) had progressive or relapsing disease and 32 of 171 (19%) underwent cytoreductive surgery. Patients' median age at this subsequent surgery was 63 years (range: 46 – 78). Complete tumor resection was achieved in 19 patients (60%), while 5 (16%) had postoperative residual disease (n = 8 missing data). Sixteen patients (50%) commenced systemic treatment within 90 days from surgery, as documented. Thirty- and 90-day surgical mortality rates were 1 (3%) and 2 (6%), respectively. Within a postoperative median follow-up time of 43.8 months, 12 (38%) deaths were reported. Median overall survival after surgery (OS) was 54.0 months. One- and 2-year OS rates were 91% and 84%, respectively. **Conclusions:** Cytoreductive surgery for subsequent ovarian cancer relapse appears feasible and with low mortality in selected patients who received non-surgical treatment at 1st relapse despite a positive AGO-score. Surgery should be considered as an option in carefully selected patients also later in their journey within a specialized gynecological cancer setting. Clinical trial information: NCT01166737. Research Sponsor: Grants received from GSK and medac.

5521 **Poster Discussion Session**

Basket study of oral progesterone antagonist onapristone extended release (ONA-XR) in progesterone receptor positive (PR+) recurrent granulosa cell (GCT), low-grade serous ovarian (LGSOC), or endometrioid endometrial cancer (EEC). *First Author: Rachel N. Grisham, Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY*

Background: ONA-XR is a type I full progesterone antagonist that inhibits progesterone-mediated PR activation and stabilizes PR association with corepressors. GCT (98% of cases PR+), LGSOC (58% of cases PR+) and EEC (67% of cases PR+) are hormonally driven cancers that generally have poor responses to chemotherapy. **Methods:** This is an open-label, single-institution basket study of ONA-XR in patients with PR+ recurrent GCT (cohort 1), LGSOC (cohort 2), or EEC (cohort 3) (NCT03909152). Eligible patients required receipt of >1 prior line of chemotherapy, measurable disease by RECIST 1.1, and tumor tissue collected ≤3 years prior to enrollment with PR ≥ 1% by IHC. Patients received ONA-XR 50 mg PO BID until progression or intolerable toxicity. The study was designed as 3 parallel Simon 2-Stage studies. The primary objective was to evaluate efficacy, determined by RECIST 1.1, with at least 1/14 (cohort 1), 2/16 (cohort 2) or 4/19 (cohort 3) responses needed during stage 1 for advancement to stage 2. Secondary objectives included safety and tolerability, clinical benefit rate (CBR; stable disease lasting ≥ 16 weeks), and progression-free survival (PFS) as estimated by Kaplan Meier method. **Results:** The study enrolled patients to cohorts 1-3 from 5/2019 to 5/2020. Cohort 2 (LGSOC) enrolled 5 patients and cohort 3 (EEC) enrolled 1, both closed early due to slow accrual. Cohort 1 (GCT) enrolled 14 patients and completed Stage 1 accrual. There were no responses by RECIST 1.1 criteria observed in cohorts 1-3. In cohort 2 (LGSOC), 4/5 enrolled patients were evaluable, the median PFS was 4.4 months (1.8-NE) and CBR was 50% (6.8-93.2%). All 14 patients enrolled to cohort 1 (GCT) were evaluable with a median PFS of 3.5 months (1.6-8.8%), 6-month PFS rate of 30.1 % (8.4-56%), and 12-month PFS rate of 20.1% (3.5-46.4%). The CBR was 35.7% (12.8-64.9%). Two patients with GCT remain on active treatment for > 18 months. Grade 3 adverse events occurred in 5 patients: abdominal pain (2), small bowel obstruction (1), syncope (1), thromboembolism (1), urinary tract infection (1), and febrile neutropenia (1). Grade 3 laboratory toxicity occurred in 5 patients: anemia (2), neutropenia (1) and lymphopenia (2). **Conclusions:** ONA-XR was well tolerated and exhibited a 12-month PFS rate of 20.1% and a CBR of 35.7% in patients with GCT. No objective responses were observed. Cohorts 1-3 have closed to accrual, with 2 patients continuing active treatment for >18 months. Cohort 4, which combines ONA-XR with anastrozole, is currently enrolling patients with GCT. Clinical trial information: NCT03909152. Research Sponsor: Context Therapeutics.

Cohort	Evaluable (N)	Median PFS	CBR%	PFS 6M0	PFS 12M0
Cohort 1 (Granulosa Cell)	14	3.5 (1.6-8.8)	35.7% (12.8-64.9%)	30.1% (8.4-56%)	20.1% (3.5-46.4%)
Cohort 2 (LGSOC)	4	4.4 (1.8-NE)	50% (6.8-93.2%)	NR	NR
Cohort 3 (Endometrial Cancer)	1	1.6	0%	NR	NR

A pilot phase II study of neoadjuvant fulvestrant plus abemaciclib in women with advanced low-grade serous carcinoma. *First Author: Lauren P. Cobb, Department of Gynecologic Oncology & Reproductive Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Neoadjuvant chemotherapy has demonstrated limited activity in low-grade serous carcinomas (LGSOC) of the ovary, fallopian tube, and peritoneum, with objective response rate of 11% and complete gross resection (CGR) rate of 38% at the time of interval cytoreductive surgery (ICS). LGSOC has many similarities to hormone receptor positive (HR+) breast cancer, including clinical benefit from endocrine therapies in the recurrent and maintenance settings. Based on the activity of antiestrogen plus CDK4/6 inhibitor combination therapy in HR+ breast cancer, we conducted a phase II pilot study to assess the clinical benefit of neoadjuvant treatment with fulvestrant and abemaciclib for women with advanced LGSOC. **Methods:** Women with unresectable, untreated stage III or IV LGSOC of the ovary, fallopian tube or peritoneum were eligible. Patients received fulvestrant (500 mg IM on day 1 and 15 of the first 28-day cycle, followed by day 1 of subsequent cycles) and abemaciclib 150 mg orally BID. Pre/perimenopausal patients also received goserelin 10.8 mg subcutaneously every 12 weeks for ovarian suppression. Patients continued treatment until deemed resectable by the treating surgeon with imaging re-assessment every 8 weeks using RECIST 1.1. Following ICS, patients receive 4 cycles of adjuvant fulvestrant and abemaciclib and then transition to maintenance letrozole. Patients with progressive disease (PD) were removed from study and received standard of care chemotherapy. Primary endpoint is clinical benefit rate (CBR). **Results:** Fifteen patients were enrolled and evaluable. At data cutoff date (January 20, 2022), 7 of 15 patients (47%) had partial response (PR) (one patient with radiologic PR had a pathologic complete response at ICS), 5 of 15 (33%) had stable disease (SD), and 3 of 15 (20%) had progressive disease (PD), resulting in a CBR of 80%. Of the 7 patients with PR, 3 have had ICS with CGR, 3 have not yet had ICS, and 1 underwent resection of supraclavicular disease with small volume residual disease in the chest. Of the 5 patients with SD, one underwent ICS with CGR, and two have been on treatment for 8 and 16 weeks with reduction in measurable disease but not yet deemed to be candidates for surgery. Four of the 5 patients (80%) who had ICS, had CGR. Median time on study prior to surgery was 24 weeks. Adverse events (grade 3 or 4) possibly related to abemaciclib occurred in 2 patients (13.3%) and included acute kidney injury (6.7%) and neutropenia (6.7%). **Conclusions:** Neoadjuvant treatment with fulvestrant and abemaciclib was tolerable and demonstrated unprecedented response and CGR rates in this pilot study. These results compare favorably to published outcomes of neoadjuvant chemotherapy in LGSOC. Further studies are planned to explore this new treatment option in a larger study population. Clinical trial information: NCT03531645. Research Sponsor: Eli Lilly and AstraZeneca.

5523 **Poster Discussion Session**

Cervical cancer geographical burden analyzer: An interactive, open-access tool for understanding geographical disease burden in patients with recurrent or metastatic cervical cancer. *First Author: Tara Castellano, Louisiana State University, Department of Gynecologic Oncology,, New Orleans, LA*

Background: Examining geographic distributions of high and low proportions of recurrent or metastatic cervical cancer (r/mCC) can identify regions with high need of intervention and advance our understanding of r/mCC community-specific risk factors. Previous studies of epidemiologic or geographic clusters in late-stage cervical cancer were conducted prior to the availability of modern treatments for r/mCC. Due to the rapidly evolving treatment landscape for r/mCC use of commercial claims is an important way to follow dynamic practice changes. Our study objective was to understand recent geographical disparities among r/mCC patients in the US. **Methods:** We developed a web-based tool, Cervical Cancer Geographical Disease Burden Analyzer, that allows users to quantify r/mCC disease burden across metropolitan statistical areas (MSA) over multiple years. The inputs to the web-based tool were extracted through a retrospective analysis of the 2015-2020 MarketScan commercial claims database using a previously validated methodology. We then calculated the r/mCC rate as the ratio of r/mCC cases over cervical cancer (CC) cases for each of the >400 MSA considered. The calculated MSA-specific r/mCC rate was visualized in an interactive US map,. The online interactive tool allowed the users to filter the results by year, age group, and minimum number of diagnoses at the MSA level. **Results:** Our findings showed that there is large variation with respect to r/mCC disease burden across MSA in the US, with a range of 0-45%. The top five MSA with the highest r/mCC rates from 2018-2020 are presented in the table. In particular, r/mCC rates in Sacramento-Roseville-Arden-Arcade (SRAA), CA and Boston-Cambridge-Newton (BCN), MA were on an increasing trajectory (33% in 2018 to 50% in 2020 in SRAA, CA; and from 41% in 2018 to 50% in 2020 in BCN, MA). On the other hand, while disease burden remained high, we observed decreasing r/mCC rates in Grand Rapids, MI (55% in 2018 and 31% in 2020, resulting in an average r/mCC rate of 42%). Finally, in Cape Coral-Fort Myers, FL and Baltimore-Columbia-Towson, MD the r/mCC rates have fluctuated across time but were consistently >30%. **Conclusions:** Our web-based online interactive tool can help with identifying areas with high need of intervention, and inform how access, prevention and new or emerging therapies may potentially change the distribution of r/mCC disease burden. To better understand underlying drivers of geographic disparities observed, further efforts should be targeted towards identifying local-level factors. Research Sponsor: Seagen Inc.

MSA	r/mCC rate 2020	r/mCC rate 2019	r/mCC rate 2018	Average r/mCC rate
Cape Coral-Fort Myers, FL	40%	31%	64%	45%
Sacramento-Roseville-Arden-Arcade, CA	50%	46%	33%	45%
Grand Rapids, MI	31%	36%	55%	42%
Boston-Cambridge-Newton, MA	50%	45%	41%	40%
Baltimore-Columbia-Towson, MD	38%	33%	39%	36%

Pressurized intraperitoneal aerosol chemotherapy (PIPAC) versus intravenous chemotherapy in unresectable peritoneal metastases secondary to platinum-resistant ovarian cancer: Interim analysis of Indian randomized control trial. *First Author: S.P. Somashekhar, Manipal Comprehensive Cancer Center, Bangalore, India*

Background: PIPAC has emerged as a novel way to deliver intraperitoneal chemotherapy. PIPAC has shown improved response rate and quality of life in patients with inoperable peritoneal carcinomatosis. **Methods:** The trial is registered with Clinical Trials Registry – India (CTRI) REF/2018/08/021223. Interim analysis is presented here. Primary endpoint was to assess the objective response rate (With RECIST 1.1) between PIPAC and IV chemotherapy arm. Secondary endpoints were to assess quality of life (QLQ C-30) and morbidity (CTCAE 4.0 and Clavien dindo) between the two groups. PIPAC was done with dose of cisplatin 15mg /m2 and doxorubicin at 3mg/m2. The choice of chemotherapy was left at the discretion of treating physician. The response rate (With MRI & Ca-125) & quality of life assessment (QLQ C-30) of both the group was done periodically and recorded. **Results:** 40 patients underwent 105 PIPAC applications with nearly 25 (62.5%) had 3 cycles completed. 40 patients underwent IV chemotherapy same time with nearly 23 (57.5%) having received atleast 5 cycles. Mean age 57.3±8.05, PCI 24.45±6.39, with nearly 45.5% of patients had previous surgery and 72.5% of patients having received atleast 2 lines of prior chemotherapy and nearly 60 % having ascites. The objective response rate is 66.6% versus 22.5%, grade 3-4 events were 10.0% vs. 35.7 % in PIPAC and IV arm respectively. Histological regression was seen in 67.5% of patients with 3 cycles PIPAC. Functional, symptom and global health score at day 120 was significantly better with PIPAC arm when compared to IV arm. **Conclusions:** PIPAC is safe and feasible for patients with unresectable platinum resistant ovarian cancer. PIPAC showed better objective response rates and improved quality of life when compared to chemotherapy arm with acceptable morbidity. Clinical trial information: REF/2018/08/021223. Research Sponsor: None.

Cytoreductive surgery plus HIPEC for advanced epithelial ovarian cancer: Analysis from a multicentric national Indian HIPEC registry of 1,470 patients—An ISPSM Collaborative study. *First Author: S.P. Somashekhar, Manipal Comprehensive Cancer Center, Bangalore, India*

Background: Improved long-term results can be achieved in advanced epithelial ovarian cancer (EOC) patients using optimal cytoreductive surgery (CRS) with hyperthermic intraperitoneal chemotherapy (HIPEC). **Methods:** Indian society of peritoneal surface malignancy (ISPSM) is a registered body which maintains prospective data of 26 centers across India who perform CRS –HIPEC. From February 2017 until January 2022, 1470 patients with advanced EOC were treated with CRS-HIPEC. He general practice patterns and the oncological outcomes in terms of progression free survival (PFS) and overall survival (OS) & post-operative morbidity and mortality is reported. **Results:** Upfront (n = 156), interval (n = 645) and recurrent (n = 669) cytoreductions were performed based on the timeline at presentation. Mean age 54.5±10.74, PCI 13. 6±5.2, duration of surgery 10.6±1.h hrs. 36.4% had total peritonectomy, 12.7% had multivisceral resection, 41.8%had bowel resections and stoma rate was 7.4% . 60.3% had semi-open HIPEC, 83.1% used cisplatin for HIPEC and 83.1 % had HIPEC for 90 minutes. Overall G3-G5 morbidity was 25.4% with major ones being post-operative intra-abdominal collection (21.8%), electrolyte imbalance (16.4%), pulmonary (16.4%) followed by hematological (12.7%). Surgical morbidity was more in upfront cytoreduction group compared to interval group (20% versus 13.5%) and recurrent group (20% versus 15%), respectively. The 30 day mortality was 3.8%. With a median follow-up of 46 months, median PFS was 33 months in primary (upfront plus interval) group and 16 months in recurrent cytoreduction group. Median OS was not achieved in both primary and recurrent groups (4 year OS rates: 60 and 55%, respectively). **Conclusions:** This prospective database provides a collation and audit of the management of advanced epithelial ovarian cancer with CRS HIPEC in multiple centers registered under ISPSM. In advanced EOC patients, CRS plus HIPEC offers potential benefits in PFS and OS rates, with acceptable rates of morbidity and mortality and can be practiced even in resource constrained setting. Efficacy and safety of the anti–PD-L1 monoclonal antibody socazolimab for recurrent or metastatic cervical cancer: Results from the phase I dose-escalation and expansion study. *First Author: Jusheng An, Cancer Institute and Hospital, Chinese Academy of Medical Sciences, Beijing, China*

Background: The study (NCT03676959) is an open-label, phase I study investigating the safety and efficacy of the recombinant, fully human anti-programmed death-ligand 1 (PD-L1) monoclonal antibody socazolimab for recurrent or metastatic cervical cancer. **Methods:** Patients received socazolimab every 2 weeks until disease progression. The study was divided into a dose-escalation phase and a dose-expansion phase. Safety and tolerability were primary endpoints of the dose-escalation phase. Primary endpoints of the dose-expansion phase were safety and overall response rate (ORR) of the 5mg/kg dose. Efficacy was assessed by a third-party independent review committee (IRC) using the Response Evaluation Criteria in Solid Tumors version 1.1 (RECIST 1.1) as the evaluation standard. Pharmacokinetics and pharmacodynamics were also studied. **Results:** One hundred four patients were enrolled. Twelve patients were included in the dose-escalation phase, with one complete and two partial responses in the 5mg/kg treatment group. Ninety-two patients (5mg/kg) were enrolled in the dose-expansion phase, with 54 patients (59.3%) expressing baseline PD-L1-positive tumors. ORR was 15.4% (95% CI, 8.7 to 24.5%). Median PFS was 4.44 months (95% CI, 2.37 to 5.75 months), and the median OS was 14.72 months (95% CI, 9.59 to NE months). ORRs for PD-L1-positive and PD-L1-negative patients were 16.7% and 17.9%, respectively. Treatment-related grade 3 to 4 adverse events occurred in 7.7% of patients. No treatment-related deaths had occurred. **Conclusions:** Our study demonstrates that socazolimab has remarkable safety and efficacy for the treatment of recurrent or metastatic cervical cancer and exhibits a safety profile similar to other anti–PD-1/PD-L1 monoclonal antibodies. Clinical trial information: NCT03676959. Research Sponsor: Lee's Pharmaceutical Holdings Limited.

SPECT-defined, active bone marrow–sparing, volumetric-modulated arc therapy reduces the incidence of acute hematologic toxicity in patients with locally advanced cervical cancer who receive chemoradiotherapy. *First Author: Shan Bing Wang, Department of Oncology,the Second People Hospital of YiBin City, Yibin, China*

Background: Acute haematologic toxicity is the most common side effect of chemoradiotherapy in patients with locally advanced cervical cancer .We are aim to test the efficacy of defined active bone marrow sparing volumetric-modulated arc therapy reduces grade 3 or higher (grade 3+) acute haematologic toxicity for patients with locally advanced cervical cancer treated with chemoradiotherapy. **Methods:** This was a prospective, single-center, open label, randomized clinical trial that enrolled locally advanced cervical cancer.Patients were randomized to ^{99m}Tc sulfur colloid SPECT-defined active bone marrow sparing volumetric-modulated arc therapy group (ABMS group) or control group.The control group received weekly cisplatin concurrently with volumetric-modulated arc therapy(VMAT),followed by high-dose-rate intracavitary brachytherapy. The active bone marrow sparing volumetric-modulated arc therapy group additionally received ^{99m}Tc sulfur colloid SPECT-defined active bone marrow dose constrain. The primary endpoint was the incidence of grade 3 or higher (grade 3+) acute haematologic toxicity. Secondary objectives included acute gastrointestinal toxicity, planning Target Volume (PTV) coverage and dosimetric parameters of organs at risk(OARs). **Results:** A total of 148 patients with Federation of Gynaecology and Obstetrics(FIGO) stage IB-IIIB from-January 2017 to April 2019 were randomized， and 146 were treated(74 in ABMS group and 74 in control group). The median follow-up was 20.0 months.The incidence of grade 3 or higher (grade 3+) acute haematologic toxicity in the ABMS group was 29.7%,significantly lower than the 48.6% incidence in the control group(p = 0.03).The incidence of grade 3+ neutropenia (ABMS group： 20.3%,control group:36.5%;p = 0.04), Grade 3+ leukopenia (ABMS group： 25.7%,control group:44.6%;p = 0.02) and Grade 3+ lymphopenia (ABMS group： 4.1%,control group:14.9%;p = 0.04) were significantly differences between the two group.The were no differences in Grade 3+ anemia (ABMS group： 1.4%,control group:5.5%;p = 0.37) and Grade 3+ acute gastrointestinal toxicity(ABMS group： 1.4%,control group:1.4%;p = 1.00) between the two group.The number of patients completing five cycles of cisplatin in the ABMS group was 88.5%,,significantly higher than the 75% in the control group(p = 0.02).There were no differences in PTV coverage and dosimetric parameters of OARs between the two group. **Conclusions:** SPECT-defined active bone marrow sparing VMAT significantly reduced grade 3+ acute haematologic toxicity,and improved chemotherapy delivery compared with control group. Clinical trial information: ChiCTR-IOR-16010214. Research Sponsor: the Sichuan Medical Association youth innovation project (NO. Q16082) and the health commission of YIbin City (NO.2019yw029).

Phase 1 trial of first-line bintrafusp alfa in combination with other anticancer therapies in patients (pts) with locally advanced or advanced cervical cancer. *First Author: Ana Oaknin, Vall d'Hebron Institute of Oncology, Hospital Universitari Vall d'Hebron, and Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain*

Background: Until the recent FDA approval of pembrolizumab in combination with chemotherapy ± bevacizumab, there have been limited treatment options that address the underlying biology for pts with persistent, recurrent, or metastatic (P/R/M) or locally advanced (LA) cervical cancer. Persistent HPV infection is associated with 99% of cervical cancers and is linked to upregulation of TGF-β. Bintrafusp alfa, a first-in-class bifunctional fusion protein composed of the extracellular domain of TGF-βRII (a TGF-β "trap") fused to a human IgG1 mAb blocking PD-L1, has shown promising clinical activity and manageable safety in pts with recurrent or metastatic cervical cancer. We report data from a phase 1 trial evaluating safety of first-line bintrafusp alfa plus chemotherapy ± bevacizumab for pts with P/R/M cervical cancer or bintrafusp alfa plus chemoradiotherapy for pts with LA cervical cancer (INTR@PID 046; NCT04551950). **Methods:** Pts with P/R/M cervical cancer who had not received prior systemic therapy received bintrafusp alfa 2400 mg Q3W plus cisplatin/carboplatin and paclitaxel with (cohort 1A) or without (cohort 1B) bevacizumab. Pts with LA cervical cancer received bintrafusp alfa 2400 mg Q3W plus concurrent weekly cisplatin and radiotherapy followed by maintenance therapy with bintrafusp alfa (cohort 2). Pts were treated until disease progression, death, unacceptable toxicity, or withdrawal. Primary endpoints were safety and tolerability of bintrafusp alfa in combination with current standard-of-care therapies in pts with P/R/M or LA cervical cancer. **Results:** As of November 25, 2021, 8 pts in cohort 1A, 9 in cohort 1B, and 8 in cohort 2 had received bintrafusp alfa for a median of 11.6, 10.0, and 5.6 cycles, respectively. At the time of this analysis, 11 of 25 pts remained on bintrafusp alfa therapy. Any-grade bintrafusp alfa–related adverse events (AEs) occurred in 75.0%, 100.0%, and 75.0% of pts in cohorts 1A, 1B, and 2, respectively (Table). The most-common grade ≥3 AEs were anemia and hematuria (25.0% each) in cohort 1A and vaginal hemorrhage (22.2%) in cohort 1B. One pt had grade 4 anemia and vaginal hemorrhage in cohort 1B. No treatment-related deaths occurred. AEs led to permanent discontinuation of bintrafusp alfa in 37.5%, 33.3%, and 12.5% of pts in cohorts 1A, 1B, and 2, respectively; the most common any-grade AE was vaginal hemorrhage (22.2%). **Conclusions:** No new safety signals were observed with first-line bintrafusp alfa plus chemotherapy ± bevacizumab or chemoradiotherapy in pts with P/R/M or LA cervical cancer. Clinical trial information: NCT04551950. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany.

	Cohort 1A, % n = 8	Cohort 1B, %n = 9	Cohort 2, %n = 8
Bintrafusp alfa–related AEs			
Any grade	75.0	100.0	75.0
Grade ≥3	50.0	44.4	25.0
Any-grade AEs of special interest			
Anemia	75.0	77.8	62.5
Bleeding events	75.0	77.8	62.5
Immune-related AEs	37.5	33.3	37.5

GOTIC-018: Phase I, open-label, multicenter study to assess the safety of pre- and co-administration of ONO-4538 (nivolumab) with concurrent chemoradiation (CCRT) in patients (pts) with locally advanced cervical carcinoma (LACvCa). *First Author: Akira Yabuno, Department of Gynecologic Oncology, Saitama Medical University International Medical Center, Hidaka, Japan*

Background: LACvCa has a poor prognosis. CCRT is the standard treatment for LACvCa, and the 5-year survival rate is estimated at around 60%. Nivolumab (Nivo), an anti-PD1 monoclonal antibody, showed clinical activity in recurrent or persistent CvCa pts. Nivo may enhance antitumor immune responses induced by CCRT. The safety and feasibility of Nivo plus CCRT for LACvCa pts has not yet been reported. We report data from a phase I trial evaluating safety and feasibility of pre- and co-administration of Nivo with CCRT in pts with LACvCa (GOTIC-018; JMA-IIA00425). **Methods:** The treatment plan in cohort A is co-administration of Nivo (240mg/body once every 2 weeks) with CCRT followed by maintenance therapy with Nivo. The treatment plan in cohort B is pre- (two doses of Nivo before CCRT) and then co-administration of Nivo with CCRT followed by Nivo maintenance. The CCRT regimen includes 4 or more cycles of cisplatin (40 mg/m^2 weekly) and external beam radiotherapy (EBRT) followed by brachytherapy. The Nivo maintenance therapy was scheduled for 52 weeks after completion of CCRT. The primary objective is the rate of Grade≧3 adverse events (AEs) during the acute phase, which is defined as 90 days from the start date of EBRT. Secondary objectives include the incidence of dose limiting toxicity (DLT) and progression-free survival. **Results:** A total of 30 patients, 15 patients in each cohort, was enrolled in this study. This report is a safety evaluation in the acute phase of the study. There were 1 stage IVA, 11 stage IIIB, 16 stage II and 2 stage IB tumors based on FIGO 2009. 28 squamous cell and 2 adeno/adenosquamous carcinomas were included. No DLT was observed in the first 6 DLT-evaluable pts in each cohort. All 30 patients completed planned EBRT and brachytherapy. 2 and 0 patients required a break from EBRT in cohort A and B, respectively. The median cycles of cisplatin administration was 5 and 6 in cohort A and B, respectively. 2 and 0 patient required cisplatin dose reduction in cohort A and B, respectively. 1 patient required cisplatin discontinuation in each cohort. The median cycles of Nivo administration were 6 and 9 in cohort A and B, respectively. 1 patient required Nivo discontinuation due to AEs in each cohort. All patients experienced Grade≧3 AEs. Most common Grade≧3 AEs were neutropenia (60.0 and 26.7% in cohort A and B, respectively), anemia (13.3 and 16.7%) and diarrhea (13.3 and 26.7%). In cohort B, no patients required delay in starting CCRT due to the AEs related to pre-administration of Nivo, and no patients had disease progression before starting CCRT. **Conclusions:** No DLT was reported during the acute phase in both cohort A and B, and no new safety signals were observed. Addition of pre-and co- administration of Nivo appears safe and feasible in patients with LACvCa treated with CCRT. Clinical trial information: JMA-IIA00425. Research Sponsor: Ono Pharmaceutical CO., LTD..

Cervical cancer prevention program in Nepal: A comprehensive "train the trainer" approach. *First Author: Samantha Batman, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Cervical cancer is the leading cause of cancer and cancer-related deaths among women in Nepal, due in part to a lack of access to screening and limited medical providers trained to diagnose and treat women with preinvasive cervical disease. Cancer Care Nepal has partnered with The University of Texas MD Anderson Cancer Center (MD Anderson) and the American Society of Clinical Oncology (ASCO) to implement a 'train the trainer' (TOT) program to teach visual inspection with acetic acid (VIA), colposcopy, cervical biopsy, cryotherapy, thermal ablation, and loop electrosurgical excision procedure (LEEP). **Methods:** An initial cervical cancer prevention course was held in Kathmandu, Nepal in November 2019, supported by ASCO and with faculty from Civil Service Hospital, Bhaktapur Cancer Hospital, and National Academy of Medical Sciences and MD Anderson. As a continuation of this program, a TOT course was implemented for local specialists from five participating institutions throughout Nepal to learn how to deliver these trainings. Each participating institution then holds their own local course for nurses and doctors in their region. The training is complemented with monthly Project ECHO (Extension for Community Healthcare Outcomes) telementoring videoconferences. **Results:** The program was launched in November 2021. To date, two TOT training courses (2-day duration) have been held for clinicians from the 5 participating regions. Due to COVID-19 pandemic travel restrictions, didactic lectures were held virtually with MD Anderson and ASCO staff and included epidemiology of cervical cancer, screening guidelines, colposcopy, and treatment of cervical dysplasia. This was followed by hands-on training using simulation models to teach VIA, colposcopy, ablation and LEEP, led by the Nepalese faculty who had participated in the 2019 course. There were 41 participants in total (23 in the first course and 18 in the second course), including 21 gynecologists, 4 gynecologic oncologists, 1 medical oncologist, 1 general practitioner, and 14 nurses. 39 participants (73%) completed both the pre- and post-survey results. 86% of respondents from the first course and 100% of respondents from the second course reported that they intended to change their practice as a result of knowledge gained from the course. In addition, Cancer Care Nepal became a new hub for Project ECHO and held its first session in January 2022, with 20 participants representing two regions. The specialists from each of the 5 participating sites will be holding local courses for doctors and nurses in their respective regions throughout 2022. **Conclusions:** Our work shows that the TOT strategy can widen the reach of training in cervical cancer prevention in Nepal. Despite travel restrictions during the COVID-19 pandemic, global health training and mentoring can continue, though they require adaptions and use of virtual platforms. Staging locally advanced cervical cancer with FIGO 2018 versus FIGO 2008: Impact on overall survival and progression-free survival in the OUTBACK trial (ANZGOG 0902, RTOG 1174, NRG 0274). *First Author: Linda R. Mileshkin, Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: The International Federation of Obstetrics and Gynecology staging system for cervical cancer (FIGO 2008) was revised in 2018 to incorporate lymph node involvement (FIGO 2018). OUTBACK is an international, randomized phase 3 trial of adjuvant chemotherapy versus observation after standard of care treatment with chemoradiation for women with locally advanced cervical cancer. OUTBACK found no benefit from the addition of adjuvant chemotherapy. We evaluated the effects of classifying participants with these 2 staging systems in the OUTBACK trial population. **Methods:** OUTBACK recruited April 2011 to June 2017 and staged participants according to FIGO 2008. Lymph node status, smoking status, age, race and histological subtype were documented at trial entry as important prognostic factors. We assessed the effects of stage grouping into stage I, II, and III/IVa with FIGO 2008 versus FIGO 2018, on progression-free survival (PFS) and overall survival (OS) at 5 years using Kaplan-Meier estimates, and in univariable proportional-hazards regression analyses, and in multivariable analyses adjusting for important prognostic factors and randomly allocated treatment. **Results:** All 919 study participants had complete data for staging according to the 2 staging systems and most prognostic factors for adjustment. Among all participants, the 5-year outcomes were PFS = 62% and OS = 72%. Classification according to FIGO 2018 rather than FIGO 2008 yielded higher 5-year PFS and OS in each stage group (see table for numbers of participants, PFS and OS for each stage group). Predictors of PFS in multivariable analysis included squamous vs non-squamous histology (HR 0.71 for FIGO 2008 and 0.74 for FIGO 2018), but not nodal involvement when FIGO 2018 was used. Both staging systems were the only independently significant prognostic factors in both univariable and multivariable analyses (all $p < 0.0001$) for both PFS and OS. **Conclusions:** Compared to FIGO 2008, reclassifying pts by FIGO 2018 staging resulted in more pts being classified as stage 3 due to the incorporation of nodal status. Staging locally advanced cervical cancer using FIGO 2018 rather than FIGO 2008 resulted in higher PFS and OS in each stage grouping that reflected stage migration, not a true improvement in outcomes. FIGO stage remains the strongest predictor of overall survival after CRT but survival outcomes by stage in trials using the old vs new staging system are not comparable. Clinical trial information: ACTRN12610000732088. Research Sponsor: NHMRC Project Grant (APP1044349), U.S. National Cancer Institute.

	Number (%)	Number (%)	PFS 5Y %		OS 5Y %	
Stage Group	FIGO 08	FIGO 18	FIGO 08	FIGO 18	FIGO 08	FIGO 18
I	242 (26%)	105 (12%)	71	81	78	89
II	457 (50%)	261 (28%)	65	68	75	78
III/IVa	220 (24%)	553 (60%)	48	56	58	66

Factors associated with receipt of second-line recurrent or metastatic cervical cancer treatment in the United States: A retrospective administrative claims analysis. *First Author: Kalyani Sonawane, University of Texas Health Science Center at Houston, Houston, TX*

Background: There is limited real-world data on the proportion of eligible patients who received second-line (2L) treatment following progression on first-line (1L) systemic therapy for recurrent or metastatic cervical cancer (r/mCC). In addition, factors impacting selection of 2L are not well-understood. The objective of this study was to determine the prevalence and predictors of subsequent therapy among patients with 1L-treated r/mCC. **Methods:** We conducted a retrospective analysis of the 2015-2020 MarketScan claims database. Women ≥18 years of age with at least one inpatient claim or two outpatient claims with a diagnosis for malignant neoplasm of the cervix followed by 1L therapy codes were identified. The last recorded date of 1L treatment was assigned as the index date for each woman. Continuous enrollment criteria of minimum 3-month pre-index and 12-month post-index were applied. Women with claims for a new therapy after 60 days but no later than 365 days from the end of 1L treatment were identified as those who continued r/mCC treatment. We used descriptive statistics to examine the baseline characteristics of the final analytical cohort. A multivariable logistic regression model examined the factors associated with treatment discontinuation. All analyses were performed using SAS, Cary, NC. P-value was tested at 0.05. **Results:** A total of 1,080 patients with 1L-treated r/mCC were identified, of whom 384 met the study criteria. Post-1L treatment, 196 (51.0%) patients received a new therapy within a median duration of 122 days. A total 188 (49.0%) patients did not receive subsequent therapy. The geographic location of patient (identified based on census region as Northeast, Midwest, South, or West) and prior bevacizumab exposure were significant predictors of receiving subsequent therapy. Specifically, patients from the Midwest (odds ratio [OR] = 0.43; 95% CI: 0.23-0.84) and Southern (OR = 0.53; 95% CI: 0.29-0.96) regions had lower likelihood of receiving 2L treatment after 1L, compared to those living in the Northeast. Women without prior bevacizumab treatment were also less likely to receive subsequent therapy (OR = 0.65; 95% CI: 0.42-0.99). Age, type of health plan, and comorbidities were not associated with the likelihood of receiving subsequent treatment. **Conclusions:** Overall, nearly half of the 1L-treated r/mCC patients did not continue to 2L therapy, with findings showing treatment drop-off differing significantly by geographic region and prior treatment. Additional research and targeted outreach efforts are needed to understand geography-, population-, or practice-specific barriers impacting access to therapy among r/mCC patients. Research Sponsor: Seagen.

Examining differences based on gender and sexual orientation for cervical cancer screening and prevention behaviors. *First Author: Prajakta Adsul, University of New Mexico Comprehensive Cancer Center, Albuquerque, NM*

Background: Population-based studies to examine cervical cancer screening (CCS) and prevention among sexual and gender diverse (SGD) individuals have been limited. We conducted a state-wide survey in New Mexico to examine differences in CCS and HPV vaccination uptake based on gender and sexual orientation. **Methods:** The survey was advertised using mailed flyers, social media, and targeted internet ads across the state. We received a total of 2534 responses, of which 797 respondents were CCS eligible (i.e., between 21-65 years old, had a cervix, and did not have a prior cervical cancer diagnosis) and provided information about CCS and were included in this analysis. Descriptive statistics were conducted using SAS 9.4. **Results:** Of the 797 respondents, 83% were 21 - 40 years old, 44% were white, 34% reported an annual household income below $50,000, 83% were employed, 81% had health insurance, and 73% reported having a primary care provider. Fourteen percent were transgender men or nonbinary, 86% were cisgender women, 34% were bisexual, 48% were lesbian, and 18% were queer. While there were no statistical differences in self-reported CCS based on gender identity, 31% of cisgender women and 25% of transgender men and nonbinary individuals reported never receiving a Pap test. The top reason for never receiving a Pap test among cisgender women was that their healthcare provider told them they did not need it (17%) and for transgender men and nonbinary individuals the top reasons were that they had an HPV vaccine (21%) or that it was too painful, unpleasant, or embarrassing (21%). There were significant statistical differences based on sexual orientation for receiving a Pap test ($p < 0.001$) and for being up to date on screening (Pap test in the past 3 years, a co-test, or primary HPV test in the past 5 years) ($p = 0.03$). Among lesbians, 39% reported never having a Pap test, compared with 17% of bisexuals and 30% of queer individuals. For lesbians, the top reason for not receiving a Pap test was not knowing that Pap tests existed (19%), while the top reason for both bisexual and queer individuals was that their healthcare provider told them they did not need it (17% and 19%, respectively). No significant differences were noted in HPV vaccination uptake among respondents. **Conclusions:** In order to address sexual orientation differences noted in our study, future research is needed to explore mechanisms through which these differences operate using community-based approaches. Additionally, educational interventions inclusive of different gender identities and sexual orientations are needed to improve motivations for screening uptake among SGD individuals. Finally, specific considerations for SGD individuals should be incorporated into screening recommendations and guidelines and clearly communicated to providers, further enabling them to make recommendations for these populations. Combination of nivolumab with chemoradiotherapy for locally advanced cervical cancer: NiCOL phase I trial. *First Author: Manuel Rodrigues, Medical Oncology, Institut Curie, Paris, France*

Background: Current management of locally-advanced cervical cancers (LACC) relies on chemoradiotherapy (CRT) and brachytherapy. The causal relation between cervical cancer and human papillomavirus infection, which engenders tumor expression of immunoreactive neo-antigens, together with high PD-L1 expression, warrants consideration of immune checkpoint inhibitors (ICI) in the definitive treatment of this disease. We assessed the safety of concurrent and maintenance nivolumab in addition to CRT in patients with LACC. **Methods:** This prospective, multi-center, dose-confirmation, phase I clinical trial (NiCOL trial; NCT03298893) evaluated the tolerance profile of concurrent and maintenance nivolumab in addition to CRT (45 Gy in 25 fractions with cisplatin 40mg/m^2 q1w, followed by a brachytherapy boost to 85 Gy) for stage IB3-IVA cervical cancers. Nivolumab was administered at 240 mg q2w starting on day 1 of CRT and in maintenance after CRT completion for up to 6 months (13 cycles). The primary endpoint was the incidence of dose-limiting toxicities (DLT) within 11 weeks after the initiation of treatment (defining the DLT assessment period), corresponding to the first 6 cycles of nivolumab. DLT were defined as grade ≥3 non-hematological toxicities, grade ≥3 immune-related adverse event (irAE), persistent grade ≥2 irAE for ≥1 week despite optimal supportive care, or ≥1-week radiotherapy delay related to treatment toxicity. Secondary endpoints included overall response rate (ORR), progression-free survival (PFS) and treatment tolerance profile. **Results:** 16 patients (pts) were recruited between 11/2017 and 07/2020. Median age was 46 years [range: 27-77]. Histological types were squamous cell carcinomas (n = 14) and adenocarcinomas (n = 2). Tumors were staged as FIGO IB3 (n = 2), IIB (n = 8), IIIB (n = 1), IIIC1 (n = 4) and IVA (n = 1); 13 tumors were HPV-positive. Three patients experienced DLT, corresponding to grade 3 hypotension (n = 2) and grade 3 acute kidney injury (n = 1). Following the DLT assessment period, while receiving maintenance nivolumab, one patient developed a grade ≥3 irAE corresponding to a grade 3 diarrhea. Two months after brachytherapy completion, ORR was 93.8% [95%CI: 69.8%-99.8%]. With a median follow-up of 16.6 months, three patients experienced disease control failure (at 3,4 and 5 months); site of disease progression was local for two patients, and simultaneously local and distant for one patient. One-year PFS was 81.2% [95% CI: 64.2%-100%]. **Conclusions:** Concomitant nivolumab with definitive CRT, followed by maintenance nivolumab, appears to be a safe and feasible therapeutic option for LACC, associated with encouraging PFS rates. Further trials evaluating ICI combined with CRT for LACC are warranted in light of these promising results and of those from recent studies evaluating ICI in the metastatic setting. Clinical trial information: NCT03298893. Research Sponsor: Bristol-Myers Squibb.

Efficacy and safety of QL1706, a novel dual immune checkpoint blockade containing a mixture of anti-PD1 IgG4 and anti-CTLA4 IgG1 antibodies, for advanced cervical cancer: Cohort data from a phase 1b trial. *First Author: Jihong Liu, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Anti-cytotoxic T lymphocyte antigen 4 (CTLA-4) and anti-programmed cell death 1 (PD-1) antibodies have synergistic effect. QL1706 is a novel dual immune checkpoint blockade containing a mixture of anti-PD-1 IgG4 and anti-CTLA4 IgG1 antibodies produced by a single cell line. QL1706 showed promising anti-tumor activity in multiple solid tumors. Here we reported the cervical cancer cohort data from the phase 1b trial of QL1706 (NCT05171790). **Methods:** Eligible patients had a pathologically confirmed diagnosis of squamous cell carcinoma, adenosquamous carcinoma, or adenocarcinoma of the cervix, with recurrent or metastatic, immunotherapy-naive disease at the time of enrollment. Patients were required to have ≥one lesion measurable by RECIST v1.1 and disease that had relapsed after a first-line, platinum-based regimen. Patients were included regardless of PD-L1 expression status at baseline. Patients received intravenous QL1706 5.0 mg/kg q3w (i.e., recommended phase 2 dose, defined in a phase 1a trial), for up to 24 months. The primary endpoint was confirmed overall response rate (ORR) per RECIST v1.1 by investigator. The secondary endpoints included disease control rate, duration of response (DoR), progression-free survival (PFS), overall survival (OS), safety, etc. **Results:** As of Dec 31, 2021, totally 53 patients with cervical cancer were enrolled (median age, 52 years [range 33-72]). Median follow-up was 5.6 months. Most patients (45 [85%]) had ECOG performance status of 1. Histological breakdown was squamous cell carcinoma (44 [83%]) and adenocarcinoma (nine [17%]). 33 (62%) patients had received one prior chemotherapy, 20(38%) patients had received ≥two prior chemotherapy. The confirmed ORR was 28% (95% CI 17%-42%; 15 patients), including one (2%) complete response and 14 (26%) partial response, with median duration of response not reached (95% CI 2.8 months-not estimable). Disease control was observed in 29 (55%; 95% CI 40%-68%) patients. Median PFS was 4.2 months (95% CI 1.7-6.9), and 6-month PFS rate was estimated as 37% (95% CI 24%-51%). Treatment-related adverse events (TRAE) were observed in 40 (75%) patients. Nine (17%) experienced grade ≥3 TRAE. The most common TRAE were rash (eight [15%]), hyperthyroidism (eight [15%]), and pyrexia (seven [13%]). Three (6%) patients suffered TRAE leading to dose discontinuation. The immune-related TRAE and serious TRAE were observed in 28 (53%) and eight (15%) patients, respectively. **Conclusions:** QL1706 demonstrated promising and durable clinical activity, with favorable tolerability in patients with recurrent and/or metastatic cervical cancer. Further investigations in this setting are continuing. Clinical trial information: NCT05171790. Research Sponsor: Qilu Pharmaceutical Co,.Ltd.

Overall survival results from a phase II trial of anlotinib plus sintilimab in patients with recurrent advanced cervical cancer. *First Author: Qin Xu, Fujian Cancer Hospital, Fuzhou, China*

Background: The anlotinib (a novel multi-target TKI, inhibiting tumor angiogenesis and proliferative signaling) plus sintilimab (an antibody against PD-1) in patients with advanced cervical cancer trial was a multicenter, single-arm, phase II study (ChiCTR1900023015) that showed promising activity. The results of this trial have been previously reported and here we present updated survival data after a median follow-up of 13.0 months. **Methods:** Pts who have received at least once platinum-based chemotherapy, recurrent advanced cervical cancer, PD-L1 for CPS≥1, ECOG 0-1 were considered eligible for enrollment. Anlotinib was taken orally (10mg, qd, d1-14, 21 days per cycle), and sintilimab was administered intravenously (200mg, q3w, d1). The primary endpoint was objective response rate (ORR) and the secondary endpoints included disease control rate (DCR), progression free survival (PFS), overall survival (OS), safety and biomarkers. **Results:** Between December 2019 and December 2020, 42 patients with a median age of 53 years (range 36 to 67 years) were enrolled and received study treatment (ITT population and safety population). The data cutoff date was February 10, 2022. The patients were followed up for median duration of 13.0 months (range 0.03 to 24.8 months). In the ITT population, 2 (4.8%) patients achieved CR and 21 (50%) attained PR, the confirmed ORR was 54.8% (95% CI 38.7% to 70.2%). Fourteen (33.3%) patients had SD and the DCR was 88.1% (95% CI 74.4% to 96.0%). In the efficacy-evaluable patients (n = 39), the ORR was 59% (95% CI 42.1% to 74.4%) and the DCR was 94.9% (95% CI 82.7% to 99.4%). The median PFS was 9.46 months (95% CI 8.2 to 11.9) and the 6-month PFS rate was 73.4% (95% CI 60.6% to 89.0%). OS events occurred in 18 patients (42.9%). The median OS was 17.4 months (95% CI 12.4 to not reached). The 12-month OS rate and 24-month OS were 71.8% (95% CI 59.0% to 87.4%) and 49.1% (95% CI 34.5% to 69.9%), respectively. **Conclusions:** Anlotinib plus sintilimab showed a long-term survival benefit for patients with recurrent advanced cervical cancer. Additional investigations in larger randomized controlled trials are warranted in the future. Clinical trial information: ChiCTR1900023015. Research Sponsor: None.

Immunological correlatives of durable responses and survival benefit for patients with cervical cancer in a trial of combined chemotherapy and immune therapy. *First Author: Amanda M Honan, Department of Microbiology and Immunology, University of Miami Miller School of Medicine, Miami, FL*

Background: Recurrent, metastatic, or persistent cervical cancer is largely an incurable disease due to lack of effective therapies. New treatment strategies are needed to provide long-term anti-tumor responses. We sought to gain insight into the immune pathways contributing to treatment response to immunotherapy. **Methods:** Fourteen patients with recurrent, persistent, or metastatic cervical cancer were enrolled in a single-arm phase II clinical trial (NCT03367871) with the combination of chemotherapy, bevacizumab and pembrolizumab regardless of tumor PD-L1 status. We designed a 40-color full spectrum flow cytometry panel to profile the protein markers of immune cells in peripheral blood mononuclear cells (PBMCs) at the single cell level to assess immunological correlates in blood with patients' anti-tumor responses. **Results:** In this trial with a cohort of predominantly Black and Hispanic patients (93%), 50% had durable responses to a combination therapy, and no difference was observed in the combined PD-L1 score (CPS) between responders and non-responders. With 40-color flow cytometry multiplex assays, we detected several differences between the non-responders and responders within the B and T cell populations. Within the B cell population, we observed a significant increase in the HLA^+CD200^{hi} B cells, a potentially suppressive cell subset, within the non-responders while among the responders we observed an increase in the number of HLA^+CD200^{lo} B cells. This HLA^+CD200^{lo} subset was mainly composed of IgD^-CD27^- memory B cells, a population suggested to have effector function. Moreover, the HLA^+CD200^{hi} B cell population contained a higher percentage of PD-L1 expressing cells than the HLA^+CD200^{lo} population, further supporting the suggestion that the HLA^+CD200^{hi} population may be an immunosuppressive subset. Within the T cell compartment, we observed an increase in the number of $CD4^+CD69^+$ T cells, which represent an activated CD4 T cell population, in the responder group compared to the non-responder group. The number of activated $CD4^+$ T cells was observed to correlate ($r = 0.5$) with the HLA^+CD200^{hi} B cell subset. **Conclusions:** This study identified novel immunological correlates in peripheral blood that were associated with durable antitumor responses and survival benefit for cervical cancer patients. These results suggest a role for T-B collaboration in effective antitumor immunity induced by combination of chemotherapy and immune therapy against cervical cancer. Toripalimab combined with chemoradiotherapy for patients with locally advanced cervical squamous cell carcinoma. *First Author: Dan Ou, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China*

Background: To assess the safety and efficacy of toripalimab combined with chemoradiotherapy for locally advanced cervical squamous cell carcinoma (Chinese Clinical Trial Registry number, ChiCTR2000032879). **Methods:** Twenty-two locally advanced cervical cancer patients, regardless of programmed death ligand-1 status, received toripalimab treatment combined with concurrent chemoradiotherapy. Concurrent chemoradiotherapy(CCRT) includes cisplatin (40 mg/m2, once a week for 5 weeks), radiotherapy (external irradiation 45-50.4Gy/25-28Fx, 5 fractions a week, followed by brachytherapy 24-30Gy/3-5Fx) and toripalimab (240mg on days 1, 22 and 43). The primary end-point was safety and feasibility. Secondary endpoints included progression-free survival (PFS), objective response rate (ORR), overall survival (OS). **Results:** The median age was 55 years old (range, 42 to 72 years old), with 2 patients in FIGO stage II, 15 patients in stage IIIC, and 5 patients in stage IVA. All patients have received CCRT successfully. Grade III and higher adverse events (AEs) were observed in 10 patients (10/22, 45.5%), and no patient had a grade V AE. The most frequent grade III AE was leukopenia (8/22, 36.4%). The most common immunotherapy-related adverse reaction was hypothyroidism (2/22, 9.1%). The 3-month ORR rate was 95.5%. At data cutoff (Jan 31, 2022), the median follow-up was 10 months (range, 3.30 to 16.73 months). One patient developed multiple metastases 3 months after treatment, and 1 patient developed lung metastasis 6 months after treatment. The ORR was 100%, while the PFS rate was 90.1%, and the OS rate was 95.5%. **Conclusions:** Toripalimab combined with concurrent chemoradiotherapy demonstrated a manageable safety profile and promising anti-tumor activity in patients with locally advanced cervical cancer, thus might represent a novel treatment option for this patient population. Longer follow-up results and further phase II/III studies are expected. Clinical trial information: ChiCTR2000032879. Research Sponsor: None.

A phase 1 trial of the PARP inhibitor fuzuloparib in combination with the anti-angiogenic apatinib in recurrent ovarian or triple-negative breast cancer. *First Author: Huiping Li, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Breast Oncology, Peking University Cancer Hospital and Institute, Beijing, China*

Background: The combination of an anti-angiogenic agent with a poly (ADP-ribose) polymerase (PARP) inhibitor has demonstrated improved clinical outcomes as treatment/maintenance treatment in gynecological cancers. Here we aimed to characterize the safety profile and recommended phase 2 dose (RP2D) of the combination of fuzuloparib (formerly fluzoparib), a PARP inhibitor, and apatinib, a VEGFR inhibitor in recurrent ovarian cancer (OC) or triple-negative breast cancer (TNBC). **Methods:** This was a dose-escalation and PK-expansion phase 1 trial conducted in China. Patients with recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer or metastatic TNBC were eligible. No prior PARP/VEGFR inhibitors were allowed. The study used a standard 3+3 dose-escalation design, with additional patients (a total of 8-12 patients per dose level) enrolled for PK assessment. Patients received orally a single dose of fluzoparib on D1 and apatinib on D4, followed by continuous dosing of fluzoparib (bid) plus apatinib (qd) starting on D8. Endpoints were RP2D, safety, PK, and anti-tumor activity. **Results:** Between 03/17/2017 and 03/02/2021, 52 patients (30 OC, 22 TNBC) were enrolled to 7 dose levels (up to fuzuloparib 100 mg plus apatinib 500 mg). A total of 2 DLTs occurred: grade 4 decreased white blood cell count (WBC)/febrile neutropenia (fuzuloparib 100 mg plus apatinib 250 mg) and grade 4 thrombocytopenia (fuzuloparib 100 mg plus apatinib 375 mg). No maximum tolerated dose was reached. The most common treatment-related grade ≥3 toxicities included hypertension, anemia/decreased hemoglobin, thrombocytopenia, and decreased WBC. In PK analysis, steady-state plasma concentrations of apatinib was decreased when combined with fuzuloparib, as compared with apatinib alone. Higher dose of apatinib in combination with fuzuloparib 100 mg was associated with higher exposure and improved clinical activity. The ORR was 44% (95% CI, 32-58; OC, 60% [95% CI, 42-75]; TNBC, 23% [95% CI, 10-43]) across all dose levels and 62.5% (95% CI, 31-86) at fuzuloparib 100 mg plus apatinib 500 mg (all OC), which was determined to be the RP2D. **Conclusions:** Fuzuloparib plus apatinib has acceptable safety in patients with recurrent ovarian cancer and triple-negative breast cancer. With the promising clinical activity observed in ovarian cancer, this combination is warranted to be further explored as a potential alternative to chemotherapy. Clinical trial information: NCT03075462. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co. LTD.

The effect of advances in epithelial ovarian cancer treatment on population mortality. *First Author: Aifen Wang, Suzhou Municipal Hospital Affiliated to Nanjing Medical University, Suzhou, China*

Background: Epithelial ovarian carcinoma is the most common and progressive subtype of ovarian cancer. Mortality trends based on race remains unclear. **Methods:** SEER was used to assess epithelial ovarian cancer mortality and relevant deaths from epithelial ovarian cancer to incident cases. Population-level mortality trends were evaluated according to specific causes. In addition, epithelial ovarian cancer incidence and survival was assessed according to calendar year and race. We applied Joinpoint software to evaluate trends in incidence or incidence-based mortality. **Results:** Age-adjusted incidence of white patients was the highest, followed by Asians and Black patients. Incidence-based mortality of Asian patients was the lowest among all patients, followed by White and Black patients. Incidence-based mortality of all causes of death of epithelial ovarian cancer increased sharply by 65.09% annually from 2000 through 2002, then rose gradually by 9.45% annually from 2002 through 2005, and then increased more slowly annually from 2005 through 2018. Other causes of death of incidence-based mortality displayed similar trends. However, incidence-based mortality of specific ovarian epithelial cancer deaths displayed an annual decrease of 0.08% from 2005 through 2018, following a sharp annual increase of 65.68% from 2000 through 2002 and 6.55% from 2002 through 2005. White patients with epithelial ovarian cancer showed the highest 2-year relative survival, followed by Asians, Black patients and Native Americans, with all patients showing an improved survival rate. Among White patients with epithelial ovarian cancer, incidence increased annually by 1.98% from 2000 through 2011 and then flattened out to an annual increase of 0.03%. Incidence-based mortality of White patients increased sharply by 56.70% annually from 2000 through 2002, then increased slowly by 7.90% annually from 2002 through 2005, and 2.00% annually from 2005 through 2018. Among Asian patients with epithelial ovarian cancer, incidence increased at an annual rate of 2.39% from 2000 through 2018. Incidence-based mortality of Asian patients increased steeply by 78.70% annually from 2000 through 2002, then slowed down to an annual rate of 2.50% from 2002 through 2018. Among Black patients with epithelial ovarian cancer, incidence increased annually by 10.83% from 2000 through 2002 and 2.43% from 2006 through 2016 and declined annually by 0.82% from 2002 through 2006 and by 1.82% from 2016 through 2018. Incidence-based mortality of Black patients displayed a sharp annual increase of 63.70% from 2000 through 2002, then slowed to an annual rate of 1.90% from 2002 through 2018. **Conclusions:** Incidence-based mortality of specific ovarian epithelial cancer death decreased annually from 2005 through 2018. These results may be related to treatment advances of epithelial ovarian carcinoma, particularly surgical strategy and chemotherapy. Efficacy and toxicity of carboplatin and gemcitabine dosed on day 1/day 8 versus day 1 alone for platinum-sensitive recurrent epithelial ovarian cancer. *First Author: Erika Joelle Lampert, Cleveland Clinic Department of Obstetrics and Gynecology, Cleveland, OH*

Background: Carboplatin, gemcitabine +/- bevacizumab is a preferred regimen for recurrent, platinum-sensitive ovarian cancer (PSOC). A phase III trial established that the regimen of carboplatin on Day 1 (D1) and gemcitabine on D1 and Day 8 (D8) was associated with acceptable toxicity and improved progression free survival (PFS) compared to carboplatin alone. Treatment with gemcitabine on D8 incurs more exposure to cytotoxic therapy and increased burden on patients and the healthcare system, especially during the COVID-19 pandemic. However, it is unknown whether D1/D8 gemcitabine imparts an improvement in efficacy compared to D1 alone. Our objective was to compare efficacy and toxicity of carboplatin and gemcitabine D1/D8 (CG-D1/8) with a modified D1 regimen (CG-D1). **Methods:** A retrospective single-institution cohort study was performed in women with recurrent PSOC treated with carboplatin, gemcitabine +/- bevacizumab from 2009-2020. Data was analyzed by intention to treat comparing women who received CG-D1/8 vs CG-D1. Data was also analyzed by 3 groups: CG-D1/8 vs CG-D1/8 but dropped D8 vs CG-D1. The primary endpoint was response rate (RR), defined as complete or partial response at 6 cycles or maximum cycles if <6. Secondary outcomes included PFS, overall survival (OS), toxicity, Neulasta use and dose reduction. **Results:** Of 200 patients, 26% completed CG-D1/D8, 21.5% started CG-D1/D8 but dropped D8, and 52.5% received CG-D1. There were no significant differences in age, race, or ECOG between cohorts. Among CG-D1/D8, 45.3% dropped D8 primarily due to neutropenia (51.2%) or thrombocytopenia (30.2%). The RR at 6 cycles was 68.7% for CG-D1/8 completed, 70.7% for CG-D1/8 dropped D8, and 69.3% for CG-D1 (p=0.97). The median PFS was 13.1, 12.1 and 12.4 months for CG-D1/8 completed, CG-D1/8 dropped D8, and CG-D1, respectively (p=0.29). Similarly, median OS was 28.2, 33.5 and 34.3 months for the above groups respectively (p=0.42). While there was no difference in concurrent bevacizumab use for CG-D1/8 and CG-D1 (34.7% vs 29.5%, p=0.43), among the CG-D1/8 patients, a significantly higher proportion of patients who dropped D8 received bevacizumab (51.2% vs 21.2%, p=0.006). Table 1 lists secondary outcomes. **Conclusions:** There was no significant difference in RR, PFS or OS among women with PSOC receiving CG-D1/8 vs CG-D1, regardless of whether D8 was dropped. CG-D1/8 was associated with significantly greater hematologic toxicity. These findings suggest a modified D1 regimen may be a suitable alternative to standard CG-D1/8 treatment and warrant prospective validation. Research Sponsor: None.

Extracellular vesicle-based biomarker assay for the detection of early-stage ovarian cancer. *First Author: Laura Bortolin, Mercy BioAnalytics, Inc., Natick, MA*

Background: Detection of cancer with improved discrimination compared to current blood tests could be achieved using an approach that assesses extracellular vesicles (EVs). This approach should have high sensitivity (se) because of EVs abundance in blood and high specificity (sp) by assaying EVs with multiple cancer-related protein and glycosylation epitopes (PGEs) co-localized on their surfaces. We are developing a platform technology that detects multiple cancer-related PGEs co-localized on the same EV using immunoaffinity-capture and proximity-ligation qPCR. In this study, we compare the performance of this technology vs plasma CA125 for correctly categorizing early-stage high-grade serous ovarian cancer (HGSOC) vs healthy/benign ovarian tumors (OT). **Methods:** We evaluated our EV-based platform technology using 7 PGE combinations to discriminate HGSOC from benign adnexal masses. We first derived a prediction model on a retrospectively collected cohort of 42 HGSOC and 26 benign OT samples from 2 commercial vendors and 24 healthy controls (HC) using a machine-learning algorithm. We validated this model on an independent cohort [89 HGSOC: Stage I (17), II (35), III (37); 192 benign OT] from university-associated biobanks and 124 HC. We also assessed the assay's performance in plasma from 87 women with off-target cancers and 42 women with inflammatory conditions from commercial vendors. For each sample, we also measured CA125 levels using a commercial ELISA. **Results:** The prediction model distinguishes HGSOC from benign and HC with an AUC of 0.965 (95% CI 0.93-0.99), with 89.9% (0.82-0.95) se at 98% sp. For stage I/II HGSOC, the model achieves an AUC of 0.942 (0.9-0.99), with 84.6% (0.72-0.93) se at 98% sp. By comparison, CA125 achieves an AUC of 0.875 (0.81-0.94) and 44.2% (0.3-0.59) se at 98% sp. Direct comparison of CA125 and our model shows a significant difference at 98% sp for both all and stage I/II HGSOC (McNemar p-val < 0.001). When comparing HGSOC to HC, there is no significant difference between our model and CA125 (p-val = 1.0). There is a significant difference when comparing patients with all stage and stage I/II HGSOC to patients with benign OT (p-val < 0.001). Our assay had 1 false positive and CA125 had 3 false positives out of 42 inflammatory cases. **Conclusions:** These preliminary data suggest our platform technology for detecting PGEs co-localized on individual EVs may detect all stages of HGSOC from plasma with high se at a very high sp. Our assay may improve on CA125 by distinguishing stage I/II HGSOC from benign OT and could have clinical utility for both early detection and surgical referral recommendation for benign and malignant OT. While the diverse cohorts in this study may present challenges in interpretation, the reproducibility in an independent cohort is encouraging and supports further investigation using cases and controls from well-defined cohort studies. Research Sponsor: Mercy BioAnalytics, Inc.

5543 **Poster Session**

Efficacy and safety of pembrolizumab in combination with anlotinib in the treatment of refractory or recurrent high-grade serous ovarian cancer: A phase 2 nonrandomized clinical trial. *First Author: Man Jiang, The Affiliated Hospital of Qingdao University, Qingdao, China*

Background: Anlotinib, an oral multi-targeted receptor tyrosine kinase inhibitor (TKI), exhibits good safety and efficacy in many advanced refractory solid tumors. Previous studies have indicated that anlotinib has synergistic effects with anti–programmed death-1 antibodies via modulation of the tumor microenvironment. Our study aims to examine the efficacy and safety of anlotinib-pembrolizumab combination therapy as a treatment for refractory or recurrent High-Grade Serous Ovarian Cancer. **Methods:** Patients with refractory or recurrent High-Grade Serous Ovarian Cancer received pembrolizumab (200 mg, intravenously over 60 minutes, once every 3 weeks) plus anlotinib (12 mg/day, orally, 2 weeks on and 1 week off, every 3 weeks) therapy or pembrolizumab (200 mg, intravenously over 60 minutes, once every 3 weeks) monotherapy, respectively. Primary end points were progression-free survival (PFS) and overall survival (OS). The relationships of potential biomarkers with clinical efficacy were also evaluated. **Results:** A total of 33 patients were enrolled, with 15 participants received the anlotinib-pembrolizumab combination regime and 18 with pembrolizumab monotherapy, respectively. Grade 3 treatment-related adverse events (TRAEs) were recorded in 3 participants (20%) receive the combination treatment and 3 (16.7%) in the pembrolizumab monotherpay group, respectively. The PFS were 13.0 months and 8.0 months to anlotinib-pembrolizumab combination regime and pembrolizumab mono-treatment, respectively. And the OS of the two groups were equal as 31 months. In the anlotinib-pembrolizumab combination treatment group, patients with ARID1A mutation indicated a significantly survival benefit compared patient with the wide type (PFS: 12.5 VS. 7.0, P = 0.004). **Conclusions:** The anlotinib-pembrolizumab combination showed promising efficacy and favorable safety as treatment for refractory or recurrent High-Grade Serous Ovarian Cancer. The ARID1A are potential biomarkers for predicting the efficacy of this novel regimen. Research Sponsor: None.

Efficacy and safety of rucaparib maintenance treatment in patients from ARIEL3 with platinum-sensitive, recurrent ovarian carcinoma not associated with homologous recombination deficiency. *First Author: Robert L. Coleman, U.S. Oncology Research, The Woodlands, TX*

Background: In ARIEL3 (NCT01968213), rucaparib maintenance treatment led to significant improvement vs placebo for the primary endpoint of investigator-assessed progression-free survival (PFS) in patients (pts) with platinum-sensitive, recurrent ovarian carcinoma responsive to the last line of platinum therapy (Coleman et al. *Lancet.* 2017;390:1949–61). The largest benefit was observed in pts with carcinomas with a BRCA mutation or high loss of heterozygosity (LOH), a marker of homologous recombination deficiency (HRD). However, rucaparib also improved PFS in pts with carcinomas negative by HRD test (ie, BRCA wild-type with low LOH), a subset of pts for which there is no identified molecular mechanism conferring PARP inhibitor sensitivity. Among these pts (rucaparib, n = 107; placebo, n = 54), median PFS was 6.7 vs 5.4 months, respectively (HR, 0.58 [95% CI 0.40–0.85]; *P*= 0.0049), and 31.8% vs 4.3% were progression-free at 1 yr. In this post hoc exploratory analysis, we further evaluated the efficacy of rucaparib maintenance vs placebo in this subset of pts. **Methods:** Pts were randomized 2:1 to oral rucaparib (600 mg BID) or placebo. For this analysis, investigator-assessed PFS and safety were evaluated in pts with HRD-negative carcinoma, defined as BRCA wild-type with genomic LOH < 16% using Foundation Medicine's T5 NGS assay. **Results:** Visit cutoff dates for efficacy and safety were Apr 15, 2017, and Dec 31, 2019. Across subgroups based on demographic or disease characteristics, the trend of rucaparib benefit vs placebo was consistently observed in pts with HRD-negative carcinoma (Table). The safety profile of rucaparib in the HRD-negative population was consistent with that of the overall safety population reported previously. **Conclusions:** Rucaparib maintenance reduced risk of progression in pts with ovarian carcinomas, including those not associated with HRD, regardless of clinical prognostic factors. Research Sponsor: Clovis Oncology, Inc.

Clinical implications of tumor-based next-generation sequencing in ovarian cancer. *First Author: Katherine Foster, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Epithelial ovarian cancer is genetically heterogeneous, both among and within histologic subtypes. Advances in next-generation sequencing have made it feasible to ascertain the somatic genetic signature of each patient, however, critical analysis of population-level sequencing results is required to maximize the potential of this technology. Here, we aimed to assess the clinical relevance of tumor-based next-generation sequencing (tbNGS) in a large cohort of patients with high-grade epithelial ovarian cancer. **Methods:** Our study population comprised patients with high-grade serous (n = 972), clear cell (n = 33), endometrioid (n = 28), mucinous (n = 4), and mixed (n = 34) or unspecified (n = 21) epithelial ovarian carcinoma diagnosed between April 2013 and September 2021. tbNGS results were identified within the electronic medical record using optical character recognition and natural language processing. Genetic, clinical, and demographic information was collected for patients who had undergone tbNGS. Progression-free survival (PFS) and overall survival (OS) were calculated from date of first treatment to date of first recurrence and date of death, respectively. Data were analyzed using descriptive statistics, univariate and multivariate Cox regression models, and clustering analyses. **Results:** Of 1092 patients in the described population, 409 (37.5%) had tbNGS results identified. Nearly all (96.1%) revealed one or more genetic aberrations. Most patients (74.6%) had an actionable mutation, defined as relaying eligibility for a targeted treatment or clinical trial. The most frequent alterations were *TP53, PIK3CA*, and *NF1* mutations; and *CCNE1* amplification. Ten different targeted institutional and commercial panels were employed, covering a range of 35 to 600+ gene loci. The median time from diagnosis to testing was 14.5 months, likely corresponding to time of recurrence. Though no standalone alterations were significantly related to survival, multivariate and clustering analyses identified several genetic patterns which corresponded to patient outcomes. Mutation of *BRAF, PIK3R1, NOTCH3, MET*, and/or *ATR* was correlated with shorter PFS (HR 1.84, p = 0.001); mutation of *ATM, RB1, CDKN2A, FGFR1*, and/or *FGFR2* was associated with improved PFS (HR 0.64, p = 0.04), as was mutation of *NBN* and/or *ATRX* (HR 0.54, p < 0.05). *MYC, NOTCH3*, and/or *CREBBP* mutations were significantly correlated with worse OS (HR 1.95, p = 0.02). In our population, 40 patients (9.78%) were enrolled in genotypically-relevant clinical trials. **Conclusions:** tbNGS is prevalent at our institution, and often yields actionable information. We identified several mutational patterns that correlate to patient survival. Detailed analysis of population-level tumor genomics may help to identify therapeutic targets and guide development of clinical decision support tools. Research Sponsor: MD Anderson Ovarian Cancer Moon Shot.

Validation of the integrated prediction model algorithm for outcome of cytoreduction in advanced ovarian cancer. *First Author: Sabrina Piedimonte, University Health Network, Toronto, ON, Canada*

Background: In advanced ovarian cancer, the decision for primary cytoreductive surgery(PCS) or neoadjuvant chemotherapy(NACT) remains a challenge and may impact survival. We previously developed the integrated prediction model(IPM) using a 4-step algorithm of unresectable stage IVb, patient factors, surgical resectability and surgical complexity to predict outcome of optimal cytoreduction in advanced epithelial ovarian cancer(AEOC) and triage patients to NACT or PCS. The objective of the current study was to validate this model on a retrospective historical cohort of patients. **Methods:** This is a retrospective cohort study of 107 patients with AEOC treated at the Princess Margaret Cancer Centre between January 2017 and September 2018 undergoing PCS or NACT. All diagnostic imaging was retrospectively reviewed to assign surgical resectability score (SRS) for sites of disease and the surgical complexity score (SCS) for procedures anticipated to be required to achieve optimal cytoreduction based on preoperative imaging. Those scores were modified from previously validated tools. Patient factors (PF) included age, ECOG and albumin. We previously developed an IPM algorithm to achieve outcome of optimal cytoreduction and determined cut-offs using the Youden index J. Triaging patients to PCS without stage IVb unresectable disease, PF≤ 2, SRS≤5 and SCS≤ 9 led to an 85% specificity and 75% accuracy for outcome of optimal cytoreduction < 1 cm. The current validation study was performed reporting sensitivity, specificity, negative (NPV) and positive predictive value (PPV) on an external cohort. **Results:** Among 107 patients, 61 had PCS and 46 had NACT followed by ICS. Patients treated with NACT were significantly older (63.5 vs 61 years, p = 0.037), more likely stage IV (52% vs 18%, p < 0.001), had a higher proportion of ECOG > 1 (30% vs 11%, 0.045), a lower pre-operative album (37 vs 40, p < 0.001) and higher CA-125 (970 vs 227.5, p < 0.001) compared to PCS. They also had higher PF (2 vs 0, p = 0.013), SRS (4 vs 1, p < 0.001) and SCS (8 vs 5, p = < 0.001). There was no significant difference in outcome of cytoreduction; the optimal cytoreduction rate was 85% vs 87%, p = 0.12 between PCS and ICS patients. In this validation cohort, triaging patients without unresectable stage IVb disease, PF≤ 2, SRS≤ 5 and SCS≤ 9 to PCS had a sensitivity of 91% to correctly identify patients who will have optimal cytoreduction of < 1 cm at PCS and a specificity of 81%. The PPV was 83%, NPV was 90% and accuracy was 86%. Application of the IPM would have prevented 5 suboptimal patients and correctly triaged them to NACT. **Conclusions:** We validated a triage algorithm integrating patient factors, surgical complexity and surgical resectability for patients with AEOC to achieve optimal cytoreduction at PCS with high sensitivity and specificity. This may therefore be used in a clinical setting to decide between PCS and NACT. Research Sponsor: None.

Copy number features as a novel biomarker of homologous recombination (HR) status in high-grade serous ovarian cancer (HGSOC). *First Author: Paula Romero Lozano, VHIO, Barcelona, Spain*

Background: Copy number alterations (CNA) arise as a result of somatic changes to chromosome structure, resulting in gain or loss of genomic regions. A likely source of copy number variation is an incorrect repair of DNA damage that causes chromosome instability (CI). Hence, many tumors with a high degree of CNAs suffer CI. This is the case of high grade serous ovarian cancer (HGSOC), where deficiency in homologous recombination (HRD) is highly prevalent, and so are CI and CNAs. Clinically, HR status in HGSOC is a biomarker of iPARP response and required for proper patient management. Available HRD tests measure genomic loss of heterozygosity (LOH) features, closely related to CI. Such features are complex to acquire in samples with low tumor content; overall, 15% of HGSOC specimens fail HR testing. CNA profiling is technically more amenable to lower tumor cellularity and may be captured by a wider range of techniques and applications (gene panels, low pass WGS...). We present here the analysis and identification of CNA features in HGSOC as a novel biomarker of HR status. **Methods:** A cohort of 123 primary HGSOC tumors were analysed with a custom hybrid capture-based NGS panel (VHIO-300) that provides, along mutations in 450 genes, genome-wide CNA profiles. B-allele fractions, obtained from single nucleotide polymorphisms also in the panel, allowed HRD-LOH score calculation (Marquard et al., 2015). 41 CNA segments correlated to HRD-LOH scores (proportions test, FDR < 0.001) and selected as features to calculate a CNA-HGSOC score (range 0-100). Among them, 10 segments appeared altered almost exclusively in *BRCA1/2* pathogenic/likely pathogenic mutant tumors. **Results:** The density plot of the CNA-HGSOC score showed a bimodal distribution with modes at 7 and 65. A cut-off value of 34 was selected based on the lowest density CNA-score value between the modes. Hence, high CNA-HGSOC was defined as tumors with scores ≥ 34. Our CNA-HGSOC score was strongly correlated as a continuous variable to HRD-LOH (Pearson correlation = 0.72; p < 0.0001) and ROC analysis (AUC = 0.84; CI 95% 0.77-0.91; p < 0.0001) demonstrated high predictability to classify tumors as if using an HRD-LOH test (HRD-LOH score; "very high": 100-75, "high": 74-50,"mid": 49-25 and "low": 24-0). BRCA mutation status was also accurately predicted using a subset of CNA features (AUC = 0.71; CI 95% 0.59-0.82; p < 0.0001). **Conclusions:** CNAs may provide a new powerful genomic resource to HRD determination. We identified 41 CNA features in tumors to inform HR status and a subset of 10 revealed mutation status of *BRCA1/2* in HGSOC. Upon further validation, a CNA-HCSOC score would be easily implemented in routine analysis pipelines in clinical labs, allowing HR testing or even broaden its application to emerging fields, such as liquid biopsy. Genomic analysis of clear cell carcinoma. *First Author: Nirav Haribhakti, Department of Medicine, Brown University, Providence, RI*

Background: Clear cell carcinomas (CCC) are rare histologies outside of the kidney and are typically less sensitive to standard treatments. Genomic alterations in chromatin remodeling pathways involving ARID1A or the intracellular PI3K-mTOR signaling pathway are found in both renal and ovarian CCC. It is unclear whether CCCs originating from different anatomic sites share a common genomic landscape. This CARIS Precision Oncology Alliance project sought to determine whether CCC of different organs shared similar genomic signatures and to identify potential pathways that could be targeted in a tumor-agnostic clinical trial. **Methods:** CCCs (N = 861) from multiple primary tumor sites, including kidney (30.5%), ovary (39%), endometrium (23.9%), other gynecologic sites (e.g., cervix, fallopian tube, 3.3%), and miscellaneous (non-kidney or gynecologic sites, 3.3%) were analyzed at the Caris Life Sciences Laboratory (Phoenix, AZ). Using hierarchical clustering (HC) and principal component analysis (PCA), the samples were compared across 648 total genes from five metabolic gene sets consisting of angiogenesis, glycolysis, hypoxia, oxidative phosphorylation, and fatty acid metabolism. Gene Set Enrichment Analysis (GSEA) was further conducted on the samples across fifty hallmark gene sets representing specific biologic processes and expression. Samples were also analyzed for individual genomic alterations and immune-oncology associated biomarkers. PD-L1 (SP142) expression was evaluated by immunohistochemistry (positive threshold: 2+ stain intensity and ≥ 5% tumor cells). **Results:** HC and PCA demonstrated that renal CCC formed distinct clusters compared to non-renal CCC. Tumors from gynecologic sites could not be separated into distinct clusters. GSEA showed that the hypoxia gene set was significantly upregulated in the renal but not in non-renal CCCs. Mutations involving TP53, ARID1A, PIK3CA were found to be the most altered genes in endometrial (62%, 26%, 31%), ovarian (13%, 55%, 48%), other gynecological sites (33%, 38%, 44%), and non-gynecologic CCC (13%, 17%, 12%) respectively. PD-L1 expression, high tumor mutational burden (≥10 mutations/Mb), and deficient mismatch repair/microsatellite instability rates across sites were: kidney (11%, 2%, 2%), endometrium (13%, 12%, 7%), ovary (9%, 4%, 3%), other gynecological sites (31%, 11%, 11%), and miscellaneous sites (11%, 19%, 4%). **Conclusions:** Initial metabolic gene expression clustering analysis shows that CCCs do not separate by organ of origin beyond renal versus extra-renal. TP53, ARID1A, and PIK3CA were the most frequently altered genes in non-renal CCC. Out of fifty hallmark gene sets, only two were statistically significantly different among gynecological CCCs. This similarity between gynecological CCC can be leveraged by targeting pathways such as PI3K-AKT-mTOR, DNA repair, and MYC targets in a site agnostic manner. Furthermore, high PD-L1 expression is found in other gynecological sites. Research Sponsor: None.

Prior authorizations for PARP inhibitors in ovarian cancer. *First Author: Audra Hugo, University of Pennsylvania, Philadelphia, PA*

Background: PARP inhibitors improve survival in ovarian cancer, especially in patients with BRCA 1/2 mutations or homologous recombination deficiency (HRD). However, these FDA-approved drugs cost $100,000 annually on average, and concerns have been raised about insurance barriers like prior authorization to such medications. Our objective was to examine the prevalence of prior authorization for PARP inhibitors in ovarian cancer overall, by frontline or recurrent maintenance, and by genetic status. **Methods:** We performed a retrospective cross-sectional study of ovarian cancer patients prescribed a PARP inhibitor within the University of Pennsylvania oncology practices from May 2020-2021. Using electronic medical records, we assessed the prevalence of prior authorization for PARP inhibitors overall, by frontline or recurrent maintenance, and by BRCA or HRD status. We then assessed the associated approval and appeal rates. **Results:** We identified 110 patients with ovarian cancer who were prescribed a PARP inhibitor. Of these, 67% (95%CI 57-75) experienced prior authorization for their PARP inhibitor. In contrast, 31 (95%CI 23-40) experienced prior authorization for other components of their gynecologic oncology care. Of patients in the frontline setting, 74 (95%CI 58-86) experienced prior authorization for FDA-approved PARP maintenance. Of patients prescribed PARP maintenance after recurrence, 58 (95%CI 45-71) experienced prior authorization. Of patients with germline BRCA, 70% (95%CI 47-85) experienced prior authorization for PARP inhibitors. Of patients with germline or somatic BRCA or HRD+, 76% (95%CI 61-87) experienced prior authorization. 95% (95%CI 86-94) of prior authorizations for PARP inhibitors were approved on their 1st appeal, and 99% (95%CI 95-100) were approved by the 2nd appeal. **Conclusions:** Two-thirds of patients of ovarian cancer patients who were prescribed PARP inhibitor experienced prior authorization, including equally high rates among women with germline or somatic BRCA mutations, as well as with HRD-deficient tumors. Given the nearly 100% approval after prior authorization, improvements in insurance processes are needed to streamline PARP inhibitor access in ovarian cancer. Research Sponsor: University of Pennsylvania Basser Center for BRCA, Other Foundation, Other Government Agency.

Safety and efficacy of mitoxantrone hydrochloride liposome in patients with platinum-refractory or platinum-resistant ovarian cancer: A prospective, multicenter, open-label, single-arm, phase Ib clinical trial. *First Author: Yu Huang, Gynecological Oncology Center, Chongqing University Cancer Hospital, Chongqing, China*

Background: Platinum-refractory or platinum-resistant ovarian cancer remains unmet medical need with an unfavorable prognosis. Its treatment options are limited and sequentially with multiple single-agent regimens or bevacizumab plus single-agent regimens are recommended. Mitoxantrone hydrochloride liposome (PLM60) is the first approved mitoxantrone nano-drug, which has shown favorable pharmacokinetic characteristics with long circulation and high cumulation in tumor tissue, thus has a promising anti-tumor activity. This trial aimed to explore the efficacy and safety of PLM60 in patients with platinum-refractory or platinum-resistant ovarian cancer. **Methods:** In this multi-center, open-label, single arm study, patients with histologically confirmed, epithelial ovarian, fallopian tube, or primary peritoneal carcinoma, either platinum-refractory or platinum-resistant, with at least one measurable lesion were recruited. PLM60 20 mg/m^2 was administered on day 1 of each 21-day cycle for up to 8 cycles treatment or until disease progression or intolerable toxicities. The primary endpoint was safety, adverse events were graded according to CTCAE 5.0. Second endpoint included overall response rate (ORR), duration of response (DoR), disease control rate (DCR), progression free survival (PFS) and overall survival (OS) as per RECIST 1.1. **Results:** 47 eligible patients with a median age of 54 years (range, 35-67) were treated in 7 institutions in China, including 15 platinum-refractory patients and 32 platinum-resistant patients. 32 (68.1%) of 47 patients received at least 3 prior lines of therapy. Treatment related adverse events (TRAEs) of any grade occurred in 45 (95.7%) of 47 patients, in which 31 (66.0%) were ≥ grade 3. The most common ≥ grade 3 TRAEs (incidence ≥10%) were leucopenia (51.1%), neutropenia (40.4%), anemia (19.1%), lymphocytopenia (17.0%) and thrombocytopenia (17.0%). At the cut-off data of October 31 2021, 39 patients were evaluable for response. ORR was 17.9% (7/39, 95% CI:7.5-33.5%, 7 PRs) and DCR was 56.4% (22/39, 95% CI:39.6-72.2%, 15 SDs). Among 21 platinum-resistant patients with ≥3 prior lines, the median DoR was 4.6 month, 2 responders had a DoR of > 6 months. The ORR and DCR of this cohort were 28.6% (6/21, 95% CI: 11.3-52.2%, 6 PRs) and 61.9% (13/21, 95% CI: 38.4-81.9%, 7 SDs), respectively. Median PFS was 3.6 month (95% CI 1.4-4.6), OS data was not mature. Objective response was not observed in platinum-refractory patients. **Conclusions:** PLM60 had an encouraging efficacy especially in platinum-resistant patients who had received at least 3 prior lines with tolerable safety profiles. Clinical trial information: NCT04718376. Research Sponsor: CSPC Zhongqi Pharmaceutical Technology Co., Ltd.

Efficacy of niraparib maintenance therapy in patients with newly diagnosed advanced ovarian cancer in phase 3 PRIME study: A subgroup analysis by response to first-line platinum-based chemotherapy. *First Author: Rutie Yin, Department of Gynecology and Obstetrics, and Key Laboratory of Obstetrics and Gynecologic and Pediatric Diseases and Birth Defects of the Ministry of Education, West China Second University Hospital, Sichuan University, Chengdu, China*

Background: In PRIME (NCT03709316), niraparib significantly reduced the risk of disease progression or death versus placebo (PBO) (hazard ratio [HR], 0.45; 95% confidence interval [CI], 0.34–0.60) in Chinese patients (pts) with newly diagnosed, advanced ovarian cancer (OC), regardless of biomarker status. As response to chemotherapy is deemed to be associated with prognosis in OC, this subgroup analysis of the PRIME study aims to better understand niraparib treatment effect in pts based on response to first-line platinum-based chemotherapy (1L CT). **Methods:** This randomized, double-blind, PBO-controlled, phase 3 trial enrolled adults with newly diagnosed, stage III or IV OC who achieved a complete response (CR) or partial response (PR) to 1L CT and received primary or interval cytoreductive surgery, irrespective of residual disease status after surgery. Pts were randomized (2:1) to receive niraparib or PBO, whose starting doses were individualized based on baseline bodyweight and platelet count, with stratification according to status of germline *BRCA* mutations (yes or no), tumor homologous recombination status (deficient or proficient), receipt of neoadjuvant chemotherapy (yes or no), and clinical response to 1L CT (CR or PR). This prespecified exploratory analysis reports progression-free survival (PFS) and HRs based on clinical response to 1L CT. The data cut-off date was 30 September 2021. **Results:** Of the 384 pts randomized, 315 (82.0%) and 69 (18.0%) had a CR (212 niraparib, 103 PBO) or PR (43 niraparib, 26 PBO) to 1L CT, respectively. Baseline characteristics are presented in the Table. The overall PFS median follow-up was 27.5 months. Niraparib significantly extended PFS compared with PBO: the median PFS was 29.4 months for niraparib versus 8.3 months for PBO (HR=0.45; 95% CI, 0.32–0.61; *P*<0.001) in the CR group and was 19.3 months for niraparib versus 8.3 months for PBO (HR=0.45; 95% CI, 0.23–0.86; *P*=0.014) in the PR group. **Conclusions:** In pts with newly diagnosed advanced OC, PFS was substantially prolonged with niraparib versus PBO, regardless of response to chemotherapy and biomarker status. Moreover, pts who achieved a CR appeared to receive larger PFS benefit from niraparib than those with a PR. Clinical trial information: NCT03709316. Research Sponsor: The study was funded by Zai Lab (Shanghai) Co. Ltd. This work was also partially supported by the National Major Scientific and Technological Special Project for "Significant New Drugs Development" in 2020, China [grant number 2020ZX09101-014].

Baseline characteristics.

Characteristic, n (%)		Complete response		Partial response	
		Niraparib (N=212)	Placebo (N=103)	Niraparib (N=43)	Placebo (N=26)

Real-world use, tolerability, and dose modifications of PARP inhibitors in ovarian cancer. *First Author: David M. O'Malley, The Ohio State University, Columbus, OH*

Background: Tolerability is a key consideration when selecting a PARP inhibitor (PARPi) for ovarian cancer (OC). Here we expand on earlier work (Arend *et al* 2021) to further characterize real-world tolerability and dose modifications in US patients (pts) with OC receiving PARPi therapy. **Methods:** A retrospective cohort of OC pts starting olaparib (ola), niraparib (nir) or rucaparib (ruc) between Jan 2017 and Dec 2020 was identified from MarketScan® Commercial/Medicare Supplemental databases, increasing the period covered and number of pts included vs our previous analysis. Pts were followed up from first PARPi prescription (index) for ≥30 days until end of study period, disenrollment or death; baseline was 6 months pre-index. Clinical events of interest (CEIs; acute myeloid leukemia/myelodysplastic syndromes, anemia, leukopenia/neutropenia, thrombocytopenia, acute kidney injury, arthralgia, constipation, diarrhea, nausea, vomiting, dermatitis/rash/photosensitivity, fatigue, hypertension, infection, insomnia, pneumonitis, transaminitis) were identified via ICD-9/10 codes. Multivariable Cox regression compared the likelihood of CEIs, dose modifications and hospitalizations between PARPis, adjusting for baseline CEI, Charlson Comorbidity Index score, prior bevacizumab and cancer-related surgery. Persistence was defined as no PARPi treatment gaps of >90 days in pts with ≥6 months' continuous enrollment. **Results:** Overall, 637, 538 and 227 pts received ola, nir and ruc, respectively (median [IQR] follow-up 10.5 [13.4] months). Baseline characteristics were similar across groups. The proportion of pts initiating PARPi at the highest indicated dose was 89.2%, 57.6% and 89.9% for ola, nir and ruc, respectively; 22.6%, 34.8% and 28.6%, respectively, required dose decreases. The likelihood of experiencing CEIs varied across the PARPis after adjusting for *a priori* confounders as shown in the table. Persistence with index PARPi was higher with ola (83.4%) vs nir (73.3%; $P<0.001$) and similar vs ruc (80.2%; $P>0.05$). Among all pts, mean time to non-persistence was shorter with nir vs ola and ruc (6.4 vs 7.9 and 7.6 months, respectively; both $P<0.05$). CEIs by PARPi dose and calendar year will also be presented. **Conclusions:** This is the largest real-world comparison of PARPi use in OC pts reported to date. It supports differences between PARPis in persistence with therapy and risk of experiencing a CEI, even after adjusting for confounders. Research Sponsor: AstraZeneca.

Adjusted HR (95% CI)	Nir vs ola	Ruc vs ola	Nir vs ruc
Any CEI	1.34 (1.19–1.52)*	1.13 (0.96–1.33)	1.19 (1.01–1.40)‡
Any hematologic CEI	1.51 (1.30–1.77)*	1.18 (0.96–1.45)	1.28 (1.05–1.57)‡

Identification of patients with ovarian cancer who are experiencing the highest benefit from bevacizumab in first-line setting based on their tumor intrinsic chemosensitivity (KELIM): GOG-0218 validation study. *First Author: Benoit You, Institut de Cancérologie des Hospices Civils de Lyon (IC-HCL), Lyon, France*

Background: In patients with high-grade ovarian cancer in first-line setting, predictive factors of bevacizumab efficacy are needed, for selecting patients. In ICON-7 trial, a poor tumor intrisic chemosensitivity (defined by unfavorable modeled CA-125 kinetic ELIMination rate constant KELIM) was a predictive biomarker. Among patients with high-risk diseases, only those with unfavorable KELIM had survival benefit from bevacizumab (mOS: 29.7 vs 20.6 months, HR = 0.78)(Colomban. *JNCI CS* 2020). The objective was to perform an external validation in GOG-0218 trial (NCT00262847). **Methods:** In GOG-0218, 1,873 patients were treated with carboplatin-paclitaxel +/- concurrent bevacizumab/placebo followed by a 15 month maintenance. Patient KELIM values were estimated with longitudinal CA-125 kinetics during the first 100 chemotherapy days. The association between KELIM score (categorized as favorable ≥ 1, or unfavorable < 1) and efficacy of bevacizumab (bevacizumab-concurrent + maintenance, vs placebo) for PFS and OS was assessed using univariate/multivariate analyses, in a Training set with 2/3 patients managed the investigators, and then a Validation set with all patients, managed by NGR-GOG. **Results:** KELIM was assessable in 1,662 patients with ≥ 3 CA-125 available values. In both sets, the patients with unfavorable KELIM derived benefit from bevacizumab compared to placebo (Training: PFS, HR = 0.65 [0.54-0.80]; OS, HR = 0.80 [0.65-0.99]; Validation: PFS, HR = 0.69 [0.59-0.82]; OS, HR = 0.87 [0.73-1.03]), whilst those with favorable KELIM had no benefit from bevacizumab (Training: PFS, HR = 0.96 [0.75-1.23]; OS, HR = 1.05 [0.80-1.37]; Validation, PFS, HR = 0.96 [0.79-1.17]; OS HR = 1.11 [0.89-1.84]). The highest benefit was observed in patients with high-risk diseases (stage IV or sub-optimally resected stage III) characterized by unfavorable KELIM, for PFS (Learning (n = 276): mPFS: 9.0 vs 5.2 months, HR = 0.61 [0.48-0.78]; Validation (n = 433): mPFS: 9.1 vs 5.6 months, HR = 0.64 [0.53-0.78]), and for OS (Learning (n = 278): mOS: 38.9 vs 27.9 months, HR = 0.72 [0.56-0.93], Validation set (n = 438): mOS: 35.1 vs 29.1 months, HR = 0.79 [0.65-0.97]). **Conclusions:** This validation analysis of GOG-0218 trial confirms the outcomes of ICON-7 trial about the association between poor tumor chemosensitivity and benefit from concurrent + maintenance bevacizumab, suggesting that bevacizumab is mainly effective in patients with poorly chemosensitive diseases. No benefit was found in patients with favorable KELIM. The patients who derived the highest benefit from bevacizumab in PFS and OS (OS absolute benefit ~ 6 to 9 months) were those with high-risk diseases (stage IV, or incompletely resected stage III) associated with an unfavorable KELIM score (calculator on https://www.biomarker-kinetics.org/CA-125). Research Sponsor: GOG-0218 was funded by NRG-GOG.

Immune tumor microenvironnement (iTME) post-neoadjuvant chemotherapy, beyond PD-L1: Novel immune targets in ovarian cancer, data from the CHIVA trial, a GINECO/GINEGEPS study. *First Author: Felix Blanc-Durand, Institut Gustave Roussy, Villejuif, France*

Background: Antibodies targeting PDL1 or PD1 have been disappointing so far in the treatment of ovarian cancer (OC). A greater understanding of the complex iTME and of the impact of chemotherapy on immune features could uncover promising immune targets. We previously reported that neoadjuvant chemotherapy (NACT) increased CD4+ and CD8+ immune cells (IC) and depleted FOXP3+ suppressive T-regs in OC iTME. Here we aimed to describe the expression of PDL1 as well as other co-regulatory molecules in OC and their changes under NACT. **Methods:** Tumor samples and clinical data were prospectively collected from patients (pts) in the randomized CHIVA trial of NACT +/- nintedanib. Samples were evaluable for immune profiling for 116-124 pts at diagnosis and 89-107 at surgery after 3 cycles of NACT. IC stained for CD4, CD8 were scored as number of IC+/mm^2. Expression of immune co-regulatory molecules PDL1, TIM3, LAG3 and IDO was scored as percentage of positive cells, and tumors were classified as PDL1/TIM3/IDO/LAG3 positive if > 1% of IC and/or tumor cells (TC) were positive. Highly sensitive pts, defined as objective response to NACT and prolonged median progression-free survival (mPFS > 24months), were compared to refractory pts (progressing during or within 3mo of platinum). **Results:** As expected, about one third (36%) of tumors were PDL1+ at diagnosis. In contrast, the prevalence of other co-regulatory molecules was higher with 52%, 54% and 93% of tumors being positive for IDO, LAG3 and TIM3, respectively. There was no significant change in PDL1 expression with NACT. However, in paired samples NACT significantly increased IDO and LAG3 expression ($p < 0.05$), such that 60% and 66% of tumors post-NACT were positive for IDO and LAG3, respectively. TIM3 expression remained high post-NACT with 92% of positive tumors. Highly sensitive tumors (vs refractory tumors) had significantly higher IC expression of TIM3 after NACT (24% vs 6%, $p = 0.005$), and were significantly more infiltrated by CD4+ (441 vs 228 cells/mm2, $p = 0.04$) and CD8+ (460 vs 225 cells/mm2, $p = 0.045$) T cells. **Conclusions:** Other immune targets beyond PDL1 are highly expressed in OC. In addition NACT appears to prime the iTME by increasing effector T cell infiltration and the expression of other relevant co-regulatory molecules (LAG3, TIM3 and IDO). Future studies could be performed by priming the iTME with NACT and testing novel immune therapies based on target expression in samples obtained at interval debulking surgery. Research Sponsor: ARCAGY-GINECO Grant.

Real-world outcomes associated with bevacizumab combined with chemotherapy in platinum-resistant ovarian cancer. *First Author: Gordon Taylor Moffat, Queen's University, Kingston, ON, Canada*

Background: In the pivotal Aurelia study, addition of bevacizumab (bev) to physician's choice chemotherapy (paclitaxel, liposomal doxorubicin or topotecan) for platinum-resistant (PL-R) ovarian cancer (OC) was associated with improved progression-free survival (PFS; 6.7 vs 3.4 mos; hazard ratio (HR) 0.48, p = 0.001) but not overall survival (OS; 16.6 vs 13.3 mos HR 0.85, p = 0.174); the latter finding may relate to extensive crossover. In an exploratory subgroup analysis by treatment arm, benefits were particularly marked for bev + paclitaxel where median PFS (mPFS) increased from 3.9 to 10.4 mos (HR 0.46; 95%CI 0.30-0.71) and increases in OS approached statistical significance (HR 0.65; 95%CI, 0.42-1.02; 22.4 *v* 13.2 mos). Here we describe utilization of bev for PL-R OC and outcomes in routine clinical practice. **Methods:** The Ontario Cancer Registry and the New Drug Funding Program databases were utilized to identify all patients treated with bev plus chemotherapy (paclitaxel, liposomal doxorubicin or topotecan) for PL-R OC following its approval in 2017. Time on treatment (ToT) was defined as time from first to last bev treatment; this was used as a surrogate for PFS in routine practice. Median OS (mOS) was determined using the Kaplan-Meier method. Factors associated with ToT and OS were identified using a Cox proportional hazard model. A before and after comparison analysis was performed to determine mOS for patients treated pre- (2011-2017) and post-bev (2017-2019) approval. **Results:** From Oct 2017 to Dec 2019, 180 patients received bev + chemotherapy for first-line PL-R OC. Mean age was 63 years old, and 80% had serous OC. Bev was most often combined with liposomal doxorubicin (64 %) followed by paclitaxel (34%) and topotecan (2%). Median ToT was 3 months and OS was 11 months. ToT and OS were longer in patients who received paclitaxel as chemotherapy backbone (5 mos [ToT]; 14 mos [OS]) than those who received bev with liposomal doxorubicin (2 mos; 9 mos) or topotecan (2 mos; 6 mos). In multivariable models, ToT was superior in patients who received bev + paclitaxel than bev + liposomal doxorubicin (HR 0.40; 95%CI 0.28-0.57; p < 0.0001), and worse with longer time from diagnosis to bev start (1.03; 1.01-1.05; p = 0.0120). OS was also significantly longer in those who received paclitaxel vs liposomal doxorubicin (HR 0.54; 95%CI 0.30-0.98; p = 0.043). In a before and after analysis, patients treated in the pre- (n = 1290) and post-bev (n = 360) era had mOS of 8 and 9 months respectively. Post mOS increased for patients receiving paclitaxel (7 vs 12 months) but not with liposomal doxorubicin (9 vs 7 months). **Conclusions:** ToT and OS associated with bev for PL-R OC are shorter in a real-world population compared to results reported in AURELIA. ToT and OS were longer with bev + paclitaxel than with other chemotherapy agents. Research Sponsor: Queen's University Health Sciences Grant/Clare Nelson Bequest Fund.

Prospective identification of prognostic factors for patients with early failure of advanced ovarian cancer who undergo primary cytoreductive surgery followed by chemotherapy: The AGO-OVAR 19/FRAGILE study (NCT02828618). *First Author: Felix Hilpert, Krankenhaus Jerusalem Hamburg, Hamburg, Germany*

Background: Standard treatment for advanced ovarian cancer (aOC) includes primary cytoreductive surgery followed by chemotherapy (PDS > CTX). There is strong evidence that this strategy is accompanied by high risk for early failure in some patients (pts) but prospective multicenter data for this specific question are lacking. **Methods:** 64 AGO-sites prospectively registered pts with suspected aOC and collected following variables prior to start of therapy: age, Charlson Comorbidity Index (CCI), timed up and go test (TUG), ASA and ECOG performance score, weight, height, estimated ascites, albumin, creatinine, hemoglobin, leucocytes, platelets, CA125, patient reported outcome measures according to EORTC QLQ-C30 and OV28, hospital anxiety and depression score (HADS), physician-assessed suspected FIGO IV stage, abdominal pain requiring treatment, abdominal bloating, dyspnea and required palliative paracentesis (ascites, pleural effusions). Treatment followed according to investigator's decision. Primary objective was to predict the unfavorable event of death or progression within 10 months after primary diagnosis. We applied univariate and multiple logistic regression with stepwise variable selection after multiple imputation of missing data in order to identify relevant predictors. **Results:** 223 pts with aOC FIGO IIIB to IVB and PDS were analyzed. Median age was 63 years (range 31-86). 52 (23.3%) pts experienced progression or death within 10 months from time of enrolment. In univariate regression, age (odds ratio (OR) 1.612 per 10 years), ASA (III vs I/II: OR 3.217), TUG (OR 1.087), body height (OR 0.541 per 10cm), ECOG (1 vs 0 OR 2.326, 2-3 vs 0 OR 4.102), estimated ascites (> 500cc vs. none OR 2.811), paracentesis (OR 1.991), platelets (upper limit of normal (ULN) vs norm or < lower limit of normal (LLN) OR 1.998), albumin (< LLN vs norm or > ULN OR 2.053), creatinine (> ULN vs norm OR 3.969) and baseline QoL single-item subscales appetite loss ("very much" vs "not at all" OR 2.611), constipation ("quite a bit" vs "not at all" OR 4.903), and multi-item subscales global health status (OR 0.982 per 1 point) and nausea/vomiting (OR 1.013 per 1 point) were significant ($p < 0.05$). Multiple logistic regression identified age (OR 1.459 per 10 years), ASA (III vs I/II: OR 2.427), constipation ("quite a bit" vs "not at all" OR 3.786) and global health (OR: 0.985 per 1 point) as independent predictors of progression or death within 10 months after primary diagnosis ($p < 0.05$). **Conclusions:** A significant proportion of aOC pts undergoing PDS > CTX are at high-risk for early failure. The finding of independent risk factors including self-ratings of QoL at time of diagnosis should be confirmed and tested against other models to facilitate a more tailored treatment of high-risk pts and design of future trials in aOC. Clinical trial information: NCT02828618. Research Sponsor: Roche Pharma AG, Grenzach-Wyhlen, Germany.

Phase Ib INEOV neoadjuvant trial of durvalumab +/- tremelimumab with platinum chemotherapy for patients (pts) with unresectable ovarian cancer (OC): Final complete resection and pathological response rates. *First Author: Alexandra Leary, Medical Gynecology, Gustave Roussy, Villejuif, France*

Background: We have shown that neoadjuvant carboplatin and paclitaxel (NACP) increased tumor infiltrating lymphocytes and PDL1 expression in OC pts. INEOV evaluated NACP with durvalumab (D) +/- tremelimumab (T) in pts with unresectable OC. We previously reported that NACP with D+/-T was feasible and safe but the addition of T did not improve interval debulking surgery (IDS) rates after 3 cycles (C3) (ESMO 2021). Here we provide an update with longer follow up including data on delayed IDS performed after 6 cycles of neoadjuvant treatment. Key secondary endpoints include complete resection (CC0) and complete pathological response rates. **Methods:** Pts with stage IIIC/IV OC were randomized to NACP + D (1125mg) alone (arm A) or with T (75mg once at C2) (arm B). Interval debulking surgery (IDS) was planned after C3, or delayed after C6. Pts in arm A not operable after C3 crossed over to arm B, pts in arm B crossed over to standard of care (SOC). Pts were assessed for delayed IDS after C6. Complete pathological response (pCR) was defined as no residual tumor cells found on any surgical specimens, or no residual tumor cells on any samples outside the ovary at IDS. **Results:** Sixty four (N = 64) of 66 pts (IIIC/IV: 70%/30%) randomized were evaluable. After C3, 66% (21/32) of pts in arm A and 59% (19/32) in arm B had IDS. The 11 pts in arm A not candidate for IDS after C3 crossed over to arm B until C6 and 5/11 benefited from delayed IDS. The 13 pts in arm B inoperable at C3 went on to receive SOC (NACP +/- bevacizumab), and 5/13 became eligible for delayed IDS after C6. Overall, IDS was performed in 50 of 64 evaluable pts, and most (45/50) achieved macroscopically complete resection (CC0), so that the overall CC0 rate was 70% (45/64), with no significant difference between arms (CC0 = 75% vs 65% in arm A vs B). Among the 50 pts who had IDS, complete pathological responses were observed in 18% of pts. **Conclusions:** Taking into account the whole treatment strategy including delayed IDS after 6 cycles of neoadjuvant treatment, we have shown that neoadjuvant CP with D+/- T results in encouraging CC0 (70%) and pCR (18%) rates. However there was no apparent benefit to the addition of T to D. Studies are ongoing to describe the immune features predictive of pCR as well as the impact of treatment on the immune microenvironment. Clinical trial information: NCT03249142. Research Sponsor: AstraZeneca.

OReO/ENGOT Ov-38 trial: Impact of maintenance olaparib rechallenge according to ovarian cancer patient prognosis—An exploratory joint analysis of the BRCA and non-BRCA cohorts. *First Author: Frédéric Selle, GINECO & Groupe Hospitalier Diaconesses Croix Saint Simon, Paris, France*

Background: In the Phase IIIb OReO/ENGOT Ov-38 trial (NCT03106987), maintenance olaparib (O) rechallenge significantly improved progression-free survival (PFS) vs placebo in patients (pts) with platinum-sensitive relapsed ovarian cancer (PSROC) regardless of their BRCA status (Pujade-Lauraine, ESMO 2021). The impact of prognostic factors on this PFS benefit were unknown. **Methods:** Pts had PSROC, one prior line of PARP inhibitor (PARPi) maintenance and were in response to platinum-based chemotherapy (Cx). Pts were enrolled into two cohorts – BRCA mutated (BRCAm) and non-BRCAm – and randomized to receive maintenance O (300 mg bid) or placebo. Primary endpoint was PFS. Post-hoc individual patient data meta-analysis was used to combine both cohorts using fixed and random effect models, interaction, and stratified tests in the Cox model. Stepwise Cox multivariate model for PFS and logistic regression models were used for late relapse, defined as disease progression occurring >24 weeks after randomization. Randomization stratification criteria and cohort effect were included in all models. **Results:** This study included 220 pts from the BRCAm (n=112) and non-BRCAm (n=108) cohorts recruited between October 3, 2017 and February 10, 2021. No heterogeneity was detected between cohorts: Cochran's Q test *P*=0.53 (fixed and random); interaction test *P*=0.63. The O effect was consistent, and no significant interactions were observed between subgroups. In the multivariate PFS analyses, the main independent factors for prognosis were CA-125 level, visceral disease (liver, lung, pleura, brain), and treatment arm. These factors were independent predictive factors for late relapse among the 181 evaluable pts with the opportunity of at least 6 months of follow-up (Table). **Conclusions:** In the OReO/ENGOT Ov-38 trial, CA-125 level and presence of visceral disease at baseline were the best predictors of patient outcome. Maintenance olaparib rechallenge was effective overall regardless of prognostic subgroup. Clinical trial information: NCT03106987. Research Sponsor: AstraZeneca, Pharmaceutical/Biotech Company.

BRCA reversion mutations mediated by microhomology-mediated end joining (MMEJ) as a mechanism of resistance to PARP inhibitors in ovarian and breast cancer. *First Author: Natalia Lukashchuk, AstraZeneca, Cambridge, United Kingdom*

Background: PARP inhibitors exploit synthetic lethality in tumor cells with deficiency in homologous recombination repair (HRR). In line with this, most reported mechanisms of PARP inhibitor resistance restore HRR. Of multiple resistance mechanisms reported preclinically, reversion mutations in BRCA genes are the only confirmed mechanism of resistance to both platinum and PARP inhibitors in patients (pts) to date (Lin K *et al. Cancer Discov* 2019), with most studies focusing on ovarian cancer. MMEJ is an alternative DNA damage repair pathway, in which DNA polymerase θ (POLθ) has a key role; MMEJ has been suggested to play a role in BRCA reversion mutations (Tobalina L *et al. Ann Oncol* 2021). **Methods:** Targeted circulating tumor DNA (ctDNA) sequencing analyzed over 500 plasma samples collected at baseline and at progression to therapy in pts with ovarian or breast cancer and a mutation in *BRCA1* and/or *BRCA2* (BRCAm) who were treated with olaparib or chemotherapy in one of three Phase II/III clinical studies (LIGHT NCT02983799, SOLO3 NCT02282020, OlympiAD NCT02000622). Only pts with an original pathogenic BRCAm detected in ctDNA were evaluable. BRCA reversion mutations were identified using internal computational framework; DNA sequences surrounding BRCA reversion sites were analyzed for MMEJ signatures. **Results:** At baseline, in pooled data across treatment arms and across all available samples, BRCA reversion mutations were detected in 4/114 (3.5%) and 6/133 (4.5%) of breast and ovarian cancer pts, respectively, which may have developed on prior platinum therapy. At progression, BRCA reversion mutations were detected in 34/79 (43%) breast cancer pts and in 26/101 (26%) ovarian cancer pts who received olaparib, with at least 2/79 and 4/101 reversions already present at baseline, respectively. At progression, in the chemotherapy arm, BRCA reversion mutations were detected in 3/34 (9%) breast cancer pts and 1/29 (3%) ovarian cancer pts, with 2/34 and 0/29 reversions present at baseline, respectively. Reversion mutations varied in allelic frequency and were either present as single or multiple reversions, suggesting multiple events within the tumor were driving resistance. The location and type of reversion mutations reflected the functional importance of BRCA protein domains. A large proportion of BRCA reversion mutations (47/69 [68%] that were evaluable) were mediated by the MMEJ pathway based on the presence of MMEJ signatures around BRCA reversion sites. **Conclusions:** We detected BRCA reversion mutations in at least ~40% of breast and ~20% of ovarian cancer pts following treatment with olaparib. A large proportion of these reversion mutations are likely to have been mediated by MMEJ repair, suggesting that POLθ inhibitors in combination with platinum or PARP inhibitors might prevent or delay emergence of PARP inhibitor resistance. Clinical trial information: NCT02983799, NCT02282020, NCT02000622. Research Sponsor: This study was supported by AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA, who are codeveloping olaparib.

5560 **Poster Session**

Quality of life in patients with advanced high-grade ovarian cancer (HGOC) receiving maintenance therapies after first-line (1L) chemotherapy in the randomized phase III PAOLA-1/ENGOT-ov25 trial (NCT02477644). *First Author: Jean Emmanuel Kurtz, ICANS (Institut de Cancérologie Strasbourg Europe), Strasbourg, France*

Background: In the Phase III PAOLA-1/ENGOT-ov25 trial, maintenance olaparib + bevacizumab (bev) provided a significant progression-free survival (PFS) benefit vs placebo (pbo) + bev in patients (pts) with newly diagnosed advanced ovarian cancer in response to platinum-based chemotherapy. Subgroup analyses revealed a substantial PFS benefit in homologous recombination deficiency (HRD)-positive (including BRCA1/2 mutation) pts, leading to US/EU labels for this combination. Preliminary analyses reported that olaparib did not alter global health-related quality of life (G-HQoL; Ray-Coquard I *et al. NEJM* 2019). We analyzed HQoL by domains and molecular subgroups and explored the impact of disease progression (DP) on HQoL in the 1L setting. **Methods:** Eligible pts with newly diagnosed advanced (FIGO stage IIIIV) HGOC were randomized 2:1 to maintenance olaparib + bev or pbo + bev. Pts completed European Organisation for Research and Treatment of Cancer QLQ-C30 and QLQ-OV28 HQoL questionnaires at baseline and every 12 weeks for 2 years follow-up, irrespective of DP. The minimal important difference for clinically relevant change was fixed at 10 points. Longitudinal data were analyzed by mixed model for repeated measures (MMRM) and time until definitive deterioration (TUDD). Analyses were in the intent-to-treat population and HRD-positive subgroup. HQoL analyses at DP (± 60 days) were explored. **Results:** 806 pts were randomized to olaparib + bev (n=537) or pbo + bev (n=269). 465 pts had DP over 2 years follow-up. Compliance to HQoL questionnaires was high at baseline (95%) and over time (>70%). MMRM models by HQoL domain did not reveal a clinically relevant difference between treatment arms over time. TUDD of G-HQoL did not differ between arms (hazard ratio [HR] 0.88, 95% confidence interval [CI] 0.721.07). In the HRD-positive subgroup (n=372), we observed no difference by HQoL domain between treatment arms. Interestingly, TUDD of G-HQoL was statistically significantly in favor of olaparib + bev compared with pbo + bev (HR 0.70, 95% CI 0.520.93). We also observed a clinically significant deterioration in emotional (mean change −12.30 points, 95% CI −16.46 to −8.13) and social (−11.17 points, 95% CI −16.21 to −6.12) functioning in both treatment arms at DP, among 103 pts with HQoL questionnaires at DP. **Conclusions:** The substantial PFS benefit provided by maintenance olaparib + bev in the newly diagnosed setting was achieved without detrimental effect on HQoL domains, even with longer TUDD of G-HQoL in the HRD-positive subgroup. Use of an effective maintenance therapy (ie one with a significant PFS benefit) in HGOC patients in the 1L setting is likely to delay the clinically significant deterioration in emotional and social functioning we identified in patients at DP across PAOLA-1 treatments arms. Clinical trial information: NCT02477644. Research Sponsor: ARCAGY Research, Pharmaceutical/ Biotech Company.

Identifying disparities in gynecologic cancer: Results and analysis from a patient preference survey. *First Author: Eloise Chapman-Davis, Division of OB/GYN and Gynecologic Oncology, Weill Cornell Medicine-New York Presbyterian Hospital, New York, NY*

Background: Health disparities exist in gynecologic cancers, with data revealing lower survival among certain racial/ethnic groups. Studies suggest underrepresented patients of color with gynecologic cancers may not receive guideline-concordant care to adequately manage their disease, including molecular testing. We conducted a patient preferences survey evaluating treatment choices and provider interactions influencing adherence to guideline-based care. **Methods:** From July 7 to August 18, 2021, a survey was sent to women with gynecologic cancers who participate in the SMART Patients advocacy group. Survey questions covered topics of preparedness to discuss care with provider, biomarker testing specific to gynecologic tumor type, patients' considerations informing treatment choices, and confidence to work with providers to improve their clinical and survival outcomes. Information regarding cancer diagnosis, stage, race, ethnicity, treatment, and genetic testing was obtained. Survey responses between non-Hispanic White patients (W) versus non-White (NW) underrepresented patients of color were compared and analyzed using descriptive statistics. **Results:** A total of 89 women with gynecologic cancers (67% ovarian, fallopian tube, and peritoneal; 21% endometrial; 9% vulvar or vaginal; and 2% cervical) participated in the patient survey. Amongst responders, 55% had localized disease while 36% indicated they had metastatic disease, and 9% did not know. Overall, 86.5% were W and 13.5% were NW (Asian, Black/ African American, Native American or Pacific Islander, Hispanic, or mixed race). A higher proportion of NW compared to W patients said they were not at all prepared to discuss cost of treatment (18.2% vs 9.5%), treatment options (12.5% vs 4.5%), and side effects of treatment (20% vs 0%) with their provider; 31% of W patients discussed genetic testing and received resources from their provider compared with only 16.7% of NW patients, and a higher proportion of NW compared to W patients (37.5% vs 28.1%) indicated they were not confident in their ability to work with providers to improve their cancer treatment outcome. **Conclusions:** While a limitation of this study was low participation from diverse populations, the findings indicate that underrepresented NW patients felt less prepared to discuss treatment-related issues compared to W patients. Moreover, a large proportion of all patients with OC were not informed and/or aware about genetic testing, and approximately a third of participants were not confident in their ability to interact with provider to improve their outcomes. The results highlight opportunities to enhance health care provider education and community outreach to reduce gaps in care delivery. Research Sponsor: None.

Time without symptoms or toxicity (TWiST) in patients with newly diagnosed advanced ovarian cancer receiving maintenance olaparib or placebo plus bevacizumab: Analysis of PAOLA-1/ENGOT-ov25 phase III trial. *First Author: Florence Joly, Centre François Baclesse, Caen, France*

Background: In the Phase III PAOLA-1/ENGOT-ov25 trial (NCT02477644), maintenance olaparib plus bevacizumab (bev) provided a significant progression-free survival (PFS) benefit, compared with placebo plus bev, in patients (pts) with newly diagnosed advanced ovarian cancer in response after platinum-based chemotherapy (Ray-Coquard *et al. NEJM* 2019). A subgroup analysis revealed a substantial PFS benefit in HRD-positive (including *BRCA1/BRCA2* mutation) pts (median PFS 37.2 vs 17.7 months) leading to US and EU labels for this combination. We analyzed TWiST in PAOLA-1, using several definitions of toxicity (TOX) and by molecular subgroups. **Methods:** Pts were randomized 2:1 to maintenance olaparib (300 mg bid) plus bev (15 mg/kg, Day 1, q3w) or placebo plus bev, stratified by first-line treatment outcome and tumor BRCAm status. TWiST is defined as PFS minus time with TOX after randomization and before disease progression or censoring for progression, and was a prespecified exploratory endpoint. Definitions of significant symptoms or TOX were explored using the following approaches: 1) all grade ≥2 adverse events (AEs); and 2) all grade ≥2 AEs selected to be correlated to olaparib (fatigue, nausea, vomiting, and anemia). Area under PFS curve was split into TOX:TWIST ratio and compared between the two arms. **Results:** Between May 7, 2015 and August 31, 2017, 806 eligible pts were randomly assigned to olaparib plus bev (n = 537) or placebo plus bev (n = 269), with a median duration of treatment with olaparib of 17.3 months (range 0.0333.0) for olaparib plus bev arm and 15.6 months (range 0.0726.2) for placebo plus bev at data cutoff for primary endpoint analysis. In the Intent-to-treat population, median duration of TWiST for all grade ≥2 AEs for olaparib plus bev vs placebo plus bev arms was 14.1 months (95% confidence interval [CI] 12.516.1) vs 7.7 months (95% CI 5.99.1), respectively; and 21.9 months (95% CI 20.222.5) vs 16.6 months (95% CI 14.618.0) considering only grade ≥2 AEs linked to olaparib. The difference was particularly significant within the HRD-positive subgroup where median duration of TWiST was 24.4 months (95% CI 19.3not evaluable [NE]) vs 7.4 months (5.811.2) for TOX linked to all grade ≥2 AEs, and 36.6 months (95% CI 31.9NE) vs 17.4 months (15.119.4) linked to olaparib AEs only for the olaparib plus bev and placebo plus bev arms, respectively. **Conclusions:** The substantial PFS benefit provided by maintenance olaparib plus bev vs placebo plus bev in pts with newly diagnosed advanced ovarian cancer was supported by significant TWiST benefit. TWiST analyses, including all grade ≥2 symptoms or toxicity related to treatment, confirmed the clinically meaningful benefit from the combination, notably in the HRD-positive subgroup. Clinical trial information: NCT02477644. Research Sponsor: ARCAGY Research, Pharmaceutical/Biotech Company.

Potential indicators in circulating cell-free DNA for monitoring PARP inhibitor resistance in high-grade serous ovarian cancer. *First Author: Gang Chen, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*

Background: Although the clinical application of PARP inhibitors (PARPis) has brought great survival benefits to patients with high-grade serous ovarian carcinoma (HGSOC), its resistance has gradually become a major challenge for clinicians with the widespread use of PARPis. Unfortunately, there are no effective, non-invasive means for monitoring PARPis resistance in time during maintain therapy. **Methods:** We collected peripheral blood samples (n = 37) from 37 healthy subjects and a series of longitudinal peripheral blood samples (n = 61) of 25 platinum-sensitive HGSOC patients undergoing Olaparib maintenance therapy. The genome of white blood cell and cfDNA in plasma was extracted for germline and somatic mutation detection by Circular Ligation Amplification and sequencing (CLAmp-seq) based on a targeted 42-gene panel, respectively. Before cfDNA mutation analysis, background noise introduced by random NGS error was removed and clonal hematopoietic mutations were filtered. Variant-supporting reads > 2 and without germline mutations were defined as the criterion for somatic mutations. Progression-free survival (PFS) was collected through regular follow-up. We analyzed the dynamic changes of cfDNA mutation profiles, the correlation between cfDNA mutations and the prognosis of patients, and screened specific mutation sites that closely associated with Olaparib resistance. **Results:** The elevation of maximum mutant allele frequency (Max MAF) in cfDNA during Olaparib maintenance therapy predicted a poor prognosis of patients (P = 0.0043). Pathogenic germline mutations in *BRCA1/2 or RAD51* were strongly associated with longer PFS (P = 0.0229) and acquired new *MRE11A* mutations significantly shortened the PFS in patients (P = 0.0005). Dynamic fluctuations of somatic mutation sites in *CHEK2:p.K373E* (P = 0.0091) and *CHEK2:p.R406H* (P = 0.0002) can be used to evaluate the therapeutic efficacy of patients. Remarkably, *MRE11A:p.K464R* may be a vital driving factor of Olaparib resistance and all patients who acquired new *MRE11A:p.K464R* in post-treatment cfDNA developed resistance to Olaparib and had significantly shorter PFS than those without it (P = 0.0005). Besides, the combination of *CHEK2:p.R406H* and acquired new *MRE11A:p.K464R* in post-treatment improved the predictive efficiency of patients' prognosis compared with them alone (P < 0.0001). **Conclusions:** Olaparib resistance was robustly associated with the mutation load of tumor cells, and analysis of mutation profiles in cfDNA can be accurately monitor the status of Olaparib resistance in patients with HGSOC. Acquired new *MRE11A:p.K464R* may be a vital driver of Olaparib resistance and is expected to be a target for anti-tumor drug development. Research Sponsor: the Nature and Science Foundation of China, Other Government Agency.

A multicenter phase II randomized trial of durvalumab (D) versus physician's choice chemotherapy (PCC) in patients (pts) with recurrent ovarian clear cell adenocarcinoma (MOCCA/APGOT-OV2/GCGS-OV3). *First Author: David Shao Peng Tan, National University Cancer Institute, Singapore and Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore*

Background: The optimal treatment of recurrent ovarian clear cell carcinoma (rOCCC) remains unknown. Prior data suggests rOCCC is a chemo-resistant disease that may respond to programmed cell death protein 1 (PD-1)/programmed death-ligand 1 (PD-L1) immune checkpoint inhibition (ICI). We aimed to determine the efficacy of D versus PCC in pts with rOCCC. **Methods:** In this multicentre, open-label, randomised phase 2 trial, 9 academic centres across Singapore, South Korea and Australia, enrolled rOCCC (determined histologically) and Eastern Cooperative Oncology Group performance status (PS) 0-2 pts, who had recurred after prior platinum-based chemotherapy and had not received more than 4 prior lines of systemic therapy, nor prior ICI therapy. Eligible pts were randomly assigned (2:1), using dynamic block randomization with block size of 6, and stratification by ECOG PS, to receive D (1500mg on day 1, in 28-day cycles) or PCC until disease progression (PD), intolerable toxicity or withdrawal of consent. Pts with PD on PCC were allowed to crossover to D. The primary endpoint was investigator-assessed progression-free survival (PFS) by RECIST version 1.1 and analyses included pts who had commenced at least 1 cycle of study treatment. **Results:** Between 7 Nov 2017 and 17 Feb 2020, 57 pts were assessed for eligibility, of whom 47 (PS 0-1) were randomly assigned to treatment with D (31 pts) or PCC (16 pts). At the data cut-off date (10 Jan 2022), the median follow-up was 83.0 weeks (IQR: 54.1—97.0) in the PCC group and 107.0 weeks (IQR: 82.7—116.4) in the D group. Median PFS was 7.4 weeks (IQR: 6.0—16.0) in the D group and 14.0 (IQR: 7.0—28.6) in the PCC group (HR 1.5 [95% CI 0.8-2.8], log-rank p = 0.89). The objective response rate (ORR) was 10.7% in pts randomised to D and 18.8% in the PCC group (p = 0.884). Clinical benefit rate (CR/PR/SD for ≥16weeks) was similar for PCC (37.5%) and D (32.1%) (p = 0.756). 9 pts on PCC crossed over to receive D, with 2 of the 8 evaluable pts achieving partial response (PR). When crossover D pts were included, ORR to D was 13.9% (5/36) with a clinical benefit rate of 30.6% (11/36). Median duration of response was 44 weeks for the 3 PCC responders (PR to gemcitabine 24.9wks, PR to liposomal doxorubicin 65.7wks, CR to carboplatin/liposomal doxorubicin 44wks), and 18 weeks (range 2.1-45.3) for the 5 responders to D . Frequency of adverse events (AEs) across all grades was 68.8% for PCC and 38.7% for D. Grade 3/4 AEs were observed in 37.5% of PCC pts and 9.7% of D pts. **Conclusions:** No significant differences in PFS, ORR or clinical benefit rate were observed between D and PCC treatment in rOCCC. Treatment with D was associated with less grade 3-4 adverse events. Correlative translational analyses to elucidate predictive biomarkers of response and resistance are ongoing. Clinical trial information: NCT03405454. Research Sponsor: Astra Zeneca, Other Foundation, National Medical Research Council Singapore.

Breast cancer incidence in patients with *BRCA*-related advanced ovarian cancer receiving olaparib-based maintenance therapy: A pooled analysis from phase III clinical trials. *First Author: Michele Bartoletti, Unit of Medical Oncology and Cancer Prevention, Department of Medical Oncology, Centro di Riferimento Oncologico di Aviano (CRO), IRCCS, Aviano, Italy*

Background: As the prognosis of *BRCA*-related advanced ovarian cancer (AOC) continues to improve thanks to the introduction of targeted therapies like poly ADP-ribose polymerase inhibitors (PARPi) and bevacizumab, the occurrence of second primary tumors, in particular breast cancer (BC), is assumed to be more common. Despite this, data on the incidence of BC in this population are poor and guidelines for BC screening or risk reducing strategies are lacking. **Methods:** Published data from recent PARPi-based, phase III clinical trials involving germline *BRCA* mutated AOC were reviewed and analyzed. Only studies in which the incidence of at least one second primary solid tumor was reported were included. Cases of second primary BC cancers were pooled to calculate cumulative incidence according to the median follow-up period for each trial. 95% confidence interval (CI) was considered. **Results:** Four trials (SOLO1, PAOLA1, SOLO2 and SOLO3) involving 1186 germline *BRCA* 1-2 mutated AOC patients were included (*BRCA1*, n = 816; *BRCA2*, n = 360; *BRCA1* + *BRCA2*, n = 4; missing, n = 6). In all trials, patients were randomized to receive olaparib +/- bevacizumab (n = 788) versus placebo or standard therapies (n = 398). Median age at diagnosis of AOC was 56 years (range, 29-87). With a follow-up ranging from 3.9 months to 5 years, 16 new cases of BC were recorded, 10 in PARPi-based arms and 6 in control arms. Only two patients had a previous history of BC. The total cumulative incidence of BC was 1.37% (95% CI, 0.77-2.18), while cumulative incidences were 1.26% (95% CI, 0.61-2.31) and 1.51% (95% CI, 0.55-3.25) in PARPi-based arms and control arms, respectively. In a sensitivity analysis excluding the SOLO3 trial with the shortest follow-up, the total cumulative incidence was 1.63% (95% CI, 0.92-2.67). Other 20 cases of second primary solid tumors were registered, including 4 cases of non-small cell lung cancer. **Conclusions:** Patients with germline *BRCA*-related AOC receiving PARPi-based maintenance therapy can be reassured about the risk of second primary BC and intensive screening should be avoided at least in early treatment phase. More data with long term follow-up are needed. Research Sponsor: None.

A phase Ib study of IN10018 in combination with pegylated liposomal doxorubicin (PLD) in patients with platinum-resistant ovarian cancer. *First Author: Lingying Wu, Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China*

Background: IN10018 is a highly potent and selective oral inhibitor of focal adhesion kinase (FAK). IN10018 is synergistic with PLD against ovarian cancer in PDX models. This study evaluated the safety, tolerability, and antitumor activities of IN10018 in combination with PLD in patients with platinum-resistant ovarian cancer (PROC). **Methods:** This is an open-label phase Ib trial in patients with PROC (high-grade serous carcinoma only). Patient were treated with IN10018 in combination with PLD. This study has a dose-confirmation part and a dose-expansion part. Dose-expansion part was conducted at RP2D dose level to evaluate the primary endpoint of objective response rate (ORR). Secondary endpoints included disease control rate (DCR, CR + PR + SD ≥ 6 weeks), duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety. **Results:** As of December 31, 2021 (cutoff date for all assessments), a total of 42 PROC patients were enrolled. 92.9% (39/42) patients had 1-3 prior lines of therapy and 14.3% (6/42) had prior bevacizumab use. The RP2D of the combination was determined as IN10018 100 mg QD in combination with PLD 40 mg/m^2 Q4W in the dose-confirmation part since no DLTs were observed in 6 patients treated. The safety profile of the combination is comparable to these single agents alone without additive toxicities. No IN10018 related death was observed, and 9.5% (4/42) patients reported IN10018 related SAEs which were also PLD related. The most frequently reported IN10018 related AEs were proteinuria, decreased appetite, fatigue and AEs of gastrointestinal origin such as nausea, diarrhea, vomiting. Majority of these IN10018 related AEs were CTCAE grade 1 and 2, and 14.3% (6/42) had grade 3 AEs. No IN10018 related grade 4 or 5 AEs were reported. Proteinuria was noted asymptomatic, reversible, could be managed with appropriate dose interruption/reduction and only one proteinuria event resulted in IN10018 dose reduction. Antitumor response (as assessed by investigator) was evaluable in 30 patients. 17 patients had best overall response of PR including 13 confirmed PRs and 4 unconfirmed (2 in follow-up to be confirmed). No patient had CR and 9 patients had SD. The ORR is 56.7% (95% CI: 37.4%, 74.5%), the DCR is 86.7% (95% CI: 69.3%, 96.2%), and the median DOR was 4.5 months (95% CI: 2.7 months – NA) and is continuing to mature. Among the 20 efficacy evaluable patients who had at least 6 months of follow up, the ORR is 65.0% (13/20, 95% CI: 40.8%, 84.6%) and the DCR is 90.0% (18/20, 95% CI: 68.3%, 98.8%). In all 42 enrolled patients, the observed median PFS is 6.2 months (95% CI: 6.2 months - NA) and maturing. **Conclusions:** The combination of IN10018 with PLD showed promising antitumor activities and manageable safety profile in PROC patients. This combination warrants further confirmation in a randomized controlled trial. Research Sponsor: InxMed (Shanghai) Co., Ltd.

Cisplatin-induced nephrotoxicity in hyperthermic intraperitoneal chemotherapy (HIPEC) is mitigated by sodium thiosulfate: Clinical and toxicotranscriptomic results of a prospective trial. *First Author: Nicole Lugo Santiago, City of Hope National Medical Cente, Chicago, CA*

Background: Hyperthermic intraperitoneal chemotherapy (HIPEC) with cisplatin confers a survival benefit in epithelial ovarian cancer (EOC). Unfortunately, cisplatin is associated with significant renal toxicities. Sodium thiosulfate (ST) has been suggested as a nephroprotectant for patients undergoing HIPEC with cisplatin. **Methods:** A feasibility trial (*ClinicalTrials.gov: NCT01970722*) evaluated safety outcomes of HIPEC with cisplatin 75 mg/m^2 during optimal cytoreductive surgery (CRS) in patients with EOC and endometrial cancer (n = 40), with or without ST. Twenty-one patients received no sodium-thiosulfate (nST group), and nineteen patients received sodium thiosulfate (ST group). Toxicities were reported according to CTCAE v. 5. Progression-free survival was followed. Normal tissue biopsies were collected intra-operatively immediately following HIPEC and cisplatin exposure in a subset of patients (n = 21), and profiled with transcriptomic sequencing to identify RNAseq signatures correlating with toxicities. Hierarchical cluster analyses identified distinct transcriptomic signatures in post-HIPEC normal samples of patients with renal AEs (rAEs) compared to no renal AEs (nrAEs). KEGG pathway analysis identified up- or downregulated gene sets using GSEA. **Results:** Forty patients had HIPEC at time of optimal CRS. Renal toxicities were higher in the nST group (no sodium thiosulfate) compared to the ST group. nST patients had 17% any grade, and 9% Grade 3 AEs for acute and chronic kidney injuries. In contrast, ST patients suffered 0% renal AEs. rAE patients demonstrated upregulation of immune signaling pathways (Toll-like receptor, Natural killer cell, Nod-like receptor); and downregulation of metabolic pathways. Top upregulated genes in rAE patients included immune (e.g. neutrophil) related genes, while downregulated genes included metabolism genes. Kaplan-Meier curves demonstrated improved PFS in primary ovarian cancer patients undergoing HIPEC who were treated with ST vs no ST (p = 0.04, NR vs 13.4 mo). **Conclusions:** HIPEC with cisplatin results in significant renal toxicities. The mechanisms of cisplatin-induced nephrotoxicity in HIPEC are immune-related and reflect reduced metabolism. Sodium thiosulfate abrogated renal toxicities and did not decrease PFS. Clinical trial information: NCT01970722. Research Sponsor: U.S. National Institutes of Health.

Efficacy of maintenance olaparib plus bevacizumab in patients with newly diagnosed advanced ovarian cancer according to BRCA mutation genotype in the phase III PAOLA-1/ENGOT-ov25 trial.

First Author: Sana Intidhar Labidi-Galy, Department of Oncology, Hôpitaux Universitaires de Genève, Genève, Switzerland

Background: In the Phase III PAOLA-1/ENGOT-ov25 trial, the addition of maintenance olaparib (ola) to bevacizumab (bev) in patients (pts) with newly diagnosed advanced high-grade ovarian cancer (HGOC) resulted in prolonged progression-free survival (PFS), particularly for pts with HRD-positive tumors including a *BRCA1/BRCA2* mutation (BRCAm; Ray-Coquard *et al. NEJM* 2019). Preclinical data suggest that pts with mutations (mut) in the RING domain of *BRCA1* are less sensitive to ola. The magnitude of benefit from ola + bev, according to the location of mut in the functional domains (FD) of BRCA, remains to be explored. **Methods:** Pts with newly diagnosed advanced HGOC in response after platinum-based chemotherapy + bev received maintenance bev (15 mg/kg q3w for 15 months [mo]) + either ola (300 mg bid for 24 mo) or placebo (pbo). In this *post hoc* exploratory analysis, PFS was analyzed in pts with BRCAm according to mut location in the FDs of *BRCA1* (RING, DNA-binding domain [DNA-BD], or *BRCA1* C terminus [BRCT]) and *BRCA2* (RAD51-BD; DNA-BD). **Results:** Among the 806 randomized pts, 235 (29.2%) harbored a BRCAm: 160 (19.9%) with a *BRCA1* mut and 76 (9.4%) with a *BRCA2* mut. *BRCA1* mut in FDs of RING, DNA-BD and BRCT were detected in 19 (11.8%), 41 (25.6%) and 34 (21.2%) pts, respectively. *BRCA2* mut were detected in FDs of RAD51-BD and DNA-BD in 37 (48.7%) and 14 (18.4%) pts, respectively. With a median follow-up of 25.5 mo, 24-mo PFS rates and hazard ratios (HRs) according to mut locations are reported in the Table. In pts with a *BRCA1* DNA-BD mut, 24-mo PFS was 89% and 14% (ola + bev vs pbo + bev; HR 0.08, 95% confidence interval [CI] 0.02–0.26) compared with 64% and 24% for pts with mut in RING + BRCT + other domains (HR 0.33, 95% CI 0.19–0.57). In pts with *BRCA2* mut, 24-mo PFS for pts with mut in the DNA-BD was 91% vs 100% (ola + bev vs pbo + bev) compared with 82% and 44% for pts with mut in RAD51-BD + other domains (HR 0.21, 95% CI 0.08–0.54). **Conclusions:** In this exploratory analysis, pts with newly diagnosed advanced HGOC and a BRCAm had a PFS benefit from maintenance ola + bev regardless of mut locations in *BRCA1/BRCA2*. Sensitivity to ola + bev maintenance was particularly high for pts with mut in the DNA-BD of *BRCA1*. Pts with a mut in the DNA-BD of *BRCA2* commonly had excellent outcomes. Clinical trial information: NCT02477644. Research Sponsor: ARCAGY Research, Pharmaceutical/Biotech Company.

Potential clinical activity of pembrolizumab monotherapy in ovarian sex cords, rare epithelial carcinoma, and other rare ovarian tumor histotypes: The French AcSé pembrolizumab study from Unicancer.

First Author: Isabelle Laure Ray-Coquard, Centre Léon Bérard, University Claude Bernard, Lyon, France

Background: AcSé Pembrolizumab is a Phase 2, non-randomized parallel arms, multicentric basket trial investigating the efficacy and safety of pembrolizumab monotherapy in different cohorts of patients with rare cancers (NCT03012620). Here we report the results in the rare ovarian tumors cohort. **Methods:** Selected histotypes were all rare ovarian cancers (incidence < 6/100,000/year). Main inclusion criteria were age > 18, ECOG PS≤1, resistant disease to platinum based chemotherapy, and systematic histological central review by expert pathologist from TMRG network. Patients (pts) received pembrolizumab 200 mg IV on Day 1 of every 21-day cycle for a maximum of 2 years. The primary endpoint was the confirmed objective response rate according to RECIST v1.1 at 12 weeks. Secondary endpoints included best response rate, duration of response, progression-free survival (PFS), overall survival (OS), and safety. The 7 subgroups of pts analyzed were carcinosarcoma (CS), clear cell carcinoma (CCC), low grade serous carcinoma (LGSC), mucinous carcinoma (MEOC), sex cord tumors (SCT), germ cell tumor (GCT), and smarcA4 deficient hypercalcemic ovarian tumor (SCHOCCT). **Results:** 62 pts from 22 centers, were included from 08/2017 to 12/2020. Median Age was 53.5 years old [36-64]. Median number of previous lines of chemotherapy was 2 (range 1-4). The median number of cycles was 8 (range, 1-35) with 44 pts (70.9%) who discontinued the trial after a mean number of 6.8 cycles. There were 2 pts (3.2%) with partial response (PR) at 12 weeks. The best response in ITT was complete response (CR) in 1 patient (1%), PR in 3 (14.3%), and stable disease (SD) in 21 (33.8%). The occurrence of best response depended on the histotype with 1 CR (33%) in GCT (cancerized teratoma), 2 PR (20%) in CCC, and 1 PR (4%) in LGSC. 4/4 pts (100%) reported PD as best response in SCOOHT (Table 1). Median duration of response or stabilized disease was 7.8 months [IQR, 4.1 to 9.0]. At the data cut off, 6-month PFS was 29% [19.7-42.8] and 6-month OS was 77.8% [67.7-89.3] on the overall population. Outcomes differed according to subgroups and will be presented. There were a total of 62 adverse events (AEs) reported in 28 pts. For 5 pts (8%) AEs lead to drug discontinuation. AEs were of grade 1 (n = 9), grade 2 (n = 8), or grade ≥ 3 (n = 45: 42 grade 3, 2 grade 4, and 1 grade 5). **Conclusions:** Pembrolizumab is safe and well tolerate in this population of rare ovarian cancer pts. AcSé study reports prolonged responses in very selected subtypes of rare ovarian tumor (CCC, cancerized teratoma, and LGCS). MOONSTONE/GOG-3032: Interim analysis of a phase 2 study of niraparib + dostarlimab in patients (pts) with platinum-resistant ovarian cancer (PROC).

First Author: Leslie M. Randall, Massey Cancer Center, Richmond, VA

Background: PROC is poorly responsive to anticancer therapy. PARP inhibitors such as niraparib may increase neoantigen load and synergize with anti-PD-1 agents. TOPACIO reported a preliminary objective response rate (ORR: 18%) and disease control rate (DCR: 65%) to niraparib + pembrolizumab in pts with OC of any *BRCA* status. MOONSTONE sought to determine efficacy in pts without *BRCA* mutation (*BRCA*m). **Methods:** In this phase 2 open-label, single-arm study, eligible pts received 1–3 prior lines of therapy including platinum, taxane, and bevacizumab, had RECIST v1.1 radiographic progression within 6 mo of last platinum line and had no known germline *BRCA*m. Pts were treated with niraparib 300/200 mg PO daily (based on weight/platelets) and 500 mg dostarlimab IV Q3W (cycles 1–4) followed by 1000 mg Q6W until disease progression, toxicity or consent withdrawal. Programmed death-ligand 1 (PD-L1) positive status was determined by Ventana SP263 assay using visually-estimated combined positive score ≥5%. The primary endpoint was investigator-assessed ORR per RECIST v1.1. Secondary endpoints included duration of response (DOR), progression-free survival (PFS), DCR, and safety. Futility was prespecified as ≤5 responses in the first 40 pts. **Results:** At interim analysis (data cutoff Oct 6, 2021), 41 pts were enrolled; median age was 65.0 y (range 35–77). At baseline, 8 (20%)/22 (54%)/11 (27%) pts had received 1/2/3 prior lines of therapy, respectively; 26 (63%) pts had primary resistance to platinum therapy and 15 (37%) were sensitive to first platinum treatment. Overall, tumors were PD-L1+/PD-L1–/unknown in 13 (32%)/25 (61%)/3 (7%), respectively. Efficacy results are shown in the Table. Treatment-related adverse events were reported in 95% of pts, most commonly nausea (56%), fatigue (34%), vomiting (32%), and anemia (29%). **Conclusions:** PROC remains difficult to treat; the ORR observed with niraparib + dostarlimab did not reach the threshold for 2nd-stage accrual in this cohort of pts with PROC, no known *BRCA*m, and prior bevacizumab treatment. PD-L1 status did not predict response; HRD testing is in process. Although DCR was 29%, futility was declared based on low ORR. The safety of the combination was similar to the safety profile of each monotherapy. Clinical trial information: NCT03955471. Research Sponsor: GlaxoSmithKline.

Integrated safety summary of single-agent mirvetuximab soravtansine in patients with folate receptor α (FRα)-positive recurrent ovarian cancer: Phase 1 and 3 clinical trials.

First Author: Kathleen N. Moore, Division of Obstetrics and Gynecology, Department of Gynecologic Oncology, University of Oklahoma Health Science Center, Stephenson Cancer Center, Oklahoma City, OK

Background: Available chemotherapies for platinum-resistant ovarian cancer (PROC) have limited clinical activity and considerable toxicity. Mirvetuximab soravtansine (MIRV) is a first-in-class antibody drug conjugate (ADC) comprising a folate receptor alpha (FRα)-binding antibody, cleavable linker, and the maytansinoid payload DM4, a potent tubulin-targeting agent that has demonstrated significant anti-tumor activity in this difficult to treat population. The objective is to characterize the tolerability profile of MIRV in a pooled analysis of experience when administered as monotherapy in patients (pts) with FRα positive recurrent ovarian cancer. **Methods:** Retrospective pooled analysis included pts enrolled across three studies: phase 1 first-in-human, phase 3 FORWARD I, and phase 3 SORAYA. Analysis included pts with FRα positive recurrent ovarian cancer and those pts with low, medium, and high FRα expression by immunohistochemistry (Roche FOLR1 Assay ≥ 25% of cells with PS2+ staining intensity). All pts received intravenous MIRV at 6 mg/kg, adjusted ideal body weight, on Day 1 of a 21-day cycle until disease progression or unacceptable toxicity. **Results:** 464 pts were included from 15 countries, with key characteristics: median age 63 yrs, 87% 1-3 prior therapies, 91% platinum free interval ≤6 months, 65% prior bevacizumab, and 25% prior PARPi. The most common treatment-related adverse events (TRAE) (all grade, grade 3+) included blurred vision (42%, 3%), nausea (40%, 2%), diarrhea (33%, 2%), fatigue (31%, 2%), keratopathy (26%, 3%), and dry eye (22%, 1%). TRAEs leading to a dose delay or reduction occurred in 33% and 21% of pts, respectively. Seven % discontinued due to a TRAE. Four pts (< 1%) discontinued MIRV due to an ocular event. Ninety % of pts with a grade 2+ blurred vision resolved to grade 0 or 1, 93% of pts with grade 2+ keratopathy resolved to grade 0 or 1. No corneal ulcers or perforation have been reported and no patient with a serious ocular event has been reported to have permanent sequelae. **Conclusions:** In a pooled analysis of 464 patients, MIRV monotherapy has a differentiated and predictable safety profile consisting primarily of low grade and reversible gastrointestinal and ocular events. These events were managed with supportive care and dose modifications if needed, with a low rate of treatment-related discontinuation. The safety profile of MIRV in recurrent ovarian cancer along with the anti-tumor activity in PROC (32.4% ORR Matulonis SGO 2022) support a favorable benefit/risk in this population. Clinical trial information: NCT01609556, NCT04296890, NCT02631876. Research Sponsor: ImmunoGen.

PemBOv trial: Pembrolizumab plus bevacizumab with or without pegylated liposomal doxorubicin-based chemotherapy in patients with platinum-resistant ovarian cancer.

First Author: Judith Michels, Gustave Roussy Comprehensive Cancer Center, Villejuif, France

Background: Few platinum resistant ovarian cancer (PROvC) patients respond to anti-PD1 monotherapy (ORR 7.6%) with little impact on survival (OS 10.1 mo). Among responders the median duration of response is impressive (18.7 mo) (Hamanishi 2021). **Methods:** We have evaluated the combination of pembrolizumab (200mg), with bevacizumab (400mg) for 6 cycles plus minus peglyated liposomal doxorubicin (PLD) q3w in PROvC patients with no limit in previous treatment lines, allowed to be previously treated with bevacizumab. An initial safety run evaluated the dual combination of pembrolizumab plus PLD (cohort A). The triple combination was evaluated at MTD-1 and at MTD of PLD (30mg/m^2 q3w) (cohort C). The dual combination of pembrolizumab + bevacizumab was run in parallel (cohort B). This is an open label phase I trial with a modified toxicity probability interval design. The evaluation criteria endpoints were safety and efficacy. Pharmacokinetics of bevacizumab were evaluated. NCT03596281 **Results:** A total of 47 patients (pts) were enrolled between January 2019 and February 2021. Median age was 70 years (38-77). 30/12 pts (63.8/25.5%) had an initial FIGO stage III/IV, 44 pts (93.6%) had a HGSOC. 40 pts (85.1%) underwent surgery, out of which 13 pts (32.5%) had a primary debulking. BRCA mutations were present in 9 pts (19.1%). Pts had a median of 3 previous treatment lines (0-13), including pretreatment with antiangiogenic agents in 36 (76.6%) and PARP inhibitors in 21 pts (44.7%). No DLT was reported. Grade 3/4 treatment-related adverse events were reported in 2 pts (30%), 4 (20%) and 11 (50%) in cohorts A, B and C respectively. The ORR was 0, 26.3 (95% CI 6.5-46.1) and 30% (9.9-50.1) with a DCR of 0, 78.9 and 75% in cohorts A, B and C respectively. According to investigator assessment, the median PFS was 2.1, 4.7 and 4.8 mo (table). The blinded independent central review is currently under evaluation. A large inter-patient variability in bevacizumab plasma concentrations was observed among patients. The 400 mg flat dosing achieved residual concentrations similar to that of 5 mg/kg Q2W or 7.5 mg/kg q3w (51± 30 μg/ml in cohort B and 63 ± 55 μg/ml in cohort C (p>0.05) after C1). Overall, 22 % of pts of cohort B and 18 % of cohort C showed trough levels below the targeted threshold (i.e. < 25 μg/ml). Correlative studies are ongoing. **Conclusions:** Short-term flat dose bevacizumab potentiates the response to anti-PD1 therapy even in the absence of chemotherapy in heavily pre-treated PROvC patients. The long-term treatment with bevacizumab could potentially improve the outcome. The combination of anti-PD-1 plus anti-angiogenic agents should be a backbone for the treatment of PROvC patients. Clinical trial information: NCT03596281. Research Sponsor: MSD, Other Foundation.

Landscape of homologous recombination reversion mutations in gynecologic malignancies.

First Author: Susan M. Domchek, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Background: Homologous recombination (HR) reversion mutations (REV) are biomarkers for predicting resistance to platinum and PARP inhibitor therapies. The biologic diversity of REV represents a diagnostic challenge. An automated computational approach was used to detect REV for analysis of genomic features of REV-positive ovarian epithelial, fallopian tube, and peritoneal cancers. **Methods:** Retrospective study of tissue (n = 23,612) and liquid biopsy (n = 869) samples from patients undergoing hybrid-capture comprehensive genomic profiling during routine clinical care 11/2012-03/2021. A proprietary algorithm tested for seven distinct REV mechanisms in *BRCA1*, *BRCA2*, *PALB2*, *RAD51C*, or *RAD51D*. For subjects with multiple samples, the earliest REV-positive sample was used for downstream analyses. **Results:** Among 23,866 ovarian epithelial, fallopian tube, and peritoneal cancers, 16.4% (n = 3,920) had at least one pathogenic variant (PV) in *BRCA1* (10%, n = 2,383), *BRCA2* (5.5%, n = 1,320), *PALB2* (0.67%, n = 160), *RAD51C* (0.64%, n = 152), or *RAD51D* (0.47%, n = 113). 3.9% (154/3,920) of patients with one or more PV had REV. REV were found in tumors with PV in *BRCA2* at twice the frequency of *BRCA1* (6.0%, [79/1,320] vs 3.0% [71/2,383]; p < 0.001). REV involving *RAD51D* (1.8%, 2/113), *RAD51C* (0.7%, 1/152), or *PALB2* (0.6%, 1/160) were rarer. A total of 193 REV pairs were identified. The most frequent REV mechanism was an exonic non-frameshift deletion completely encompassing a PV (45%, 87/193). Other recurrent mechanisms included restoration of the reading frame of a frameshift PV (21%, 42/193), replacement of a PV with a benign missense substitution at the same codon (16%, 32/193), and deletion with intronic breakpoints encompassing a PV (15%, 29/193). REV were significantly more prevalent in liquid biopsies than in tissue samples with PV (16% [20/124] vs. 3.5% [134/3,796]; p < 0.001). A range of 1-6 REV pairs were found per sample (liquid: 1-6, tissue: 1-3). Multiple REV per sample was more common in liquid biopsies (35% [7/20] vs. 11% [15/134]; p = 0.011). These differences likely reflect stage of disease and sampling of multiple subclones. **Conclusions:** *BRCA2* PV are most frequently reverted in gynecologic tumors. REV are also common in tumors with BRCA1 PV and can more rarely occur in other HR genes. Liquid biopsy is enriched for detection of polyclonal resistance. Diverse REV mechanisms highlight a need for robust detection to incorporate REV in identifying treatment resistance and guiding downstream therapy selection. Research Sponsor: Foundation Medicine.

CeNtuRIOn: Rucaparib (R) with nivolumab (N) and ipilimumab (I) in patients (pts) with relapsed ovarian cancer (ROC)—Results of an initial safety cohort.

First Author: Marcia Hall, Mount Vernon Cancer Centre, Northwood, United Kingdom

Background: There is an urgent need to improve outcomes for ROC pts; progression free (PFS)/overall survival (OS) are 4-9 months (mo), 12-20mo respectively. ~50% ROC pts harbour homologous repair deficiencies (HRD), identified by *BRCA* mutations (m) & Loss of Heterozygosity (LoH). R, a PARP inhibitor (PARPi) has demonstrated efficacy when used as maintenance after chemotherapy (CT), and is superior to CT if used as treatment for ROC *BRCA*m pts. However repeating PARPi, even in highly selected *BRCA*m/HRD pts has limited benefit (1.5-2.5mo extra PFS). Single agent immunotherapy (PD-1/PD-L1/CTLA4 antibodies (Ab)) in ROC pts has been disappointing. Response rate to combined PD-1/CTLA4 Ab in ROC pts is 31.3%. *In vitro* evidence suggests that combinations of PD-1/CTLA4 Ab /PARPi may be more effective. CeNtuRIOn aims to explore the activity/toxicity of repeat PARPi (R) versus R+I (CTLA4 Ab) versus R+I+N (PD-1 Ab). Here we report safety data from the run-in cohort of 15 ROC pts treated with the triplet combination, RNI. **Methods:** Eligible pts had received ≥1 and <3 lines CT, were > 3 to <12 months from last platinum CT. Only 1 pt could experience a dose limiting toxicity (DLT) over initial 6 weeks of treatment. Pts received N 240mg q14 days, I 1mg/kg q42 days intravenously for up to 12mo and R orally, 600mg bd continuously. All bar 1 of 7 pts (recruited 06/19–12/19) received N+I to meet DLT evaluability, but 5 of remaining 6 received < 43% R during safety period. 6 further pts were recruited (08/20-06/21), with ≥60% starting dose R in first 6 weeks now required for evaluability. Review of toxicity/tolerability prompted reduction of R starting dose to 400mg bd and ipilimumab limited to 4 cycles for the last 4 pts. **Results:** Of all 15 recruits, median age was 64. Adverse events (AE)s are detailed in Table. 7 pts were evaluable for safety assessment: n = 4 started on 600mg bd and n = 3 on 400mg bd R. Median R dose intensity in these 7 was 82.5%. There was 1 DLT: G3 nephritis on day 18. 1 pt died of E. Coli sepsis related to colitis. Outcome data will be presented. **Conclusions:**R (400mg bd)+N+I (4 cycles only) will be taken forward to phase II. Pts will be randomised 1:1:2 to single agent R, R+I or RNI. Pts recruited to R alone are eligible for 2nd randomisation (1:1) to add I or N+I at progression. Clinical trial information: ISRCTN10490346. Mutational landscape of low-grade serous carcinoma of the ovary.

First Author: Julian C. Schink, Cancer Treatment Centers of America, Part of City of Hope, Zion, IL

Background: Tumor genomic profiling is a critical component of precision oncology allowing the detection of genomic alterations (GA) that are potential therapeutic targets. We present an analysis of comprehensive genomic profiling (CGP) of a large series of low grade serous ovarian carcinoma patients assayed in a nationwide cancer network. **Methods:** 40 Pts with advanced low grade serous ovarian carcinoma (LGSOC) underwent hybrid-capture based CGP for up to 324 cancer-related genes on archival tumor tissue or 62 genes on circulating tumor DNA ordered during clinical care for treatment decision-making between 01-2013 thru 06-2021. Clinically relevant genomic alterations (CRGA) were defined as associated with targeted therapies or mechanism-driven clinical trials. The treatment histories for these patients were obtained with IRB-approved retrospective review. **Results:** Median age was 44 years (range, 25-65), 68% were White and 23% were Black. Genomic alterations (GA) were identified in 80% (32/40) of LGSOC, of which 22 (55%) had a clinically relevant genomic alteration (CRGA). There were no apparent racial differences between mutation frequencies. The table below details the frequency of the most common of these clinically relevant mutations. Additionally, 1 patient had an ESR1 activating mutation commonly seen in acquired hormone therapy resistance in breast cancer; and single cases of the following mutations were also noted: *TSC1, PTCH1, PTEN, FGFR1,* and *AKT2.* **Conclusions:** In a large series of Low Grade Serous Ovarian Cancer patients assayed with CGP, 55% of pts had mutations potentially targeted by precision medicine therapy. The most common target is *KRAS*, seen in 33% of patients, these are potentially treatable with FAK and MEK inhibitors. Another 10% of patients had either a *BRCA* or *ATM* mutations making PARP inhibitor therapy an additional targeted treatment option. While mutations in the *RAS* pathway are most common in LGSOC they are not the only actionable target. Furthermore, this approach might also help identify baseline or acquired resistance to the hormone therapies often used to treat this cancer. The results of this study demonstrate the significant heterogeneity of genomic alterations in this rare cancer and highlight the importance of genomic profiling in this cancer which has a marked propensity for recurrence. Research Sponsor: None.

Pharmacokinetic and pharmacodynamic analysis of adavosertib in advanced ovarian cancer. *First Author: Amit M. Oza, Princess Margaret Cancer Centre, University of Toronto, Toronto, ON, Canada*

Background: Adavosertib (AZD-1775) is a potent small molecule inhibitor of Wee-1, currently in clinical development. In a double-blind, placebo-controlled, phase 2 trial (NCT02151292), adavosertib and gemcitabine significantly prolonged progression-free survival (PFS) and overall survival (OS) in patients with recurrent platinum-resistant or platinum-refractory high grade serous ovarian cancer (HGSOV) compared to gemcitabine alone. We investigated whether plasma and intra-tumoral adavosertib concentrations correlated with survival in these patients. **Methods:** Adavosertib was administered orally on Days 1, 2, 8, 9, 15 and 16 at 175 mg per day, and gemcitabine was administered on Days 1, 8 and 15 at 1000 mg/m^2 every 28 days. Serial blood samples were collected on Day 1 of cycle 1 after adavosertib administration. Tumor biopsies were taken 1-2 weeks after initiation of study treatments. Plasma and tumor adavosertib concentrations were determined using validated HPLC-MS/MS. Patients were divided into groups with plasma or tumor adavosertib concentrations above or below the biologically active concentration (BAC) of 125 ng/ml (Leijen et al, J Clin Onco 2016). Survival was described using the Kaplan-Meier method. **Results:** Among 61 HGSOV patients who received adavosertib, plasma samples were available in 47, and tumor samples were available in 31 patients. Among 25 non-HGSOV patients (exploratory cohort), plasma and tumor samples were available in 21 and 17 patients respectively. The mean maximum adavosertib concentration (Cmax) was 355.3 ± 120.9 ng/ml and 358.6 ± 117.9 ng/ml respectively. Cmax was above BAC in all patients. The mean tumor adavosertib concentration was 609.2 ± 1129.2 ng/ml (range: 0.47 – 5501 ng/ml) for HGSOV patients, and 964.2 ± 1611.2 ng/ml (range: 0.22 – 6116 ng/ml) for non-HGSOV patients. There was no correlation between Cmax and tumor adavosertib concentrations. In HGSOV, the median PFS was 5.8 months for patients with tumor concentrations above BAC, and 3.5 months for those with tumor concentrations below BAC (Hazard ratio (HR): 0.46, 95% confidence interval: 0.19 – 1.14, p = 0.06). No difference in PFS was seen in non-HGSOV patients according to tumor adavosertib concentration. Tumor adavosertib concentration did not correlate with OS. **Conclusions:** Although Cmax was above BAC in all patients, there was a high variability in tumor adavosertib concentrations. In HGSOV, higher tumor adavosertib concentration was associated with a trend towards improved PFS, but not OS. Our results indicate that the current adavosertib dosing regimen may not produce the desired concentrations in tumors for some patients, and further optimization may be needed. Exploring the nuances between BRCA1 and 2: A multiomic analysis. *First Author: Radhika Gogoi, Wayne State University, Detroit, MI*

Background: Emerging data suggests that key differences exist between BRCA1 and BRCA2 associated OC, including response to therapy and survival. The purpose of this study was to identify the gene expression profiles, interacting pathways and immune microenvironment of BRCA1 mutant (BRCA1mut), BRCA2 mutant (BRCA2mut) and homologous recombination wild-type (HRwt) associated high grade serous OC (HGSOC). **Methods:** Next-generation sequencing (592, NextSeq; WES, NovaSeq) and Whole Transcriptome Sequencing (NovaSeq) (Caris Life Sciences, Phoenix, AZ) were performed in 8196 OC tumors classified into 3 groups: BRCA1mt; BRCA2mt; and HRwt. BRCA mutations were defined as variants that result in loss-of-function of the BRCA protein and HRwt was defined as samples negative for aberrations in both BRCA1 and BRCA2, as well as for 28 other homologous recombination genes Microsatellite instability (MSI) was tested by fragment analysis, IHC and NGS. Tumor mutational burden (TMB) was measured by totaling somatic mutations (TMB-H: >10 mutations/MB). LOH cut-off >16%. Immune cell infiltrates were calculated by XCell. Differential gene expression was calculated using Limma. Significance was determined using chi-square and Wilcoxon rank sum test and adjusted for multiple comparisons (q-value < 0.05). **Results:** We identified 677 BRCA1mt, 439 BRCA2mt, and 7080 HRwt OC tumors. HGSOC made up the largest portion of BRCA1mt (523; 77%), BRCA2mt (306; 70%), and HRwt (4281; 60%) tumors. TP53 was most commonly mutated gene in all three groups. LOH (>16%) was highest in BRCA1mt (86.8%) compared to BRCA2mt (74.8%) and HRwt (38.4%). TMB-H was highest in BRCA2mt (6.29%) than in BRCA1mt (1.35%) and HRwt (0.91%) HGSOC (all q < 0.05). Expression of immune checkpoint genes *CD80, CD86, CD274, CTLA4, HAVCR2/TIM3*, *IFNG*, *IDO1*, *LAG3*, *PDCD1* and *PDCD1LG2* were significantly higher in BRCA1 and BRCA2 mt compared to HRwt HGSOC (FC: 1.12-1.59, q < 0.05). HRwt tumors had decreased infiltration of Activated Dendritic cells compared to BRCA1mt, and lower Macrophage M1 compared to both BRCA1mt and BRCA2mt (all q < 0.05). Additionally, T-inflamed score was higher in BRCA1mt compared to HRwt, while IFN score was higher in BRCA1mt compared to both BRCA2mt and HRwt (all q < 0.05). From 17,408 genes with measured expression. 522 (3.0%) differentially expressed genes (DEG) were found between BRCA2mt vs BRCA1mt; 1487 (8.54%) between BRCA2mt vs HRwt; and 9297 (53.4%) between BRCA1mt and HRwt HGSOC. Pathway analysis identified Fatty Acid Metabolism, Myc targets, ROS pathway, Oxidative Phosphorylation, and Wnt B-catenin signaling pathways as differentially regulated between the 3 groups. **Conclusions:** We describe the genomic, pathway and immunologic analyses in the largest cohort of BRCA1 and 2 mutated HGSOC to date. Both metabolic and immune response pathways are differentially regulated between the groups. Results can potentially inform targeted therapeutic studies based on unique BRCA genotype. Research Sponsor: Michigan Ovarian Cancer Alliance.

Trends in frontline PARP inhibitor maintenance in advanced epithelial ovarian cancer across the United States. *First Author: Erica Huelsmann, Fox Chase Cancer Center, Philadelphia, PA*

Background: Advanced epithelial ovarian cancer (AEOC) is the fifth commonest cancer mortality among women in the United States. Despite 80% initial treatment response, most recur within two years and succumb from disease. Prolonging disease free interval with maintenance therapy is of interest. Options include Poly-(ADP) ribose polymerase inhibitors (PARPi's) and Bevacizumab, an anti-angiogenesis agent; eligibility criteria are based on clinical trials. Here we examine national approach to front line maintenance therapy following treatment in AEOC with focus on PARPi use. **Methods:** Protocol for data collection was IRB approved and institutional IRB approved. A retrospective, observational cohort study using Flatiron Health electronic health record (EHR)-derived, de-identified database patients diagnosed with AEOC between March 2017-June 2020, following FDA approval of PARPi use in AEOC. Demographics were summarized using descriptive statistics by use of maintenance treatment, and associations were tested using ANOVA and Chi-squared tests. Trends in use and type of maintenance therapy were summarized by year. Time trends assessed by Cochran–Armitage tests. **Results:** 1196 patients met inclusion criteria: Age>18, Stage III-IV, 90-day gap rule, systemic therapy after diagnosis. Majority were >65, White, Stage III with ECOG 0 at diagnosis. Only 31.6% of patients received maintenance after frontline therapy. Single agent PARPi was most used (12.9%), and Olaparib was most used PARPi (57%). Use of maintenance therapy significantly differed by ECOG value at diagnosis (p=.005), region of practice (p=.003), use of surgery (p=<.001) and extent of debulking (p=.002). Maintenance therapy was used more often when ECOG low at diagnosis, optimal debulking achieved and with treatment in the Southern US. Maintenance therapy significantly increased by year (p=<0.001); highest in 2020 (46.9%). Type of maintenance therapy had a significantly different trend by year with PARPi becoming more common (p=<.001). **Conclusions:** Despite known high rates of response to maintenance PARPi and increased use over time, less than 50% of patients with AEOC receive this regimen. Reasons for low adoption of maintenance PARPi in this population with poor prognosis deserves further investigation. Olaparib, approved for single use in BRCA mutation carriers in the front-line maintenance setting was used more often than Niraparib, approved for all comers. Research Sponsor: IVV Young Investigator Pilot Project.

Bevacizumab combined with platinum-based chemotherapy in patients with primary or relapsed ovarian cancer: Meta-analysis and literature review. *First Author: Faith Abodunrin, Department of Internal Medicine, Creighton University School of Medicine, Omaha, NE*

Background: Epithelial ovarian cancer has the highest mortality rates among all gynecological malignancies and is the fifth leading cause of cancer-related deaths in females. Previously, the treatment of ovarian cancers included cytoreductive surgery in combination with platinum-based chemotherapy. While this treatment regimen initially resulted in a good response, most of the patients subsequently relapsed. Given the role of Vascular Endothelial Growth factor (VEGF) and angiogenesis in the progression of ovarian cancer, VEGF inhibitors such as Bevacizumab were considered in the treatment of advanced or relapsed ovarian cancer patients. We conducted a meta-analysis to compare the efficacy of Bevacizumab with platinum-based chemotherapy to platinum-based chemotherapy. **Methods:** A thorough systematic literature review identified five eligible studies reporting the efficacy of bevacizumab with platinum-based chemotherapy in the treatment of advanced or recurrent Ovarian cancer as compared to control group receiving platinum-based chemotherapy alone. These studies were randomized Phase III clinical trials, one of which was recently published in 2021. Summary estimates of the clinical endpoints were calculated with risk ratio (RR) and 95% confidence intervals using the random-effects model. Heterogeneity between studies was examined with COCHRAN'S Q based 12 statistics. The primary endpoint was progression free survival at 12 months while secondary endpoints were overall survival and certain adverse effects. **Results:** Our pooled analysis from the five studies included 4,648 patients. 2,641 were in the Bevacizumab and platinum-based treatment group while 2007 patients in sole-platinum based chemotherapy group. There was a statistically significant difference in primary outcome of progression free survival at 12 months was noted (RR = 1.56 (95% CI: 1.09 to 2.24; p = 0.020). 33,4% of patients in the treatment group as compared to 22.9% observed in the control group attained PFS at 12 months. The secondary outcome of overall survival at 12 months was seen in 76.7% patients in treatment group as compared to 73.02% observed in control group. This was no statistically significant difference in this case (RR = 1.04 (95% CI: 0.96 to 1.12; p = 0.34). Adverse effects including hypertension, proteinuria, arterial and venous thromboembolism, posterior reversible leukoencephalopathy syndrome occurred more frequently in the treatment group. **Conclusions:** Results from our meta-analysis support the superiority of Bevacizumab with platinum-based chemotherapy over platinum-based chemotherapy with regards to PFS. However, the OS benefit remains questionable. Research Sponsor: None.

Dysfunctional CD8+ T cells in the tumor microenvironment are associated with response to nivolumab in mismatch repair deficient (dMMR) or hypermutated ovarian (OVCA) or endometrial cancer (EC). *First Author: Claire Frances Friedman, Memorial Sloan Kettering Cancer Center and Weill Medical College at Cornell University, New York, NY*

Background: EC and a subset of OVCA are associated with high rates of dMMR and are responsive to PD-1 blockade. It is unknown what additional biomarkers beyond dMMR may enrich for benefit in these patients (pts). **Methods:** This was an investigator-initiated, single-arm, phase II study. Eligible pts had recurrent EC or OVCA that met one of the following criteria: 1) dMMR, as determined by immunohistochemical loss of expression of 1+ MMR genes; 2) MSI-H, as determined by next generation sequencing (MSK-IMPACT); or 3) hypermutated, defined as 20+ non-synonymous somatic mutations. Pts received nivo 240mg IV every 2 weeks or 480mg IV every 4 weeks until toxicity or progression. The co-primary endpoints were 1) the progression-free survival (PFS) rate at 24 weeks (PFS24) and 2) the objective response rate (ORR) by RECIST v1.1. The study was designed using Simon's two-stage design, with a sample size of 40 pts based on a promising ORR of 25% with a type I error rate of 0.025 and a type II error rate of 0.05. Overall survival (OS), PFS and duration of response (DOR) were calculated using the method of Kaplan-Meier. Adverse events (AEs) were graded per CTCAE and tabulated. Biomarker analyses on the available archival tissue were performed using multiplex immunofluorescence (mIF) labeling for CD8, PD-1, TOX, PD-1, PD-L1, and FoxP3. Quantification of immune phenotypes and interaction studies between CD8+ T cells and PD-L1+ cells was performed in HALO. **Results:** Between 9/2017 and 5/2021, 35 pts were enrolled; the study closed early due to slow accrual. The median duration of follow-up was 33.2 months. The median age was 64 years (range 36-87); 82% of pts were white, 54% had high grade EC, and 65% had confirmed MLH1 hypermethylation. The ORR was 57.1% (97.5% CI 39.4-100%) [37% PR, 20% CR]. The PFS24 was 62.9% and median PFS was 26.7 months (95% CI 4.9-NE). Neither median DOR nor OS was reached. OS at 1 year was 76.4% (95% CI 58.2-87.4%). The ORR in patients with MLH1 hypermethylation was 52%; 4 of 5 patients with confirmed germline MMR alterations had a response by RECIST. AEs were consistent with the reported literature. Notable treatment related AEs included Grade 4 myocarditis with associated grade 4 AV block, grade 2 extraocular paresis, grade 3 Type 1 diabetes mellitus, and grade 3 elevations in AST/ALT. On mIF analysis, PD-L1 expression did not distinguish responders from non-responders, though interaction between $CD8^+$ T cells and $PD\text{-}L1^+$ cells was associated with CR/PR. Increase in relative fraction of dysfunctional $CD8^+$ T cells (characterized by $CD8^+TOX^+PD\text{-}1^+$ phenotype) was also associated with CR/PR. **Conclusions:** Nivo is an effective and tolerable treatment option for patients with MMR-D/MSI-H or hypermutated EC or OVCA. Presence of dysfunctional $CD8^+$ T cells in the tumors was associated with response, while expression of PD-L1 was not predictive. Clinical trial information: NCT03241745. Research Sponsor: Stand Up to Cancer, Pharmaceutical/Biotech Company.

Clinicopathologic and molecular features associated with response to anti-HER2 therapy in endometrial cancer. *First Author: Sherry Shen, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Endometrial cancer (EC) is the most common gynecologic malignancy in the United States. Human epidermal growth factor 2 (HER2) overexpression or gene amplification occurs in 10-60% of EC. The addition of trastuzumab to carboplatin-paclitaxel chemotherapy improves survival in women with HER2-positive serous EC. However, criteria for assessment of HER2 status in EC are not standardized, and furthermore, intratumor heterogeneity may impact therapeutic efficacy. We aimed to identify factors associated with treatment response and survival outcomes in a retrospective cohort of ECs treated with anti-HER2 therapy. **Methods:** Patients with advanced/recurrent EC treated with trastuzumab or trastuzumab emtansine alone or in combination with chemotherapy from 2013-2021 at our institution were identified. Clinical and treatment information were retrieved from medical records. Central pathology review, HER2 immunohistochemistry (IHC) and fluorescence in-situ hybridization (FISH) were performed. HER2 IHC was scored using modified ASCO/CAP 2007 guidelines for breast cancer. HER2 expression heterogeneity was defined as a 2-degree difference in staining intensity in ≥5% of tumor cells or discordant IHC score on different specimens. *HER2* amplification (tumor/normal fold change) was also estimated from targeted next-generation sequencing (NGS). Best response was assessed by RECIST v1.1 as complete response (CR), partial response (PR), stable disease (SD), or progressive disease (PD), with clinical benefit defined as CR/PR/SD. **Results:** Among 39 patients included, median age was 69. Histologic subtypes included serous (n = 18, 46%), carcinosarcoma (n = 7, 18%), high-grade EC with ambiguous features (n = 13, 33%) and low-grade endometrioid carcinoma (n = 1, 3%). HER2 IHC results were 0 or 1+ (n = 2, 5%), 2+ (n = 17, 46%), 3+ (n = 18, 49%), with HER2 heterogeneity in 15 cases. By FISH, the HER2/CEP17 ratio was ≥2.0 in 34 (92%) and < 2.0 in 3 (8%); HER2 copy number (CN) was ≥6.0 in 25 (68%) and < 6.0 in 12 (32%). HER2 copy number ≥6.0 was significantly correlated with *HER2* amplification by NGS (p< 0.001). 18 (49%) patients had a co-existing somatic *PIK3CA* mutation. Amongst parameters assessed, only higher level of *HER2* amplification by NGS was significantly associated with clinical benefit (p= 0.036). None of these features were associated with progression-free survival. Notably, 2 patients with IHC 0/1+ had PD and 1 patient with IHC 3+, but non-amplified by FISH, achieved PR. **Conclusions:** In our cohort of EC patients treated with anti-HER2 therapy, higher level of *HER2* amplification was associated with clinical benefit. Further studies with larger sample sizes are needed to determine whether any additional characteristics are associated with treatment response and survival. Research Sponsor: None.

Outcomes of recurrent and metastatic endometrial cancer (RMEC) treated with systemic progestins. *First Author: Anjali Kulkarni, Ottawa Hospital Research Institute, Ottawa, ON, Canada*

Background: Recurrent endometrial cancer has a poor prognosis with limited treatment options. Systemic therapy for RMEC includes chemotherapy, immunotherapy and hormonal therapy. Although studies on hormonal therapy have described modest results, agents such as megestrol acetate (megace) continue to be used mainly for low grade, ER+/PR+ve tumors in the advanced and recurrent setting. Overall response rates have been reported in the range of 20-25% with responses up to 25-35% in ER+/PR+ve tumors. Despite comparative response rates to chemotherapy, the use of hormonal therapy in clinical trials in RMEC is hampered by a lack of clear progression-free survival (PFS) data. The primary objective of this study is to determine the PFS in RMEC patients treated with progestins. **Methods:** A retrospective chart review on RMEC was conducted at The Ottawa Hospital with data sourced from medical records. Main inclusion criteria were a diagnosis of RMEC between 2000 and 2019, endometrioid histology, and ≥1 one line of progestin treatment. PFS was the time from initiation of progestin therapy until progression of disease (PD) by imaging, biopsy or death. Overall survival (OS) was the time from initiation of progestins until death. Median time to PFS and OS were estimated using the Kaplan-Meier method and compared using a Log-rank Test with 95% confidence interval (CI). **Results:** Of 2342 cases reviewed, 75 met inclusion criteria. The mean age at the time of primary diagnosis was 66.7 years and the range of follow-up was 1-199 months (mo). Sixty-six (88.0%) patients received megestrol acetate and 9 (12.0%) received a progestin alternative. The distribution of all patients by grade was: 1: 25 (33.3%), 2: 30 (40.0%) and 3: 20 (26.7%). The median PFS for all patients with grade 1 and 2 RMEC was 15.7 mo (95% CI: 8.0, 19.5), compared to 5.0 mo (3.0, 23.0) for grade 3 disease (p=0.28). The median OS for all patients with grade 1 and 2 versus grade 3 RMEC, was 25.9 mo (15.3, 40.3) versus 12.5 mo (5.7, 35.9), respectively (p=0.12). The number of patients treated with 0 and ≥1 line of chemotherapy was 34 (45.3%) and 41 (54.7%). The median PFS for patients who were naïve to chemotherapy was 17.9 mo (14.3, 27.0), compared to 6.2 mo (3.9, 14.8) for patients who had received ≥1 prior lines of treatment (p=0.09). The median OS was 29.1 mo (17.9, 61.1) for patients who were naïve to chemotherapy, versus 23.0 mo (10.5, 37.6) for patients who were previously exposed (p=0.64). **Conclusions:** This real-world data suggests that progestins for RMEC have comparable outcomes to other systemic therapies in chemotherapy-exposed patients. Progestins such as megestrol acetate may be considered in the design of RMEC clinical trials. Research Sponsor: AstraZeneca.

The ENSURE trial for women with low-risk, early-stage endometrial cancer: A randomized controlled trial comparing the effect of a reduced (4 visits/3 yr) versus usual (8-11 visits/3 yr) follow-up schedule on patient satisfaction, health care use, and disease perception. *First Author: Lonneke V van de Poll-Franse, Division of Psychosocial Oncology and Epidemiology, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Research suggests that most early-stage endometrial cancer patients do not need intensive follow-up to detect recurrences, improve survival, or discuss consequences of treatment. However, a minimal number of follow-up visits is needed to support necessary patient counselling and information provision. The aim of the ENSURE (ENdometrial cancer SURvivors' follow-up carE) trial was to compare, for three years after diagnosis, satisfaction with care between women who received reduced follow-up (FU) care (4 visits) and women who received usual FU care according to the Netherlands guideline (8-11 visits). **Methods:** In this multicenter non-inferiority trial from the Netherlands, 316 women from 42 hospitals with FIGO stage IA/B low-risk endometrial cancer were randomized after treatment. Women allocated to reduced FU (n = 160) and usual FU (n = 156) completed questionnaires at baseline (after surgery), and after 6, 12 and 36 months. The primary outcome was satisfaction with FU care (Patient Satisfaction Questionnaire III total scale: PSQ-III). The predefined noninferiority margin was 6 points. Mixed linear regression and intention-to-treat analyses were used. Secondary outcomes were health care utilization, disease perception (Brief Illness Perception Questionnaire: BIPQ) and cancer recurrence. **Results:** 299 (95%) women completed the questionnaire at baseline; 291 (92%) at 6-months; 272 (86%) at 12 months and 222 (70%) at 36 months. Overall satisfaction with care was similar in the reduced FU (average 82; SD = 15) and usual FU (average 80; SD = 15) group. At 6, 12 and 36 months, more women (93%, 94% and 90%) in the reduced FU group were satisfied with their FU schedule than patients in usual FU group (79%, 79% and 82%; p < 0.001; p < 0.001; p = 0.050). During three years of FU care, women in the reduced FU group had an average of 3.8 (SD = 1.5) visits with their specialist/nurse compared to 6.8 (SD = 2.4) visits for women in the usual FU group. We observed a non-significant trend of less severe disease perception in patients in the reduced vs. the usual FU group: impact on life (M = 1.8; SD = 2.2 vs. M = 2.5; SD = 2.8); concern about disease (M = 1.5; SD = 2.1 vs. M = 2.3; SD = 2.9); emotional impact (M = 1.4; SD = 2.1 vs. M = 2.2; SD = 2.9). Nine women in the reduced FU group and five in the usual FU group developed a recurrence within three years after diagnosis (n.s.). **Conclusions:** Women with low-risk, early-stage endometrial cancer receiving reduced follow-up care were just as satisfied with their care as those women receiving follow-up care according to Netherlands guidelines. Compared with usual care, women in the reduced care group had fewer medical visits and, at the same time, more often reported being satisfied with this reduced frequency. Clinical trial information: NCT02413606. Research Sponsor: Dutch Cancer Sciety.

Efficacy of next line of therapy after treatment with lenvatinib (LEN) in combination with pembrolizumab (pembro) versus treatment of physician's choice (TPC) in patients (pts) with advanced endometrial cancer (aEC): Exploratory analysis of Study 309/KEYNOTE-775. *First Author: Vicky Makker, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In the multicenter, open-label, randomized, phase 3 Study 309/KEYNOTE-775, LEN + pembro had significant PFS and overall survival benefits, and improved objective response rate vs TPC in pts with aEC following systemic platinum-based treatment (Makker 2022, *NEJM*). These results were seen in all-comer pts and in pts with DNA mismatch repair proficient (pMMR) disease. Here, we assessed PFS on next line of therapy (PFS2) of each arm. **Methods:** Pts with aEC and 1 prior platinum-based chemotherapy regimen (or up to 2 if 1 was given in neoadjuvant/adjuvant setting) were randomized (1:1) to receive LEN 20 mg orally QD + pembro 200 mg IV Q3W or TPC (doxorubicin at 60 mg/m^2 IV Q3W or paclitaxel at 80 mg/m^2 IV QW [3 weeks on; 1 week off]). Randomization was stratified by MMR status (determined centrally); pts with pMMR tumors were further stratified by Eastern Cooperative Oncology Group performance status, geographic region, and history of pelvic radiation. In this prespecified exploratory analysis, PFS2 (defined as the time from randomization to disease progression on next line of treatment or death, whichever came first) was analyzed per investigator assessment in the pMMR and all-comer populations. **Results:** 827 Pts (pMMR, n=697; MMR deficient [dMMR], n=130) were randomized to LEN + pembro (n=411) or TPC (n=416). At data cutoff (October 26, 2020), 567 pts (LEN + pembro, n=282; TPC, n=285) had discontinued study treatment and 315 (LEN + pembro, n=115; TPC, n=200) had received a subsequent systemic anticancer therapy (Table): most commonly doxorubicin (n=58) in the LEN + pembro arm and paclitaxel (n=57) in the TPC arm. Median PFS2 was longer in the LEN + pembro arm vs the TPC arm in the pMMR population (14.4 vs 9.8 mo; HR 0.62, 95% CI 0.50–0.75) and in the all-comer population (16.0 vs 9.5 mo; HR 0.56, 95% CI 0.46–0.67). Additionally, the PFS2 rate at 6 months favored LEN + pembro vs TPC in the pMMR population (82.0% vs 74.8%) and in the all-comer population (81.7% vs 72.5%). **Conclusions:** Clinically meaningful improvements in PFS2 were seen in the LEN + pembro group compared with TPC in pMMR and all-comer pts. Clinical trial information: NCT03517449. Research Sponsor: Eisai Inc., Nutley, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co. Inc., Kenilworth, NJ, USA.

HER2 in endometrioid endometrial adenocarcinoma (E-EMCA): Defining incidence, molecular profiles, and outcomes. *First Author: Shaina F. Bruce, Washington University School of Medicine, Saint Louis, MO*

Background: Immunohistochemistry (IHC) for HER2 in E-EMCA is not standard of care. We aimed to establish the correlation of HER2 transcript to IHC expression in the much more frequently tested uterine serous carcinoma (USC). We applied the threshold calculated in USC to E-EMCA and compared molecular and immune profiles among HER2+ and HER2- E-EMCA tumors, which may affect response to targeted therapy. **Methods:** 1462 E-EMCA tumors were analyzed using next-generation sequencing (592, NextSeq; WES, NovaSeq), WTS (NovaSeq) (Caris Life Sciences, Phoenix, AZ). PD-L1 was tested by IHC (SP142, >1%). Microsatellite instability (MSI) was tested by FA, IHC and NGS. TMB was measured by totaling somatic mutations per tumor (TMB-H: >10 mutations/MB). LOH cut-off was > 16%. HER2+ cut-off by WTS was determined by Receiver Operator Characteristic (ROC) analysis in USC tumors by comparing to HER2 IHC/CISH results using 2018 Breast Cancer ASCO/CAP Guidelines. Immune cell infiltrates were calculated by Quantiseq. Real world overall survival (OS) was extracted from insurance claims data and calculated using Kaplan-Meier survival curves for molecularly defined cohorts. Significance was determined using chi-square and Wilcoxon rank sum test and adjusted for multiple comparisons (q-value < 0.05), $p < 0.05$ but $q > 0.05$ was considered a trend. **Results:** We determined a cut-off of > 62.99 TPM for HER2+ with a sensitivity of 81.5%, specificity of 87.6% and AUC of 0.92 in Uterine Serous. When this cut-off is applied to E-EMCA, 76 of 1462 (5.2%) E-EMCA tumors were HER2+. HER2+ tumors had fewer mutations (mt) in *PI3KR1*, *PTEN* and *CTNNB1* but higher mts in *TP53* and more frequent LOH (q < 0.05). HER2+ tumors had a trend towards decreased MSI-H status (22.4% vs 39.1%; $p = 0.003$, $q = 0.058$) and TMB-H (25.4% vs 41.5%; $p = 0.007$, $q = 0.084$). MSS HER2+ E-EMCA had a similar mutational profile compared to all HER2+ tumors; MSI-H HER2+ E-EMCA had a trend towards higher DDR pathway gene mts compared to MSI-H HER2- EMCA tumors. HER2+ tumors had increased Dendritic cell (3.84% vs 2.97%) but decreased Neutrophil (2.66% vs 5.20%) and T-reg (1.38% vs 2.07%) infiltration (q < 0.01). HER2+ tumors had higher immune checkpoint gene expression of *CD80, HAVCR2* and *PDCD1LG2* (q < 0.01), and increased T-cell inflamed and MAPK activation score (q < 0.01). MSS HER2+ E-EMCA tumors had a similar immune profile when compared to all HER2+ tumors; MSI-H HER2+ E-EMCA tumors had increased Treg infiltration and MAPK activation score. Median OS was significantly worse for HER2+ pts compared to HER2- (64.3 vs. 23.6 months, HR: 1.93(1.32-2.80), $p < 0.001$). **Conclusions:** Using a WTS cutoff from USC, we found 5% of E-EMCA are HER2+ and showed distinct molecular and immune profile compared to HER2- tumors. HER2+ confers a worse OS compared to HER2- tumors. Furthermore, HER2+ tumors demonstrate an immune hot phenotype suggesting that immunotherapy may be a potential therapeutic option. A phase II trial of IDO-inhibitor, BMS-986205 (IDO), and PD-1 inhibitor, nivolumab (NIVO), in recurrent or persistent endometrial cancer (EC; CA017-056). *First Author: Chrisann Kyi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Indoleamine 2,3-dioxygenase 1 (IDO1) allows tumor escape through kynurenine production, which induces regulatory T cells and suppresses effector T-cell proliferation. NIVO, an anti-PD-1 inhibitor can upregulate IDO1, supporting the rationale for combining NIVO with IDO. We report results of NIVO as monotherapy and in combination with IDO inhibitor BMS-986205 in the treatment of pts with recurrent EC. **Methods:** In this single-institution, randomized phase 2 study, eligible pts must have received 1-4 prior lines of chemotherapy and have measurable disease by RECIST v 1.1. All EC histologies, including carcinosarcoma, were allowed. Pts with microsatellite insufficient (MSI-H) or mismatch repair (MMR)-deficient tumors were excluded. Pts were randomized to NIVO 480mg IV every 4 weeks (wks) with or without IDO 100mg orally daily. Primary endpoints were Overall Response Rate [ORR = Complete Response (CR) + Partial Response (PR)] by RECIST v 1.1. Secondary objectives were duration of response (DOR), median progression free survival (mPFS), PFS rate at 24 wks (PFS_{24wks}) and safety. Overall survival (OS) was also evaluated. **Results:** Between 10/2019 and 11/2021, pts were randomized to receive either NIVO (n = 12) or NIVO + IDO (n = 12). Median age was 67 years (range 48-82) and median number of prior lines of therapy was 2 (range 1-3). Histologies included serous (n = 5, 21%), endometrioid (n = 10, 42%), clear cell (n = 1, 4.2%), carcinosarcoma (n = 6, 25%), undifferentiated (n = 1, 4.2%), and mucinous (n = 1, 4.2%). In the NIVO + IDO arm, 1 pt achieved partial response (8.3%, CI: 0.9-100%) with DOR of 17.6 months. In the NIVO arm, no responses were observed. Efficacy outcomes are summarized in the table. Treatment-related adverse events (TRAEs) grade ≥ 3 in the NIVO arm included acute kidney injury (n = 1, 8.3%), hypokalemia (n = 1, 8.3%), and thromboembolic event (n = 1, 8.3%). In the NIVO + IDO arm, TRAEs grade ≥ 3 included fatigue (n = 1, 8.3%), and elevated liver function (n = 1, 8.3%). No TRAEs led to study-drug interruption or dose reductions. **Conclusions:** NIVO monotherapy and in combination with IDO showed acceptable safety in pts with recurrent EC. NIVO in combination with IDO showed ORR of 8.3%. No responses were observed with NIVO monotherapy. The trial closed to accrual due to lack of observed clinical efficacy. Clinical trial information: NCT04106414. Research Sponsor: Bristol-Myers Squibb.

Arm	Evaluable (N)	ORR	DOR (months)	mPFS (wks)	PFS at 24wks	mOS	OS at 24wks
NIVO alone	12	0%		7.3(6.4-15.1)	16.7% (5.8-32.3%)	27.5(17-NE)	58.3% (38.2-74%)
NIVO + IDO	12	8.3% (0.9-100%)	17.6	12.3(4.1-22.1)	25% (11.1-41.8%)	Not Reached	66.7% (46.2-80.8%)

Primary objective ORR is reported as 1-sided 90% CI. All other secondary objectives are 2-sided 80% CI per protocol.

HER2 in uterine carcinosarcoma: Testing platforms and implications for targeted therapy. *First Author: Navin Maredia, University of Minnesota, Minneapolis, MN*

Background: Uterine carcinosarcomas (UCS) are rare, aggressive tumors accounting for 5% of all uterine cancers. Recurrence rates are high and 5-year survival is only 18-39%. HER2 is an emerging prognostic and therapeutic target in uterine cancer including UCS. Testing algorithms and platforms in breast and gastric cancers are well studied and validated, but optimal HER2 testing in uterine cancer is not yet established. We aimed to determine HER2 prevalence in UCS and the concordance of chromogenic in situ hybridization (CISH), immunohistochemistry (IHC), and next generation sequencing (NGS) platforms to aid in the development of UCS specific testing guidelines. We also evaluated the rate of downstream mutations and immune biomarkers that may affect response to HER2 directed therapy. **Methods:** Eight hundred and seventy-five UCS tumor samples (primary 81.4%; metastatic 17.1%; unknown 1.5%) were analyzed using NGS (592, NextSeq; WES, NovaSeq, Caris Life Sciences, Phoenix, AZ). A subset of tumors with HER2 positivity were tested with IHC (4B5, Ventana) and/or CISH (INFORM DUAL HER2 ISH Assay, Ventana) based on 2018 ASCO/CAP HER2 Breast Cancer guidelines. Amplification of ERBB2/HER2 by NGS used a copy number cut-off >6. PD-L1 expression was analyzed by IHC (SP142, positive cut-off ≥1%, Ventana). Tumor mutational burden (TMB) was measured by counting all somatic mutations found per tumor (TMB high cut-off > 10 mutations per Mb). Microsatellite instability (MSI) was tested by fragment analysis (FA), IHC and NGS. **Results:** Rates of HER2 positivity were 3.4% (28/820) by NGS. Among the IHC/CISH-tested cohort, 7.2% was positive (10/139) by IHC, and 19.5% (27/133) by CISH. In the 105 samples tested with both IHC and CISH, the concordance was 100%. Specifically, 9/105 patients (8.6%) were IHC+/CISH+ and 96 patients (91.4%) were IHC-/CISH-. The concordance between CISH and NGS (N = 127) was 90.6% (sensitivity 100% and specificity 89.3%). Common gene alterations in CISH HER2+ UCS tumors that may implicate resistance to HER2 targeted therapy included mutations in *TP53* (100%), *FBXW7* (22.2%), *PIK3CA* (33.3%), *PIK3R1* (18.5%), *PTEN* (3.7%) and *KRAS* (3.7%) and gene amplification of *KRAS* (11.1%). CISH+ HER2+ UCS tumors had low immunotherapy biomarker prevalence (0% MSI-H, 0% TMB high, 7.7% PD-L1+). **Conclusions:** Increased HER2 positivity was detected via CISH testing compared to IHC and NGS, which may reflect the heterogeneity of HER2 amplification due to mixed histology between the sarcoma and carcinoma portion of the tumor. High concordance rates were observed between CISH and IHC. These testing platforms need to be validated by response to HER2 targeted therapies in order to develop UCS specific testing guidelines. Research Sponsor: None.

Camrelizumab plus apatinib in patients with advanced or recurrent endometrial cancer after failure of at least first-line therapy: Interim results of a single-arm phase II trial. *First Author: Huaying Wang, Department of Gynecologic Oncology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China*

Background: For advanced or recurrent endometrial cancer (EC), therapeutic options remain scarce. Immune or antiangiogenic monotherapy has shown moderate efficacy in EC. Preclinical and clinical data showed that camrelizumab (an anti-PD-1 antibody) plus apatinib (a selective VEGFR2 inhibitor) markedly enhanced anti-tumor efficacy in multiple solid tumors. This study was designed to assess the efficacy and safety of the combination of camrelizumab and apatinib as second-line or above therapy for advanced or recurrent EC. **Methods:** This was an open-label, single-arm, phase II trial conducted in China. Patients with advanced or recurrent EC who progressed after at least first-line therapy received camrelizumab (200 mg, intravenously, q2w) plus apatinib (250 mg, orally, qd). Using a minimax Simon two-stage design, 21 patients were enrolled at stage I and if a complete or partial response was observed in at least four patients, the enrollment would be continued to 40 patients. The primary endpoint was the objective response rate (ORR) per RECIST version 1.1. Secondary endpoints included time to objective response (TTR), disease control rate (DCR), duration of Response (DoR), progression-free survival (PFS), overall survival (OS), time to treatment failure (TTF) and safety. Here, the results of stage I are reported. **Results:** Between January 20, 2020 and July 8, 2021, 21 patients were enrolled. The median age was 57 years (range 29–72). Thirteen patients (61.9%) had ECOG PS of 0, and eight patients (38.1%) received at least two prior therapies. As of November 9, 2021, the median follow-up time was 13.5 months (IQR 11.3-16.3). Among 21 evaluable patients, the confirmed ORR was 47.6% (95% CI 25.7%-70.2%) with complete response in one patient (4.8%) and partial response in nine patients (42.9%); eight patients had stable disease for a DCR of 85.7% (95% CI 63.7%-97.0%). The median PFS was 11.8 months (95% CI 5.2-14.4). Treatment-related adverse events (TRAEs) of any grade and of grade ≥ 3 were reported in 21 (100%) patients and 10 (47.6%) patients, respectively. The most common grade ≥ 3 TRAEs included gamma-glutamyltransferase increased (six [28.6%]), direct bilirubin increased (four [19.0%]), alanine aminotransferase increased (three [14.3%]), aspartate aminotransferase increased (three [14.3%]) and hyperglycaemia (three [14.3%]). Four patients (19.0%) experienced reactive cutaneous capillary endothelial proliferation, all of which were grade 1-2. No treatment-related deaths were reported. **Conclusions:** Camrelizumab plus apatinib demonstrated promising antitumor activity and a manageable safety profile in patients with advanced or recurrent EC after failure of at least first-line therapy. Clinical trial information: ChiCTR2000031932. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Cell-free DNA analysis as a molecular tool to monitor response to immune checkpoint inhibition in endometrial cancer. *First Author: Beryl Manning-Geist, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Immune checkpoint inhibitors (ICI) targeting PD-1 have meaningful activity in microsatellite instability high (MSI-H), hypermutated or mismatch repair deficient (dMMR) advanced endometrial cancer (EC). We investigated if high-depth circulating cell free (cf)DNA sequencing can be used to assess MSI status and monitor ICI response in EC patients enrolled in a phase II trial (NCT03241745). **Methods:** Patients with recurrent/persistent MSI-H/dMMR/hypermutated EC with measurable disease and ≥1 prior lines of cytotoxic therapy were treated from 06/2018-01/2022 with nivolumab until progression of disease (PD) or unacceptable toxicity. Radiologic tumor response was assessed every 12 wks by RECIST 1.1 criteria.Pre-treatment ECs and matched normal blood-derived DNA were subjected to whole-exome sequencing (WES); cfDNA from plasma at baseline, 2 wks and every 6 wks thereafter was subjected to high-depth MSK-ACCESS sequencing (129 genes). MSI in WES and cfDNA was calculated by MSIsensor and ADMIE, respectively. **Results:** Ten patients with ≥10 ng cfDNA at baseline and 2 weeks after nivolumab initiation were included. Most (80%) had grade 3 endometrioid EC; 70% had *MLH1* hypermethylated EC. Two patients had partial response (PR), 3 had stable disease (SD) and 5 had PD on nivolumab. A high-depth sequencing assay captured somatic mutations in cfDNA at baseline in all patients (median, 29.5; range, 2-75). Median circulating tumor (ct)DNA fraction in cfDNA was 13.1% at baseline (range, 0.0-86.0%). In 8 cases, ctDNA fraction was sufficient to perform MSI assessment. Liquid biopsy MSI status matched tumor MSI status assessed by WES: in 7 patients with MSI-H disease by tumor WES, cfDNA MSI status was also MSI-H (> 0; range, 0.21-5.46); in 1 patient with MSI-low but hypermutated tumor, cfDNA MSI was 0.0. In all cases, changes in ctDNA fractions reflected ICI response. Median ctDNA fraction percent change from week 0 to week 8 was -51.6% (IQR, -6.2, -85.1) in patients with PR and SD vs +17.7% (IQR, -6.6, +356.6) in patients with PD (p = 0.08). In patients with PR, ctDNA fraction decreased at week 2 and stayed low at week 8 and weeks 32-55 of nivolumab in concordance with ongoing response. In 3 patients with SD, ctDNA fractions decreased by week 2. In 1 patient with SD at week 8 and PD at week 22, ctDNA fraction increased from week 8 to week 20. In 5 patients with PD, 4 had increased ctDNA fraction by week 8. The last patient had a stable ctDNA fraction but increasing allele frequency of 2 truncating *B2M* alterations, possibly associated with ICI resistance. **Conclusions:** In patients with advanced hypermutated ECs, cfDNA sequencing can be used to accurately detect MSI status. Early changes in ctDNA fraction may be associated with durable response to ICI or may anticipate radiological progression. Future studies may use ctDNA to assess mechanisms of ICI resistance and offer opportunities for adaptive therapy intervention. Clinical trial information: NCT03241745. Research Sponsor: None.

Survival outcomes for dostarlimab and real-world (RW) treatment (tx) paradigms in post-platinum patients (pts) with advanced/recurrent (A/R) endometrial cancer (EC): The GARNET trial versus an external control arm from the Flatiron Health database. *First Author: Robert L. Coleman, Texas Oncology, US Oncology Research, The Woodlands, TX*

Background: There are limited treatment options for pts with A/R EC progressing on or after platinum-based chemotherapy (PBCT) and their prognosis is poor. This study compared the efficacy of the anti-programmed death (PD)-1 antibody dostarlimab evaluated in the single-arm, Phase I GARNET trial with current RW tx. Overall survival (OS) of pts with A/R mismatch repair deficient (dMMR)/microsatellite instability-high (MSI-H) EC receiving dostarlimab in Cohort A1 of the GARNET trial was compared with an equivalent RW cohort receiving non-anti-PD-(ligand [L])1 tx. **Methods:** The dostarlimab arm was the GARNET (Cohort A1) dMMR/MSI-H EC safety population. For the external control arm, a RW cohort was constructed using the Flatiron Health database and aligning eligibility criteria with those for GARNET, including pts with A/R EC, Eastern Cooperative Oncology Group (ECOG) performance status (PS) ≤1, who had received ≤2 lines of chemotherapy (≥1 line PBCT) and no anti-PD-(L)1 therapy. GARNET pts who received anti-PD-(L)1 therapy following dostarlimab (n=5/129) were excluded. Inverse probability of tx weighting (IPTW) was performed based on propensity scores constructed from key prognostic factors identified by literature review and clinical experts. With IPTW, Kaplan–Meier curves were created, OS rates estimated, and adjusted hazard ratios (HR) estimated by a Cox regression model. MMR/MSI status, only partially available in Flatiron and considered not significantly prognostic for OS as per a recent meta-analyses, was not included in the IPTW. **Results:** Baseline characteristics for GARNET (N=124) and RW (N=185) after IPTW are shown in the Table. Dostarlimab was associated with a 44% lower risk of death compared with RW tx (OS HR [95% confidence interval {CI}] 0.56 [0.385–0.812]; p=0.002) (see Tablefor median OS). Survival rates (95% CI) were higher for dostarlimab than RW tx at 12 months (mos) (72% [57%–82%] vs 51% [43%–59%]), 18 mos (57% [41%–70%] vs 40% [32%–48%]), and 24 mos (53% [37%–67%] vs 34% [26%–42%]). **Conclusions:** These results indicate that pts with A/R EC receiving dostarlimab in the GARNET trial had significantly lower risk of death than those receiving current non-anti-PD-(L)1 tx in the RW. Research Sponsor: GlaxoSmithKline.

Identification of a novel subtype of endometrial cancer with unfavorable outcome using artificial intelligence-based histopathology image analysis. *First Author: Amirali Darbandsari, University of British Columbia, Vancouver, BC, Canada*

Background: Molecular subtyping of endometrial cancer (EC), unlike histopathological evaluation, offers an objective and reproducible classification system that has strong prognostic value and therapeutic implications. The Proactive Molecular risk classifier for Endometrial cancer (ProMisE) was developed by our team as a pragmatic, cost-effective, and clinically applicable molecular classifier for EC patients. ProMisE has four subtypes: (i) *POLE* mutant (*POLE*mut), (ii) mismatch repair deficient (MMRd), (iii) p53 abnormal (p53abn) by immunohistochemistry, and (iv) NSMP (No Specific Molecular Profile), lacking any of the defining features of the other three subtypes. While ProMisE subtypes are associated with clinical outcomes, within each subtype, there are clinical/prognostic outliers. This is particularly true within the largest ProMisE subtype; NSMP (representing ~50% of ECs), where a subset of patients experience a very aggressive disease course, comparable to what is observed in patients with p53abn ECs. **Methods:** We hypothesized that objective assessment of the digitized hematoxylin and eosin (H&E)-stained histopathology slides of the largest and most diverse EC subset, NSMP, could potentially identify clinical outcome outliers. As such, we developed an artificial intelligence (AI)-based image analysis model to identify the NSMP cases that had similar histopathological features to the p53abn subtype, as assessed by H&E stain. We used a discovery cohort of 182 and an external validation cohort of 195 NSMP ECs. **Results:** Our AI-based image analysis model, based on deep convolutional neural networks, identified 21 (11.5%) out of the 182 NSMP cases with similar histopathological features as p53abn cases. We refer to these cases as 'p53abn-like' NSMPs. Compared to the rest of the NSMP cases, these cases had markedly inferior disease-specific survival (DSS) (10-year DSS 58.9% vs. 93.1% (p<3.44e-8)) and progression-free survival (PFS) (10-year PFS 55.1% vs. 91.4% (p<3.76e-6)). These findings were confirmed in our validation cohort, with 10.7% of the 195 patients categorized as 'p53abn-like' tumors with 10-year DSS of 82% vs. 51.3% (p<5.28e-5) and PFS of 89.3% vs. 56.6% (p<2.15e-4). **Conclusions:** Utilizing an AI-based approach for histopathology image analysis, we have discovered 'p53abn-like' NSMPs, a novel subtype of NSMP ECs with morphological features similar to p53abn cases. 'p53abn-like' NSMPs exhibit similar clinical behavior as p53abn, having noticeably inferior outcome compared to the rest of the NSMP cases in two independent cohorts. These findings warrant further molecular investigation of this novel subtype of EC to identify the biological underpinning and future therapeutic strategies. Research Sponsor: CCSRI, MSFHR.

Interaction of race and socioeconomic status as risk modulators of treatment delay and cancer-specific mortality in uterine cancer. *First Author: Larissa H Mattei, Wayne State University, Detroit, MI*

Background: The majority of studies of uterine cancer combine high and low-grade histologies and do not sample a diverse cohort of patients. In many studies race is treated as biologic construct, when it may be better thought of as a proxy for socioeconomic inequity and deprivation. Socioeconomic (SE) deprivation may play a significant role in the disease trajectory of women with uterine cancer. **Methods:** Data were drawn from the Metropolitan Detroit Cancer Surveillance System which covers a tri-county area of approximately 4 million people. We included non-Hispanic Black (NHB) and White (NHW) women diagnosed with uterine cancer between 2010 and 2018. Poorly differentiated and undifferentiated endometrioid, serous, clear cell, mixed, carcinosarcoma and mucinous histologies were considered high grade. Patients diagnosed by death certificate, or with unknown stage or histology were excluded. Socioeconomic status was assessed using the Yost Score, an area-level composite measure of socioeconomic deprivation derived from census-tract data at cancer diagnosis. Lower Yost quintile indicates higher deprivation. Competing risk analysis was used to determine risk of uterine cancer specific mortality (reported as subdistribution hazard ratio [SHR]) and to assess statistical interaction between race and Yost score. **Results:** A total of 4,840 patients were identified. Race conferred significant increased risk of cancer-specific mortality (SHR 2.11, $p < 0.0001$). Race and Yost score interacted to increase risk of cancer-specific mortality in NHB women in the lowest Yost quintile (SHR 2.23, $p < 0.0001$) compared to NHW and NHB women in the highest quintiles. The interaction between race and Yost score persisted only among women with low grade cancers (SHR 1.7, $p = 0.04$). Time from diagnosis to surgery increased as Yost score decreased. Women in the lowest Yost quintile had lower likelihood of receiving surgery within 6 weeks of diagnosis (OR 0.74, $p = 0.001$). This effect persisted among women with low grade cancer (NHB OR 0.75, $p = 0.014$; lowest Yost quintile OR 0.68, $p < 0.0001$). An association between race, Yost score and delays in time to surgery was not seen among women with high grade cancers. **Conclusions:** Race and Yost score, an area-based measure of socioeconomic deprivation, are associated with increased cancer-specific mortality risk among women with low grade cancer. NHB race and high socioeconomic deprivation are associated with delayed primary surgery. The interaction between race and socioeconomic deprivation may underlie known disparities in uterine cancer survival, particularly in low grade disease where there is the greatest opportunity for timely curative surgery. Biomarker associations of immune checkpoint inhibitor versus chemotherapy effectiveness in first-line metastatic endometrial carcinomas: A real-world study. *First Author: Alessandro Santin, Yale University School of Medicine, New Haven, CT*

Background: Limited evidence exists comparing outcomes of single-agent anti-PD1 immune checkpoint inhibitors (ICPI) vs. chemotherapy in the 1st line among metastatic endometrial carcinoma (mEC) patients. dMMR, MSI status, and Tumor Mutational Burden (TMB) have been characterized as predictive biomarkers of ICPI response in many solid tumors, including mEC. We sought to evaluate ICPI vs. chemotherapy effectiveness in 1st line mEC, stratified by TMB ≥ 10 mut/MB and MSI as assessed by next-generation sequencing. **Methods:** Following a prespecified analysis plan, this study used the nationwide (~280 US cancer clinics) de-identified, EHR-derived, Flatiron Health-Foundation Medicine mEC clinico-genomic database (FH-FMI CGDB), with tissue CGP between 1/2011 - 6/2021. Cohort inclusion criteria: recurrent mEC patients with stage I-III at original diagnosis, 1st line ICPI or platinum chemotherapy treatment with TMB and MSI assessments available. Adjusted hazard ratios (aHR) from multivariable Cox proportional hazard models were utilized for time to next treatment (TTNT) and overall survival (OS) comparisons between 1L chemotherapy and 1L ICPI from start of 1L treatment stratified by TMB (≥ 10 vs. < 10) and adjusted for ECOG, BMI, and stage at diagnosis. **Results:** Among the 1st line cohort, patients received either Chemotherapy (n = 139, 87%) or first-line ICPI (n = 20, 13%). While the overlap between the TMB ≥ 10 (n = 46) population and MSI-H (n = 39) populations was high, with 38/46 (83%) of TMB ≥ 10 classified as MSI-H and 38/39 (97%) of MSI-H with a TMB ≥ 10, there were also 8 (17%) TMB ≥ 10 patients who were MSS. TMB ≥ 10 was associated with more favorable TTNT (aHR: 0.11 [0.03 - 0.44]) and OS (aHR: 0.1 [0.01 - 0.82]) on single-agent ICPIs vs. chemotherapy; however, TMB < 10 patients exhibited no observed differences in TTNT (aHR: 1.66 [0.79 - 3.48]) or OS (aHR: 1.79 [0.66 - 4.8]) between treatments. MSI-H pts were associated with more favorable TTNT (aHR: 0.1 [0.02 - 0.39]) and OS (aHR: 0.1 [0.01 - 0.86]) on single-agent ICPIs over chemotherapy; however, MSS pts did not observe differences in TTNT (aHR: 1.5 [0.65 - 3.5]) or OS (aHR: 2.14 [0.63 - 7.26]) between ICPI vs. chemotherapy. **Conclusions:** Recurrent 1st line mEC patients with TMB ≥ 10 and/or MSI-H exhibit more favorable outcomes on single-agent ICPI than standard chemotherapy in real-world settings. These findings warrant prospective randomized validation. Future studies should assess the utility of a combined biomarker approach across TMB and MSI status to identify the broadest group of patients who might benefit from ICPI. Impact of molecular features on outcome in African American or Black women with type 1 endometrial cancer. *First Author: Roy Khalife, Protean BioDiagnostics, Orlando, FL*

Background: Among women with endometrial cancer (EC), African American or Black (AAoB) population share a disproportionate burden of cancer deaths. Previous research exploring genetic and molecular explanations revealed White (W) women with EC are more likely to have mutations in PTEN, while AAoB women have higher rates of mutations in p53. However, these studies did not stratify EC by subtype, which occur at different rates among racial groups. Here, we aim to focus on molecular differences between racial groups, specifically in Type 1 EC (T1EC). **Methods:** Molecular data from TCGA Uterine Corpus Endometrial Carcinoma datasets on cBioPortal was used. Cancer type was filtered to Uterine Endometrioid Carcinoma Type 1 and separated by race. A total of 711 cases were analyzed for gene alterations, expression versus copy number variations, survival curves, and OncoPrints; significant findings and differences between racial groups were noted. The Surveillance, Epidemiology, and End Results (SEER) database was used to access the frequency, rate, and survival of AAoB and W with EC. **Results:** The genes analyzed on cBioPortal (575 W, 136 AAoB) depicted a similar alteration rate between the two groups, except for the most altered gene, PTEN (66% altered in W, 38% in AAoB). W women with a PTEN and PIK3CA alterations had significantly increased 5-year survival periods (P-value = 1.573e-3), while these alterations had no effect survival in AAoB. Six of the ten most altered genes between the two subgroups, and 6 of the 17 most actionable genes, were statistically significant for W but not for AAoB. SEER analyses depicted a frequency of 51,677 W and 3,915 AAoB, with a rate of 5.7% and 3.9%, respectively. The observed survival was 96.1% after 1 year and 85.6% after 5 years for W, compared to 92.8% after 1 year and 76.9% after 5 years for AAoB. **Conclusions:** Based on 5 years of data, overall survival (OS) rates among W women with T1EC are better than AAoB. PTEN mutation confers a survival advantage in W but not in AAoB, indicating that in AAoB, PTEN may play a different role or other factors may override the PTEN advantage. Additional analyses revealed non-remarkable findings, suggesting that molecular factors play a minor role in T1EC disparities or that a larger AAoB sample size is necessary. A better understanding of the downstream signaling pathways of common mutations in T1EC is necessary to further elucidate factors that contribute to racial disparities in T1EC. Stage 1 results of BrUOG 354: A randomized phase II trial of nivolumab alone or in combination with ipilimumab for people with ovarian and other extra-renal clear cell carcinomas (NCT03355976). *First Author: Don S. Dizon, Lifespan Cancer Institute and Brown University, Providence, RI*

Background: Clear Cell Carcinoma (CCC) outside the kidney is a rare tumor that can arise from multiple organs, including the ovary, endometrium and cervix. Extra-renal CCC is chemoresistant and has a poor prognosis. Data suggest that CCC of the gynecologic tract resembles the genomic profile of Renal Cell Carcinoma (RCC), which is responsive to immune checkpoint inhibition (ICI) therapy. We are conducting a two-stage phase 2 trial evaluating immunotherapy for extra-renal CCC. The primary objective is to assess overall rate of response (ORR); Progression-Free (PFS), Overall Survival (OS), and correlative biomarker studies are secondary. Here we present the results of Stage 1. **Methods:** This is a randomized two-stage non-comparative phase II study evaluating nivolumab (240mg IV every two weeks) alone (N) and in combination with ipilimumab (1mg/kg every six weeks, [N+I]) in patients with relapsed extra-renal CCC after at least one prior chemotherapy (no prior ICI), and measurable disease. Treatment was continued until disease progression or unacceptable toxicity. Stage 1 of this trial called for up to 30 volunteers (15 per arm) after which the study was closed. Consideration to reopen to stage 2 called for two or more responses in either arm. Here we present the completion of Stage 1; the release of results was approved by Brown University Oncology Group (BrUOG) Data Safety and Monitoring Committee. **Results:** Between July 2018 and October 2021, 30 patients were enrolled and 29 were treated (Table). The majority (83%) had CCC of the ovary (n=24). The ORR with N and N+I was 14.2 and 26.7%, respectively. The 6 month PFS rate was 19.1 and 43.8%; median PFS was 2.7 (95%CI 1.3-5.1) and 5.1 months (95%CI 0.9-NR), respectively. Grade ≥3 treatment-related toxicities occurred in 4 (28.6%) on N and 5 (33.3%) on N+I. There were no treatment-related deaths and no new safety signals. One volunteer enrolled on N+I stopped treatment after two years and remains in CR to date. **Conclusions:** Although sufficient activity was seen in CCC in both arms, the single-agent activity of N is similar to published reports in platinum-resistant epithelial ovarian cancer and decision made not to pursue it further. However, the combination of ipilimumab and nivolumab warrants additional investigation, and the second stage of this study will enroll 14 more patients to receive N+I. Clinical trial information: NCT03355976. Research Sponsor: Bristol Myers Squibb.

Best Response	Nivolumab (n, %) n=13*	Nivolumab + Ipilimumab (n,%) n=15
CR	0	3 (20)
PR	2 (15.4)	1 (6.7)
SD	3 (23.8)	6 (40)
PD	8 (61.5)	5 (33.3)

Immune phenotypes and T-cell density at the invasive margin correlate with prognosis in epithelial vulvar cancer. *First Author: Eike Burandt, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Tumor infiltrating lymphocytes (TILs) in the cancer microenvironment are of prognostic value in many solid tumors. However, only little is known about TILs infiltration and its predictive value in vulvar cancer. **Methods:** Immunohistochemistry and automated digital image analysis was applied to measure the densities of $CD3^+$ (DAKO, Santa Clara, US; #IR503) and $CD8^+$ (DAKO, Santa Clara, US; #IR623) TILs at the invasive margin (IM) and in the center of 530 vulvar carcinomas. **Results:** At the IM the mean immune cell density was significantly higher compared to the center of the tumor (CD3: 1772±1105, CD8: 769±644 cells/mm^2 vs. CD3: 518±570, CD8: 301±445 cells/mm^2, $p \leq 0.0001$). An elevated density of $CD3^+$ T-cell at the IM was significantly associated with low tumor stage ($p = 0.0012$). The 2-years OS and PFS rate was significantly different between the group with a high (OS: 82%, PFS: 65%), moderate (OS: 76%, PFS: 55%), or low $CD3^+$ T-cell density at the IM (OS: 64%, $p = 0.008$, PFS: 44%, $p = 0.02$). The prognostic impact of $CD3^+$ cells in the center of the tumor was weaker compared to the IM (OS $p = 0.046$, PPS $p = 0.031$) and lacking for $CD8^+$ T-cell densities at any location ($p \geq 0.14$ each). Unsupervised clustering of $CD3^+$ and $CD8^+$ T-cell densities identified three major subgroups corresponding to the immune desert (137 patients), immune excluded (220 patients) and immune inflamed phenotypes (133 patients). Survival analysis revealed a particular poor prognosis for the immune desert phenotype for OS (0.0071) and PFS (0.0027). **Conclusions:** This study demonstrates a prognostical relevance of the immunphenotype and the distribution of CD3+ T-cells in vulvar cancer. Their value for therapeutic decision making has to be determined in the future. Research Sponsor: None.

Racial differences in the mutational landscape of serous endometrial cancer. *First Author: Julian C. Schink, Cancer Treatment Centers of America, Part of City of Hope, Zion, IL*

Background: Tumor comprehensive genomic profiling (CGP) identifying genomic alterations (GA) that have diagnostic, prognostic and are potentially therapeutically targetable is essential to precision oncology. 2022 NCCN Uterine Neoplasm guidelines recommend tumor genetic evaluation as part of initial evaluation. As racial disparities in endometrial cancer outcomes have been widely reported, we analyzed our CGP results from a large series of serous endometrial cancer patients treated in a nationwide cancer network to identify GA differences that may contribute to worse prognosis and help inform better therapy selection. **Methods:** 86 Pts with serous endometrial underwent hybrid-capture based CGP for up to 324 cancer-related genes of archival tumor tissue or 62 genes on circulating tumor DNA ordered during clinical care for treatment decision-making between 01-2013 to 07-2021. Clinically relevant genomic alterations (CRGA) were defined as associated with targeted therapies or mechanism-driven clinical trials. Statistical analysis performed with Fisher Exact test comparing Black and White women. **Results:** Median age was 63 years (range, 38-85), 37% were White, 58% were Black and 5% were Asian. GA were identified in 94% (81/86) of these patients. TP 53 mutations which is characteristic of serous cancer were present in 80 of 86 patients (93%). GA predicted to activate PI3-Kinase pathway signaling (*PIK3CA, PIK3R1, PTEN*) were significantly more common in White women occurring in 13 of 32 (41%), compared with 8 of 50 (16%) of Black women ($p < 0.02$). An important, but not statistically significant trend of greater percentage of CCNE1 amplification in Black women is also noted, see table below: Mutation frequencies were similar between Black and White women for the following genes: *PPP2R1A* 23%; *MYC* 19%; *FBXW7* 14%; *ARID1A* 9%. **Conclusions:** In this 86 patient series of women with Serous Endometrial Cancer we note that PIK3CA mutations, an important resistance factor in anti-HER2 therapy, were significantly more common in White women (41%) compared with Black women (16%) ($p < 0.02$) and ERBB2 mutations occurred in 19% of White women and only 10% of Black women. This study cohort also identified a larger percentage of black women with CCNE1 amplification. Increased CCNE1 amplification has been linked to the racial disparities in cancer outcomes and may explain the disparities seen with endometrial cancers. Research Sponsor: None.

Surgical window-of-opportunity study of megestrol acetate compared with megestrol acetate and metformin for endometrial intraepithelial neoplasia. *First Author: Yanfei Xu, Northwestern University, Chicago, IL*

Background: Endometrial Intraepithelial Neoplasia (EIN) is a precursor lesion to endometrial carcinoma (EC), the most common gynecologic cancer among women in the US. The current standard of care for women with EIN is hysterectomy. Non-surgical treatments are needed for women desiring fertility preservation, and for those who are medically unfit for a major surgical procedure. Progestin therapy is the cornerstone of current nonsurgical management of EIN. However, approximately 30% of patients with EIN do not respond to progestin therapy, or respond incompletely. EIN is closely related to insulin resistance and metabolic syndrome with evidence that increased insulin resistance is a significant risk factor for development of EC. Metformin, an inhibitor of insulin/PI3K/AKT pathway, has been demonstrated to reduce endometrial proliferation *in vitro* and *in vivo*. We hypothesize that the combination of metformin and progestin therapy may synergize to arrest EIN progression and prevent the development of EC. **Methods:** This is a randomized pre-surgical window of opportunity study, comparing a commonly used oral progestin, megestrol acetate (MA), to MA and metformin (M). Patients with pathologically confirmed EIN or complex atypical hyperplasia (CAH) who present for hysterectomy will be approached. After enrollment, participants will receive MA 80mg PO BID ± M 500mg BID for 4 ± 1 weeks pre-operatively. Post-therapy endometrial biopsy will be obtained in the operating room prior to the hysterectomy, and compared to the pre-therapy diagnostic endometrial biopsy sample. The primary endpoint is the change in the percentage (%) of Ki-67 expressing cells (%Ki-67) between the pre- and post-treatment biopsies. Based on a two-sample *t*-test comparing the pre- to post-treatment changes in %Ki-67 between the two arms, a sample size of 21 patients per arm achieves 80% power with two-sided $\alpha = 0.05$ to detect an absolute reduction in %Ki-67 of 10% vs. 17.6% in the MA vs. MA + M arms. An interim analysis is planned after enrollment of 32 patients, and an internal pilot approach based on variance re-estimation will be used to increase the sample size if needed, to maintain the original planned power. Secondary endpoints will include comparison of changes in protein expression of ER, PR, PTEN/PAX2, markers of the PI3K/AKT/MTOR pathway, cell death and intratumoral insulin signaling. We will randomize 50 subjects at five sites: Northwestern University, Cedars-Sinai (Los Angeles), Duke University, University of Colorado, and University of North Carolina. Participants will be randomized 1:1 and stratified by menopausal status to ensure balance between the two arms. Since September 2021, four sites have opened and 22 patients have been pre-screened. Three participants were enrolled and two have completed intervention. The study is expected to complete accrual by the end of 2023. Clinical trial information: NCT04576104. Research Sponsor: U.S. National Institutes of Health.

TPS5602 **Poster Session**

A phase 1 adoptive cell therapy using drug-enhanced, tumor-infiltrating lymphocytes, DeTIL-0255, in adults with advanced malignancies. *First Author: Eugenia Girda, Rutgers Cancer Inst of New Jersey, New Brunswick, NJ*

Background: Tumor-infiltrating lymphocytes (TIL) are a heterogeneous population of T cells that recognize multiple endogenous tumor antigens but may have developed an exhausted phenotype due to the tumor microenvironment. While existing TIL therapies produce durable responses in patients with melanoma, cervical, and head and neck cancers, poor in vitro cell expansion, limited short-lived in vivo persistence, and diminishing potency restrict this approach's broader application. DeTIL-0255 (drug-enhanced TIL [DeTIL]) is an autologous adoptive cell therapy (ACT) derived from a patient's tumor and expanded *ex vivo* with NX-0255, a small-molecule inhibitor of the E3 ligase, Casitas B-lineage lymphoma proto-oncogene B (CBL-B). CBL-B is expressed in T cells, where it functions as a regulator of immune cell activation, in part by requiring CD28 co-stimulation in addition to T-cell receptor activation. Desirable properties enhanced by DeTIL-0255 when compared with TIL include increased number of stem-like CD39-/CD69-, and CD8+ T cells associated with persistence, as well as enhanced cytolytic function. ACT with T cells expanded *ex vivo* using NX-0255 demonstrated increased anti-tumor activity, longer survival, increased stem-like phenotype, and persistence of tumor antigen-specific T cells in mouse tumor models. Adoptive cell transfer of DeTIL-0255, therefore, may exhibit broader functional activity than conventional TIL, potentially conferring improved anti-tumor activity and response. **Methods:** NX-DeTIL-0255-201 is a Phase 1 multicenter, open-label study of DeTIL-0255 administered with systemic high-dose IL-2 following nonmyeloablative lymphodepleting chemotherapy in patients with advanced gynecological malignancies for whom standard therapy with proven clinical benefit does not exist, is no longer effective, or is inappropriate. The primary objectives are to evaluate the safety, tolerability, and preliminary antitumor activity of DeTIL-0255. A safety run-in will consist of 3 to 6 patients treated with DeTIL-0255 and evaluated for dose-limiting toxicity (DLT). The DLT period starts with DeTIL-0255 infusion and ends after a total of 28 days. The safety run-in will investigate DeTIL-0255 at a dose range of 1 to 150 x 109 CD3+ T cells (exact dose varying based on expansion potential of DeTIL-0255 from tumor biopsies). Following the safety run-in, cohort expansion will further evaluate the safety and antitumor activity of DeTIL-0255 in patients with recurrent/persistent platinum-resistant epithelial ovarian cancer, cervical carcinoma, and endometrial cancer. Key eligibility criteria include measurable disease, a resectable lesion for TIL harvest, ≥2 prior lines of therapy, and an Eastern Cooperative Oncology Group performance status 0 or 1. The study is expected to enroll ~54 patients in ~10 sites across the United States. Clinical trial information: NCT05107739. Research Sponsor: Nurix Therapeutics, Inc.

TPS5603 **Poster Session**

Trial in progress update on ENGOT-cx8/GOG-3024/innovaTV 205: Addition of a new cohort with first-line (1L) tisotumab vedotin (TV) + pembrolizumab (pembro) + carboplatin (carbo) ± bevacizumab (bev) in recurrent/metastatic cervical cancer (r/mCC). *First Author: Ignace Vergote, Belgium and Luxembourg Gynaecological Oncology Group (BGOG), Leuven Cancer Institute, and University Hospital Leuven, Leuven, Belgium*

Background: Despite the use of platinum-taxane doublets ± bev in eligible patients (pts), overall survival (OS) outcomes for pts with r/mCC remain poor. With the US approval of pembro + chemotherapy ± bev in the 1L setting for r/mCC with ≥1% of programmed death ligand 1–positive cells in the tumor, an unmet need remains for pts who do not meet this threshold and for pts who progress or are intolerant to standard treatment (tx). TV is a tissue factor–directed antibody–drug conjugate that has been granted accelerated approval in the United States for the tx of adults with r/mCC with disease progression on or after chemotherapy. To develop more effective treatments, we investigated TV in combination with agents with known activity in cervical cancer. We conducted a 2-part, multicohort phase 1b/2 trial, ENGOT-cx8/GOG-3024/innovaTV 205 (NCT03786081), to evaluate TV in combination with bev, pembro, or carbo. The phase 1b dose-escalation phase of innovaTV 205 established the recommended phase 2 dose (RP2D) and the feasibility of these doublet combinations (Monk et al, IGCS 2021). Moreover, we recently reported encouraging antitumor activity from the dose-expansion cohort of TV + carbo (1L; confirmed objective response rate [ORR], 55%; median duration of response [DOR], 8.3 mo) and TV + pembro (second-line; confirmed ORR, 38%; median DOR, 13.8 mo) (Vergote et al, ESMO 2021). The current report describes the design of a new, ongoing dose expansion cohort in the innovaTV 205 study to evaluate the combinations of TV, pembro, and carbo ± bev. **Methods:** A new cohort has been added to the innovaTV 205 study, comprising adult pts with recurrent or stage IVB squamous, adenosquamous, or adenocarcinoma of the cervix with no prior systemic therapy and an Eastern Cooperative Oncology Group score of 0 or 1. Pts will be treated with the RP2D of TV (2.0 mg/kg) + carbo (AUC 5 mg/mL), pembro (200 mg), and bev (15 mg/kg) every 3 weeks or with TV + carbo (AUC 5 mg/mL) and pembro (200 mg). To assess the regimen's initial tolerability, there will be a dose-limiting toxicity evaluation period that will consist of completion of 1 tx cycle of 21 days for 6 pts enrolled to receive the quadruplet combination. The primary endpoint of this dose expansion phase is confirmed ORR per RECIST v1.1; secondary endpoints include DOR, time to response, progression-free survival, OS, and safety. Enrollment is ongoing in the United States and Europe, with additional sites planned globally. Clinical trial information: NCT03786081. Research Sponsor: Genmab A/S and Seagen Inc. in collaboration with Merck & Co., Inc.

TPS5604 **Poster Session**

Randomized controlled trial of the efficacy of lymph node dissection on stage IIICr of cervical cancer (CQGOG0103). *First Author: Misi He, Chongqing University Cancer Hospital, Chongqing, China*

Background: In FIGO 2018, allowing assessment of retroperitoneal lymph nodes by imaging and/or pathological findings and, if deemed metastatic, the case is designated as stage IIIC (with r and p notations). Patients with lymph node metastases have lower overall survival (OS), progression free survival (PFS), and survival after recurrence, especially those who have unresectable macroscopically positive lymph nodes. Retrospective analysis suggests that there may be a benefit to debulking macroscopic nodes that would be otherwise difficult to sterilize with standard doses of radiation therapy. No prospective study reported that resecting macroscopic nodes before Concurrent chemoradiation therapy (CCRT) would improve PFS or OS of cervical cancer. The CQGOG0103 study is a national, prospective, multicenter and randomized clinical study evaluating lymph node dissection on stage IIICr of cervical cancer. **Methods:** Eligible patients are histologically confirmed cervical squamous cell carcinoma, adenocarcinoma, adeno-squamous cell carcinoma. Stage IIICr (confirmed by CT/MRI/PET/CT) and the short diameter of image-positive lymph node ≥15mm. 452 patients will be equally randomized to receive either CCRT (Pelvic EBRT/Extended-field EBRT + cisplatin (40mg/m2) or carboplatin (AUC = 2) every week for 5 cycles + brachytherapy) or Open/minimally invasive pelvic and para-aortic lymph node dissection followed by CCRT. Randomization is stratified by status of para-aortic lymph node. The primary endpoint is PFS. Secondary endpoints are OS and surgical complications. The sample size calculation of 346 patients provides 80% power to detect a difference in survival at the two-sided 5% significance level using the log-rank test, considering a 20% reduction, a total of 452 patients are required. This study began in January 2021 and will be accrued within 4 years. Enrollment is ongoing. Research Sponsor: None.

TPS5605 **Poster Session**

ROCC/GOG-3043: A randomized non-inferiority trial of robotic versus open radical hysterectomy for early-stage cervical cancer. *First Author: Kristin Leigh Bixel, The Ohio State University Wexner Medical Center and James Cancer Hospital, Columbus, OH*

Background: Minimally invasive surgery (MIS) is associated with improved perioperative safety outcomes, but, in 2018, the Laparoscopic Approach to Cervical Cancer (LACC) trial, a non-inferiority study comparing laparoscopic versus open radical hysterectomy for early stage cervical cancer, reported significantly worse disease-specific (DSS) and overall survival (OS) in the MIS group. Criticisms of the LACC trial include lack of proper preoperative imaging and assessment, use of transcervical uterine manipulators, and lack of proper tumor containment leading to peritoneal contamination. Subsequent retrospective studies have reported conflicting results. Given the potential benefit of MIS, the ROCC trial seeks to address the limitations of the LACC trial. **Methods:** ROCC is a multi-center, prospective, randomized, non-inferiority trial. The primary objective is to determine whether robotic-assisted (RBT) radical hysterectomy is not inferior to abdominal (OPEN) approach with respect to 3-year disease-free survival (DFS). Secondary objectives include DSS, OS, patterns of recurrence, peri- and postoperative complications, long-term morbidity, impact on patient-reported outcome (PRO) measures and development of lower extremity lymphedema (LEL). Key inclusion criteria include patients with histologically confirmed adenocarcinoma, squamous cell, and adenosquamous cell carcinoma of FIGO 2018 stage IA2-IB2. All patients must have a preoperative pelvic MRI confirming that the cervical tumor is < 4 cm in size, no obvious evidence of extracervical extension and no nodal or other regional metastasis. Intraoperatively, the use of transcervical uterine manipulators is not allowed and specific detailed surgical techniques for proper tumor containment is required. Photographic evidence of specimen with tumor contained is mandated. We estimate the 3-year DFS to be 92% in the control (OPEN) arm. If the DFS does not differ by more than 7% and the one-sided 95% CI does not cross the non-inferiority boundary, then the RBT arm will be deemed non-inferior. 840 patients will be enrolled (420 per arm, 89 events total), which provides 90% power to exclude an absolute decrease in DFS by 7% (HR < = 1.375) with a log-rank test for non-inferiority with a one-sided alpha of 0.05. The primary analysis will be conducted in all randomized patients (ITT). Given the LACC findings of worse oncologic outcomes with MIS, a formal DSMC will conduct periodic reviews of safety including two planned formal interim analyses for futility (harm) after accrual of 370 and 640 patients using an aggressive Lan-DeMets beta-spending function similar to a Pocock boundary. Results of this trial may be practice changing and will either support or refute the findings of the LACC trial. The study is currently activating sites for enrollment. Clinical trial information: NCT04831580. Research Sponsor: Intuitive Foundation, GOG Foundation.

TPS5606 **Poster Session**

Pivotal study of ofra-vec (VB-111) combined with paclitaxel versus paclitaxel for treatment of platinum-resistant ovarian cancer (OVAL, VB-111-701/GOG-3018). *First Author: Richard T. Penson, Harvard Medical School, Massachusetts General Hospital, Boston, MA*

Background: Ofranergene obadenovec (Ofra-vec, VB-111) is an anti-cancer gene based immune activator and targeted vascular disruptor. The dual mechanism of action triggers a broad antiangiogenic effect and induces of a tumor directed immune response. A phase II trial in patients with platinum resistant ovarian cancer (PROC) demonstrated that ofra-vec in combination with weekly paclitaxel was well tolerated and associated with a CA-125 Objective Response Rate (ORR) of 58%, a trend for improved survival and induction of an immunotherapeutic effect of tumor infiltration with CD-8 T cells. Based on these observations, a pivotal phase III study was initiated in collaboration with the GOG Foundation, Inc. **Methods:** Study NCT03398655 is an international, randomized, double-blind, placebo-controlled, phase III study. Eligible patients have recurrent PROC and may have been previously treated with up to 5 prior lines of therapy (but not >2 for PROC). Patient are randomized 1:1 to receive ofra-vec ($1x10^{13}$ Viral Particles) with weekly paclitaxel ($80mg/m^2$), or weekly paclitaxel with placebo. Randomization is stratified by number of prior treatment lines, prior antiangiogenic therapy and platinum refractory disease status. The dual primary endpoints are OS and PFS. A pre-planned interim analysis of CA-125 response (GCIG) performed by the DSMC met the pre-defined criteria showing that CA-125 ORR in the treatment arm was at least 10% higher than in the control arm. Study is enrolling in the US, EU, Japan and Israel, with 90% enrollment to date. Completion of accrual is anticipated in Q1 2022. Clinical trial information: NCT03398655. Research Sponsor: VBL therapeutics.

TPS5607 **Poster Session**

Frontline therapy of anlotinib combined with carboplatin/paclitaxel and maintenance anlotinib in patients with newly diagnosed advanced ovarian cancer: A phase II, single-arm, multicenter study. *First Author: Yi Jiang, Jiangsu Province Hospital, Nanjing, China*

Background: It has been reported that antiangiogenic drug combined with chemotherapy as first-line treatment, and subsequent antiangiogenic drug as maintenance therapy for ovarian cancer can achieve better clinical benefits. Anlotinib is a highly effective VEGFRs, FGFRs, PDGFRs and c-kit multi-target tyrosine kinase inhibitor which has been approved for the treatment of several solid tumors in China. This single arm, multicentric, phase II study is expected to investigate the efficacy and safety of anlotinib combined with carboplatin/paclitaxel as front-line treatment in patients with advanced ovarian cancer. **Methods:** Eligible patients with FIGO stage III–IV primary epithelial ovarian cancer, fallopian tube cancer, or primary peritoneal cancer and ECOG PS 0-1 undergo primary debulking surgery or interval debulking surgery, will receive 6-8 cycles of chemotherapy (paclitaxel 175 mg/m2 + carboplatin area under the curve [AUC] 5 q3w) and anlotinib (12 mg po qd, days 1-14, 21 days per cycle, anlotinib will be omitted from the first treatment cycle to prevent delayed wound healing). Anlotinib as maintenance monotherapy will be continue until disease progression, unacceptable toxicity, or death. Patients with prior anti-angiogenic therapy and major surgical procedure within 28 days before the first date of anlotinib therapy will be excluded. This study will recruit approximately 56 patients. The primary endpoint is progression free survival. Key secondary endpoints include overall response rate, disease control rate per RECIST1.1, overall survival, safety. The study began enrolling patients in August 2021 and is ongoing. Clinical trial information: NCT04807166. Research Sponsor: None.

TPS5608 **Poster Session**

SCOUT-1: Prospective non-interventional study in patients with *BRCA*/HRD-tested ovarian cancer (OC) eligible for first-line (1L) platinum-based chemotherapy (NOGGO ov54). *First Author: Pauline Wimberger, North-Eastern German Society of Gynecological Oncology (NOGGO) and Department of Gynecology and Obstetrics, University Hospital Carl Gustav Carus, TU Dresden, Dresden, Germany*

Background: Two third of patients with OC, have an advanced stage at initial diagnosis accompanied with poor prognosis. Results from landmark trials of maintenance therapy (MTX) with poly ADP ribose polymerase inhibitors (PARPi), especially in tumors associated with homologous recombination deficiency (HRD), like *BRCA*-mutated tumors, led to the strong recommendation on testing and treatment procedures in the clinical routine in patients newly diagnosed with advanced high-grade epithelial OC. The translation of these guidelines into clinical routine affects care management and therefore needs to be evaluated. This study aims to gain new insights into current real-world biomarker testing and 1L-treatment patterns together with clinical and patient-reported outcomes of patients with newly diagnosed advanced OC in Germany and to capture the influence of 1L treatment (with or without PARPi MTX) on medical routine and patient needs. **Methods:** SCOUT-1 is a national prospective, observational study (NCT04830709) to collect clinical real-world and patient-reported outcome (PRO) data in patients newly diagnosed with histologically confirmed advanced (FIGO stage III or IV) high-grade epithelial ovarian, fallopian-tube, or primary peritoneal cancer in Germany. Selection criteria include written informed consent, completed surgery (if applicable), eligible for platinum-based chemotherapy, *BRCA*1/2 mutation tested and willingness/ability to report PROs electronically. About 750 patients are planned to be included in up to 80 sites (hospitals or office-based). The primary objective is to determine the effectiveness of standard treatment sequences by estimating progression-free survival according to investigator's assessment. Further focus is to describe biomarker-testing algorithm, patient selection and to assess patients' QoL, symptoms, needs, as well as patients' expectations. Importantly, SCOUT-1 will help to collect long-term data as patients will be followed for up to 7 years. First-subject-was included in the study in June 2021. Study completion date is planned in Q2 2032. Research Sponsor: AstraZeneca, in cooperation with North-Eastern German Society of Gynecological Oncology (NOGGO e.V.).

TPS5609 **Poster Session**

ARTISTRY-7: A phase 3, multicenter study of nemvaleukin alfa in combination with pembrolizumab versus chemotherapy in patients (pts) with platinum-resistant epithelial ovarian, fallopian tube, or primary peritoneal cancer. *First Author: Thomas J. Herzog, University of Cincinnati, University of Cincinnati Cancer Institute, Cincinnati, OH*

Background: ARTISTRY-7 will evaluate the novel engineered cytokine nemvaleukin alfa (nemvaleukin, ALKS 4230) in pts with gynecologic cancers. Epithelial ovarian cancer (OC) is the 7th most common cause of cancer mortality in women. OC is an area of high unmet need, as many pts become resistant or refractory to frontline platinum-based chemotherapy. Nemvaleukin was designed to selectively bind to the intermediate-affinity interleukin-2 (IL-2) receptor, preferentially activating and expanding antitumor $CD8^+$ T and NK cells with minimal expansion of T_{regs}. This selectivity may provide enhanced tumor killing and improved safety/tolerability compared with high-dose IL-2. In clinical studies, nemvaleukin, as monotherapy and in combination with pembrolizumab, has shown evidence of clinical benefit in multiple tumor types, including OC. In ARTISTRY-1, 4 responses were observed in pts with OC, including 2 complete responses, 1 in a pt with platinum-resistant OC and 5 prior lines of therapy, and 2 partial responses. **Methods:** ARTISTRY-7 is a phase 3, multicenter, open-label randomized study of nemvaleukin and/or pembrolizumab vs chemotherapy. Eligible pts are women (≥18 y) with histologically confirmed epithelial OC (high-grade serous, endometrioid, clear cell), fallopian tube cancer, or primary peritoneal cancer. Pts must have received ≥1 prior line of systemic therapy in the platinum-sensitive setting, ≤5 prior lines in the platinum-resistant setting, and prior bevacizumab, with radiographic progression on most recent therapy. Primary platinum-refractory disease (progression on first-line platinum therapy) or primary platinum resistance (progression < 3 months after completion of first-line platinum therapy) is exclusionary. Pts must have ECOG performance status of 0 or 1, estimated life expectancy of ≥3 months, and adequate hematologic reserve and hepatic and renal function. Approximately 376 pts will be randomized (3:1:1:3) to receive nemvaleukin 6 μg/kg IV on days 1-5 and pembrolizumab 200 mg IV on day 1 of each 21-day cycle, pembrolizumab monotherapy, nemvaleukin monotherapy, or chemotherapy (pegylated liposomal doxorubicin, paclitaxel, topotecan, or gemcitabine) and stratified according to PD-L1 status, histologic subtype (high-grade vs non–high-grade serous), and chemotherapy (paclitaxel vs other). Pts will continue treatment until disease progression or intolerable toxicity (maximum 35 cycles for pembrolizumab; nemvaleukin can be continued). The primary endpoint is investigator-assessed PFS (RECIST v1.1) in the nemvaleukin/pembrolizumab vs chemotherapy group. Secondary/exploratory endpoints include overall survival, other antitumor measures, safety, health-related quality of life, and pharmacokinetic/pharmacodynamic effects. Clinical trial information: NCT05092360. Research Sponsor: Alkermes, Inc.

TPS5610 **Poster Session**

A single-arm, phase II study of niraparib and bevacizumab maintenance therapy in patients with platinum-sensitive, recurrent ovarian cancer previously treated with a PARP inhibitor: Korean Gynecologic Oncology Group (KGOG 3056)/NIRVANA-R trial. *First Author: Jung-Yun Lee, Department of Obstetrics and Gynecology, Institute of Women's Life Medical Science, Yonsei University College of Medicine, Seoul, South Korea*

Background: Given the expanding clinical use of poly(adenosine diphosphate [ADP]-ribose) polymerase inhibitors (PARPis), there is a significant need for optimal strategies with which to treat patients whose cancer progresses while using a PARPi. However, the treatment consensus after PARPi has not been established. The aim of the Korean Gynecologic Oncology Group (KGOG) 3056/NIRVANA-R trial is to investigate the efficacy of niraparib in combination with bevacizumab as a maintenance therapy in platinum-sensitive ovarian cancer patients who were previously treated with a PARPi. **Methods:** The KGOG 3056/NIRVANA-R is a multi-centre, investigator-initiated, single-arm, phase II trial of patients with platinum-sensitive recurrent ovarian cancer recruited from seven KGOG sites. This study included patients with platinum-sensitive recurrent epithelial ovarian cancer who received at least 2 previous courses of platinum-containing therapy and had been treated with a PARPi. Mucinous histology type was excluded. Patients who had responded to the last platinum regimen (either complete or partial response) were eligible to participate in this study. Forty-four patients will be recruited. All enrolled patients are treated with niraparib and bevacizumab for maintenance therapy until disease progression, unacceptable toxicity, or withdrawal of patient consent. The primary endpoint of the study is 6-month progression-free survival rate and 4 of planned 44 patients have been enrolled. Clinical trial information: NCT04734665. Research Sponsor: Takeda.

TPS5611 **Poster Session**

AGO-OVAR 2.29 (ENGOT-ov34): Atezolizumab in combination with bevacizumab and chemotherapy versus bevacizumab and chemotherapy in recurrent ovarian cancer (ROC). *First Author: Philipp Harter, AGO Study Group & Department of Gynecology and Gynecologic Oncology, Ev. Kliniken Essen-Mitte, Essen, Germany*

Background: Paclitaxel or pegylated liposomal doxorubicin in combination with bevacizumab constitutes a standard treatment option in patients with relapsed ovarian cancer who are not considered candidate for platinum, but responses are short-lived. Immune checkpoint inhibitors like atezolizumab as single agents have limited activity in ovarian cancer. There is a biologic rationale to combine checkpoint inhibitors with chemotherapy and bevacizumab, however, the role of such combination for the management of ovarian cancer is so far undefined. Because of the intimate relationship between angiogenesis and immunosuppression, it is expected that the inhibition of both pathways could lead to synergism and more durable clinical benefit. The addition of a chemotherapeutic agent is expected to lead to the release of tumor antigens and enhance the efficacy of immunotherapy in turn. Therefore, we aim to test the efficacy of atezolizumab in combination with non-platinum-based chemotherapy and bevacizumab vs the combination of a non-platinum-based chemotherapy and bevacizumab alone. **Methods:** AGO-OVAR 2.29 is a randomized (1:1), double blinded, phase III trial evaluating the efficacy and safety of atezolizumab plus bevacizumab and chemotherapy (weekly paclitaxel or pegylated liposomal doxorubicin) compared with placebo plus bevacizumab and chemotherapy in patients with recurrent ovarian, fallopian tube, or primary peritoneal cancer with 1st or 2nd relapse within 6 months after completing platinum-based chemotherapy or 3rd relapse. A de novo tumor biopsy to determine the PD-L1 expression status prior to randomization for stratification is mandatory. Patients are treated with chemotherapy plus bevacizumab + atezolizumab/placebo until progression or unacceptable toxicity. Co-primary endpoints are overall survival and progression-free survival. It is planned to randomize approximately 664 patients. Safety interim analyses were performed after inclusion of 24 and an additional 60 and 120 patients who had completed at least one treatment cycle. As of 09th February 2022, 461 patients have been randomized. Clinical trial information: NCT03353831. Research Sponsor: F. Hoffmann-La Roche Ltd.

TPS5612 **Poster Session**

AGO-OVAR 28/ENGOT-ov57: Niraparib versus niraparib in combination with bevacizumab in patients with carboplatin-taxane based chemotherapy in advanced ovarian cancer—A multicenter, randomized, phase III trial. *First Author: Florian Heitz, AGO Study Group & Ev. Kliniken Essen-Mitte, Essen, Germany*

Background: Standard of care chemotherapy in patients (pts) with advanced ovarian cancer (AOC) is the combination of carboplatin and paclitaxel. Data from the PRIMA trial has shown a significant benefit in pts by the addition of a maintenance treatment (MT) with niraparib irrespective of BRCA or HRD-status in high-grade ovarian cancers (OC). The PAOLA-1 trial evaluated MT in pts with AOC with the combination of olaparib and bevacizumab and has also shown a significant benefit compared to bevacizumab monotherapy. However, it is unclear if a PARP-inhibitor (PARPi) MT monotherapy is sufficient or if the addition of bevacizumab is needed. Therefore, we investigate, if the treatment strategy of carboplatin / paclitaxel / bevacizumab / PARPi is superior to the treatment of carboplatin / paclitaxel / PARPi in an all-comer population. **Methods:** AGO-OVAR 28/ENGOT-ov57 (NCT05009082; EudraCT Number: 2021-001271-16) is an Arbeitsgemeinschaft Gynäkologische Onkologie (AGO) Study Group led, international, multicenter, randomized, prospective phase III trial within the ENGOT trial network. The trial population is composed of adult pts with newly diagnosed, advanced high-grade epithelial OC, primary peritoneal cancer or fallopian tube cancer FIGO III/IV (except FIGO IIIA2 without nodal involvement). All pts should have completed the first cycle of chemotherapy (carboplatin and paclitaxel) as part of Study Run-In-Period. Prior to day1 of cycle2, pts with a valid central tumor BRCA (*tBRCA*) test result will be randomized 1:1 into either Arm1 and will receive 5 additional cycles of carboplatin and paclitaxel, q21d followed by niraparib for up to 3 years; or into Arm2 where pts will receive 5 additional cycles of carboplatin and paclitaxel plus bevacizumab, q21d followed by bevacizumab, q21d (for up to 1 year) and niraparib for up to 3 years. Patients who are scheduled for neoadjuvant chemotherapy and interval debulking surgery are also allowed to be included in the trial. The primary objective is progression free survival (PFS). Secondary objectives include but are not limited to: PFS according to *tBRCA*-status, overall survival, PFS2, safety and tolerability, and quality of life. The trial will start in Q1/2022 with First Patient First Visit expected in Q2/2022. It is planned to recruit 970 patients. Clinical trial information: NCT05009082. Research Sponsor: GlaxoSmithKline (GSK).

TPS5613 **Poster Session**

PERCEPTION: Phase II investigational study of pembrolizumab combination with chemotherapy in platinum-sensitive recurrent low-grade serous ovarian cancer— A NOGGO trial. *First Author: Jacek P. Grabowski, North-Eastern German Society of Gynaecological Oncology (NOGGO) and Department of Gynecology with Center for Oncological Surgery, Charité-University Medicine of Berlin, Campus Virchow Klinikum, Berlin, Germany*

Background: Low-grade serous ovarian cancer (LGSOC) represents a minority within the group of invasive epithelial ovarian malignancies. Recent analyses showed a very limited responsiveness to chemotherapy in LGSOC. Since bevacizumab many years ago, none other agents have been approved in LGSOC. There is a high demand of new therapy combinations with modern substances to improve the response rate and prognosis in this group of patients. Immune check-point inhibitors provide a new possibility which showed to be effective in different malignant diseases as well as in selected ovarian cancer patients. In this study, the standard chemotherapy is going to be combined with pembrolizumab in recurrent LGSOC cases with therapy free interval (TFI) over 6 months after last platinum-based chemotherapy. To the authors knowledge no comparable studies have been performed or planned. If our trial should show pembrolizumab effectivity in LGSOC, it would be a signal and impulse for future clinical studies in this rare disease. **Methods:** PERCEPTION/NOGGO-ov44 (NCT04575961) clinical trial is a multicenter, single-arm phase 2 study to evaluate pembrolizumab therapy concomitant to platinum-based chemotherapy (carboplatin plus pegylated liposomal doxorubicin, carboplatin plus gemcitabine or carboplatin monotherapy) and as maintenance in recurrent low-grade serous ovarian cancer cases. LGSOC patients with progression or recurrence at least six months after most previous platinum-containing therapy and in good general performance (ECOG 0 or 1) are eligible to participate in this clinical trial. The primary objective is the 12 months progression free survival (PFS) rate. Secondary end-points include overall survival, response rate (RR), PFS and RR according to Ki67 expression levels, time to first subsequent therapy (TFST) and its response, safety and quality of life. The trial is planned according to Simon's two-stage design with total sample size up to 33 patients. The null hypothesis is PFS-rate after 12 months of 20%. In the first phase 18 patients will be enrolled and if at least 5 patients show PFS after 12 months the study is going to be continued with an additional 15 patients. The trial is claimed successful, if at least 11 patients show PFS after 12 months. Assuming a true PFS-rate of 40%, this trial has 5% type I error rate and 80% power. Clinical trial information: NCT04575961. Research Sponsor: MSD Sharp & Dohme GmbH.

TPS5614 **Poster Session**

TEDOVA/GINECO-OV244b/ENGOT-ov58 trial: Neo-epitope based vaccine OSE2101 alone or in combination with pembrolizumab versus best supportive care (BSC) as maintenance in platinum-sensitive recurrent ovarian cancer with disease control after platinum. *First Author: Alexandra Leary, Gustave-Roussy Cancer Campus, Villejuif, and Groupe d'Investigateurs Nationaux pour l'Etude des Cancers Ovariens, Villejuif, France*

Background: Besides PARP inhibitors and bevacizumab, there are no approved maintenance therapies after platinum based chemotherapy for patients with a platinum sensitive relapsed epithelial ovarian cancer (OC). Immune checkpoint inhibitors (ICI) as single agents have limited activity in OC. One attractive strategy is to turn OC from immunogenic "cold" to "hot" tumors via vaccination with tumor-associated antigens (TAAs). OSE2101 is a multiple-neoepitope vaccine restricted to HLA-A2-positive patients (45% of OC patients) targeting 5 TAAs: TP53, MAGE2, MAGE3, CEA and HER2. These neo-epitopes are modified to increase both major histocompatibility complex and the T cell receptor binding affinity. The proof of concept for this approach was recently demonstrated with OSE2101 improving overall survival in a phase III trial in lung cancer progressing after ICI (Besse *et al.* 2021). The combination of OSE2101 with an ICI may most effectively harness anti-tumor immunity. **Methods:** TEDOVA is an international randomized open-label, phase II trial evaluating the benefit of maintenance by OSE2101 alone or in combination with PD1 inhibition (pembrolizumab) after platinum based chemotherapy in relapsed OC, previously treated with bevacizumab (if eligible) and a PARP inhibitor (if eligible). Patients (N=180) with CR/PR/SD at the end of chemotherapy are randomized (1:1:2) to: Observation/BSC (Arm A), OSE2101 alone (Arm B), or OSE2101 in combination with pembrolizumab (Arm C). Experimental treatments are continued until progression, or intolerance, for up to 2 years. The primary endpoint is progression-free survival (PFS). Secondary endpoints include overall response rate, safety, time to subsequent first or second treatment (TTST-1, TTST-2) and overall survival. 180 HLA-A*02 positive patients will be randomized. HLA-A*02 negative patients will be followed in a separate observational cohort. The sample size is calculated to provide 90% power to detect an improvement in PFS for Arm C vs Arm A with a HR of 0.57. Three one-sided Log-rank tests will be considered in a pre-defined sequence: H1: C (OSE2101+pembrolizumab) vs A (BSC); H2: C (OSE2101+pembrolizumab) vs B (OSE2101) and H3: B vs A. The type I error will be α=5%. The type II error will be β=10%. Tests will be one-sided. Status: The TEDOVA/GINECO-OV244b/ENGOT-ov58 trial is currently recruiting. Clinical trial information: NCT04713514. Research Sponsor: OSE Immunotherapeutics, Pharmaceutical/Biotech Company.

TPS5615 **Poster Session**

ENGOT-ov60/GOG-3052/RAMP 201: A phase 2 study of VS-6766 (RAF/MEK clamp) alone and in combination with defactinib (FAK inhibitor) in recurrent low-grade serous ovarian cancer (LGSOC). *First Author: Susana N. Banerjee, The Royal Marsden NHS Foundation Trust and Institute of Cancer Research, National Cancer Research Institute (NCRI), London, United Kingdom*

Background: Low-grade serous ovarian cancer (LGSOC) constitutes up to 10% of all ovarian cancer and has clinical and molecular characteristics distinct from high-grade serous ovarian cancer. Approximately a third of patients (pts) with recurrent LGSOC harbor KRAS mutations (mt) and pts with KRAS wild-type (wt) LGSOC may have mutations in NRAS, BRAF, or other RAS pathway-associated genes. Prior clinical studies with single agent MEK inhibitors have shown response rates of 16-26% in recurrent LGSOC. VS-6766 is a unique small molecule RAF/MEK clamp that inhibits both RAF and MEK activities by trapping them in inactive complexes. This mechanism of blockade has been shown to limit compensatory MEK activation, thereby potentially enhancing efficacy of MEK inhibition. Focal adhesion kinase (FAK) activation is a putative resistance mechanism to RAF and MEK inhibition, and defactinib, a small molecule inhibitor of FAK, has shown synergistic anti-tumor activity with VS-6766 in preclinical models, including organoids from LGSOC pts. Furthermore, FAK inhibition combined with VS-6766 induces tumor regression in a KRAS mt ovarian cancer xenograft model. The combination of VS-6766 and defactinib is currently being evaluated in the ongoing Investigator Sponsored FRAME study (NCT03875820). In this proof-of-concept study, durable objective responses (ORR = 46%; 11/24) have been reported in recurrent LGSOC pts, including pts who have had a prior MEK inhibitor (Banerjee ESMO 2021) and the combination of VS-6766 + defactinib has received FDA Breakthrough Therapy Designation for recurrent LGSOC. These initial preclinical and clinical results support the ongoing phase 2 ENGOT-ov60/GOG-3052 in recurrent LGSOC. **Methods:** This is an international phase 2, adaptive, multicenter, randomized, open label study designed to evaluate the efficacy and safety of VS-6766 vs VS-6766 in combination with defactinib currently open to enrollment (NCT04625270). The study will be conducted in two parts. Part A will determine the optimal regimen based on confirmed overall response rate (independent radiology review) in KRAS mt and KRAS wt LGSOC. Part B will determine the efficacy of the optimal regimen identified in Part A in KRAS mt and KRAS wt LGSOC. The minimum expected enrollment is 104 pts, 52 pts with KRAS mt and 52 KRAS wt (64 pts in Part A and 40 pts in Part B). Pts will be randomized to receive VS-6766 (4.0 mg orally (PO), twice weekly 3 wks on, 1 wk off) or VS-6766 with defactinib (VS-6766 3.2 mg PO, twice weekly + defactinib 200 mg PO BID 3 wks on, 1 wk off) till progression. Key inclusion criteria include histologically confirmed LGSOC, known KRAS mutation status, prior systemic therapy including platinum for metastatic disease and up to 1 prior line of MEK inhibitor therapy permitted. Part A of this study has completed enrollment and Part B is currently enrolling pts. Clinical trial information: NCT04625270. Research Sponsor: Verastem.

TPS5616 **Poster Session**

GRN300–001: Phase 1/1B evaluation of the safety, pharmacokinetics, and efficacy of GRN-300, a salt-inducible kinase inhibitor, alone and in combination with paclitaxel, in recurrent ovarian, primary peritoneal, and fallopian tube cancers. *First Author: Siqing Fu, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Salt-induced kinase 2 (SIK2) is a serine-threonine kinase that regulates centrosome splitting, activation of PI3 kinase and phosphorylation of Class IIa HDACs. SIK2 is overexpressed in 30% of ovarian cancers and associated with decreased progression-free survival (Ahmed et al., 2010). Treatment with GRN-300, an orally bioavailable small-molecule inhibitor of SIK2, was shown to improve the response to paclitaxel in human ovarian cancer cells grown in culture and in immunocompromised mice (Zhou et al., 2017). **Methods:** Part 1 of the study will evaluate the safety, MTD, RP2D (Recommended Phase 2 Dose), and PK of daily GRN-300 monotherapy. For the dose-escalation enrollment of patients with advanced solid tumors of any histology, four dose levels of GRN-300 are planned: 100, 200, 300, and 400 mg BID. Subsequently, GRN-300 will be administered at the determined RP2D in an ovarian cancer expansion cohort. Part 2 will evaluate the safety, PK, and preliminary clinical activity in an open-label study of the combination of GRN-300 and paclitaxel weekly x3. Paclitaxel will be administered in one of two different dosing levels: 60 mg/m2 initially, then dose escalated to 80 mg/m2. In the combination regimen, GRN-300 will be administered at the RP2D dose as determined in Part 1 of this study. The two dose findings will be conducted independently using the BOIN design (Liu 2015, Yuan 2016). Study drug may be administered per protocol for continuous 28-day cycles until disease progression, adverse events, or other criteria as described in the protocol. Tumor biopsies and blood plasma samples including peripheral blood mononuclear cells (PBMCs) will be collected for exploratory biomarker analysis to predict and to monitor responses to GRN-300 treatment. Major eligibility criteria At least 18 years of age. Recurrent or persistent, locally non-resectable or metastatic ovarian, primary peritoneal or fallopian tube epithelial cancer (advanced solid tumors of any other histology only for the monotherapy dose escalation enrollment in Part 1) In Part 2, diagnosis of recurrent or persistent, locally non-resectable or metastatic ovarian, primary peritoneal or fallopian tube epithelial cancer for which treatment with paclitaxel is indicated. Received at least one prior second-line treatment. The first 3 dose groups (100, 200, and 300 mg BID of GRN-300) have been completed without DLT and preliminary PK analysis indicate dose proportionality. Enrollment to dose group 4 (400 mg BID) began in February 2022. Clinical trial information: NCT04711161. Research Sponsor: GreenfireBio LLC.

TPS5617 **Poster Session**

ENGOT-ov65/KEYNOTE-B96: Phase 3, randomized, double-blind study of pembrolizumab versus placebo plus paclitaxel with optional bevacizumab for platinum-resistant recurrent ovarian cancer. *First Author: Nicoletta Colombo, University of Milan-Bicocca, European Institute of Oncology (IEO) IRCCS, Milan, Italy*

Background: Despite therapeutic advances in ovarian cancer, platinum-resistant recurrent ovarian cancer (PROC) remains an area of high unmet clinical need and there is an urgent need for new treatments to further improve clinical outcomes. Addition of bevacizumab to non-platinum-based chemotherapy significantly improved PFS in patients with PROC but did not show a clear OS benefit. Thus far, the combination of paclitaxel and bevacizumab has shown the most promise in treatment of PROC, although the proportion of patients eligible for bevacizumab is limited by treatment-associated toxicities. Combination of the anti-PD-1 antibody pembrolizumab with weekly paclitaxel showed antitumor activity and manageable toxicity in patients with PROC in a single-arm, phase 2 study (Wenham *Int J Gynecol Cancer* 2018). The current study ENGOT-ov65/KEYNOTE-B96 (NCT05116189) compares the efficacy and safety of the addition of pembrolizumab to standard of care chemotherapy (weekly paclitaxel) with/without bevacizumab vs placebo plus weekly paclitaxel with/without bevacizumab in patients with PROC. **Methods:** In this randomized, placebo-controlled, double-blind, phase 3 study, eligible patients are aged ≥18 y with histologically confirmed epithelial ovarian, fallopian tube, or primary peritoneal carcinoma with 1-2 prior lines of systemic therapy, including at least 1 prior platinum-based therapy with ≥4 cycles in first line. Patients must have platinum-resistant disease (radiographic evidence of PD ≤6 mo after last platinum-based therapy dose), be eligible for paclitaxel (with/without bevacizumab per investigator discretion), have ECOG PS ≤1, radiographically evaluable disease per RECIST v1.1, and have a tumor sample for central evaluation of PD-L1 status. Approximately 616 patients will be randomized 1:1 to receive pembrolizumab 400 mg IV or placebo Q6W for up to 18 cycles (~2 y) plus paclitaxel 80 mg/m^2 on days 1, 8, and 15 of each Q3W cycle (with/without bevacizumab 10 mg/kg Q2W per investigator discretion) until PD or unacceptable toxicity. Randomization is stratified by planned bevacizumab use (yes vs no), region (US vs Europe vs rest of world), and PD-L1 status (combined positive score [CPS] < 1 vs CPS 1- < 10 vs CPS ≥10). Tumor PD-L1 status is determined using the PD-L1 IHC 22C3 pharmDx (Investigational Use Only) diagnostic kit. Tumor imaging is performed Q9W from randomization to week 54 and Q12W thereafter. The primary endpoint is PFS per RECIST version 1.1 by investigator review in patients with tumor PD-L1 CPS ≥1 and in all patients. Secondary endpoints are OS in patients with tumor PD-L1 CPS ≥1 and in all patients, PFS per RECIST version 1.1 by blinded independent central review in patients with tumor PD-L1 CPS ≥1 and in all patients, safety, and patient-reported outcomes. Enrollment is ongoing. Clinical trial information: NCT05116189. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS5618 **Poster Session**

A randomized phase II trial of mirvetuximab soravtansine (IMGN853), in folate receptor alpha (FRα)-high recurrent ovarian cancer eligible for platinum-based chemotherapy. *First Author: Fabian Trillsch, University Hospital LMU Munich, Munich, Germany*

Background: Despite radical primary surgery and carboplatin/paclitaxel-based chemotherapy in combination with anti-angiogenic bevacizumab and/or PARP inhibitors (PARPi), most patients (pts) with advanced ovarian cancer (OC) will relapse. Following the implementation of these targeted therapies to first-line treatment, repeated use of bevacizumab and/or PARPi is often not approved nor has conclusively been proven efficacious for all pts with recurrent OC. New combination partners for platinum-based chemotherapy remain important to improve outcome. The antibody-drug conjugate Mirvetuximab soravtansine (MIRV) is comprised of a folate receptor alpha (FRα)-binding antibody, cleavable linker, and the maytansinoid DM4, a potent tubulin-targeting agent. Results from the phase III trial FORWARD I revealed in an exploratory analysis that pts with high FRα expression following PS2+ Scoring (cut off: ≥75% of tumor cells with FRα membrane staining and ≥ 2+ intensity) had significant progression-free survival (PFS) improvements with a hazard ratio of 0.55 compared to mono-chemotherapy (median PFS 5.6 vs 3.2 months, P=0.015) and high activity was most recently confirmed in the SORAYA trial with an overall response rate (ORR) of 32.4%. Preliminary data for the combination of MIRV with carboplatin exist from the Phase 1b FORWARD II trial, which resulted in an ORR of 71%, observed in 17 pts with a median PFS of 15 months, and an ORR of 80% in the FRα medium/high (>50% PS2+) subset of 10 pts. MIRV is well-tolerated with a manageable safety profile. **Methods:** Eligible pts for this multicenter, randomized, two-arm, open-label, comparative phase II trial must have recurrent, FRα high epithelial cancer of the ovary, fallopian tube or peritoneum and have measurable disease. Pts are eligible for platinum-based chemotherapy with a platinum-free interval of more than 3 months and had at least one prior chemotherapy, but are not candidates to receive bevacizumab for the current relapse. Pts can be included irrespective of wildtype BRCA1/2 mutation status, pts with a deleterious mutation are required to have received prior PARPi therapy. Following pre-screening for high FRα expression in FFPE tumor tissue according to PS2+ scoring, 136 pts are randomized (1:1) to: a) Control arm: Platinum-based combination chemotherapy (for 6 cycles) followed by PARPi if indicated or standard of care or b) Experimental arm: Carboplatin + MIRV 6 mg/kg adjusted ideal body weight (AIBW) IV d1 (6 cycles q21d) followed by MIRV monotherapy 6 mg/kg AIBW IV q21d until disease progression. The primary endpoint of PFS will be assessed by modified RECIST 1.1. Key secondary endpoints include overall survival, ORR, and quality of life. Enrollment started in September 2021. Clinical trial information: NCT04274426. Research Sponsor: ImmunoGen.

TPS5619 **Poster Session**

FLORA-5/GOG3035: Frontline chemo-immunotherapy (paclitaxel-carboplatin-oregovomab [PCO] versus chemotherapy (paclitaxel-carboplatin-placebo [PCP]) in patients with advanced epithelial ovarian cancer (EOC)—Phase III, double-blind, placebo-controlled, global, multinational study. *First Author: Angeles Alvarez Secord, Duke Cancer Institute, Duke University Medical Center, Durham, NC*

Background: Oregovomab, a murine IgGκ1 monoclonal antibody, has high affinity binding to tumor associated antigen CA125, thus, rendering the target antigen CA125 more immunogenic or "neoantigen-like" through altered and enhanced antigen processing and presentation to specific T cells. This phenomenon is hypothesized to bypass tumor-associated immune suppression when oregovomab is combined with chemotherapy. In a randomized phase II study, oregovomab in combination with paclitaxel and carboplatin (PC) induced tumor immunity and demonstrated significant improvement in median PFS (41.8 months(m) PCO vs 12.2 m PC, HR 0.46, p=0.0027) and median OS (N.E. PCO vs 43.2 m PC, HR 0.35, p=0.043) in patients with previously untreated EOC. Oregovomab combined with PC had a favorable toxicity profile. FLORA-5/GOG3035, the definitive confirmatory global registration trial, is currently recruiting patients in the front-line setting. **Methods:** The study is a phase 3, multicenter, double-blind, placebo-controlled trial. Optimally debulked patients with FIGO III/IV EOC and serum CA125 ≥ 50 U/ml receiving adjuvant (Cohort 1) or patients receiving neoadjuvant chemotherapy post-interval cytoreductive surgery (Cohort 2) will be randomized to PC + oregovomab or placebo (PCO vs. PCP). Patients with germline *BRCA1/2* mutations are excluded. Chemotherapy will be administered every 3 weeks in both cohorts. Oregovomab/placebo is administered simultaneously at cycles 1, 3, and 5 of chemotherapy with an additional dose at 12 weeks following cycle 5 in Cohort 1. Neoadjuvant patients will be administered oregovomab/placebo after debulking surgery at cycles 4 and 6 with two additional doses at 6- and 18-weeks following cycle 6 in Cohort 2. No other front-line maintenance therapy is permitted. The primary objective is PFS determined by RECIST 1.1. Cohort 1 will recruit 372 patients with a 90% power to detect a difference with an alpha of 0.025 and a hazard ratio of 0.65 when 252 PFS events have been observed. Cohort 2 will be analyzed separately recruiting 232 patients with a 90% power to detect a difference with an alpha of 0.025 and a hazard ratio of 0.60 when 165 PFS events have been observed. An interim futility analysis will be performed. Secondary objectives include OS, frequency and severity of AEs, and QoL. Exploratory objectives include iRECIST, TFST, TSST, PFS2, and evaluation of correlative biomarkers. The study is actively enrolling in the US, Canada, Belgium, Italy, Spain, Czech Republic, Hungary, Poland, Korea, Taiwan, Mexico, Argentina, and Chile. 179 patients were enrolled at time of submission. Clinical trial information: NCT04498117. Research Sponsor: OncoQuest Pharmaceuticals, Inc.

TPS5620 **Poster Session**

ROSELLA: A phase 3 study of relacorilant in combination with nab-paclitaxel versus investigator's choice in advanced, platinum-resistant, high-grade epithelial ovarian, primary peritoneal, or fallopian-tube cancer. *First Author: Alexander Olawaiye, University of Pittsburgh, Pittsburgh, PA*

Background: Chemotherapy resistance is a major concern in the treatment of advanced platinum-resistant and platinum-refractory ovarian cancer. One mechanism of resistance is driven by cortisol, which can suppress the apoptotic pathways that chemotherapy agents rely upon, eg, suppression of BCL2 and FOXO3a pathways. Preclinical and clinical data indicate that glucocorticoid receptor (GR) antagonism may reverse the anti-apoptotic effects of cortisol, thereby restoring the efficacy of cytotoxic agents. Relacorilant is a selective GR modulator that has shown promise in overcoming resistance when combined with taxanes (particularly nab-paclitaxel) in preclinical models (Greenstein & Hunt 2021) and early-phase clinical studies (Munster et al. 2019) in various solid tumors. A randomized, controlled phase 2 study of relacorilant + nab-paclitaxel found clinically meaningful improvements in progression-free survival (PFS) and duration of response (DOR) without increased side effect burden in patients with recurrent, platinum-refractory and platinum-resistant ovarian cancer (Colombo et al. 2021). The aim of this phase 3 study is to confirm these phase 2 findings in a larger patient population. **Methods:** ROSELLA (EudraCT 2022-000662-18, NCT pending) is a phase 3, randomized, 2-arm, open-label, multicenter study of relacorilant + nab-paclitaxel compared to investigator's choice of chemotherapy agents in patients with confirmed high-grade serous epithelial ovarian, primary peritoneal, or fallopian tube cancer. The trial is being conducted at multiple sites in North America and Europe and has a planned enrollment of 360 patients. Patients are randomized 1:1 to either relacorilant (150 mg the day before, day of, and day after nab-paclitaxel infusion) + nab-paclitaxel (80 mg/m^2 on days 1, 8, and 15 of each 28-day cycle) or investigator's choice of chemotherapy (liposomal doxorubicin, paclitaxel, topotecan, or nab-paclitaxel). Randomization is stratified by prior lines of therapy (1 vs > 1), region of world (North America vs Europe), and prior bevacizumab (yes/no). Adult female patients with platinum-resistant disease (progression within 6 months of completion of platinum-containing therapy), excluding patients with primary platinum refractory disease, who have received 1–3 lines of prior systemic anticancer therapy and at least 1 prior line of platinum therapy are being enrolled. Life expectancy ≥3 months, adequate organ function, and ECOG performance status of 0 or 1 are required. The primary study endpoint is PFS by blinded independent central review. Key secondary endpoints include overall survival, PFS by investigator, overall response rate, best overall response, DOR, clinical benefit rate, safety, quality of life, CA-125, pharmacodynamics, and pharmacokinetics. Clinical trial information: 2022-000662-18. Research Sponsor: Corcept Therapeutics.

TPS5621 **Poster Session**

OZM-114: Phase Ib expansion study of CX-5461in patients with solid tumors and *BRCA2* and/or *PALB2* mutation. *First Author: Husam Alqaisi, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Pre-clinical and clinical data demonstrate that CX-5461 selectively kills HR deficient cancer cells through stabilizing G4 structures and inducing replication-dependent DNA damage. Phase 1 studies suggest CX-5461 has clinical activity and warrants further investigation in HR-deficient tumors, including those with pathogenic *BRCA2* and *PALB2* mutation. The recommended phase 2 dose (RP2D) requires further refinement to establish the chronic tolerable dose for further phase 2 trials, particularly regarding the incidence of ocular toxicity. The doses of 325mg/m2 and 250mg/m2 were selected for this study expansion cohorts because it is well within the efficacy range and below the first occurrence of ocular toxicity in a previous study. **Methods:** This is an open-label, multi-center, phase 1b study designed to determine a tolerable dose of CX-5461 in patients with ovarian, pancreatic, prostate, and breast cancers for Phase II trials. Eligible patients will be enrolled into two cohorts: A) Main cohort (target accrual: 32 patients) and B) Exploratory cohorts (target accrual: 20 patients), see table-1 below. The primary outcomes include assessment of: 1) Safety and tolerability of CX-5461, in particular to determine late onset ocular toxicity 2) Anti-tumor activity of CX-5461 in patients with solid tumors and germline *BRCA2* and/or *PALB2* mutation, and 3) Effect of CX-5461 on Quality of Life measures. Secondary outcomes include evaluation of :1) Safety: CTCAE v 5.0, SAEs, dose modifications due to AEs, 2) Activity: best overall response from tumor evaluations performed every 2 cycles, according to RECIST v1.1, and duration of response., and 3) patient-reported outcomes: PRO (PRO-CTCAE v1.0 questionnaires to evaluate cutaneous, gastrointestinal, visual/perceptual, cardio/circulatory, sleep/wake and miscellaneous symptoms. Exploratory Objectives include assessment of: 1) anti-tumor activity of CX-5461 in patients with ovarian cancer and pathogenic/likely-pathogenic *BRCA1* mutation and/or other HRD-associated somatic mutation, and 2) molecular profile of tumors and predictive value of mutational signatures in predicting response or resistance to CX-5461. Clinical trial information: NCT04890613. Research Sponsor: Senhwa Biosiences.

STRO-002-GM2: A phase 1, open-label, safety, pharmacokinetic, and preliminary efficacy study of STRO-002, an anti-folate receptor alpha (FolRα) antibody-drug conjugate (ADC), in combination with bevacizumab in patients with advanced epithelial ovarian cancer (EOC, including fallopian tube or primary peritoneal cancers). *First Author: R. Wendel Naumann, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: STRO-002 is a novel FolRα targeting ADC, generated using cell-free antibody production and site-specific conjugation technology. STRO-002 demonstrates potent *in vitro* cytotoxicity in EOC cell lines and anti-tumor activity in xenograft models, including induction of immunogenic cell death. STRO-002 is currently being studied as a single agent in ovarian and endometrial cancer (Phase 1 Study STRO-002-GM1; NCT03748186). Preliminary efficacy data in relapsed/progressive platinum resistant EOC compared favorably to standard chemotherapy (Naumann W., *et al*, ASCO 2021). Pre-clinical models tested with STRO-002/bevacizumab combinations demonstrated additive anti-tumor activity compared to monotherapy. This study is a first in human study of STRO-002 plus bevacizumab in patients with advanced ovarian cancer that have progressed on standard therapy. **Methods:** STRO-002-GM2 is a Phase 1, open-label, multicenter, dose escalation study with a standard 3+3 design with a 21-day dose-limiting toxicity (DLT) assessment period followed by dose expansion. The study will assess safety, establish recommended phase 2 dose (RP2D), and preliminary efficacy of STRO-002/bevacizumab combination in patients with recurrent high-grade EOC. Bevacizumab will be administered at the labeled dose of 15 mg/kg given with STRO-002 starting at 3.5 mg/kg, both administered IV q 3 weeks. Planned dose escalation doses of STRO-002 include 3.5, 4.3, and 5.2 mg/kg and will continue until MTD/MAD is reached. Additional intermediate dose level cohorts may be added for RP2D optimization. Once a cohort is cleared per dose escalation rules, up to 10 additional subjects may be enrolled and treated at that cleared dose level in order to obtain additional safety and efficacy data for RP2D determination and ungating of the expansion stage. Dose expansion will enroll approximately 40 patients treated at the RP2D. The patient population is relapsed high-grade EOC with up to 4 prior regimens. Subjects with primary platinum refractory disease will be enrolled in dose escalation only. Key inclusion criteria include: measurable disease, adequate bone marrow and renal function. Key exclusion criteria include: contraindication to receive bevacizumab and prior treatment with a FolRα ADC or ADC containing a tubulin inhibitor. Efficacy evaluation is per RECIST v1.1. Tumor tissue (archival or fresh biopsy) is required. Study oversight includes a Safety Evaluation Team. Samples will be collected to assess the PK and immunogenicity. No formal statistical hypothesis testing will be conducted in this study. This study is currently open for enrollment in the U.S. Clinical trial information: NCT05200364. Research Sponsor: Sutro Biopharma.

TPS5623 **Poster Session**

KEYNOTE-C93/GOG-3064/ENGOT-en15: A phase 3, randomized, open-label study of first-line pembrolizumab versus platinum-doublet chemotherapy in mismatch repair deficient advanced or recurrent endometrial carcinoma. *First Author: Brian M. Slomovitz, Division of Gynecologic Oncology, Mount Sinai Medical Center, Miami Beach, FL*

Background: Carboplatin-paclitaxel chemotherapy (with trastuzumab for HER2+ uterine serous carcinoma) is the standard of care first-line systemic treatment for recurrent or metastatic endometrial carcinoma (EC), which has a 5-year relative survival rate of only 17%. Worse survival outcomes have been shown for the mismatch repair deficient (dMMR) subtype of EC. Pembrolizumab (pembro), an anti-PD-1 antibody, showed compelling antitumor activity in previously treated, advanced MSI-H/dMMR EC in the phase 2 KEYNOTE-158 study (ORR, 48%; median duration of response [DOR], not reached; O'Malley *JCO* 2022). KEYNOTE-C93/GOG-3064/ENGOT-en15 (NCT05173987) is a phase 3, randomized, open-label study evaluating first-line pembro versus carboplatin-paclitaxel chemotherapy in patients with dMMR advanced or recurrent EC. **Methods:** Patients aged ≥18 years with histologically confirmed stage III/IV recurrent EC including carcinosarcoma (mixed Mullerian tumor), radiographically evaluable disease (measurable or nonmeasurable per RECIST v1.1), no prior systemic therapy (prior radiation with or without radiosensitizing chemotherapy > 2 weeks before first dose or prior hormonal therapy ≥1 week before randomization is permitted), and an ECOG PS ≤1 are eligible. Patients must have central confirmation of dMMR status. Approximately 350 patients will be randomized 1:1 to receive pembro 400 mg IV Q6W for 18 cycles (~2 years) or carboplatin AUC 5 or 6 mg/mL/min IV Q3W and paclitaxel 175 mg/m^2 IV Q3W for 6 cycles (with option for > 6 cycles). Trastuzumab is permitted for patients in the chemotherapy arm with HER2+ serous EC. Randomization is stratified by disease status (newly diagnosed advanced EC vs recurrent EC) and histology (endometrioid vs nonendometrioid). Treatment will continue for the specified number of cycles or until PD or unacceptable toxicity. Patients in the chemotherapy arm have the option to receive pembro following confirmed PD by blinded independent central review (BICR). Tumor imaging will be performed Q9W from randomization to week 54 and Q12W thereafter. AEs will be assessed from randomization to 30 days (90 days for serious AEs) after treatment discontinuation and graded per NCI CTCAE version 5.0. Dual primary endpoints are PFS per RECIST v1.1 by BICR and OS. Secondary endpoints are ORR, disease control rate, and DOR per RECIST v1.1 by BICR; PFS per RECIST v1.1 by investigator review; PFS2 (ie, time from randomization to PD per investigator assessment or death from any cause after start of subsequent anticancer therapy); safety; and patient-reported outcomes. PFS and OS will be estimated by the Kaplan-Meier method, with treatment differences assessed by the stratified log-rank test and HRs with 95% CIs determined using a Cox proportional hazard model. Enrollment is ongoing. Clinical trial information: NCT05173987. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS5624 **Poster Session**

Trial in progress: Phase II activity trial of high-dose radiation and chemosensitization in patients with macrometastatic lymph node spread after sentinel node biopsy in vulvar cancer: Groningen International Study on Sentinel Nodes in Vulvar Cancer III (GROINSS-V III/NRG-GY024). *First Author: Lilian T. Gien, Sunnybrook Odette Cancer Centre, Toronto, ON, Canada*

Background: Early stage invasive squamous cell carcinoma of the vulva is treated by radical excision of the primary tumor combined with a sentinel node (SN) procedure for the groins. GROINSS-VI and GOG-173 demonstrated that if there is no metastasis to the SN, then standard of care is observation. GROINSS-VII/GOG-270 demonstrated that micrometastatic disease (<2mm) to the SN requires standard radiotherapy (50 Gy) without the need for an inguinofemoral lymphadenectomy (IFL). This study also found that patients with macrometastasis (> 2mm) required IFL in order to have an acceptably low groin recurrence rate. However, IFL is associated with significant morbidity such as lymphedema, wound healing issues, and recurrent infections. It is hypothesized that for those with macrometastasis (> 2 mm) in the SN, the efficacy of treatment can be increased by giving a higher dose of radiotherapy along with chemosensitization. **Methods:** This is an international multicenter single-arm phase II prospective clinical trial. The primary objective is to investigate the safety of replacing IFL by chemoradiation in early-stage vulvar cancer patients with a macrometastasis (> 2mm) and/or extracapsular extension in the SN. The primary endpoint is the groin recurrence rate in the first two years after primary treatment. Secondary endpoints are short and long-term morbidity associated with the SN procedure and chemoradiation and quality of life as measured by EORTC-QLQc30. Patients with invasive (> 1mm) squamous cell carcinoma of the vulva, stage T1, tumor size < 4 cm diameter and no suspicious lymph nodes by imaging of the groins will proceed with SN detection. Institutions enrolling patients must demonstrate prior surgical experience with SN detection with the submission of at least 10 successfully completed cases in vulvar cancer. Patients with SN metastases > 2mm and/or with extracapsular extension or those with > 1 SN with micrometastases will be eligible for this study. Treatment will consist of chemoradiation with a dose of 56 Gy to the groin combined with weekly cisplatin 40 mg/m2 IV on days 1, 8, 15, 21 and 29 of radiotherapy. One hundred and fifty-seven patients in Europe, United States and Canada will be enrolled. The study includes continuous monitoring of groin recurrences with stopping rules. Results of this trial may be practice changing and eliminate the need for IFL in all women with clinically early stage vulvar cancer. The study is currently open for enrollment. Clinical trial information: NCT05076942. Research Sponsor: Dutch Cancer Society, U.S. National Institutes of Health.

Radiotherapy alone versus concurrent chemoradiotherapy in intermediate risk nasopharyngeal carcinoma: A multicentre, open-label, noninferiority, randomised phase III trial. *First Author: Jun Ma, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: The benefit of concurrent chemotherapy to treat intermediate-risk (stage II and T3N0M0) nasopharyngeal carcinoma (NPC) remains controversial. We aimed to assess whether concurrent chemotherapy can be omitted safely for intermediate-risk NPC patients treated with intensity-modulated radiotherapy. **Methods:** This multi-centre, noninferiority, open-label, randomised controlled, phase III trial was done at 4 hospitals in China. Patients aged 18–65 years, with histologically confirmed, stage T1-2N1/T2-3N0M0, a Karnofsky score of at least 70 were randomly assigned (1:1) to receive either concurrent chemoradiotherapy (CCRT) (cisplatin 100 mg/m^2 on days 1, 22, and 43) or radiotherapy alone (RT). Key exclusion criteria included: maximal axial diameter of neck lymph node ≥30mm, positive neck lymph node at level IV or lower, pretherapy plasma EBV DNA level ≥4000 copy/ml. Randomisation was performed with a random number code stratified by treatment centre and stage. The primary endpoint was failure-free survival （FFS) .The calculated sample size was 169 per group, with an 80% power (one-sided α 0.05). **Results:** Between November 11, 2015 and August 4, 2020, 341 NPC patients were randomly assigned to receive either RT (n=172) or CCRT （n=169). After a median follow-up of 41 months, intention-to-treat analysis showed that 3-year FFS was 90.7% (95% CI 86.2–95.2) in the RT group, and 92.1% (95%CI 88.8–96.4) in the CCRT group, with a difference of -1.4% (upper limit of the one-sided 95% CI 4.5; $p_{non\text{-}inferiority}$=0.00017). Similarly excellent FFS was found in the per-protocol analysis: 3year FFS for RT versus CCRT was 90.3% (95% CI 85.6–95.0) and 92.1% (95% CI 87.8–96.4), respectively, with a difference of -1.8% (upper limit of the one-sided 95% CI 4.3; $p_{non\text{-}inferiority}$=0.00014). No differences were observed between groups in terms of overall survival, locoregional relapse and distant metastasis. Patients in the CCRT group developed significantly more grade 3-4 hematologic and nonhematologic adverse events such as vomiting (CCRT group 14.8% vs. RT group 1.2%), anorexia (29.9% vs. 4.8%), mucositis (18.9 % vs. 9.7%) and weight loss(4.7% vs. 0.6%) . No patients died from treatment-related causes. **Conclusions:** Radiotherapy alone provides comparable disease control or survival and less toxicity compared to CCRT in the intermediate risk NPC. Clinical trial information: NCT02633202. Research Sponsor: Sun Yat-sen University Clinical Research 5010 Program.

	RT group(%)	CCRT group (%)	P value
Intention-to-treat population	n = 172	n = 169	
3-yr overall survival	98.7	99.4	0.178
3-yr distant metastasis-free survival	95.6	98.1	0.136
3-yr locoregional recurrence-free survival	94.4	93.9	0.975
Per-protocol population	n = 165	n = 169	
3-yr overall survival	98.7	99.4	0.159
3-yr distant metastasis-free survival	95.4	98.1	0.118
3-yr locoregional recurrence-free survival	94.2	93.9	0.890

Nimotuzumab plus chemoradiotherapy versus placebo plus chemoradiotherapy in patients with locally advanced nasopharyngeal carcinoma (NPC): A prospective, randomized-controlled, double-blinded, multicenter phase III clinical trial. *First Author: Yan Sun, Beijing Cancer Hospital, Beijing, China*

Background: Epidermal growth factor receptor (EGFR) is highly expressed in most NPC, and it is also an essential factor of prognosis for NPC. nimotuzumab is a humanized anti-EGFR monoclonal antibody. Retrospective clinical studies showed that nimotuzumab combined with chemo-radiotherapy had better survival benefits in locally advanced NPC. The present study is a confirmatory study that aims to assess the clinical efficacy of long-term survival and safety of nimotuzumab combined with chemo-radiotherapy in locally advanced NPC patients. **Methods:** Patients with locally advanced NPC were randomized (3:1) to receive nimotuzumab (200 mg, weekly, 7-8 weeks) plus chemo-radiotherapy (Arm A) versus chemo-radiotherapy (intensity-modulated radiation therapy or conventional radiotherapy, cisplatin100mg/m^2/d, 21days/cycle, three cycles) plus placebo (Arm B) as front-line therapy. The primary endpoint was a 5-year OS rate, and the secondary endpoints included disease-free survival and safety. **Results:** 482 patients in 24 study sites were enrolled (361 in Arm A vs. 121 in Arm B). Both groups were well balanced regarding age, gender, race and ethnicity. The 5-year OS rate was 76.9% in Arm A compared to 64.3% in Arm B (log-rank=4.125, p=0.042). The median DFS was 50.6 months and 42.6 months in Arm A and B, respectively. The 5-year DFS rate was 40.0% in Arm A compared to 14.4% in Arm B (log-rank=1.701, p=0.192). The combination of nimotuzumab plus chemo-radiotherapy was well tolerated. The incidence of adverse drug reactions (ADRs) in Arm A was similar to Arm B (35.7% vs. 42.1%, p=0.207), and the grade 3-5 ADRs as well (17.7% vs.15.7%, p=0.609). **Conclusions:** Nimotuzumab plus chemo-radiotherapy increase 5-year OS of NPC patients with good safety profile. Clinical trial information: 01074021. Research Sponsor: None.

6002 **Oral Abstract Session**

Reduced-dose radiotherapy for pretreatment EBV DNA selected low-risk stage III nasopharyngeal carcinoma: A single-arm, phase II trial. *First Author: Hai-Qiang Mai, Department of Nasopharyngeal Carcinoma, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: The radiotherapy (RT)-related toxicities of nasopharyngeal carcinoma (NPC) caused by the standard dose of 70 Gy still remained a critical issue. It is necessary to select optimal candidates for reduced-dose RT. The pretreatment Epstein-Barr virus (EBV) DNA level has been universally applied to select low-risk NPC patients and the response to induction chemotherapy (IC) can be used to screen patients sensitive to RT. In this trial, we assessed whether RT dose of 60Gy was noninferior to standard dose in low-risk stage III NPC patients with favorable response to IC. **Methods:** We did a single-arm, single-center, phase II clinical trial in Sun Yat-sen University Cancer Center in China. Patients aged 18-70 with low-risk (EBV DNA level < 4,000 copies/ml) stage III NPC were treated with two cycles IC of TPF regimen (paclitaxel liposome 135 mg/m^2 on days 1, cisplatin 25 mg/m^2 on days 1-3, fluorouracil 750 mg/m^2 as a continuous 120 hours infusion on days 1-5) intravenously given every 3 weeks. Patients with complete/partial response (CR/PR) and undetectable EBV DNA level were assigned 60Gy intensity modulated RT, currently with 100 mg/m^2 cisplatin intravenously on days 1, 22, and 43. The primary end point was 2-year progression-free survival (PFS). The second end points included: overall survival (OS), locoregional relapse-free survival (LRRFS) and distant metastasis-free survival (DMFS), etc. The trial was registered with ClinicalTrials.gov, number NCT 03668730. **Results:** Between Nov 19, 2018, and Mar 13, 2020, a total of 216 patients were enrolled in this study, and 1 patient withdrew from the informed consent. 215 patients completed two cycles IC, after which 116 (54.0%) and 99 (46.0%) patients were assigned 60Gy and 70Gy RT, respectively. For patients treated with 60 Gy RT, 2-year PFS, OS, LRRFS and DMFS were 94% (95% confidence interval [CI], 89 to 99), 100%, 95% (95%CI, 91 to 99) and 97% (95%CI, 93 to 100), respectively, with the median follow-up of 25.8 months (interquartile range 22-28). During RT, the most common toxicity was nausea, with the proportion of 61% (71/116), 5% (6/116) for grade 1-2 and 3. The major grade 3-4 toxicities were leucopenia, neutropenia, mucositis and pain, which were reported in 16 (14%), 16 (14%), 13 (11%) and 15 (13%) patients, respectively. The most common late toxicity was grade 1-2 dry mouth with the incidence of 54% (63/116). No grade 3+ long-term adverse event was observed and no patients died from treatment-related causes. All quality of life items, domains, and symptom scores returned to baseline by 6 months, with the exception of dry mouth and sticky saliva. **Conclusions:** Our findings show that reduced-dose RT (60Gy) is associated with favorable survival outcomes and limited treatment-related toxicities for low-risk stage III NPC patients sensitive to IC. Clinical trial information: 03668730. Research Sponsor: None.

Results of phase 3 randomized trial for use of docetaxel as a radiosensitizer in patients with head and neck cancer unsuitable for cisplatin-based chemoradiation. *First Author: Vijay Maruti Patil, Tata Memorial Centre, Mumbai, India*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

6004 **Oral Abstract Session**

An open-label, noninferiority phase III RCT of weekly versus three weekly cisplatin and radical radiotherapy in locally advanced head and neck squamous cell carcinoma (ConCERT trial). *First Author: Atul Sharma, All India Institute of Medical Sciences, New Delhi, India*

Background: CCRT using 3 weekly cisplatin (DDP) 100mg/m^2 is considered standard nonsurgical option for LAHNSCC. Many prefer DDP 40 mg/m^2 weekly assuming this to be non inferior, with better radio sensitization, and less toxic but without robust supporting evidence. We designed this non inferiority trial to compare 3 weekly DDP to weekly DDP. **Methods:** Multicentric non inferiority RCT to compare DDP 100 mg/m^2 (Control as C) 3 weekly x 3 times to 40 mg/m^2 (Test as T) weekly DDP x7 times with concurrent RT as definitive therapy in non nasopharyngeal LAHNSCC. Primary objective was 2 years loco regional control (LRC) rates. Secondary endpoints included OS, PFS, toxicity, compliance, others. Assuming LRC of 60%, power of 80%, alpha error of 5%, and non inferiority margin of 10% 143 patients in each arm were required (including 10% non evaluable etc). **Results:** Between April 2018 and January 2021, 278 were randomised. Median age was 56 years (range 19-70), 89.6% were males. Primary sites were, oropharynx (59.6%), larynx (17.5%), hypopharynx, and oral cavity (11.6%) each. TNM stage was, stage III (29.1%), stage IVA (50.5%), and IVB (20.4%). 13% of oropharyngeal who were tested for p16 were found positive. ECOG PS was 0-1 in 78.9%. 135 in each arm were eligible for treatment and 132 received some form of treatment. Baseline characteristics (Chi square/Fisher's exact test) were well balanced except higher number of patients with LVEF <50% in T arm (p=0.035). 87.2% of patients in C arm, and 81.6% in T arm received ≥ 60 Grays (p=.94), 78.6% in C and 81.6% patients in T arm received ≥ 200 mg/m2 of DDP (p=.31). There were more treatment delays in treatment in C arm (p=NS). Treatments interruptions (p=0.035), hospitalizations (p=0.004), use of additional IV fluids (p= <.001), mucositis (p=.029), myelosuppression (P=.021), renal toxicity (p=<.001), vomiting ((p=.002), hyponatremia (p=.004) were all significantly more in C arm. There were 10 toxic deaths in C arm and 7 in T arm. 81.6% in C arm and 85.4% patients in T arm achieved CR+PR (p=.055). LRC rates at 2 years were 57.69% in C arm and 61.53% in T arm, with an absolute difference of 3.84% and (one sided 95% CI= -6.15, 13.80) which is within the pre defined non inferiority margin of -10%. Cumulative 2 year LRC rates were 52.6% in T and 47.4% in C (log-rank p=0.426; HR 0.86 [95%CI: 0.60-1.23]) by parametric survival estimates with an absolute difference of 5.2% (95%CI= -7.7, 18.2) again within pre defined margin. There was no significant difference in median time to loco-regional failure (C=21.23 months and T= NR; p=.45), OS (C=30.50 months and T= 25.46; p=.59) and PFS (C=20.60 months and T= 20.66; p=.46). **Conclusions:** This academic trial confirms that CCRT with weekly DDP is non inferior to 3 weekly DDP, is better tolerated with less interruptions, hospitalizations, and toxicity and should now be considered as one of the standards. Clinical trial information: CTRI/2018/03/012422. Research Sponsor: None.

6005 **Oral Abstract Session**

ROMAN: Phase 3 trial of avasopasem manganese (GC4419) for severe oral mucositis (SOM) in patients receiving chemoradiotherapy (CRT) for locally advanced, nonmetastatic head and neck cancer (LAHNC). *First Author: Carryn M. Anderson, The University of Iowa Hospitals & Clinics, Iowa City, IA*

Background: Intensity-modulated radiotherapy (IMRT) plus cisplatin is an established treatment for LAHNC, but ~70% of patients develop SOM (WHO grade 3 or 4), limiting their ability to eat solids (grade 3) or liquids (grade 4), and often requiring nutrition by feeding tube. Management focuses on symptoms and supportive care (Elad 2020). There are no US-approved drugs to reduce SOM in LAHNC. A radiotherapy (RT)-induced burst of superoxide initiates oral mucositis (OM) development (Sonis 2004). Avasopasem (GC4419, AVA) is an investigational selective small molecule dismutase mimetic designed to convert superoxide to hydrogen peroxide, which may protect normal cells from, and potentially sensitize cancer cells to, radiation (Riley DP 2006, El-Mahdy 2020). In a randomized, double-blind phase 2b trial, AVA reduced duration and incidence of SOM due to CRT for LAHNC vs placebo (PBO) (Anderson 2019). The present trial (NCT03689712) further assessed safety and efficacy of AVA to reduce SOM due to CRT for LAHNC of the oral cavity (OC) or oropharynx (OP). **Methods:** Double-blind, PBO-controlled trial; patients receiving 60-72 Gy of IMRT (>50 Gy to ≥2 oral mucosal sites) plus cisplatin (weekly or q3 weeks) were randomized 3:2 to AVA 90 mg vs PBO by 60-minute IV infusion, M-F before each RT fraction. OM by the WHO scale was assessed by trained evaluators biweekly during RT & weekly for 2 weeks thereafter. Primary endpoint: SOM (WHO grade 3 or 4) incidence through the end of IMRT. Secondary endpoints included SOM duration through 2 weeks post-IMRT and grade 4 OM incidence through the end of IMRT. **Results:** N = 407 (241 AVA/166 PBO); median age 61; 86% male; 82% OP. Statistically significant 16% relative reduction in SOM incidence (54% vs 64%; p= 0.045) and 56% relative reduction in SOM duration (median, 8 vs 18 days; p= 0.002) were observed. Grade 4 incidence was reduced 27% (p= 0.052). Improvement was seen in multiple secondary and exploratory endpoints (table). Adverse event frequencies (all grade, grade 3+, serious) were comparable between treatment groups without clear AVA-specific toxicity or increase in cisplatin-attributable toxicity. **Conclusions:** AVA produced statistically significant, clinically meaningful improvement of SOM vs PBO that was consistent across multiple measures of SOM, and was well tolerated, with an adverse event profile consistent with expectations for IMRT/cisplatin in LAHNC. Clinical trial information: NCT03689712. Research Sponsor: Galera Therapeutics, Inc.

	PBO	AVA	AVA vs PBO	
			Relative Δ	p value
SOM incidence through IMRT	64%	54%	16%	0.045*

Association of plasma tumor tissue modified viral HPV DNA (TTMV) with tumor burden, treatment type, and outcome: A translational analysis from NRG-HN002. *First Author: Sue S. Yom, University of California-San Francisco, San Francisco, CA*

Background: NRG-HN002 was a phase II trial that randomized patients with p16-positive oropharynx cancer to 60 Gy IMRT with concurrent cisplatin (IMRT-C) or 60 Gy accelerated IMRT. The protocol specified plasma collection at pretreatment (t0), intratreatment (20-28 Gy, t1), and 2 weeks to 1 month posttreatment (t2); at these timepoints, TTMV was assayed. A prespecified analysis evaluated: association of t0 TTMV to gross tumor volume (GTV) of primary and lymph nodes; t0-t1 decrease in TTMV; and association of t2 TTMV to treatment and outcome. **Methods:** TTMV was quantified as fragments/mL of plasma. If TTMV-HPV16 was not detected (<5 fragments/mL) or was a low value, the specimen was tested for TTMV-HPV18, -HPV31, -HPV33, and -HPV35. The distribution of t0 TTMV fragments was highly skewed, so these data were log-transformed; their correlation to GTV was measured by Pearson coefficient. Paired and two-sample t-tests were used to compare t0 and t1 log-transformed fragments within and between arms. Proportions of TTMV detection at t2 between arms were compared using Fisher's exact test. Rates of undetectability and fragment clearance (≥94% reduction from t0) at t2 were estimated. The negative predictive value (NPV) was estimated for 2-year locoregional failure (LRF) and progression-free survival (PFS). **Results:** Of 306 eligible patients, 164 (53.6%) donated at least one specimen. The median collection time/RT dose was -2.6 days before RT (Q1-Q3, -4.0-0.0), at 24 Gy (22-28), and 25.5 days after RT end (18-31). The t0, t1, and t2 patient participation rates were 53.6%, 45.4%, and 42.5%. Zero TTMV fragments were detected in 10.4% at t0, 19.4% at t1, and 93.1% at t2. At t0, t1, and t2, 83.5%, 79.1%, and 6.2% had detectable TTMV; 78.0%, 73.4%, and 5.4% had TTMV-HPV16. In correlating GTV to t0 TTMV fragments, the Pearson coefficient was 0.30 (95% CI 0.15-0.44). In a linear model, T stage (p=0.01) and N stage (p=0.004) were positively associated with t0 TTMV fragments. On the IMRT-C arm, the t0-to-t1 mean change was -1.06 (p=0.0009), and for IMRT, it was -0.22 (p=0.35) (p=0.03 between arms). The t2 TTMV detectability rate was 3.3% for IMRT-C vs 8.7% for IMRT (p=0.28). The t2 TTMV undetectability rate was 93.8% and the fragment clearance rate was 95.4%. Two-year LRF and PFS were 6.2% and 91.4%. The NPV of t2 undetectability was 95.0% (95% CI 89.4-98.1) for 2-year LRF and 93.3% (95% CI 87.3-97.1) for 2-year PFS, and for fragment clearance was 94.3% and 92.7%. **Conclusions:** Feasibility of the TTMV-HPV assay in clinical trial specimens was established. About 10% of p16-positive patients had zero TTMV fragments at baseline. Among those with TTMV detectability, 6.6% had types other than TTMV-HPV16. T and N stage were positively associated with TTMV fragments. The IMRT-C arm achieved rapid TTMV undetectability unlike IMRT. The NPV of posttreatment undetectability was 93-95% for 2-year LRF and PFS. Research Sponsor: U.S. National Institutes of Health.

6007 **Oral Abstract Session**

A randomized phase II study evaluating concurrent or sequential fixed-dose immune therapy in combination with cisplatin and intensity-modulated radiotherapy in intermediate- or high-risk, previously untreated, locally advanced head and neck cancer (LA SCCHN). *First Author: David Anthony Clump, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: Optimal timing, either concurrent or sequential, of anti-programmed death (PD)-1 antibody with chemoradiotherapy (CRT) for LA SCCHN is unknown. Recently, JAVELIN-100 showed no benefit of adding concurrent avelumab to CRT. **Methods:** In this randomized, phase 2 study, patients (pts) with intermediate risk human papillomavirus (HPV) positive oropharyngeal (> 10 pack years or T4 or N3) or HPV negative previously-untreated LA SCCHN of the oropharynx, hypopharynx, larynx, or oral cavity (unselected PD-L1 status) were randomized 1:1 (stratified by HPV and nodal stage) to receive CRT (cisplatin 40 mg/m^2 weekly + radiation therapy consisting of 70 Gy in 35 fractions and concurrent or sequential pembrolizumab (pembro) 200 mg q 3 week X 8 doses total . Pembro was started 1 week prior to CRT and 2 weeks after CRT in the concurrent and sequential arms respectively. The primary objective was to evaluate two schedules of pembro (concurrent vs. sequential) combined with CRT in order to recommend the regimen to be tested subsequently. The study was powered to detect a signal of antagonism, defined as a 1-year local failure rate exceeding 60% and each arm had to meet all of the following: dose limiting toxicity (DLT) rate £ 20%, 1-year local failure rate (LRF) < 60%, and 1-year PFS ^{3} 60%. If all three were met the arm with a numerically superior 1-year PFS would be selected for further study. Extensive correlatives were collected and will be reported in the future. **Results:** Between 05/2016 and 05/2021, 80 patients were randomized, 41 participants received concurrent while 39 patients received sequential pembro along with CRT. Minimum follow-up is 9 months with a median > 24 months. Both treatment schedules met the predefined composite endpoints of rate of DLT, LRF, and 1-year PFS. The 1 and 2-year PFS for sequential pembro of 89% was numerically higher than that of 82% and 78% for concurrent pembro. OS at 1 and 2 years was 94% for sequential and 82% and 78% for concurrent pembro. Median PFS and OS was not reached in either arm. 3-year PFS and OS will be reported along with PD-L1 status and other exploratory correlatives. Grade 3 adverse events were 76.7% with concurrent vs 58.9% with sequential pembro added to CRT. There were 2 Grade 5 events with sequential and 3 Grade 5 with concurrent pembro. **Conclusions:** This randomized phase II trial evaluated fixed-dose concurrent versus sequential pembro added to standard CRT in LA SCCHN. Sequential pembro had a numerically superior 1 and 2-year PFS compared to concurrent therapy. Sequential pembro is the preferred regimen to compare with standard of care CRT for LA SCCHN in a phase III trial. Clinical trial information: NCT02777385. Research Sponsor: Merck, Inc.

6008 **Oral Abstract Session**

A phase II trial of pembrolizumab and cabozantinib in patients (pts) with recurrent metastatic head and neck squamous cell carcinoma (RMHNSCC). *First Author: Nabil F. Saba, Winship Cancer Institute Emory University School of Medicine, Atlanta, GA*

Background: Pembrolizumab (pembro) is an immune checkpoint inhibitor (ICI) approved for treating pts with recurrent/metastatic (RM) HNSCC. Cabozantinib (cabo) is a multiple receptor tyrosine kinase inhibitor (TKI) targeting MET and VEGFR2 shown to reduce tumor growth, metastasis, and angiogenesis and has immuno-modulatory properties. **Methods:** This is a phase II, open label multi-center, single arm trial evaluating the tolerability and clinical benefit of pembro administered at 200 mg/m2 every 3 weeks and cabo 40 mg daily for pts with RM HNSCC who have not received prior ICI. It had a lead-in safety cohort allowing reduction of cabo dose to 20mg daily. Eligible pts had RM HNSCC, deemed incurable, with a tumor PD-L1 CPS > 1, RECIST 1.1 measurable disease, a life expectancy of > 3 months, an Eastern Cooperative Group (ECOG) Performance Status (PS) of 0-1. Enrollment was initiated in March of 2019. We estimated that the ORR will improve to 35% with pembro+ cabo (from a historic of 18%) with a significance level of 0.05 and 80% power. **Results:** A total of 47 pts were screened, 13 screen failures [cavitation on scan (4), inability to swallow pills (2), other exclusions (7)]; 34 pts were enrolled, 32 were dosed and 31 evaluable (at least one follow-up scan). Pts had cancers of the oropharynx (21, 65%), nasopharynx (6, 19%), larynx/hypopharynx (4, 13%) and oral cavity (1,3%). 32 patients received cabo at 40 mg daily; 13 patients (41%) were dose reduced to 20mg daily [mucositis, increased liver function (LFT) tests, diarrhea]; males (n=29, 90%), median age 63 years (range 53-67); presence of distant metastases (34, 100%); prior radiation (29, 90%), chemotherapy (14, 43%); ECOG PS =0 (16, 50%), 1 (16,50%); HPV/p16 positive (17, 53%), negative (5, 16%), not applicable (10, 29%); the most frequent adverse event (AE) (all grades) was fatigue (16,50.0%), grade 3 or 4 treatment-related AE were increased LFTs, hyponatremia (3, 9.3% each). With a median follow up of 12.7 months (mos) (range 6.9- 20.5 mos), a RECIST 1.1 overall response rate ORR= 45.2% (CR=0; PR=14, 45.2%; SD =14, 45.2%; PD=3.0, 10%) with an overall clinical benefit of 90.4% were observed; The 1-yr OS was 67.7% (95% CI, 42.9%-83.6%; median 22.3 mos) and 1-yr PFS was 51.8% (95% CI, 28.8%-70.7%; median 14.6 mos). **Conclusions:** This phase II trial of pembro + cabo met its primary endpoint of ORR. The regimen is well-tolerated with very encouraging clinical activity in RM HNSCC and warrants further exploration in this disease. The study was supported by a grant from Exelixis to NFS. Clinical trial information: NCT03468218. Research Sponsor: exelixis.

6009 **Poster Discussion Session**

Deintensification of postoperative radiotherapy in head and neck cancer independent of human papillomavirus status: Results of a prospective multicenter phase II trial. *First Author: Marlen Haderlein, Universitaetsklinikum Erlangen, Erlangen, Germany*

Background: Long-term toxicity is highly relevant for cancer survivors. Therefore, in a clearly defined patient population with HNSCC individualized risk-adapted De-intensification of radiotherapy(RT) should be investigated to reduce long-term toxicity without compromising locoregional control rates (LRRR). **Methods:** Patients with newly diagnosed HNSCC after surgery with the following tumor stages (TNM 7th Edition) were eligible for the study: Oral cavity, oropharynx, larynx: pT1-3, pN0-pN2b. Hypopharynx: pT1-2; pN1, resection margin (R) ≥1mm, cM0.Patients were treated in 3 different arms adapted to tumor stage and quality of surgery performed (table below). Concomitant chemotherapy was applied according to standard. Primary endpoint was the LRRR after 2 years (y). After 2y a LRRR up to 10% was expected and an additionally LRRR in non-irradiated or dose-reduced areas of 6% would be accepted. The calculated sample size was 150 patients. Secondary endpoints were overall(OS)/ disease-free(DFS) survival and late toxicity according to CTC-AE v4.0. **Results:** Between Oct 2014 and March 2021 150 patients were enrolled. 8 (5%) patients were treated in arm A, 88 (59%) in arm B and 54 (35%) in arm C. Median age was 59 years. Tumor localisation was: 35% oral cavity, 63% oropharynx (82% HPV-positive), 1% Hypopharynx, 1% Larynx. 61 patients (41%) were stage IVA, 81 (54%) stage III and 8(5%) stage II. Median follow up was 36 months. LRRR after 2 and 3y was 6% (95%-CI 2-10%), and 7% (CI 3-12%). LRRR in not irradiated or dose-reduced regions was 4 % (CI 1-7%) after 2 and 5 % (CI 1-9%) after 3y. The 2 and 3y DFS rates were 90% (CI 85-95%) and 88% (CI 82-94%) and the OS rates were 94% and 94% (CI 90-98%). Late dysphagia was as follows: 0°: 55%, I°: 29%, II°: 9%, III°: 3%. Other grade ≥3 toxicities: Xerostomia 1%, esophageal stenosis 2%, osteonecrosis of the mandible 1%. **Conclusions:** The trial met its primary endpoint. De-intensification of RT independent of HPV status in a pre-defined low-risk patient population is safe and results in very low rates of late toxicity. Clinical trial information: NCT02528955. Research Sponsor: None.

ARM	Pathologic Tumor stage	Intervention
A	≤ pT2, R ≥ 5 mm, L0, Pn0 and >3 LN (lymph node) metastasis or ≤ 3 unilateral LN metastasis and a bilateral primary tumor without adequate contralateral neck dissection	***Dose reduction in primary tumor region to 56 Gy*** Elective RT: both neck sides
B	> pT2 and/or R < 5mm and/or L1 and/or Pn1 and ≤ 3 ipsilateral LN metastasis, contralateral pN0 or contralateral cN0 in unilateral oral cavity or oropharyngeal cancer	64 Gy in primary tumor region ***Reduction of target volume: elective RT: ipsilateral neck only***

Effectiveness of adjuvant chemoradiotherapy for oral cavity squamous cell carcinoma with minor and major extranodal extension: A multi-institutional consortium study. *First Author: Mirko Manojlovic Kolarski, University of Toronto, Toronto, ON, Canada*

Background: Extranodal extension (ENE) in oral cavity squamous cell carcinoma (OSCC) is a poor prognostic feature and an indication for adjuvant chemoradiotherapy. Recent pathology reporting guidelines recommend stratifying ENE into minor (≤2mm) or major (>2mm) extent. Prior studies have suggested that the addition of chemotherapy to adjuvant radiation may not improve oncologic outcomes in minor ENE. We evaluated this through a large multi-institutional cohort study. **Methods:** Surgically resected primary T1-4,N1-N3,M0 OSCC with pathologic nodal disease treated between 2005-2018 from four institutions in three countries were included. Extent of ENE was re-classified by pathologists on archived tissue. Adjuvant radiotherapy or chemoradiotherapy was recommended as per standard guidelines, unless contraindicated. Uni- (UVA) and Multivariable analysis (MVA) assessed the effect of chemotherapy on survival and disease control in minor and major ENE subgroups. Outcomes were also assessed in propensity score matched cohorts for each subgroup. **Results:** A total of 764 patients were included, of whom 126 (16%) had minor ENE and 242 (32%) had major ENE. Adjuvant chemoradiotherapy was given in 51 (40.5%) with minor ENE and 115 (47.5%) with major ENE. On MVA, chemotherapy was not associated with improved overall survival (OS) (HR 0.97, 95% CI 0.55-1.73, p=0.92) for patients with minor ENE, however, there was significant OS benefit for patients with major ENE (HR 0.61, 95% CI 0.38-0.98, p=0.041) after adjusting for age, T-category, N-category, margin status, adjuvant radiation, LN ratio, LVI, PNI, and ECOG status. Patients with major ENE receiving adjuvant chemoradiotherapy had improved locoregional control (LRC) (HR 0.67, 95% CI 0.42-1.09, p=0.1) although this did not reach statistical significance. Propensity score matched analysis found that patients with minor ENE who did and did not receive chemotherapy had no difference in OS (52% vs. 52%, p=0.85), but those with major ENE did (44% vs 13%, p=0.008). **Conclusions:** In OSCC, the addition of chemotherapy to adjuvant treatment is beneficial in major ENE, but our group failed to demonstrate a benefit for minor ENE. The benefit of chemotherapy in major ENE may result from improved LRC. Minor ENE is a clinically relevant subgroup in OSCC that warrants distinctive adjuvant treatment considerations. Research Sponsor: None.

Swallowing and quality-of-life outcomes of response adaptive de-escalated therapy following nivolumab-based induction for HPV+ oropharyngeal cancer. *First Author: Ari Rosenberg, University of Chicago, Department of Medicine, Chicago, IL*

Background: Despite the survival benefit of anti-PD1 therapy in recurrent/metastatic head and neck cancer, its role in locoregional disease remains undefined. Swallowing and quality of life (QoL) outcomes for patients with human papillomavirus associated (HPV+) oropharyngeal cancer (OPC) treated with de-intensified local therapy following anti-PD1 based induction is unknown. Here we report functional swallowing and QoL outcomes with response-adaptive de-escalation after induction chemoimmunotherapy in the context of a prospective investigator initiated trial, OPTIMA II. **Methods:** OPTIMA II enrolled locoregionally advanced HPV+ OPC. Treatment consisted of induction therapy with 3 cycles of nivolumab, nab-paclitaxel, and carboplatin, followed by risk and response de-escalated local therapy. High-risk (HR) included: T4, N2c-N3 (AJCC 7th edition), > 20 pack year smoking history, or non-HPV16 subtype; All others were low-risk (LR). Single-modality de-escalation received radiation (RT) alone to 50 Gy or transoral robotic surgery, and was administered to LR with ≥50% post-induction shrinkage by RECIST. Intermediate-dose de-escalation received chemoradiation (CRT) to 45-50Gy and was administered to HR with ≥50% shrinkage or LR with < 50% shrinkage. All others received regular-dose CRT to 70-75 Gy. Adjuvant nivolumab was administered for 6 months. Swallowing and QoL was assessed with the Rosenbek score and EORTC QLQ-C30 questionnaires, respectively. Higher values indicated greater degree of swallowing dysfunction and worse QoL, respectively. **Results:** Seventy-three eligible patients (pts) initiated treatment on protocol. Median age 61 (range 37-82). Primary site was tonsil in 70% and base of tongue in 29%. T3 or T4 primary tumor in 30%. De-escalated therapy was administered in 62 pts, of which 28 pts received single-modality and 34 pts received intermediate-dose. Rosenbek mean and standard deviation (SD) at baseline among single-modality, intermediate-dose, and regular-dose, was 1.3 (SD 0.6), 1.7 (SD 1.3), and 1.4 (SD 0.7), respectively. Rosenbek mean at 1 month following local therapy (n = 45) among single-modality, intermediate-dose, and regular-dose was 2.3 (SD 1.6), 3.8 (SD 2.5), and 4.7 (SD 2.1), respectively (p = 0.06). Feeding tube rates at the end of local therapy among single-modality, intermediate-dose, and regular-dose was 7%, 44%, and 75% respectively (p < 0.01). QoL scores (n = 30) were worse among regular-dose as compared with de-escalated treatment for activities of daily living (p = 0.01), neuropathy (p = 0.01), and eating in social settings (p = 0.09). **Conclusions:** Response adaptive de-escalated treatment for HPV+ OPC following nivolumab/nab-paclitaxel/carboplatin induction is associated with improved swallowing function, reduced rates of enteral feeding, and an improvement in QoL across several domains. Clinical trial information: NCT03107182. Research Sponsor: Bristol Myers Squibb.

Efficacy and safety of camrelizumab and apatinib combined with induction chemotherapy and concurrent chemoradiotherapy for stage $T_{any}N3M0$ nasopharyngeal carcinoma: A phase II QUINTUPLED trial. *First Author: Hu Liang, Department of Nasopharyngeal Carcinoma, Sun Yat-Sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center of Cancer Medicine, Guangzhou, China*

Background: Prognosis of nasopharyngeal carcinoma (NPC) with stage $T_{any}N3M0$ remains unsatisfactory due to high-risk of distant metastasis, indicating the need of more comprehensive treatment strategy. Synergistic effects are observed when immune checkpoint blockade anti-PD-1 is combined with chemotherapy or anti-angiogenic agents. This trial investigated the efficacy and safety of anti-PD-1 camrelizumab and anti-angiogenic agent apatinib in combination with induction chemotherapy and concurrent chemoradiotherapy (CCRT) in patients with $T_{any}N3M0$ NPC. **Methods:** In this phase II trial, patients with $T_{any}N3M0$ NPC (AJCC 8th edition) were enrolled and treated with induction chemotherapy (NAB-paclitaxel, 200 mg/m^2, day 1; cisplatin 60 mg/m^2, day 1; and capecitabine, 1000 mg/m^2, orally twice a day, days 1-14; every 21-day for 3 cycles) and apatinib (250 mg, 5 days/week, for up to 8 weeks), followed by CCRT (cisplatin, 100 mg/m^2, day 1, every 21-day for 2 cycles and IMRT). Camrelizumab (200 mg once every 3 weeks) was given from the first cycle of induction chemotherapy until one year. Prescribed radiation doses were 68-72 Gy, 64-68 Gy, 60-64 Gy, and 54-58 Gy in 30-33 fractions for PTVnx, PTVnd, $PTV_{high\text{-}risk}$, and $PTV_{low\text{-}risk}$, respectively. Primary endpoint was 1-year distant metastasis-free survival (DMFS). Patient's response to the therapy was evaluated using RECIST 1.1. **Results:** From May 2020 to July 2021, 50 eligible patients were enrolled. Median age was 45 years (range 20-65), median EBV DNA concentration was 4520 copy/ml (IQR 1595-17550), and 13 patients (26%) were female. Among 50 patients evaluable for response assessment after induction therapy, all patients had overall response, including 12 patients (24%) with complete response (CR). After 1-3 cycles of induction therapy, 84.8% (28/33 available) patients achieved negative pathological finding in the primary tumor site from endoscopic biopsy and 50% (17/34 available) from lymph nodes biopsy. Except one patient achieved regional partial response and one patient died from liver and bone metastases, the other patients all achieved CR at 3 months after radiotherapy. One-year DMFS rate was 98% (95% CI 96-100) with a median follow-up of 12.3 months (range 6.4-20.2). Grade ≥3 toxicity appeared in 32 (64%) of 50 patients and mainly consisted of nausea/vomiting (9 [18%]), neutropenia (8 [16%]), leukopenia (7 [14%]), anemia (7 [14%]), rash (5 [10%]) and thrombocytopenia (5 [10%]). Safety profile was anticipated without treatment or immune-related deaths. **Conclusions:** Camrelizumab and apatinib combined with induction chemotherapy of NAB-paclitaxel, cisplatin and capecitabine and CCRT shows excellent distant metastatic control with acceptable safety, which is a new promising and effective systemic therapy regimen for high-risk of metastatic NPC patients. Clinical trial information: ChiCTR2000032317. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd., Other Foundation.

6013 **Poster Discussion Session**

Phase 3 randomized study comparing docetaxel-platinum with docetaxel-platinum-5 fluorouracil as neoadjuvant chemotherapy in technically unresectable oral cancer. *First Author: Ajaykumar Singh, Tata Memorial Centre, Mumbai, India*

Background: Neoadjuvant chemotherapy (NACT) with DCF (Docetaxel, Cisplatin, and 5FU) is one of the treatment options in very locally advanced oral cancer (LAOC) and has a survival advantage over the CF (Cisplatin and 5FU) regimen. DC regimen (Docetaxel, Cisplatin) had shown promising results in small series, with a lower rate of adverse events but has never been compared with DCF. **Methods:** This was a phase 3 open-label superiority randomized study. Adult patients with very LAOC (technically unresectable), ECOG PS 0-2 and adequate organ function were eligible. They were randomly assigned in a 1:1 fashion to either DCF or DC regimen. After the administration of 2 cycles, these patients were evaluated in the multidisciplinary clinic. Based on the response, further treatment either surgery followed by adjuvant or radical chemoradiation or palliative therapy was planned. The primary endpoint was overall survival (OS). The key secondary endpoint was adverse events. **Results:** 495 patients were randomized in this study, 250 patients in arm A and 245 in arm B. At a median follow-up of 39.5 months. The 2-year OS was 29.1% in the DCF and 23.5% in the DC arm respectively (HR=0.81; 95%CI 0.66-0.99, P-value= 0.043). Grade 3 or above adverse events were higher in the DCF arm - oral mucositis (10.6% versus 1.2%), diarrhea (13.6% versus 9.6%), febrile neutropenia (23.2% versus 2.6%), hyponatremia (40.8% versus 20.8%), and hypokalemia (17.9% versus 1.6%). **Conclusions:** NACT with DCF has a survival benefit over DC in oral cancers but it comes at the cost of an increment in acute adverse events. Clinical trial information: CTRI/2016/04/006804. Research Sponsor: Tata memorial center research administrative council.

Dose-finding and efficacy confirmation trial of the superselective intra-arterial infusion of cisplatin and concomitant radiotherapy for locally advanced maxillary sinus cancer (JCOG1212): Results of the efficacy confirmation phase in the T4a cohort. *First Author: Akihiro Homma, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan*

Background: The JCOG1212 trial seeks to evaluate the safety and efficacy of the superselective intra-arterial infusion of high-dose cisplatin with concomitant radiotherapy (RADPLAT) for patients (pts) with T4aN0M0 or T4bN0M0 maxillary sinus squamous cell carcinomas (MS-SCC). T4aN0M0 MS-SCC requires radical surgery with or without complete resection of the orbital contents as a standard treatment, which results in disfigurement and functional impairment. We herein report the results of the efficacy confirmation phase in the T4a cohort. **Methods**: Eligible pts with T4aN0M0 MS-SCC were registered and received cisplatin 100 mg/m^2 intra-arterially weekly for 7 weeks with concomitant radiotherapy (total 70 Gy) as determined by the results of the previous dose-finding phase. The trial investigated the 3-year overall survival (3yr OS) of RADPLAT to demonstrate its non-inferiority to surgery, the current standard of care, and its superiority to IV-CRT, which is used for pts refusing surgery. From the results of observational study undertaken by our group, the historical control for the 3yr OS was set at 80% for surgery and 65% for IV-CRT. A margin of 15% was set to demonstrate its non-inferiority to surgery and superiority to IV-CRT. Thus, when the lower boundary of the two-sided 90% confidence interval (CI) exceeds the threshold of 65% for 3yr OS, RADPLAT will be confirmed as the new standard. A sample size of 62 was required to achieve 80% power with a one-sided 5% significance level. **Results**: From April 2014 to August 2018, 65 pts were registered in the T4a cohort from 18 institutions, consisting of 54 males and 11 females with a median age of 64 years (range, 40-78 years) and ECOG PS 0/1 (58/7). After the exclusion of one ineligible patient, 64 pts were included in the primary analysis of efficacy and safety. The complete clinical remission rate was 73.4% (47/64, 95% CI, 60.9%-83.7%), with 15 showing CR and 32 showing good PR. The median follow-up was 4.5 years in all eligible pts and the primary endpoint for 3yr-OS was 82.8% (90% CI, 73.4%-89.2%), which met the prespecified hypothesis. The 3yr event-free survival and 3yr local event-free survival were 60.9% (95% CI, 47.9%-71.7%) and 65.6 % (95% CI, 52.5%-75.8%), respectively. With regard to acute adverse events, neutropenia (≥ grade 3), increased creatinine (≥ grade 2), hearing impairment (≥ grade 2), mucositis (≥ grade 3), and stroke (≥ grade 2) were observed in 14.1%, 3.1%, 3.1%, 20.3%, and 1.6% of pts, respectively. One treatment-related death due to a thromboembolic event was reported. **Conclusions**: RADPLAT is non-inferior to surgery and superior to IV-CRT for pts with T4aN0M0 MS-SCCs and showed manageable toxicities. Therefore, RADPLAT, as well as surgery, should be considered the new standard treatment option for these pts. Clinical trial information: UMIN000013706. Refining nodal category in TNM staging with extent of extranodal extension for oral cavity squamous cell carcinoma. *First Author: John R de Almeida, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: The TNM 8th edition N classification (TNM-8-N) has limitations based on evidence that: (1) extent of extranodal extension (ENE), classified as minor($_{min}$) (≤ 2mm) or major ($_{maj}$)(> 2mm), is prognostic, and (2) N3a category (i.e. lymph node (LN)s > 6 cm, no ENE) is rare and redundant. Refining N classification may improve staging performance. **Methods:** Patients with surgically resected T1-4,N0-3 OCSCC at four centers between 2005 - 2018 were included. Pathologists were asked to measure extent of ENE on archived slides for all cases. Thresholds for stratification of adverse LN features were determined using the Contal O'Quigley method. Multivariable analyses for overall survival (OS) were performed using Cox proportional hazard models. Two new N classification proposals were created based on LN features using (1) adjusted hazard ratios (aHR) and (2) recursive partitioning analysis (RPA). These were ranked against two published proposals and TNM-8-N with the following criteria: hazard consistency, hazard discrimination, explained variance, likelihood difference, sample size balance. **Results:** In total, 1460 patients were included, 764 (52%) were LN positive, and 135 (18%) had contralateral LNs. The following TNM-8-N subgroups were rare and had poor prognosis: LN between 3-6 cm without ENE (N2a) [n=4] and LN(s) > 6 cm without ENE (N3a) [n=1]. All 5 either recurred or died. TNM-8-N N2b and N2c categories had disordered 5-year OS (45% vs. 67%). Thresholds for stratification of LN features, rounded to the nearest whole number, were <=1 vs >1 for number of LNs; ≤ 3 vs. > 3 cm for size of largest LN, and ≤ 2 mm vs. > 2 mm for extent of ENE. Significant predictors of OS included (1) the presence of ENE_{maj} and no ENE vs. ENE_{min} (HR 1.37; 95% CI 1.03-1.82 and HR=0.66, 95%CI 0.49-0.88), (2) multiple LNs vs. 1 LN (HR 1.72; 95% CI, 1.33-2.22), and (3) size of largest LN > 3 cm vs. <=3 (HR 1.86; 95% CI 1.42-2.43), but contralateral LN(s) vs. ipsilateral LN(s) was not (HR 1.08; 0.83-1.40). The aHR proposal ranked highest (table). **Conclusions:** A new N-classification proposal based on aHR provides improved staging information. Major changes include: (1) stratification by ENE extent (2) elimination of N2c (3) stratification of multiple LNs without ENE by size, and (4) elimination of the 6 cm threshold. New TNM iterations may incorporate these changes. Research Sponsor: None.

Liquid Biopsy for Minimal Residual Disease Detection in Head and Neck Squamous Cell Carcinoma (LIONESS): A personalized cell-free tumor DNA analysis for patients with HNSCC. *First Author: Susanne Flach, Hospital of the University of Munich, München, Germany*

Background: Despite improvements in multimodal treatment options for patients with head and neck squamous cell carcinoma (HNSCC), survival has only improved modestly over the past decades as patients frequently develop recurrences. Detection of cell-free circulating tumor DNA (ctDNA) post-operatively and during clinical follow-up has the potential to identify patients with molecular residual disease (MRD) or who are at an increased risk of relapse, and who may therefore benefit from personalized treatment strategies. **Methods:** We conducted LIONESS, a single-center prospective cohort study to investigate ctDNA in patients with HNSCC who received primary surgical treatment with curative intent. 58 patients have been recruited as of January 2022, with disease stage I (15.5%), II (13.8%), III (36.2%) and IV (34.5%). Whole exome sequencing was performed on FFPE tissue. RaDaR, a highly sensitive personalized assay using deep sequencing of tumor-specific variants, was used to analyze serial pre- and post-operative plasma samples for evidence of molecular residual disease and recurrence. In addition, pre-operative saliva samples were collected for detection of tumor DNA in saliva. **Results:** 236 longitudinal plasma samples from 35 patients have been analyzed so far, using personalized panels designed targeting a median 48 (20-60) somatic variants. Preliminary data shows 94.28% ctDNA detection in baseline samples taken prior to surgery. In post-surgery samples, ctDNA could be detected at levels as low as 0.0005% variant allele fraction (eVAF). Survival analysis showed a significant difference (p-value = 7e-7) in recurrence rates between patients who tested ctDNA+ during follow-up (8/11, 72.7%) and those who were negative for ctDNA (0/24, 0%). In all eight cases with clinical recurrence, ctDNA was detected prior to progression, with lead times ranging from 56 to 265 days. Patients were followed for clinical recurrence with a median follow-up of 9.5 months to date, but longer follow-up is necessary for patients who may be at increased risk of recurrence. Work is ongoing for analysis of the full cohort of plasma and saliva samples, which will be presented at the congress. **Conclusions:** In this prospective observational study, detection of residual disease using ctDNA was associated with poorer progression-free survival and much earlier detection of disease prior to clinical relapse. The implementation of a highly sensitive ctDNA assay such as RaDaR into clinical practice has the potential to tailor personalized treatment strategies for molecular residual disease and recurrence in patients with HNSCC. In future, ctDNA analysis with subsequent ctDNA-guided treatment may reduce morbidity for HNSCC patients. Research Sponsor: None.

Phase II study of trastuzumab-pkrb and docetaxel anhydrous combination therapy in recurrent or metastatic salivary ductal carcinomas (KCSG HN18-08/KM11). *First Author: Jiyun Lee, Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: Salivary gland cancers (SGCs) are relatively rare, accounting for 1-6% of all neoplasms of the head and neck, have diverse disease course with respect to origin and pathology. Salivary duct carcinoma (SDC) is the most aggressive tumor subtype of primary SGC, showing high rates of local recurrence and distant metastases. In regard to previous studies which reported a high prevalence of HER2 positivity in SDCs, we conducted a single-arm, phase II study to evaluate the antitumor activity and safety of Herzuma (a trastuzumab biosimilar which demonstrated an equivalent efficacy to reference trastuzumab) in combination with docetaxel anhydrous (Nanoxel) in patients with HER2-positive advanced SDCs. **Methods:** Eligible patients had histologically confirmed HER2-positive (defined as IHC≥2+ and/or FISH HER2/CEN17 ratio ≥2.0) recurrent/metastatic SDC, or subtypes of SGC that were pathologically similar to SDC (excluding ACCs). They received Herzuma (8mg/kg i.v. loading dose, followed by 6mg/kg i.v.) and Nanoxel (75mg/m2 i.v.) every 3 weeks. The primary endpoint was the investigator-assessed objective response rate (ORR) according to RECIST v1.1. Secondary endpoints were overall survival (OS), progression-free survival (PFS), and safety. The calculated sample size was 43 patients for H1 of ORR ≥40%. Safety was evaluated by CTCAE v4.0. **Results:** A total of 43 patients were enrolled. Patient characteristics included: median age 60 (range 35–81); 86% male; 84% ECOG1; 84% SDC, 9% adenocarcinoma, 2% high grade mucoepidermoid carcinoma, and 5% other subtypes. Confirmed ORR was seen in 67% (95% CI, 52–81). No patient had a complete response as their BOR, 29 (67%) had a partial response, 11 (26%) had stable disease, 1 (2%) had progressive disease, and 2 (5%) were unevaluable. The DCR was 93% (95% CI, 81–99). The median PFS and OS were 8.2 months (95% CI, 6.7–9.7) and 23.3 months (95% CI, 19.9–26.7), respectively. Thirty-eight (88%) patients experienced a treatment-related AE (TRAE), with 15 (35%) patients experiencing ≥grade 3 TRAE including: neutropenia (10), febrile neutropenia (4), anemia (1), sepsis (1), anaphylaxis (1), decreased LVEF (1). There were no treatment-related deaths. **Conclusions:** The study met the primary endpoint of ORR. Herzuma and Nanoxel combination therapy demonstrated a promising treatment outcome in patients with HER2-positive recurrent/metastatic SDC. Clinical trial information: NCT03614364. Research Sponsor: Celltrion, Samyang.

6019 **Poster Discussion Session**

A phase 2 clinical trial of axitinib and avelumab in patients with recurrent/metastatic adenoid cystic carcinoma (ACC). *First Author: Renata Ferrarotto, Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ACC is a heterogeneous neoplasm and there is no standard treatment for patients (pts) with recurrent/metastatic (R/M) disease. Vascular endothelial growth factor receptor inhibitors (VEGFRi) are frequently used to treat R/M ACC rendering mostly disease stabilization. ACC is resistant to PD-1/PD-L1 inhibitors (PD-L1i), consistent with its low mutational burden and uninflamed immune microenvironment. We hypothesized that the immunomodulatory role of VEGFRi (axitinib) would enhance PD-L1i (Avelumab) activity and be a more effective therapy for R/M ACC. **Methods:** Eligible pts had R/M ACC with radiological or clinical progression within 6 months (mos) of enrollment. Treatment consisted of axitinib 5 mg PO bid and avelumab 10 mg/Kg IV every 2 weeks. Primary endpoint was objective response rate (ORR) per RECIST 1.1; secondary endpoints included duration of response (DOR), progression-free survival (PFS), overall survival (OS), and toxicity. Simon 2-stage design was applied to test the null hypothesis of ORR ≤ 5% versus the alternative ORR ≥ 20%; ≥ 4 responses out of 29 pts was required to reject the null hypothesis. **Results:** 41 pts enrolled from 07/24/19 to 06/29/21; 28 were evaluable for the primary endpoint (7 screen failures, 6 evaluable for safety only due to loss of insurance/logistics issues related to COVID-19 pandemic); 16 pts were treated in first-line. Mutation data was available for 23 of 28 evaluable pts; 7 had *NOTCH1* activating mutations. The ORR was 17.9% (5/28, 95%CI: 6.1-36.9%). One response was unconfirmed (pt progressed in non-target lesions 2 mos after achieving a PR), for a confirmed ORR of 14.3% (95%CI: 4-32.7%). The median follow-up time for the 15 alive pts was 11.6 mos (min-max: 7.7-29.2 mos). Median PFS was 7.2 mos (95%CI: 3.7-11.7 mos) with a 6-mos PFS rate of 57% (95%CI: 41-79%). Median OS was 17.4 mos (95%CI: 13-NA). 5 pts remain on therapy, 2/5 with a PR. The median DOR for the 5 responders was 5.2 mos (95% CI: 3.7–NA mos). The most common treatment-related adverse events (TRAEs) were fatigue (62%), hypertension (32%), diarrhea (29%), and stomatitis (29%). Serious TRAEs occurred in 8 (24%) pts, all grade 3 and manageable. 4 (15%) pts discontinued avelumab and 9 (32%) underwent axitinib dose reduction due to toxicity. **Conclusions:** The study reached its primary endpoint with ≥ 4 responses out of 28 evaluable pts (ORR of 17.8%; confirmed ORR of 14.3%). The ORR and 6-mos PFS rate of 57% with axitinib and avelumab compares favorably with single agent axitinib and warrants further study of the combination. Clinical trial information: NCT03990571. Research Sponsor: Pfizer, Other Foundation.

6020 **Poster Discussion Session**

A phase 2 study of the oral vascular endothelial growth factor receptor 2 (VEGFR2) inhibitor, rivoceranib, for recurrent or metastatic (R/M) adenoid cystic carcinoma (ACC). *First Author: Hyunseok Kang, Hematology/Oncology, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: ACC is a rare tumor that overexpresses VEGF, primarily affecting salivary glands. Often indolent, it can progress, with metastases common in lungs, liver, and bone. There are no FDA-approved systemic treatments (tx) for R/M ACC. Rivoceranib is an oral tyrosine kinase inhibitor (TKI) that potently and selectively inhibits VEGFR2. **Methods:** In this single-arm, open-label trial, patients (pts) with R/M ACC with evidence of ≥20% progression by RECIST v1.1 or new lesions within the preceding 6 mo were eligible; there was no limit on prior tx. Pts received rivoceranib 700 mg once daily until progression or withdrawal with pre-planned dose reductions for toxicity. Primary endpoint was objective response rate (ORR) per RECIST v1.1 by investigator (PI) and by Independent Review Committee (IRC). Secondary endpoints included duration of response (DoR), progression-free survival (PFS), time to progression (TTP), overall survival, and safety. Exploratory analysis included disease control rate (DCR), and ORR using CHOI criteria by IRC. **Results:** 80 pts (72 evaluable) were enrolled at 11 sites in the US and Korea (53% male; median age: 55 yr). Primary tumor sites: major (34%) and minor (59%) salivary glands and other (8%). 5 (6%) pts had locoregional disease only and 74 (93%) had metastatic disease. Most had prior surgery (89%) and radiation (96%); 53% had prior systemic tx (44% chemotherapy; 18% VEGFR TKI). Median follow-up was 15 mo (2–19); 20 pts remain on tx. PI-assessed efficacy data are listed in the table. ORR in pts with or without prior systemic tx was 13.9% and 16.9%, respectively. ORR by CHOI was 50.8% overall (51% VEGFR TKI-naive and 50% VEGFR TKI treated). 18% of pts discontinued tx, 74% had at least 1 dose reduction, and 93% dose interruption for adverse events (AEs). All pts had ≥1 AE and 80% had Grade ≥3 AEs, including 3 Grade 5 AEs (2 epistaxis [1 related], 1 acute respiratory failure). Common (> 30%) AEs were hypertension (65%), fatigue (61%), nausea and headache (50%), stomatitis (46%), diarrhea (40%), decreased appetite (38%), proteinuria (36%) and palmar-plantar erythrodysesthesia syndrome (34%). Grade ≥3 AEs in ≥5% of pts were hypertension (43%), stomatitis (8%), fatigue and anemia (6%), and back pain and pneumothorax (5%). **Conclusions:** In this population of R/M ACC with unmet medical need, rivoceranib showed promising antitumor activity, particularly among VEGFR TKI-naïve pts. The safety profile was consistent with other VEGFR TKIs. Clinical trial information: NCT04119453. Research Sponsor: Elevar Therapeutics.

Predicting emergency department use and unplanned hospitalization in patients with head and neck cancer: Development and validation of a machine learning algorithm. *First Author: Christopher W Noel, Department of Otolaryngology Head and Neck Surgery, Faculty of Medicine, University of Toronto, Toronto, ON, Canada*

Background: We recently demonstrated that patient reported symptom burden is strongly associated with emergency department use and unplanned hospitalization (ED/Hosp) in head and neck cancer (Noel et. al 2021 J. Clin Oncol - DOI: 10.1200/JCO.20.01845). We hypothesized that symptom scores could be used to build a tool that would accurately risk stratify patients. **Methods:** This was a population-based study of patients diagnosed with head and neck cancer between 2007 and 2018. All outpatient clinical encounters were identified. Edmonton Symptom Assessment Scores (ESAS) and clinical and demographic factors were abstracted. Training and test cohorts were randomly generated in a 4:1 ratio. Various machine learning algorithms were explored including: (1) logistic regression, (2) random forest, (3) gradient boosting machines (4) k-nearest neighbors and an (5) artificial neural network. Our main outcome was any 14-day ED/Hosp event following symptom assessment. The performance of each risk model was assessed on the test cohort using the area under the receiver operator characteristic (AUROC) curve and calibration plots. Shapley values were used to identify the variables with greatest contribution to the model. **Results:** The training cohort consisted of 9,409 patients undergoing 59,089 symptom assessments (80%). The remaining 2,352 patients and 14,193 symptom assessments were set aside as the test cohort (20%). Several models had high predictive accuracy, particularly the gradient boosting machine algorithm (validation AUROC 0.80 [95%CI 0.78-0.81]). A Youden-based cut-off corresponded to a validation sensitivity of 0.77 and specificity of 0.66. A second model built only with symptom severity data had an AUROC of 0.72 [95%CI 0.70-0.74]. **Conclusions:** Machine learning approaches can be used to predict ED/Hosp in head and neck cancer patients. This tool can risk stratify patients and may help direct targeted intervention. Research Sponsor: Challenge Grant, CIHR Terry Fox New Investigator Award.

Preliminary safety and efficacy of toripalimab combined with cetuximab in platinum-refractory recurrent or metastatic head and neck squamous cell carcinoma (R/M-HNSCC): A phase Ib/II clinical trial. *First Author: Ye Guo, Shanghai East Hospital, School of Medicine, Tongji University, Shanghai, China*

Background: PD-1 inhibitors and EGFR inhibitors are effective and may provide potential synergy in R/M HNSCC. We launched an open-label, single-arm, multicenter phase Ib/II study of toripalimab (a humanized IgG4K monoclonal antibody specific for PD-1) with cetuximab in platinum-refractory R/M-HNSCC (NCT04856631). We report the results of the phase Ib portion of this study. **Methods:** Eligible patients with R/M HNSCC progressed upon 1st-line platinum-containing treatment or developed R/M disease within 6 months of platinum-containing neo-adjuvant/adjuvant or chemo-radiation therapy were enrolled in this study. Exclusion criteria included prior immunotherapy or EGFR inhibitors therapy. Toripalimab was administered at 240mg intravenously Q3W and cetuximab was given as a loading dose of 400mg/m^2 IV followed by 250mg/m^2 QW. Dose-limiting toxicities (DLTs) and de-escalating dose were evaluated by a Safety Monitoring Committee (SMC). If less than 2 DLTs were observed in the first 6 patients, 6 more patients were enrolled to confirm safety. If 2 or more DLTs were observed, the next 6 patients would be enrolled at a lower dose level. The primary endpoint was safety. Secondary endpoints included determination of recommended phase 2 dose (RP2D), ORR, DCR, DOR, and PFS by an independent review committee (IRC) per RECIST v1.1, OS, and PK. **Results:** A total of 13 patients were enrolled in the phase Ib portion, including 11 (84.6%) male and 2 (15.4%) female patients. The median age was 58 (range 36-74) years. 7 (53.8%) patients had distant metastases and 9 (69.2%) were PD-L1 CPS ≥1. By the data cutoff date of Dec 21, 2021, the median follow-up was 19.3 (1.6-36.3) weeks. No DLT was observed, and the initial dose was chosen as RP2D. 10 (76.9%) patients experienced TRAEs; the most common TRAEs were rash (46.2%) and paronychia (38.5%). 5 (38.5%) patients experienced irAEs, including immune-related skin adverse reactions, hypothyroidism, thyroid function abnormal and duodenitis. No Grade≥3 TRAEs or irAEs occurred. No TRAEs led to discontinuation of study drug. 2 patients reported fatal AEs, both of which were caused by tumor hemorrhage and were judged not related to the study treatment by the SMC. Among 12 patients with at least one post-treatment tumor assessment, 6 confirmed PR (ORR 50%) and 6 SD (DCR 100%) were observed as assessed by the IRC. By the cutoff date, 5 patients have ongoing responses, with 3 over 12 weeks. **Conclusions:** Toripalimab combined with cetuximab were well tolerated and showed preliminary clinical efficacy in patients with R/M HNSCC. Clinical trial information: NCT04856631. Research Sponsor: Shanghai Junshi Biosciences, Pharmaceutical/Biotech Company.

Neoadjuvant toripalimab combined with gemcitabine and cisplatin in resectable locally advanced head and neck squamous cell carcinoma (NeoTGP01): An open-label, single-arm, phase Ib clinical trial. *First Author: Zhigang Liu, Cancer Center, The Fifth Affiliated Hospital of Sun Yat-sen University, Zhuhai, China*

Background: The positive outcome of first-line programmed death receptor-1 (PD-1) inhibitors has been revealed in recurrent/metastatic head and neck squamous cell carcinoma (HNSCC). Researches about neoadjuvant immunotherapy for resectable locally advanced HNSCC have been proceeding continuously, however the optimal regimen was inconclusive. Here, we combined a powerful chemotherapy regime, gemcitabine plus cisplatin (GP), and a PD-1 inhibitor to treat the potentially resectable locally advanced HNSCC followed by operation for exploring the safety and efficacy of the combination regime in this phase I trial. **Methods:** This was an open-label, single-arm, phase Ib clinical trial. Untreated patients, aged 18-70, with histologically confirmed localized advanced HNSCC (stage III-IVB), were enrolled. The eligible patients are scheduled to administered PD-1 inhibitor (Toripalimab) 240 mg on day 1, gemcitabine 1000 mg/m^2 on days 1 and 8, and cisplatin 80 mg/m^2 on day 1 every 21 days for two cycles. Radical resection was performed in 4-6 weeks after the first day of the second cycle. The primary endpoints were safety and no surgical-delay rate. Safety evaluation was performed in total participants in 90 days from the first day of treatment (or 30 days after surgery). The second endpoints consisted pathological complete response (pCR) rate, major pathological response (MPR) rate, objective response rate (ORR) and R0 resection rate. **Results:** By December 10, 2021, twenty-three patients were enrolled. Up to now, 18 out of 23 patients successfully finished the operation on schedule. Grade 3/4 adverse events (AEs) occurred in totally 3 patients (13.0%), 2 (8.7%) case of neutropenia, and one each of fatigue (4.3%), hyperglycemia (4.3%), vomiting (4.3%) and diarrhea (4.3%). The most shared adverse events of grade 1/2 were anorexia (30.4%), fatigue (21.7%), vomitting (17.4%) and hyperglycemia (17.4%). The median interval between second administration and surgery was 33 days. For the 20 patients with available radiological examination at pre- and post-neoadjuvant therapy, the assessment per RESCIST criteria was as follow: 1 (5.0%) CR, 7 (35.0%) PR, 12 (60.0%) SD. R0 resection rate reached 100% in a total of 18 patients with complete surgical resection. Three patients achieved pCR at primary site (viable tumor = 0), 5 achieved MPR (0 < viable tumor≤10%) and 2 among 5 were near-pCR (viable tumor = 1%), and the other 11 patient did not reach MPR. **Conclusions:** Triweekly neoadjuvant Toripalimab plus GP was generally tolerated by the locally advanced HNSCC and contributed to a major pathological response in 44.4% patients at present. Research Sponsor: Shanghai Junshi Biosciences Co., Ltd. Clinical trial information: NCT04947241. Research Sponsor: None.

A phase Ib study of SHR-1701, a bifunctional fusion protein targeting PD-L1 and TGF-β, in patients with recurrent or metastatic nasopharyngeal carcinoma (RM-NPC). *First Author: Yunpeng Yang, Medical Oncology Department, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Immune checkpoint inhibitors (ICIs) demonstrated favorable antitumor activity in RM-NPC. However, only a subset of patients derived benefits. Combining ICIs with agents blocking immunosuppressive pathway may expand the clinical benefit of ICIs to more patients. Transforming growth factor β (TGF-β) participates in tumor immune escape. SHR-1701 is a bifunctional fusion protein composed of a mAb against PD-L1 fused to the extracellular domain of TGF-β receptor II. Here, we report the safety and efficacy of SHR-1701 in RM-NPC patients. **Methods:** This is an ongoing, multicenter, open-label, phase Ib study (NCT04282070). Patients with confirmed RM-NPC who failed prior platinum-based chemotherapy (Arm 1) or both platinum-based chemotherapy and anti-PD-1/PD-L1 antibody treatment (Arm 2) were enrolled to receive SHR-1701 30 mg/kg intravenously once every three weeks until disease progression, unacceptable toxicity, or patient withdrawal. The primary endpoint was safety. The secondary endpoints were objective response rate (ORR), duration of response (DoR), disease control rate (DCR), progression-free survival (PFS), and overall survival (OS). **Results:** 54 patients with RM-NPC were enrolled (Arm 1, n = 30; Arm 2, n = 24). All patients had stage IVb disease and 34 (63%) had received ≥2 lines prior therapies. At data cutoff on Nov 19, 2021, the median SHR-1701 exposure was 6.7 cycles (range 2-23) in Arm 1 and 2.1 cycles (range 1-17) in Arm 2. Grade ≥3 treatment-related adverse events (TRAEs) were observed in 10 patients (18.5%), with the most common being anemia (7.4%) and hemoptysis (3.7%). Two patients (3.7%) discontinued study treatment due to AEs (peripheral nerve injury and epistaxis, n = 1 each), and 10 patients (18.5%) had dose delay caused by AEs. Investigator reported immune related AEs (irAEs) of grade ≥3 occurred in five patients (9.3%). One death (1.9%) from unknown cause was observed, and the causality was deemed as not assessable. At data cutoff, the ORR was 33.3% (95% CI 17.3-52.8) in Arm 1 and 4.2% (95% CI 0.1-21.1) in Arm 2. Responses were ongoing in nine (90.0%) and no patients, respectively, and the median DoR was not reached in Arm 1 and 4.1 months in Arm 2. The DCR was 53.3% (95% CI 34.3-71.7) and 25.0% (95% CI 9.8-46.7), respectively. The median PFS was 5.3 months (95% CI 1.3-not reached) in Arm 1 and 1.4 months (95% CI 1.3-2.7) in Arm 2. At data cutoff, five patients (16.7%) in Arm 1 and eight patients (33.3%) in Arm 2 had died, and the median OS was not reached in both Arms. The 12-month OS rate was 79.9% (95% CI 53.2-92.3) and 71.9% (95% CI 47.6-86.4), respectively. **Conclusions:** SHR-1701 showed tolerable toxicity profile and promising antitumor activity in patients with RM-NPC who failed prior platinum-based chemotherapy. Clinical trial information: NCT04282070. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

6025 **Poster Session**

Efficacy and safety of chemotherapy plus subsequent locoregional radiotherapy and toripalimab in de novo metastatic nasopharyngeal carcinoma. *First Author: Si-Yuan Chen, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Approximately 50% of primary metastatic nasopharyngeal carcinoma (mNPC) patients who received sequential chemoradiotherapy experience disease progression within one year. Improvements in therapy are greatly needed. This phase II study aimed to investigate the efficacy and safety of programmed cell death protein-1 (PD-1) inhibitor combined with sequential chemoradiotherapy in de novo mNPC. **Methods:** Patients who demonstrated complete or partial response following 3 cycles of cisplatin and fluorouracil (PF) were enrolled. Eligible patients received 3 more cycles of PF and subsequent radiotherapy plus toripalimab every three weeks at a fixed dose of 240 mg. The primary end point was objective response rate (ORR) at three months after radiotherapy, and the secondary end points were progression-free survival (PFS), disease control rate (DCR) and safety profiles. Exploratory study included biomarker analysis and efficacy comparation based on a historical cohort. A Simon's two-stage optimal design with one-sided type I error rate of 5% and power of 80% was utilized to compare a null hypothesis ORR of 54% against an alternative of 80%. Target accrual was a minimum of 22 patients (stage 1 and 2 combined). **Results:** Of the 22 enrolled patients (7 women and 15 men; median age of 54.5 years [IQR 40.5-57.5 years]), the ORR at three months after radiotherapy was 81.8% (22.7% complete response, n = 5; 59.1% partial response, n = 13), and the DCR was 81.8%. The median PFS was 19.4 months (95% CI 10.8-NR). Grade 3-4 adverse events occurred in 15 (68.2%) patients; two patients (9.1%) had grade 2 or 3 immune-related adverse events and discontinued toripalimab. This trial met its primary objective of demonstrating a significant ORR versus historical controls (81.8% vs. 54%, $P = 0.024$). Elevation of plasma EBV DNA post radiation was associated with worse median PFS (10.5 vs. 19.4 months; hazard ratio = 4.23, 95% CI 1.0-17.9; $P = 0.033$). **Conclusions:** The addition of toripalimab to sequential chemoradiotherapy displayed promising tumor response and manageable safety profile in primary mNPC. These results support a potential role of PD-1 inhibition as consolidation therapy in the first-line treatment of primary mNPC. Clinical trial information: NCT04398056. Research Sponsor: the National Natural Science Foundation of China, Other Foundation.

A new prognostic model in patients with recurrent or metastatic head and neck cancer treated with chemotherapy: An analysis of ECOG-ACRIN E1305. *First Author: Athanassios Argiris, Department of Medical Oncology, Thomas Jefferson University, Philadelphia, PA*

Background: We examined a large patient dataset based on E1305, a completed phase III randomized trial of platinum-based chemotherapy with or without bevacizumab (Argiris et al. JCO 2019), to evaluate prognostic factors in the first-line treatment of patients with recurrent or metastatic squamous cell carcinoma of the head and neck (RM SCCHN) and expand on our previous observations in cooperative group trials (Argiris et al. Cancer 2004). **Methods:** All 403 patients enrolled in E1305 were analyzed. Overall survival (OS) was the outcome of interest. Clinical and tumor characteristics were examined using Cox proportional hazards models. Variables which were significant in the univariate setting at a level of ≤ 0.10 were included in a multivariable model, and backwards selection was performed (threshold of $p \leq 0.05$). The final multivariable model was then applied to the two treatment arms, separately. Variables for which the hazards ratio (HR) within an arm was more than 10% different than that for the whole cohort, were removed from the final cohort model. **Results:** The median OS in the whole study cohort was 11.8 months. A prognostic score model for OS was built, using the 4 independent prognostic factors identified in the multivariable model: ECOG performance status (1 vs 0), prior radiation, primary region (non-oropharynx vs oropharynx), and metastatic disease bone or liver (vs other sites/no metastases). Prognostic score was dichotomized (0-2 and > 2). Patients with 0-2 risk factors (n = 249) had a median OS of 15.2 months (90% CI: 13.8, 18.1), while patients with > 2 risk factors (n = 154) had a median OS of 7.6 months (90% CI: 6.5, 9.3); HR of 2.14 (95% CI: 1.73, 2.66), $p < 0.0001$. Compared to our previous 5-factor model from analysis of older trials in a similar setting, the variable "bone/liver metastasis" is new, but "tumor cell differentiation" and "weight loss" were not significant and not included in the new model for OS. **Conclusions:** The new proposed model includes 4 prognostic factors for OS (performance status, primary site, prior radiation, presence of bone/liver metastasis) in the first-line treatment of RM SCCHN. Research Sponsor: U.S. National Institutes of Health.

Penpulimab plus anlotinib in patients with recurrent or metastatic head and neck squamous cell carcinoma after the failure of first-line platinum-based chemotherapy: A single-arm, multicenter, phase 2 study. *First Author: Changgong Zhang, Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study On Anticancer Molecular Targeted Drugs, Beijing, China*

Background: Penpulimab is a novel human immunoglobulin G1 (IgG1) anti-programmed cell death-1 (PD-1) antibody. The effect of antibody-dependent cell-mediated cytotoxicity and antibody-dependent cellular phagocytosis was eliminated completely by the modification of crystallizable fragment to avoid the FcγR binding. ALTN-AK105-II-01 (NCT04203719) is a single-arm, multi-cohort, multicenter phase 2 study to explore the efficacy and safety of penpulimab plus anlotinib, a multikinase inhibitor inhibiting angiogenesis and tumor cell proliferation simultaneously, in the treatment of various advanced cancers. Here we report the results of the cohort 1 for patients (pts) with recurrent or metastatic head and neck squamous cell carcinoma (R/M HNSCC). **Methods:** Eligible pts were diagnosed with histologically confirmed R/M HNSCC and had failed at least one line of platinum-based chemotherapy. Other inclusion criteria included aged 18 years or older, ECOG PS 0-1, and previous anti-angiogenic agents or immune checkpoint inhibitors treatment-naïve. Pts were given penpulimab 200mg intravenously on day 1 and oral anlotinib 12mg once daily from day 1 to day 14 every 3 weeks until disease progression or unacceptable toxicities. The primary endpoint was objective response rate (ORR) per RECIST 1.1. Secondary endpoints included progression-free survival (PFS), overall survival (OS), disease control rate (DCR), duration of response (DoR), and safety. **Results:** From June 1, 2020 to November 22, 2021, 38 pts were enrolled in 8 cencers in China. The sites of primary tumors included oral cavity (15/38, 42.9%), oropharynx (6/38, 15.8%), hypopharynx (4/38 4.5%), larynx (10/38, 26.3%) and others (3/38, 7.9%). As of January 6, 2022 (data cut-off),The study met its primary endpoint that 13 pts achieved partial response (PR) and the ORR (confirmed at least 4 weeks after initial response) was 34.21%. 14 pts obtained stable disease (SD) lasting for at least 4 weeks, given a DCR of 76.32%. After a median follow-up of 6.96 months (95%CI: 4.40, 8.80). PFS events were observed in 17 pts and the median PFS was 8.35 months (95%CI: 5.45, 13.11). The PFS at 6 months was 62.5%. 9 pts died and the median OS was not reached (95% CI: 9.43, NE). For pts with tumor response, the median DoR was not reached (95% CI: 2.37, NE). Treatment-related adverse events (TRAEs) occurred in 89.47% pts, TRAE of grade 3 or above occurred in 39.47% of pts. The most common TRAEs were hypertension (28.95%) and hypothyroidism (28.95%). **Conclusions:** The combination of penpulimab and anlotinib demonstrated promising efficacy and manageable toxicities in R/M HNSCC pts who failed standard first-line therapy. Further investigation is warranted. Clinical trial information: NCT04203719. Research Sponsor: None.

6028 **Poster Session**

Comprehensive immune landscape and molecular characteristics of clinical responses to chemotherapy, antiangiogenic agents, and PD-1 inhibitors in recurrent or metastatic nasopharyngeal carcinoma. *First Author: Mingyuan Chen, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: The role of a triple combination of gemcitabine (chemotherapy) plus apatinib (anti-VEGF) and toripalimab (anti-PD-1) (GAT) in recurrent/metastatic nasopharyngeal carcinoma is unclear. **Methods:** Between August 2019 and April 2020, 54 patients with recurrent or metastatic NPC were screened, of whom 41 eligible patients were enrolled and received study treatment. Patients were treated with gemcitabine (1000 mg/m^2) on days 1 and 8 once every 3 weeks for a maximum of 6 cycles plus toripalimab (240 mg) on day 1 once every 3 weeks and apatinib (orally administered at 250 mg) once a day until disease progression, death, dose-limiting toxicities, or at the patient's request to stop. The primary endpoint was the safety. The secondary endpoints included the objective response rate (ORR) and progression-free survival (PFS). **Results:** By the data cutoff date, the median follow-up time was 13.4 months. G3-4 hematologic, gastrointestinal and kidney toxicities were observed in no more than 3 (3/41, 7.3%) patients, while G3-4 nasopharyngeal wall necrosis was observed in 9 (9/41, 21.9%) patients. High-risk factors for nasopharyngeal necrosis, included repeated radiotherapy and an interval of less than 12 months from the last radiotherapy. Among all 41 patients, the ORR was 90.2% (95% CI: 76.9%-97.2%). The median PFS was 13.93 months (95% CI: NR-NR), and the 12-month PFS rate was 72.0% (95% CI: 57.1%-86.9%). A substantial increase of CD28+ and ICOS+ CD4+/CD8+ T cells and a decrease of PD1+ CD4+/CD8+ T cells were observed in the peripheral blood after the GAT treatment. 11q13.3 amplification and MRGPRF high expression in tumors correlated with poor PFS from the triple combination therapy. NPCs with 11q13.3 amplification was characterized by high epithelial mesenchymal transition (EMT) and immune suppressive transcriptional signatures. Furthermore, serial circulating tumor DNA (ctDNA) sequencing could predict PFS outcomes to combination therapy. **Conclusions:** The triple combination of GAT exhibits a promising antitumor activity and manageable toxicities in patients with recurrent/metastatic NPC. Patients with repeated radiotherapy and an interval of less than 12 months from the last radiotherapy should be carefully selected for antiangiogenic therapies. An integrated genomic and transcriptional analyses may aid to identify the beneficial patient populations in response to this novel combination therapy. Clinical trial information: NCT04073784. CA209-9KY: Results of a phase II study of intensity modulated radiotherapy (IMRT) re-irradiation and concurrent/adjuvant nivolumab (nivo) in patients with loco-regionally recurrent or second primary (RSPT) head and neck squamous cell carcinoma (HNSCC). *First Author: Nabil F. Saba, Winship Cancer Institute Emory University School of Medicine, Atlanta, GA*

Background: RSPT HNSCC within a previously irradiated field presents a technical challenge portending worse outcome. Anti-PD-1 therapy is an approved standard of care in the treatment of advanced HNSCC. CA209-9KY aimed to investigate the progression-free survival (PFS), tolerability, overall survival (OS) and patient reported outcomes (PRO) of nivo during and after IMRT re-irradiation. We report here the results for 51 enrolled and evaluable patients **Methods:** Following IRB approval at 3 participating institutions (Emory University, Cleveland Clinic, Medical College of Wisconsin), patients (pts) were enrolled if they had RSPT in a previously irradiated field (>40Gy) and met criteria for recursive partition analysis (RPA) classes I or II (Ward et al, IJROBP 2018). Salvage resection was allowed provided the presence of pos margins, ENE, pN2/3 or pT3/4 disease, multifocal PNI, or LVI. IMRT re-irradiation to a total of 60-66 Gy in 30-33 daily fractions were delivered over 6-6.5 weeks with nivo (240 mg) two weeks prior and every 2 weeks x 5 during IMRT then at 480 mg every 4 weeks up to 52 weeks. The primary endpoint was improvement in 1-yr PFS from 40% to 55% (one-sided alpha of 0.05 and an 85% power). **Results:** As of 1/2022, a total of 51 evaluable pts completed IMRT with nivo. Median age 62 (56-67), RPA status 1 (23, 46%), 2 (27, 54%), Males (41, 80%), ECOG performance status 0 (13, 25%) 1 (36, 71%), 2 (2, 4%); p16 pos (16, 31%), neg (9,18%), not applicable (26, 51%). With a median follow up of 12.5 mos (11.2-14.0) the 1- yr PFS was 57.8% (95% CI, 41.3-71.1%) and OS was 81.7% (95% CI, 65.2-90.9%). Among 38 pts with available flow cytometry, pts with a 1.5-fold increase in peripheral blood PD1+KI67+CD8+ T cells (baseline to weeks 2 or 4) had an OS of 19.3 mos (vs 13.3 mos) (p=0.1617). Adverse events (AEs) (CTCAE version 4.0) included fatigue(40, 78%), dermatitis (30,58%), dysphagia (28, 54%). Most frequent serious AEs were anorexia and dyspnea (2, 4% each). Treatment related >3 AEs were lymphopenia (2, 4%), colitis, diarrhea, mucositis and nausea (1, 2% each). FACT-G and FACT-H&N QOL scores remained stable and consistent across all time points (52 weeks) (Cronbach's alpha of > 0.7) (ASTRO 21, abstract # 2738). **Conclusions:** CA209-9KY met its primary endpoint of 1-yr PFS; IMRT reirradiation with concurrent and adjuvant nivo is clinically effective, well tolerated and deserves further exploration in patients with RSPT HNSCC. CA209-9KY was supported by a grant from BMS. Clinical trial information: NCT03521570. Research Sponsor: BMS.

A retrospective analysis of patients administered neoadjuvant chemotherapy (NACT) with paclitaxel plus carboplatin with oral metronomic chemotherapy (OMCT) in locally advanced borderline resectable/technically unresectable head and neck cancers. *First Author: Shruti Pathak, Tata Memorial Centre, Mumbai, India*

Background: Neoadjuvant chemotherapy with TPF though the standard is seldom used in India due to its adverse events rate. Two drug regimen of Paclitaxel and Carboplatin (PC) though favoured has inferior outcomes. Hence, we did an analysis to estimate the efficacy and adverse event rate of addition of 3 drug metronomic schedule to PC. **Methods:** Patients of locally advanced head and neck cancer referred from multidisciplinary board for neoadjuvant chemotherapy and unsuitable for TPF were selected for this analysis. These patients had received 2 drug regimen of intravenous PC with 3 drug regimen of weekly methotrexate 9 mg per m2, Celecoxib 200 mg twice daily, erlotinib 150 mg once daily all administered orally. All patients underwent a response assessment at 5-7 weeks post start of therapy and we're discussed in MDT for further treatment. Adverse events were recorded in accordance with CTCAE version 4.03 and response in accordance with RECIST version 1.1. PFS and OS were estimated with Kaplan Meier method. **Results:** 72 patients were identified with the median age being 45 (27-80) and M:F ratio (67:5). The indication for NACT were borderline resectability in all patients. . The response rate was 61.1% and grade 3 and above adverse event rate was 33.5% . A total number of 34 among 40 borderline resectable patients underwent surgery. The overall estimated PFS and OS were 18.5 (95%CI = 14.4-22.7) months and 18.05 (95%CI = 14.2-21.8) months respectively. The three most adverse events observed were grade 3 thrombocytopenia in 2 patients (2.8%), grade 3 aspartate aminotransferase (AST) derangement in 4 patients (5.6%) and grade 3 alanine aminotransferase (ALT) in 4 patients (5.6%). **Conclusions:** The 5 drug combination regimen is safe, tolerable and seems to have similar efficacy as a three drug TPF regimen. Research Sponsor: None.

Complications and severity of COVID-19 in patients with head and neck cancer (HNC): A COVID-19 and Cancer Consortium (CCC19) registry analysis. *First Author: Vidhya Karivedu, Division of Medical Oncology, Ohio State University, Columbus, OH*

Background: Patients with cancer have worse outcomes from COVID-19 infection. However, the specific impact of COVID-19 on patients with head and neck cancer (HNC) is largely unknown. The COVID-19 and Cancer Consortium (CCC19) maintains an international registry (NCT04354701) aimed to investigate the clinical course and complications of COVID-19 in patients with cancer. Here, we report severity of COVID-19 and its complications among HNC patients. **Methods:** The CCC19 registry was queried for patients with HNC and laboratory confirmed SARS-CoV-2 infection. The co-primary outcomes were severity of COVID-19 illness on an ordinal scale (0: no complications; 1: hospitalized, no oxygen (O2); 2: hospitalized, required O2; 3: ICU admission; 4: mechanical ventilation (MV); 5: death), and severity of complications (mild, moderate, serious). The outcomes were further stratified by demographics, recent treatment (systemic vs local; surgery, radiation (RT) vs systemic), treatment intent (palliative vs curative), and cancer status (remission, responding, stable, progressing). **Results:** From March 2020 to December 2021, 356 HNC patients were identified. Median age was 65 (interquartile range 58-74), 29% were female, 56% were white, 67% were former or current smokers, 20% had a BMI >30, 15% had an ECOG performance status >2, and 57% had >2 comorbidities. 154 (43%) had no complications, 61 (17%) were hospitalized without O2, 135 (38%) were hospitalized with O2, 50 (14%) required ICU, 32 (9%) required MV, and 74 (21%) died. 88 (25%) had mild, 59 (17%) had moderate, and 132 (37%) had serious complications. 33% of patients who received systemic therapy and 30% who received RT within 3 mo prior to COVID-19 diagnosis died. Mortality was higher in patients receiving palliative when compared to curative intent treatment (44% vs 16%). In addition, 50% of patients with actively progressing cancer, and 45% who had serious complications died. Importantly, 37 (n=12 palliative systemic therapy and n=25 local therapy) patients had a treatment delay due to COVID-19 diagnosis. **Conclusions:** Our study is the largest cohort to date describing COVID-19 outcomes in HNC patients and suggest a high rate of mortality even in those receiving local and curative intent treatment. Variables stratified by COVID-19 severity. Note: Ordinal levels 3 and 4 not shown due to small case numbers. Research Sponsor: Supported by Vanderbilt Institute for Clinical and Translational Research grant support (UL1 TR000445 from NCATS / NIH).

Leukocyte interleukin injection (LI) immunotherapy extends overall survival (OS) in treatment-naive low-risk (LR) locally advanced primary squamous cell carcinoma of the head and neck: The IT-MATTERS study. *First Author: Eyal Talor, Cel-Sci Corporation, Vienna, VA*

Background: The 3-week pre-surgery peritumoral/perilymphatic administration of an investigational proinflammatory cytokine complex biologic (LI) with CIZ (single low dose cyclophosphamide IV-bolus, 300 mg/m^2), indomethacin (po 25mg tid) and Zinc as multivitamins (po 15-45mg Zinc) + Standard of Care (SOC) to oral and soft-palate SCCHN subjects, resulted in early response (CRs/PRs) prior to surgery [RECIST] (confirmed at surgery by pathology) significantly prolonged OS in the NCCN-defined LR intent to treat (ITT) population vs SOC alone. Encouraging phase 2 OS and early responders results motivated this pivotal study IT-MATTERS Clinicaltrials.gov NCT01265849. No safety issues were noted for LI in this pivotal study or previous studies. **Methods:** Subjects (923 ITT; of which 380 LR ITT) meeting protocol entry criteria (including AJCC Stage III/IVa OSCC, soft-palate SCCHN, treatment naive) were randomized 3:1:3 to treatment arms LI (+/- CIZ) + SOC or to Control (SOC alone). LI treated were administered 200IU peritumorally and the same dose peri-lymphatically daily for 3-weeks before surgery. All study subjects were to receive SOC (per NCCN Guidelines). LR for recurrence subjects were to receive RTx while high risk subjects were to receive CRTx post-surgery. Follow-up was comparable (56-57 months median per treatment group). **Results:** Pre-surgery responders (PSR; CR/PR) in ITT LI treated (+/- CIZ) groups were 8.5% (45/529; overall LI) and 16% (34/212; LR LI) vs no SOC PSRs. Early response lowered death rate to 22.2% (ITT LI treated) vs 54.1% for non-PSRs (two-sided Fisher Exact (2FE) $p < 0.0001$), for ITT LR LI PSRs with 17.6% vs 42.7% (2FE $p = 0.0067$), and for ITT LR LI responders (LI+CIZ+SOC) 12.5% vs 41% (2FE $p = 0.0101$). Proportional hazard (PH) ITT LR LI treated HR = 0.348 (95% CI: [0.152, 0.801]), ITT LR LI+CIZ+SOC HR = 0.246 (95% CI: [0.077, 0.787]). For all ITT LR (n = 380), LI+CIZ+SOC demonstrated significant OS advantage vs SOC (log rank $p = 0.0478$; Cox HR = 0.68 (95% CI: [0.48-0.95]), Wald $p = 0.0236$ [controlling for tumor stage, tumor location and geographic region]. The absolute OS advantage in ITT LR LI+CIZ+SOC vs SOC was 4.9%/9.5%/14.1%, at 36/48/60 months (M), representing 72.4% vs 67.5% (36 M); 67.3% vs 57.8% (48 M), and 62.7% vs 48.6% (60 M) with a 46.5 M median OS advantage (101.7 M [LI+CIZ+SOC] vs 55.2 M [SOC]). Percent treatment emergent adverse events (TEAEs) were comparable among all treated groups. No excess safety was reported for LI treatment over SOC alone. **Conclusions:** LI immunotherapy did not add excess safety issues or TEAEs. Early LI response decreases mortality and is OS prognostic. ITT LR LI+CIZ+SOC absolute OS advantage over SOC alone increased over time; the 0.68 HR corresponds to a 47% prolongation of median survival in a population without any new therapy options in decades. Clinical trial information: NCT01265849. Research Sponsor: CEL-SCI Corporation.

Four-year result of diffusion-weighted, MRI-guided, dose-painting radiotherapy following induction chemotherapy in patients with locally advanced recurrent nasopharyngeal carcinoma: A randomized controlled trial. *First Author: Feng Liu, Hunan Cancer Hospital and The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, China*

Background: We hypothesized that diffusion-weighted MR imaging (DWI) guided dose-painting radiotherapy (DP-RT) following induction chemotherapy (IC)was associated with improved local tumor control and progression-free survival compared with conventional MRI-based radiotherapy (RT) in locally advanced recurrentnasopharyngeal carcinoma (rNPC). The purpose of this randomized phase II trial was to compare the efficacy and toxicity of DWI guided DP-RT following IC versus standard conventional MRI-based radiotherapy following IC in locally advanced rNPC. **Methods:** Tow hundred and four patients with locally recurrent T3 to T4 NPC were randomly assigned to receive DWI-guided dose-painting radiotherapy (DP-RT) or conventional MRI-based radiotherapy. Patients in both groups received reirradiation using intensity modulated radiation therapy (IMRT) following cisplatin-based induction chemotherapy. In DP-RT group (group A, n = 102), subvolume GTVnx-DWI (gross tumor volume of nasopharynx in DWI) was defined as the areas within the GTVnx (gross tumor volume of nasopharynx) with an apparent diffusion coefficient (ADC) below the mean ADC (ADC < mean). The dose to GTVnx-DWI was escalated to DT 65.4 Gy/30 Fx in 2.18 Gy per fraction. In conventional MRI-based RT group (group B), PGTVnx was irradiated at DT 60.0 Gy/30 Fx in 2.0 Gy per fraction. This trial is registered with chictr.org.cn, number ChiCTR2100052340. **Results:** Compared with conventional MRI-based radiotherapy, DWI-guided DP-RT significantly improved 4-year progression-free survival (PFS, 48.0% vs. 33.3%; P = 0.033), local control rate (LC, 85.3% vs. 69.6%; P = 0.007), and overall survival (OS, 52.0% vs. 37.3%; P = 0.035). No statistically significant differences in acute and late toxic effects (mucosal necrosis, trismus, temporal lobe necrosis, and cranial nerve palsy) were observed between the two groups. Dose painting (DWI-guided DP-RT vs conventional MRI-based RT) was a significant independent prognostic factor for PFS and LC (P = 0.035 and P = 0.020, respectively). **Conclusions:** Diffusion-weighted MRI guided dose-painting radiotherapy following induction chemotherapy is associated with a considerable progression-free survival and local control benefit, without increasing toxicity, as compared with standard conventional MRI-based RT following IC, among patients with locally recurrent T3 to T4 nasopharyngeal carcinoma. Clinical trial information: ChiCTR2100052340. Research Sponsor: Hunan Provincial Science and Technology Department (NO. 2021JJ30426) (China), Other Foundation.

Efficacy and safety of QL1706, a novel dual immune checkpoint blockade containing a mixture of anti-PD1 IgG4 and anti-CTLA4 IgG1 antibodies, for advanced nasopharyngeal carcinoma (NPC): Pooled cohort data from phase 1a/1b trials. *First Author: Hongyun Zhao, State Key Laboratory of Oncology in South China Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Additional anti-cytotoxic T lymphocyte antigen 4 (CTLA-4) antibody could increase the anti-tumor effect of anti-programmed cell death 1 (PD-1) antibody. QL1706 is a novel dual immune checkpoint blockade containing a mixture of anti-PD-1 IgG4 and anti-CTLA4 IgG1 antibodies produced by a single cell line. Here the pooled data from phase 1a/1b trials of QL1706 in advanced NPC were reported. **Methods:** In the phase 1a dose escalation and expansion study (NCT04296994), patients received intravenous QL1706 at 0.3, 1.0, 3.0, 5.0, 7.5, or 10.0 mg/kg q3w for dose escalation in an accelerated 3+3 design, and the dose expansion cohorts received selected doses. In phase 1b (NCT05171790), patients with advanced solid tumors were given intravenous QL1706 5.0 mg/kg q3w according to the data in phase 1a. Phase 1a was primarily aimed to define the safety, tolerability, and recommended phase 2 dose of QL1706, and phase 1b was to evaluate the preliminary efficacy. Pooled analyses were conducted in the NPC cohorts receiving QL1706 5 mg/kg. Additionally, dynamic changes of plasma EBV DNA level from baseline were determined in a part of patients during the studies. **Results:** As of Dec 31, 2021, totally 110 patients with NPC were included. Median follow-up was 7.7 months. 79 (71.8%) patients had ≥two prior treatment lines. 48 (43.6%) patients received previous immunotherapy. Confirmed overall response was reached in 27 patients (24.5%; 95% CI 16.8%-33.7%). In immunotherapy-naive patients with one and ≥two prior lines of treatment, overall response rates were 39.1% (9/23) and 38.5% (15/39), respectively. Three of 48 (6.3%) immunotherapy-treated patients had partial response. Disease control was observed in 54 (49.1%; 95% CI 39.4%-58.8%) patients. Median duration of response reached 11.7 months (95% CI 8.1-not estimable). Median progression-free survival was 2.0 months (95% CI 1.4-2.9). Overall survival data were immature. Patients with ≥50% decrease in EBV DNA level on day 43 had significantly better ORR than those with < 50% decrease (67% [8/12] versus 12% [2/17]; P = 0.0045). Treatment-related adverse events (TRAE) were reported in 85 (77.3%) patients. 14 (12.7%) experienced grade ≥3 TRAE. The most common TRAE were rash, hypothyroidism (25 [22.7%], each), and pruritus (22 [20%]). TRAE leading to dose interruptions occurred in 10 (9.1%) patients. No TRAE leading to dose discontinuation or death was reported. The immune-related TRAE and serious TRAE were observed in 51 (46.4%) and eight patients (7.3%), respectively. **Conclusions:** These preliminary results indicated QL1706 had impressive anti-tumor effects on advanced NPC, with acceptable tolerability and manageable toxicity. Further investigation of QL1706 in NPC is continuing. Clinical trial information: NCT04296994; NCT05171790. Research Sponsor: Qilu Pharmaceutical Co., Ltd.

Infections and their impact on patients on pembrolizumab-based therapies for head and neck cancer. *First Author: Yuqi Zhang, Houston Methodist Hospital, Houston, TX*

Background: Immune checkpoint inhibitors (ICIs) stimulate the antitumor activity of the adaptive immune response and are used in combination with chemotherapy or as a monotherapy in metastatic head and neck squamous cell carcinoma (mHNSCC). Infections are known to impact outcomes in patients receiving chemotherapy, but the incidence and impact in patients receiving ICI is poorly defined. This analysis aims to identify the infectious burden and associated impact on clinical outcome in patients receiving pembrolizumab for mHNSCC. **Methods:** This is a retrospective study across 7 hospitals analyzing patients who received pembrolizumab from 1/1/2017-8/1/2021 and followed until 12/1/2021. Patients with mHNSCC that received pembrolizumab were dichotomized into infected and uninfected cohorts. Comparative covariates included gender, race, ECOG, comorbidities, anti-infectives use at ICI initiation, chronic infections, line of therapy (first or 1L, second or 2L, or > 2L). Risk factors for infections were assessed by univariable and multivariable analysis with reported odds ratio (OR) and 95% confidence intervals (CI). Morbidity and mortality was assessed by all-cause emergency department (ED), inpatient, and intensive care unit (ICU) admissions, median cycles of ICI-based therapy, and overall survival (OS). OS was assessed via Kaplan-Meier analysis. P-value < 0.05 was considered statistically significant. **Results:** Of the 45 evaluable patients with mHNSCC, 22 (48.9%) had at least one infection. Baseline characteristics and comorbidities were similar across cohorts. Risk factors for developing infection included anti-infective use at ICI initiation (OR 13.27, 95% CI: 1.13-156.53, p = 0.04). Fewer infections were observed with ICI as > 2L compared to 1L (OR 0.1, 95% CI: 0.01-0.91, p = 0.041). Infection was the primary cause of death in 2 (9.5%) patients. Compared to the uninfected, infected patients received fewer cycles of therapy (4 vs 7, p = 0.026), and were more frequently admitted to the hospital [20 (90.9%) vs. 8 (34.8%), p < 0.001)] and ICU [5 (11%) vs. 0, p = 0.022]. Number of ED visits were similar at 8 (36.4%) in the infected vs. 5 (21.7%) in the uninfected (p = 0.28). At median follow-up of 8 months, 13 (59.1%) in the infected cohort and 8 (34.8%) in the uninfected had died (p = 0.1). Median OS was significantly lower in the infected (9.2; 95% CI 4.9-12.8 months) compared to the uninfected (28.1; 95% CI 14.3-unreached months) (p = 0.009). **Conclusions:** For mHNSCC patients on pembrolizumab, infections are more common in the 1L setting and is associated with fewer treatment cycles, more hospitalizations, and significantly shorter OS. Risk factors for infection include anti-infective use at ICI initiation. Research Sponsor: None.

Taxanes plus cetuximab with or without platinum chemotherapy after progression on immune checkpoint inhibitors in patients with squamous cell carcinoma of the head and neck. *First Author: Khalil Saleh, Departemnt of Hematology, Gustave Roussy Cancer Campus, Villejuif, France*

Background: Salvage chemotherapy after progression on immune checkpoint inhibitors (ICIs) was associated with an objective response rate (ORR) of 30% in patients (pts) with recurrent/metastatic squamous cell carcinoma of the head and neck (R/M SCCHN). We aimed to investigate the efficacy of taxanes + cetuximab (TC) +/- platinum chemotherapy in pts with R/M SCCHN who failed ICIs in palliative setting. **Methods:** A retrospective study was conducted at 7 French university hospitals. Eligibility criteria were pts treated with ICI for R/M SCCHN, who progressed after treatment with ICI and received TC +/- platinum salvage chemotherapy between August 2017 and December 2021. Clinical and radiological data and outcome were collected from review of medical records. **Results:** Ninety-nine pts met eligibility criteria: 63 pts received TC and 36 pts received triplet regimen (TR). The median age was 61 years (range 24-78) and 79% of pts were male. Forty-two pts (42%) had platinum-refractory disease (PRD) after multimodal treatment, 13 pts received prior taxanes and 24 pts received prior cetuximab. The median PS at salvage chemotherapy was 1 (range 0-3). ICIs were given as first-line treatment in 70% of pts including those with PRD. The ORR of the entire cohort was 62% (61/99) including 5 complete responses (CR) and the disease control rate was 79% (78/99). The median progression-free survival of the entire cohort was 4.4 months and the median overall survival (OS) was 7.5 months. The 5 pts who had CR as best response are still in remission after a median follow-up of 24 months (range 8-58). The ORR of TC subgroup was 57% (36/63) and the ORR of TR subgroup was 69% (25/36). Furthermore, the ORR in the PRD subgroup of pts was 54% (39/72), and the ORR in the subgroup of pts who were not chemo naïve was 54% (39/72). The ORR in pts who previously received cetuximab was 50% (12/24) vs 75% (49/75) in those who did not. The ORR in pts who previsouly received taxanes was 38% (5/13) vs 65% in those who did not. Finally, the ORR in PRD pts and treated with TR was 50% (7/14) and the ORR in pts who previously received platinum-based treatment or PRD and treated with TR was 55% (11/20). **Conclusions:** TC +/- platinum chemotherapy was highly effective in pts R/M SCCHN who progressed on ICIs with an ORR of 62% and DCR of 79%. Further investigations are warranted. Research Sponsor: None.

Individualized prediction of distant metastases risk in oral cavity carcinoma: A validated predictive-score model. *First Author: Badr Id Said, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: We aimed to develop and validate a risk-scoring system for distant metastases (DM) in oral cavity carcinoma (OCC). **Methods:** In this IRB-approved retrospective study, OCC patients treated at 4 tertiary cancer institutions with curative surgery +/- postoperative radiation/chemo-radiation (PORT/PO-CRT) were divided into discovery and validation cohorts (randomly selected in 3:2 ratio). Staging was reviewed based on TNM 8th edition. Predictors of DM identified on multivariable analysis in discovery cohort were used to develop DM risk-score model to classify patients into risk groups using Contal and O'Quigley method for cut-off optimization. The utility of risk classification was subsequently evaluated in validation cohort. C-index was used to assess predictive ability of the continuous risk score. **Results:** Overall 2749 patients were analyzed (Table). Predictors (risk score coefficient) of DM in discovery cohort were: pT3-4 (0.4), pN+ (N1:0.8; N2:1.0; N3:1.5), histologic grade 3 (G3, 0.7) and lymphovascular invasion (LVI, 0.4). The DM risk groups were defined by cumulative sum of risk score coefficients: high risk (sum >2), intermediate risk (sum=1-2), and standard risk (sum<1). In the discovery cohort, 5-yr DM for high vs intermediate vs standard risk groups was 33% vs 19% vs 6%, p<0.001 (C-index=0.79). Similarly, in the validation cohort, 5-yr DM for high vs intermediate vs standard risk groups was 36% vs 23% vs 7%, p<0.001 (C-index=0.77). When applied to entire study population, this predictive model showed excellent discriminative ability in predicting DM only without locoregional failure (29% vs 18% vs 3%, p<0.001), late (>2 yr) DM (11% vs 5% vs 3%; p<0.001), DM in patients treated with surgery only (26% vs 11% vs 6%, p<0.001), PORT (37% vs 23% vs 7%, p<0.001), and PO-CRT (42% vs 29% vs 9%, p<0.001). Finally, 5-yr OS for high vs intermediate vs standard risk groups in the overall cohort was 24% vs 38% vs 66%, p<0.001. **Conclusions:** A predictive-score model for DM utilizing pT3-4, pN1/2/3, G3 and LVI demonstrated a validated utility in identifying patients at higher risk of DM who may be evaluated for individualized risk-adaptive treatment escalation and/or surveillance strategies. Research Sponsor: None.

Study cohorts and predictors of distant metastases in discovery cohort.

Predictors of the survival for platinum-refractory head and neck squamous cell carcinoma by using contrast-enhanced magnetic resonance imaging. *First Author: Hsueh-Ju Lu, Division of Hematology and Oncology, Department of Internal Medicine, Chung Shan Medical University Hospital, Taichung, Taiwan*

Background: Platinum-refractory head and neck squamous cell carcinoma (HNSCC) was a poor prognosis. Under the treatment of immune checkpoint therapy, overall survival (OS) was still only 7.7 months. Moreover, the prognostic factors were unclear. **Methods:** For enrolled platinum-refractory HNSCC patients, the presented images of the axial, coronal, and sagittal planes from T1-Weighted Contrast-Enhanced Magnetic Resonance Imaging (T1 CE MRI) were independently reviewed by two physicians. First, the most representative characteristics of the recurrent tumor on the three planes were manually identified, and the intersection coordinate was calculated as a circle center by computerized methods. Then, the center delineated a region of interest (ROI) with a radius of 25 pixels on each representative slice and excluded the air areas. Descriptive features and four groups of texture features (Gray Level Co-occurrence Matrix [GLCM], Gray Level Run Length Matrix [GLRLM], Gray Level Size Zone Matrix [GLSZM], and Neighbouring Gray Tone Difference Matrix [NGTDM]) were derived from the ROI to depict MRI intensities' distribution and heterogeneity. **Results:** A total of 30 patients were retrospectively enrolled, including immune checkpoint therapy (N = 19) and cetuximab-based chemotherapy (N = 11) as front-line therapy. Median OS was 7.0 months with 17 death events during follow-up. The area size of ROI was not significantly associated with the death events. However, High Gray-level Run Emphasis (HGRE) and Short-Run High Gray-level Emphasis (SRHGE) of GLRLM as well as High Gray-level Zone Emphasis (HGZE) and Short-Zone High Gray-level Emphasis (SZHGE) of GLSZM were significant to predict the event of death. The area under the curve (AUC) of HGRE, SRHGE, HGZE, and SZHGE were 0.747 (P = 0.023), 0.842 (P = 0.002), 0.819 (P = 0.003), and 0.833 (P = 0.002) at discretization levels of 16, respectively. These features also significantly differed OS of platinum-refractory HNSCC (Table). **Conclusions:** Four texture features of GLRLM and GLSZM depicted the fragmentation of extracellular volume of the recurrent tumor on T1 CE MRI and significantly correlated with the outcomes of platinum-refractory HNSCC. However, future warranted studies were needed. Research Sponsor: None.

	1-year survival	Hazard ratio (95% CI)
High Gray-level Run Emphasis (HGRE)	54.5% vs. 9.7%	2.218(0.629-7.826)
Short-Run High Gray-level Emphasis (SHRGE)	65.9% vs. 0.0%	4.254(1.213-14.915)
High Gray-level Zone Emphasis (HGZE)	75.0% vs. 0.0%	8.741(1.134-67.397)
Short-Zone High Gray-level Emphasis (SZHGE)	100.0% vs. 0.0%	45.726(0.714-2927.085)

Phase I results of gunagratinib (ICP-192), a highly selective irreversible FGFR 1-4 inhibitor in patients with head and neck cancer harboring FGF/FGFR gene aberrations. *First Author: Ye Guo, Oncology, Shanghai East Hospital, Tongji University, School of Medicine, Shanghai, China*

Background: The fibroblast growth factor (FGF) and FGF receptor (FGFR) signaling pathway has been evaluated as critical driver of carcinogenesis in multiple cancer types. However, primary results of several FGFR inhibitors showed no or limited response in head and neck cancer (HNC) with FGF/FGFR gene aberrations. Here, we evaluated the efficacy and safety of a novel irreversible pan-FGFR inhibitor gunagratinib in HNC in a first-in-human, phase I/IIa, dose escalation and dose expansion study (ICP-CL-00301 NCT03758664). **Methods:** In the dose-escalation stage of ICP-CL-00301 study, patients with advanced solid tumors (including HNC) with or without FGF/FGFR gene alterations were treated with escalating doses (range: 2mg-26mg) of gunagratinib once daily in 21-day cycles until disease progression or unacceptable toxicity. **Results:** 12 HNC patients with or without FGF/FGFR aberrations, including FGF amplification and FGFR mutation, were treated with escalating doses (range: 14mg-22mg) of gunagratinib. Among them, 9 patients harbored FGF/FGFR gene alterations with at least one tumor assessment. The median age of the 12 treated HNC patients was 56 (range: 44 to 75 years) with 75% male and ECOG performance status 1. Among the 9 HNC patients with FGF/FGFR gene aberrations who have completed at least one tumor assessment, 3 patients had partial response (PR), the overall response rate (ORR) was 33.3% (3 of 9 patients). The disease control rate (DCR) was 66.7% (6 of 9 patients). Total of 62 patients with solid tumor were enrolled in ICP-CL-00301 study. The most common treatment-related adverse events (TRAEs) (≥15%) included hyperphosphatemia, diarrhea, increased ALT or AST, increased alkaline phosphatase, hypercalcemia, increased serum creatinine, dry mouth, hypertriglyceridemia, anemia and hyperuricemia. In ICP-CL-00301 study, 3 serious TRAEs were reported, and no serious TRAE were reported in HNC patients. **Conclusions:** This study demonstrated the anti-tumor activity of gunagratinib in HNC patients carrying FGF/FGFR gene aberrations with an ORR of 33.3%. Gunagratinib is safe and well-tolerated in patients with advanced solid tumors including HNC. Clinical trial information: NCT03758664. Research Sponsor: Beijing InnoCare Pharma Tech Co., Ltd.

The impact of induction chemotherapy response to survival outcomes in oropharyngeal cancer. *First Author: Qixian Zhang, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: The role of induction chemotherapy (IC) in oropharyngeal squamous cell carcinoma (OPSCC) remains inconclusive. Previous randomized trials showed no survival advantage with IC in head and neck squamous cell carcinoma, including OPSCC. However, the impact of response to IC has rarely been considered in these trials. In this study, we aimed to investigate the prognostic value of IC response on HPV+ and HPV- OPSCC. **Methods:** Patients with stage II-IVB OPSCC (UICC 7th edition) who underwent IC (paclitaxel and platinum-based regimen for the most) and concurrent chemoradiotherapy during 2010 to 2020 were enrolled. HPV status was confirmed by p16 immunohistochemistry (p16 ≥ 70%). The clinical response to IC was assessed on MRI or CT images. Patients with complete response (CR) or major partial response (PR) (≥50% PR) were defined as sensitive subgroup (IC-s), while those with <50% PR, stable disease (SD) or progressive disease (PD) were deemed as resistant (IC-r). Progression-free survival (PFS) and overall survival (OS) were compared. **Results:** 51 HPV+ and 57 HPV- OPSCC patients were included. In the entire cohort, 55.6% patients were sensitive to IC. HPV+ OPSCC showed higher IC-s rate (62.7% vs. 49.1%) than HPV- subgroup. IC-s was associated with better clinical outcomes either in the whole cohort (3y-PFS 91.7%vs.43.7%, P < 0.001; 3y-OS 98.3% vs.67.4%, P = 0.002), the HPV+ subgroup (3-year PFS 94.7% vs. 47.9%, P < 0.001; 3-year OS 100% vs. 73.5%, P = 0.055) or the HPV- subgroup (3-year PFS 88.2% vs. 40.9%, P = 0.001; 3-year OS 96.4% vs. 63.1%, P = 0.026). Multivariate analysis demonstrated IC-s as an independent prognosticator for 3y-PFS (hazard ratio [HR], 0.088; 95% confidence interval [CI], 0.027-0.289; P < 0.001) and 3y-OS ([HR], 0.100; 95% CI, 0.021-0.477; P = 0.004) when adjusting for T, N, gender, age and smoking status. **Conclusions:** The response to IC exerts a critical predictive effect on survival outcomes in both HPV+ and HPV- OPSCC. Personalized treatment strategy based on IC response warrants further exploration in future studies. Research Sponsor: None.

PDS0101, a novel type I interferon and CD8 T-cell activating immunotherapy, in combination with pembrolizumab in subjects with recurrent/metastatic HPV16-positive head and neck squamous cell carcinoma (HNSCC). *First Author: Jared Weiss, University of North Carolina Hospitals, Chapel Hill, NC*

Background: Human papillomavirus (HPV) E6/E7 oncoproteins mediate immune evasion by down-regulating Type 1 interferons, TLR9, MHC Class I/II as well as other mechanisms, resulting in persistent infection and initiation of ~5% of all cancers globally. Similarly, established cancers evade immune surveillance utilizing parallel mechanisms including the expression of checkpoint proteins. PDS0101 is a molecularly targeted immunotherapeutic based on an enantiospecific cationic lipid nanoparticle platform containing HPV16 neoantigens that exhibits anti-tumor activity with checkpoint inhibitors (CPIs) by upregulating Type I interferons and promoting antigen processing and cross presentation. This allows generation of high levels of polyfunctional HPV16-specific CD8 and CD4 T cells *in vivo* as well as immune memory. VERSATILE-002 (NCT04260126) is a phase 2 study of the combination of PDS0101 and pembrolizumab in treatment of CPI naïve and refractory patients with recurrent or metastatic HPV16-related HNSCC. Herein, we report preliminary safety and efficacy data for CPI naïve patients at a prespecified interim analysis. **Methods:** Subjects are treated with pembrolizumab 200mg IV every three weeks plus SC PDS0101 following pembrolizumab on days one of Cycles1-4 and Cycle12; pembrolizumab continues up until 35 cycles, disease progression or intolerance to therapy. **Results:** Eighteen CPI naïve subjects with confirmed HPV16 tumors and a CPS score > = 1, median age 62 yrs (range 46-71), all male, 17 (94%) of whom were White and 16 (88.9%) not Hispanic or Latino, received at least one cycle of combination therapy. At the time of analysis, 17 (94%) subjects had received > = 4 doses of PDS0101 (median 4, range 1-5) and pembrolizumab (median 7, range 1-14). There were no Grade 3 or greater treatment-related toxicities and no drug discontinuation related to toxicity or immune-related AEs. Clinical activity (CR+PR+SD) was seen in 13 (72.2%) of 18 subjects, with best overall reponse per RECIST1.1 documenting: OR in 7 (38.9%; 2 CR, 5PR); stable disease (SD) in 6 (33.3%) and progressive disease in 3 (16.7%); 2 subjects had missing data. Tumor reduction was seen in 4 of 6 (67%) subjects with SD. Nine-month PFS and OS rates (95% CI) were 52% (22.5, 74.7) and 81% (37.8, 95.5) respectively; median PFS and OS have not been reached. **Conclusions:** The combination of PDS0101 and pembrolizumab demonstrates an excellent safety profile with preliminary evidence of clinical activity in the majority of CPI naïve patients with HPV-related HNSCC. Clinical trial information: NCT04260126. Research Sponsor: PDS Biotechnology.

Efficacy and safety of camrelizumab combined with apatinib in previously treated recurrent or metastatic nasopharyngeal carcinoma: A phase II clinical trial. *First Author: Lin-Quan Tang, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: The synergistic antitumour effect immune checkpoint inhibitors combined with antiangiogenic targeted therapy in refractory RM-NPC patients remains unknown. This phase 2 trial assessed the efficacy and safety of camrelizumab (an anti-programmed death 1 [PD-1] inhibitor) plus apatinib (a VEGFR-2 tyrosine kinase inhibitor) after at least first-line therapy in refractory RM-NPC patients. **Methods:** We did a phase 2 single-armed study to evaluate the activity of camrelizumab plus apatinib in platinum-resistant (cohort 1) and PD-1 inhibitor resistant (cohort 2) NPC. Eligibility required measurable disease (RECIST 1·1), Eastern Cooperative Oncology Group (ECOG) performance status of 0-1, age of 18-75 years, and disease progression on platinum but PD-1 inhibitor-naive (cohort 1) or disease progression on PD-1 inhibitor (cohort 2) after at least first-line therapy. Patients in cohort 1 received 200 mg intravenous camrelizumab every 3 weeks plus 250 mg oral apatinib daily. Patients in cohort 2 received apatinib monotherapy in the first two weeks to modify the immune-resistant microenvironment, and were then administered camrelizumab plus apatinib until disease progression or unacceptable toxicity. The primary endpoint was the objective response rate (ORR). This study was registered with ClinicalTrials.gov (NCT04547088, NCT04548271). **Results:** From August 20, 2020 to September 6, 2021, 72 patients were enrolled into the trial: 40 patients were enrolled in cohort 1 and 32 in cohort 2. Median follow-up was 13.1 months (IQR 10.0-15.2 months) for cohort 1 and 9.0 (5.9-10.7) months for cohort 2. Among the 40 evaluable patients in cohort 1, an objective response was achieved by 26 (65%; 95% CI, 49.6-80.4). A total of 16 (40%) patients had tumor progression, and the median PFS was not reached. Among the 32 evaluable patients in cohort 2, an objective response was achieved by 11 (34.4%; 95% CI, 17.0-51.8). A total of 22 (69%) patients had tumor progression, and the median PFS was 6.0 months (95% CI, 4.4 to 7.6). Grade ≥ 3 treatment-related adverse events (TRAE) were reported in 34 (47.2%) of 72 patients, with the most common TRAE being hypertension (18.1%), an increase of serum transaminase (13.9%) and hand and foot syndrome (12.5%). No treatment-related deaths occurred. **Conclusions:** In patients with platinum-resistant or PD-1 inhibitor resistant RM-NPC, camrelizumab plus apatinib achieved promising outcomes. Further studies of the camrelizumab plus apatinib treatment regimen are warranted in a phase 3 trial. Clinical trial information: NCT04547088, NCT04548271. Research Sponsor: None.

Clinicopathologic characteristics of HRAS-mutant head and neck squamous cell carcinoma (HNSCC). *First Author: Coral Olazagasti, Sylvester Comprehensive Cancer Center, Miami, FL*

Background: RAS mutations are often associated with tumor development and immune evasion and therefore unfavorable clinical outcomes. Farnesyl transferase inhibitors (FTI) are an emerging therapeutic option for HRAS mutant HNSCC (Hm), thus understanding the genomic and immunologic landscape of Hm is important for further development of this therapeutic approach. **Methods:** A total of 2,407 HNSCC tissue went through tumor molecular profiling at Caris Life Science (Phoenix, AZ). Analyses included next-generation sequencing of DNA (NextSeq, 592 Gene or NovaSeq, WES) and RNA (NovaSeq, WTS), and immunohistochemistry (IHC). HPV 16/18 status was assessed using WES. MAPK pathway activation and the likelihood of a tumor's response to anti PD1 therapy were tested via MPAS and IFN signatures, respectively. Wilcoxon, Fisher's exact were used for statistical significance (p without and q values with multiple comparison correction). Overall survival was calculated from date of tissue collection to last contact from insurance claims data and compared using Kaplan-Meier method. All comparisons were made between Hm and the entire HNSCC general cohort (GC). **Results:** Of the 2,407 HSNCC tested, 69 (2.87%) were pathogenic/likely pathogenic Hm. The most prevalent mutation (mt) was G12 (34.8%), G12 (31.9%) and Q61 (30.3%). Hm significantly correlated with male gender (59.4%, q <0.01) and older age (median 68.6 vs 64.1, q <0.01). No difference in HPV status was observed. Hm had worse prognosis (HR 1.49, 95 CI: 1.03 -2.13, p<0.05) and correlated with more TERT, FAT1 mt, lower p16, PD-L1 expression and TMB-H (cutoff: >=10mt/MB) (Table). Interestingly, PIK3CA Hm were mutually exclusive with TMB-H tumors in Hm (p<.0001). All Hm had higher MPAS scores (all: 0.88, Q61: 0.88, G13: 1.07 vs -0.34, q <0.05) compared to GC. Hm showed higher immunogenicity, evidenced by higher IFN score (all: -0.1, G12: -0.04 vs GC: -0.21, q < 0.05), higher ratio of macrophage M(MM)1 to MM2 (Fold change = 2.27, q <0.0001), more CD8+ T cells and elevated expression level of MHC1 class I genes (Table). **Conclusions:** Hm was associated with poor outcomes, higher MAPK activation, PD-L1 levels, TMB and IFN scores. This points to the oncogenic and immunomodulatory role of HRAS in HNSCC. Our findings provide additional evidence for ongoing clinical trials on combinatorial immunotherapy or PI3KCA inhibitors with FTI and demonstrate unique landscape of different point mutations; further evaluation is warranted. Differentially regulated features between Hm and GC (*p<0.05, q<0.05) for all results. Research Sponsor: None.

The effect of opioids on the efficacy of immunotherapy in recurrent/metastatic squamous cell carcinoma of the head and neck (R/M HNSCC). *First Author: Nicole N Scheff, UPMC Hillman Cancer Center, Pittsburgh, PA*

Background: HNSCC can cause severe pain, exceeding the levels seen in other cancers. Opioids, the mainstay for cancer pain treatment, can have an immunomodulatory effect. We hypothesized that immunotherapy efficacy is impaired by immunosuppressive actions of opioids. **Methods:** We conducted a retrospective analysis of R/M HNSCC patients who received anti-PD-1 mAb therapy in the first line or platinum failure setting at UPMC Hillman from 2015–2020. Pretreatment (most recent visit prior to day of treatment) and day of treatment opioid prescription, calculated as morphine milligram equivalent (MME) per day, were evaluated. Opioids were analyzed as a continuous and a categorical (yes/no) variable. CD8 T and T regulatory (Treg) cells in the tumor microenvironment (TME) were evaluated on archival tumor samples via immunofluorescent imaging via ImageJ software. Linear regression and logistic regression were used to determine the effect of opioids on oncologic factors, disease control rate (DCR) and TME, depending on the data types. Univariable and multivariable Cox Proportional Hazard models were used to identify factors associated with progression free survival (PFS) and overall survival (OS). **Results:** The 66 patients analyzed were 79% male, median age was 67, 26% were HPV positive oropharyngeal, and 56% were platinum failure. The median time between pretreatment and day of treatment visits was 29 days. 63.3% of patients were on opioids pretreatment and day of treatment; median MME/day was 60 mg and 85 mg, respectively. When measured as a continuous variable, increased opioid dosage was significantly associated with worse PFS and OS at pretreatment (PFS, $p = 0.002$; OS, $p < 0.001$) and day of treatment (PFS, $p = 0.021$; OS, $p = 0.017$). Multivariate analyses, which included significant variables from univariate analysis (neutrophil/lymphocyte ratio (NLR), platinum failure) revealed that opioid dose given pretreatment (PFS, $p = 0.047$, OS $p = 0.001$) and day of treatment (OS, $p = 0.019$) are independently associated with worse survival. Receipt of pretreatment opioids, assessed as a categorical variable, were associated with a significant decrease in CD8+ T cells ($p = 0.03$), and on day of treatment, a significant decrease in CD8 T cells ($p = 0.015$) and the ratio of CD8 T cells to Treg (CD8/Treg, $p = 0.011$) in the TME. There was no correlation of opioid variables with DCR, PD-L1 expression, or NLR. **Conclusions:** In our analysis, opioids were associated with significantly lower PFS and OS as well as decreased CD8 T cells and CD8/Treg ratio in the tumor microenvironment. To our knowledge, this is the first study of the effect of opioids on the efficacy of anti-PD-1 mAb treatment for R/M HNSCC as well as on the TME. Our findings suggest the need for further study into the impact of opioids on immunotherapy efficacy to improve patient outcomes. Research Sponsor: Virginia Kaufman Foundation.

A phase 1 dose-escalation and expansion study of CUE-101, a novel HPV16 E7-pHLA-IL2-Fc fusion protein, given alone and in combination with pembrolizumab in patients with recurrent/metastatic HPV16+ head and neck cancer. *First Author: Christine H. Chung, Moffitt Cancer Center, Tampa, FL*

Background: Immuno-STATs are novel, modular fusion proteins designed to locally deliver cytokines for the selective activation of tumor-antigen specific CD8+ T cells. CUE-101, the first Immuno-STAT in clinical trials, is composed of a human leukocyte antigen (HLA) complex, HLA-A*0201, a peptide epitope derived from the HPV16 E7 protein, and 4 molecules of reduced affinity human interleukin-2 (IL-2) that is designed to bind, expand, and activate HPV16-specific CD8+ T cells for the treatment of HPV16+ cancers. **Methods:** CUE-101-01 is an ongoing first-in-human study in HLA-A*0201 patients with HPV16+ recurrent/metastatic head and neck squamous cell carcinoma (R/M HNSCC). Escalating doses of CUE-101 monotherapy or in combination with pembrolizumab was evaluated, followed by expanded enrollment at the recommended phase 2 dose (RP2D). Patients with R/M HNSCC refractory to ≥ 1 platinum- or pembrolizumab-based systemic therapies received CUE-101 monotherapy. Patients with previously untreated PD-L1+ R/M HNSCC received CUE-101 and pembrolizumab 200 mg as first-line treatment. Therapy was administered every 3 weeks until disease progression or toxicity. Objectives included evaluation of safety, pharmacokinetics (PK), pharmacodynamics (PD), and antitumor activity. **Results:** As of January 20, 2022, 53 patients received CUE-101 ranging from 0.06 to 8 mg/kg/dose. The most common adverse events included grade ≤ 2 fatigue (40%), anemia (28%), lymphopenia (23%), chills (23%), and hyponatremia (21%). In the monotherapy dose escalation cohort, a MTD was not identified. A RP2D of 4 mg/kg/dose was chosen based on PK, PD, and clinical data in the absence of an MTD. Dose escalation of CUE-101 from 1 to 4 mg/kg in combination with pembrolizumab is ongoing with no DLTs identified as of data cut-off. CUE-101 PK data demonstrated dose-dependent increases in drug exposure that were sustained upon repeat dosing. PD data demonstrated selected expansion of HPV-16 $E7_{11-20}$-specific CD8+ T cells, sustained increase in NK cells and transient increase in Treg cells. Of the 14 evaluable patients treated with CUE-101 monotherapy at the RP2D, there was 1 PR and 6 with SD for ≥ 12 weeks. Of the 7 evaluable patients treated with CUE-101 plus pembrolizumab, there were 2 PR (1 confirmed) and 2 with SD for ≥ 12 weeks. **Conclusions:** CUE-101 is a novel immunotherapeutic that facilitates the targeted delivery of high concentrations of IL-2 to relevant tumor-specific CD8+ T cells. We demonstrate safety and tolerability with encouraging PD signals and antitumor activity. Enrollment continues in the combination cohort. Other novel Immuno-STATs, targeting local delivery of IL-2 for selective expansion and activation of additional tumor-antigen specific T cells, are in development. Clinical trial information: NCT03978689. Research Sponsor: Cue Biopharma Inc.

Results of ACCURACY: A phase 2 trial of AL101, a selective gamma secretase inhibitor, in subjects with recurrent/metastatic (R/M) adenoid cystic carcinoma (ACC) harboring Notch activating mutations ($Notch^{mut}$). *First Author: Renata Ferrarotto, Thoracic/Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Notch signaling plays a key role in ACC tumorigenesis. $Notch^{mut}$ are found in ~20% of ACC tumors, which are aggressive with a poor prognosis. Approved or standard therapies for relapsed/metastatic ACC are lacking, regardless of Notch status. Investigational drug AL101, a γ-secretase inhibitor, blocks Notch signaling and inhibits tumor growth in $Notch^{mut}$ patient-derived ACC xenografts. AL101 has clinical activity at 4 mg once weekly (QW) with a disease control rate (DCR) of 68% (15% partial response, (PR)) and appears to be well tolerated. An additional cohort of 42 patients was enrolled at 6 mg QW, and here we update the final results of the trial. **Methods:** ACCURACY is an open-label, multicenter phase 2 study of AL101 (4 and 6 mg intravenous QW) in subjects with R/M ACC with $Notch1\text{-}4^{mut}$ (ASCO '19, Abstr TPS6098). Subjects required evidence of disease progression within 6 months of entry or newly diagnosed metastatic disease and an ECOG performance status of 0-1. The primary endpoint was overall response rate (ORR) by RECIST v1.1 (or modified MD Anderson bone criteria), as assessed by investigators. Secondary endpoints were ORR by central review, duration of response, and safety. The study provided ≥80% power to detect an increase of the ORR from 8% to 25% using a type I error of 5%. **Results:** A total of 82 subjects were enrolled in the study. The data cutoff date used was Oct 25, 2021. Most common (≥20%) treatment-related adverse events of all grades in the study were diarrhea (78%; grade 3 (gr3) 10%), fatigue (67%; gr3 6%), nausea (60%; gr3 7%). Pharmacokinetics (PK) and blood pharmacodynamics (PD) both displayed a dose dependent change in AL101 plasma concentration and modulation of Notch target gene expression (Hes1 and Hes4), respectively. Of the 77 evaluable subjects, there were 9 PRs (12%) and 44 SDs (57%) for a disease control rate of 69%. **Conclusions:** Investigational drug AL101 at both 4 and 6 mg QW appears to be well tolerable in $Notch^{mut}$ R/M ACC. Additional efficacy and PK/PD data will be presented Clinical trial information: NCT03691207. Research Sponsor: Ayala Pharmaceuticals.

Imaging biomarkers of collagen architecture on baseline biopsies in association with response in patients with head and neck squamous cell carcinoma treated with immunotherapy. *First Author: Reetoja Nag, Case Western Reserve University, Cleveland, OH*

Background: Though immunotherapy (IO) has robust clinical efficacy, only a subset of head and neck squamous cell carcinoma (HNSCC) patients have shown to benefit from it. Collagen, a major component of the Tumor Microenvironment (TME), is involved in cancer fibrosis and collagen fiber organization has been shown to be associated with patient outcome for different cancers. In this work, we evaluated whether computationally extracted collagen fiber orientation disorder (CFOD) features from tumor related stroma regions (TS) in digitized H&E-stained slides can help in distinguishing between responders and non-responders to immunotherapy in HNSCC patients. **Methods:** Whole slide images (WSIs) from 43 HNSCC patients treated with immunotherapy (23 non-responders and 20 responders) were obtained from University Hospitals, Cleveland; response was defined as per RECIST v1.1. A derivative-of-Gaussian model was used to identify collagen fiber orientations in TS of the digitized WSIs. Different statistics (e.g. mean, standard deviation, skewness) of the various disorder descriptors (e.g., contrast and entropy) were calculated across all the neighborhood windows in the tumor region to generate the final CFOD feature set. Minimum Redundance Maximum Relevance algorithm was employed to identify the top 3 features, which were combined with a Naive Bayes classifier to differentiate between responders and non-responders. Cross-validation was used to validate the classifier over 100 iterations via the area under the receiver operating characteristics curve (AUC). Multivariable analysis was done using a logistic regression method to see how different parameters (gender, age, smoking status) will affect IO response. **Results:** WSIs of responders to immunotherapy showed more disorganized collagen fiber structure as compared to non-responders WSIs. The selected top 3 features were related to the contrast feature descriptor from the orientation co-occurrence matrix. The average AUC for the model based on CFOD was 0.77±0.24. The results for multivariable analysis are shown in Table 1. **Conclusions:** We demonstrated an association between the architectural organization of collagen fiber from baseline biopsies of HNSCC patients with response to immunotherapy. Furthermore, we demonstrate a classifier based on computationally derived CFOD features able to derive detailed assessments of collagen orientation. None of the parameters analyzed were significantly associated with change in IO response ($p<0.05$). Further validation on a larger independent cohort is warranted. Research Sponsor: U.S. National Institutes of Health, Other Foundation, Other Government Agency.

Multivariable analysis for IO response.

Outcomes and adverse events of low-dose nivolumab in platinum refractory head and neck cancers. *First Author: Hemanth Kumar, Tata Memorial Hospital, Mumbai, India*

Background: Nivolumab is one of the recommended regimens for platinum refractory and second line treatment in head and neck cancers as per NCCN guidelines. However, accessibility of nivolumab in low- and middle-income countries is less than 1-3%. There is data suggesting that low doses of nivolumab can also be effective. Hence in this analysis we explore the outcomes and adverse events with low doses of nivolumab. **Methods:** The head and neck medical oncology unit of Tata memorial hospital maintains a prospective database of all patients undergoing immunotherapy. A query was raised in this database to identify head and neck cancer patients who were treated with low doses of nivolumab. We identified 42 patients. The baseline characteristics, compliance to nivolumab, the reason for administration of low dose and the outcomes (progression free survival, date of progression, date of death) were recorded. The dose of nivolumab used in this study was 40mg flat dose every 2 weeks. Descriptive statistics were performed. Kaplan Meier estimates were used to see overall survival (OS) and progression free survival (PFS). **Results:** The median age of the patients was 48.8 (IQR: 43 - 56.4) Male to female ratio was 13:1. The site of the disease was oral cavity in 29 (69%) patients, oropharynx in 3 (7%) patients, larynx in 4 (9.5%) patients, and others in 7(17%) patients. All patients were platinum refractory and had progressive disease within last 6 months of last dose of platinum. The ECOG performance status was 1 in 37 (88.1%) patients and 2 in 5 (11.9%) patients. All patients received low dose nivolumab in view of financial constraints to access full dose. The response was recorded in 32 patients. Out of them 6 had a partial response (14.3%). The median PFS was 4.9 months (95% Confidence interval: 3.4 - 6.4) and OS was 8 months (95% confidence interval: 5.9-10.1). The details regarding PD L-1 expression and effectiveness of nivolumab will be presented at the conference. **Conclusions:** Low doses of nivolumab can be an option which is efficacious in patients who do not have access to standard dose nivolumab. There is need for testing this regimen in large randomized studies as full dose of nivolumab is not accessible in low- and middle-income countries. Research Sponsor: None.

Racial disparity in receipt of immunotherapy treatment among elderly patients with head and neck cancer. *First Author: Nosayaba Osazuwa-Peters, Duke University School of Medicine, Department of Head and Neck Surgery & Communication Sciences, Durham, NC*

Background: The United States Food and Drug Administration in 2016 approved immune checkpoint inhibitors (immunotherapy) as a treatment option for head and neck squamous cell carcinoma. However, it is unclear if there are clinical or sociodemographic differences among patients receiving immunotherapy as part of their care. We aimed at characterizing the clinical and non-clinical factors associated with receipt of immunotherapy among elderly patients with head and neck cancer. **Methods:** We utilized data from *Navigating Cancer*, which included information on systemic therapy for elderly patients (≥ 65 years), diagnosed with head and neck cancer in a community oncology setting between 2017 and 2021. We estimated clinical (tumor stage [grouped as early, or stage I and II vs. advanced stage, or stage III and IV] and anatomic subsite [oropharyngeal vs. non-oropharyngeal]) and non-clinical (age, smoking history, race, sex, and marital status) factors associated with immunotherapy use based on multivariable logistic regression analysis. **Results:** There were 4,619 patients in our study cohort, 74.3% male and 87.1% white. Among these patients, 11.1% had received immunotherapy. We found an association between race and receipt of immunotherapy. After adjusting for covariates, white patients with head and neck cancer had 74% increased odds of receiving immunotherapy as part of their treatment (aOR: 1.74; 95% CI 1.25, 2.42), compared to non-whites. There were no statistically significant differences in the odds of immunotherapy use based on age, sex, or smoking history. Patients with non-oropharyngeal disease were significantly more likely to receive immunotherapy than those with oropharyngeal cancer (aOR: 1.26; 95% CI 1.01, 1.56), as were those with advanced stage disease (aOR: 2.72; 95% CI 1.90, 3.91) compared with those early-stage. **Conclusions:** We identified clinical and non-clinical factors associated with receipt of immunotherapy in this cohort of elderly patients with head and neck cancer, and white patients were significantly more likely to receive immunotherapy as part of their care. Equitable access to immunotherapy and other treatment options will reduce cancer-related health disparities and improve survival of patients with head and neck cancer. Research Sponsor: None.

Digital spatial profiling to uncover biomarkers of immunotherapy outcomes in head and neck squamous cell carcinoma. *First Author: Niki Gavrielatou, Department of Pathology, Yale School of Medicine, New Haven, CT*

Background: Immunotherapy (ITx) has become the standard of care in the treatment of recurrent or metastatic head and neck squamous cell carcinoma (R/M HNSCC). However, response rate is limited to 13-18% of patients, underlining the need to identify mechanisms implicated in response or resistance. This study aims to uncover novel biomarkers of ITx outcomes in R/M HNSCC using digital spatial profiling (DSP) technology. **Methods:** Pre-treatment biopsy samples of 50 ITx-treated R/M HNSCC patients, constructed in the form of tissue microarray (YTMA496), were included in our discovery cohort. Cases underwent DSP with the Human Immuno-Oncology protein panel (NanoString Technologies), comprising 71 photocleavable oligonucleotide-labeled primary antibodies, used for target-protein quantification in 4 distinct molecularly defined compartments: tumor (CK+), leukocyte (CD45+), macrophage (CD68+) and immune stroma (CD45+/CD68+). All markers were explored for associations with progression-free (PFS) and overall survival (OS) using a univariate Cox regression model. Significant markers were validated using an alternative quantitative immunofluorescence method as well as in an independent validation cohort of 29 ITx-treated R/M HNSCC cases (YTMA523). **Results:** Univariate DSP data analysis revealed high beta2-microglobulin (B2M), LAG-3, CD25 and 4-1BB in tumor, high B2M, CD45 and CD4 in stroma, and low fibronectin in the macrophage compartment, as markers associated with improved PFS. Increased levels of B2M and CD25 in tumor and CD11c in stroma were also correlated with prolonged OS. Focusing on B2M, cases at the top tertile of tumor B2M expression were associated with improved PFS and OS [HR, 0.43; 95% confidence interval (CI), 0.21-0.9; p = 0.034 and HR, 0.41; 95% CI, 0.18-0.90; p = 0.047, respectively], by an orthogonal QIF method. Findings were replicated in our validation cohort for PFS [HR, 0.41; 95% CI, 0.19-0.93; p = 0.034] and showed a similar trend for OS [HR, 0.44; 95% CI, 0.19-1.0; p = 0.074]. B2M-high tumors also had significant enrichment with immune-cell markers (CD3, CD4, CD8, CD11c, CD68 and CD163) and increased immune checkpoint expression (PD-L1, ICOS, TIM-3, LAG-3, IDO1, B7-H3), predominantly in the tumor compartment. **Conclusions:** Our study indicates that intact, highly functional antigen presentation, sustained by high B2M expression in tumor, confers survival benefit in ITx treated R/M HNSCC patients, an effect driven by increased intra-tumoral immunogenicity. Research Sponsor: U.S. National Institutes of Health.

Immune-related gene expression signature in patients with recurrent/metastatic head and neck cancer treated with immunotherapy. *First Author: Lisa F. Licitra, Fondazione IRCCS Istituto Nazionale dei Tumori, University of Milan, Milan, Italy*

Background: In platinum-resistant recurrent-metastatic (R/M) head and neck squamous cell carcinoma (HNSCC) patients (pts), survival improvements have been achieved with immune checkpoint inhibitors (ICI), however this benefit is limited to a relatively small subgroup of pts. Predictive biomarkers are still under investigation and their contribution to the clinic has been limited. An immune-related cluster (CI6) has been defined by means of a metanalysis in locally advanced HNSCC. **Methods:** Gene expression profiling was performed on two cohorts of platinum resistant R/M HNSCC pts treated with ICI alone: i) 20 patients as training set, divided in long-term (OS >18 months; n=12) and short-term (OS < 6 months; n=8) survivors matched according to site of recurrence (distant metastases only, or locoregional recurrence with/out metastases); ii) 80 patients enrolled in a phase II trial (EudraCT number: 2017-000562-30; NIVACTOR study) as testing set. The molecular subtyping stratification (De Cecco, Oncotarget 2015) was applied. Subsequently, a score was determined between each sample and the centroids for the 6 clusters previously identified. The threshold point was imputed in the training set as the closest value to the observed prevalence. A Cox multivariable analysis including TMB, CPS and TPS PD-L1 status, age, tumoral subsite and performance status (PS) was performed. **Results:** Among all the clusters, CI6 turned out to be significant and applied to training set it provided evidence to discriminate pts' survivals (AUC=0.86, 95%CI=0.7-1.0; p=2E-05). The stratification based on CI-6 along with the cut-off point defined in the training set were challenged in the testing set: samples were divided in 28 (35%) having high CI-6 scores and 52 (65%) with low scores, reaching HR=0.46 (95% CI= 0.27-0.76; p=0.0024). Multivariate analysis showed that only CI6 (high vs low, HR=0.44; p=0.00443) and PS (1,2 vs 0, HR 1.85; p=0.02686) resulted to be significant on pts' OS. **Conclusions:** By analysing two series of pts receiving immunotherapy alone, we identified an immune-related gene expression signature, able to discriminate the prognosis of platinum-resistant R/M HNSCC pts. The multivariate analysis confirmed the immune-related CI6 as factor linked to outcome in pts treated with immunotherapy, as well as it confirmed the importance of PS. An analysis of the signature on pts receiving first line treatment with immunotherapy is currently ongoing. Research Sponsor: AIRC (IG 21740 to PB), Pharmaceutical/Biotech Company.

Personalized circulating tumor DNA (ctDNA) analysis in patients with recurrent/metastatic head and neck squamous cell cancer (R/M HNSCC). *First Author: Kirsty Taylor, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Immuno-oncology agents (IO) have become standard-of-care in the treatment of R/M HNSCC, but only a subset of patients (pts) benefit. Highly sensitive quantification of plasma circulating tumor DNA (ctDNA) may permit real time assessment of disease under selective pressures of treatment. **Methods:** R/M HNSCC pts treated with platinum-based chemotherapy (CT) or IO (anti-PD1/L1 +/- second IO) underwent serial ctDNA collection pre-cycles 1/2/3 and at disease progression, corresponding to timepoints (T) 1-4. T1 was considered baseline. Whole exome sequencing of pt tumor tissue identified patient specific somatic variants which were used as targets for RaDaR, a personalized multiplexed PCR-based NGS assay. Matched buffy coat DNA was sequenced to filter germline mutations and identify confounding CHIP. RaDaR was applied at each available T, an estimated variant allele frequency (eVAF) was calculated and correlated with progression free- (PFS) and overall- survival (OS). Findings were compared against prior (ESMO 2021) data generated using a fixed 580 gene CAPP-seq (CAncer Personalized Profiling by deep Sequencing) panel designed specifically against squamous cell carcinoma. **Results:** A total 114 plasma samples from 38 pts were analyzed. Of 35 pts with ctDNA detected at T1 and/or T2, 26 received IO and 9 CT. Median age was 62 (20-84), 77% were male, 69% prior smokers and 26% HPV positive. Median PFS and OS, for all 35 pts, was 2.57 mo (95% CI 0.48-4.66) and 8.37 mo (95% CI 5.42-11.32) respectively. For IO treated pts, median PFS was 2.45 mo (95% CI 0-5.18) and median OS 7.38 mo (95% CI 3.84-10.93). RaDaR panels targeted a median 48 variants (17-50). ctDNA was detected in 35/38 (92%) patients at baseline, with median eVAF 0.345% (range 0.0004% - 43.37%). ctDNA abundance at baseline did not correlate with PFS or OS. A decrease in Δ eVAF from T1 to T2, by > 30%, or > 50% identified pts with improved PFS, with HR 0.45 (0.21, 0.96) $p = 0.04$, 0.31 (0.14, 0.70) $p < 0.01$, and 0.23 (0.10, 0.56) $p < 0.01$, respectively. Similar results were observed for the 26 IO pts, with HR 0.40 (0.16, 1.03) $p = 0.06$, 0.19 (0.05, 0.66) $p < 0.01$, and 0.06 (0.01, 0.47) $p < 0.01$, respectively. A similar, but non-significant, trend was seen in median OS for pts with a decrease vs. increase in Δ eVAF (T1 to 2), 8.8 mo vs 7.3 mo (HR = 0.87 (0.42, 1.79)). For 31 pts, a comparison of Δ ctDNA levels, based on personalized RaDaR vs. CAPP-seq assays, from T1 to T2 demonstrated a correlation coefficient of $R = 0.57$, $P < 0.01$. **Conclusions:** In pts with R/M HNSCC, a decrease in ctDNA eVAF after first treatment correlated with improved PFS. There was a significant correlation between fixed CAPP-seq and personalized RaDaR assays when comparing Δ in ctDNA levels. Clinical Trial: NCT03712566. Tumor cell budding as a prognostic and potentially therapeutically targetable biomarker in head and neck cancer. *First Author: Jan Budczies, Institute of Pathology, University of Heidelberg, Heidelberg, Germany*

Background: Several studies have demonstrated a negative prognostic impact of tumor cell budding (TCB) in HPV- head and neck squamous cell carcinoma (HNSCC), but analyses of its prognostic impact in HPV+ HNSCC and of the underlying molecular alterations are lacking. **Methods:** The study cohort included 331 HPV- and HPV+ HNSCC from TCGA with digitalized H&E-stained slides available. Corresponding mutation, methylation, and gene expression data were obtained from the pan-cancer atlas web page. Tumor buds were defined as clusters of up to four tumor cells separated from the tumor mass. The numbers of tumor buds were evaluated in ten digital high-power fields by a senior pathologist. A two-tier cellular dissociation grading system was introduced by separating tumors with six or more tumor buds (TCB-high) from tumors with fewer tumor buds (TCB-low). The impact of TCB on overall survival (OS) was analyzed using Cox proportional hazard models. Results with $p < 0.05$ were considered significant. Association of TCB with mutations was analyzed using the Wilcoxon test. Association of TCB with gene expression and methylation was analyzed using Spearman correlations. Lists of altered genes were compiled correcting the p-values with the Benjamin-Hochberg method and controlling the FDR at 5%. **Results:** In a univariate analysis, OS was significantly shorter in TCB-high tumors compared to TCB-low tumors in HPV- HNSCC (HR = 1.4, 95% CI 1.0-2.3) and HPV+ HNSCC (HR = 5.0, 95% CI 1.9-13.7). Shorter OS in TCB-high HNSCC was confirmed in a multivariate analysis including age, sex, HPV status, tumor site, tumors stage, and tumor margin status (HR = 1.7, 95% CI 1.2-2.4). Significant association of TCB with mutations was detected for two genes: NSD1 mutations correlated negatively with TCB in HPV- HNSCC, while TP53 mutations correlated positively with TCB in HPV+ HNSCC. Methylation of 126 (1%) genes was associated with TCB in HPV- HNSCC, while methylation of 511 (3%) genes was associated with TCB in HPV+ HNSCC. Expression of 422 (2%) genes was associated with TCB in HPV- HNSCC, while expression of 786 (4%) genes was associated with TCB in HPV+ HNSCC. Among these genes, those annotated to the epithelial mesenchymal transition were highly significantly enriched in both HPV- HNSCC (5.5-fold enrichment) and HPV+ HNSCC (2.7-fold enrichment). **Conclusions:** Evaluation of TCB based on digital HE slides was conducted in a large clinically and molecularly characterized HNSCC cohort. The prognostic impact of TCB could be validated in HPV- HNSCC, while a prognostic impact of TCB could be demonstrated for the first time in HPV+ HNSCC. TCB correlated with mutations of only two genes and theses correlations were imperfect. A plethora of genes correlated with TCB on the level of methylation and gene expression level. These genes should be further analyzed and prioritized for the evaluation of therapeutic targeting. Research Sponsor: German Cancer Aid.

The mutational landscape of medullary thyroid carcinoma using whole-exome sequencing in China. *First Author: Chen Huang, China-Japan Friendship Hospital, Beijing, China*

Background: Medullary thyroid carcinoma (MTC) is a rare malignancy, and its molecular pathogenesis is far from being understood. Therefore, a relatively comprehensive and accurate genomic profiling is needed for the future molecular diagnosis, treatment and early prevention of MTC patients. **Methods:** In this study, we investigated both the somatic and germline mutational spectrum of MTC, whole-exome sequencing (WES) was performed on tumor samples and matched noncancerous tissues from 30 MTC patients. Genetic alterations were defined and analyzed using MutSigCV and novel germline mutations were identified using MutationTaster and cross-referenced in PubMed. **Results:** In somatic mutational spectrum we found the top three significantly mutated genes (SMGs) in our MTC samples were RET, FAM186A and PRG4 genes (33%, 33% and 27%, respectively). For the germline mutations, FAT4 was detected as the most common mutated genes, following by RET and FAT1. Besides, we identified 30 novel germline mutations such as IGF1R, PDK1, NOTCH1, RPTOR, MPL, SETD2 and ARID2. Those mutated genes have been previously associated with neurofibromatosis, Lynch syndrome and other diseases respectively and now predicted potential functional pathogenicity in the patients with MTC. **Conclusions:** The study elucidated a relatively more comprehensive genomic landscape of MTC. In addition to the RET gene, which has been studied extensively, other SMGs may also be of interest including novel germline mutations. These findings may indicate the potential basis of molecular diagnosis, early prevention and targeted therapeutic options for patients with MTC in the future. Research Sponsor: None.

Gut microbiome/metabolome predicts response to immune checkpoint blockers (ICB) in patients with recurrent metastatic head and neck squamous cell cancer (RM HNSCC). *First Author: Shahla Bari, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL*

Background: Gut microbiome has emerged as an important predictor of response to ICB therapy in various cancers, most notably in melanoma. Due to functional redundancy of microbiota, there has been lack of consistency in gut microbial signature associated with ICB response. Microbial metabolites in addition to taxonomy may play a superior role in predicting response to ICB. Gut microbiome/metabolome signatures of ICB response is unknown in RM HNSCC patients. **Methods:** Two cohorts of patients were included (stool and plasma samples were collected)- cohort 1, newly diagnosed RM HNSCC patients starting first line ICB, for whom samples were collected before ICB initiation (baseline) and post-treatment at 3, 6, and 12 months. Cohort 2 with durable response (disease control lasting $\geq$ 6 months), with single sample collected at study entry. 16s rRNA sequencing was performed on stool samples while plasma metabolites were quantitated using Q Exactive plus Orbitrap mass spectrometer. Response was defined as partial response (PR) or complete response (CR) as per RECIST 1.1 **Results:** The 16-S sequence was carried on 31 samples (cohort 1- 16 baseline, 7 post treatment; cohort 2- 8 durable responders). Targeted metabolomics was completed on 92 plasma samples [cohort 1-27 baseline and 50 post-treatment, cohort 2- 15]. Responders had a significantly higher Shannon's diversity index, lower Fermicutes to Bacteroidetes ratio, and were enriched with genus Bacteroides and Lachnospiracea incerate sedis at baseline and post treatment, compared to non-responders ($p < 0.05$). At species level, baseline and post treatment microbiome of responders was enriched with Eubacterium oxidoreducens and Bacteroides uniformis. Ruminococcus was preferentially enriched in durable responders. Targeted analysis of plasma metabolites (associated with gut microbial metabolism) showed that responders had a significantly lower baseline adenosine, Inosine and xanthine level as compared to non responders. Further, Inosine levels decreased with response, while levels increased in non-responders ($p < 0.05$), suggestive of consumption by re-activated T cells Further, ICB responders had significantly lower Kynurenine to tryptophan ratio compared to non responders **Conclusions:** This is the first study evaluating association of gut microbiome and metabolome on response to first line ICB, in RM HNSCC patients. We found higher diversity and specific gut microbial signatures associated with ICB response. Interestingly, we found that inosine and kynurenine/tryptophan pathways, both which play a crucial role in host as well as gut microbial metabolism were differentially expressed in ICB responders. Our results if validated in larger cohort, lays groundwork for gut microbiome and importantly microbial metabolite modulation to improve response to ICB in RM HNSCC. Research Sponsor: Circle of Hope For Cancer Research, Moffitt cancer center internal funding.

Cataloging targetable dependencies of head and neck cancer cell lines in the DepMap CRISPR screens. *First Author: Devraj Basu, The University of Pennsylvania, Philadelphia, PA*

Background: The DepMap genome-wide loss of function CRISPR screens offer new insight into gene dependencies in HPV(-) head and neck squamous cell carcinoma (HNSCC) cell lines. We aimed to leverage this data to guide preclinical studies by cataloging targetable dependencies and identifying ones predicted to offer a therapeutic window. We also aimed to identify targets representing potential synthetic lethalities by testing for associations between genetic alterations and dependency profile. **Methods:** DepMap was queried for gene probability and effect scores in cell lines from 77 tumors, including 62 HPV(-) HNSCCs plus 15 ESCCs, which have comparable etiology, genetic features, and tissue of origin. A probability score of ≥ 0.5 was used as the threshold for essentiality. Essential genes were selected for analysis by 3 criteria: (1) presence in ≥10% cell lines, (2) lack of dependency in CRISPR screens of normal human cell lineages, and (3) designation as druggable by the Drug-Gene Interaction Database. Gene set enrichment analysis was performed using the Hallmark Gene Sets. DepMap gene effect scores were used to prioritize targets likely to have a useful therapeutic window based on median scores greater than for *EGFR* (0.676), a target with established albeit modest utility for HNSCC. The Open Targets platform was used to identify targets with inhibitors used in trials for other cancers and/or nonmalignant diseases. Associations between dependencies and genetic alterations were defined using two-sample t-tests, with filter conditions of $p < 0.05$ and effect size ≥1. **Results:** The 231 genes meeting selection criteria had a median gene effect score of 0.56. The criteria captured targets of standard therapeutic agents including *TYMS* (5-FU), tubulin genes (paclitaxel), *EGFR* (cetuximab), plus known oncogenes like *PIK3CA*. GSEA showed enrichment of known oncogenic signaling pathways including PI3K/AKT and JAK/STAT, as well as hallmark cancer processes like DNA repair and apoptosis. 90% were not known oncogenes cataloged in the OncoKB Database. 45 genes had a median gene effect score between that of *EGFR* and the median for common essential genes, including 7 without known cancer-promoting roles: *OTOP1, DHRSX*, *UTP11*, *MBTPS1*, *SLC25A3, PPIAL4G*, and *RBM10*. 17% had inhibitors that reached a non-HNSCC phase II trial, including 10 targets not previously tested in cancer. Novel associations between dependencies and genetic alterations included *DDX3X* with *NOTCH1-mut*, *ITGB1* with *CDKN2Amut*, and *ATP1A1* with *HRASmut*. **Conclusions:** We catalog targetable dependencies in cell line models of HNSCC. While well-studied targets were captured, many genes lacked known roles in malignancy. Targets of inhibitors tested in other diseases provide new tools to guide preclinical studies. Association of some dependencies with known molecular subgroups in HNSCC may enhance use of cell line models to personalize therapy. Research Sponsor: U.S. National Institutes of Health.

Association between up-front surgery and risk of stroke in U.S. veterans with oropharyngeal squamous cell carcinoma. *First Author: Lova Sun, University of Pennsylvania, Philadelphia, PA*

Background: Cardiovascular disease and stroke are important causes of long-term morbidity and mortality in patients with oropharyngeal squamous cell carcinoma (OPSCC). Cancer treatments including radiotherapy to the neck and chemotherapy have been associated with increased risk of stroke. In the era of treatment de-intensification for OPSCC, up-front surgical treatment has been proposed as one strategy that allows for de-escalation or avoidance of (chemo)radiotherapy. We sought to quantify the cumulative incidence of stroke in patients treated for non-metastatic OPSCC, and then evaluate whether patients receiving up-front surgery for OPSCC have decreased risk of stroke compared to those undergoing non-surgical treatment. **Methods:** We identified a cohort of 10,436 United States veterans diagnosed with non-metastatic OPSCC from 2000-2020, of whom 2,717 received up-front surgery (with or without perioperative radiotherapy or chemoradiotherapy) and 7,719 received non-surgical therapy (definitive radiotherapy or chemoradiotherapy). We estimated the cumulative incidence of stroke in this population, accounting for death as a competing risk. To assess the association between up-front surgery and risk of stroke, we generated a propensity score for the probability of receiving surgical treatment and used inverse probability weighting to construct pseudo-populations balanced on all potential confounders. Cox regression models of the inverse probability weighted population were used to estimate the cause-specific hazard ratio of stroke associated with surgical vs non-surgical treatment. **Results:** The 10-year cumulative incidence of stroke was 12.5% (95% CI 11.8-13.23) and death was 57.3% (95% CI 56.2-58.4). Up-front surgical patients who underwent perioperative (chemo)radiotherapy had shorter radiation and chemotherapy courses compared to non-surgical patients, suggestive of lower treatment intensity. Propensity score generation and inverse probability weighting yielded good overlap and covariate balance between surgical and non-surgical treatment groups. The inverse probability weighted cause-specific hazard ratio of stroke associated with up-front surgical treatment was 0.77 (95% CI 0.66-0.91, p = 0.002). This association was consistent across subgroups defined by age (> /≤65 years) and baseline cardiovascular risk factors (hypertension, hyperlipidemia, diabetes). **Conclusions:** In over 10,000 US veterans with OPSCC, cumulative incidence of stroke was 12.5% at 10 years. Up-front surgical treatment was associated with a 23% reduced risk of stroke compared to definitive (chemo)radiotherapy. These findings present an important additional risk-benefit consideration to factor into treatment decisions and patient counseling, and should motivate future studies to examine cardiovascular events in this high-risk population. Intraoperative radiation therapy for locally advanced and recurrent head and neck cancer. *First Author: Celina Chiodo, Loyola University Chicago, Arlington Heights, IL*

Background: Intraoperative Radiation Therapy (IORT) allows precise delivery of radiation therapy (RT) to a limited target area at high risk of cancer recurrence while minimizing RT to nearby organs at risk. IORT may be particularly beneficial for patients with locally recurrent head and neck cancer (HNC) in a previously irradiated field and for locally advanced HNC cases, in which obtaining negative surgical margins may be difficult. This study aims to present a single institution experience with IORT for HNC patients. **Methods:** This study included HNC patients treated consecutively with IORT at our institution between 2014 and 2018. Charts were reviewed for patients' and tumors' characteristics, IORT technical details, IORT-induced adverse events, and treatment outcomes. **Results:** The study included 23 eligible patients. Median patient age was 66 (range 33-91). Tumor sites included parotid gland (43%), lymph nodes (43%), oral tongue (9%), and ear (4%). 52% of patients received IORT upfront with or without postoperative adjuvant external beam radiation therapy (EBRT), while 48% received salvage IORT after local tumor recurrence. The median prescribed IORT dose was 7.5 Gy (range 5-14 Gy) in a single fraction prescribed to 5 mm depth with Flat applicators (median diameter of 5 cm). 92% of patients did not experience wound healing complications. One patient (4%) developed postoperative acute thromboembolic stroke, a second patient (4%) experienced protracted wound healing. At a median follow-up of 36 months (range 2-81), 42% of patients presented with no evidence of disease (NED), overall survival was 54%, 13% of patients were alive with disease, and 46% died with disease. Local-regional recurrence rate was 39% (median time to local recurrence was 18 months, range 2-60), rate of distant metastasis was 43% (median time to distant metastasis was 23 months, range 5-60), and 30% of patients had both local-regional recurrence and distant metastases. The percent of local-regional recurrence and distant metastases among patients receiving salvage IORT was 64% and 73% respectively, compared to 23%, and 15% respectively in those receiving upfront IORT with or without adjuvant EBRT. **Conclusions:** In this single institution chart review study, IORT to locally advanced and recurrent HN cancer patients was a safe treatment modality, with tumor control comparable to historical EBRT data. Larger prospective studies are needed to further assess the utility of IORT in the management of locally advanced and recurrent HN cancer. Research Sponsor: None.

Impact on xerostomia for patients with nasopharyngeal carcinoma treated with superficial parotid lobe-sparing intensity-modulated radiation therapy (SPLS-IMRT): A prospective phase II randomized controlled study. *First Author: Huageng Huang, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: In the intensity-modulated radiation therapy (IMRT) era, xerostomia remains one of the most common radiation-induced toxicities in nasopharyngeal carcinoma (NPC) patients. We first proposed the superficial parotid lobe–sparing IMRT (SPLS-IMRT) technique in NPC, which has been proved to significantly reduce the mean doses of bilateral entire parotid glands and superficial parotid lobes. To further validate its clinical benefits, we conducted a prospective phase II randomized controlled study to compare the incidence of xerostomia in NPC patients treated with SPLS-IMRT and conventional IMRT (C-IMRT). **Methods:** Patients with histologically confirmed NPC who met the eligibility criteria were randomly assigned in a 1:1 ratio to receive either SPLS-IMRT or C-IMRT. The V36 (the percentage volume receiving a dose of 36 Gy) of the entire parotid gland was constrained to be less than 40% in both groups. Additionally, V26 (the percentage volume receiving a dose of 26 Gy) of the superficial parotid lobe was constrained to be less than 30% in the SPLS-IMRT group. The primary endpoint was the incidence of xerostomia at 12 months post-IMRT. The secondary endpoints included the xerostomia questionnaire (XQ) score, unstimulated salivary flow rate (USFR), stimulated salivary flow rate (SSFR), and survival outcomes. **Results:** From January 2018 to September 2018, 90 patients were enrolled (45 per group). Eighty-two patients were included for xerostomia analysis (42 in the SPLS-IMRT group and 40 in the C-IMRT group). At 12 months post-IMRT, the incidence of xerostomia in the SPLS-IMRT group was significantly lower than that in the C-IMRT group (83.4% vs. 95.0%; $P = 0.007$), especially the grade 3 xerostomia (0% vs. 12.5%; $P < 0.001$). However, the median change in XQ score (XQ_{change}) was similar between the two groups (11.9 points vs. 14.1 points; $P = 0.194$). Moreover, there was a significantly higher median fractional USFR (0.67 vs. 0.35; $P = 0.024$) and SSFR (0.66 vs. 0.32; $P = 0.021$) in the SPLS-IMRT group than the C-IMRT group. All 90 patients were included for survival analysis. With a median follow-up time of 37.8 months (IQR, 33.9–38.5 months), the 3-year locoregional relapse-free survival, distant metastasis-free survival, and overall survival in the SPLS-IMRT and C-IMRT groups were 92.5% vs. 90.9% (hazard ratio [HR], 1.84; $P = 0.477$), 83.8% vs. 81.7% (HR, 1.13; $P = 0.816$), and 88.9% vs. 88.2% (HR, 0.96; $P = 0.949$), respectively. **Conclusions:** SPLS-IMRT significantly reduced the incidence of xerostomia at 12 months post-IMRT in NPC by recovering parotid gland function earlier than C-IMRT, without compromising survivals. Phase III clinical trials are needed to confirm this result. Clinical trial information: NCT05020067. Research Sponsor: the National Natural Science Foundation of China (No. 82003081).

Camrelizumab plus apatinib as induction therapy for locally advanced head and neck squamous cell carcinoma (IMplus): A single-arm phase II study. *First Author: Lulu Ye, Department of Oral and Maxillofacial-Head Neck Oncology, Shanghai Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine; College of Stomatology, Shanghai Jiao Tong University; National Center for Stomatology, Shanghai, China*

Background: Immune checkpoint inhibitor combined with antiangiogenic agent has been investigated in many solid tumors, including advanced head and neck squamous cell carcinoma (HNSCC; NCT02501096), but the evidence is limited. This study was conducted to investigate the efficacy and safety of anti-programmed cell death-1 antibody camrelizumab plus antiangiogenic agent apatinib as induction therapy in patients with locally advanced HNSCC. **Methods:** In this single-center phase II trial (NCT04440917), patients with untreated locally advanced HNSCC who had inoperable lesions, could not tolerate surgery, or refused surgery were enrolled. Patients received camrelizumab 200 mg once every 2 weeks and apatinib 250 mg once daily for two 28-day cycles, followed by local treatment based on the re-examination results. The primary endpoint was objective response rate (ORR) after induction therapy, as assessed according to the Response Evaluation Criteria In Solid Tumors version 1.1. Simon's two-stage design was adopted for this study. **Results:** Between December 2019 and July 2021, 18 patients were enrolled in the first stage. Eight (44%) patients had oropharyngeal carcinoma, nine (50%) had oral carcinoma, and one (6%) had hypopharyngeal carcinoma. There were six (33%), three (17%), and nine (50%) patients with stage III, IVA, and IVB disease, respectively. After induction therapy, six patients achieved complete response, nine achieved partial response, and three had stable disease, with an ORR of 83%. The study proceeded to the second stage and the enrollment for another 14 patients is ongoing. Two (11%) patients with partial response received surgery and adjuvant radiotherapy, and 16 (89%) received radical radiotherapy. With a median follow-up duration of 18 months (range, 9-26), only one disease recurrence and no deaths occurred. The most common adverse events during induction therapy were hypertension (ten [56%]), oral pain (nine [50%]), and increased aspartate aminotransferase (five [28%]). Only one [6%] grade 3 hypertension and one [6%] grade 3 proteinuria were observed, and no grade 4 or 5 adverse events occurred. **Conclusions:** Camrelizumab plus apatinib showed promising antitumor activity as induction therapy in patients with locally advanced HNSCC, with acceptable safety profile. Clinical trial information: NCT04440917. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Recombinant human endostatin combined with intensity-modulated radiotherapy in low-risk locoregionally advanced nasopharyngeal carcinoma: A phase II, randomized, multicenter clinical trial. *First Author: Min Kang, Department of Radiation Oncology, The First Affiliated Hospital of Guangxi Medical University, Nanning, China*

Background: Concurrent chemoradiotherapy (CCRT) is currently considered to be the standard treatment for locoregionally advanced nasopharyngeal carcinoma (LA-NPC), accompanied with non-neglectable toxicity and unsatisfactory compliance. Therefore, it is highly warranted to explore an alternative regimen for LA-NPC. This trial aimed to assess and investigate the efficacy and safety of recombinant human endostatin (Rh-endostatin) with intensity-modulated radiotherapy (IMRT) for low-risk LA-NPC. **Methods:** Patients with low-risk LA-NPC were randomly assigned into ERT group (n=60, receiving Rh-endostatin plus radiotherapy) and CCRT group (n=60, receiving cisplatin plus radiotherapy). The primary endpoint was the 5-year overall survival (OS). Non-inferiority was shown if the upper limit of the 95% CI for the difference in 5-year OS between the ERT group and CCRT group did not exceed 15%. The secondary endpoint was 3-year progression-free survival (PFS). **Results:** A total of 120 patients were included in the trial. After a median follow-up of 71 months (IQR 62-75), the 5-year OS rate was 88.1% in the ERT group and 77.6% in the CCRT group, with a difference of 10.5% (95% CI: -0.03 to 0.24; $P_{non\text{-}inferiority} = 0.002$). Patients in the ERT group had better 3-year PFS than that in the CCRT group (89.8% vs 70.6%; HR = 0.362; 95% CI: 0.150-0.873; $P_{log\text{-}rank} = 0.018$). The overall all-grade toxicity burdens were heavier in CCRT group. No patients died of treatment-related causes. **Conclusions:** Rh-endostatin combined with IMRT had favorable efficacy, fewer toxic effects and more improved quality of life, which might be a promising alternative regimen to CCRT for low-risk LA-NPC in clinic. Clinical trial information: NCT02237924. Research Sponsor: National Natural Science Foundation of China (No. 81760542 and No. 82160467), the Projects for Research and Development of Medical and Health Appropriate Technology of Guangxi Zhuang Autonomous Region (No. S2018087), the Key Research and Development Prog.

Survival outcomes for intention-to-treat analysis.

Dynamic cell free HPV DNA is an early measure of treatment responsiveness in patients receiving induction chemotherapy for HPV-related head and neck cancer. *First Author: Linda (Yilin) Cao, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD*

Background: Induction chemotherapy (IC) is being studied as a chemoradiation (CRT) de-intensification strategy in HPV-related head and neck cancer (HNC), but using imaging response for eligibility selection is distinctly limited by delayed correlation with biological response and difficulty in distinguishing active tumor from treatment effect. We report serial cell free HPV DNA (cfHPV DNA) dynamics as a quantitative measure of early treatment responsiveness for HPV-related HNC patients receiving IC followed by CRT. **Methods:** Patients with high-risk HPV-positive (by in situ hybridization), locally advanced HNC who received IC followed by definitive CRT were enrolled starting on Sept 26, 2021. Patients received 1-2 cycles of platinum/taxane IC prior to initiating standard-dose CRT. Peripheral blood cfHPV DNA levels were measured biweekly during IC and weekly during CRT with the SafeSEQ HPV test from Sysmex Inostics, an NGS-based, CLIA-certified assay designed to sensitively detect and quantify HPV16 and HPV18 DNA in plasma. Tumor volumes were assessed on the pre- and post-IC planning CT scans by the treating radiation oncologist. **Results:** To date, 72 plasma samples have been processed across 11 enrolled patients with median age 66 years (range: 35-79). The primary disease sites included 7 oropharynx (OPX), 1 sinonasal, 2 nasopharyngeal, and 1 larynx. All patients had at least cT3 disease or cN3 disease (AJCC 8), with 6 patients having cT4 disease. Five (45.5%) have a smoking history, each > 10 pack-years. We report cfHPV DNA and tumor volume measurements at key timepoints for the 8 patients who have completed IC below. **Conclusions:** Serial cfHPV DNA identifies a group of locally advanced HPV-related HNC patients who have complete/near-complete cfDNA clearance during IC. This may provide an earlier readout of individualized treatment responsiveness compared to radiologic assessment, and may therefore be a preferred metric for CRT de-intensification eligibility. Clearance velocity will be evaluated with our granular biweekly IC and weekly CRT cfHPV DNA dataset to help further elucidate tumor response kinetics with this paradigm. Research Sponsor: Sysmex Inostics.

Camrelizumab in combination with concurrent chemoradiotherapy as first-line treatment for nonoperative head and neck cancer: A comparative study. *First Author: Feng Liu, Hunan Cancer Hospital and The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha, China*

Background: We hypothesized that concurrent chemoradiotherapy (CCRT) plus concurrent and adjuvant camrelizumab as first-line treatmentwas associated with improved survival compared with concurrent chemoradiotherapy alone for nonoperative locoregionally advanced head and neck squamous cell carcinoma (HNSCC). The purpose of this comparative study was to compare the efficacy and toxicity of CCRT plus concurrent and adjuvant camrelizumab versus CCRT alone in nonoperative locoregionally advanced HNSCC. **Methods:** One hundred and eighty patients with nonoperative locoregionally advanced HNSCC (cancer of the oral cavity, oropharyngeal cancer, hypopharyngeal cancer and laryngeal cancer) received either CCRT plus concurrent and adjuvant camrelizumab (camrelizumab + CCRT group, n = 90) or CCRT alone (CCRT alone group, n = 90). Patients in both groups received curative cisplatin-based concurrent chemoradiotherapy. The radiation dose was 70 Gy (2.0 Gy/fraction). In camrelizumab + CCRT group, concurrent camrelizumab (200mg/day on days 1, 22, 43) was added to CCRT, followed by adjuvant camrelizumab (200mg, every 3 weeks for 6 months or until disease progression, unacceptable adverse events or withdrawal of consent). **Results:** Compared with CCRT alone, the addition of concurrent and adjuvant camrelizumab significantly improved complete response (CR) rates (92.2% vs. 80.0%; P = 0.018), 3-year disease free survival (DFS, 72.2% vs. 56.7%; P = 0.029), locoregional recurrence-free survival (LRRFS, 76.7% vs. 61.1%; P = 0.024), and overall survival (OS, 78.9% vs. 63.3%; P = 0.033). Reactive cutaneous capillary endothelial proliferation was higher in the camrelizumab + CCRT group (6.7% vs. 0.0%; P = 0.013). No statistically significant differences in other acute (mucositis, leukopenia, thrombocytopenia, anemia, etc.) and late toxic effects (mucosal necrosis, trismus, cranial nerve palsy, etc.) were observed between the two groups. The addition of camrelizumab (CCRT plus camrelizumab vs. CCRT alone) was a significant independent prognostic factor for 3-year DFS, LRRFS and OS (P = 0.038, P = 0.032, and P = 0.048, respectively). **Conclusions:** Concurrent chemoradiotherapy plus concurrent and adjuvant camrelizumab as first-line treatment is associated with a considerable survival benefit, with acceptable adverse events, as compared with concurrent chemoradiotherapy alone, among patients with nonoperative locoregionally advanced head and neck squamous cell carcinoma. Our ongoing prospective clinical trial (registered with chictr.org.cn, number ChiCTR2200056298) will further investigate the efficacy of camrelizumab in combination with chemoradiotherapy for HNSCC. Pathologic response after induction chemo-immunotherapy with single or double immune checkpoint inhibition in locally advanced head and neck squamous cell carcinoma (HNSCC): Expansion cohorts of the CheckRad-CD8 trial. *First Author: Markus Hecht, Department of Radiation Oncology, Universitatsklinikum Erlangen, Friedrich-Alexander-Universitat Erlangen-Nürnberg, Erlangen, Germany*

Background: Targeting the immune checkpoint CTLA-4 in addition to PD-1/PD-L1 alone did not increase efficacy in HNSCC, whereas this has not been studied in combination with chemotherapy. Induction chemo-immunotherapy followed by pathologic response-based patient selection for chemotherapy-free radioimmunotherapy was efficient in locally advanced HNSCC (J Immunother Cancer. 2022 Jan;10(1):e003747). The expansion cohorts of the CheckRad-CD8 trial studied safety and efficacy of induction chemo-immunotherapy with increased dose or without CTLA-4 inhibition. **Methods:** Patients with previously untreated stage III-IVB (AJCC 8th edition) HNSCC were eligible for this multicenter phase II trial. Induction chemo-immunotherapy of the main cohort (MC) consisted of a single cycle of cisplatin 30mg/m^2 d1-3, docetaxel 75mg/m^2 d1, durvalumab 1500mg fix dose d5 and tremelimumab 75mg fix dose d5. Patients in expansion cohort 1 (EC1) received this combination with high dose tremelimumab 300mg fix dose d5 and patients in expansion cohort 2 (EC2) received no tremelimumab. In EC1 and EC2 prophylactic G-CSF was recommended. Patients with at least 20% increase of intratumoral CD8+ immune cell density or pathological complete response (pCR) in the re-biopsy entered chemotherapy-free radioimmunotherapy up to a total dose of 70Gy. The current analysis focuses on toxicity and pathologic response after induction chemo-immunotherapy. **Results:** Between Sep 2018 and Sep 2021, 80 patients were enrolled in the MC (one excluded), 20 in EC1 and 20 in EC2 (one excluded) subsequently. In the MC, EC1 and EC2 a total of 56%, 50%, 58% were stage IV and 29%, 30%, 26% had p16 positive oropharyngeal tumors. Baseline median intratumoral CD8+ immune cell density was 395/mm^2, 505/mm^2 and 763/mm^2 in MC, EC1 and EC2. After induction chemo-immunotherapy 41 (52%), 12 (60%) and 11 (58%) of the patients had pCR in the re-biopsy in MC, EC1 and EC2. Patients with residual tumor after induction therapy had a median intratumoral CD8+ immune cell density of 670/mm^2, 781/mm^2 and 1605/mm^2, which was a median increase by factor 3.0, 2.1 and 4.8 in the corresponding patients' tissue samples. In the cohorts MC, EC1 and EC2 the overall rate of grade 3-4 adverse events per patient was 1.38, 1.35 and 0.58. The corresponding rate of non-hematologic adverse events per patient was 0.84, 0.95 and 0.37, respectively. **Conclusions:** Neither increase of tremelimumab dosage nor its omission did significantly affect pathologic response to induction chemo-immunotherapy with cisplatin/ docetaxel/ durvalumab. Non-hematologic toxicity was slightly increased for high dose tremelimumab and clearly decreased without tremelimumab. The role of concomitant administration of tremelimumab with radiotherapy cannot be assessed until the final study analysis. Clinical trial information: NCT03426657. Research Sponsor: AstraZeneca.

Quality of life and two-year results of a randomized phase III study of dysphagia-optimized intensity modulated radiotherapy (DO-IMRT) versus standard IMRT (S-IMRT) in head and neck cancer. *First Author: Christopher Nutting, Royal Marsden NHS Foundation Trust, London, United Kingdom*

Background: Most newly diagnosed oro- & hypopharngeal cancers (OPC, HPC) are treated with (chemo)RT with curative intent but at the consequence of adverse effects on quality of life. We investigated if using DO-IMRT to reduce RT dose to the dysphagia/ aspiration related structures (DARS) improved swallowing function compared to S-IMRT. **Methods:** Patients with T1-4, N0-3, M0 OPC/HPC were randomised 1:1 to S-IMRT (65 Gray (Gy)/30 fractions (f) to primary & nodal tumour; 54Gy/30f to remaining pharyngeal subsite & nodal areas at risk of microscopic disease) or DO-IMRT. The volume of the superior & middle pharyngeal constrictor muscle (PCM) (OPC) or inferior PCM (HPC) lying outside the high-dose target volume was set a mandatory mean dose constraint in DO-IMRT. Treatment allocation was by minimisation balanced by centre, use of induction/concomitant chemotherapy, tumour site & AJCC stage. Primary endpoint was mean MD Anderson Dysphagia Inventory (MDADI) composite score 12 months after RT. Secondary endpoints included University of Washington (UW)-QoL, Performance Status Scale Head & Neck (PSS-HN) domain scores (range: 0-100), swallow volume, swallow capacity and local control. **Results:** 112 patients (56 S-IMRT, 56 DO-IMRT) were randomised from 22 UK & Ireland centres from 06/2016 - 04/2018. 111/112 had RT doses as prescribed (1 patient died before RT). Outcome measures at 12 and 24 months are summarised below. DO-IMRT had higher MDADI scores at 12 (p = 0.04) and 24 (p = 0.07) months. Clinically important improvements in swallowing function were seen in patients receiving DO-IMRT using PSS-HN domains and the UW-QoL tool. **Conclusions:** DO-IMRT improved patient reported swallowing function compared with S-IMRT. Improvements were seen in overall MDADI as well as functional scores in both PSS-HN and UW-QoL. Clinical trial information: 25458988. Research Sponsor: Cancer Research UK and National Institute for Health Research.

Feasibility and quality of life of postoperative concurrent radiotherapy and toripalimab in elderly patients with head and neck squamous cell carcinoma (IMPORT trial). *First Author: Ximei Zhang, Department of Radiotherapy, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China*

Background: For elderly patients with locally advanced head and neck squamous cell carcinoma (HNSCC), the role of postoperative concurrent chemotherapy was controversial since the intolerable toxicities and increased acute mortality, thus, radiotherapy alone was recommended. Aimed to seek out a feasible regimen for concurrent treatment, we evaluated the feasibility and quality of life of postoperative concurrent radiotherapy and toripalimab (anti-PD-1 antibody) in elderly HNSCC patients. **Methods:** The IMPORT trial was an investigator-initiated, multicentre, open-label, parallel-group, phase 2, randomized study. Patients were enrolled at 3 hospitals in China. We randomly assigned (1:1) patients aged > 65 years, with ECOG Performance Status(PS) of 0–2, and with postoperative Stage III-IV (AJCC 8th Staging system) HNSCC to concurrent radiotherapy (60-66Gy) and toripalimab (240mg on D0, D21 and D42)(RT+PD-1 group) or radiotherapy alone(RT group). Following stratification by PS(0-1 vs 2) and pathological adverse features (extranodal extension or positive margin vs others), patients were randomly assigned using a computer-generated randomization list. Acute toxicities were reported. Quality of life were evaluated by EORTC QLQ-C30 and QLQ-H&N35 at baseline, week3, week6 and 1 month after radiotherapy, and the standard scores were compared between groups by linear mixed-effects models. **Results:** Between September 2020 and December 2021, 38 patients randomly assigned(19 per group). The median age were 70 years (range 66-81) for the RT+PD-1 group and 73 years (range 67-78 years) for RT group. 16 (84.2%) patients in the RT+PD-1 group and 15 (78.9%) patients in the RT group complete the planed radiation dose. In the RT+PD-1 group, 13 (68.4%) patients completed 3 cycles of toripalimab, 3 (15.8%) patients completed 2 cycles due to adverse events and 3 (15.8%) patients declined toripalimab; The most common adverse events of grade 3-5 was oral mucositis (55.6% vs 58.8%) and lymphocyte count decreased(61.1% and 41.2%) in RT+PD-1 group and RT group. In the RT+PD-1 group, only 1 patients experienced grade 3 immune-related enteritis. As to the quality of life scores evaluated by QLQ-C30, no difference was found in standard score of global health status, as well as in most functional scales including: physical, emotion, cognitive and social, except for role functioning (p = 0.045). As to the symptom scale scores evaluated by QLQ-H&N35, no difference was found in standard score of pain, swallowing, dry mouth, opening mouth, and stick saliva, except for speech problem (p = 0.032). **Conclusions:** For elderly patients with locally advanced HNSCC, postoperative concurrent radiotherapy and toripalimab was safe and feasible. Concurrent toripalimab did not worsen quality of life scores in the majority of cases. Clinical trial information: NCT04523883. Research Sponsor: Shanghai Hospital Development Center, WU JIEPING MEDICAL FOUNDATION and Shanghai Anti-Cancer Research Foundation.

Transoral robotic surgery (TORS)-guided radiotherapy (RT) volume de-intensification in p16-positive unknown primary squamous cell carcinoma (SCC) of the neck: A phase 2 trial (FIND). *First Author: John R de Almeida, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: TORS has improved the likelihood of identifying an oropharyngeal cancer for patients presenting with unknown primary. We evaluate the oncologic and functional outcomes after reduction of RT volumes based on TORS findings. **Methods:** Patients with p16-positive, neck SCC (cN1-N3) with no primary on examination and CT/MRI were included between 08/2017 and 12/2019. All patients underwent PET-CT, surgical evaluation with either therapeutic intent including neck dissection for cN1 without extranodal extension (Group 1, n=9) or diagnostic intent (Group 2, n=13). Patients underwent excision of palatine tonsil (PT) followed by lingual tonsil (LT), if the PT was negative, or excision of PET-CT avid regions. Pharyngeal-sparing radiotherapy (PSRT) was given when no primary was found (pT0) and for primaries completely excised (margins >= 3mm). Unilateral neck radiotherapy (UNRT) was given for lateralized (>1 cm from midline) primaries or pT0 with unilateral disease. The primary outcome was 2-year out-of-treated volume failures (OTVF). Swallowing-related quality of life (SR-QOL) was measured using MD Anderson Dysphagia Inventory (MDADI) composite score. A sample size of 22 was required assuming OTVF cannot exceed 15% (vs. 1% historical), power of 0.8, alpha of 0.05 (one-sided), and loss to follow-up of 10%. **Results:** All 22 patients [median age 60 (46-68); 86% male; 86% N1, 9% N2, 5% N3] underwent surgical evaluation. PET-CT showed suspicious findings in 12 (55%) [sensitivity = 0.44, specificity = 0.29]. Excision of PT and LT were performed in 14 (64%) and 14 (64%) patients respectively; and 8 (36%) had previous PT. Oropharyngeal primaries were found in 17 patients (77%) [14 (64%) single primary, 3 (13%) two primaries]. RT volume de-intensification was achieved in 11 patients (50%) who had PSRT and 10 (45%) who had UNRT. In Group 1, adjuvant RT was given to 6 (67%) and CRT to 1 (11%). In group 2, 8 (62%) had RT and 5 (38%) had CRT. There were no OTVF, local, or regional failures [median follow-up 29 months]. Two-year OS, DFS, and LRC were 100%, 95%, and 100%. SR-QOL showed good recovery (Table). Grade III/IV surgical as well as acute and late toxicities occurred in 2 (9%), 5 (23%), and 1 (5%) respectively. **Conclusions:** TORS evaluation for p16-positive unknown primary SCC allowed RT volume de-intensification with excellent disease control and quality of life. Future randomized trials can compare transoral surgery versus existing diagnostic approaches. MDADI composite scores. Clinical trial information: NCT03281499. Research Sponsor: Surgical Oncology Innovation Fund - Princess Margaret Cancer Center.

mean (SD)	Baseline	Post-Op	End of Treatment	12 month
Cohort (n=22)	93.8 (9.9)	76.8 (16.6)	64.3 (19.6)	85.0 (14.4)
Primary RT (n=11)	97.1 (3.4)	72.8 (19.3)	55.9 (17.8)	86.8 (12.8)

Neoadjuvant chemotherapy plus tislelizumab followed by concurrent chemoradiotherapy in patients with locoregionally advanced nasopharyngeal carcinoma: A single-arm, phase II trial. *First Author: Qiu-Yan Chen, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Neoadjuvant treatment with gemcitabine plus cisplatin (GP) prior to concurrent chemoradiotherapy (CCRT) has favorable survival outcomes with acceptable toxicity in patients with locoregionally advanced nasopharyngeal carcinoma (LANPC), 10% of whom achieved complete response (CR) after neoadjuvant treatment. Immune checkpoint blockade therapy plus GP regimen has been shown to improve the survival in recurrent or metastatic NPC. We investigated the efficacy and safety of neoadjuvant treatment with GP plus tislelizumab, an anti-PD-1 monoclonal antibody, in previously untreated LANPC. **Methods:** In this phase II, single-armed Simon two-stage study, eligible patients are of age 18-70, with adequate haematological, renal, and hepatic function, diagnosed with staged III-IVa (AJCC 8th) non-keratinizing LANPC. Enrolled patients received intravenous gemcitabine (1000 mg/m2) on days 1 and 8, cisplatin (80 mg/m2) on day 1, and tislelizumab (200mg) on day 1 every 3 weeks for 3 cycles followed by standard CCRT. The primary endpoint was CR rate after neoadjuvant treatment, using Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1 by investigator. The secondary endpoints included pathology complete response (pCR) rate, 2-year progress-free survival (PFS), overall survival (OS), locoregional failure-free survival (LRRFS), distant metastasis-free survival (DMFS), and toxicity. This study is registered with ClinicalTrials.gov, NCT04833257, all enrolled patients have finished their treatment and the follow-up is ongoing. **Results:** From April 14th 2021 to August 5th, 2021, a total of 63 patients (median age 46y, 74.6% male) were enrolled at Sun Yat-sen University Cancer Center. As of January 31st, 2022, the median follow-up is 7.37 months, no patients had disease progression. The CR rate after neoadjuvant treatment was 41.3% (95% CI, 28.8% to 53.8%). The ORR and pCR rate were 88.9% (95% CI, 80.9% to 96.9%) and 75.8% (95% CI, 64.8% to 86.8%), respectively. The incidence of acute treatment-related AEs (trAEs) and immune-related adverse events (irAEs) of grade 3 or 4 was 69.8% and 3.2%, respectively. All of irAEs for grade 3 or 4 were hepatotoxicity and skin rash. Long-term efficacy is awaited. **Conclusions:** Neoadjuvant treatment with GP plus tislelizumab achieved impressive CR rate and pCR rate with manageable toxicities. Further follow-up is needed to confirm the long-term efficacy. Clinical trial information: NCT04833257. Research Sponsor: None.

TPF induction chemotherapy versus PF adjuvant chemotherapy plus concurrent chemoradiotherapy for locoregionally advanced nasopharyngeal carcinoma: A multicenter, randomized controlled, III trial. *First Author: He Qianyong, Affiliated Hospital of Guizhou Medical University, Guiyang, China*

Background: To investigate the efficacy and safety of the two modes of concurrent chemoradiotherapy combined with induction or adjuvant chronotherapy for the treatment of locoregionally advanced nasopharyngeal carcinoma. **Methods:** A total of 266 patients with locoregionally advanced NPC were enrolled from May 2018 to July 2021 and randomly divided into a test (n = 133) and a control (n = 133) group. In the test group, the docetaxel and cisplatin plus fluorouracil (TPF) regimen was used to induce chronological chemotherapy for 3 cycles (docetaxel 75mg / m2, D1, cisplatin 75mg / m2, d1-d5, fluorouracil 750mg / m2 / D, d1-d5) + 3 cycles of concurrent chemoradiotherapy (cisplatin 100mg / m2; The control group was treated with three cycles of concurrent chemoradiotherapy (cisplatin 100mg / m2) + cisplatin plus fluorouracil (PF) regimen with adjuvant schedule chemotherapy for three cycles (cisplatin 80mg / m2 on days d1-d5, fluorouracil 800mg / m2 / d on days d1-d5). In both groups, intensity-modulated radiation therapy was used with a total dose of 69.96 Gy to the primary tumor at T1 and T2, 72.6 Gy to the primary tumor at T3 and T4, and 69.96 Gy to the positive lymph nodes. Acute adverse effects and survival were compared between the two groups. **Results:** A median follow-up of 19 months, 129 patients in the test group and 124 in the control group were evaluable for efficacy and adverse effects.Compliance was 96.99% and 90.22%, respectively. The 2-year overall survival rates were 91.7% and 90.5%, and the 2-year progression free survival rates were 92.4% and 90.4% in the test and control groups, respectively, with no significant difference ($P > 0.05$). The test group had a lower incidence of radiation mucositis, dry mouth, and dysphagia than the control group ($P < 0.05$), whereas the test group had a higher incidence of leukopenia, neutropenia, hemoglobin loss, vomiting ($P < 0.05$), decreased radiation dermatitis, platelets There were no significant differences in the categories of creatinine elevation and transaminase elevation ($P > 0.05$). **Conclusions:** The patients' compliance was good and the toxic effects such as radiation mucositis, dry mouth and dysphagia were reduced under the treatment mode in which the TPF induced chemotherapy combined with concurrent chemoradiotherapy.Although the toxic effects such as leukopenia, neutropenia, hemoglobin reduction and vomiting were increased, the efficacy was comparable with that of the PF in which the adjuvant schedule chemotherapy combined with concurrent chemoradiotherapy. Clinical trial information: NCT-03574324. Research Sponsor: None.

Neoadjuvant nivolumab with or without IDO inhibitor in head and neck squamous cell carcinoma (HNSCC): Final pathologic and clinical outcomes. *First Author: Adam Luginbuhl, Department of Otolaryngology, Thomas Jefferson University, Philadelphia, PA*

Background: Indoleamine 2,3-dioxygenase (IDO) catalyzes the degradation of tryptophan to kynurenine. In order to improve the clinical efficacy of PD-1 inhibition, we designed a novel neoadjuvant trial to test the immunological and therapeutic effects of nivolumab (nivo) and the IDO inhibitor BMS986205 in combination in previously untreated HNSCC utilizing an interim radiographic assessment to determine response treatment prior to surgery. **Methods:** We conducted an investigator-initiated, multi-institutional, two-arm, 3:1 randomized neoadjuvant trial in patients with previously untreated HNSCC of any stage who were candidates for complete surgical resection. Patients were stratified by HPV status. Patients in arm A received 480 mg of nivolumab alone. Subjects in arm B received BMS986205 100 mg po qday beginning 1 week prior to nivolumab 480 mg. Both groups were evaluated at week 5 with CT scans. Radiographic response was evaluated at both the primary site and any involved lymph nodes. Patients with at least a 10% reduction in volume at either the primary or lymph nodes with no evidence of progression continued on to a second cycle of the assigned treatment. Patients with stable disease or progression proceeded to surgery at week 5 without additional study treatment. Imaging, blood and tumor were obtained pretreatment and post treatment and used for immunological correlatives. 2 blinded independent pathologist provided pathologic treatment effect (pTE) scores for primary tumor and lymph nodes. The primary endpoint was radiographic response leading to additional study treatment. **Results:** 42 patients were randomized and completed treatment to the primary endpoint evaluation including 22 HPV+ oropharyngeal HNSCC. Four patients did not proceed with planned surgery: 2 progression, 1 patient preference, and 1 toxicity. 3 patients in Arm B developed hepatitis with 2 subjects having a delay in surgery. 36% of patients (n=4) in Arm A (nivo alone) and 42% of patients (n= 13) in Arm B (nivo+IDO) were considered radiographic responders and continued to a second cycle of therapy (p= 1.0). Pathologic treatment effect (pTE) was significantly higher in subjects who were treated with a second cycle: median of 85% pTE (responders) compared to median of 5% pTE (nonresponders) at the primary site (p=0.018) with 6/16 (38%) subjects in the radiographic responders and 1/20 (5%) in radiographic non-responders demonstrating a CR at the primary site. In the lymph node compartment, the median pTE was 73% compared to 23% in radiographic responders vs non-responders (p=0.04). **Conclusions:** In previously untreated HNSCC, nivolumab +/- IDO inhibitor demonstrated a significantly greater pTE after a second dose in radiographic responders. The addition of IDO-inhibitor to anti-PD1 did not result in a significant increase in radiographic or pathologic response over nivolumab alone. NCT03854032. Clinical trial information: NCT03854032. Research Sponsor: Bristol Myers Squibb.

Six-year follow-up from the weekly-three-weekly study comparing cisplatin once-a-week to once-every-three-weeks as concurrent chemoradiation for locally advanced head and neck squamous cell carcinoma. *First Author: Vanita Noronha, Tata Memorial Centre, Mumbai, India*

Background: In the weekly-3-weekly (W3W) study, cisplatin at 100 mg/m^2 once-every-3-weeks led to superior locoregional control compared to cisplatin 30 mg/m^2 once-a-week in combination with radical radiation for locally advanced head and neck squamous cell carcinoma (LAHNSCC). We report the updated analysis of the study. **Methods:** In this phase III open label non-inferiority study conducted between 2013 and 2017, 300 patients with LAHNSCC were randomly assigned to receive cisplatin 100 mg/m^2 once-in-3-weeks or cisplatin 30 mg/m^2 once-a-week, concurrently with radiation. The primary endpoint was locoregional control. Secondary outcomes included progression free survival (PFS), overall survival (OS), toxicity, and quality of life. **Results:** As of February 5, 2022 (median follow-up, 77.3 months), 132 patients (44%) have had an event for locoregional recurrence; 75 (50%) in the once-a-week cisplatin arm and 57 (38%) in the once-every-3-weeks cisplatin arm. The updated estimated cumulative 2-year locoregional control rates were 59.3% and 75.3% in the once-a-week and once-every-3-weeks cisplatin arms, respectively; absolute difference, 16% (95% CI, 7.19 to 24.81). The estimated 5-year locoregional control rates were 48.2% and 55.2% in the once-a-week and once-every-3-weeks cisplatin arms respectively; absolute difference, 7% (95% CI, -2.5 to 16.5). The median time to locoregional failure was 46.1 months (95% CI, 31.63 to 60.56) in the once-a-week cisplatin arm, and 57.9 months (95% CI, 47.1 to 68.6) in the once-every-3-weeks cisplatin arm; HR, 1.43 (95% CI, 1.01 to 2.02); P = 0.042. The estimated median PFS was 17.5 months (95% CI, 0 to 38.31) in the once-a-week cisplatin arm, versus 37.5 months (95% CI, 28.45 to 46.45) in the once-every-3-weeks cisplatin arm; HR, 1.13 (95% CI, 0.85 to 1.5); P = 0.41. Events for OS included 173 (57.7%) deaths; 109 (36.3%) patients are alive, and 18 (6%) are lost to follow-up. The 5-year OS in the once-a-week and once-every-3-weeks cisplatin arms were 43.1% and 48.6%, respectively. Estimated median OS was 38.5 months (95% CI, 16.3 to 60.7) in the once-a-week cisplatin arm, versus 57.3 months (95% CI, 38.6 to 75.9) in the once-every-3-weeks cisplatin arm; HR, 1.19 (95% CI, 0.89 to 1.6); P = 0.238. Details regarding chronic toxicities and second primaries will be presented. **Conclusions:** Long term follow-up confirms that cisplatin at 100 mg/m^2 administered once-every-3-weeks concurrently with radical radiation for LAHNSCC leads to superior locoregional control and should remain the standard of care. The study was not powered to test for a difference in OS; OS was numerically higher in the once-every-3-weeks cisplatin arm, but the difference did not attain statistical significance. Clinical trial information: CTRI/2012/10/003062. Research Sponsor: Tata Memorial Center Research Administration Council.

6072 **Poster Session**

Preoperative durvalumab (D) with or without tremelimumab (T) for resectable head and neck squamous cell carcinoma (HNSCC): Updated results with high dimensional profiling of circulating immune cells. *First Author: Chang Gon Kim, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: Although PD-1 blockade has improved survival in patients with recurrent and/or metastatic HNSCC, safety and efficacy of neoadjuvant immunotherapy with PD-L1 inhibitor with or without CTLA-4 inhibitor has not been investigated. Here, we report the updated results of the safety and efficacy of a preoperative D with or without T (D+/-T) in patients with resectable HNSCC, accompanied with high dimensional profiling of circulating immune cells. **Methods:** Patients with locally advanced but resectable HNSCC were eligible. Enrolled patients were randomized into D or D+T, stratified by primary site and human papilloma virus (HPV) infection status. A single dose of preoperative D (1500mg) or D+T (1500mg+75mg) was administered, with surgery planned 2 to 8 weeks later for curative resection. Postoperative (chemo) radiation was prescribed based on standard guidelines, followed by maintenance with D every 4 weeks for 1 year. Dynamic changes in circulating immune cells were tracked with mass cytometry. The primary objective was to determine the local recurrence rate. Secondary endpoints included pathologic response, safety, survival outcome, and exploration of immune dynamics. **Results:** As of January 25th 2022 for the interim analysis, a total of 45 patients were completely enrolled and received surgical resection (D: 21 patients, D+T: 24 patients). Oropharyngeal cancer was most common (n = 23; 51.1%) and HPV-mediated cancer was observed in 20 patients (44.4%). Neoadjuvant D+/-T had acceptable safety profiles and was not associated with delays in surgery or unexpected adverse events. Tumor shrinkage was observed in 31 patients (68.9%), with 15.6% of average tumor shrinkage (range; 100.0% to -80.0%). Major pathologic response (no more than 10% of viable tumor cells) was achieved in 3 patients (6.7%), including 2 cases with pathologic complete response (4.4%). During median follow-up duration of 407 days after surgery, local recurrence and systemic recurrence were documented in 9 patients (20.0%) and 7 patients (15.6%), respectively. Median disease-free survival and overall survival was 910 days and not reached, respectively. High dimensional immune profiling with mass cytometry revealed that D+T disproportionally increased the frequency of regulatory T cells accompanied with the upregulation of their functional markers, which was absent in patients treated with D monotherapy. **Conclusions:** These updated data suggested that preoperative D+/-T was safe and feasible and had the potential to provide clinical benefits for patients with resectable HNSCC. Distinct immunologic changes in circulating immune cells were induced by each treatment regimen, warranting further investigation. The trial is ongoing and the updated outcomes with immune correlates will be presented in this ASCO. Clinical trial information: NCT03737968. Research Sponsor: None.

Phase III randomized control study evaluating adjuvant metronomic chemotherapy in locally advanced head and neck cancers post-radical chemoradiation (MACE-CTRT). *First Author: Sunil Chopade, Tata Memorial, Mumbai, India*

Background: Locally advanced head and neck cancer treated with radical chemoradiation have unsatisfactory outcomes. Oral metronomic chemotherapy improves outcomes in comparison to maximum tolerated dose chemotherapy in the palliative setting. There is also limited evidence that it may do so in an adjuvant setting. Hence this randomised study was conducted. **Methods:** Patients of HN cancer with primary in oropharynx, larynx or hypopharynx, with PS 0-2 post radical chemoradiation with documented complete response were 1:1 randomised to either observation or oral metronomic adjuvant chemotherapy (MAC) for 18 months. MAC consisted of weekly oral methotrexate (15 mg/m2) and celecoxib (200 mg PO BD). The primary endpoint was OS and the overall sample size was 1038. The study had 3 planned interim analyses for efficacy and futility. **Results:** 137 patients were recruited and an interim analysis was done. The 3 year PFS in the observation arm was 67.1% (95% CI 53.8-77.3) and the same in the MAC arm was 62.5%(95%CI 49.4-73.1). The corresponding hazard ratio was 1.402 (95% CI 0.7393-2.66, P-value = 0.3). The 3 year OS in the observation arm was 77.3% (95% CI 64.4-86) and the same in the MAC arm was 64.1% (95%CI 51-74.5). The corresponding hazard ratio was 1.588 (95% CI 0.8734-2.886, P-value = 0.1). Any grade mucositis was seen in 30 patients (45.5%) in the MAC arm and 20 patients (28.2%) in the observation arm (P-value = 0.05). The rate of grade 3 or above mucositis was 7.6%(n = 5) in the MAC arm and 1.4%(n = 1) in the observation arm (P-value = 0.106). **Conclusions:** Both arms had similar OS. Hence observation post complete response post radical chemoradiation remains the standard of care. Clinical trial information: CTRI/2016/09/007315. Research Sponsor: Tata Memorial Center Research Administration Council.

Recurrence pattern after chemoradiotherapy for HPV-associated oropharyngeal squamous cell carcinoma with respect to induction chemotherapy and escalated radiation dose-results from a prospective randomized phase II study. *First Author: Signe Friesland, Dep. of Oncology, Karolinska Institute, Stockholm, Sweden*

Background: Patients with HPV associated squamous cell carcinoma of the oropharynx have a favorable outcome with respect to tumor control and overall survival (OS) after treatment with chemoradiotherapy (CRT). The leading cause of death in these patients is reported to be peripheral metastases. Because of the favorable outcome for these patients, the medical community tries to find methods to ameliorate treatment intensity, mainly in order to reduce long term morbidity. However, between 10 and 15 % of patients relapse locally in the primary tumor as first site of disease failure. **Methods:** In this multicentre, randomized, controlled, phase II trial 152 patients with locoregionally advanced oropharyngeal cancer were randomized in a 1:1 ratio to either radiotherapy with cetuximab (arm B) versus the same regimen preceded by 2 cycles of induction chemotherapy (IC) with taxotere/cisplatin/5-FU (arm A). To decrease risk of local failure, an escalated radiation (RT) dose of 74.8 Gy was delivered to T3/T4 tumors and to T2 tumors > 3 cm in the base of tongue. Eligibility criteria included patients 18-75 years, ECOG performance status 0-1 and adequate organ functions. Primary endpoint of the study was to compare PFS between the treatment arms, secondary objectives were recurrence pattern, locoregional control, OS and toxicity. **Results:** PFS at 2 years was 84.2% (95%CI 76.4-92.8) in arm A and 78.4 (95%CI 69.5-88.3) in arm B (p = 0.20). At the time of analysis there were 26 disease failures, 9 in arm A and 17 in arm B. In arm A there were 3 local, 2 regional and 4 distant relapses as first site of recurrence, and in arm B 4, 4 and 9 relapses in corresponding sites. Local relapse rate as first site of failure was low, i.e. in 4.7%. Local failures constituted 7 relapses out of all 26 (27%), and in 4 of these local failures (57%), the escalated dose was given. In arm B, patients who had no IC, there were more than twice as many patients who had distant metastases as first site of relapse compared to arm A (n.s.). No patient who had a response to IC in the primary tumor or in regional lymph nodes, respectively, measured with CT or MRI, of either CR+CR or CR+PR, had any recurrence, local, regional or distant. So, IC could identify 22 out of 73 evaluable patients (30%) in arm A, who never had any recurrence during follow up. **Conclusions:** A high incidence of distant metastases as first site of failure is recognized while local failure rate is low. However, despite a high RT dose of 74.8 Gy, delivered to the primary tumor, relapses can appear in this site. Radiological response of tumor to IC could identify patients with no tumor relapse, at least within the first years of follow up, possible candidates for de-escalation treatment protocols. Clinical trial information: 2009-013438-26. Research Sponsor: None.

Nivolumab-based induction chemoimmunotherapy and PD-L1 expression in locoregionally advanced HPV-associated oropharyngeal squamous cell carcinoma. *First Author: Ari Rosenberg, University of Chicago, Department of Medicine, Chicago, IL*

Background: Blockade of the PD-1/PD-L1 immune checkpoint improves survival in recurrent/metastatic head and neck cancer. PD-L1 expression is a biomarker that enriches for clinical benefit with anti-PD-1 therapy alone or in combination with chemotherapy in this setting. The role of PD-L1 expression as a predictive biomarker in locoregional human papillomavirus associated (HPV+) head and neck cancer (HNC) treated with induction nivolumab-based chemoimmunotherapy is unknown. We evaluate PD-L1 expression and response to induction chemoimmunotherapy in the context of an investigator initiated trial, OPTIMA II. **Methods:** Patients with locoregionally advanced HPV+ HNC were enrolled to the prospective OPTIMA II study evaluating induction chemoimmunotherapy followed by response adaptive de-escalated locoregional therapy. Induction therapy consisted of nivolumab, nab-paclitaxel, and carboplatin, for three cycles. Anatomic imaging of the head and neck with either CT or MRI was obtained at baseline and following induction therapy. Expression of PD-L1 was assessed by immunohistochemistry on baseline biopsies and calculation of tumor proportion score (TPS) and combined positive score (CPS) was performed. Response is defined as percentage of tumor shrinkage per RECIST 1.1 criteria. Deep response rate is defined as the proportion of patients with > = 50% tumor shrinkage. Kruskal-Wallis and Mann-Whitney tests were used for analysis. **Results:** Twenty-nine patients (pts) underwent evaluation of PD-L1 expression and started treatment with induction chemoimmunotherapy. Median age 61 (range 37-81), smoker > 20 pack years in 24%, tonsil primary in 79%, and HPV16 subtype in 97%. The median response following induction was 63% (range 29% to 100%). PD-L1 TPS scores were < 1, 1-19, and > = 20 in 28%, 34%, and 38% respectively. PD-L1 CPS scores were < 20 and > = 20 in 55% and 45% respectively. Median response among PD-L1 TPS of < 1, 1-19, and > = 20 was 49%, 59%, and 66% respectively (p = 0.16). Among PD-L1 CPS of < 20 and > = 20, median response was 57% and 69% respectively (p = 0.11). The deep response rate among PD-L1 CPS < 20 and > = 20 was 69% and 77% respectively. **Conclusions:** Deep responses were observed following induction chemoimmunotherapy in locoregionally advanced HPV+ HNC. There was a non-significant increase in median response and deep response rate with higher expression of PD-L1. Evaluation of PD-L1 expression as a biomarker for response with induction chemoimmunotherapy is worthy of further investigation in locoregional HPV+ disease. Clinical trial information: NCT03107182. Research Sponsor: Bristol Myers Squibb.

Factors associated with adherence to remote patient monitoring for early detection of dehydration risk during radiation treatment for head and neck cancer. *First Author: Sarah Phillips, Eastern Virginia Medical School, Norfolk, VA*

Background: Remote patient monitoring (RPM) may improve the early detection and mitigation of cancer treatment-related complications, health-related outcomes and quality of life. RPM's success may depend, in part, on patients' adherence to remote monitoring protocols. However, factors that influence adherence to RPM are largely unknown. Daily blood pressure/pulse (BP/P), weight, and electronic patient-reported outcomes (ePROs) were monitored remotely in head and neck cancer (HNC) patients undergoing radiation treatment (RT) to identify dehydration risk. We evaluated potential factors associated with RPM adherence. **Methods:** During RT (average 6 to 7 weeks), participants were asked to take daily (Monday-Friday) measures of BP/P and weight using Bluetooth-enabled devices and to complete daily ePROs using a mobile tablet application (app). Data were provided to their physicians for daily review. The MD Anderson Symptom Inventory-Head and Neck (MDASI-HN) was completed at baseline and end of RT, and 6-8 weeks post-RT completion. The Patient Activation Measure (PAM) was completed at baseline and 6-8 weeks post-RT completion. A device usability survey measuring perceived usefulness of RPM was completed at the end of RT. Adherence to daily monitoring was recorded objectively. Longitudinal analyses compared the relationship between demographic, clinical, and PRO data and monitoring adherence. **Results:** Participants (n = 169) were 80% male, 87% White, and 91% married. Overall adherence to monitoring BP/P, weight, and ePROs was 83%, 82% and 74%, respectively. Greater HN-specific symptom severity and interference was associated with decreased adherence to daily monitoring of BP/P, weight, and ePROs (P< 0.021). Higher PAM scores were associated with higher adherence to daily monitoring of BP/P only (p = 0.006). Participants reported modest levels of perceived usefulness of RPM across four categories: symptom management, early problem detection, illness monitoring by healthcare provider, and feeling of security during RT. Only a single item indicating perceived feeling of security was associated with greater adherence to daily monitoring of blood pressure/pulse (p = 0.032) and weight (p = 0.007). **Conclusions:** A benefit of frequent RPM may be early detection and mitigation of symptoms during RT for HNC, however, increasing symptom burden experienced during treatment may interfere with adherence to daily monitoring. Better adherence may be attributed to patients perceiving a sense of security from daily monitoring and may suggest a potentially important value that patients gain from RPM. Understanding factors that impact patient adherence to RPM may help improve acceptability and clinical utility of RPM in oncology. Clinical trial information: NCT02253238. Research Sponsor: U.S. National Institutes of Health.

Outcomes by tobacco history in E3311, a phase II trial of transoral surgery (TOS) followed by pathology-based adjuvant treatment in HPV-associated (HPV+) oropharynx cancer (OPC): A trial of the ECOG-ACRIN Cancer Research Group. *First Author: Ranee Mehra, Greenebaum Comprehensive Cancer Center, University of Maryland, Baltimore, MD*

Background: E3311 is a phase II randomized study which showed favorable outcomes among intermediate (INT) risk HPV+ OPC patients (pts) who underwent TOS followed by pathology-guided or adapted, deintensified adjuvant treatment. Among HPV+ pts treated with definitive chemoradiation, survival outcomes are worse among those who smoked > 10 pack years (pk-yrs). **Methods:** We retrospectively analyzed demographics, pathologic results, and efficacy outcomes from E3311 by smoking group (current (C) vs. former (F) and > 10 vs. ≤10 pk-yrs the latter a pre-specified stratification factor for INT patients). Binary and categorical variables were compared using a chi-square test (or Fisher s exact test for small sample sizes). Ordinal variables were compared using a Wilcoxon rank sum test. Progression-free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method and compared using a log-rank test. **Results:** Among 359 evaluable pts, performance status (PS) was significantly worse for pts with > 10 pk-yrs vs. ≤10 pk-yrs (15.4% vs. 7.9% with PS of 1, p = 0.034). Primary site, margin status, histologic grade, stage, and extranodal extension were not significantly different between the groups of > 10 vs. ≤10 pk-yrs. Smoking status (F vs. C) was available for 182 pts with a history of smoking. Slightly more C vs. F smokers had tonsil as primary site (79.5% vs. 65.0%, p = 0.09). Positive margins were significantly more frequent among C smokers (10.3% vs. 2.1%; p = 0.029). Overall, there were no significant differences in PFS (p = 0.55) or OS (p = 0.94), comparing those with > 10 vs. ≤10 pk-yrs, or comparing C vs. F smokers (p = 0.76, p = 0.82, respectively). Similarly, no significant differences were observed within the treatment arms. (Table 1) **Conclusions:** In this analysis of smoking status in E3311, INT risk HPV+ OPC pts who are C smokers or have a history of > 10 pk-yrs had favorable 3-yr PFS and OS rates that were not significantly worse than those with < 10 pk-yrs history. This data represents the first treatment approach for HPV+ OPC in which outcomes were not influenced by smoking status. Clinical trial information: NCT01898494. Research Sponsor: U.S. National Institutes of Health.

Phase 2 pilot trial of RRx-001 as an anti-mucositis agent in patients with head and neck cancer treated with chemoradiation (PREVLAR). *First Author: Marcelo Raul Bonomi, James Cancer Hospital Solove Research Institute, The Ohio State University, Columbus, OH*

Background: Severe oral mucositis (SOM) is a dose limiting toxicity during radiotherapy and cisplatin for head and neck cancers. The aim of this 4-arm randomized controlled pilot trial was to evaluate the efficacy of different schedules of a novel radioprotectant, RRx-001 versus standard-of-care (SOC), to reduce duration, time to onset and incidence of SOM in patients received cisplatin-based chemoradiotherapy (CRT) for oral cavity or oropharyngeal cancer (OCC). **Methods:** Patients with locally advanced OCC treated with definitive or postoperative CRT were randomized to receive RRx-001 by 15-minute intravenous infusion in one of three different schedules versus none. The days and severity of mucositis were prospectively evaluated. Oral mucositis was assessed weekly during and after CRT as well as 28 days after completion. The pre-specified efficacy endpoints were duration of grade 3-4 SOM, resolution of SOM, time to onset of SOM and incidence of SOM. **Results:** A total of 53 patients were enrolled between June 2018 and July 2019 across 11 institutions. Forty-five (out of 53) patients received study drug and were efficacy evaluable. RRx-001 were well tolerated with no associated serious adverse events. All RRx-001 arms numerically outperformed SOC on the pre-specified efficacy measures, and the greatest effect estimate was observed on Arm 1 (RRx-001 pretreatment only + CRT). The following endpoints favored treatment with RRx-001. Median SOM duration by treatment was 22 and 40 days for Arm 1 and SOC respectively. Time to onset of SOM was by 38 days (Arm 1) vs. 26 days (SOC). On Arm 1, 83% of patients had SOM resolution vs 60% on SOC). Gastrostomy requirement was reduced by 45%. No patients on Arm 1 developed grade 4 mucositis vs 30% developed grade 4 mucositis on the SOC arm. Furthermore, the incidence of oropharyngeal dysphagia, which can substantially impair nutrition, was reduced by treatment with RRx-001, occurring at 50% vs 70% for Arm 1 vs SOC respectively. Treatment with RRx-001 resulted in highly significant decrease in the duration of SOM through 60 Gy with a median SOM of 1 day vs 17 days for Arm 1 vs SOC respectively (Wilcoxon rank-sum test p < 0.001). Median cumulative cisplatin dose was significantly greater for RRx-001 Arm 1 than SOC (557.4 mg vs. 438 mg, Wilcoxon p = 0.025). **Conclusions:** Compared with SOC, SOM among RRx-001-treated patients given 3 different treatment schedules was less severe, of shorter duration, demonstrated delayed time to onset and resolved earlier. Overall, the incidence, duration and severity of SOM and dysphagia was reduced. The safety profile of RRx-001 was similar to SOC. These results will inform the design of a Phase 3 pivotal study of RRx-001 in the prevention of SOM in at-risk cancer patients. Clinical trial information: NCT03515538. Yatagarasu: A single-arm, open-label, phase 2 study of apalutamide (APA) plus goserelin (GOS) for patients (pts) with far locally advanced or recurrent/metastatic (fLA/RM) and androgen receptor (AR)-expressing salivary gland carcinoma (SGC). *First Author: Yoshitaka Honma, Department of Head and Neck, Esophageal Medical Oncology, National Cancer Center Hospital, Tokyo, Japan*

Background: Overexpression of AR is identified as a potential molecular target of SGC treatment. Combined androgen blockade (CAB) with bicalutamide has been evaluated previously, but the clinical usefulness of CAB with a next generation AR inhibitor has been unclear in SGC. We prospectively assessed the efficacy and safety of APA+GOS for pts with AR-expressing SGC. **Methods:** Eligible pts had fLA/RM SGC, and AR expression with at least 1% of cell nuclei immunohistochemistry staining positive. Pts were treated with APA 240 mg orally once daily and GOS 3.6 mg subcutaneously once 28 days. Primary endpoint was overall response rate (ORR) by central review according to RECIST v1.1, and a response (complete response [CR] or partial response [PR]) was confirmed by repeat assessments at least 4 weeks after the initial evaluation showing a response. Primary analysis was performed based on first 24 response evaluable (RE) pts who had been observed at least 24 weeks (Primary RE pts). The ORR was tested using exact test based on the binominal distribution, the null hypothesis for ORR of 14% was rejected when at least 8 of the 24 Primary RE pts were responders, and the efficacy was to be declared. Key secondary endpoints included clinical benefit rate (CBR), disease control rate (DCR), duration of response (DOR), and time to response (TTR) in the Primary RE pts, and overall survival (OS), progression free survival (PFS), and safety in the treated pts. **Results:** Twenty-six of the 31 pts treated with APA+-GOS were regarded as RE by central review. For the 24 Primary RE pts, ORR was 25.0% (6/24), while 37.5% (9/24) including unconfirmed PR. Clinical benefit rate and DCR in the Primary RE pts were 50.0% and 70.8%, respectively. At the data cut-off (Apr 28, 2021), 5 of 6 pts with confirmed response were still on protocol treatment. Median PFS and OS in the treated pts were 7.43 months (mos) and not reached, respectively, with the median follow-up period of 8.57 mos. Grade 3 or higher treatment-related adverse events were reported in 4/31 (12.9%) pts, and the events were rash maculo-papular (n=2), anemia (n=1), and leukopenia (n=1). **Conclusions:** This is the first prospective trial evaluating CAB with APA for AR-expressing SGC. Although this study did not meet the predefined criteria of efficacy, clinically meaningful activity with well-tolerated safety profile of APA+GOS was shown. Clinical trial information: NCT04325828. Research Sponsor: Janssen Pharmaceutical K.K.

Pralsetinib in patients (pts) with advanced or metastatic *RET*-altered thyroid cancer (TC): Updated data from the ARROW trial. *First Author: Aaron Scott Mansfield, Mayo Clinic, Rochester, MN*

Background: Alterations in *RET* are targetable oncogenic drivers in TC. Pralsetinib is a highly potent, selective RET inhibitor, with demonstrated efficacy in pts with *RET*-altered TC. In a previous analysis of the Phase I/II ARROW trial (NCT03037385; data cutoff: 22 May 2020), overall response rates [ORR; measurable-disease population] with pralsetinib at 400 mg once daily (QD) were 60% (33/55) and 71% (15/21) in pts with *RET*-mutant medullary TC (*RET*-mutant MTC) who had received prior multikinase inhibitors cabozantinib and/or vandetanib (C/V), and those who were treatment naïve, respectively, and 89% (8/9) in pts with previously treated *RET* fusion-positive TC (*RET*-fp TC). Here we report an updated analysis of these cohorts in the intention-to-treat (ITT) population. **Methods:** Adult pts with *RET*-altered locally advanced/metastatic TC who had enrolled in ARROW and initiated pralsetinib at 400 mg QD, were included. Phase II primary endpoints: ORR (by blinded independent central review, per RECIST v1.1) and safety. Efficacy endpoints for this analysis were assessed in the ITT population. Safety was assessed in all pts with *RET*-altered TC who initiated pralsetinib at 400 mg QD. Enrolment cutoff: 23 August 2020 for the ITT population; data cutoff: 12 April 2021. **Results:** The ITT population comprised 145 pts with *RET*-mutant MTC (with or without prior systemic therapy, including C/V) and 22 pts with *RET*-fp TC, 21 of whom had received prior systemic therapy (including multikinase inhibitor[s] and/or radioactive iodine). In pts with *RET*-mutant MTC who had received prior C/V (n = 67), ORR was 51% (34/67; 95% CI 38–63; 2 complete responses [CR]; 32 partial responses [PR]), median duration of response (DoR) was 25.8 months (95% CI 18.0–not reached [NR]) and median progression-free survival (PFS) was 24.9 months (95% CI 19.7–31.2). In treatment-naïve pts with *RET*-mutant MTC, ORR was 72% (48/67; 95% CI 59–82; 4 CR; 44 PR), and median DoR and median PFS were not reached. In pts with previously treated *RET*-fp TC, ORR was 86% (18/21; 95% CI 64–97; 3 CR; 15 PR), median DoR was 17.5 months (95% CI 16.0–NR) and median PFS was 19.4 months (95% CI 13.0–NR). Median overall survival (OS) was not reached in any of the cohorts. The safety population comprised 172 pts with *RET*-altered TC treated at 400 mg QD. The most common treatment-related adverse events (TRAEs) were increased aspartate aminotransferase (n = 67; 39%), anemia (n = 60; 35%), hypertension (n = 57; 33%) and decreased white blood cell count (n = 52; 30%). Serious TRAEs were reported in 27 pts (16%); the most frequent was pneumonitis (n = 5; 3%). Nine pts (5%) discontinued pralsetinib due to a TRAE and one patient (< 1%) died due to a TRAE (*pneumocystis jirovecii* pneumonia) following 44 days (< 3 cycles) on pralsetinib. **Conclusions:** In this updated analysis including more pts, pralsetinib continues to be efficacious with a manageable safety profile in pts with *RET*-altered TC. Clinical trial information: NCT03037385. Research Sponsor: F. Hoffmann-La Roche Ltd and Blueprint Medicines.

6081 **Poster Session**

Cabozantinib versus placebo in patients (pts) with radioiodine-refractory (RAIR) differentiated thyroid cancer (DTC) who progressed after prior VEGFR-targeted therapy: Outcomes in prespecified subgroups based on histology subtypes. *First Author: Jaume Capdevila, Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology (VHIO), Universitat Autònoma de Barcelona, Barcelona, Spain*

Background: DTC comprises multiple histology subtypes, the most common being papillary and follicular. Based on results of the phase 3 COSMIC-311 trial, the multikinase inhibitor cabozantinib was recently approved by FDA for the treatment of pts with RAIR DTC who progressed after prior VEGFR-targeted therapy (Brose et al. 2021). In an extended follow-up, median (m) progression-free survival (PFS) was 11 months (mo) for cabozantinib vs 1.9 mo for placebo (HR 0.22, 96% CI 0.15–0.32, *P*< .0001) in the intent-to-treat (ITT) population (Capdevila et al. ESMO 2021. Abstr LBA67). Here we present outcomes for prespecified subgroups based on the baseline histology subtypes of papillary and follicular thyroid cancers. **Methods:** Pts were randomized 2:1 to cabozantinib (60 mg QD) or placebo. Placebo pts could cross over to open-label cabozantinib upon disease progression per blinded independent radiology committee (BIRC). Primary endpoints were PFS (ITT) and objective response rate (ORR, first 100 randomized pts), per RECIST v1.1 assessed by BIRC. **Results:** After a median follow-up of 10.1 mo, 258 pts (170 cabozantinib, 88 placebo) had been randomized (data cutoff 8 Feb 2021); 150 pts (96 cabozantinib, 54 placebo) had papillary thyroid cancer (PTC) and 113 pts (78 cabozantinib, 35 placebo) had follicular thyroid cancer (FTC), with the PTC and FTC subgroups each including 5 pts with both PTC and FTC. Sixty-three pts (~56%) within the FTC subgroup had Hurthle cell and poorly differentiated variants. mPFS was 9.2 mo for cabozantinib vs 1.9 mo for placebo in the PTC subgroup (HR 0.27, 95% CI 0.17–0.43) and 11.2 mo vs 2.6 mo in the FTC subgroup (HR 0.18, 95% CI 0.10–0.31). The mPFS was 11.1 mo for cabozantinib and 1.9 mo for placebo for pts with Hurthle cell and poorly differentiated variants (HR 0.12, 95% CI 0.05–0.27). The ORR was 15% for cabozantinib vs 0% for placebo in the PTC subgroup and 8% vs 0% in the FTC subgroup. Median duration of cabozantinib exposure was 5.5 mo for the PTC subgroup and 7.3 mo for FTC. Grade 3/4 treatment-emergent adverse events (TEAE) in the cabozantinib arm occurred in 59% of pts in the PTC subgroup and 68% of pts in the FTC subgroup; discontinuations due to TEAE occurred in 17% and 15% of pts, respectively. **Conclusions:** In the extended follow-up, cabozantinib maintained superior efficacy vs placebo irrespective of histology subtype, including the aggressive Hurthle cell and poorly differentiated variants. The moderately higher rates of grade 3/4 TEAE in the FTC vs the PTC subgroup could be attributed to the longer median duration of exposure of cabozantinib in the FTC subgroup. Clinical trial information: NCT03690388. Research Sponsor: Exelixis, Inc.

6082 **Poster Session**

Impact of intensive multimodal treatment on the outcomes of patients with anaplastic thyroid cancer. *First Author: Firas Baidoun, Department of Hospital Medicine, Cleveland Clinic, Cleveland, OH*

Background: Anaplastic thyroid cancer (ATC) is a rare and aggressive type of thyroid malignancy with very poor prognosis and outcome despite therapy. The rarity of this disease and the poor functional status of ATC patients limit the ability to conduct clinical trials, thus there is a lack of large, controlled trials to guide treatment and evaluate the benefit of combined modality therapy. **Methods:** The National Cancer Database (NCDB) was queried for patients diagnosed with ATC at age 18 or older between 2004 and 2018. After excluding patients with unknown number of treatment modalities, Charlson-Deyo score of 3 or more and patients lost follow-up, we split the cohort into three groups according to the number of treatment modalities they received. Treatment modalities include surgery, radiation, and systemic therapy. Then, we evaluated the overall survival (OS) between the three groups. We studied the OS using Kaplan-Meier estimates and multivariate cox regression analyses to evaluate factors associated with OS. Additionally, propensity score matching (accounting for age, gender, race, Charlson-Deyo score, and clinical M stage) was used for more robust results. **Results:** A total of 3,460 patients with ATC were included in the analysis, of which 1,472 (42.5%) either received one type of therapy or did not receive any therapy (group1), 1,092 (31.6%) received bimodal therapy (group 2), and 896 (25.9%) received trimodal therapy (group 3). We found that group 3 had better OS compared to group 1 and group 2 (median OS 9.1 months vs 1.7 months and 4.9 months, respectively with P < 0.001 for all). Propensity score matching yielded 896 patients in each group. We found that group 3 had better OS compared to group 1 and group 2 (median OS 9.1 months vs 1.9 months and 5.2 months, respectively with P < 0.001 for all). Same trend was found in subgroup analysis when we split the cohort according to the metastatic status; in M0 group (median OS was 10.4 months vs 1.9 months and 6.1 months, respectively with P < 0.001 for all), in M1 group (median OS was 5.9 months vs 1.4 months and 3.7 months, respectively with P < 0.001 for all). On multivariate analysis, group 1 and group 2 were associated with worse OS compared to trimodal treatment (HR 2.721; 95% CI: 2.466 - 3.002 and HR 1.434; 95% CI: 1.299 - 1.582, P < 0.001 for all). **Conclusions:** Patients with ATC who were treated with intensive trimodal therapy had statistically significant improvement in OS compared to patients who received less intense therapy. This survival benefit was observed in both metastatic and non-metastatic groups. While we acknowledge the limitations of this retrospective analysis, our results showed the critical role of intensive therapy approach in this aggressive malignancy. Research Sponsor: None.

6083 **Poster Session**

Cabozantinib (C) versus placebo (P) in patients (pts) with radioiodine-refractory (RAIR) differentiated thyroid cancer (DTC) who have progressed after prior VEGFR-targeted therapy: Outcomes in prespecified subgroups based on prior VEGFR-targeted therapy. *First Author: Jorge Hernando, Medical Oncology Department. Vall Hebron University Hospital, Vall Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Based on the results of the phase 3 COSMIC-311 trial, the multikinase inhibitor C was recently approved by the FDA for the treatment of RAIR DTC pts who progress after prior VEGFR-targeted therapies, such as lenvatinib (L) or sorafenib (S), and for whom there was no standard of care (Brose et al. *Lancet Oncol.* 2021). In an extended follow-up of the intent-to-treat (ITT) population, C-treated pts achieved a median (m) progression-free survival (PFS) of 11 months (mo) vs 1.9 mo with P (HR 0.22, 96% CI 0.15–0.32, *P* < .0001); here we present outcomes for prespecified subgroups who received prior L, S, or both. **Methods:** Pts were randomized 2:1 to C (60 mg QD) or P. P pts could cross over to open-label C upon disease progression per confirmation by blinded independent radiology committee (BIRC). The primary endpoints were PFS (ITT) and objective response rate (first 100 randomized pts), per RECIST v1.1 by BIRC. Pts must have received L or S and progressed during or after 1–2 prior VEGFR inhibitors. **Results:** After a median follow-up of 10.1 mo, 258 pts (170 C, 88 P) had been randomized (data cutoff 8 Feb 2021); 96 (~37%) had received prior S (no L), 102 (~40%) prior L (no S), and 60 (~23%) prior S and L. Median PFS was 16.6 for C vs 3.2 mo for P in prior S (no L) (HR 0.13, 95% CI 0.06–0.26); 5.8 vs 1.9 mo in prior L (no S) (HR 0.28, 95% CI 0.16–0.48), and 7.6 vs 1.9 mo in prior S and L (HR 0.27, 95% CI 0.13–0.54). In the C arm, 21% of pts in prior S (no L), 3% in prior L (no S), and 8% in S and L subgroups had confirmed partial response, and 1 pt had a confirmed complete response in prior L (no S); there were no responses with P. Stable disease as best response was 67% for C vs 45% for P in prior S (no L), 68% vs 32% in prior L (no S), and 74% vs 38% in prior S and L. Median duration of C-exposure was 7.0 mo in prior S (no L), 5.6 mo in prior L (no S) and 5.9 mo in prior S and L. Grade 3/4 treatment-emergent adverse events (TEAE) occurred in 63% pts in prior S (no L), 57% in prior L (no S), and 69% in prior S and L. Discontinuations of C due to TEAE occurred in 16% of pts in prior S (no L), 13% in prior L (no S), and 23% in prior S and L. There were no treatment-related deaths. **Conclusions:** In the extended follow-up, C maintained its superior PFS vs P irrespective of prior L and/or S. AEs in each subgroup were consistent with that of the overall population. This is also the first phase 3 study demonstrating a clinical benefit with C after prior L in RAIR DTC pts. Clinical trial information: NCT03690388. Research Sponsor: Exelixis, Inc.

The efficacy and safety of anti–PD-1 antibody toripalimab combined with surufatinib in neoadjuvant treatment of locally advanced thyroid cancer: A phase II study. *First Author: Jiaying Chen, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Surgery is the primary treatment for locally advanced thyroid cancer. However, some locally advanced patients are not candidates for R0/1 resection. There is limited evidence of neoadjuvant treatment in locally advanced thyroid cancer. Surufatinib targets multiple kinases (VEGFR1-3, FGFR1 and CSF-1R) involved in tumor angiogenesis and tumor immune evasion. It is efficient, tolerable and safe for patients with radioiodine-refractory differentiated thyroid cancer to receive surufatinib. In addition, surufatinib plus toripalimab (an anti-PD-1 antibody) showed encouraging antitumor activity and an acceptable safety profile in advanced solid tumors. This study aimed to evaluate the efficacy and safety of surufatinib plus toripalimab in locally advanced thyroid cancer in the neoadjuvant setting. **Methods:** In this single-arm phase II study, patients with pathologically confirmed diagnosis of unresectable or borderline resectable differentiated thyroid cancer were eligible and received a combination of 250 mg surufatinib (oral, qd) with 240 mg toripalimab (IV, q3w). Treatment was continued until satisfied for curative surgery, disease progression, withdrawal of consent, unacceptable toxicity or investigator decision. Primary endpoint was objective response rate (ORR) by RECIST 1.1. Secondary endpoints included R0/1 resection rate, disease control rate (DCR), time to remission (TTR), adverse events (AEs), etc. **Results:** This study is ongoing. 10/10 patients were enrolled. 6 patients received ≥4 cycles of surufatinib plus toripalimab treatment and were also evaluated for efficacy. The ORR was 66.7% with 4 partial response (PR) and 2 stable disease (SD). 4 PR and 1 SD patients received R0 resections after neoadjuvant treatment. The safety was consistent with previously reported. No grade ≥3 AEs were observed. Specific AEs data are still being counted. **Conclusions:** Surufatinib in combination with toripalimab as neoadjuvant therapy for locally advanced thyroid cancer was feasible and majority of patients achieved R0 resection. AEs were mainly grade 1-2, and this combination was well-tolerated. The combination of these two agents should be further investigated for neoadjuvant treatment of locally advanced thyroid cancer based on good results. Clinical trial information: NCT04524884. Research Sponsor: Fudan University.

A phase II study to evaluate the efficacy and safety of camrelizumab plus famitinib in advanced or metastatic thyroid cancer. *First Author: Dongmei Ji, Department of Head & Neck tumors and Neuroendocrine tumors, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: Many studies have confirmed that the combination with anti-vascular drugs can significantly improve the efficacy of anti-PD-1/PD-L1 inhibitor in a variety of tumors. Camrelizumab is a humanized anti-programmed cell death receptor 1 (PD-1) antibody. Famitinib is a tyrosine kinase inhibitor which exhibits anti-angiogenesis and antiproliferative effects via targeting VEGFR-2, c-Kit and PDGFR-β. Herein, we aimed to evaluate the efficacy and safety of camrelizumab plus famitinib in the treatment of advanced or metastatic thyroid cancer. **Methods:** A single-arm, open-label phase II study was conducted, patients (pts) with advanced or metastatic thyroid cancer were recruited, including radioiodine-refractory differentiated thyroid cancer (group 1), differentiated thyroid cancer ineligible for 131I treatment (group 2), medullary thyroid cancer (group 3) and anaplastic thyroid cancer (group 4). Pts received camrelizumab 200mg i.v. on day 1 of each 21-day cycle and oral famitinib 20mg po qd in 21-day cycles until progressive disease or drug intolerance. The primary endpoint was objective response rate (ORR). The secondary endpoints were safety, adverse events (AEs), duration of response (DoR), disease control rate (DCR), progression-free survival (PFS) and overall survival (OS). **Results:** Between Jan 14, 2020 and Feb 9, 2022, 74 pts were enrolled. There were 12/26/5/31 pts in group 1/2/3/4 respectively. Median follow-up time was 11.4 months. In group 1, of 12 evaluable pts, confirmed ORR, ORR and DCR accounted for 33.3%, 41.7% and 100.0%, respectively. In group 2, of 25 evaluable pts, the confirmed ORR and DCR were 44.0% and 96.0%, respectively. In group 3, of 5 evaluable pts, the confirmed ORR and DCR were 40.0% and 100.0%, respectively. In group 4, of 24 evaluable pts, the confirmed ORR, ORR and DCR were 62.5%, 75% and 95.8%, respectively. PFS and OS were not yet mature for group 1-3, and in group 4, of all enrolled pts, estimated median PFS was 8.4 months and estimated median OS was 13.6 months. 73 pts were included in safety set. The most common treatment related AEs were diarrhea (37.0%), palmoplantiplanar swelling syndrome (34.2%), hypertension (31.5%) and fatigue (31.5%). **Conclusions:** Camrelizumab plus famitinib demonstrated promising anti-tumor efficacy with acceptable toxicity in pts with advcanced or metastatic thyroid cancer. Clinical trial information: NCT04521348. Research Sponsor: None.

The prevalence and prognostic impact of mutations promoting chromatin remodelling dysregulation in non-resectable or recurrent/metastatic adenoid cystic carcinoma. *First Author: Samuel Rack, Christie Hospital NHS Foundation Trust, Manchester, United Kingdom*

Background: Few effective drug therapies exist for patients with recurrent/metastatic (R/M) adenoid cystic carcinoma (ACC). Mutations in genes encoding chromatin remodelling proteins are described in almost 50% of ACC patients (pts). Novel drug therapies are being developed to target these pathways, and may have clinical utility in this subgroup. We sought to classify mutations in chromatin remodelling genes in ACC based on predicted pathogenicity and to determine the impact of chromatin remodelling dysregulation (CRD) on clinical outcomes. **Methods:** Matched clinical-genomic data from 269 pts with non-resectable or R/M ACC were included in this study. 130 pts were prospectively recruited to an ethically approved study. For these pts, DNA extracted from FFPE tissue was sequenced on a commercially available platform to detect point mutations, indels and copy number variation in 324 genes. In addition, clinical-genomic data from 139 ACC pts were collected from cBioPortal (MetTropism, Cell 2021) for analysis. Mutations were classified as pathogenic using COSMIC, ClinVar and OncoKB. Univariate survival analysis was performed to determine the impact of one or more mutations in chromatin remodelling genes on survival from first recurrence or metastasis. p values determined using Kaplan-Meier and log-rank. **Results:** In 269 pts with non-resectable or R/M ACC, mutations promoting CRD were identified in ARID1A (11%), CREBBP (5%), EP300 (5%), KMT2C (1%), KMT2D (5%), KDM6A (13%), and SETD2 (3%). CRD mutations were identified in 94/269 (35%) pts, with 27/269 (10%) having 2 or more CRD mutations. For patients in whom CRD mutations were present survival from recurrence was decreased (median OS 4.6 v 8.2 years, HR 1.65 (95% confidence interval (CI) 1.13-2.40), p = 0.01). Analysis of each individual CRD gene identified that association with decreased survival from recurrence was significant for mutations in KDM6A (n = 35; median OS 4.2 vs 6.5 years; HR 2.01 (95% CI 1.25-3.22); p = 0.004), CREBBP (n = 11; median OS 4.2 vs 5.9 years; HR 2.97 (95% CI 1.20-7.38); p = 0.019) and SETD2 (n = 7; median OS 3.7 vs 5.9; HR 2.47 (95% CI 1.002-6.09); p = 0.042). Previous studies have identified NOTCH pathway activation and TP53 loss-of-function as prognostic. In a secondary analysis of pts without NOTCH activation and/or TP53 mutations (n = 202), OS from recurrence was decreased in those with CRD mutations (n = 58 median OS 5.7 vs 9.2 years, HR 1.5 (CI 95% 0.95-2.55), p = 0.07). **Conclusions:** We have identified a novel prognostic group of ACC pts characterised by mutations promoting CRD, which may have potential therapeutic options. Alterations in EP300/CREBBP/ARID1A may provide a rationale for treatment with CREBBP/EP300 inhibitors currently in clinical development. Significant co-occurrence with NOTCH gain of function may provide a rationale for future combination studies. 6088 **Poster Session**

A pilot study of trametinib in combination with paclitaxel in the treatment of anaplastic thyroid cancer. *First Author: Eric Jeffrey Sherman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Anaplastic Thyroid Cancer (ATC) is a rare and highly aggressive tumor with extremely poor prognosis. Outside of the recent approval of dabrafenib/trametinib for BRAF mutant tumors, there are no other standard treatment available for metastatic ATC. The majority of ATC is driven through the MAPK pathway. Data in lung cancer suggested synergy with trametinib, a MEK inhibitor, and taxanes. **Methods:** In this pilot study we used Trametinib (2 mg) daily with Paclitaxel (80 mg/m^2) administered weekly for the first 3 weeks out the 4 week-cycle. Restaging imaging was performed every 6-8 weeks (1.5-2 cycles). Eligible patients had ATC with baseline ECOG performance status ≤ 1 and were enrolled at Memorial Sloan Kettering Cancer Center. Prior treatment allowed. Prior brain metastases were allowed if treated and stable off of steroids. Primary objective was PFS at 6 months with the target of > 2 subjects out of 12 at the time point. **Results:** 12 patients (6 men and 6 women) were enrolled between 11/2017 and 10/2021. Seven (58%) had prior radiation to the neck; 4 (33%) had prior treatment (not including with radiation) for ATC; 1 (8%) had prior brain metastases. Three (25%) partial responses were reported, and five (41.67%) reported stable disease. Subjects with partial responses had a BRAF V600E mutation (1), BRAF fusion gene (1), and a RAS mutation (1). Median time on treatment was 10.5 weeks (3-47+ weeks). Median overall survival was 26 weeks (3-59+). Six-month progression free survival (PFS) was achieved in 3 patient (25%), one of whom remains on study. 2 patients discontinued treatment due to unacceptable toxicity. The most frequent adverse events observed (all grades) were anemia (75%), increased AST, diarrhea and leukopenia (all 50%). Grade 3/4 AEs included neutropenia (25%), with anemia, AST increased, febrile neutropenia, and lymphopenia, all 16.67%. Grade 4 reactions included lymphopenia (n = 2) and leukopenia (n = 1). **Conclusions:** Our target progression-free survival (PFS) at 6 months was observed on this study. The combination of trametinib and paclitaxel should be evaluated in a larger cohort of patients in the future. Clinical trial information: NCT03085056. Research Sponsor: Novartis, Philanthropy.

6089 **Poster Session**

Phase 2 of trametinib plus radioiodine in *RAS*-mutant and wild-type, radioiodine-refractory thyroid cancer (ETCTN9446). *First Author: Bharat Burman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: A pilot study showed MEK inhibition could enhance radioiodine (RAI) avidity/efficacy in 5 *RAS* mutant (MUT), RAI-refractory (RAIR) thyroid cancer (TC) patients (pts). This phase 2 trial with the MEK 1/2 inhibitor trametinib (tram) was conducted to define the efficacy of this "redifferentiation" strategy in *RAS* MUT RAIR pts and separately in a *RAS* wild-type (WT) cohort. **Methods:** Recurrent and/or metastatic, RAIR TC pts w/ *RAS* MUT (Cohort A) or *RAS* WT (excluding $BRAF^{V600E}$) (Cohort B) tumors were treated w/ tram (2 mg orally daily). Progressive disease or new/worsening disease-related symptoms was required for Cohort A pts. ^{124}I PET was performed at baseline and the fourth week of tram. If the second ^{124}I PET showed increased RAI avidity allowing > 2000 cGy to be delivered to a tumor w/ < 300 mCi ^{131}I, pts were treated w/ ^{131}I, guided by whole body and blood dosimetry. Tram was continued through 2 days s/p ^{131}I. Pts who did not qualify for ^{131}I from A/B were taken off study or continued tram alone (Cohort C). For Cohort A (n = 25), the two co-primary endpoints were objective response rate (ORR) and progression-free survival (PFS) 6 months (mos) s/p ^{131}I. Observing either >4 pts w/ confirmed complete or partial response (cCR or cPR) or > 9 progression-free at 6 mos would be considered promising. Secondary endpoints were the proportion of pts w/ increased ^{124}I, safety/tolerability of tram and thyroglobulin changes s/p RAI. The Cohort B primary endpoint was the proportion of pts whose tumors exceeded the lesional dosimetry threshold for ^{131}I w/ tram. An exploratory endpoint for Cohort C was best objective response (BOR) w/ tram. **Results:** 25 *RAS* MUT pts enrolled in Cohort A. 23 had at least one (> 1) ^{124}I (-) lesion, 21 had >1 ^{124}I (+) lesions and 4 pts had tumors lacking any ^{124}I uptake. After tram treatment, 22/25 had increased ^{124}I uptake; 17/23 had ^{124}I (-) tumors convert positive. Importantly, 15/25 (60%) pts had increased ^{124}I uptake and met lesional dosimetry criteria for ^{131}I on tram. Of 14 pts treated w/ ^{131}I, 8 (57%) achieved cPR, 3 (21%) stable disease (SD) and 3 (21%) progression of disease (PD) 6 mos s/p RAI, translating to 32% ORR and 44% 6-month PFS among all 25 pts. Cohort B had 9 pts (4 Class II *BRAF* alterations, 4 *RET* rearrangements, 1 *STK11* mutation). 3/4 pts w/ Class II *BRAF* altered tumors qualified for ^{131}I, leading to 1 cPR, 2 SD 6 mos s/p ^{131}I. 1/4 pts w/ *RET* rearranged tumors qualified for ^{131}I, producing SD at 6 mos. The *STK11* MUT pt did not have increased ^{124}I uptake w/ tram. 7 ^{131}I-ineligible pts enrolled to continue tram (Cohort C). Two serious adverse events (grade 3 anemia [Cohort A], grade 3 ejection fraction decrease [Cohort C]) and 3 grade 1 blurred vision/decreased visual acuity AEs were related to tram. **Conclusions:** Trametinib enhanced RAI uptake/efficacy in a subset of *RAS* MUT and Class II *BRAF* altered tumors. Further study to define the efficacy and optimal application of this therapeutic strategy is warranted. Clinical trial information: NCT02152995. Research Sponsor: U.S. National Institutes of Health.

Single-cell immune mapping of adenoid cystic carcinoma (ACC) reveals potential therapeutic targets for the aggressive solid subtype. *First Author: Luana Guimaraes de Sousa, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ACC is a common salivary gland malignancy for which there is no FDA approved therapies. Despite a quiet genome, ACC has significant tumoral heterogeneity, which may facilitate the metastatic relapse. Studies focusing on the deep profile of ACC tumor microenvironment (TME) are lacking. Here we explored the TME of ACC using imaging mass cytometry (IMC) and assessed TME attributes and its association with histology and clinical outcomes. **Methods:** Two tissue microarrays from 62 ACC patients (pts) were built and stained with 37 metal-tagged markers. IMC was performed with the Fluidigm Helios CyTOF instrument utilizing the Hyperion Imaging System Laser ablation. Tissue and cell segmentation and multiplex imaging analysis were performed with Visiopharm software using pre-trained artificial intelligence algorithms. Comparison of cell types and markers densities among histology sub-groups were analyzed with Wilcoxon signed-rank test and its association with overall survival (OS) with log-rank and Cox Proportional Hazards. **Results:** Of 62 pts, 37% (23/62) had solid histology, 19% (12/62) were metastatic at diagnosis, and 55% (30/54) had disease recurrence during follow-up. With a median follow-up of 7.9 y, the median OS was 9.3y (CI 95%, 7.8-NR). Pts with solid subtype had poorer OS than non-solid histology (5.2 vs 14.6 y, p = 0.004). The IMC final dataset comprised 507,524 single-cells. No significant differences were found in cell subpopulations density between solid and non-solid histology. The most represented cell population in the stroma were macrophages, followed by CD8+ T cells, and fibroblasts. A higher percentage of M2-macrophage was associated with poor survival (p = 0.001), whereas, a higher percentage of M1-macrophage (M1:M2 ratio) was associated with better prognosis. No other immune cell type, fibroblasts or immune cell functional markers (TIGIT, TIM3, granzyme B, and PD-L1) correlated with survival. Regarding tumor markers, a higher expression of BCL-2, B7-H4, and Ki67 in the tumor cells were associated with worst survival; and remained statistically associated after adjustment for histology and staging (all p < 0.001). Solid histology had a significantly higher density of tumor cells expressing B7-H4, BCL-2, and Ki67 compared to cribriform and tubular histology. A higher expression of myoepithelial marker (p63+) were associated with a better survival when compared with tumors with low p63 expression. **Conclusions:** ACC's TME is composed mainly of macrophages. Despite having no significant differences in cellular composition, a higher density of tumor cells expressing BCL-2, B7-H4 and Ki67 were found in the solid histology and these markers were independent predictors of poor prognosis. The overexpression of BCL-2 and B7-H4 in the solid histology provides a scientific rationale for BCL-2 and/or B7-H4 targeting for the most aggressive ACC. Research Sponsor: U.S. National Institutes of Health.

Efficacy and safety of selpercatinib in RET-altered tumors: A systematic review and meta-analysis. *First Author: Mina Choudhry, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA*

Background: RET proto-oncogene encodes receptor tyrosine kinase. Selpercatinib was the first RET-specific tyrosine kinase inhibitor approved by FDA in RET-altered tumors (pralsetinib was approved afterward). This systematic review and meta-analysis will assess the efficacy and safety of selpercatinib in RET-altered tumors. **Methods:** A search was performed on PubMed, Embase, Cochrane, WOS, and clinicaltrials.gov. We used the following mesh and Emtree terms, "selpercatinib" AND "proto oncogene proteins c ret," from the inception of literature till 10/15/2021. We screened 187 articles and included 2 phase I/II clinical trials (N = 309) in this meta-analysis. We excluded preclinical trials, case reports, case series, review articles, observational studies, meta-analysis, and clinical trials not providing any information about the efficacy of selpercatinib in RET-altered tumors. The quantitative analysis was performed using the R programming language. **Results:** In 2 clinical studies (N = 309), 144 patients had RET-altered advanced non-small cell lung cancer (NSCLC) and 162 had thyroid cancer. RET mutations were reported in 143 patients and RET-fusion in 163 tumors. 179 patients were previously treated with systemic therapy while 127 patients were treatment naïve. Pooled overall response (OR), complete response (CR), partial response (PR), progressive disease (PD), and stable disease (SD) were 72% (95% CI = 0.64-0.78, I^2= 40%), 6% (95% CI = 0.03-0.13, I^2= 49%), 66% (95% CI = 0.57-0.74, I^2= 50%), 3% (95% CI = 0.01-0.06, I^2= 0), and 24% (95% CI = 0.18-0.30, I^2= 22%), respectively, in RET-altered thyroid/NSCLC patients. Pooled OR was 67% (95% CI = 0.60-0.73, I^2= 0), 78% (95% CI = 0.64-0.87, I^2= 51%), 75% (95% CI = 0.58-0.87, I^2= 68%), and 71% (95% CI = 0.63-0.78, I^2= 0%) in previously treated, treatment naïve, RET-fusion tumor, and RET-mutation tumor patients, respectively. Pooled incidence of ≥grade 3 any adverse event, rise in ALT, rise in AST, diarrhea, hypertension, and QT abnormalities were reported in 58% (95% CI = 0.43-0.72, I^2= 85%), 10% (95% CI = 0.08-0.14, I^2= 0), 11% (95% CI = 0.07-0.15, I^2= 17), 5% (95% CI = 0.03-0.08, I^2= 0), 17% (95% CI = 0.11-0.26, I^2= 62%), and 4% (95% CI = 0.02-0.07, I^2= 18%) of the participants, respectively. **Conclusions:** Selpercatinib was safe and effective in patients with RET-altered NSCLC and thyroid cancer regardless of prior treatment status and type of RET alteration. On indirect comparison, the safety profile with selpercatinib was better than previously used non-specific RET-inhibitors. Randomized clinical trials (RCTs) NCT04211337 and NCT04194944 are in progress to compare selpercatinib with non-specific RET inhibitors and chemotherapy/PD-1 inhibitor. More RCTs are needed to assess the combinations of selpercatinib with other drugs. Research Sponsor: None.

Prognostic factors in sinonasal cancers: A multicenter pooled analysis. *First Author: Alberto Hernando-Calvo, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Sinonasal cancers (SC) are heterogeneous diseases. Despite multimodality treatment, overall survival (OS) remains unsatisfactory. We aimed to identify prognostic factors (PFs) associated with patterns of failure and OS in non-metastatic SC (nmSC). **Methods:** We retrospectively reviewed a pooled dataset of nmSC from Princess Margaret (Canada) and Catalan Institute of Oncology (Spain) treated with definitive surgery ± postop radiotherapy (RT) or RT ± chemo according to institutional protocols between 2010-2019. In squamous cell carcinoma (SCC), HPV status was tested by p16 staining, and HPV DNA (ISH or PCR) if equivocal. The primary goal was to assess the association of tumor histology, stage (by 7th edition TNM), and other clinicopathological variables on locoregional control (LRC), distant control (DC) and OS. Actuarial rates were calculated with Kaplan–Meier (KM) method. Multivariable analysis (MVA) calculated hazard ratios (aHR) adjusted for histology type, T-/N-categories, and primary treatment. **Results:** Out of 342 pts, median age was 62 years (y) (range 21-96), Male:Female = 212:130, 95% had ECOG 0-1. Tumor histology types were: 192 (56%) SCC (p16+: 35; p16-/untested: 157), 40 (12%) adenocarcinoma (AD), 33 (10%) sinonasal undifferentiated carcinoma or sinonasal neuroendocrine tumors (SNUC/SNEC), 28 (8%) malignant melanoma (MM), 27 (8%) esthesioneuroblastoma (ES) and 22 (6%) adenoid cystic carcinoma (ACC). Median follow up was 3.6 y (range 0.1-11.3). Three-year actuarial rates for each endpoint are included in table. The PFs for LRC by MVA were: SNUC/SNEC (vs SCC) histology, T3-4 (vs T1-2: aHR 2.4, p = < 0.01) and N+ (vs N-: aHR 1.7, p = 0.02) diseases. The PFs for DC were: MM (vs SCC) and SNUC/SNEC (vs SCC) histology, and T3-4 (vs T1-2: aHR 6.0, p = 0.01) disease. The PFs for OS were: MM (vs SCC) histology, older age (aHR 1.0, p < 0.01), T3-4 (vs T1-2: aHR 5.6, p < 0.01), and N+ (vs N-: aHR 2.5, p < 0.01) disease. There was no difference in primary surgery vs RT in any outcome endpoint (all p > 0.05). p16+ SCC had a marginally higher LRC but similar DC and OS vs p16-/untested SCC (table). **Conclusions:** This large multicentre cohort of nmSC shows different patterns of relapse and survival with different tumor histologies. Our results suggest that individualization of treatment and follow-up strategies by histologic type is recommended to optimize outcomes in these orphan diseases. Research Sponsor: None.

Phase I study of AIC100 in relapsed and/or refractory advanced thyroid cancer and anaplastic thyroid cancer. *First Author: Jing Mei Hsu, Weill Cornell Medicine, New York, NY*

Background: ICAM-1 is a cell surface glycoprotein that is typically expressed on endothelial cells and immune cells and a ligand for LFA-1 integrin. It is also overexpressed in several malignancies, in particular anaplastic and advanced thyroid cancer. We designed an affinity tuned ICAM-1-directed CAR T cell (micromolar affinity) that preferentially binds overexpressed ICAM-1 on tumor cells and spares normal cells. The CAR T cells also express somatostatin receptor 2 (SSTR2), which allows tracking of CAR T cells in vivo via DOTATATE PET/CT scan. Murine studies showed excellent responses in ICAM-1 expressing thyroid cancer without significant toxicities. We are conducting a first-in-human phase 1 clinical trial to evaluate the feasibility, safety and preliminary efficacy of ICAM-1 in patients with relapsed/refractory thyroid cancer or anaplastic thyroid cancer who are BRAF wild-type, or BRAF mutated after failure of BRAF specific therapy (NCT04420754). **Methods:** This is a dose-escalation study with modified toxicity probability interval design and cohorts of 3 Patients. Patients receive a single dose of 1x 10^7 (Cohort 1), 1 x 10^8 (Cohort 2) or 5 x 10^8 (Cohort 3) ICAM-1 CAR T cells after FLU/CY lymphodepleting (LD) chemotherapy. Additional CAR T infusion is allowed if patients achieve partial response or stable disease. Whole-body Fluorodeoxyglucose (FDG) and DOTATATE PET/CT is used to stage tumor and track CAR T cells in vivo, respectively. **Results:** All ICAM-1 CAR T infusion products met target transduction efficiency. Two patients with progressive anaplastic thyroid cancer received ICAM-1 CAR T therapy at dose-level I. Evaluation of CAR T cellular kinetics demonstrated transient peripheral blood CAR T cell expansion. One patient developed grade 1 cytokine release syndrome (CRS) with fever. Several tumor lesions from this patient showed DOTATATE avidity, indicating CAR T homing to the tumor, concomitant with decrease in FDG avidity, suggesting biological activity at ~2 weeks post CAR T infusion. DOTATATE avidity at 2 weeks post CAR T infusion also appeared to match that of CAR T abundance in the blood. Updated results on additional patients and cohorts will be presented. **Conclusions:** Adoptive cellular therapy with ICAM-1 directed CAR T is safe and feasible at dose level 1 in patients with anaplastic thyroid cancer. DOTATATE PET allows visualization of expansion and homing of SSTR2 expressing CAR T cells, while concomitant FDG PET permits correlation with biological activity. Clinical trial information: NCT04420754. Research Sponsor: Affyimmune Therapeutics.

Self-care for head and neck cancer survivors with lymphedema and fibrosis: A pilot randomized clinical trial. *First Author: Jie Deng, University of Pennsylvania School of Nursing, Philadelphia, PA*

Background: Lymphedema and fibrosis (LEF) are debilitating late effects in head and neck cancer survivors (HNCS). Initial therapy is usually directed by therapists following which patients undertake a LEF self-care program (SCP). No evidence based LEF-SCP are available. We report on the feasibility and preliminary efficacy data of a multifaceted LEF-SCP. **Methods:** 59 HNCS with LEF were randomized to: Usual care (n = 20), usual care + LEF-SCP (n = 20), and usual care + LEF-SCP + routine follow-up with a lymphedema therapist (n = 19). Assessments were conducted at baseline, 3-, 6-, 9-, and 12-months. Outcome measures include feasibility and preliminary efficacy (LEF progression, symptom burden, and jaw range of motion [ROM]). Multivariate covariance pattern model analysis was used to test for difference between arms. **Results:** 1) Feasibility: LEF-SCP training sessions - 80% completion rate; 90% satisfaction with the LEF-SCP; self-care adherence was similar between arms; no adverse event. 2) Preliminary Efficacy: Compared to usual care, participants randomized to LEF-SCP (+/- follow-up) showed a decrease in LEF severity ($p < 0.05$), reduction in symptom burden ($p < 0.05$), without significant improvement in jaw ROM. No significant differences were noted between the patients +/- follow-up with a lymphedema therapist. There was a trend to improved self-efficacy in patients participating in the LEF-SCP. **Conclusions:** The LEF-SCP is feasible and potentially efficacious for HNCS. Further testing is warranted. Clinical trial information: NCT03030859. Research Sponsor: American Cancer Society.

Apatinib versus placebo in patients with locally advanced or metastatic, radioactive iodine-refractory, differentiated thyroid cancer: Post hoc analyses from the REALITY randomized clinical trial. *First Author: Yansong Lin, Department of Nuclear Medicine, Peking Union Medical College Hospital, Beijing, China*

Background: In the multicenter, double-blind, randomized, phase 3 REALITY study, apatinib significantly improved clinical benefits in terms of progression-free survival (PFS), overall survival (OS) and objective response rate (ORR) compared to placebo with a tolerable safety profile in patients with progressive locally advanced or metastatic radioactive iodine-refractory, differentiated thyroid cancer (RAIR-DTC). Here, we investigate the association between baseline characteristics and survival endpoints. **Methods:** Post-hoc analyses of PFS and OS were done in patients treated with apatinib according to the following subgroups: ECOG performance status (PS) (0 vs 1-2), thyroglobulin (Tg) (< 223 vs ≥ 223 ng/mL), and tumor target lesions diameter (< 33.2 vs ≥ 33.2 cm). **Results:** Among 92 patients with RAIR-DTC included in the study, 46 patients received apatinib. As of December 3, 2021, median PFS was 25.77 (95% CI 11.14-not reached [NR]) vs 11.08 months (95% CI 7.17-NR) for ECOG PS 0 / 1-2, though no statistical significance (HR 0.454, 95% CI 0.161-1.285, p = 0.1373). The median OS was significant prolonged in patients with ECOG PS of 0 compared with those ECOG 1-2 (not reached vs 29.42 months, 95% CI 18.87-NR; HR 0.199, 95% CI 0.054-0.733, p = 0.0152). In subgroups by Tg, median PFS was 25.77 (95% CI 9.11-NR) vs 11.08 (95% CI 5.65-NR) months for Tg < 223 / ≥ 223 ng/mL. A trend towards improved PFS was observed (HR 0.444, 95% CI 0.145-1.361, p = 0.1556). The median OS was significantly improved in patients with Tg < 223 in contrast to those Tg ≥ 223 ng/mL (NR vs 25.87 months, 95% CI 13.58-NR; HR 0.151, 95% CI 0.033-0.689, p = 0.0147). The median PFS for tumor target lesions diameter < 33.2 cm was significantly improved relative to those ≥ 33.2 cm (25.77, 95% CI 11.14-NR vs 9.11 months, 95% CI 5.65-NR) with a significant difference (HR 0.289, 95% CI 0.097-0.859, p = 0.0255); OS data in two subgroups were not mature (NR, 95% CI 29.42-NR vs NR, 95% CI 17.95-NR; HR 0.364, 95% CI 0.112-1.184, p = 0.0932). **Conclusions:** Post-hoc analysis indicated that among patients receiving apatinib, longer OS benefits were associated with better ECOG PS, lower Tg levels; longer PFS benefits were associated with smaller tumor diameter. These results suggest a better prognosis for early initiation of apatinib treatment in patients with RAIR-DTC. Clinical trial information: NCT03048877. Research Sponsor: This study was funded by the National Natural Science Foundation of China (grant 81771875) and the Project on Inter-Governmental International Scientific and Technological Innovation Cooperation in the National Key Projects of Research and Development Pla, Pharmaceutical/Biotech Company.

The effect of anlotinib on unresectable differentiated thyroid cancer (T4): A retrospective study. *First Author: Xin Wu, West China Hospital, Chengdu, China*

Background: Though the majority of differentiated thyroid cancer (DTC) patients obtained a good prognosis after standardized therapy, approximately 15% of DTC patients will progress to unresectable disease. Part of locally advanced (T4) thyroid cancer patients with progressive invasion into vasculature/windpipe/esophagus lost the surgery opportunity because of difficult in achieving R0/R1 resection. The study aimed to evaluate the efficacy and safety of anlotinib in T4 PTC. **Methods:** Retrospectively included T4 papillary thyroid cancer (PTC) patients from West China Hospital of Sichuan University between Sep. 2020 and Feb. 2022. The patients were prescribed with Anlotinib (12 mg orally daily, two weeks on/one week off) at least two courses. The tumor response was defined by RECIST v. 1.1. The primary endpoint was objective response rate (ORR). **Results:** The study included 22 T4 PTC patients, including 8 patients with lung metastasis. The median age of patients was 59.2 years, 8/22 patients were male. The median follow-up was 5.5 months (2-13 months). Totally, the ORR was 68.2% (CR: 9.1%; PR: 59.1%), disease control rate (DCR) was 95.5% (SD: 27.3%), one patient progressed (PD). 8 patients with lung metastasis, the ORR was 75% (6/8). The average tumor shrinkage rate was 42.1%. And two female patients (T4aN1M1 and T4bN1M0 respectively) obtained CR. Additionally, one juvenile patient (14 y) also response to Anlotinib treatment with 55.2% tumor shrinkage, and no obvious AE was observed in this patient. Most adverse events (AEs) were grade 1 or 2. Common AEs of all grades were hypertension (68.2%), hypertriglyceridemia (36.4%), proteinuria (31.8%), and tended to discontinue when treatment ceased. **Conclusions:** Anlotinib demonstrated antitumor activity in the treatment of unresectable T4 PTC; Juvenile PTC patients also response to Anlotinib treatment; Anlotinib treatment was tolerable in T4 PTC patients. Research Sponsor: None.

Circulating tumor DNA profiling and serial analysis in salivary gland carcinomas reveal unique mutational subsets and actionable alterations. *First Author: Jeffery Scott Russell, Huntsman Cancer Institute, Salt Lake City, UT*

Background: Salivary gland carcinoma is a rare head and neck malignancy without any FDA approved treatment options. ctDNA profiling has been shown to be a valuable tool in identifying novel targets and expanding potential therapeutic options. Here, we report the landscape of ctDNA in a large dataset of salivary gland carcinomas. **Methods:** Analysis of genomic results from blood samples with a diagnosis of salivary gland carcinoma that were prospectively collected between January 2017 to December 2021 for clinical Guardant360 testing. Histologic subtype was documented by ordering providers as available. Serial tests were defined as having Guardant360 analysis performed on more than one sample collected at more than one timepoint. **Results:** Among 222 patients tested with Guardant360, 59.5% were male and the median age was 64 years (range 22-93 years). Of reported diagnoses, 137 (61.7%) patients had salivary gland carcinoma NOS. The remaining samples were designated by specific salivary histology: 13 (5.9%) salivary gland mucoepidermoid carcinoma (SGMC), 19 (8.6%) salivary gland adenocarcinoma (SGA), 37 (16.7%) salivary gland adenoid cystic carcinoma (SGACC), and 16 (72%) salivary duct carcinoma (SDC). ctDNA genomic alterations (GAs) were identified in 205 (81.3%) of 252 samples. The median variant allele fraction was 0.6% (range 0.01%-46.4%). TMB was evaluated in 45 samples of which 33 were evaluable and the median and 80th percentile of TMB was 8.44 and 11.81 mut/Mb. MSI-H was not detected in any of the 181 samples tested for MSI. The most commonly altered genes were TP53, PIK3CA, ERBB2, ATM, EGFR and HRAS across all collected salivary samples. Further analysis stratified genetic alterations by tissue subtype. Other than TP53, common mutations by salivary gland carcinoma subtype included: PI3KCA (SGACC/SDC), ERBB2 (SGA), and EGFR (SGMC). In regards to serial analysis, 16 patients had at least 2 serial tests. When comparing the subsequent testing within the same patient, 3 patients had potentially new actionable GAs (including *BRAF*, *KRAS* mutations and *EGFR* amplification) on the subsequent test that were not identified on the original test. **Conclusions:** Blood-based liquid biopsy can be applied in salivary gland tumors to detect genomic alterations in ctDNA which may provide opportunities for therapeutic intervention in a cancer with limited treatment options. Additionally, ctDNA testing may be used to identify resistant alterations to potential therapy. Finally, longitudinal assessment of ctDNA may shed light on tumor evolution and additional therapeutic targets may be found. Further assessment of serial ctDNA analysis and the potential impact on patient clinical outcomes needs to be elucidated. Research Sponsor: None.

TPS6098 **Poster Session**

A phase II/III trial of chemotherapy plus cetuximab versus chemotherapy plus bevacizumab versus atezolizumab plus bevacizumab following progression on immune checkpoint inhibition in recurrent/metastatic head and neck cancers: ECOG-ACRIN EA3202. *First Author: Aarti K. Bhatia, Yale School of Medicine & Yale Cancer Center, New Haven, CT*

Background: There is no standard treatment beyond progression on first-line pembrolizumab (P) in patients with R/M HNSCC. Vascular endothelial growth factor (VEGF) modulates anti-tumor immunity via proliferation of inhibitory T regulatory and myeloid-derived suppressor cells, inhibition of dendritic cell maturation and suppression of effector T cell responses. Efficacy data from other disease sites and from early-phase trials done in HNSCC suggests promising clinical activity of VEGF and PD-1 inhibitor combination therapy. We have thus designed a Phase II/III, randomized, multi-arm trial to evaluate the efficacy of atezolizumab (A) and bevacizumab (B) beyond progression on P in patients with R/M HNSCC. **Methods:** EA3202 is enrolling patients with CPS ≥1% R/M HNSCC previously treated with P either alone or in combination with other checkpoint inhibitors without progression for at least 12 weeks. In phase II, patients will be randomized to one of three treatment arms: platinum doublet chemotherapy (C) plus cetuximab (E) for six cycles followed by E maintenance (control arm), C + B for six cycles followed by B maintenance, or A + B. Therapy in each arm will continue until progression, toxicity, or for a total period of two years. Patients will be stratified by p16 status, CPS score (≥ 20 vs. < 20), distant metastases (M0 vs M1), and disease progression pattern with first-line P (while on P vs. after discontinuation). 216 patients will be enrolled. The primary endpoint for phase II is progression-free survival (PFS). Each experimental arm will be compared to the control arm at a one-sided alpha level of 0.10. Pre-specified rules will be used to pick a winner among the two experimental arms, which will then advance to phase III against the control arm. 214 patients will be enrolled in phase III for a total sample size of 430 patients. The primary endpoint for phase III is overall survival (OS) which will be compared using a stratified log-rank test. Secondary endpoints include OS in the two phase III arms among the CPS ≥ 20 cohort and comparison of grade 3 or higher treatment-related adverse events between the two arms. A total of 277 OS events will be required for full information for phase III evaluation to give a nominal ~90% power at one-sided alpha level 0.0125. 144 patients enrolled in phase II (from the control and selected experimental arms) will be included in the phase III analysis. With this design the overall study power is at least 80% under a true 40% hazard reduction for PFS and 35% hazard reduction for OS. Blood and tumor tissue will be banked. EA3202 was activated in December 2021. It is the first randomized study to compare systemic treatments for R/M HNSCC in the immunotherapy era and will define the best second-line treatment approach beyond P. Clinical trial information: NCT05063552. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

TPS6099 **Poster Session**

TACTI-003: A randomized phase IIb study of eftilagimod alpha (soluble LAG-3 protein) and pembrolizumab as first-line treatment of patients with recurrent or metastatic head and neck squamous cell carcinoma. *First Author: Douglas Adkins, Washington University School of Medicine, St. Louis, MO*

Background: Eftilagimod alpha (efti) is a soluble LAG-3 protein targeting a subset of MHC class II molecules that mediate antigen presenting cell (APC) and CD8 T-cell activation. Data from a non-randomized, phase II trial of efti plus pembrolizumab (TACTI-002) showed encouraging antitumor activity and manageable safety when given as second-line treatment of patients with recurrent or metastatic head and neck squamous-cell carcinoma (RM-HNSCC). TACTI-003 (NCT04811027) is a multicenter, open label, randomized phase IIb trial to investigate efti plus pembrolizumab in the first-line setting for RM-HNSCC. **Methods:** A total of 154 patients (pts) are currently being recruited into two cohorts (A+B). In cohort A, pts with tumors that are CPS≥1 will be randomly assigned 1:1 to receive either efti (30 mg subcutaneously Q2W for initial 6 months, thereafter Q3W) plus pembrolizumab (400 mg intravenously Q6W) for up to two years or pembrolizumab alone. Randomization will be stratified by CPS (1-19 vs. ≥ 20) and ECOG PS (0 vs. 1). Pts with tumors that are CPS < 1 will receive efti plus pembrolizumab (cohort B). Imaging will be performed every 9 weeks. The primary endpoint (EP) is objective response rate (ORR) by RECIST1.1. Secondary EPs include overall survival, ORR according to iRECIST, time to and duration of response, disease control rate, progression-free survival, occurrence of anti-efti -specific antibodies, safety, and quality of life. Exploratory endpoints comprise biomarkers. The study has been approved by relevant competent authorities, ethic committees and IRBs. Clinical trial information: NCT04811027. Research Sponsor: Immutep S.A.

innovaTV 207: New combination dosing cohorts in the open label phase 2 study of tisotumab vedotin in solid tumors. *First Author: Xiuning Le, Department of Thoracic Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Tisotumab vedotin (TV; TIVDAK) is a tissue factor (TF)-directed antibody-drug conjugate that has been granted accelerated approval in the US for treatment of adults with recurrent/metastatic (r/m) cervical cancer with disease progression on or after chemotherapy. TV remains investigational in other tumor types including squamous cell carcinoma of the head and neck (HNSCC) and squamous non-small cell lung cancer (sqNSCLC). This abstract presents the addition of Part D to innovaTV 207 (NCT03485209), a global, open label, multicenter phase 2 trial investigating the safety, tolerability, and activity of TV in solid tumors. Untreated patients (pts) with r/m HNSCC or sqNSCLC enrolled in Part D will receive either TV in combination with pembrolizumab (pembro) or TV + pembro and a platinum agent. Based on encouraging preliminary safety and efficacy results with 2.0 mg/kg TV once every 3 weeks (Q3W) in combination with pembro or carboplatin (carbo) in innovaTV 205 cervical cancer study cohorts, TV is being evaluated at 2.0 mg/kg Q3W in combination with pembro or pembro + carbo (or cisplatin). **Methods:** Up to 140 treatment-naive pts with r/m HNSCC or sqNSCLC will be enrolled in Part D of innovaTV 207. First, the All-Comers cohorts for HNSCC and sqNSCLC will each enroll up to 30 pts, regardless of PD-L1 expression, for Q3W dosing with 2.0 mg/kg TV in combination with 200 mg pembro and AUC 5 carbo. After enrollment in the HNSCC All-Comers Cohort is complete, up to 20 pts with HNSCC will be enrolled into a Cisplatin Safety Cohort for dosing with 2.0 mg/kg TV in combination with 200 mg pembro and 100 mg/m^2 cisplatin. Completion of enrollment in the All-Comers Cohort for each tumor type will also be followed by enrollment of up to 30 pts with HNSCC (CPS ≥1) and 30 pts with sqNSCLC (TPS ≥1%) into PD-L1 Selected cohorts for dosing with TV in combination with 200 mg pembro. Response will be assessed every 6 weeks for the first 6 months, every 12 weeks for the next 6 months, and then every 6 months after that. Pts with HNSCC must have had no previous systemic therapy for metastatic disease (exception is systemic therapy given as part of multimodal treatment for locally advanced disease completed > 6 months prior). Pts with NSCLC must have histologically or cytologically documented squamous cell NSCLC and must not have had any previous systemic therapy for metastatic disease or radiation therapy to the lung that is > 30 Gy within 6 months of the first dose of study drug. The primary endpoint is investigator-determined confirmed ORR per RECIST v1.1. Secondary endpoints include confirmed and unconfirmed ORR per RECIST v1.1, disease control rate, duration of response, time to response, PFS, OS, safety and tolerability, pharmacokinetics, and immunogenicity. The trial opened in June 2018 and was amended to add Part D in November 2021. Part D enrollment will begin in early 2022; updates will be provided at the meeting. Clinical trial information: NCT03485209. Research Sponsor: Seagen Inc., Pharmaceutical/Biotech Company.

TPS6101 **Poster Session**

TIRA study: A phase III, multicenter, randomized controlled study of toripalimab plus radical chemoradiotherapy with or without concurrent cisplatin in patients with high-risk locoregionally advanced nasopharyngeal carcinoma. *First Author: Cheng Xu, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Patients with locoregionally advanced nasopharyngeal carcinoma (LA-NPC) suffer a high risk of distant metastasis and require guideline-recommended multimodality therapy. However, cisplatin-based concurrent chemotherapy leads to a high incidence of severe toxicities and low patient compliance, consequently limiting survival improvement. Toripalimab, an immune checkpoint inhibitor targeting programmed cell death 1 (PD-1), has a novel anti-cancer mechanism and mild toxicity spectrum. Robust evidence showed that given toripalimab + gemcitabine-cisplatin (GP) chemotherapy regimen, the median progression-free survival could be markedly improved in patients with recurrent and metastatic NPC. Besides, PD-1 antibody + radiotherapy is also regarded as a promising therapeutic strategy due to the synergistic effect. Therefore, we hypothesized that the de-intensification strategy using toripalimab + induction chemotherapy (IC) followed by radiotherapy alone would obtain equivalent survival and low toxicity in patients with LA-NPC compared with toripalimab + IC followed by concurrent chemoradiotherapy. **Methods:** TheTIRA study is a multicenter, randomized, controlled, open-label, phase III study. Since August 2021, we have been recruiting high-risk LA-NPC patients (stage III-IVa, except $T_{3\text{-}4}N_0M_0$ & $T_3N_1M_0$) from 12 Chinese centers. Our target sample size is temporarily set at 494 patients with 247 for each arm. Patients will be 1:1 ratio randomized to the experimental or control arm. Patients in the experimental arm will receive induction-concurrent toripalimab (240 mg, d1, Q3W $\times$ 6 cycle) with IC (gemcitabine 1000 mg/m^2, d1 & d8 + cisplatin 80 mg/m^2, d1, Q3W $\times$ 3 cycle) + intensity-modulated radiotherapy (IMRT, 70 Gy in 33 fractions), and thereafter adjuvant toripalimab (240 mg, d1, Q3W $\times$ 11 cycle). Patients in the controlled arm will receive an additional concurrent cisplatin (100 mg/m^2, d1, Q3W $\times$ 2 cycle). The primary endpoint is the 3-year failure-free survival. Secondary endpoints include 3-year overall survival, 3-year distant metastasis-free survival, 3-year locoregional recurrence-free survival, quality-of-life assessment according to the systems of the European Organization for Research and Treatment of Cancer and the Functional Assessment of Cancer Therapy, and safety profile. Exploratory analysis will be performed for potential biomarkers of survival prediction including PD-L1 expression and tumor-infiltrating lymphocytes. Clinical trial information: NCT04907370. Research Sponsor: None.

TPS6102 **Poster Session**

Phase 2 trial of enoblituzumab plus retifanlimab or tebotelimab in first-line treatment of patients (pts) with recurrent or metastatic squamous cell carcinoma of the head and neck (R/M SCCHN). *First Author: Grzegorz Obara, Comprehensive Cancer Centers of Nevada, Las Vegas, NV*

Background: Head and neck cancer accounts for ~900,000 cases and over 400,000 annual deaths worldwide as of 2021. Pts with R/M SCCHN have a poor prognosis with median overall survival <1 year. Programmed death (PD)-protein 1 (PD-1) and PD-ligand 1 (PD-L1) blockade has shown antitumor activity in advanced SCCHN. Enoblituzumab (MGA271) is an investigational monoclonal antibody (mAb) that binds B7-homolog 3 (B7-H3) with enhanced binding to the activating Fc gamma receptor CD16A, particularly the low-affinity allele CD16A-158. B7-H3 is overexpressed in many cancers, including SCCHN, but not in most normal tissues. Retifanlimab (MGA012, INCMGA00012) is an investigational anti-PD-1 mAb, blocking binding of PD-L1 or PD-ligand 2 (PD-L2) to PD-1. Tebotelimab (MGD013) is an investigational, Fc-bearing bispecific, tetravalent DART® molecule designed to bind PD-1 and lymphocyte activation gene 3, inhibiting their interaction with PD-L1 or PD-L2 and major histocompatibility complex class II. In vitro data suggest that both retifanlimab and tebotelimab have potential to sustain enoblituzumab-mediated immune activation and antitumor activity (Obara G, et al. *Ann Oncol.* 2021;32[suppl 5]:S814). Combination of enoblituzumab with retifanlimab or tebotelimab sustained the ability of natural killer cells and CD8+ T cells to produce interferon gamma upon restimulation. Both retifanlimab and tebotelimab enhanced enoblituzumab-dependent cytotoxicity targeting B7-H3–expressing tumor cells. In a phase 1/2 study, the combination of enoblituzumab with pembrolizumab was well tolerated (Aggarwal C, et al. *J Immunother Cancer.* 2022 [under review]). The overall response rate in anti-PD-1/PD-L1–naïve pts with SCCHN (post platinum) was 33% (6/18), including 1 confirmed complete and 5 confirmed partial responses, warranting further development of this combination in R/M SCCHN. **Methods:** This is an open-label, nonrandomized study in first-line treatment of pts with R/M SCCHN. Approximately 50 pts with PD-L1 combined positive score (CPS) ≥1 will receive enoblituzumab 15 mg/kg plus retifanlimab 375 mg and 30 pts with CPS <1 will receive enoblituzumab 15 mg/kg plus tebotelimab 600 mg. Dosing is once every 3 weeks with tumor assessment at the end of Cycle 2 and every 3 cycles thereafter. Pts with no prior systemic therapy for R/M SCCHN are eligible. Pts who completed systemic therapy >6 months before the study, if given as part of multimodal treatment for locally advanced disease, are eligible. In the tebotelimab cohort, safety data will be reviewed for dose-limiting toxicities through Cycle 2 Day 7 on the first 12 pts (2 mini cohorts of 6 pts each). All pts will be followed for survival after the last dose of study drug. The first pt was enrolled in March 2021, and 28 pts are on treatment as of January 19, 2022. Clinical trial information: NCT04634825. Research Sponsor: MacroGenics, Inc.

TPS6103 **Poster Session**

A phase 1, first-in-human, drug dose-escalation study of RM-1995 photoimmunotherapy, as monotherapy or combined with pembrolizumab, in patients with advanced cutaneous squamous cell carcinoma or with head and neck squamous cell carcinoma. *First Author: David M. Cognetti, Thomas Jefferson University, Philadelphia, PA*

Background: RM-1995 comprises an antibody against CD25, conjugated with a light-activatable dye (IRDye 700DX), which can subsequently be activated by illumination with 690 nm non-thermal red light for precise, targeted cell killing. Administration of the antibody-dye conjugate followed by local illumination results in target cell membrane disruption, while limiting damage to surrounding tissue. CD25 (IL-2Rα) is highly expressed by regulatory T cells (Tregs), thereby providing an opportunity to specifically target intratumoral Tregs for depletion via photoimmunotherapy. Tregs are critical in promoting immune homeostasis; however, in the context of solid tumors, Treg-mediated suppression detrimentally constrains anticancer T-cell responses, and a low ratio of CD8+ T cells:Tregs in the tumor is negatively correlated with clinical outcomes. Preclinical data suggest that RM-1995 photoimmunotherapy treatment alleviates local Treg-mediated restraint within the tumor microenvironment. Anticancer responses were further improved when combined with anti-PD-1 checkpoint inhibition. **Methods:** A phase 1 first-in-human dose-escalation study of RM-1995 photoimmunotherapy as monotherapy, or in combination with pembrolizumab, in patients with advanced cutaneous squamous cell carcinoma (cuSCC) and head and neck squamous cell carcinoma (HNSCC) is now enrolling (NCT05220748). The phase 1a portion will evaluate safety, pharmacokinetics, pharmacodynamics, and preliminary efficacy of single-agent RM-1995 photoimmunotherapy and determine the maximum tolerated dose or maximum administered dose of RM-1995 with a fixed light dose for tumor illumination. The phase 1b portion will include combination therapy with pembrolizumab. Enrolled patients will receive RM-1995 IV, followed 24±4 hours later by local tumor illumination. Pembrolizumab (200 mg) will be administered 5–7 days prior to RM-1995 infusion, then again 3 weeks later. Patients may be eligible to receive repeated photoimmunotherapy cycles for up to 12 months. Primary outcomes include safety and tolerability, and dose finding. The study will include cuSCC or HNSCC patients with locally advanced or locoregional disease with or without metastases that has recurred or progressed on or after platinum-based chemotherapy, and who are not eligible for further locoregional treatment. Other criteria include ECOG 0–2 and having ≥1 tumor accessible for illumination. Key exclusion criteria are: tumor sites located in sensitive or vital anatomic structures or invading a major blood vessel (unless treated to prevent hemorrhage); and other clinically significant or uncontrolled disease processes. An estimated 18 patients will be enrolled into each portion of the study. Clinical trial information: NCT05220748. Research Sponsor: Rakuten Medical Inc.

TPS6104 **Poster Session**

A phase 1/2 trial to evaluate the safety and antitumor activity of tipifarnib and alpelisib for patients with PIK3CA-mutated/amplified and/or HRAS-overexpressing recurrent/metastatic head and neck squamous cell carcinoma. *First Author: Glenn J. Hanna, Dana-Farber Cancer Institute, Boston, MA*

Background: Understanding connections between key cellular pathways is particularly important when selecting combinatorial cancer therapies. HRAS preferentially activates PI3K 5-fold more efficiently than KRAS, while KRAS is a more efficient activator of RAF (Yan et al. 1998). Further, mutant HRAS is insufficient for oncogenic transformation if it is unable to recruit PI3K in preclinical models (Gupta et al. 2007). Conversely, mutant PI3K requires RAS to drive tumor growth (Zhao and Vogt 2008). HRAS mutation/overexpression and *PIK3CA* mutations/amplifications account for up to 50% of head and neck squamous cell carcinoma (HNSCC). Recognition of these interdependencies was the basis for the evaluation of HNSCC PDX models which demonstrated additive or synergistic anti-tumor effects that confirmed the codependency of these pathways, thus providing robust rationale for investigating combined pathway inhibition in the clinic. The KURRENT trial is enrolling patients with HRAS and/or *PIK3CA*-dependent tumors who will receive combination treatment with tipifarnib (a potent and selective inhibitor of farnesyltransferase, a critical enzyme for HRAS activity) and alpelisib, a PI3K inhibitor. **Methods:** The KURRENT trial (KO-TIP-013, NCT04809233) is an ongoing multicenter, open-label, 2-cohort, phase 1/2 trial designed to evaluate the safety of the combination of tipifarnib and alpelisib, determine the recommended combination dose(s) regimen, and evaluate preliminary anti-tumor activity in patients with recurrent/metastatic (R/M) HNSCC whose tumors are dependent upon HRAS and/or *PIK3CA* signaling. The trial will enroll 40 HNSCC patients; 20 each into two biomarker defined cohorts (Cohort 1; *PIK3CA*; Cohort 2; HRAS). Participants must have documented treatment failure from at least one prior therapy in the R/M setting and have measurable disease by RECIST v1.1. At the starting dose level, participants will receive tipifarnib at 300 mg twice daily on days 1-7 and 15-21 and alpelisib 200 mg each morning continuously during a 28-day cycle. The trial will use an adaptive dose escalation design (based on a Bayesian logistic regression model) to characterize safety, tolerability, and clinical activity of the combination to identify the Optimal Biologically Active Dose (OBAD) while maintaining a dose limiting toxicity (DLT) rate < 33%. No formal interim analysis is planned as the model-based dose escalation process requires decisions based on real-time evaluation of aggregate toxicity and efficacy data. All observed/available data among each cohort will be evaluated before choosing the combination dose for a subsequent cohort. Enrollment into the *PIK3CA* cohort began in October 2021. Clinical trial information: NCT04809233. Research Sponsor: Kura Oncology, Novartis.

TPS6105 **Poster Session**

A phase II study evaluating the efficacy of niraparib and dostarlimab (TSR-042) in recurrent/metastatic head and neck squamous cell carcinoma. *First Author: Vidhya Karivedu, Division of Medical Oncology, Ohio State University, Columbus, OH*

Background: Despite improvement in outcomes with checkpoint (PD-1) inhibitors in some patients (pts) with recurrent and metastatic head and neck squamous cell carcinoma (RM HNSCC), overall survival (OS) remains poor, necessitating novel therapy combinations. Fanconi Anemia (FA) and FA-related DNA repair pathways alterations have been associated with cumulative tumor mutational burden (TMB) due to genomic instability. High TMB is associated with improved response to PD-1 inhibitors. DNA pathway repair mutations have been reported in 17% of sporadic HNSCC. Ataxia-Telangiesctasia Mutated (ATM) loss has been reported in 60% of human HNSCC biopsies and FA-related defects were reported in 15-21% of human HNSCC biopsies and cell lines. Poly (ADP-ribose) polymerase (PARP) inhibition has already demonstrated efficacy as a single agent in multiple cancers which harbor a DNA repair defect. Preclinical data also showed PARP inhibitor (PARPi) upregulates PD-L1 expression in cancer lines and animal models via inactivation of glycogen synthase kinase 3 (GSK3β). Importantly, blockade of PD-1 re-sensitized PARPi treated cells to induce T-cell mediated cytotoxicity. Combination of PARPi and anti-PD-1 therapy significantly increased therapeutic efficacy in vivo compared to single agent. Therefore, we hypothesized that the combination of a PARPi (niraparib) and PD-1 blockade (dostarlimab) in our ongoing phase II study would enhance overall response (OR) and survival in R/M HNSCC pts (NCT04313504). **Methods:** Eligible pts must have a confirmed histopathology of non-cutaneous RM HNSCC not amenable to local therapy, progressive disease (PD) after at least one line of platinum-based chemotherapy and/or immunotherapy, age>18, ECOG <2, no prior therapy with PARPi and adequate bone marrow, liver, and renal function. Seven of 14 pts have been enrolled in the first stage of the study. If 8 or more pts develop either stable disease (SD), partial (PR) or complete response (CR), 9 additional patients will be accrued for a total of 23 patients. Pts will receive 200 mg PO niraparib daily in 28-day cycles along with dostarlimab 500mg (Q3W) for 4 doses followed by 1000mg (Q6W) until PD or unacceptable toxicity. An interim analysis will be performed to assess efficacy and safety after 14 patients become evaluable. Tumor response will be assessed per RECIST v1.1. Primary endpoint is best OR including SD, PR, and CR; Secondary endpoints include adverse events determined by CTCAE v5.0, progression free survival and OS. Integrated tissue analysis includes DNA pathway repair defects and TMB. Additional exploratory analyses including peripheral and immune cell activation will be performed on tissue and plasma samples. Clinical trial information: NCT04313504. Research Sponsor: GSK is providing both funding and drug for this study.

TPS6106 **Poster Session**

Phase 3 randomized study for evaluation of physician's choice treatment and triple metronomic as second-line therapy in head and neck cancer. *First Author: Ashay Karpe, Cardinal Gracias Memorial Hospital, Vasai, India*

Background: Around 85% of head and neck cancer patients in India are seen in locally advanced stage which either relapse or fail after the first line treatment. The options of systemic therapy treatment in second line (after first line palliative chemotherapy or failure within 6 months of chemotherapy as part of multimodality treatment) are limited. The median progression free survival (PFS) of 1-3 months and median overall survival (OS) of 4-6 months are reported across various studies. There is need for having effective medical treatment option. Rationale- Triple metronomic is oral, cheap and requires minimum resources. We will be comparing physician choice of standard systemic therapies with ASCO recommended triple metronomic therapy. **Methods:** Design- Open label randomized, superiority. Study Period- 4 years. Inclusion- Head and Neck cancer patients (Age > 18 years) either platinum refractory or planned for second line (ECOG PS ≤2 and adequate organ function). Exclusion- Uncontrolled comorbidities, Pregnancy & lactating women. Baseline - blood parameters, EORTC QOL & HN module and baseline axial imaging. Central stratified randomization (Computer generated randomization sheet) will be done- ; the stratification will be for site of tumor (oral cavity versus others) and ECOG PS (0-1/2). Arm A: Triple metronomic (Per Oral)- Erlotinib 150 mg once daily, Celecoxib 200 mg twice daily & Weekly Methotrexate 9 mg/m^2. Arm B: Physician choice therapy- Docetaxel, Paclitaxel, Cetuximab, Nivolumab, Afatinib, Pembrolizumab, 5-Flurouracil, Capecitabine Therapy will be continued till progression or intolerable side effects. Adverse events monitoring as per the NCI CTCAE 5 criteria. The response will be monitored in accordance with institutional standards. Quality of life (EORTC) would be collected at baseline, at 2 months and at 6 months. The 6 month OS assumed on the basis of previous data of docetaxel was 55, we assume that it would increase with a target hazard ratio 0.561 with type 1 error of 5%, type 2 error of 20% and 10% lost to follow up rate. The sample size is 114. Events required for analysis-93. Outcome measures & Statistical analysis:OS- from date of randomization to date of death. Patients alive at their last follow ups would be censored. PFS from date of randomization to date of progression or death whichever is earlier. Patients who have not progressed at their last follow ups would be censored. OS and PFS will be estimated by Kaplan meier analysis and would be compared between the arms by the log rank test. Cox proportional hazard model would be constructed for calculation of hazard ratio. The model would also be used to see the impact of chemotherapy regimen on overall survival in accordance with known prognostic factors. Age (below or above 60 years), gender, site, hemoglobin level (equal to or below 12 g/dl or above it) and PS (0-1 versus 2). To compare the QOL scores between the 2 arms. Clinical trial information: CTRI/2021/08/036002. Research Sponsor: None.

TPS6107 **Poster Session**

A phase 1b/2 study of nanatinostat and valganciclovir in patients with advanced Epstein-Barr virus positive (EBV$^+$) solid tumors and in combination with pembrolizumab in patients with recurrent/metastatic nasopharyngeal carcinoma (RM-NPC). *First Author: A. Dimitrios Colevas, Stanford Cancer Institute, Stanford, CA*

Background: Epstein-Barr virus (EBV) is linked to the development and pathogenesis of nasopharyngeal carcinoma (NPC). Most patients present with advanced stage disease at diagnosis (Li 2014); first-line chemoradiation is commonly followed by recurrence and poor prognosis emphasizing the need for new treatment options. Targeting EBV in NPC represents a novel therapeutic approach. EBV is predominantly latent in NPC; pre-clinical studies demonstrated that induction of the viral lytic phase by histone deacetylase inhibitors (HDACi) renders EBV$^+$ tumor cells susceptible to the cytotoxic activity of ganciclovir (GCV) (Hui 2016). Nanatinostat (Nstat), a potent Class-I HDACi, induces the expression of the lytic BGLF4 protein kinase in EBV$^+$ tumor cells, which activates the nucleoside analog GCV via phosphorylation. Phosphorylated GCV becomes incorporated into the cellular DNA causing chain termination and apoptosis. The all-oral combination of Nstat and valganciclovir (VGCV), a pro-drug of GCV, has demonstrated favorable safety and preliminary efficacy in a phase 1/2 study in patients with recurrent EBV$^+$ lymphoma (NCT03397706). This phase 1b/2, open-label, multicenter study will evaluate the safety, tolerability, pharmacokinetics, and preliminary activity of Nstat + VGCV in patients with advanced EBV$^+$ solid tumors. Additionally, the combination of pembrolizumab together with Nstat + VGCV will be evaluated in recurrent/metastatic NPC (RM-NPC) patients. NPC frequently exhibits high PD-L1 expression levels; however, PD-1 inhibitors resulted in limited response rates ranging from 20-30% in the RM-NPC setting. **Methods:** Phase 1b utilizes a 3+3 dose escalation design to determine the recommended Phase 2 dose (RP2D) of Nstat + VGCV in patients with EBV$^+$ RM-NPC. In Phase 2, up to 60 patients with EBV$^+$ RM-NPC will be randomized 1:1 to receive Nstat + VGCV at the RP2D with or without pembrolizumab to evaluate safety, tolerability, overall response rate, and potential pharmacodynamic markers of drug activity, including plasma EBV DNA levels. Additionally, patients with EBV$^+$ solid tumors other than RM-NPC will receive Nstat + VGCV at the RP2D in a separate Phase 1b dose expansion cohort. Patients eligible for the phase 1b dose escalation and phase 2 will have EBV$^+$ RM-NPC with 1-3 prior lines of platinum-based chemotherapy and no available curative therapies. Patients with advanced EBV$^+$ non-NPC solid tumors (gastric cancer, lymphoepithelioma-like carcinoma, leiomyosarcoma) and no curative therapies are eligible for the phase 1b expansion cohort. All patients must have measurable disease per RECIST v1.1 and adequate bone marrow, liver, and renal function. Enrollment began in January 2022. Clinical trial information: NCT05166577. Research Sponsor: Viracta Therapeutics.

TPS6108 **Poster Session**

Phase I trial of the ATR inhibitor BAY 1895344 combined with stereotactic body radiation therapy and pembrolizumab for recurrent head and neck squamous cell carcinoma. *First Author: Yvonne Marie Mowery, Duke University Medical Center, Department of Radiation Oncology, Durham, NC*

Background: Despite aggressive multimodal treatment that typically includes radiation therapy (RT), recurrence rates approach 50% for patients with non-HPV-related locally advanced HNSCC. Treatment options for unresectable recurrent or metastatic HNSCC are limited, though PD-1 inhibitors improve survival for a subset of patients. Radiation resistance contributes to locoregional recurrence—a major driver for HNSCC morbidity and mortality. In preclinical studies, we observed significant HNSCC radiosensitization by targeting ataxia telangiectasia and Rad 3-related (ATR) kinase with small molecule inhibitor BAY 1895344. ATR inhibition with RT has also been shown preclinically to increase antigen presentation and anti-tumor T cell activity. Similarly, preclinical data suggest synergy between BAY 1895344 and anti-PD-1 therapy. We hypothesize that treating recurrent HNSCC with concurrent anti-PD-1 therapy, ATR inhibition and RT will improve tumor control through radiosensitization and stimulating a host anti-tumor immune response. An ongoing clinical trial (NCT04095273) is assessing concurrent BAY 1895344 and pembrolizumab, but BAY 1895344 with concurrent RT has not been evaluated in patients. To determine the safety and optimal dosing of concurrent RT and BAY 1895344, we opened a multi-institutional, CTEP-sponsored phase I trial (NCT04576091) evaluating reirradiation with stereotactic body radiation therapy (SBRT) combined with BAY 1895344 and pembrolizumab for patients with recurrent HNSCC. **Methods:** Eligible patients for this single-arm trial are adults with recurrent, unresectable HNSCC who received prior head and neck RT and cisplatin. Exclusion criteria include gross skin or mandible involvement, disease encasing >180° of the carotid artery, and prior RT < 6 months before enrollment. Patients with oligometastatic disease (<5 metastases) are eligible. The initial dose escalation phase utilizes a Bayesian Optimal Interval design to determine the MTD for concurrent SBRT and BAY 1895344. In cycle 1, patients receive 200 mg pembrolizumab, followed by 2 weeks of BAY1895344 (30 mg PO Q12h, 3 days on/4 days off). In cycle 2, patients receive pembrolizumab followed by SBRT with concurrent BAY1895344. SBRT dose levels are 21 Gy or 24 Gy delivered in 3 fractions every 2-3 days. Three doses of BAY 1895344 (dose levels: 10 mg, 20 mg, or 30 mg) are given Q12h with each RT fraction. Up to 8 patients will be treated at the starting dose level (24 Gy; 10 mg BAY 1895344). The target DLT rate is 0.33 and the dose elimination rate is 0.75. DLT is defined as any grade >4 AE within 90 days of RT completion. An 18-patient expansion cohort will be enrolled at the MTD. Pre-treatment tissue and serial blood samples will be collected for correlative studies. This trial opened to accrual in November 2021, with no patients enrolled as of February 2022. Clinical trial information: NCT04576091. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

TPS6109 **Poster Session**

A pilot study of neoadjuvant cemiplimab with platinum-doublet chemotherapy and cetuximab in patients with resectable, locally advanced head and neck squamous cell carcinoma (HNSCC). *First Author: Lara Dunn, Memorial Sloan-Kettering Cancer Center, New York, NY*

Background: Definitive treatment of locally advanced HNSCC can require radical surgery and reconstruction often resulting in unacceptable functional consequences. Radiotherapy, often with concurrent chemotherapy, is administered postoperatively to achieve the best chance for cure. Induction chemotherapy has previously been shown to reduce the extent of surgical resection and need for adjuvant radiation (RT). The purpose of this trial is to evaluate if an induction regimen combining cytotoxic chemotherapy, EGFR targeting, and immune checkpoint blockade can pathologically downstage resectable HNSCC sufficiently to decrease surgical morbidity and justify omission of adjuvant RT-based therapy. Compared to standard docetaxel, cisplatin, and 5-FU (TPF), docetaxel, cisplatin, and cetuximab (TPC) has been shown to be a therapeutic alternative with a more favorable toxicity profile. Targeting PD-1 alone can induce significant pathologic responses in resectable HNSCC patients. Combining PD-1 inhibitors with cetuximab has shown promising activity in incurable HNSCC; cetuximab may optimize the tumor immune microenvionment for PD-1 therapy by stimulating IFN-gamma secretion to increase dendritic cell maturation and CD8 T cell expression of PD1. Based on this rationale, we are evaluating the novel induction regimen of platinum, docetaxel, cetuximab plus cemiplimab (anti-PD1 antibody). **Methods:** This is a 10-patient pilot study for locally advanced, resectable HNSCC patients for whom standard management requires adjuvant RT +/- chemotherapy. Patients will receive neoadjuvant treatment with a loading dose of cetuximab and cemiplimab followed by 3 cycles of cisplatin or carboplatin, docetaxel, cetuximab and cemiplimab followed by definitive surgical resection of the primary site +/- neck dissection(s). Post-operative RT +/- radiosensitizing agent(s) will be administered per standard of care (SOC) based on pathologic staging (rather than clinical staging at presentation). If the pathologic stage following induction and surgery is ypT0-2N0 without adverse features, adjuvant RT will not be administered and 6 months of adjuvant cemiplimab will be given. Otherwise, patients will receive SOC adjuvant RT-based treatment. The primary endpoint is safety and tolerability. Secondary endpoints include feasibility assessed by the number of patients whose definitive surgery was delayed due to toxicity and quantifying the number in whom clinical to pathologic downstaging is achieved and the planned surgery and/or need for adjuvant-RT based therapy is modified. Exploratory endpoints include evaluating the association between biomarkers in the tumor microenvironment and peripheral blood with pathologic response. 8 of 10 patients have been enrolled. Clinical trial information: NCT04722523. Research Sponsor: Regeneron Pharmaceuticals, Internal Grants: Serra Initiative on the Management of Head and Neck Cancer Side Effects and Department of Medicine Investigator Initiated Trial RFA.

TPS6110 **Poster Session**

NANORAY-312: A phase III pivotal study of NBTXR3 activated by investigator's choice of radiotherapy alone or radiotherapy in combination with cetuximab for platinum-based chemotherapy-ineligible elderly patients with locally advanced head and neck squamous cell carcinoma. *First Author: Christophe Le Tourneau, Institut Curie, Paris, France*

Background: Elderly patients with locally advanced head and neck squamous cell carcinoma (LA-HNSCC) are largely underrepresented in clinical trials (CT). Broad access to CTs in this population is challenging due to an increased prevalence of comorbidities and ageing-related conditions. However, as population-age increases, more and more elderly patients are diagnosed with LA-HNSCC although many are not eligible to receive standard cisplatin-based concurrent chemoradiation (CRT). CRT-related toxicities, treatment burden and compliance are a concern. NBTXR3, a first-in-class radioenhancer, composed of functionalized hafnium oxide nanoparticles, is administered by one-time intratumoral injection and activated by radiotherapy (RT). NBTXR3 is designed to locally amplify the tumor-killing effect of radiotherapy without additional toxicity to surrounding healthy tissue. NBTXR3 has been shown to prime the adaptive immune response in cancer models. NBTXR3 obtained EU marketing approval in preoperative treatment of locally advanced soft tissue sarcomas. In a Phase I trial of NBTXR3 + RT alone in elderly LA-HNSCC patients, the combination was shown to be safe and an Objective Response Rate (ORR) of 85.4% and CRR of 51.2% was reported at ASTRO 2021. A pivotal randomized phase III study was initiated and is now recruiting. **Methods:** NANORAY-312 [NCT04892173] is a global, open-label, randomized (1:1), 2-arm, Investigator's choice Phase III (Pivotal Stage) study to investigate the efficacy and safety of NBTXR3/RT±cetuximab versus RT±cetuximab in treatment-naïve, platinum-ineligible, elderly patients with LA-HNSCC. 500 patients will be enrolled. Eligible patients are ≥65 years with at least one measurable (RECIST 1.1) biopsy-confirmed T3-4 (AJCC v8) SCC of the oral cavity, oropharynx, hypopharynx, or supraglottic larynx which is amenable for intratumoral injection. For patients with oropharyngeal cancer, human papilloma virus (HPV) status must be known. In addition to the primary tumor, a single accessible LN in the neck is eligible for intranodal injection. The primary objective is PFS. The key secondary endpoint is OS. Other secondary endpoints include ORR, safety and tolerability and quality of life. Enrollment began in January 2022 and is ongoing. Clinical trial information: NCT04892173. Research Sponsor: Nanobiotix.

TPS6111 **Poster Session**

A phase II study of pemetrexed and pembrolizumab in recurrent and/or metastatic salivary gland malignancies. *First Author: Katharine Andress Rowe Price, Department of Oncology, Mayo Clinic, Rochester, MN*

Background: Treatment options for recurrent and/or metastatic (R/M) salivary gland cancer (SGC) are limited with response rates to standard cytotoxic chemotherapy (CT) low at 10-30%, and responses to single-agent immune checkpoint inhibition (ICI) <10%. Current therapeutic agents used to treat R/M SGC have an unfavorable toxicity profile including cytotoxic CTs such as cisplatin and doxorubicin and the targeted therapy lenvatinib. Treatments with general applicability and acceptable side effect profile are urgently needed. Pemetrexed (PTX) is a multi-targeted anti-folate CT with an excellent safety and toxicity profile with promising responses reported in a case series of patients (pts) with R/M SGC (Viscuse P and Price K. Marked responses to pemetrexed chemotherapy for metastatic adenocarcinoma of the parotid gland: case series. *Head Neck* 2019;41(6):E99-103.). As the combination of PTX and pembrolizumab (PMB) showed enhanced responses and survival in pts with lung cancer, we hypothesize that PTX and PMB will have efficacy in pts with R/M SGC and that the combination will have improved anti-cancer activity compared with historical controls. Correlative studies on archived tissues include methylthioadenosine phosphorylase loss, PDL1 expression, and thymidylate synthase expression as potential biomarkers of response. **Methods:** MC200708 is a single institution (3-site), open-label, single arm phase II study of PTX and PMB in patients with R/M SGC. Pts will be treated in two cohorts: one for pts with adenoid cystic carcinoma (ACC) and the other for pts with all other types of SGC (non-ACC cohort). Eligible pts must be ≥18 years old, have a pathologically confirmed SGC that is not amenable to curative-intent therapy, ECOG 0-2, adequate organ function, and at least 1 measurable lesion by RECIST 1.1. Any number of lines of prior therapy is allowed; prior treatment with checkpoint inhibitors and/or PTX is allowed. Key exclusion criteria: serious medical co-morbidity or autoimmune disease, prior grade 3-4 adverse event (AE) or grade 2-4 lung AE with ICI, and uncontrolled brain metastases. Simon's two-stage design will be used for each cohort separately given the expected difference in responses in pts with ACC and non-ACC. Primary endpoint is overall response rate. Secondary endpoints are progression free and overall survival and toxicity. All patients will receive the same treatment of PTX 500 mg/m2 IV + PMB 200 mg IV every 3 weeks until disease progression or treatment intolerance. Response assessments will occur every 3 cycles. Enrollment began July 2021 and 16 of the planned 45 patients (ACC cohort 9 of 20 pts, non-ACC 7 of 25) have been accrued. Clinical trial information: NCT04895735. Research Sponsor: Merck.

TPS6112 **Poster Session**

Abemaciclib in metastatic or locally advanced anaplastic thyroid cancer. *First Author: Vishesh Khanna, Stanford Cancer Center, Palo Alto, CA*

Background: Anaplastic thyroid cancer (ATC) is a rare and lethal tumor of thyroid epithelium, with disease-specific mortality approaching 100%. ATC accounts for > 50% of the 1200 annual deaths attributable to thyroid cancer. In the pre-molecular era, treatment options were largely ineffective, reflected in a median overall survival of 3-4 months following diagnosis. Outcomes have improved in *BRAF V600E*-mutated ATC with the FDA approval of dabrafenib and trametinib (Subbiah et al. *JCO*, 2018). However, a significant need exists for patients with BRAF wild-type tumors and patients with BRAF-mutated tumors who progress following treatment with BRAF-directed therapies. Abemaciclib is a CDK4/6 inhibitor currently FDA-approved in combination with endocrine therapy for hormone-positive breast cancer. Genomic analyses of ATC have indicated the presence of an intact Rb (Retinoblastoma) expression as well as the existence of *CDKN2A* (the gene encoding human p16) mutations in up to 32% of patients with ATC (Khan et al., *Head Neck*, 2019). Moreover, Lee et al. in 2008 reported undetectable p16 levels in 24 out of 27 (89%) patients with ATC. Low p16 levels would be expected to result in accelerated S phase entry, leading to uncontrolled ATC growth. Finally, studies in mouse xenograft models have demonstrated that ribociclib (a CDK4/6 inhibitor) slows proliferation and induces apoptosis of ATC cells (Lee et al., *Cancer Letters,* 2018). These molecular alterations and pre-clinical data provide a mechanistic rationale by which to evaluate CDK4/6 inhibitors in ATC and, to date, no CDK4/6 inhibitors have been evaluated in thyroid cancer. **Methods:** This multicenter, single-arm Phase 2 study will evaluate the safety and efficacy of treatment with abemaciclib in patients with histologically confirmed unresectable or metastatic ATC, using an optimal Simon two-stage design. Patients with BRAF V600E+ ATC must have progressed on or have an intolerance to dabrafenib and trametinib. The study intervention is abemaciclib 200 mg orally twice daily. The primary endpoint is overall response rate at eight weeks from the start of treatment. Secondary endpoints include progression-free survival and overall survival. Currently, 6 patients have been enrolled. Planned genomic analysis will be conducted to identify potential predictive biomarkers. Clinical trial information: NCT04552769. Research Sponsor: None.

6500 **Oral Abstract Session**

The effect of a multilevel community health worker-led intervention on health-related quality of life, patient activation, acute care use, and total costs of care: A randomized controlled trial. *First Author: Manali I. Patel, Stanford University School of Medicine, Stanford, CA*

Background: Low-income and minority populations have less activation in their cancer care, lower health-related quality of life, greater acute care use and total costs of care than affluent and white populations. Community-based interventions are needed to improve patient experiences and quality of cancer care equitably among these populations. We used community-based participatory methods to refine a previously tested intervention for use in urban communities. The intervention, LEAPS, uses community health workers trained to activate patients in discussions with their cancer clinicians regarding advance care planning and symptom-burden and to connect patients with community-based resources to overcome social determinants of health. We conducted a randomized controlled trial of LEAPS in collaboration with an employer-union health plan in Atlantic City, NJ and Chicago, IL. Members of the employer-union health plan with newly diagnosed with hematologic and solid tumor cancers were randomized to the 6-month LEAPS intervention. The objective of the study was to determine whether LEAPS improved quality of life (primary). Secondarily, we evaluated the effect of LEAPS on patient activation, acute care use, and total costs of care. **Methods:** We used generalized linear regression models to evaluate differences in quality of life and patient activation scores between groups from baseline to 4- and 12-months post-enrollment and regression models offset for length of follow-up to compare emergency department use, hospitalizations, and total costs of care. **Results:** A total of 160 patients were consented and randomized into the study (80 intervention; 80 control). There were no differences in demographic or clinical factors across groups. The majority were non-White (74%), female (53%), mean age 57 years with breast (31%) or lung cancer (21%) and Stage 3 or 4 (63%) disease. At 4- and 12-months follow-up, the intervention group had greater improvements in quality of life overtime as compared to the control group (difference in difference: 11.5 $p < 0.001$) and greater change in patient activation overtime (difference in difference: 11.9 ($p < 0.001$)). At 12-months follow-up there were no differences in emergency department use (0.44 (0.71) versus 0.73 (0.22) $p = 0.22$) however intervention group participants had fewer hospitalizations (1.55 (0.86) vs. 2.29 (1.31), $p = 0.002$) and lower median total costs of care ($72,585 vs. $153,980, $p = 0.04$). **Conclusions:** Integrating community-based interventions into clinical cancer care delivery for low-income and minority populations can significantly improve patient activation, reduce hospitalizations and total costs of care. These interventions may represent a sustainable resource to facilitate equitable, value-based cancer care. Clinical trial information: NCT03699748. Research Sponsor: U.S. National Institutes of Health.

6501 **Oral Abstract Session**

The PACES Study: A controlled before and after pragmatic trial of a cancer clinic–based intervention to increase early referral to specialist palliative care. *First Author: Aynharan Sinnarajah, Queen's University, Kingston, ON, Canada*

Background: Early referral to specialist palliative care (SPC) can improve symptom and quality of life outcomes that matter most to cancer patients during the late stage of their illness. We tested a multifaceted oncologist-facing intervention (Palliative Care Early and Systematic) in the real-world setting of a busy cancer clinic for its ability to increase the proportion of patients who receive early SPC (defined as SPC ≥90 days before death). **Methods:** This is a pragmatic controlled before-and-after study performed in 18 outpatient cancer clinics in two tertiary cancer centers in neighboring metropolitan cities. The control city was chosen to match as closely as possible the intervention city for population size, characteristics, and health services availability. Adults deceased from colorectal cancer (CRC) between April 2017 to December 2020 residing in either the intervention or control city. Decedents who did not visit an oncologist in the year prior to death were excluded as they were unlikely to have received the intervention. Patients who died ≤120 days after diagnosis with CRC were excluded as providers would have had insufficient time to implement the intervention. In the baseline phase (April 2017 to December 2018) patients received usual care. In the intervention phase (April 2019 to December 2020), new clinical practice guidelines and resources were implemented to increase early SPC referrals by oncologists. These changes included: a) systematically screening patients attending treatment clinics for unmet PC needs and alerting the primary oncologist, b) addition of a community-based palliative clinical nurse specialist to handle increased referrals and enhance communication and co-management of patient needs among providers, and c) implementation of templated 'shared care' letters (all providers and patient) to improve awareness of patients' needs. The primary outcome was the proportion of CRC decedents who received early SPC. **Results:** 695 decedents were included: 341 in the baseline phase (153 control, 188 intervention) and 354 in the intervention phase (145 control, 209 intervention). From baseline to intervention, in the intervention arm, the proportion of decedents who received early SPC increased from 45% to 57%; in the control arm the proportion decreased from 48% to 44% (17% difference in differences; 95%CI -2% to 32%; P=0.03). **Conclusions:** A multifaceted intervention aimed at increasing oncologists' awareness of their patients' appropriateness for early SPC increased by 17% the proportion of patients receiving early SPC as compared to controls. Additional research is needed to determine if in a real-world clinical setting further increasing the proportion of patients receiving early PC beyond 57% is feasible, and to understand the role of screening and alerting for oncologists. Research Sponsor: Canadian Institute for Health Research (CIHR), Other Government Agency.

6502 **Oral Abstract Session**

Impact of an interdisciplinary goals of care program on hospital outcomes at a comprehensive cancer center during the COVID-19 pandemic: A propensity score analysis. *First Author: David Hui, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Many hospitals have established goals-of-care (GOC) programs in response to the COVID-19 pandemic; however, few have reported their outcomes. MD Anderson Cancer Center launched a multicomponent interdisciplinary GOC (myGOC) program in March 2020 that involved risk stratification, team huddles to discuss care planning, oncologist-initiated GOC discussions, communication training, palliative care involvement, rapid-response GOC team deployment, and daily monitoring with immediate feedback. We examined the impact of this myGOC program among medical inpatients. **Methods:** This single-center study with a quasi-experimental design included consecutive adult patients with cancer admitted to medical units at MD Anderson Cancer Center, Texas during an 8-month pre-implementation (May 1, 2019 to December 31, 2019) and post-implementation period (May 1, 2020 to December 31, 2020). The primary outcome was intensive care unit (ICU) mortality. Secondary outcomes included ICU length of stay, hospital mortality, and proportion/timing of patients with in-hospital do-not-resuscitate (DNR) orders, medical power of attorney (MPOA), living will (LW) and out-of-hospital DNR (OOHDNR). Propensity score weighting was used to adjust for differences in potential covariates, including age, sex, cancer diagnosis, race/ethnicity, and Sequential Organ Failure Assessment (SOFA) Score. With a sample size of 600 ICU patients over each time period and a baseline ICU mortality of 28%, we had 80% power to detect a 5% reduction in mortality using a two-tailed test at 5% significance level. **Results:** This study involved 12,941 hospitalized patients with cancer (Pre n = 6,977; Post n = 5,964) including 1365 ICU admissions (Pre n = 727; Post n = 638). After myGOC initiation, we observed a significant reduction in ICU mortality (28.2% vs. 21.9%; change -6.3%, 95% CI -9.6, -3.1; $P = 0.0001$). We also observed significant decreases in length of ICU stay (mean change -1.4 days, 95% CI -2.0, -0.7 days; $P < 0.0001$) and in-hospital mortality (7% vs. 6.1%, mean change -0.9%, 95% CI -1.5%, -0.3%; $P = 0.004$). The proportion of hospitalized patients with an in-hospital DNR order increased significantly from 14.7% to 19.6% after implementation (odds ratio [OR] 1.4, 95% CI 1.3, 1.5; $P < 0.0001$) and DNR was established earlier (mean difference -3.0 d, 95% CI -3.9 d, -2.1 d; $P < 0.0001$). OOHDNR (OR 1.3, 95% CI 1.1, 1.6, $P < 0.0007$) also increased post-implementation but not MPOA and LW. MPOA, LW and OOHDNR were documented significantly earlier relative to the index hospitalization in the post-implementation period ($P < 0.005$ for all). **Conclusions:** This study showed improvement in hospital outcomes and care plan documentation after implementation of a system-wide, multicomponent GOC intervention. Our findings may have implications for GOC programs during the pandemic and beyond. Research Sponsor: None.

Impact of high-deductible health plans on delays in metastatic cancer diagnosis. *First Author: Nicolas Trad, Harvard Medical School, Boston, MA*

Background: High-deductible health plans (HDHPs) have grown rapidly in recent years, and now cover over one-half of U.S. workers. Patients in HDHPs are liable for the costs of all cancer-related care until their annual deductible is met, with the exception of screening tests such as colonoscopy and mammography. Due to increased out-of-pocket obligations, patients may postpone presenting for concerning symptoms or diagnostic testing, leading to delayed diagnosis. We therefore assessed the impacts of HDHPs on the timing of metastatic cancer detection. **Methods:** Using a nationally representative cohort of privately insured members in a national commercial and Medicare Advantage database (2003-2017), we studied 345,401 individuals age 18-64 years whose employers mandated a switch from a low-deductible (≤$500) plan to a high-deductible (≥$1,000) plan. Our control group consisted of 1,654,775 contemporaneous individuals whose employers offered only low-deductible plans. Both groups had a 1-year baseline period when all members were enrolled in low-deductible plans, and we followed members for a maximum of 13.5 years. Participants were matched with respect to age, gender, race/ethnicity, morbidity (ACG) score, poverty level, geographic region, employer size, baseline primary cancer, baseline medical and pharmacy costs, and follow-up duration. We used a validated claims-based algorithm to detect incident metastatic cancer diagnoses. We assessed time to metastatic cancer diagnosis in the baseline period (pre-HDHP switch) and follow-up period (post-HDHP switch) using a weighted Cox proportional hazards model. **Results:** After matching, there were no systematic differences between the HDHP and control groups with regard to observable baseline characteristics (standardized differences < 0.1). The mean age of participants was 42 years and the mean ACG score was 0.75. 49% were female, 48% lived in low-income neighborhoods, and 62% were White. We detected 1,668 metastatic events over a mean follow-up period of 38 months. There were no differences in time to metastatic diagnosis in the baseline year, prior to the HDHP switch (HR 0.96, $p = 0.67$). After employer-mandated HDHP switch, HDHP participants had lower odds of metastatic cancer diagnosis (HR 0.88, $p = 0.01$), indicative of delayed detection relative to the control group. **Conclusions:** Compared with conventional health plans, HDHPs are associated with delayed detection of metastatic cancer. These findings imply that patients postpone seeking care for concerning symptoms or defer diagnostic testing when exposed to high cost-sharing. Given recent advances that have improved survival of patients with advanced-stage cancers, future research efforts should investigate the impacts of HDHPs on quality of life, engagement in palliative care, and use of treatments in this patient population. Research Sponsor: Thomas O. Pyle Fellowship (Harvard Medical School - Department of Population Medicine).

6504 **Oral Abstract Session**

Growing financial burden from targeted oral anticancer medicines among Medicare beneficiaries with cancer. *First Author: Meng Li, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The rapidly rising costs of targeted oral anticancer medicines (TOAMs) raise concerns over their affordability. Our goal was to examine recent trends in the uptake of TOAMs among cancer patients with Medicare Part D, the share of TOAM users who reached catastrophic coverage, and the annual spending on TOAMs in the catastrophic phase. **Methods:** Using the 5% SEER-Medicare, we included patients aged 65 and older who had one primary cancer diagnosis between 2011 and 2016. We included person-years where patients were enrolled in a Part D plan for the entire year, did not receive the Low-Income Subsidy (LIS) at any time of the year, and received anticancer systemic therapies. We estimated the trends in the share of patients who used TOAMs, the percentage of TOAM users reaching catastrophic coverage, and the total and patient out-of-pocket spending on TOAMs in the catastrophic phase in a year. **Results:** From 2011 to 2016, the uptake of TOAMs among our study population increased from 3.6% to 8.9%. The percentage of non-LIS TOAM users who reached catastrophic coverage increased from 54.6% to 60.3%. Among those who reached the catastrophic phase, mean total gross spending on TOAMs in the catastrophic phase increased from $16,074 to $64,233 and mean patient out-of-pocket spending from $596 to $2,549. The mean 30-day total spending increased from $4,011 to $8,857, and the mean 30-day out-of-pocket spending from $154 to $328. **Conclusions:** The high and growing burden from TOAMs highlighted the need for reining in drug prices and capping out-of-pocket spending. Research Sponsor: None.

The Medicaid expansion of the Affordable Care Act and participation of patients with Medicaid in cancer clinical trials. *First Author: Joseph M. Unger, Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The Affordable Care Act (ACA) Medicaid Expansion (ME) resulted in increased use of Medicaid insurance nationwide. However, the impact of the ACA ME on access to clinical trials has not been examined. **Methods:** We examined the number and proportion of patients insured by Medicaid at enrollment over time using data from the SWOG Cancer Research Network. We examined all patients 18-64 years old enrolled to treatment trials between April 1, 1992 to February 28, 2020 using Medicaid vs. private insurance. Interrupted time-series analysis was used; first implementation of the ACA ME (in 2014) was the independent exposure variable. Segmented logistic regression was used to estimate the difference between actual enrollment of patients using Medicaid to the expected rate had the ACA ME not been implemented. To account for secular trends related to economic conditions, we adjusted for the monthly unemployment rate using data from the Bureau of Labor Statistics. Indicator variables to reflect administrative differences in Medicaid by presidential administration were included. **Results:** In total, 47,042 patients age < 65 years were analyzed, including 31,565 (67.1%) females, 18,987 (40.4%) age < 50 years, and 4,709 (10.0%) with Medicaid coverage. Overall, a 20% (OR = 1.20, 95% CI, 1.11-1.30, p < .001) increase per year in the odds of patients using Medicaid was detected following the ACA ME. Based on pre-ACA patterns, the proportion of patients using Medicaid decreased during periods of economic growth and low unemployment; thus, the model-based estimate of the proportion of patients with Medicaid insurance had the ACA ME not occurred was only 7.4% (95% CI, 4.8%-9.5%) at the end of the study period (February 2020), when national unemployment was low (3.5%). In contrast, the actual rate was 20.8% (95% CI, 17.1%-25.0%). Patterns were consistent by age but not by sex, with a stronger 29% (OR = 1.29, 95% CI, 1.17-1.42, p < .001) annual increase in the proportion of Medicaid use for female patients compared to only 7% (OR = 1.07, 95% CI, 0.94-1.23, p = .26) for males. The increase per year of Medicaid use for patients from states that implemented the ME in 2014 or 2015 was 27% (OR = 1.27, 95% CI, 1.16-1.41, p < .001) compared to 7% for patients from other states (OR = 1.07, 95% CI, 0.94-1.22, p = .28). **Conclusions:** The implementation of the ACA ME was associated with nearly a threefold increase (20.8% vs. 7.4%) in the proportion of patients using Medicaid in cancer clinical trials by early 2020. Improved access to clinical trials for more vulnerable patients is critical for improving confidence that trial findings apply to the general cancer population. These findings suggest that the recently enacted Cancer Treatment Act – which mandates that state Medicaid programs cover the routine care costs of clinical trial participation – may continue to improve access to clinical trials for those with Medicaid insurance. 6506 **Oral Abstract Session**

Changes in opioid prescription, potential misuse, and substance use disorder in pediatric cancer survivors following the 2016 CDC opioid prescribing guideline. *First Author: Xu Ji, Emory University and Children's Healthcare of Atlanta, Atlanta, GA*

Background: The 2016 Centers for Disease Control and Prevention (CDC) guideline for prescribing opioids, despite not being intended for cancer-related pain, has been shown to be associated with declines in opioid prescriptions among adults with cancer. We examine the changes in opioid prescription, potential misuse, and substance use disorder (SUD) following the guideline release among pediatric cancer survivors, a population at high risk for chronic pain. **Methods:** Using nationwide private insurance claims data, we identified survivors (aged ≤21 years at cancer diagnosis) who completed treatment for leukemia, lymphoma, central nervous system, bone, or gonadal cancers in 2009-2018 (N=8,969). We also identified enrollees without cancer who were matched based on age, gender, and region as a control group (N=44,845). Outcomes included (1) any opioid prescription and (2) any indicator for potential misuse or SUD within 1-year post-therapy. We conducted interrupted time series analysis, where time period was assessed by quarters based on the quarter-year of patients' therapy completion. Segmented linear regression was conducted to estimate the immediate change ("level" change) and the change in the time trend ("slope" change) in each outcome after the guideline release in March 2016, accounting for autocorrelation. **Results:** Before the guideline release, opioid prescription rate (21.1% vs. 7.2%) and rate of potential misuse or SUD (5.6% vs. 1.9%) were higher among survivors than controls (p<0.05). Post guideline release, we found a declining trend in opioid prescription rate among survivors (slope change = -1.0 percentage point [ppt]; p<0.001). Survivors also experienced an immediate level decrease (-2.0 ppt; p=0.040) and a decreasing trend (slope change = -0.4 ppt; p=0.004) in the rate of potential misuse or SUD. Among controls, there were decreasing trends in opioid prescription rate (slope change = -0.3 ppt; p<0.001) and rate of potential misuse or SUD (slope change = -0.1 ppt; p=0.042). By three years post guideline release, relative reductions in opioid prescription rate and rate of potential misuse or SUD were 51.8% and 76.0%, respectively, among survivors (p<0.05), with controls experiencing smaller relative reductions (29.4% and 36.5%; p<0.05). **Conclusions:** Following the release of the CDC opioid prescribing guideline in March 2016, there were reductions in opioid prescription rate and rate of potential opioid misuse or SUD among both pediatric cancer survivors and controls, with survivors experiencing greater reductions. Association of Medicaid expansion under the Affordable Care Act and overall survival among children with cancer. *First Author: Justin Michael Barnes, Washington University School of Medicine, St. Louis, MO*

Background: State Medicaid expansions under the Affordable Care Act are associated with increased Medicaid coverage among children, including those with cancer. Since the expansions did not directly affect Medicaid eligibility criteria for children, these changes suggest "welcome mat" effects, where previously uninsured children become enrolled in Medicaid after their parents gain coverage. Insurance improvements from the expansions have been associated with improved cancer outcomes for non-elderly adults. However, it is unclear whether the expansions also impacted childhood cancer outcomes. **Methods:** Data for children ages 0-14 years diagnosed with cancer from 2011-2017 were queried from central cancer registries covering cancer diagnoses from 43 states as part of the Centers for Disease Control's National Program of Cancer Registries. The primary outcome was 2-year overall survival. We utilized difference-in-differences analyses to compare changes in 2-year survival from 2011-2013 to 2014-2017 between children who resided in states expanding Medicaid by 2014 vs. states not expanding Medicaid within the study period. Analyses were adjusted for covariates including age, race/ethnicity, sex, metropolitan residence, cancer type, and stage at diagnosis. **Results:** A total of 42,970 children with cancer were included. Overall, there were increases in 2-year survival among children in expansion states (90.5% in 2011-2013 to 91.4% in 2014-2017) but no change among children in non-expansion states (90.0% in 2011-2013 to 90.0% in 2014-2017). In adjusted difference-in-differences analyses, there was no significant change in survival after Medicaid expansion for children in expansion vs. non-expansion states (1.01 percentage points, 95% CI = -0.23 to 2.25, p = 0.11). In difference-in-differences analyses by race/ethnicity, there was a significant expansion-associated improvement in survival in Black children (3.97 percentage points, 95% CI = 0.02 to 7.93, p = 0.049) but not in White children (0.4 percentage points, 95% CI = -1.07 to 2.04, p = 0.54). There were also expansion-associated improvements in survival among children residing in counties with the lowest quartile of county income (5.88 percentage points, 95% CI = 0.38 to 11.38, p = 0.036) but not for those in higher income counties (1.15, 1.23, and 0.12 percentage points for 2nd, 3rd, and 4th quartiles, respectively). **Conclusions:** Medicaid expansion, through presumed increases in Medicaid coverage via welcome mat effects, was associated with increased 2-year survival for Black children and children residing in low-income counties. However, the concentration of Black children in states that have not expanded Medicaid highlights the need for further advocacy to more fully achieve improved outcomes. Future data are needed to clarify potential long-term impacts of Medicaid expansion on childhood cancer outcomes. Research Sponsor: None.

A health insurance navigation intervention tool (HINT) for survivors of childhood cancer: Randomized pilot trial results from the Childhood Cancer Survivor Study.

First Author: Elyse R. Park, Department of Psychiatry and Medicine, Massachusetts General Hospital, Boston, MA

Background: Childhood cancer survivors are vulnerable to being underinsured and health insurance-related financial burden. Low health insurance literacy reduces survivors' ability to utilize health insurance. We conducted a pilot randomized controlled trial (RCT) to assess a virtually delivered health insurance navigation tool (HINT) intervention to improve health insurance literacy (HIL) and decrease financial burden. **Methods:** Using a multiphase, mixed methods design, we developed and tested a theoretically-driven 4-session intervention that included: 1) Learning About Survivorship Healthcare Needs, 2) Learning About Your Plan in Relation to Policy, 3) Navigating Your Plan and Obstacles, and 4) Managing Care Costs. Eligible CCSS participants were insured and had wireless device access. We assessed feasibility and preliminary efficacy of HINT versus enhanced usual care (EUC; health insurance booklet) on HIL (16-item instrument assessing knowledge and confidence with health insurance terms and activity, ACA provisions knowledge (8-items), psychological financial burden (7-items assessing worry due to medical costs), and satisfaction with health insurance coverage (1 item) using multivariable linear regression. **Results:** From 8/20 to 5/2021, 82 participants enrolled (39.7% participation rate); 53.7% female; 82% white, 7% Hispanic, and 7% black; 52.4% <40 years of age; and 57.3% from a Medicaid expansion state. 25.6% reported previously being uninsured. 57.3% were diagnosed <10 years of age, and 40.1% had ≥1 severe chronic health condition. There were gaps in health insurance literacy (HIL mean 28.5, sd=9.0; 16-60 (high-low); 39.0% were not familiar with the Affordable Care Act (ACA), and many lacked ACA provisions knowledge (e.g., appeals for coverage denials (56.1%). 82% completed 4 sessions; 92.6% completed the 5-month follow-up survey. Compared to EUC, HINT significantly improved HIL, ACA provisions knowledge, psychological financial hardship, and health insurance satisfaction (p's ≤ 0.03). **Conclusions:** Findings affirm health insurance literacy gaps among a national sample of insured long-term survivors. Results support the feasibility and preliminary efficacy of HINT on improving health insurance literacy, satisfaction, and psychological financial burden. HINT is the first intervention to demonstrate improvements in long-term survivors' health insurance literacy and psychological financial burden. Clinical trial information: NCT04520061. Research Sponsor: ACS.

State public welfare spending and racial/ethnic disparities in overall survival among adults with cancer.

First Author: Justin Michael Barnes, Washington University School of Medicine, St. Louis, MO

Background: State public welfare spending may partially address social determinants of health and mitigate structural racism. However, its association with racial and ethnic disparities and overall survival for newly diagnosed patients with cancer is unknown. **Methods:** Adults ages 18 and older with a new cancer diagnosis from 2007-2016 were queried from the Surveillance, Epidemiology, and End Results program. Annual state spending data were obtained from the US Census Bureau. We evaluated the association of 5-year overall survival (OS) and public welfare spending using cluster-robust regression. Analyses were conducted overall, by race and ethnicity, and by cancer site. To determine whether public welfare spending was associated with changes in racial and ethnic disparities in survival, we additionally assessed for interaction effects between public welfare spending and race and ethnicity. Analyses were adjusted for covariates including age, sex, metropolitan residence, state, county-level income and education, insurance status, cancer site, stage at diagnosis, and year of diagnosis. Sensitivity analyses were conducted also accounting for state Medicaid expansion effects and state spending on health care and hospitals. **Results:** A total of 2,925,550 individuals were identified in our cohort. 5-year OS was 10.6% lower in non-Hispanic Black vs. White patients. Public welfare spending was not associated with 5-year OS overall (0.25 % per 10% increase in spending, -1.47 to 1.96, p = .78) or for non-Hispanic White patients (0.52% per 10% increase in spending, 95% CI -1.30 to 2.33, p = .58). However, increased public welfare spending was associated with increased 5-year OS among non-Hispanic Black patients (2.02% per 10% increase in spending, 95% CI = 0.01 to 4.03, p = .049). There was a 4.46% (95% CI = 2.63 to 6.30, $p_{interaction}$< .001) narrowing of the 5-year OS disparity in non-Hispanic Black relative to White patients per 10% increase in spending, or a 42% closure of the 10.6% OS disparity. Specifically, increased public welfare spending was associated with a narrowed Black vs. White 5-year OS disparity for patients with breast (7.50% increase in 5-yr OS for non-Hispanic Black relative to White per 10% increasing in spending, corresponding to closing 42.1% of the disparity), cervical (12.2%, 45.9%), colorectal (3.37%, 44.9%), head and neck (8.23%, 35.7%), liver (4.54%, 44.8%), lung (1.76%, 63.3%), ovarian (6.43%, 35.9%), prostate (2.89%, 41.9%), bladder (7.62%, 42.9%), and uterine cancers (14.9%, 40.9%). Results were similar after accounting for state health care and hospital spending and state Medicaid expansion effects. **Conclusions:** State investment in public welfare was associated with improved 5-year OS for non-Hispanic Black individuals with cancer, decreasing racial disparities in cancer outcomes overall and for many cancer sites. Research Sponsor: None.

6510 **Poster Discussion Session**

Racial and ethnic disparities in adherence and reported symptoms during routine collection of patient-reported outcomes (PROs).

First Author: Samuel U Takvorian, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Background: Routine collection of PROs for patients with cancer is an evidence-based practice and critical component of high-quality cancer care, but real-world adherence and reporting patterns are poorly understood. We examined differences in PRO adherence and reported symptoms by race and ethnicity. **Methods:** We conducted a retrospective cross-sectional study using de-identified electronic health record data from a National Cancer Institute Comprehensive Cancer Center. Participants included adults seen in follow-up at one of two medical oncology practices (1 academic, 1 community) from June 2019 to February 2020, during which two validated PRO instruments (NCI PRO-CTCAE and PROMIS Global v1.2) were routinely administered electronically via portal or tablet at return visits. Adherence was defined for each participant as the proportion of visits in which a PRO questionnaire was completed within 30 days. Using ordinary least squares regression, we modeled patient adherence as a function of race/ethnicity and adjusted for age, sex, insurance, median area income, ECOG performance status, cancer type, cancer stage, visit site, and number of visits during the study. Among study participants completing at least one PRO questionnaire, we modeled reported symptoms from the first questionnaire using a similar approach. **Results:** From June 2019 to February 2020, there were 29,726 patients (mean [SD] age 60.8 [15.1] years; 18,045 [60.7%] female) seen across 111,262 medical oncology visits. Of these patients, 19,971 (67.2%) completed at least one PRO questionnaire. Adjusted mean PRO adherence and reported symptoms varied by race/ethnicity, with Black and Hispanic patients reporting significantly higher symptom burden than White patients (Table). **Conclusions:** In this large cohort reflecting real-world PRO collection patterns, Black and Hispanic patients were less likely than White patients to complete PRO questionnaires, but more likely to report more severe symptoms. There is urgent need to ensure equitable PRO access and implementation and to address greater reported symptom burden among minority patients. Research Sponsor: None.

Racial and socioeconomic disparities in telemedicine use among US patients initiating cancer treatment during the COVID-19 pandemic.

First Author: Jenny S Guadamuz, University of Southern California, Los Angeles, CA

Background: The COVID-19 pandemic was associated with declines in in-person clinical visits. While telemedicine visits have increased, uptake has varied. Here we assess demographic and socioeconomic factors associated with telemedicine use among patients initiating treatment for 21 common cancers at community oncology clinics. **Methods:** This retrospective study uses the nationwide Flatiron Health electronic health record-derived de-identified database of patients with cancer. Patient characteristics were determined using structured and unstructured data curated via technology-enabled abstraction. We included patients (≥ 18 years) who initiated first-line cancer treatment between March 2020 and September 2021 (follow-up through December 2021). We focused on differences in telemedicine use (≥ 1 telemedicine visit within 90 days after treatment initiation) across race/ethnicity, insurance coverage, rurality (per Rural-Urban Commuting Areas), and socioeconomic status (SES). SES was defined using census block group data from the American Community Survey (2015-2019) (quintiles representing least to most affluent areas) based on patient addresses and measured using the Yost Index (incorporating income, home values, rental costs, poverty, blue-collar employment, unemployment, and education information). We used logistic regression models adjusted for clinical characteristics (*i.e.*, age, sex, performance status, and stage) to examine differences in telemedicine use. **Results:** This study included 24,164 patients (48.1% women, median age: 69 [interquartile range: 61-77] years), of whom 15.9% used telemedicine services. Black patients were less likely to use telemedicine services than White patients (11.4% vs. 15.6%, odds ratio [OR] 0.69 [95% confidence interval [CI]: 0.59-0.79], p<0.01). Telemedicine use was also lower among patients without documented insurance than well-insured (commercial and Medicare payers) patients (10.7% vs. 15.9%, OR 0.62 [95% CI: 0.54-0.72], p<0.01). Those in rural (9.8%, OR 0.51 [95% CI: 0.45-0.58], p<0.01) and suburban areas (13.1%, OR 0.71 [95%: 0.64-0.79], p<0.01) were less likely to use telemedicine services than patients in urban areas (17.6%). Finally, patients in the least affluent areas had lower telemedicine use than those in the most affluent areas (10.2% vs. 24.3%, OR 0.35 [95% CI: 0.31-0.40], p<0.01). **Conclusions:** During the COVID-19 pandemic, nearly one-fifth of patients initiating cancer treatment used telemedicine services. However, there were substantial disparities: Black, uninsured, non-urban, and less affluent patients are less likely to use telemedicine services. While telemedicine may expand access to specialty care, the proliferation of these services may widen cancer care disparities if vulnerable populations do not have equitable access. Research Sponsor: Flatiron Health.

6512 **Poster Discussion Session**

Parental informed consent comprehension in childhood cancer clinical trials: Associations with social determinants of health. *First Author: Paula Aristizabal, University of California San Diego Moores Cancer Center, Population Sciences, Disparities and Community Engagament, La Jolla, CA*

Background: Adequate informed consent (IC) comprehension is an ethical right prior to participation in clinical trials. Research investigating IC comprehension and associations with social determinants of health (SDoH) is lacking. We assessed whether SDoH and related contextual factors were associated with parental IC comprehension in therapeutic childhood cancer clinical trials. **Methods:** We prospectively enrolled parents of children with newly-diagnosed cancer. Univariable and multivariable regression were used to assess whether objective IC comprehension and related domains (*Purpose/Procedures/Randomization, Risks/Benefits, Alternatives*, and *Voluntariness*) were associated with SDoH (ethnicity, marital status, language, education attainment, employment, insurance, socio-economic status, health literacy [HL]) and contextual factors (cancer type, voluntariness, satisfaction with IC). **Results:** Of 223 parents included, 112 (50%) were Hispanic and 38% of Hispanics were monolingual Spanish-speaking. In adjusted multivariable analyses, limited HL was significantly associated with lower overall IC comprehension (β = -7.22; 95% CI, -10.9 to -3.59; P < 0.001) and lower comprehension of *Purpose/Procedures/Randomization* (β = -7.53; 95% CI, -11.3 to -3.73; P < 0.001), *Risks/Benefits* (β = -8.14; 95% CI, -15.5 to -0.772; P = 0.031), and *Alternatives* (β = -17.0; 95% CI, -30.5 to -3.57; P = 0.013). Preferred Spanish language of written/verbal medical information was significantly associated with lower comprehension of *Purpose/Procedures/Randomization* (β = -8.50; 95% CI, -15.1 to -1.89; P = 0.012) and *Voluntariness* (β = -20.1; 95% CI, -34.9 to -5.33; P = 0.008). Lower satisfaction with informed consent (β = 0.988; 95% CI, 0.460 to 1.52; P < 0.001) and single marital status (β = -4.42; 95% CI, -7.81 to -1.02; P = 0.011) were significantly associated with lower IC comprehension. **Conclusions:** Among parents of children with newly diagnosed cancer who provided consent for their child's participation in a therapeutic clinical trial, limited HL was consistently associated with lower IC comprehension in all domains analyzed, except for *Voluntariness*. Spanish language preference for medical information was associated with lower comprehension of two domains; and lower satisfaction was associated with lower overall IC comprehension. These findings suggests that parents with limited HL, limited English-proficiency, and lower satisfaction may not fully comprehend the IC and thereby not truly make informed decisions. Our findings highlight the potential role of language-concordant interventions tailored to the participant's HL level in order to ultimately improve IC comprehension and contribute to a reduction of disparities in clinical trial participation and promote equitable translation of discoveries and treatments to underserved groups. Analysis of patient (pt) withdrawal of consent using 11,993 pts from 58 alliance for clinical trials in oncology trials. *First Author: Sumithra J. Mandrekar, Alliance Statistics and Data Management Center, Mayo Clinic, Rochester, MN*

Background: Pt recruitment receives well-deserved attention, but pt retention is also important for trial interpretability and generalizability. We report on trends and predictive factors for withdrawal of pt consent, defined as pt cessation from trial participation for reasons not mandated in the protocol. **Methods:** Alliance phase II/III trials that enrolled pts during 2013 – 2019 were included. All pts had ≥2 years (yrs) of follow-up. Primary outcome was withdrawn consent (yes; no) within 2 yrs of enrollment. Pt factors included year of enrollment, age, race, ethnicity, and gender. Trial factors included randomization, use of placebo, and use of radiation. Univariable (Uni) and full multivariable (MV) logistic regression models (including all factors from Uni setting) with a Bonferroni p-value correction (p < .004 considered significant) were used. **Results:** Median age was 62 yrs, with 67% female, 82% White, 9% Black or African American, and 7% Hispanic. 52% of trials were phase II, 5% II/III and 43% III. Common (> 10%) trial categories included 22% experimental therapeutics or rare tumors, 12% gastrointestinal, 12% genitourinary, 12% neuro-oncology and 10% symptom intervention. 78% of trials were randomized, 22% placebo-controlled and 14% used radiation. 1060 (9%) pts withdrew consent within 2 yr of enrollment (range,5.7% -9.8%) during 2013-2019. In Uni models, all trial and pt factors significantly predicted pt withdrawal except age, race, and gender (See table). In MV models, pts of Hispanic origin, and >75 yrs were more likely to withdraw. Trials using radiation had less likelihood of pt withdrawal. Placebo-controlled randomized trials had higher likelihood of withdrawal. **Conclusions:** Both trial and pt factors contribute to higher rates of pt withdrawal from clinical trials. Understanding these factors will enable investigators to focus on pt education and optimization of trial design to improve pt retention and the overall clinical trial plan. Neighborhood socioeconomic disadvantage, tobacco use, and cessation indicators among adults with cancer in the United States: Results from 10 ECOG-ACRIN trials. *First Author: Angela Wangari Walter, University of Massachusetts Lowell, Lowell, MA*

Background: Tobacco use is a modifiable risk factor for adverse outcomes among patients diagnosed with cancer. Despite ASCO's recommendation for assessment and treatment of tobacco use, integration into cancer care is suboptimal. Socioeconomic contexts influence access and utilization of tobacco treatment, but little is known about the relationship between neighborhood socioeconomic disadvantage (NSD) and tobacco assessment, assistance, and cessation among cancer patients enrolled in clinical trials. **Methods:** The NCI Cancer Patient Tobacco Use Questionnaire (C-TUQ) was centrally administered to participants enrolled in 10 ECOG ACRIN clinical trials (9 therapeutic, 1 imaging). We examined associations of NSD with patient-reported rates of receiving brief tobacco cessation support (i.e., Ask, Assist (counseling)) and cessation (past 30d quit attempts and duration). NSD was measured using the national Area Deprivation Index (ADI) based on participant's zip code. Associations between ADI (low, intermediate, and high) and tobacco variables were evaluated using logistic regression and ANOVA. **Results:** 740 patients, completing the C-TUQ between June 2017-October 2021, can be classified as 402 (54%) never smokers, 81 (11%) current smokers, and 257 (35%) former smokers. Patients were 70% male; 94% white; 3% Hispanic; mean age 58.8 (SD 9.0). Cancer diagnoses were 36% leukemia; 19% lymphoma, 18% prostate, 11% breast; 9% melanoma, 7% myeloma, and 0.5% head and neck. Patients were categorized into high (33%), intermediate (34%) and low (33%) disadvantaged neighborhoods. Patients in high (vs. low) disadvantaged neighborhoods were more likely to report being asked about smoking (OR = 3.90; 95% CI (confidence interval), 1.61 to 9.46; p = 0.0062) but less likely to report receiving counseling to help quit smoking (OR = 0.20; 95% CI, 0.06 to 0.73; p = 0.0234). Patients from high disadvantaged neighborhoods had the shortest quit duration, followed by patients from intermediate and low disadvantaged neighborhoods (mean = 145.78, 187.66, and 210.98 months, respectively, p = 0.0372). **Conclusions:** Greater socioeconomic neighborhood disadvantage was associated with increased assessment of tobacco use but decreased tobacco treatment referral, and the shortest quit duration. More research is needed to promote increased referral to tobacco treatment for individuals with cancer from disadvantaged neighborhoods to promote and sustain cessation. Breast cancer screening in persons experiencing homelessness. *First Author: Sarah S Kilic, Department of Radiation Oncology, Taussig Cancer Institute, Cleveland Clinic Foundation, Cleveland, OH*

Background: Persons experiencing homelessness (PEH) suffer from poor health outcomes, including worse cancer mortality, compared to persons not experiencing homelessness. A portion of the disparity in cancer outcomes is attributable to reduced access to cancer screening, leading to more advanced-stage disease and a higher risk of death compared to the general population. Data regarding cancer screening rates in PEH are scarce. We therefore sought to evaluate baseline rates of breast cancer screening in PEH. **Methods:** All patients presenting for care from January 1, 2014 onward at a hospital system spanning five counties in a populous Midwestern state were screened for homelessness. Homelessness was identified by two criteria: presence of the Z-code for homelessness (Z59) in the patient's electronic medical record, and/or patient's address on record listed as an address matching that of a regional homeless shelter, transitional housing, or "homeless." Identified PEH were maintained in a prospective registry. For each female PEH in the screening age range, billing data for completed breast cancer screening mammography performed in the previous five years (1/1/17-12/31/21) were extracted (CPT codes 77063, 77067). Data were also extracted for a cohort of non-PEH patients eligible for screening. Demographic and clinical data were extracted for all patients. This study was approved by the hospital system's IRB. **Results:** A total of 3,474 female (biological sex) PEH were identified, with 1,320 eligible for screening mammography (alive and between the ages of 40 and 79) in the study timeframe. The median age was 53.5 years old; 44% were Black, 48% White, 8.5% unknown/other race, and 3% Hispanic ethnicity. 28% of PEH were uninsured, and 67% had government insurance; 66% had an assigned primary care physician (PCP). Of PEH eligible for screening mammography, 237 (18%) had at least one screening mammogram during this five-year interval (2017, 2.2%; 2018, 4.3%; 2019, 3.6%; 2020, 3.7%; 2021, 4.3%). In a cohort of 6,240 non-PEH eligible for screening over the same timeframe, the screening mammography rate was 32%, which was significantly higher than the screening rate for PEH (p < 0.00001). Compared to PEH who did not undergo screening mammography, PEH who underwent screening mammography were more likely to have an assigned PCP (90% vs 38%, p < 0.00001), to be a non-current tobacco user (56% vs 35%, p < 0.00001), and to be a non-current illicit drug user (84 % vs 68%, p = 0.0015). PEH who underwent screening mammography were significantly less likely to be uninsured (12% vs 31%, p < 0.00001). **Conclusions:** In the largest study of its kind to date, we identified low rates of breast cancer screening in female PEH. Interventions to increase breast cancer screening in this vulnerable population are urgently needed and may include increased access to PCPs, tobacco and drug cessation programs, and provision of health insurance. Associations between interpersonal violence and cancer risk factors for transgender and cisgender people. *First Author: Ash B. Alpert, Brown University School of Public Health, Providence, RI*

Background: Cancer risk factors for transgender people are largely unexplored. Extreme rates of interpersonal violence experienced by transgender people may increase the risk of cancer. The associations between exposure to interpersonal violence and cancer risk factors have not been investigated. **Methods:** We searched for experiences of violence in cohorts of 923 transgender and 1846 cisgender people matched by age, follow-up time, and year of the first encounter and measured the association between these experiences and smoking as well as BMI ≥ 40. We then estimated the prevalence ratios for these risk factors using robust Poisson regression models including gender identity, violence, and their interaction, adjusted for age and follow-up time. **Results:** Transgender people experienced more violence than cisgender people. Among transgender people, there were significantly higher rates of smoking among those who had experienced any type of violence (50% vs 35%, p<.0001) and borderline significantly higher rates of BMI ≥ 40 (23% vs 18%, p=.05). Among cisgender people, significantly higher rates of smoking in those who had experienced violence (52% vs 31%, p<.0001) and significantly higher rates of BMI ≥ 40 (23% vs 11%, p<0.001) were also demonstrated. No statistically significant difference was demonstrated in the association between violence and smoking in transgender compared with cisgender people (prevalence ratio (PR) .87, p=.17). A statistically significant difference was demonstrated in the association between violence and BMI ≥ 40 in transgender compared to cisgender people (PR .65, p=.02). **Conclusions:** Given the association between violence and cancer risk factors, eliminating violence is of profound concern to the oncology community. Violence across the life course is markedly higher in transgender versus cisgender people. Interventions are urgently needed to eliminate violence. Cancer prevention research should investigate the efficacy of methodologies known to impact interpersonal violence, including those modifying structural factors to decrease socioeconomic disparities, stigma, and oppression. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Violence experienced by transgender and cisgender people.

Description	Total N=2769 (%)	Transgender cohort N=923 (%)	Cisgendercohort N=1846 (%)	Chi-square p-value
Any violence	718 (25.93)	438 (47.45)	280 (15.17)	<0.0001
Any childhood violence	396 (14.3)	278 (30.12)	118 (6.39)	<0.0001
Any childhood sexual violence	184 (6.64)	126 (13.65)	58 (3.14)	<0.0001
Any adult violence	557 (20.12)	338 (36.62)	219 (11.86)	<0.0001
Any adult sexual violence	126 (4.55)	95 (10.29)	31 (1.68)	<0.0001
Familial violence	345 (12.46)	244 (26.44)	101 (5.47)	<0.0001

A case-control study of healthcare disparities in sex and gender minority patients with breast cancer. *First Author: Erik Eckhert, Stanford University School of Medicine, Stanford, CA*

Background: Disparities in the quality of diagnosis and treatment of breast cancer in sex and gender minority (SGM) populations are largely undefined. Only 24% of studies funded by the National Cancer Institute capture data on sexual orientation, while only 10% capture data on gender identity. To address this gap, the National Academies 2020 Report calls for adding sexual orientation and gender identity (SOGI) to ongoing data collection efforts. This case-control study matching SGM patients with breast cancer to cisgender heterosexual controls is the result of linking SOGI data to the Stanford University Healthcare (SHC) Oncoshare breast cancer database, which integrates data from the electronic medical record (EMR) and California Cancer Registry. **Methods:** An initial database query across the SHC EMR was performed for charts containing SOGI terms in patients with breast cancer seen in SHC Oncology. 686 charts were identified for manual review and after eliminating false positives, the sample was reduced to 92 SGM patients, who were then matched by year of diagnosis, age, stage, ER-status, and HER-2 status to cisgender heterosexual controls within Oncoshare. Additional data on demographics, diagnosis, treatment, and relapse were then manually abstracted from the EMR. **Results:** The SGM cohort was comprised of 80% lesbians, 13% bisexuals and 6% transgender men. The median age at diagnosis across both groups was 49. SGM patients were 72% white, 4% Asian, 12% Black or Latinx 6% other compared to 63% white, 24% Asian, 6% Black or Latinx, 6% other in the controls (p = 0.0006). Thirteen percent and 32% of SGM patients engaged in risky alcohol and illicit drug use respectively, compared to 3% and 6% of controls (p = 0.028; p < 0.0001). Estrogen exposure risk factors including median age of menarche, first delivery, menopause, and use of exogenous estrogens were balanced between the two groups, but SGM patients had fewer children (median 0 vs 2, p < 0.0001). There was a delay in time to diagnosis from symptom onset in SGM patients versus controls (median 64 days vs 37 days, p = 0.043). There was no difference in surgical approach, use of post-lumpectomy radiation, or use of neoadjuvant chemotherapy for stage III disease. However, SGM patients were less likely to undergo chest reconstruction (55% vs 82%, p = 0.0098) and if ER+, to complete ≥5 years of ER-directed therapy (53% vs 72%, p = 0.048). SGM patients used more alternative medicine (46% vs 29%, p = 0.033) and had a higher rate of documented refusal of recommended oncologic treatments (38% vs 21%, p = 0.0088). Correspondingly, SGM patients experienced a higher recurrence rate (31% vs 14%, p = 0.0124). **Conclusions:** To our knowledge, this is the first study to examine quality of diagnosis and treatment of breast cancer in SGM patients. Several novel potential healthcare disparities are identified, which should be further evaluated in population-based studies to inform interventions. Research Sponsor: Breast Cancer Research Foundation.

6518 **Poster Discussion Session**

Validity and efficiency of progression-free survival (PFS)-2 as a surrogate endpoint for overall survival (OS) in advanced cancer. *First Author: Rachel Woodford, NHMRC Clinical Trials Centre, Camperdown, Australia*

Background: PFS is used widely as a primary endpoint in oncology trials and as a surrogate for OS. PFS-2, defined as time from randomization to progression on second line therapy, is potentially a more reliable surrogate than PFS but requires additional follow-up time. We evaluated the validity and efficiency of PFS-2 as a surrogate endpoint for OS and compared its performance with PFS. **Methods:** We performed an electronic search to identify randomized trials of advanced solid tumors reporting on PFS, PFS-2 and OS as pre-specified endpoints. We compared the correlations in the relative treatment effect for OS with PFS and PFS-2. We extracted data from Kaplan-Meier survival curves to create individual patient data to estimate time to statistical significance (TSS), defined as logrank P < 0.05. We further computed the samples size (person-year follow-up) required to reach statistical significance and assessed for the effect of survival post-progression (SPP). If trials failed to reach statistical significance for a particular endpoint, the maximal follow-up time was used. **Results:** Our study consisted of 39 analysis units with 20714 patients. Correlations of the OS treatment effect with the PFS and PFS-2 treatment effects were r= 0.12 (95% CI 0.00-0.13) and r= 0.67 (95% CI 0.08-0.69) respectively. The median differences in TSS between OS with PFS, OS with PFS-2, and PFS2 with PFS were 8.7, 8.4, and 3.2 months respectively. For trials with a SPP < 12 months, smaller differences in the median TSS as compared to SPP ≥12 months were seen. The median differences in follow-up required to reach statistical significance were 329, 151 and 122 person-years (PY) respectively. These differences were equivalent to a median 18.3% increase in sample size required for PFS-2 over PFS. The median increase in sample sizes were 18.2% and 22.3% for trials with SPP < 12 and ≥12 months respectively. **Conclusions:** PFS-2 has a stronger correlation with OS benefit than PFS. When PFS-2 is used as primary endpoint, trials will require an additional median 3.2 months to achieve statistical significance, and an additional 18.3% increase of sample size over PFS. PFS-2 balances between improved correlation with OS but modest increase in follow-up time and sample size. PFS-2 should therefore be considered as a primary endpoint in future trials of advanced cancers. Research Sponsor: None.

	N	OS-PFS	OS-PFS-2	PFS2-PFS
Difference in TSS (months) [95% CI]	39	8.7 [8.5-9.0]	8.4 [8.2-8.6]	3.2 [2.3-3.4]
SPP < 12 months, difference in TSS	15	3.2 [2.9-3.5]	1.0 [0.7-1.3]	1.8 [1.4-2.2]
SPP≥12 months, difference in TSS	20	18.2 [17.9-18.6]	13.0 [12.6-13.3]	3.2 [2.9-3.5]
Difference in PY follow-up [95% CI]	39	329 [315-342]	151 [140-162]	122 [113-130]
SPP < 12 months, difference in PY follow-up	16	63 [49-76]	38 [24-52]	18 [16-20]
SPP≥12 months, difference in PY follow-up	20	593 [574-613]	320 [303-336]	156 [148-165]

Is health-related quality of life (HRQoL) reporting keeping pace with new drug approvals in hematology and oncology: A five-year analysis of 245 drug approvals. *First Author: Medhavi Gupta, Women & Infants Hospital, Brown Alpert School of Medicine, Providence, RI*

Background: HRQoL data in cancer clinical trials can inform tolerability of new drugs, facilitate informed decision-making, and influence health care and policy decisions, but are frequently underreported. We reviewed all registration trials that informed Food and Drug Administration (FDA) approval between 2015-2020 for latency and quality of HRQoL reporting. **Methods:** HRQoL data for each clinical trial associated with FDA drug approval between 7/2015-5/2020 was collected retrospectively from multiple sources including the FDA and clinicaltrials.gov website, conference abstracts, and journal manuscripts. The aim of the study was to analyze the proportion of trials reporting HRQoL, quality of HRQoL data, latency between FDA approval and first reporting of HRQoL data, and association between changes in HRQOL and overall survival (OS) and progression-free survival (PFS) outcomes. **Results:** Of the 259 trials involving 245 drug approvals, majority involved solid tumors (61.4%), were phase III (59.1%), and led to approval based on a non-PFS/OS endpoint (52.9%). HRQoL was a pre-specified endpoint in 55.2% and reported in 49.8% trials. HRQoL data was published by the time of FDA approval in only 41.8% cases, 24.8% reported HRQoL data > 12 mo after approval. Further, among trials reporting HRQoL (n = 129), HRQoL data was first reported in the primary paper in only 34.1%, and either in an ancillary paper in 41.9% or an ancillary abstract in 24% trials. Of the 129 trials with HRQoL data, an improvement in HRQoL was seen in 44.2%, no significant change in 41.9%, mixed results in 11.6%, and worsening in 2.3% of trials. Overall, by the time of FDA approval, OS and PFS data were reported in 59% (152/259) and 65% (168/259) trials respectively with an OS benefit seen in 23.9% (62/259) trials, and PFS benefit in 38.6% (100/259) trials. Of the 84 trials that led to FDA approvals based solely on response rate, HRQoL was reported in only 23.8% (n = 24) with a HRQoL benefit seen in only 9.5% (n = 8) trials. Trials reporting either no significant impact on HRQoL or a mixed impact on HRQoL reported median OS benefit of 4.6 months and 4.2 months respectively. In trials reporting HRQoL data > 6 mo from FDA approval, OS benefit of < 3 mo was seen in 17.8% (8/45) trials. No significant time trends were noted during the study period. **Conclusions:** There was significant underreporting of HRQoL outcomes in trials (< 50%) associated with FDA drug approvals between 2015-2020 with majority of trials reporting HRQoL data in an ancillary paper/abstract, and at a much later time than the FDA approval. While it is widely accepted that timely dissemination of HRQoL data from cancer drug trials are vital for clinical and regulatory decisions, no improvement in reporting rates were noted over past 5 years. Only 10% of drugs approved on the basis of response rates showed improvement in HRQoL in the registration trials. Real-world progression-free survival (rwPFS) and time to next line of therapy (TTNT) as intermediate endpoints for survival in metastatic breast cancer: A real-world experience. *First Author: Chris Labaki, Dana Farber Cancer Institute, Boston, MA*

Background: Real-world progression-free survival (rwPFS) and time to next line of therapy (TTNT) are two endpoints of clinical interest in patients with metastatic breast cancer (MBC). Their validation as intermediate endpoints for overall survival (OS), in a real-world setting, remains not fully established. **Methods:** We conducted a retrospective cohort study using the nationwide US Electronic Health Record-derived de-identified Flatiron Health database. The study population included pts diagnosed with MBC from Jan 1, 2011 to Feb 30, 2021. rwPFS was defined as the time from start of first-line systemic therapy for MBC to disease progression or death. TTNT was defined as the time from start of first-line systemic therapy until start of next line of therapy. The nonparametric Kendall tau correlation between each surrogate endpoint (rwPFS and TTNT) and OS was evaluated using the Hougaard copula model in the Weibull margin distribution. Kendall's tau (τ) with its 95%CI was calculated across the entire dataset, and within each disease subgroup defined by receptor (ER and/or PR status defined as hormone receptor [HR], and HER2) status. This work was conducted on behalf of the imCORE network and the Dana-Farber Cancer Institute. **Results:** Overall, 9,770 patients with MBC were included. Median age was 63 years (IQR: 54-72 years). HR+/HER2- disease represented the most frequent MBC subtype (n=6,287; 64.4%), followed by HER2+ (n=2,096; 21.5%) and triple negative (n=1,387; 14.2%) disease. Median f/u was 41.5 months (95%CI: 40.4 to 42.8). Median OS in the overall population was 32.4 months (95%CI: 31.2 to 33.3). Median rwPFS was 11.5 months (95%CI: 11.1 to 11.9), and median TTNT was 11.1 months (95%CI: 10.7 to 11.5). Across the entire population, the correlation of rwPFS with OS was 0.54 (95%CI: 0.53-0.56), while the correlation of TTNT with OS was 0.47 (95%CI: 0.46-0.48) (Table). **Conclusions:** rwPFS and TTNT may represent meaningful intermediate endpoints for OS in patients with MBC overall, and within the different disease subgroups. Research Sponsor: Roche/ Genentech.

Median OS, rwPFS and TTNT and correlation of each pair of evaluated endpoints in all subgroups.

	Overall Population (n=9,770)	HR+/HER2- MBC (n=6,287)	HER2+ MBC (n=2,096)	Triple-negative MBC (n=1,387)
Median OS, months (95%CI)	32.4 (31.2-33.3)	35.4 (34.2-36.6)	41.7 (38.9-44.0)	13.5 (12.6-14.6)
Median rwPFS, months (95%CI)	11.5 (11.1-11.9)	13.3 (12.7-14.0)	13.4 (12.6-14.4)	5.44 (5.11-5.83)

Representation of women in clinical trials supporting the FDA-approval of contemporary anticancer therapies. *First Author: Melissa A. Babcook, The Ohio State University James Cancer Center, Columbus, OH*

Background: Contemporary anticancer drugs frequently have different efficacy and side effects in men and women. Yet, whether women are well-represented in pivotal trials supporting contemporary anticancer drugs is unknown. The objective of this study was to characterize the representation of women in trials supporting the use of contemporary anticancer drugs. **Methods:** We retrospectively evaluated all pivotal (phase II and III) trials supporting FDA-approval of anticancer drugs from 1998 to 2018, derived from Drugs@FDA, clinicaltrials.gov, MEDLINE, and publicly available FDA-drug reviews. Expected population rates were derived from the National Cancer Institute Surveillance, Epidemiology, and End Results (SEER) program, and US Census databases. The primary outcome was the report of any gender-specific analysis of efficacy and/or safety, irrespective of treatment-arm. The secondary outcome was the proportional representation of women across trials, evaluated by a participation-to-prevalence ratio (PPR) of 0.85, according to cancer-type. Female representation was also assessed as change across time. Differences in pooled binary endpoint hazard ratios, by the presence or absence of adequate female representation, were also assessed. **Results:** In total, there were 97,566 participants, enrolled in 189 clinical trials, evaluating 123 anticancer therapies. Gender was reported in 182 (96.3%) clinical trials, of which 43.4% (42,299) were women, compared to 55.6% (55,267) men ($P < 0.01$). Overall, women were under-represented in clinical trials of anticancer therapies by a mean of 16.5% compared to the proportional incidence of all cancers in women. Women were the most under-represented in gastric (PPR = 0.821) and liver (PPR = 0.619) cancer trials. Sex-based drug efficacy analysis was only published in 36.8% of trials. Over time, the trend of percentage women recruited into clinical trials increased, but not at a rate comparable to prevalence (-5.0 to -5.5% of prevalence), and the gap in under-representation of women in anticancer therapy clinical trials is widening. **Conclusions:** Among pivotal clinical trials supporting contemporary FDA-approved cancer drugs, women were frequently under-represented. Additional studies are needed to understand the impact of under-representation on contemporary anticancer therapy outcomes. Research Sponsor: None.

Impact of travel burden on overall survival in patients with lung cancer. *First Author: Dragomir Stoyanov, Medical University of Varna, Varna, Bulgaria*

Background: High-volume specialized centers are more efficient at managing patients with lung cancer than low-volume centers. Centralization of cancer treatment has the potential to improve patient outcomes and quality of treatment. However, the growing centralization also increases patient's travel burden (measured as travel distance or travel time) and may negatively impact access to specialist services. The aim of our study was to evaluate the potential impact of travel burden on clinical outcomes in patients with lung cancer. **Methods:** A retrospective analysis of a single Bulgarian center was performed. A total of 9240 lung cancer patients treated between 2005-2020 were included in the study. Travel distance between patients' city of residence and the treating facility was calculated with an online tool to determine the shortest route for travel using the existing road network. The mean of travel time values for every workday of the week was calculated to control for daily changes in typical traffic. The probability of survival was estimated using the Kaplan-Meier method and differences in survival in each subgroup were evaluated with a log-rank test. **Results:** About one third of all included patients were living in the same city as the treating facility (n = 2746, 29.7%). The medians for travel distance and travel time were used to stratify patients into subgroups. According to travel distance the patients were grouped into three strata – same city, < 50 km and ≥ 50 km. A cut-off of 60 min was used to stratify patients into three groups by travel time – same city, < 60 min and ≥ 60 min. Overall survival in our patient population was significantly lower with increasing travel distance ($p < 0.001$, Mantel-Cox log rank) and travel time ($p < 0.001$, Mantel-Cox log rank). The 1-year OS rate according to travel distance was 27.1% in the same city group, 22.4% in < 50 km group and 20.5% in ≥ 50 km group ($p < 0.001$). The corresponding values for the 5-year OS rate were: 2.9%, 2.6% and 1.4% ($p < 0.001$). **Conclusions:** In this retrospective study we discovered significant differences in overall survival of patients with lung cancer depending on travel distance and travel time to the treating oncological facility. Despite having similar clinical and pathological characteristics (age, sex, stage at initial diagnosis, histologic subtype), the median overall survival was significantly lower in those subgroups of patients with a higher travel burden. Research Sponsor: None.

Overall survival in travel burden subgroups.

Parameter	Subgroup	Median OS (months)	95% Confidence Interval
Travel distance			
	Same city	6.000	5.662 – 6.338
	< 50 km	5.300	5.049 – 5.551
	≥ 50 km	5.100	4.819 – 5.381
Travel time			
	Same city	6.000	5.662 – 6.338
	< 60 min	5.267	5.038 – 5.495
	≥ 60 min	5.133	4.806 – 5.461

Disparities in speed to BMT consult and allograft in 279 adults with AML. *First Author: Warren Benjamin Fingrut, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Whether patient (pt) ancestry impacts the time to BMT is not established. **Methods:** We hypothesized that non-European (non-EURO) ancestry AML pts are at increased risk of delayed time to transplant. Thus, we analyzed time to allograft (Allo) by ancestry defining delayed (late) times as: Allo Indication to BMT Consult (Ind. – Consult) > 90 days, Consult – BMT > 120 days & Allo Indication to BMT (Ind. - BMT) > 180 days. We studied pts < 70 yrs transplanted 1/2016-7/2021. **Results:** In 279 AML pts (median 56 yrs, range 19-69), BMT indication was date of diagnosis if ELN 2017 intermediate/ high risk &/or high risk mutations &/or sAML in 261 (94%) pts, or date of refractory/ relapsed disease in 18 (6%) pts. European (EURO) pts (n = 195, 70%; median 60 yrs) were older than non-EURO pts (n = 84, 30%; median 49 yrs), p < .001. Most HLA-matched sibling (SIB) (27/33, 82%) & 8/8 HLA-matched unrelated donor (mURD, 113/138, 82%) recipients were EURO; more non-EURO pts received HLA-disparate grafts [cord blood (CB)/ haplo/ mmURD]: 48/84 (57%) vs 55/195 (28%), p < .001. Overall, median (range) times for BMT Ind. - Consult, Consult - BMT, & Ind. - BMT were 45 (1-1127), 86 (13-1628), & 135 (23-1683) days. 15% of pts had late BMT Ind. - Consult, 27% late Consult – BMT, & 28% late Ind. - BMT. In multivariate analysis (significant variables in Table), more older pts had late Consult - BMT & Ind. - BMT; more non-EURO pts had late Ind. - Consult, Consult - BMT & Ind. – BMT; & despite mostly being non-EURO (35/67, 52%), fewer CB recipients had late Consult - BMT. In mURD pts, BMT Ind. - BMT time was delayed in non-EURO (median 182 days) vs EURO (median 128 days) pts (p = 0.04); there was no difference in CB pts (BMT Ind. - BMT EURO pt median 118 vs non-EURO pt median 108 days, p = 0.42). During the pandemic, as compared with EURO pts BMT delays were further exacerbated in non-EURO pts (Ind. - Consult median 13 & Ind. - BMT median 33 days). **Conclusions:** Few older non-EURO pts are allografted. Matched SIB & 8/8 mURD transplants predominantly serve EURO pts; the majority of non-EURO pts receive HLA-disparate grafts. Older age & non-EURO ancestry are associated with delayed BMT. CB transplants (CBT) are the fastest regardless of ancestry. Finally, the pandemic further exacerbated delays for non-EURO pts. Strategies to mitigate referral barriers (esp. for older non-EURO pts), prompt adult donor evaluations, efficient URD searches, & utilization of all alternative donors are critical to ensure timely BMT for all. Given the rapid availability, CBT should have high priority in high-risk or urgent pts & speedy graft procurement can compensate for late referral. Research Sponsor: None.

Survival among patients with multiple myeloma in the U.S. military health system compared to the Surveillance, Epidemiology, and End Results (SEER) program.

First Author: Alexander Dew, Walter Reed National Military Medical Center, Bethesda, MD

Background: Multiple myeloma (MM) is the second most common hematologic malignancy and remains incurable despite therapeutic advances. The US Military Health System (MHS) provides universal healthcare to beneficiaries and has been associated with improved survival across multiple malignancies. It is unknown whether access to universal healthcare via the MHS translates to improved survival for MM patients. We sought to answer this question by comparing survival data from the Department of Defense's Automated Central Tumor Registry (ACTUR) and the NCI's SEER database. **Methods:** Patients 18 years and older diagnosed with histologically confirmed MM between 1987-2013 were identified in ACTUR (N=1,488) and SEER (N=2,976) databases. Two SEER patients were matched to an ACTUR patient by age group, sex, race, and diagnosis year group. Five and 10-year survival was compared between ACTUR and SEER patients using Kaplan-Meier curves and log-rank tests. Cox proportional hazard model was used to estimate hazard ratios (HR) and 95% confidence intervals (95% CI) adjusted for potential confounders of age at diagnosis, sex, race and diagnosis year. The proportional hazards assumption for the analysis was assessed with log-log survival curves. **Results:** Median survival in the ACTUR patients was 47.1 months (95% CI: 43.9-50.4) compared to 33.0 months (95% CI: 32.0-35.0) in the SEER group. Five and 10-year survival was superior in patients from the ACTUR group compared to the SEER group with an aHR of 0.74 (95% CI: 0.68-0.81) and 0.79 (95% CI: 0.74-0.85) after adjustment for potential confounders, respectively. The survival advantage of ACTUR patients was preserved when stratified by age, sex, race, and diagnosis year. **Conclusions:** Patients treated with MM in the MHS had superior 5 and 10-year overall survival when compared to the general population. This benefit remained despite age, sex, race, and diagnosis year. Our study findings suggest the benefits of universal healthcare provided by the MHS improve survival among MM patients. Further research is warranted to delineate factors which improve survival and reduce disparity in the treatment of MM patients. Research Sponsor: Henry M. Jackson Foundation for the Advancement of Military Medicine.

Overall cancer survival inequalities in the state of São Paulo: A comparison between public and private systems.

First Author: Bruno Casaes Teixeira, Adelphi Real World, Bollington, United Kingdom

Background: Brazilian cancer patients under the public healthcare system receive diagnoses and treatment at a later disease stage on average than private patients, likely due to the public system having less access than the private system to treatment and diagnostic technologies. The impact of the different healthcare systems on survival is unknown. We aimed to evaluate the difference in overall survival (OS) in cancer patients under public vs. private healthcare systems in São Paulo, Brazil. **Methods:** Data were drawn from the hospital-based cancer registry of the Fundação Oncocentro de São Paulo capturing clinical and demographic data including clinical setting (private/public), date of diagnosis, and disease stage. All patients had complete medical records and malignant, well classified tumors. Analyses used Cox proportional hazards regressions. For multivariate (MTV) and propensity score matched (PSM) analyses; tumor topology and morphology, patient demographics and diagnostic care setting were used as covariates. Analyses were performed for overall cancers and for 20 separate tumor types as recommended by the National Institute of Cancer. **Results:** Data from 189,850 patients were analyzed. For all cancers, the hazard ratio (HR) for OS for public vs. private healthcare was 2.30 (CI 95% 2.20 - 2.39) in univariate (UNV), 1.59 (CI 95% 1.52 - 1.66) in MTV and 1.69 (CI 95% 1.61 - 1.77) in PSM, indicating that patients under the public system were between 2.30 and 1.69 times less likely to survive their cancer (Table 1). The cancer type with the biggest HR using PSM was multiple myeloma (HR 2.37 CI95% 1.82 - 3.08). **Conclusions:** Our results show Brazilian cancer patients under the public healthcare system were in some cases more than twice as likely to die from cancer than private patients. Despite possible differences between these populations in lifestyle and other potential influencing factors, our results most likely reflect differences between the two systems in access to treatment and diagnostic technologies. Our findings highlight the inequality of care in public vs. private healthcare in Brazil. Focus should be on closing the gap between the two systems in cancer diagnosis and treatment. Research Sponsor: None.

Overall survival hazard ratio in all cancer patients by demographic characteristics.

Method	Comparator	Hazard ratio	95% Confidence interval	p-value
Univariate	Healthcare: Public vs. private	2.30	2.20, 2.39	<0.001
	Tumor grade: IV vs. I	27.37	26.31, 28.48	<0.001
	Education: Illiterate vs. college	1.76	1.68, 1.85	<0.001
	Year of diagnosis: 2011-2015 vs. 1999-2003	1.34	1.29, 1.40	<0.001
Multivariate	Healthcare: Public vs. private	1.59	1.52, 1.66	<0.001
	Tumour grade: IV vs. I	26.92	25.86, 28.02	<0.001
	Education: Illiterate vs. college	1.40	1.33, 1.47	<0.001
	Year of diagnosis: 2011-2015 vs. 1999-2003	1.21	1.16, 1.26	<0.001
Propensity Score Matching	Healthcare: Public vs. private	1.69	1.61, 1.77	<0.001

Impact of equal access by race and ethnicity on patients in the Veterans Health Administration (VHA) treated for diffuse large B-cell lymphoma (DLBCL).

First Author: Snegha Ananth, University of Texas Health at San Antonio, San Antonio, TX

Background: Racial and ethnic disparities in access to care and outcomes are well-established and are critical issues across several malignancies, including DLBCL. Previous studies from national registry datasets have shown racial disparities in DLBCL disease characteristics, treatment and outcomes. The VHA is an equal access system providing a unique environment to investigate cancer disparities across the disease continuum. **Methods:** This is a retrospective chart review of 4033 randomly selected patients with an ICD code for lymphoma treated within the VHA between 01/01/2011 and 12/31/2017. Data abstractors collected baseline patient and disease characteristics and treatment responses for those with an initial diagnosis of DLBCL in that time frame. Survival time was determined via electronic health record query on 11/30/2021. Chi-square tests were used to analyze relationship between race and variables of interest. Cox proportional hazards model was used to estimate hazard ratios (HR) for race and controlling factors. **Results:** 2141 DLBCL patients met our inclusion criteria. 97% were male. Majority were Non-Hispanic Whites (NHW 75%) followed by Non-Hispanic Blacks (NHB 12.5%), Hispanics (H 5.7%) and others (O 6.8%). NHB were diagnosed at younger median age (63 years) when compared to the NHW, H and O (68 years). There was no statistically significant difference in stage at diagnosis, IPI score, cell of origin (COO) and hit status amongst racial subgroups. Outcomes analysis (Table) revealed similar treatment and response rates, median OS, 1- and 2- year survival across all racial subgroups. However, after adjusting for age, IPI, COO, and exposure to agent orange, and including up to 10-years of survival data, H had 36% lower risk of death (HR=0.64, 95% CI 0.44-0.93) than NHW, while NHB and O had similar outcomes to NHW. **Conclusions:** This large retrospective study is a continuation of our group's work (Williams et al, 2020) that doubles the cohort size and confirms that when standard of care therapy is given with equal access to care, short-term treatment and survival outcomes are same for all races. Further studies are needed to analyze risk factors associated with differences in long term outcomes. Research Sponsor: None.

Saving TIME: Accuracy of a text intervention to minimize the time burden of cancer care.

First Author: Erin Mary Bange, Abramson Cancer Center, Philadelphia, PA

Background: Patients with cancer spend substantial time receiving cancer care. There is a need for innovative strategies to decrease the time burden of cancer therapy. The current care model consists largely of in-person visits to assess treatment toxicity. Most patients treated with immunotherapy, however, do not experience substantial toxicity. We designed and evaluated a text-based instrument to identify patients without symptoms of immunotherapy toxicity. This instrument has the potential to be combined with lab assessment to identify individuals who can safely proceed directly to treatment, lessening the need for in-person office visits. **Methods:** This cross-sectional study evaluated the performance characteristics of a text-based instrument to identify patient-reported immunotherapy toxicity, against the gold standard in-person provider assessment documented in the electronic medical record (EMR). Those eligible for inclusion spoke English, were receiving single agent immune checkpoint blockade for a solid tumor, and had access to a mobile device with text messaging capabilities. The instrument contained 16 questions adapted from the NCI Pro-CTCAE and was administered via text-message 96 hours prior to the patient's scheduled infusion visit. Patient perspectives were quantified via a 13-item questionnaire. **Results:** Between October 1 and November 25, 2021, 50 patients enrolled in the study, and 45 patients completed the instrument (90% response). The median age was 68 (IQR 60-72), 31 (62%) were male, and 44 (88%) were white. Most patients received either pembrolizumab (n=27, 54%) or nivolumab (n=17, 34%) in the palliative setting (n=37, 74%) for genitourinary (n=15, 30%), lung (n=13, 26%), or skin (n=11, 22%) cancer. Patients who completed the instrument were younger (median age 67 vs 76) than those who did not complete the instrument. The prevalence of immune related toxicity documented in the EMR was 57.8%. The sensitivity and negative predictive value of the instrument was 100% (95% CI 0.87-1.00) and 100% (95% CI 0.664-1.00), respectively; other accuracy parameters are presented in the Table. The patient user questionnaire revealed that visual impairment, lack of access to a smart phone, and lack of recognition of the instrument were barriers to completion. **Conclusions:** A text-based platform is both feasible and effective at identifying patients who are not experiencing symptoms of immune toxicity, and when combined with lab assessment, can eliminate office visits for up to 47% of patients. A prospective clinical trial to assess this is underway (NCT05134636). Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Financial toxicity in Hispanic cancer survivors: A nationally representative pancancer analysis. *First Author: Nishwant Swami, University of Massachusetts Medical School, Worcester, MA*

Background: A cancer diagnosis can pose a significant financial burden to patients and their families, both during and after treatment. Financial toxicity has long-term consequences, with cancer being the most commonly cited reason for medical cost-associated bankruptcy in the United States. We used nationally representative survey data to assess financial toxicity in cancer survivors, with a focus on Hispanic patients given known disparities in socioeconomic and cancer outcomes. **Methods:** 2013-2018 data from the National Health Interview Survey (NHIS) was used to select individuals aged 18 years old and older who reported any previous diagnosis of cancer. Financial toxicity was defined as unmet healthcare need, health care unaffordability, and/or general financial stress. Individuals were disaggregated by race/ethnicity, and patients who self-identified as Hispanic were further classified by country of origin. Survey-adjusted percentages characterize the cohort. Multivariable logistic regression generated adjusted odds ratios (aORs) with 95% CI for each category of financial toxicity, with non-Hispanic White (NHW) used as reference. **Results:** Hispanic patients in aggregate had the highest prevalence of all 3 categories of financial toxicity when compared to other racial/ethnicity groups (35% unmet healthcare need, 61% healthcare unaffordability, 61% financial stress). Mexican (aOR: 2.53 95%CI: 1.82–3.52), Cuban/Cuban-American (aOR: 1.97 95%CI: 1.17–3.34), and patients of Central/South American heritage (aOR: 2.61 95%CI: 1.67–4.10) were more likely to have healthcare unaffordability. Unmet healthcare needs were higher in Mexican patients (aOR: 1.43 95%CI: 1.03-1.99) and patients of Cuban descent (aOR: 1.96 95%CI: 1.07-3.58). Financial stress was highest among patients of Central/South American heritage (aOR: 4.20 95%CI: 2.50-7.05) and Mexican patients (aOR: 1.84 95%CI: 1.27-2.66). Mediator analyses further revealed that disparities persisted even after adjusting for socioeconomic status in Mexican patients (healthcare unaffordability - aOR: 1.65 95%CI: 1.14-2.40) and patients of Central/South American heritage (healthcare unaffordability – aOR: 1.99 95%CI: 1.23-3.21; general financial stress – aOR: 2.97 95%CI: 1.71 – 5.17). **Conclusions:** Our study highlights significant disparities in the financial impact of cancer treatments on Hispanic patients. Disaggregation by Hispanic country of origin illustrates differences within the Hispanic and Hispanic-American population and reveals specific groups that may be at particular risk of financial harm. Targeted interventions to improve health care access and affordability are needed to increase equity and improve outcomes. Research Sponsor: None.

Analysis of demographic characteristics and disparities of enrollment in cancer clinical research at the U.S. National Cancer Institute (NCI): A 15-year experience. *First Author: Nirmal Choradia, National Cancer Institute, Bethesda, MD*

Background: Racial, gender, and socioeconomic disparities in cancer clinical trials participation have been well documented. The intramural program of the NCI in the National Institutes of Health (NIH) Bethesda campus conducts clinical research where participants are referred by their physician or self-referred, treated without charge and receive aid in travel expenses. We sought to describe the demographics of participants and identify potential disparities. **Methods:** We used the clinical research data repository of the NIH, Biomedical Translational Research Information System (BTRIS), to extract self-reported demographic data of enrollees in NCI protocols from 2005-2020. Comparisons were made with the U.S. population of patients with cancer as captured in the Surveillance, Epidemiology, and End Results (SEER) Program (2005-2018). The average household income per zip code was derived from the American Community Survey at five-year increments from 2011, 2015, and 2019. **Results:** We obtained data on 40,007 participants; 38,531 (95%) came from the U.S., of which 18,606 (48%) from DC, Maryland, or Virginia (DMV). Median age at consent was 54 years (range 2 – 89). Proportions of basic demographic attributes and corresponding values from SEER data were presented. Notably, Hispanic male, non-Hispanic female, and white female participants were under-represented in NCI clinical research compared to SEER data. African Americans were under-represented in the non-DMV population (5%) vs. the DMV (19%). Also, for patients from the DMV area, median income was consistently less for African American participants compared to White and Asian participants. **Conclusions:** The identified disparities may be partially due to the specific research activities available at the NCI, but strategies aiming at increasing the participation and representation of under-represented groups are required. Research Sponsor: None.

Availability of data for screening, offering, and consenting patients to cancer clinical trials: Report from an ASCO-ACCC collaboration. *First Author: Alice R. Pressman, Sutter Health, Walnut Creek, CA*

Background: Only a small fraction of patients with cancer participate in treatment trials. Patients identifying as members of racial and ethnic minority groups are consistently underrepresented in these trials. A recent systematic review reported that patients, regardless of race and ethnicity, are willing to enroll in trials if asked to participate by their treating clinician. Prospective and longitudinal data and metrics at the site- and clinician-level are necessary to understand whether patients are equitably considered for clinical trials. **Methods:** ASCO and Association of Community Cancer Centers (ACCC) developed a self-assessment for trial sites to record and gauge the number of patients across races and ethnicities screened, offered, and enrolled into clinical trials. Research sites, from across the US, were recruited through an open call to apply to participate in the ASCO-ACCC Pilot Project. There were 65 sites assigned to this pilot study, which tested the feasibility and utility of the site assessment. Sites were asked to enter 2019 and 2020 aggregate data for each step along the clinical trial enrollment continuum by select races and ethnicities (Black, Hispanic/Latinx, White) and overall. **Results:** 62 of 65 sites completed the study and represented a range of settings and practice types (61% academic, 26% hospital/health system, 13% independent). Only 2 sites (3%) were able to provide the data requested at each enrollment step in the assessment (table). Sites that collected the data did not do so routinely (table) and most had to compile data through multiple sources and/or manual extraction (40-100% across enrollment steps). Sites with missing data reported they did not collect data at all (36-64% across enrollment steps), did not collect data in a systematic way (0-29% across enrollment steps), or stated it would be too burdensome to manually review charts to extract data (12-29% across enrollment steps). **Conclusions:** Data collection and routine evaluation of participation metrics, by race and ethnicity, are necessary to assess and monitor equity and diversity in clinical trials. Most sites in this study did not collect, or routinely collect, data for screening, offering, and consenting patients to clinical trials. Without these data, sites are unable to evaluate and monitor whether their patients have equitable access to clinical trials or establish strategies to address any inequities. ASCO and ACCC will continue to partner with sites to better understand their processes and the feasibility of collecting such data in a systematic and automated way, such as through electronic health record systems. Are pivotal clinical trials for lymphomas that led to drug approval representative of the population affected by these diseases? *First Author: Mycal Casey, Medical College of Georgia, Augusta, GA*

Background: There are significant inequities in cancer care and outcomes in the United States (US) and worldwide. Race, ethnicity, and sex all define sub-groups affected by these inequities. Randomized controlled trials (RCTs) provide new therapies in cancer care. Many new drugs have been recently approved for the management of lymphoma. We examined whether pivotal clinical trials included populations representative of those affected. **Methods:** Lymphoma clinical trials were collected from the US Food and Drug Administration (FDA) Databases 'Oncology (cancer)/Hematologic Malignancies approval notifications' and 'Novel Drug Approvals' between 2011 and 2021. Trials were also reviewed for demographic data on ClinicalTrials.gov (CT.gov) and Primary Literature related to the drug approval. Only studies for adult patients were included; one study was excluded due to inconsistencies in the total patients enrolled and the totals by race. Chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) RCTs were not included. The burden of diseases based on Surveillance, Epidemiology, and End Results (SEER) data was used as a comparison for US participants. **Results:** Thirty-three pivotal trials were identified from the FDA databases (2011-2021); 18 (54.5%) had available race data on CT.gov or in Primary Literature. Three trials focused on classical Hodgkin's Lymphoma (cHL) and 15 on Non-Hodgkin's Lymphoma (NHL). Two of the three trials for cHL with available data for race reported ethnicity data. Only 10 of 15 NHL trials that reported race demographics had available ethnicity data. Table 1 shows trials that had available data for race and ethnicity along with proportions from the SEER data. There was underrepresentation of Blacks and to some extent Hispanics in both cHL and NHL trials. Females were also underrepresented, particularly in NHL trials. **Conclusions:** There is racial, ethnic, and sex misrepresentation within clinical trials that led to approval of drugs for lymphomas in the US between 2011 and 2021. In addition, there was significant underreporting of racial and ethnic subgroups noted in the clinical trials. Research Sponsor: None.

Overcoming barriers to tumor genomic profiling through direct patient social media outreach. *First Author: Seyram A Doe-Tetteh, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Tumor genomic profiling is increasingly used to identify actionable genomic alterations as a guide to therapy selection. To overcome barriers to genomic testing for patients with rare cancers, we initiated a program to offer free clinical tumor genomic testing worldwide to patients with select rare cancer subtypes. **Methods:** Patients were recruited through social media outreach, engagement with disease advocacy groups, or via physician referral, with a focus on recruiting patients with histiocytosis, germ cell tumors and rare pediatric cancers. Tumor and patient-matched germline DNA were analyzed using the MSK-IMPACT targeted sequencing next generation sequencing panel with return of results to patients and their local physicians. Whole exome recapture of MSK-IMPACT DNA sequencing libraries was performed for patients with female germ cell tumors to define the genomic landscape of this rare cancer subtype. **Results:** 359 cancer patients expressed interest in the Make-an-IMPACT program, of whom 333 were enrolled. Tumor tissue was received for 288 (86.4%), with 250 (86.8%) having tumor DNA of sufficient quantity and quality for MSK-IMPACT testing. 14 histiocytosis patients have received genomically guided therapy to date, of whom 13 (93%) have had clinical benefit based on local MD response assessment with a mean treatment duration of 16.7 months (range 3-32+). Whole exome sequencing of ovarian GCTs identified a subset with fully haploid genotypes, a phenotype rarely observed in other cancer types. Actionable genomic alterations were rare in ovarian GCT (28%), however, 2 ovarian GCTs and squamous transformation had high tumor mutational burden, one of whom had a complete response to pembrolizumab. **Conclusions:** Social media outreach can facilitate the assembly of cohorts of rare cancers of sufficient size to define their genomic landscape. By profiling tumors in a clinical laboratory, results could be reported to patients and their local physicians where they could be used to guide treatment selection. This can also open the door to diversifying and being able to study the genomic landscape in a diverse cohort. Research Sponsor: Cycle for Survival, the Marie-Josee and Henry R. Kravis Center for Molecular Oncology.

Cost of consent document (CD) translation is a potential barrier to consenting limited English-proficient participants (LEPPs) in non-industry–sponsored studies (NISS). *First Author: Maria A Velez, Department of Medicine, Division of Hematology/Oncology, UCLA, Los Angeles, CA*

Background: Racial/ethnic minority patients (pts) are underrepresented in cancer clinical trials. Challenges specific to LEPPs include the need for translated CDs, which can cause research delays and add cost. While most enrollment barriers are similar between industry sponsored studies (ISS) and NISS, costs of CD translation are typically covered by the sponsor in ISS. NISS often have limited, or no funds allocated for CD translation. Although it is required that LEPPs sign translated CDs, we hypothesized that investigators on NISS would find ways to avoid incurring the cost of CD translation. **Methods:** All pts who consented to studies at the UCLA Jonsson Comprehensive Cancer Center from 2013-2018 were included. Electronic health record data was reviewed. Adult LEPPs had a primary language other than English and their chart either flagged them as needing an interpreter or the pt used an interpreter in their care 6 months before or after the consent date. For pediatric patients, regardless of the pt s primary language, LEPPs had a guardian who needed an interpreter within 6 months of the consent date. CD language was documented when available by chart review, but when not, we evaluated all IRB-approved CDs for the corresponding study and assumed that the pt signed appropriately translated CDs if available at the time of consent or within the following month. Chi square tests were used to compare the proportion of LEPPs who consented to NISS vs ISS and the proportion of LEPPs who consented with CDs not in their primary language. All analyses were performed using JMP, Version 16. SAS Institute Inc., Cary, NC, 19892021. **Results:** Although we do not have access to data on to whom consents were offered, of the 12202 consenting events during the study period, the proportion of consenting events for LEPPs was 2.7% in NISS vs 5.4% for ISS ($p < 0.01$). This difference did not appear to be driven by study type, as results were similar when only consenting events for interventional studies ($n = 9886$) were considered, with LEPPs representing 2.4% in NISS vs 5.5% in ISS ($p < 0.01$). Among LEPPs, 67.2% of participants who consented to NISS consented with CDs in a language other than their primary language vs 32.2% in ISS ($p < 0.01$). LEPPs who consented with language appropriate CDs represented 0.9% of those consenting to NISS vs 3.7% for ISS ($p < 0.01$). **Conclusions:** LEPPs consented less frequently to NISS compared to ISS, and when they did consent to NISS, the CDs were usually not translated into the pt s primary language. We posit that the cost of translating CD discourages investigators from consenting LEPPs to NISS. Approaches that reduce or eliminate translation costs should increase the availability of translated CDs, potentially increasing enrollment of LEPPs to NISS while ensuring that they are fully informed about the purpose, procedures, and risks involved in these trials. Association of U.S. county social vulnerability with cancer mortality. *First Author: Akhil Mehta, Loma Linda University Department of Internal Medicine, Loma Linda, CA*

Background: Social determinants of health (SDOH) can predispose underserved communities to poor cancer outcomes. The CDC has created a Social Vulnerability Index (SVI) score for US counties that integrates four SDOH: socioeconomic status, household composition & disability, minority status & language, and housing type & transportation. Scores range from 0 to 1, with higher values signifying more vulnerability. SVI is a significant determinant of overall mortality, but its association with cancer mortality is unclear. This study aimed to investigate if there is a relationship between SVI and cancer mortality. **Methods:** CDC WONDER (Wide-Ranging Online Data for Epidemiological Research) was used to estimate age-adjusted mortality rates per 100,000 person-years with 95% CIs for adults > 18 years of age from 3,030 (96%) US counties between 2014-2018 for a composite of three cancers (lung, breast, and colon cancer), individual cancer subtypes, and demographic groups (sex, ethnicity/race, urban/rural classification). Age-adjusted mortality rates were compared across SVI quartiles: 1st (least vulnerable) to 4th (most vulnerable). Linear regression was used to identify the association between the 4th vs. 1st SVI quartile and the odds of being above the median mortality rate for composite cancers, individual cancer subtypes, and demographic groups. **Results:** Overall, age-adjusted composite cancer mortality rate per 100,000 person-years was 122.9 (lung cancer 82.8, breast cancer 38.1, colon cancer 21.9). The largest concentration of most vulnerable US counties and composite cancer mortality was in the southeastern US. Age-adjusted composite cancer mortality rates increased from 1st to 4th SVI quartiles. Counties in the 4th SVI quartile vs. 1st SVI quartile were significantly more likely to be above the median mortality rate for composite cancer (OR 6.46 [95% CI, 5.16 - 8.08]), lung cancer (6.88 [5.46 - 8.66]), breast cancer (2.77 [2.17 - 3.54]), and colon cancer (6.20 [4.82 - 7.97]). Among all races, non-Hispanic Black adults in the 4th SVI quartile vs. 1st SVI quartile were significantly more likely to be above the median mortality rate for composite cancer (OR 9.46 [95% CI, 6.19 - 14.4]), lung cancer (13.8 [7.87 - 24.1]), breast cancer (5.53 [3.16 - 9.68]), and colon cancer (6.34 [3.69 - 10.9]). Moreover, rural counties in the 4th SVI quartile vs. 1st SVI quartile were between 2- to 8-times more likely to be above the median mortality rate for composite cancer and individual cancer subtypes. **Conclusions:** This study highlights the most socially vulnerable US counties have higher cancer mortality rates than the least vulnerable US counties. Furthermore, non-Hispanic Black adults and rural counties in the most socially vulnerable category have higher cancer mortality rates than those in the least socially vulnerable category. Additional work is needed to understand how SVI can be used for better resource allocation to help mitigate cancer mortality. Research Sponsor: None.

Feasibility of systematic screening for unmet social determinants of health (SDoH) needs and associated resource utilization in ambulatory oncology. *First Author: Ashley Odai-Afotey, Brigham and Women's Hospital, Boston, MA*

Background: Addressing unmet SDoH needs may reduce interruptions to cancer care caused by ED visits and hospitalizations (EDH). We aimed to determine feasibility of systematic screening for unmet patient-reported SDoH needs within a large tertiary academic comprehensive cancer center and association of unmet needs with EDH. **Methods:** We conducted a cross-sectional analysis of SDoH needs among new oncology patient (pts) consults from 5/15-9/21 at Dana-Farber Cancer Institute (DCFI). Pts completed an intake questionnaire including demographics, disease, and SDoH needs of financial distress, health literacy/numeracy, social isolation on a dichotomous or 5-point Likert scale. We ran bivariate and multivariable models on the association between demographics, SDoH and EDH within 30 days of consult using robust generalized estimating equations controlling for clustering by consult provider. **Results:** 125,997 unique new consults were seen from 5/15 – 9/21 of which 20,913 completed the intake questionnaire and were alive at 30 days after consult. Respondents were age 40-64 (50%), female (60%), non-Hispanic (84%), White (90%) and English speaking (97%), and 7% had an EDH within 30 days of consult. The most reported SDoH need was limited health numeracy (26%). In bivariate analysis, factors associated with ED visits were: non-English language, lung or GU/GYN cancer, living > 25 mi from DFCI and limited health literacy and numeracy (all $p < 0.05$). Demographics associated with hospitalizations included: White race and English as a primary language (EPL) (both $p < 0.05$). Multivariable analysis showed female gender (OR 1.53, $p < 0.01$), lung (OR 3.22*) and GU/GYN (OR 2.21*) ($p < 0.05$ for both) cancer, and living > 25 mi from DFCI (OR 2.50, $p < 0.0001$) were associated with increased likelihood of ED visit while EPL (OR 1.80, $p < 0.05$) and GU/GYN (OR 1.65, $p < 0.01$*) cancer were associated with increased likelihood of hospitalization. **Conclusions:** It is feasible to systematically screen for unmet SDoH which are associated with increased frequency of ED visits. Differences in characteristics associated with ED vs. hospitalization could indicate possible bias or suggest SDoH needs as a reason for avoidance of costly medical care. Further study will expand SDoH screening and measure impact of resource matching to reduce disruptions to cancer care. Research Sponsor: Brigham and Women's Leadership for Health Equity Grant.

Incidental pulmonary nodules, lung cancer screening, and lung cancer in the Medicare population. *First Author: Raymond U. Osarogiagbon, Multidisciplinary Thoracic Oncology Department, Baptist Cancer Center, Memphis, TN*

Background: Low-dose CT lung cancer screening (LDCT) saves lives, but only 5%-10% of eligible persons in the US have participated. Management of indeterminate pulmonary nodules (IPNs) identified on CT scans may also reduce lung cancer mortality. We assessed the frequency of IPNs, estimated cumulative lung cancer rates following IPNs, and compared characteristics of lung cancers diagnosed following IPNs versus LDCT screens. **Methods:** We defined 2 cohorts in the SEER-Medicare database: persons with 12+ months of Medicare Part A&B coverage during 2014-2019 comprised the 5% sample cohort; persons in SEER-Medicare diagnosed with lung cancer during 2015-2017 with Part A&B coverage for the prior 18-month period comprised the lung cancer cohort. We defined IPNs as chest CTs with ICD-10 codes of R91.1 (solitary pulmonary nodule) or R91.8 (other nonspecific abnormal finding of lung field) on the same date as the CT; we used corresponding ICD-9 codes through September 2015. We classified lung cancer cohort cases by whether they had an LDCT (LDCT group), an IPN without an LDCT screen (IPN-only), or neither (Referent) within 18 months before diagnosis. We compared cancer stage and survival between these groups. **Results:** Of 627,547 subjects in the 5% sample cohort, 58.6% were women; 85.6% were non-Hispanic White (NH-Whites) and 7.7% non-Hispanic Black (NH-Blacks). Over median 5.0 years follow-up, 26.3% had chest CTs and 12.0% had IPNs. The IPN rate was similar by sex but significantly higher in NH-Whites (12.7%) than NH-Blacks (9.7%). The cumulative lung cancer rate following initial IPNs was 2.27% at two years. Of the 44,194 lung cancer cohort cases (85.8% NH-White, 8.2% NH-Black), 26.9%, 2.9% and 70.2% were in the IPN-only, LDCT, and Referent groups, respectively. NH-Whites comprised a higher proportion of LDCT than of IPN-only cases (90.1% vs. 88.4%), while for NH-Blacks, the reverse was true (5.4% vs. 6.5%). The ratio of LDCT:IPN lung cancer cases was 1:9. Among IPN-only and LDCT group cases, 52.0% and 50.3%, respectively, were localized stage, compared to 21.5% for the Referent group. Among all localized cases, 45.4% and 4.9% were in the IPN-only and LDCT groups, respectively. Comparing 3-year survival between IPN vs LDCT vs Referent groups, respectively: aggregate overall survival rates were 53.5% v 59.2% v 29.2%; aggregate lung cancer-specific survival, 71.1% v 75.3% v 46.6%; overall survival for localized cases, 73.2% v 80.7% v 62.9%; lung cancer-specific survival rates for localized cases, 88.2%, 91.8% and 81.4%. **Conclusions:** Subjects with IPNs had similar stage distribution and survival as LDCT-screened subjects. Almost half of localized cases had prior IPNs, compared to a < 5% of LDCT-screened cases. IPN programs, by circumventing implementation barriers to LDCT, may expand access to early lung cancer detection, including to African American patients and in places where LDCT coverage is not available. Research Sponsor: None.

Population-based impact of rurality and neighborhood-level socioeconomic disadvantage on pediatric cancer mortality in Washington State. *First Author: Timothy James Daeeun Ohlsen, Pediatric Hematology/Oncology, Department of Pediatrics, University of Washington, Seattle, WA*

Background: Emerging evidence suggests mortality among children with cancer differs based on socioeconomic factors. The effects of residential location in relation to these factors are not well-characterized. We examined associations of rurality and neighborhood-level socioeconomic (SE) disadvantage with mortality in pediatric patients with cancer. **Methods:** We conducted a retrospective cohort study using Washington State (WA) Cancer Registry data (1992-2013) linked to state birth (1974-2013) and death records (1992-2013) to identify all children born in WA diagnosed with cancer < 20 years. We defined rural residence as patient addresses within 2010 census tract level rural-urban commuting area (RUCA) codes of ≥4.0 at diagnosis. Neighborhood-level socioeconomic disadvantage was determined using 2010 census block-group level Area Deprivation Index (ADI) quintiles normalized to WA. Patient addresses within the highest ADI quintile were categorized as having SE disadvantage. children in four mutually exclusive groups was compared using Kaplan-Meier analysis, pairwise log rank testing, and Cox proportional hazard ratios (HR): non-rural with SE disadvantage, rural without SE disadvantage, rural with SE disadvantage, and non-rural without SE disadvantage (). Models were adjusted for sex, race and ethnicity, age at diagnosis, birth year, and cancer type. **Results:** We identified 4,417 children for analysis. Median length of follow up among survivors was 5.0 years (interquartile range: 1.0-11.5). SE disadvantaged and 13% were rural. Pairwise log rank tests showed mortality differences among children living in rural, SE disadvantaged, or rural and SE disadvantaged neighborhoods when compared with children without either factor (individual p-values all < 0.005); no other differences were noted. Relative to children in non-rural areas without SE disadvantage, the mortality HR for those in non-rural areas with SE disadvantage was 1.68 (95% confidence intervals [CI] 1.37-2.07). The HR for children in rural areas without SE disadvantage was 1.59 (95% CI 1.19-2.12). The HR for children in rural areas with SE disadvantage was 1.56 (95% CI 1.20-2.03). In sub-analyses, associations for rurality and SE disadvantage remained significant for leukemia mortality, but CNS and solid tumor mortality was only associated with SE disadvantage (but not rural) status. Acute lymphoblastic leukemia mortality was associated with rural (but not SE disadvantage) status. **Conclusions:** Children with cancer living in socioeconomically disadvantaged and/or rural neighborhoods at diagnosis had higher mortality relative to those in non-rural areas with lower neighborhood deprivation. Associations varied by disease type. The individual effects of SE disadvantage and rurality suggest that interventions should be designed to target both factors. Cancer risk factors and cancer in transgender versus cisgender people: Real-world data from a tertiary health care institution. *First Author: Ash B. Alpert, Brown University School of Public Health, Providence, RI*

Background: Data are sparse regarding the prevalence of cancer and cancer risk factors among transgender people. Transgender people experience structural stigma and extreme rates of violence that may contribute to cancer through multiple mechanisms. The purpose of this study was to assess cancer risk factors and cancer in transgender people in a single institutional electronic health record (EHR) and compare the rates to those among cisgender, or non-transgender, people. **Methods:** Using a combination of structured gender identity data, diagnosis codes, and keyword searches, we identified a cohort of transgender people seen at our institution, a large tertiary care center. We next identified a cohort of cisgender people matched by age, year of first encounter in our EHR, and years of follow-up. Among these cohorts, we searched for cancer, premalignant lesions, human immunodeficiency virus (HIV), human papilloma virus (HPV), and hepatitis and assessed body mass index (BMI) and smoking status through structured EHR fields. Lastly, we compared the prevalence of cancer, premalignant lesions, and cancer risk factors between the two cohorts using chi-square tests. If expected cell sizes were <5, exact tests were used. **Results:** We identified cohorts of 923 transgender and 1846 cisgender people matched by age, follow-up time, and year of the first encounter. Rates of smoking (42 versus 34%, p < 0.0001), BMI ≥ 40 (21% versus 13%, p < 0.0001), and HIV (3 versus 0%, p < 0.0001) were significantly higher among transgender compared with cisgender people. Rates of premalignant lesions and cancer did not significantly differ between cohorts. **Conclusions:** In this large sample of patients seen at our institution, rates of several cancer risk factors were higher for transgender than cisgender people. No differences were demonstrated in prevalence of premalignant lesions and cancer between groups. These data require confirmation in larger national datasets. Interventions that decrease structural oppression and provide support for tobacco cessation, decreased transmission of HIV, and access to high-quality food and exercise are also called for. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Cancer risk factors and cancer in transgender and cisgender people.

Theory-guided assessment of barriers and facilitators to adequate informed consent for childhood cancer clinical trials: Using the Exploration, Preparation, Implementation, Sustainment (EPIS) framework. *First Author: Paula Aristizabal, University of California San Diego Moores Cancer Center, Population Sciences, Disparities and Community Engagament, La Jolla, CA*

Background: To participate in childhood cancer clinical trials, parents/legal guardians must provide informed consent (IC), which is a fundamental ethical right. However, barriers to achieving valid IC include: use of medical jargon, misunderstanding about clinical trials procedures, tremendous emotional distress surrounding the initial cancer diagnosis, and the complexity and length of the IC forms. There are scarce data on using theory to assess perspectives of parents of children with cancer on barriers and facilitators for adequate IC in diverse populations. **Methods:** Using implementation science theory and methods, we assessed parent-reported barriers and facilitators to adequate IC, in a convenience sample that included a significant number of Hispanics. Twelve qualitative semi-structured interviews and 224 open-ended surveys were conducted with 236 parents of children with newly-diagnosed cancer at Rady Children's Hospital-San Diego, a large quaternary children's hospital in California. Fifty-three percent of participants were Hispanic and 38% were monolingual Spanish-speakers. We utilized the Exploration, Preparation, Implementation, Sustainment (EPIS) Framework, specifically domains of outer context, inner context, bridging and innovation factors. Four main codes (IC concepts and delivery; desired clinical trial information; motivations and emotions related to clinical trial enrollment; and potential areas for interventions) were used as a coding guide for analysis. Interviews and surveys were transcribed and coded for thematic analysis by three independent coders to identify key barriers and facilitators. **Results:** Four main themes were identified as barriers: 1) Complexity of the IC forms and discussion (lengthy, confusing, not available in Spanish, and use of medical jargon); 2) parents feeling emotionally overwhelmed, anxious and pressured around the IC; 3) parents viewing the clinical trial as the only treatment option; and 4) mistrust and fear of clinical trial procedures. Four IC facilitators were identified: 1) simpler explanations of study procedures; 2) provider flexibility for accommodations when delivering the IC, including psychosocial support; 3) active promotion of voluntariness and trust; and 4) supplemental education in lay language, including request for peer-education, decision aids, and navigation to "bridge the provider-patient gap." **Conclusions:** Our implementation science approach identified multiple barriers and facilitators to adequate IC in a diverse sample of parents. Findings can inform potential interventions to enhance IC for childhood cancer clinical trials, including the use of decision aids, peer-navigation, and interventions tailored to the language and culture of the individual. Racial/ethnic disparities in serious illness communication for patients with cancer. *First Author: Julia L. Frydman, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Racial/ethnic disparities in serious illness communication exist between patients with cancer and their oncologists. Our prior work has shown that goals of care discussions are three minutes shorter with racial/ethnic minority patients. In this study, we sought to compare oncologist's use of serious illness communication skills, patient participatory behavior, and overall communication quality during encounters with patients with advanced cancer of different self-reported races/ethnicities. **Methods:** We analyzed baseline recordings from a two-arm multisite randomized controlled trial to test a coaching model of communication skills training for solid tumor oncologists and their newly diagnosed advanced cancer patients. We audio recorded post-imaging patient-oncologist encounters for patients receiving systemic cancer treatment and coded transcripts for oncologist's use of serious illness communication skills (coded as count/encounter): open-ended questions, reflections, empathic responses to patient empathic opportunities, empathic statements, "sorry" statements, and elicitation of questions. We also assessed global codes of oncologist communication (assessed on 5-point Likert scales): flow, concerns addressed, attention, warmth, and respect. Finally, we coded patient participatory behavior (coded as count/encounter): asking questions and assertive responses. We compared the skills and behaviors by race/ethnicity of the patient using the non-parametric Kruskal-Wallis test. **Results:** We included the 56 (38%) recordings with oncologists who did not receive the intervention. The patients in these encounters were 25 (45%) female; 32 (57%) over the age of 65; 23 (41%) White Non-Hispanic, 20 (36%) Black Non-Hispanic, and 11 (20%) Hispanic. Overall, oncologists responded empathically to patients' emotions only 19% of the time. Oncologists used fewer reflective statements with Black Non-Hispanic patients (mean 0.3 statements/encounter) as compared to White Non-Hispanic patients (1.1) and Hispanic patients (1.1), $p = 0.02$. Furthermore, coders rated oncologists as being less likely to address concerns of Black Non-Hispanic patients (mean Likert scale 3.1) as compared to White Non-Hispanic (3.8) and Hispanic (3.4) patients, $p = 0.04$. Finally, coders rated oncologists as having less warmth with Black Non-Hispanic patients (mean Likert scale 2.9) as compared to White Non-Hispanic (3.8) and Hispanic (3.3) patients, $p = 0.04$. **Conclusions:** In this diverse sample of patients with advanced cancer, oncologists used fewer reflective statements, were less attentive to concerns, and expressed less warmth with Black Non-Hispanic patients. Interventions are needed to overcome these striking racial/ethnic disparities in serious illness communication for patients with cancer. Research Sponsor: PCORI.

Health literacy in patients with cancer: A multicenter national study. *First Author: Elena Paillaud, AP-HP, Hôpital Européen Georges Pompidou, Department of Geriatrics, Paris, France*

Background: Health literacy (HL) is defined as the motivation and skills to access, understand, evaluate, and use information to make appropriate health decisions. The level of LS is low in Europe, including in France. For chronic patients, a low literacy is associated with limited skills in the self-management of the disease, the monitoring of treatments and is an obstacle in therapeutic education. In France, there is no study on patients with cancer. However, our pilot study with older adults with cancer showed that 72% had a low level of LS, a level defined by a questionnaire validated in French (Functional, Communicative and Critical Health Literacy-FCCHL, a score ≤ 4 = low level). The objective of this multicenter study is to evaluate HL in 2 cohorts of cancer patients: adults aged 65 and over (OLD) and adults aged 18 to 64 (Y). **Methods:** This multicenter cross-sectional study enrolled 1,518 patients aged 18 and over from 27/09/21 to 29/10/21 in 26 centers. Patients were either admitted in outpatient unit, or seen in oncology/geriatric oncology consultation, and with a treatment plan. They completed the FCCHL and 11 questions on the use of digital. Demographic and health data were also collected. The FCCHL consists of 3 subscales evaluating functional (access to information – 5 items), interactive (understanding of information – 5 items) and critical (use of information – 4 items) HL. The score for each subscale is calculated by taking the sum obtained for each item divided by the number of items and varies from 1 (low) to 5 (high). The overall score is calculated from the subscale scores. The primary endpoint was the rate of patients with an overall score of HL $\leq$ 4 (no. of subjects estimated at 420 per cohort, considering non-evaluable patients and an expected rate of HL ≤ 4 from 70% to 80%). Patients' characteristics and their use of digital have been described. In addition, a multivariate exploratory analysis of the factors associated with an LS≤ 4 in the OLD cohort was performed. **Results:** Most patients (1,327(87%)) had completed all the FFCHL items (658 (84%) OLD cohort; 669 (91%) Y cohort). The proportion of men was higher in the OLD cohort (48% vs 34% Y cohort). Many of the patients lived at home in the 2 cohorts (98%) and half in urban area (56% cohort OLD vs 52% cohort Y). The patients had an advanced stage of cancer (70% OLD cohort vs 61% Y cohort). A low level of HL was reported in 70% of the Y cohort and in 78.7% of the OLD cohort. The use of digital tools was lower in the OLD cohort: 41% had never used the internet for their health vs. 14% in cohort Y; this use was very low for online consultations (respectively 83 and 64% never used them). For the OLD cohort, only advanced and/or metastatic cancer stage was associated with HL≤ 4 (after center adjustment). **Conclusions:** These results show a low level of HL in older as in the younger population. Actions need to be implemented for the detection of moderate or weak HL in the way to reduce barriers in the management of cancer treatments. Research Sponsor: PACan platform / French National Cancer Institute.

Bringing experimental therapeutics clinical trials network (ETCTN) to underrepresented population. *First Author: Joaquina Celebre Baranda, University of Kansas Cancer Center-Clinical Research Center, Fairway, KS*

Background: Access to health care including clinical trials (CT) leading to paradigm-changing cancer treatments are critical for high quality cancer care and equity in society. In this report, we highlight methods in accruing to ETCTN wherein underrepresented rural, low-income, and racial minorities comprise >50% of enrollment. **Methods:** University of Kansas Cancer Center (KUCC) is one of eight National Cancer Institute (NCI) designated cancer centers awarded CATCH-UP.2020 (CATCH-UP), a congressionally mandated P30 supplement to enhance access for minority/underserved populations to ETCTN precision medicine CT. KUCC catchment area is 23% rural by Rural Urban Continuum Codes (RUCC); almost 90 % of counties are designated primary care HPSA's (Health Professional Shortage Areas). KUCC Early Phase and Masonic Cancer Alliance (rural outreach network) partnered to operationalize CATCH-UP. We engaged disease-focused champion investigators in disease working groups and MCA physicians who selected scientifically sound CT that fit catchment area needs. Patient and Investigator Voices Organizing Together, a patient research advocacy group provided practical feedback. MCA navigator coordinated recruitment. Telehealth was used for rural patients that would have a significant distance to travel just to be screened. **Results:** CATCH-UP was initiated in September 2020. Twenty-eight CT were activated, many in community sites. Average activation time was 81 days. Delays were mainly from CT amendments. KUCC enrolled the first patient in the CATCH-UP program. In 6 months, we met accrual requirements (24/year, 50% minorities). During first year, we enrolled 47 (>50% minorities), an increase of 680% from our average accrual of 6/year (>50% minorities) in ETCTN through Early Drug Development Opportunity Program (2016-2020). To date, we have enrolled 61, 54% from rural, HPSA, race and other minorities. Although the proportion of minorities did not change but remained high, this funding allowed us to substantially increase the number of patients from a catchment area with high proportion of geographically and socioeconomically underserved minorities given access to early phase CT through ETCTN. **Conclusions:** Amid COVID-19 pandemic, the NCI CATCH-UP program and methods we used allowed access to novel therapies for rural, medically underserved, and other minority groups. Funded by NIH: 3P30CA168524-09S2. Research Sponsor: U.S. National Institutes of Health.

Representativeness of patients enrolled in the Lung Cancer Master Protocol (Lung-MAP). *First Author: Riha Vaidya, SWOG Statistics and Data Management Center, Seattle, WA*

Background: A major goal of Lung-MAP, a biomarker-driven master protocol conducted within the National Clinical Trials Network of the NCI using a public-private partnership, was to improve access to novel therapeutics. Representative enrollment of patient sub-groups in clinical trials is essential for improving confidence that trial findings are valid and applicable to all patients. We examined the representativeness of patients enrolled in Lung-MAP by demographic and area-level measures compared to patients in other advanced non-small cell lung cancer (NSCLC) trials and with the US NSCLC population. **Methods:** We analyzed data on patients enrolled to Lung-MAP between 2014-2020 according to sex, age (< 65 years v. ≥ 65 years), race (White v. Black v. Asian), ethnicity (Hispanic v. not Hispanic), residence (rural v. urban), insurance type (Medicaid or no insurance v. private), and neighborhood socioeconomic deprivation (quintiles of Area Deprivation Index score). Rates were compared to SWOG-led NSCLC trials conducted between 2001-2020 (date range to provide sufficient power) and, where possible, to US NSCLC population rates using Surveillance, Epidemiology, and End Results (SEER) registry data (2014-2018). Two-sided tests of proportions at the 5% level were used for all comparisons. **Results:** 3,556 patients enrolled to Lung-MAP were compared to 2,267 patients enrolled to SWOG-led NSCLC studies. Lung-MAP patients were more likely to be ≥ 65 years old (57.2% v. 46.7%; $p < .001$) and from rural areas (17.3% v. 14.3%; $p = .002$) but less likely to be female (38.6% v. 47.2%; $p < .001$), Asian (2.7% v. 5.1%; $p < 0.0001$), or Hispanic (2.4% v. 3.7%; $p = .003$). Compared to the US NSCLC population, Lung-MAP patients were less likely to be ≥ 65 years (57.2% v. 73.5%; $p < .001$), female (38.6% v. 47.8%; $p < .001$), or a racial or ethnic minority (15.5% v. 19.3%; $p < .001$). Lung-MAP patients were more likely to be from socioeconomically deprived neighborhoods (42.2% vs. 36.5%, $p < .001$). Among patients aged < 65 years, Lung-MAP enrolled more patients reporting Medicaid/no insurance as their primary insurance (27.6% v. 17.9%; $p < .001$). **Conclusions:** Lung-MAP improved access to novel therapeutics for older patients, rural patients, those with Medicaid/no insurance, and patients from socioeconomically deprived areas compared to other NSCLC trials. Lung-MAP enrolled exclusively squamous cell lung cancers from 2014-2018, which explains decreased representation of females. Consistent with prior research, Lung-MAP patients were younger and less diverse compared to the US NSCLC population. Further examination of the underrepresentation of Asian and Hispanic patients in Lung-MAP is required to identify barriers to access and potential solutions. The conduct of a master protocol across multiple locations may improve trial participation for patients with limited access due to area-level (rural, socioeconomic deprivation) or insurance barriers. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Racial disparities in receipt of guideline-concordant care for early-onset colorectal cancer in the U.S. *First Author: Leticia M Nogueira, American Cancer Society, Atlanta, GA*

Background: Early-onset colorectal cancer patients who are Black are less likely to survive than white patients, even for early-stage disease, possibly due to differences in receipt of guideline-concordant care. This study evaluated racial disparities in receipt of timely and guideline-concordant colon and rectal cancer care in a large nationwide sample. **Methods:** Non-Hispanic Black and white individuals aged 20-49 years newly diagnosed with colorectal cancer during 2004-2019 were selected from the National Cancer Database. Patients who received all care recommended by the National Comprehensive Cancer Network (staging, surgery, lymph node evaluation, chemotherapy, and radiotherapy) for which they were eligible according to cancer subsite and clinical and pathological TNM stage were considered guideline concordant. Demographic characteristics (age and sex), comorbidities, and health insurance coverage type were added sequentially to a series of multivariable models to estimate contribution to racial disparities in receipt of guideline-concordant care. Racial disparities in time from diagnosis date (among rectal cancer patients eligible for neoadjuvant chemotherapy) and surgery date (among colon cancer patients eligible for adjuvant chemotherapy) to date of chemotherapy initiation was evaluated using restricted mean survival time. **Results:** Of the 84,728 colon and 62,483 rectal cancer patients, 20.8% and 14.5% were Black, respectively. Black patients were less likely to receive guideline concordant care than white patients diagnosed with colon and rectal cancer, respectively (Table). Demographic characteristics and comorbidities combined explained less than 5% of the disparity, while health insurance coverage type explained 28.6% and 19.4% of the disparity among colon and rectal cancer patients, respectively. Restricted mean time to chemotherapy was statistically significantly longer among Black than white patients for colon (54.0 vs 48.7 days, p < .001) and rectal cancers (49.6 vs 40.9 days, p < .001), respectively. **Conclusions:** Black patients diagnosed with early-onset colorectal cancer receive worse and less timely care than their white counterparts. Differences in health insurance coverage type, a modifiable factor, were the largest identified contributor to the racial disparities in receipt of guideline-concordant care, suggesting that improved access to care could help mitigate disparities in cancer outcomes. Research Sponsor: None.

	Guideline Concordant N (%)	Non-Guideline Concordant N (%)	Crude OR (95% CI)	Demographic Adjusted OR (95% CI)	Comorbidity Adjusted OR (95% CI)	Insurance Adjusted OR (95% CI)
Colon						
White	46,272 (69.0)	20,822 (31.0)	1.14	1.14	1.13	1.10
Black	11,672 (66.2)	5,962 (33.8)	(1.10, 1.18)	(1.10, 1.18)	(1.10, 1.18)	(1.06, 1.14)
Rectum						
White	30,317 (56.7)	23,116 (43.3)	1.36	1.36	1.35	1.29
Black	4,442 (49.1)	4,608 (50.9)	(1.30, 1.42)	(1.30, 1.42)	(1.29, 1.42)	(1.24, 1.35)

Use of modernized eligibility criteria in pancreatic cancer clinical trials. *First Author: Andrea N Riner, University of Florida, Gainesville, FL*

Background: In 2017, ASCO + Friends recommended modernized eligibility criteria to improve generalizability of clinical trial results. Traditional criteria contribute to disparities in trial participation, yet modernized criteria can equalize eligibility rates. We aimed to assess use of modernized eligibility criteria in pancreatic ductal adenocarcinoma (PDAC) clinical trials since the updated guidelines. **Methods:** Modernized eligibility criteria were obtained from ASCO + Friends guidelines. Clinicaltrials.gov was queried for "pancreas adenocarcinoma" trials from Jan. 1, 2018 onward and eligibility criteria were assessed for compliance with modernized criteria. Kruskal-Wallis and Fisher's exact tests were used to determine differences in compliance based on disease stage(s), starting year, phase, and funder. **Results:** In total, 108 clinical trials were identified - 31.5% for resectable, 56.5% for unresectable, 12.0% for both resectable/unresectable disease. Most trials were phase 1 (24.1%), phase 1l2 (15.7%) or phase 2 (45.4%). Funding sources included industry (38.0%), NIH (22.2%) and other sources (39.8%). No trial was compliant with all modernized criteria. Only 34.7% of trials allowed patients with ECOG performance status of 2. HIV+ patients were not allowed in 56.5% of trials. Only 7 trials (6.5%) were compliant with assessing renal function whereas 64.8% appropriately used upper limit of normal cutoffs for labs. Among trials that excluded patients for CHF, 59.6% used a classification system for exclusion. Specific cardiac abnormalities were excluded in 60.2% of trials. Prior malignancy was allowed in 71.3% of trials if treated > 2 years prior and concurrent malignancy, if stable, was allowed in 21.3% of trials. Prior PDAC treatment was allowed for 38.0% and required for 24.1% of trials. If prior treatment was allowed, 94% justified drug exclusions, 40.3% did not require a washout period, and 35.8% required recovery from prior adverse events. Stable/treated brain metastases were allowed in 33.8% of trials for unresectable cancer. Compliance with prior malignancy criteria improved from 2018-2019 to 2020-2022 (56.0% vs 84.5%, respectively; p = 0.001). Requirement of prior PDAC treatment was associated with disease stage (8.8% for resectable, 32.8% for unresectable, and 23.1% for both; p = 0.024), as was exclusion based on prior therapy (58.8% for resectable disease, 14.8% for unresectable, and 30.8% for both; p < 0.0001). Earlier trial phase was associated with prior treatment allowance (p = 0.002), whereas later phase trials were less likely to allow prior treatment (p = 0.021). NIH-funded trials required prior treatment (37.5%) more than industry (29.3%) or other (11.6%) funded trials (p = 0.034). **Conclusions:** Modernized eligibility criteria are inadequately implemented in PDAC clinical trials. Efforts to improve their use are warranted to produce more generalizable results and advance inclusivity. Research Sponsor: None.

Concrete resource needs and frailty among older adults with cancer: The Cancer and Aging Resilience Evaluation (CARE) Registry. *First Author: Grant Richard Williams, The University of Alabama at Birmingham, O'Neal Comprehensive Cancer Center, Birmingham, AL*

Background: Concrete resource needs (CRN: insecurity of food, utilities, and/or housing) are important and modifiable indicators of poverty. Prior work among adults with chronic cardiometabolic diseases demonstrates that CRN-targeted interventions improve health outcomes. Poverty is associated with inferior health outcomes among patients with cancer. Frailty is a recognized state of increased vulnerability and is associated with increased toxicities from cancer therapies and reduced survival. The prevalence of CRN among older adults with cancer and its role in modifying the risk of frailty remains unknown. We aimed to (1) describe the prevalence of CRN and (2) examine the association between CRN and frailty among older adults with cancer. **Methods:** The CARE registry prospectively enrolls older adults (≥60y) with cancer seen at UAB as new patients. Single-item screening measures captured food, housing and utility insecurity in addition to the baseline CARE geriatric assessment beginning 8/2020. The 44-item CARE Frailty Index (based on the principles of deficit accumulation) was used to define frailty. Multivariable analysis examined association of CRN with frailty, adjusting for age, race, sex, education, employment, marital status, and cancer type and stage. **Results:** The cohort included 485 participants with a mean age at enrollment of 69y; 63.7% were male; 20.4% were non-Hispanic Black. The most prevalent cancer types included colorectal (33.0%), pancreatic (16.3%) and hepatobiliary (12.2%) cancers. Median time from cancer diagnosis to study enrollment was 35 days. The overall prevalence of CRN was 6.6% (insecurity of housing [2.9%], food [4.3%], and utilities [4.1%]). Participants with CRN were less educated (< HS: 21.9% vs. 9.9%, p= 0.01), more often widowed/divorced (53.1% vs. 35.1%, p= 0.003) and more likely to be disabled (43.8% vs. 12.4%, p< 0.001). Overall, 33.8% of patients were frail. In multivariable analysis, patients with CRN had a 6.24 higher odds of frailty (95% CI 1.72-22.7, p= 0.005) compared to those without CRN after adjustment for above-mentioned covariates. **Conclusions:** CRN represents a novel exposure that is independently associated with frailty. In order to inform a CRN-targeted intervention for the growing number of older adults with cancer, future work is warranted to examine the CRN construct in this population, including examination of more detailed screening measures and CRN-associated cancer outcomes. Research Sponsor: U.S. National Institutes of Health.

A multilevel intervention increased accrual of Native Hawaiians and other Pacific Islanders to a national breast cancer screening trial. *First Author: Srue Wakuk, University of Hawaii Cancer Center, Honolulu, HI*

Background: The University of Hawaii Cancer Center (UHCC) Minority/Underserved NCI Community Oncology Research Program (Hawaii MU NCORP) provides access to NCI-sponsored clinical trials in Hawaii. The Hawaii MU NCORP is dedicated to increasing minority and underserved accruals to clinical trials. Native Hawaiian women have the highest breast cancer incidence and mortality; only 26% of Micronesian women in Hawaii over the age of 40 have ever had a mammogram. In 2018, the Hawaii MU NCORP became a recruitment site for the ECOG-ACRIN Tomosynthesis Mammographic Imaging Screening Trial (TMIST). A pilot study was launched in 2019, to support our NCORP recruitment of underrepresented Native Hawaiian and other Pacific Islander (NHPI) women to the TMIST study. Subsequently, specific funding was provided by the NCI's Center to Reduce Cancer Health Disparities that enabled the UHCC's Office of Community Outreach and Engagement (COE) to develop an effective multilevel recruitment strategy together with the Hawaii MIU NCORP. **Methods:** To foster community awareness of the TMIST study among NHPI women, the UHCC COE hired a Community Health Educator (CHE). The CHE, a Pacific Islander woman, utilized small group educational sessions to provide culturally and linguistically appropriate cancer prevention information and promote the TMIST study to NHPI women in Hawaii. The CHE worked in partnership with Hawaii MU NCORP clinical research associates (CRAs) in these efforts. In 2020, statewide COVID-19 health and safety protocols were enacted, limiting public group interactions in Hawaii. Despite this challenge, the CHE successfully adapted the in-person educational sessions on clinical trials and TMIST to conduct sessions using Zoom and Facebook Messenger. **Results:** Before the hire of the CHE in 2019, only one Pacific Islander (Micronesian) woman was recruited to the TMIST in Hawaii. The CHE conducted 21 community health events with 426 attendees from 2019 to 2021. The Hawaii MU NCORP NHPI TMIST enrollment went from the 9.9% in 2018 to 2019, to 20.1% in 2019 to 2020 and to 33% in 2020 to 2021. To date, 18 Micronesian, 52 Native Hawaiian and 6 Other Pacific Islander women out of 353 participants ware enrolled. **Conclusions:** The multilevel intervention of our CHE, in collaboration with NCORP staff providing clinical trial awareness training and community outreach, resulted in increasing the enrollment of NHPI women to the TMIST Trial. CHE-led community health education sessions on cancer prevention can be delivered using emergent technologies and social media. The use of culturally and gender concordant CHEs working with CRAs have the potential to increase awareness and accruals to cancer clinical trials. Research Sponsor: U.S. National Institutes of Health.

Improving access to cancer genetic testing for underserved women in southeast Texas. *First Author: Darya Aleksandrovna Kizub, UT MD Anderson Cancer Center, Houston, WA*

Background: Hereditary breast cancer accounts for 5-10% of all cases, but only 20% of eligible women undergo NCCN guideline-concordant screening. We demonstrated previously that our simple genetic risk screening tool (GRST) and telegenetics improved adherence to genetic testing guidelines and increased high-risk cancer surveillance. Our objective was to identify women eligible for genetic testing using breast cancer screening clinics in underserved communities as entry points, reach them with our tailored program, and measure impact. **Methods:** This is a prospective study in women presenting for breast cancer screening at The Rose, which provides breast imaging to underserved patients in Houston, TX. Women who consented to participate filled out the GRST and provided socio-demographic information. Those at high risk for hereditary cancer after GRST scoring were provided with educational materials and sent a saliva-based genetic testing kit. When results included a pathogenic variant (PV) or variant of uncertain significance (VUS), individuals received telegenetic counseling and risk reduction resources. Others were notified of negative results by phone. The program included education for providers about importance of genetic testing. Socio-demographic characteristics were analyzed using descriptive statistics. All statistical tests were two-sided. **Results:** 501 women filled out the GRST. Median age was 52. Median annual salary was $45,000 (IQR 21-75K). 151 (36.3%) were uninsured. 252 (50.3%) identified as White, 230 (45.9%) as Hispanic/Latino, and 106 (21.2%) as Black/African American. 150 (33%) were eligible for genetic testing; 100 could be contacted. Of the 100, 41 declined testing, 40 were lost to follow-up, 19 agreed, and 15 (10% of those eligible) returned the kits. Results included 11 negative, 2 VUS, 1 PV (NF1). Among 41 who declined testing, reported reasons included not wanting to know the results or preference to follow-up with their primary care doctor in 11 (26.8%) each, not enough time or prior genetic testing in 6 (14.6%) each, no reason given by five, and perception that testing was unnecessary in two. Completion of genetic testing was not associated with insurance, salary, family history, or race/ethnicity ($p > 0.05$). **Conclusions:** Our study was successful in identifying underserved women at high risk of hereditary cancer who have not previously undergone genetic testing using a simple screening tool. We reduced barriers to genetic testing by working with a trusted community organization and using remote testing and telegenetics. We did not find any factors associated with genetic testing completion, though results are limited by small sample size. Given the low proportion of patients who completed testing, the next project phase will focus on improving convenience for patients and exploring patient and program-related reasons for non-completion of testing and strategies to overcome these. Research Sponsor: Susan G. Komen Foundation: CGPR-2019-TX105-THAC46-00012.

Impact of depression among adolescents and young adults with cancer. *First Author: Edmund Men Qiao, Department of Radiation Medicine and Applied Sciences, University of California San Diego, La Jolla, CA*

Background: The incidence of adolescent and young adults (AYAs) with cancer continues to increase. The psychosocial burden of early cancer diagnosis within this unique AYA population remains poorly characterized. Without proper resources, these patients are likely to seek care in the acute care setting. For AYA patients, we evaluated the impact of malignancy on concurrent diagnosis with depression and on presenting to the emergency department (ED) with intentional self-injury. We further described the influence of concurrent depression diagnosis on hospital admission and extended length of stay (LOS) for AYA cancer patients. **Methods:** From the National Emergency Department Sample (NEDS), we identified patients between 15-39 years who presented to an ED in 2019. Diagnosis of cancer and depression were identified using International Classification of Diseases, 10th Revision coding. Separate multivariable logistic regressions evaluated the impact of cancer diagnosis on concurrent depression diagnosis and on presenting with intentional self-injury. For the subset of AYA cancer patients, multivariable logistic regressions evaluated the impact of depression on hospital admission and extended LOS (> 14 days). **Results:** We identified 10,570,148 AYA patients, and 35,035 had cancer (0.33%). Among AYA cancer patients, average age was 31 and the cohort skewed White (48.7%), female (58.1%), and with Medicaid insurance (48.4%). The prevalence of depression among AYA cancer patients was 9.6% vs. 4.4% for patients without cancer. On multivariable regression, AYA cancer patients had a 46% increased odds of depression diagnosis (odds ratio (OR), 95% confidence interval (CI): 1.46. [1.43-1.49] $P < 0.01$) and 32% increased odds of intentional self-injury (OR, 95% CI: 1.32 [1.19-1.47] $P < 0.01$) when compared to patients without cancer. Additional significant factors associated with depression diagnosis among AYA cancer patients were White race, female gender, and Medicaid insurance. Within AYA cancer patients, a concurrent diagnosis with depression was associated with ~3-fold increased odds of hospital admission (OR, 95% CI: 3.02 [2.90-3.14] $P < 0.01$) and a 31% increased odds of extended LOS (OR, 95% CI: 1.31 [1.23-1.39] $P < 0.01$). **Conclusions:** From this national sample, we found a significant association between cancer diagnosis and depression within AYA patients, with cancer diagnosis also increasing the risk of intentional self-injury. Furthermore, AYA cancer patients diagnosed with depression had increased risk of both hospital admission and extended LOS. Our results underscore the potential gap in psychological care for AYA cancer patients and highlight the need for stronger mental health resources for this at-risk population. Research Sponsor: None.

Disparities in delayed diagnosis, access to treatment, and treatment delays among Hispanic men with metastatic prostate cancer. *First Author: Nishwant Swami, University of Massachusetts Medical School, Worcester, MA*

Background: Reporting racial/ethnic disparities in aggregate for Hispanics could obscure differences between subgroups given heterogeneity in social determinants of health. We sought to identify differences in delayed diagnosis, treatment status, and time to treatment among Hispanic subpopulations with metastatic prostate cancer. **Methods:** 2004-2017 data from the National Cancer Database (NCDB) was used to identify patients with prostate adenocarcinoma; patients were disaggregated by racial subgroup and Hispanic country-of-origin. Ordinal logistic regression defined adjusted odds ratios (aORs) with 95% CI of 1) presenting with Stage IV cancer, 2) receiving treatment, and 3) receiving delayed treatment (defined as treatment after 90 days). Sensitivity analysis was conducted for delayed treatment after 180 days. **Results:** Among 1,305,785 patients, Hispanic men had greater odds of presenting with stage IV prostate cancer compared with non-Hispanic White (NHW) men (aOR = 1.54 95% CI 1.50-1.58, $p < 0.001$). All Hispanic racial subgroups were more likely to present with stage IV cancer with highest odds observed in Hispanic Black men (aOR 1.68 95% CI 1.46-1.93, $p < 0.001$). Disparities were also observed in all country of origin subgroups, particularly for men of Mexican heritage (aOR 1.99 95% CI 1.86-2.12, $p < 0.001$). Among men with metastatic disease, Hispanic men were less likely to receive treatment than NHW men (aOR 0.60 95% CI 0.53-0.67, $p < 0.001$). Hispanic White patients were less likely to receive treatment compared with NHW men (Hispanic White aOR 0.58 95% CI 0.52-0.66, $p < 0.001$). Upon disaggregation by country of origin, disparities persisted, particularly for men of Dominican heritage (aOR 0.52 95%CI 0.28-0.98 $p = 0.044$). Hispanic men were more likely to experience treatment delays when compared to NHW men (aOR 1.38 95%CI 1.26-1.52 $p < 0.001$). All Hispanic racial subgroups experienced greater treatment delays, particularly Hispanic Black men (aOR 1.83 95%CI 1.22-2.75 $p = 0.002$). Men of Central or South American heritage had the greatest odds of treatment delays (aOR 1.48 95%CI 1.07-2.04 $p = 0.018$). Sensitivity analysis indicated consistent findings among Hispanic patients overall, Hispanic White patients, and patients of Mexican and Puerto Rican heritage. **Conclusions:** We found notable differences in stage IV cancer at presentation, treatment for metastatic disease, and delays in treatment when outcomes were stratified by racial subgroup and Hispanic country of origin. Future studies in Hispanic populations with disaggregated data are needed to characterize outcomes, study mediators of the observed variations, and develop targeted interventions. Variation of use of targeted therapies and molecular diagnostic testing by practice type for non-small cell lung cancer and colorectal cancer. *First Author: Thomas Roberts, Dana–Farber Cancer Institute, Boston, MA*

Background: Targeted therapies are important first-line treatments for many patients with non-small cell lung cancer (NSCLC) and colorectal cancer (CRC). All patients with newly-diagnosed metastatic NSCLC and CRC should undergo molecular diagnostic testing to guide treatment selection. **Methods**: We used 100% Medicare fee-for-service data from 2015 through 2019 to identify beneficiaries with incident metastatic NSCLC or CRC receiving systemic therapy and to assign beneficiaries to oncology practices. We then assessed for use of molecular diagnostic testing and targeted therapies in these cohorts. We used linear mixed effects models to assess patient and practice characteristics associated with molecular diagnostic testing and targeted therapy use. **Results:** Rates of molecular diagnostic testing increased between 2015 and 2019 for NSCLC and CRC. In 2019, rates of molecular diagnostic testing were 85% and 65% for NSCLC and CRC, respectively. Rates of targeted therapy use did not increase over time for NSCLC or CRC, and were 8% and 5%, respectively, in 2019. Compared to National Cancer Institute (NCI)-designated cancer centers, rates of molecular diagnostic testing for CRC were 3.7 percentage points lower at practices associated with non-academic hospitals and 10.6 percentage points lower at small independent practices. Rates of targeted therapy use for NSCLC were 4.8, 5.9 and 5.5 percentage points lower at academic medical centers, large independent practices and small independent practices, respectively, compared to NCI centers. **Conclusions:** Rates of molecular diagnostic testing for NSCLC and CRC increased in recent years, but testing rates remain below recommended levels, and targeted therapy use remains low. Substantial variation in testing and targeted therapy use by practice type suggest that the practice where a patient is treated may impact access to recommended testing and efficacious treatments. Research Sponsor: None.

Adjusted and unadjusted rates of use of molecular diagnostics and first-line targeted therapies in patients with metastatic non-small cell lung cancer and colorectal cancer.

	Molecular Diagnostics				Targeted Therapy Use			
	NSCLC		Colorectal Cancer		NSCLC		Colorectal Cancer

Medicare expenditures for discarded oncology therapies. *First Author: Caleb Scheckel, Mayo Clinic, Division of Hematology, Rochester, MN*

Background: Significant amounts of expensive oncology drugs are discarded resulting in waste and financial consequences for patients. Beginning in 2023, the Infrastructure Investment and Jobs Act (IIJA) will require drug manufacturers to refund Medicare for any single-use drugs where greater than 10% of the drug is wasted. We explored potential IIJA-associated savings through assessment of patterns in spending for discarded oncology agents between 2017-2020. **Methods:** We utilized the Medicare Part B Discarded Drug Units database from 2017-2020. Using J codes, we extracted spending and reimbursement data for discarded medications for antineoplastic and classical hematology therapies. The primary outcome was identification of therapies with high percentage of waste and the economic impact of retroactive application of the IIJA for discarded therapies. **Results:** Medicare Part B utilization data was extracted for a median 77 (64-152) oncologic therapies per year with median reimbursement for discarded treatments of $590 M ($566-616). From 2017-2020, bortezomib, romiplostim, and nab-paclitaxel were consistently among the top 5 therapies by value of wasted product. Pembrolizumab waste by value declined significantly after 2017 following transition to fixed dosing. In 2020, the top 5 therapies by value of wasted product were bortezomib, nab-paclitaxel, trastuzumab, romiplostim, and cabazitaxel with a value of $278 M. In 2020, the agents with the highest percentage of wasted product were bortezomib (27%), cabazitaxel (28%), decitabine (23%), topotecan (23%), and azacitidine (22%) with a collective discarded value of $160 M. Notably, these agents have weight-based dosing and single-use vials. Based upon the average number of drug claims per recipient and volume of product discarded, eliminating drug waste would allow an additional 6564 patients to receive treatment with discarded bortezomib. The number of additionally treated patients for the other top 5 agents: cabazitaxel (1216), decitabine (1509), topotecan (291), and azacitidine (2682). Retroactive application of IIJA policy would have impacted a median 20 (12-26) oncology agents resulting in median annual cost savings of $153 M (142-157) and the median annual spending on wasted oncology therapies would decline to $440 M (410-466). **Conclusions:** The IIJA would have yielded a median annual savings of $153 M in Medicare spending if applied retroactively. Given a 10% waste cutoff, a limited number of agents would be targeted by this legislation. In our study, we observe that drugs associated with weight-based dosing and single-use drug vials account for most drug waste. Strategies to minimize discarded units (through storage of unused product, approval of multi-dose vial formulations, or fixed-dose therapies) could yield substantial savings while enabling health equity in collaboration with communities with difficult access to these drugs. Rural-urban disparities in cancer mortality in the United States from 1999 to 2019. *First Author: Syed Hussaini, Duke University Medical Center, Durham, NC*

Background: U.S. cancer outcomes have improved in recent years, but it is unclear if these gains are realized in all geographic areas. We investigated US rural-urban disparities in age-adjusted cancer mortality rates (AAMRs) over a 20-year period. **Methods:** We identified cancer deaths from 1999 to 2019 in the CDC WONDER database. We classified populations into large metropolitan (≥1 million), small-or medium-sized metropolitan (50,000-999,999), and rural (<50,000) areas based on the 2013 U.S. Census classification. We calculated annual AAMRs per 100,000 individuals and stratified results by age, sex, and race/ethnicity. We estimated annual percentage changes (APC) in AAMR using robust linear regression models of the log-scale AAMR, including population size as weights, and assessed differential changes over time by geographic area with interaction tests. **Results:** There were 12,935,840 deaths attributed to cancer (50% large metropolitan, 31.2% medium/small metropolitan, and 18.7% rural). AAMRs were highest in rural areas with least annual improvement. AAMR in large metropolitan areas decreased from 204.5 to 142.6 (APC -1.74 (95% CI [-1.78, -1.7])), and in rural areas it decreased from 209 to 168.3 (APC -1.05 (95% CI [-1.09, -1])) (P < .001 for time trend). The absolute difference in AAMRs between large metropolitan and rural areas increased 5-fold, from 4.5 in 1999, to 25.7 in 2019. This trend was larger in elderly (>65), where rural-urban disparity grew 25-fold (P < 0.001). Non-Hispanic Blacks had higher AAMR than other racial/ethnic groups, and women had lower AAMR than men. **Conclusions:** In this national analysis of 20 years, rural residents suffered higher cancer mortality than their metropolitan counterparts resulting in widening disparities. Our findings inform program interventions possible through the recent reignition of the Cancer Moonshot in achieving geographic parity, and support ongoing congressional policy deliberations to increase access through re-investment in rural infrastructure. Research Sponsor: None.

The role of rurality in cancer treatment disruptions among patients with cancer diagnosed with SARS-CoV-2: An analysis of the ASCO Survey on COVID-19 in Oncology Registry. *First Author: Jessica Yasmine Islam, Moffitt Cancer Center, Tampa, FL*

Background: U.S. rural cancer patients experience multifactorial barriers to cancer treatment; however, little is known about the impact of the pandemic on cancer treatment delays or discontinuations (TDD) in the rural context. Our objective was to evaluate the role of rurality at both the patient and clinic level on cancer TDD among patients living with cancer with SARS-CoV-2 infection. **Methods:** We used data from the ASCO Survey on COVID-19 in Oncology Registry (March 2020-July 2021), which includes cancer patients diagnosed with SARS-CoV-2 (n = 3193). Data included patient demographics, SARS-CoV-2 treatment, cancer characteristics, and modifications to cancer treatment plans. Cancer-related TDD was defined as any treatment postponed > two weeks from the original scheduled date. Rurality was defined using the USDA Rural-Urban Commuting Area schema. We compared cancer characteristics, COVID-19 outcomes, and TDD by rurality of cancer patients, and TDD by rurality of oncology practices. We computed adjusted odds ratios (aOR) using multivariable logistic regression to evaluate rurality with TDD adjusting for age, race/ethnicity, sex, comorbidities, ECOG score, cancer extent, pandemic time period based on case peaks (< 06/2020, 06-12/2020, 01-07/2021), and COVID-19 severity. **Results:** Rural cancer patients (n = 499, 16%) with SARS-CoV-2 were mostly over 50 years (87%), female (57%), and NH-White (81%) with solid tumors (76%). Most rural patients received oncology treatment in urban areas (65%, p < 0.001). Rural patients were less likely to receive care through telemedicine (18%) compared to urban patients (26%) (p < 0.001). At SARS-CoV-2 diagnosis, rural patients were scheduled to receive drug-based therapy (72%), radiation therapy (8%), surgery (4%), or transplant (1%). Rural versus urban cancer patients with SARS-CoV-2 were less likely to experience TDD (41% vs. 51%) (p < 0.001). Among patients treated at rural oncology clinics, urban cancer patients were more likely to experience TDD (65%) compared with rural patients (47%) (p < 0.001). Similarly, among patients treated at urban oncology clinics, urban cancer patients were also more likely to experience TDD (51%) compared with rural patients (38%) (p < 0.001). In multivariable analyses, rural cancer patients were 28% less likely to experience TDD (aOR:0.72, 95% CI: 0.55-0.94) than urban cancer patients. Oncology practice rurality was not associated with TDD (aOR: 1.19, 95% CI: 0.81-1.76). **Conclusions:** Rural cancer patients were less likely to experience TDD than urban patients supporting the urban-rural paradox i.e., geographic distance to cancer care facilities is not consistently associated with treatment delivery in expected ways. Future work should focus on area-level factors of the rural cancer patient experience to disentangle potential reasons for TDD during the pandemic. Access to definitive treatment and survival for intermediate-risk and high-risk prostate cancer at hospital systems serving health disparity populations. *First Author: Muhieddine Labban, Division of Urological Surgery and Center for Surgery and Public Health, Brigham and Women's Hospital, Harvard Medical School, Boston, MA*

Background: Socioeconomic and racial disparities in prostate cancer (PCa) can be attributed to patient-level and physician-level factors. However, there is growing interest in investigating the role of the facility of care in driving cancer disparities. Therefore, we sought to examine receipt of guideline-concordant definitive treatment, time to treatment initiation (TTI), and survival for men with PCa receiving care at hospital systems serving health disparity populations (HSDPs). **Methods:** We conducted a retrospective analysis of the National Cancer Database (2004-2016) among men with intermediate-risk or high-risk PCa eligible for definitive treatment. The primary outcomes were receipt of definitive treatment and TTI within 90 days of diagnosis. The secondary outcome was survival. We defined HSDPs as minority-serving hospitals – facilities in the highest decile of proportion of Non-Hispanic Black (NHB) or Hispanic cancer patients – and/or high-burden safety-net hospitals – facilities in the highest quartile of proportion of underinsured patients. We used mixed-effect models with facility-level random intercept to compare outcomes between HSDPs and non-HSDPs among the entire cohort and among men who received definitive treatment. We evaluated interactions between HSDP status and race for each of the outcomes. **Results:** The cohort included 821,931 men with intermediate-risk or high-risk PCa. We included 968 non-HSDPs (72.2%) and 373 HSDPs (27.8%) facilities. Treatment at HSDPs was associated with lower odds of receipt of definitive treatment (aOR 0.64; 95% CI 0.57-0.71; p < 0.001), lower odds of TTI within 90 days of diagnosis (aOR 0.74; 95% CI 0.68-0.79; p < 0.001), and worse survival (aHR 1.05; 95% CI 1.02-1.09; p = 0.003). However, no difference was found in survival among patients who received definitive treatment. NHB men at HSDPs had also worse outcomes than NHB men treated at non-HSDPs as well as NHW men treated at HSDPs (Table). **Conclusions:** Patients treated at HSDPs were less likely to receive timely definitive treatment and had worse survival. NHB men have worse outcomes than NHW at HSDPs. NHB men with PCa remain largely disadvantaged since they are more likely to be treated at hospitals with worse outcomes and have worse outcomes than other patients at those same institutions. Research Sponsor: American Cancer Society.

Interaction between race (NHW, n=634,917; NHB, n=119,166) and treatment at non-HSDP (n=603,346) versus HSDP facilities (n=150,737).

	Definitive Treatment		TTI within 90 days		Survival		Survival among men who received definitive treatment	
	OR (95%CI)	p-value	OR (95%CI)	p-value	OR (95%CI)	p-value	OR (95%CI)	p-value
NHB at HSDP vs. NHW at HSDP	0.68 (0.66-0.71)	< 0.001	0.74 (0.72-0.76)	< 0.001	1.17 (1.12-1.23)	< 0.001	1.13 (1.07-1.19)	< 0.001
NHB at HSDP vs. NHB at non-HSDP	0.65 (0.58-0.73)	< 0.001	0.76 (0.70-0.82)	< 0.001	1.07 (1.00-1.14)	0.05	1.04 (0.97-1.12)	0.22

Racial/ethnic disparities of cancer treatment disruptions among patients with breast cancer with SARS-CoV-2 infection: An analysis of the ASCO Survey on COVID-19 in Oncology Registry.

First Author: Jessica Yasmine Islam, Moffitt Cancer Center, Tampa, FL

Background: The COVID-19 pandemic has led to disruptions in cancer treatment delivery among breast cancer patients in the U.S. However, it is currently unknown whether racial/ethnic disparities exist in cancer treatment disruptions among patients with breast cancer and SARS-CoV-2 infection. **Methods:** We obtained data from the ASCO Survey on COVID-19 in Oncology Registry (March 2020-July 2021) describing breast cancer patients diagnosed with SARS-CoV-2 during their care treated at 46 practices across the US. Data included patient demographics, SARS-CoV-2 diagnosis and treatment, breast cancer characteristics, and modifications to cancer treatment plans. Breast cancer treatment delay or discontinuation (TDD) was defined as any treatment postponed more than two weeks from the originally scheduled date. We computed adjusted odds ratios (aOR) using multivariable logistic regression, accounting for non-independence of patients within hospitals to evaluate racial/ethnic disparities of TDD. Multivariable models were adjusted for age, sex, number of comorbidities, cancer extent, ECOG performance score, pandemic period based on case peaks (< 06/2020, 06-12/2020, 01-07/2021), and COVID-19 severity (death/hospitalization/ICU admission/mechanical ventilation). **Results:** Breast cancer patients (n = 804) with SARS-CoV-2 were mostly aged 50 years and above (75%) and urban residents (83%). The racial/ethnic makeup of the sample included: 13.3% non-Hispanic Black/African American (NH-Black), 11.7% Hispanic/Latinx, 4.9% American Indian/Alaskan Native (NH-AI/AN), 4.6% NH-Asian, and 65% NH-White. At SARS-CoV-2 diagnosis, 736 patients (91%) were scheduled to receive drug-based therapy (78%), radiation therapy (8%), or surgery (6%), of whom 39% experienced TDD. Across treatment modalities, the most commonly reported TDD reason from the clinic perspective was the patient's COVID-19 disease (~90%). Overall, NH-Black (62%), Hispanic/Latinx (44%), and NH-Asian (42%) adults with breast cancer and SARS-CoV-2 were more likely to experience TDD versus NH-White adults (34%) ($p < 0.001$). In multivariable analyses, NH-Black cancer patients were more likely to experience TDD compared to NH-White patients (aOR: 3.12, 95% CI: 1.96-5.47). The data suggest Hispanic/Latinx (aOR: 1.34, 95% CI: 0.78-2.30) breast cancer patients may also experience TDD, although not statistically significant. No association was observed among NH-Asian (aOR: 1.16, 95% CI: 0.50-2.73) or NH-AI/AN (aOR: 0.64, 95% CI: 0.28-1.52) breast cancer patients with TDD. **Conclusions:** Black or African American breast cancer patients are more likely to experience cancer care disruptions during the pandemic. Future research should evaluate the long-term impacts of care disruptions on breast cancer outcomes among minoritized US communities. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Rural disparities in oncology patient portal enrollment and use.

First Author: Bonny B. Morris, Wake Forest School of Medicine, Winston-Salem, NC

Background: Patient portals support patient access, engagement, and care coordination, yet could also widen the digital divide and exacerbate disparities among vulnerable populations. There is emerging evidence that racial/ethnic minority patients are less likely to use portals, yet prior research has not examined potential rural differences. We identified sociodemographic factors associated with portal enrollment and use among a racially and geographically diverse population of cancer patients. **Methods:** We retrospectively examined portal enrollment and use at an NCI-designated comprehensive cancer center from January 2015 until February 2022 among patients 18+ years old with a neoplastic disease diagnosis (ICD-10-CM C00-D49). Potential predictors included gender, race/ethnicity, marital status, age, rural (Rural-Urban Continuum Codes [RUCC] 4-9) vs nonrural (RUCC 1-3) residence, residential distance from the cancer center, and time since diagnosis. We used multivariable logistic regression to generate odds ratios (ORs) for portal enrollment and having ever sent a portal message, and Poisson regression to determine incidence rate ratios (IRRs) for number of logins and number of healthcare team interactions (portal messages or appointment requests), controlling for ICD-10 diagnosis (SAS 9.4). **Results:** We identified 11,333 patients (average age 67 years, 59% female, 24% rural, 10% Non-Hispanic Black, 1% Hispanic, 20% non-melanoma skin cancer, 14% breast cancer, 9% lung cancer). 36% of patients had enrolled in the portal, and of these, 80% had sent at least one message. Patients logged in a median of 203.5 times and had a median of 19 portal interactions. Rural residents were less likely to enroll in the portal than urban patients (28% vs 38%, $p < 0.0001$). Non-Hispanic Black patients and Hispanic/Latinx patients were less likely to enroll in the portal compared with non-Hispanic White patients (22% and 27%, respectively, vs 38.5%, $p < 0.0001$). Women, younger patients, more recently diagnosed cancer patients, and patients who were married/ partnered were significantly more likely to enroll. In multivariable analysis controlling for cancer type, rural patients were half as likely to enroll in the portal (OR: 0.48 [0.43-0.54]). Among those enrolled, rural residents were 25% less likely to have ever sent a portal message (OR: 0.75 [(0.62-0.92]), and had nearly half the login and interaction rates (IRR: 0.66 [0.66-0.67]; IRR: 0.58 [0.58-0.59], respectively). Patients who were Non-Hispanic Black, Hispanic, or unmarried were also significantly less likely to enroll or engage in the portal. **Conclusions:** Patient portals remain underutilized among cancer patients, despite an increased reliance on virtual communications in the COVID era. Interventions to support portal engagement among rural residents and racial/ethnic minority patients are needed to avoid potentially exacerbating health disparities. Relationship of travel distance with patient demographics, advance care planning, and survival in early-phase clinical trials (EP-CTs).

First Author: Sienna Durbin, Massachusetts General Hospital, Boston, MA

Background: EP-CTs are often conducted at large academic centers, which may require some patients to travel further for their care. Little is known about either the distance EP-CT participants travel for their care or the association of distance traveled with patient characteristics and outcomes. **Methods:** We retrospectively reviewed the electronic health records of consecutive patients enrolled in EP-CTs at Massachusetts General Hospital from 2017-2019 to obtain patient characteristics (demographics and clinical factors) and outcomes (including time spent on trial, survival, and presence or absence of an advance care planning [ACP] discussion, defined as documentation of a code status or goals of care conversation in the medical record). We also used patients' home zip codes to derive the social deprivation index (SDI; a composite demographic measurement from 0-100 quantifying social determinants of health, with higher numbers indicating more disadvantage). To estimate distance traveled, we calculated the miles traveled in one direction driving from home zip code to trial site. We used descriptive statistics to compare patient characteristics and outcomes for those traveling < 50 miles (short distance) versus those traveling 50+ miles (long distance). **Results:** Among 421 patients (median age = 63.0 years, 56.9% female, 97.6% metastatic disease), median distance traveled was 36.4 miles. Half of patients (n = 217; 51.5%) traveled 50+ miles to receive care on trial. There were no significant differences between those traveling short and long distances in most patient characteristics evaluated, including age (60.9 vs 60.6 years; $p = 0.635$), sex (53.9% female vs 57.6%; $p = 0.447$), race (85.3% white vs 84.8%; $p = 0.346$), marital status (71.8% married vs 69.3%; $p = 0.586$), insurance (51% private vs 54.4%; $p = 0.266$), cancer type (22.5% GI vs 21.2%; $p = 0.666$), prior lines of therapy (52.5% one-two lines vs 51.2%; $p = 0.981$), and performance status (62.3% ECOG 1 vs 66.8%; $p = 0.270$. However, those with a higher SDI score were less likely to travel a long distance for trial participation (mean SDI 36.7 for short distance vs 30.5 for long distance; $p = 0.026$). Patients traveling a long distance were less likely to have a documented ACP discussion (48.8% vs 66.7%; $p < 0.001$). We found no significant difference in time spent on trial between those traveling short and long distances (mean days: 98 vs 93.5; $p = 0.175$) or in time from coming off trial to death (mean days: 147.7 vs 153.7; $p = 0.099$). **Conclusions:** We found that half of EP-CT participants travel 50+ miles in one direction to their trial site, with disparities in travel distance based on the social deprivation index. Notably, those traveling long distances were less likely to have a documented ACP discussion. Our findings suggest several unmet needs in the EP-CT population and highlight opportunities for future intervention development. Research Sponsor: None.

Racial disparities in diagnostic follow-up following BIRADS 0 mammogram.

First Author: Ritika Manik, University of Pennsylvania, Philadelphia, PA

Background: Delays in follow-up after abnormal mammograms can lead to worse outcomes and may contribute to health disparities. BIRADS 0 mammograms necessitate additional diagnostic imaging, and BIRADS 4 or 5 mammograms should be followed by biopsy. The goal of this study was to investigate racial disparities in rates and timeliness of (1) diagnostic follow-up after a BIRADS 0 screening mammogram and (2) biopsy following a subsequent BIRADS 4 or 5 diagnostic mammogram. **Methods:** We included women ≥18 years old who underwent a screening mammogram at the Hospital of the University of Pennsylvania with an assessment of BIRADS 0 between September 2010 and February 2018. The distributions of time from screening to diagnostic mammogram and from BIRADS 4 or 5 diagnostic mammogram to biopsy were estimated using the Kaplan Meier method. Follow-up was censored at 365 days. Case-mix adjusted Cox proportional hazards models were used to estimate the association between race/ethnicity and time to diagnostic mammogram and biopsy. **Results:** We identified 6299 women (Asian/PI=257, Black=3223, Hispanic=124, White=2420, Other/Unknown=275) with 6880 BIRADS 0 screening mammograms during the study period. Following these BIRADS 0 mammograms, the overall rate of diagnostic mammograms within 365 days was 87.3% (n=6006 mammograms), with a rate of 90.6% (2432) for White women and 85.3% (2971) for Black women. For the 1151 BIRADS 4-5 diagnostic mammograms in the cohort, the overall rate of follow-up biopsies within 365 days was 91.8% (n=1057 biopsies), with a rate of 93.8% (396) for White women and 91.1% (575) for Black women. Compared to mammograms obtained by White women, those obtained by Black women were less likely to be followed up with a diagnostic mammogram (HR 0.71, 95% CI 0.63-0.80, p<0.001) and biopsy (HR 0.74, 95% CI 0.55-0.98, p=0.037) when indicated (Table). Almost 1/4 (24.2%, 95% CI 23.1-25.9%) of BIRADS 0 screening mammograms among Black women were not followed by diagnostic imaging within 30 days as compared to 14.6% among White women (95% CI 13.3-16.0%, p<0.001). 23.6% (95% CI 20.5-27.2%) of BIRADS 4-5 diagnostic mammograms among Black women were not followed up with biopsy within 30 days vs 18.7% for White women (95% CI 15.4-22.8%, p=0.61) (Table). These disparities persisted at 90 days. **Conclusions:** Racial disparities exist in rates of follow-up after BIRADS 0 mammograms. The additive effects of delays at each diagnostic step put Black women at disproportionately greater risk for worse outcomes. Research Sponsor: None.

	Adjusted HR for Diagnostic Mammogram	P-Value	% Without Diagnostic Mammogram 30 days Post-BIRADS 0 Mammogram	P-Value	Adjusted HR for Biopsy	P-Value	% Without Biopsy 30 days Post-Diagnostic Mammogram	P-Value

Disparity of treatment-related adverse events and outcome in patients with early-onset metastatic colorectal cancer (mCRC). *First Author: Lingbin Meng, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: While the incidence of newly diagnosed early-onset mCRC has been increasing, disparity of treatment-related adverse events (AE) and outcomes of this patient population has been inadequately studied with inconclusive findings. We aimed to evaluate such age-related disparity and explore potential underlying causes. **Methods:** We used individual patient data from 3 clinical trials in Project Data Sphere where 756 and 467 patients with mCRC received first-line FOLFOX in study 1 (NCT 00305188, NCT00272051) and study 2 (NCT00364013), respectively. Clinical NGS data of 763 patients with mCRC from prospectively maintained Moffitt Clinical Genomics Database were used to assess genomic alterations. Patients were categorized into 3 age groups: <50, 50-65, and >65 years. Continuous and categorical variables were compared with *t* test and χ^2 test, respectively. Kaplan-Meier method and log-rank test were used for survival analysis. Benjamini-Hochberg procedure was used to adjust for multiple comparisons. **Results:** Among 1986 patients included, 341 (17.2%) in the <50 group, 912 (45.9%) in the 50-65 group, 733 (36.9%) in the >65 group had similar baseline characteristics. Outcomes: Patients in the <50 group had shorter median OS compared to the 50-65 (15.5 vs 20.5 month, p=0.003) and >65 groups (15.5 vs 20.8 months, p=0.004) and shorter median PFS compared to the 50-65 (8.1 vs 9.4 month, p=0.039) and >65 groups (8.1 vs 8.6 months, p=0.07) in study 1. Findings were confirmed in study 2. Toxicity: Compared to other age groups, the <50 group had a higher incidence of severe (grade≥3) abdominal pain (8.4% vs 3.4%, p=0.01), severe anemia (6.1% vs 1.2%, p=0.001), nausea/vomiting (69.3% vs 58.8%, p=0.02), but lower incidence of severe diarrhea (6.1% vs 10.8%, p=0.02), severe neutropenia (25.7% vs 44.2%, p<0.001), and severe fatigue (4.5% vs 7.3%, p=0.02). The <50 group had earlier onset of nausea/vomiting (1.0 vs 2.3 weeks, p=0.01), mucositis (3.6 vs 5.4 weeks, p=0.05), and neutropenia (8.0 vs 9.0 weeks, p=0.04), and shorter duration of mucositis (0.6 vs 0.9 weeks, p=0.006). Outcomes + toxicity: In the <50 group, abdominal pain was associated with worse OS (HR 1.6, p=0.01). In contrast, fatigue (HR 0.66, p=0.03) and mucositis (HR 0.67, p=0.046) were associated with better OS. Neuropathy was associated with better PFS (HR 0.61, p=0.009). Genomics: Our NGS data showed that the <50 group had more ERBB2 amplification (10.5% vs 4.0%, p=0.04) and a trend of more TP53 mutations (80.2% vs 72.0%, p=0.07). These findings were confirmed in an independent mCRC cohort (n=471, MSK, Gastroenterology 2020). **Conclusions:** Patients with early-onset mCRC had worse outcome and unique treatment-related AE patterns. Distinct genomic profiles could explain some of the disparities. Our findings might improve a personalized management approach in patient selection for chemotherapy, counseling and AE monitoring. Reducing oncology readmissions through a multidisciplinary discharge approach. *First Author: Samantha DiBenedetto, University of Virginia, Charlottesville, VA*

Background: Hospital readmissions are associated with increased health care utilization and unfavorable patient outcomes. Oncology patients have an increased risk of hospital readmission compared to the general patient population. The 30-day readmission rate for cancer patients at our institution is 27.7% which is higher than the reported national average of 20.2%. We sought to reduce 30-day hospital readmission rates by 25% for solid tumor oncology patients through a prospective integrated multidisciplinary discharge approach. **Methods**: Hospital readmissions for adult patients with a known solid tumor cancer diagnosis admitted to the oncology service at UVA from Jan 2019 – Apr 2019 were identified. Baseline information on tumor type, reason for readmission, interventions, length of stay (LOS), and inpatient morbidity and mortality (including ICU admission and transition to hospice) were collected via retrospective review. Qualitative and quantitative tools including process maps, cause-and-effect diagrams, Pareto charts, and priority matrix were used to identify potential areas for intervention. Two PDSA cycles were implemented: daily multidisciplinary discharge rounds with physicians, nursing, social work, case management, and PT/OT (PDSA1), and a templated discharge email to patients' primary oncology team including attending oncologist, mid-level providers, nurse coordinator, pharmacist, and urgent care team (PDSA2). An SPC chart with 3-σ limits and t-test of unequal variance with 2-sided p-value was used to evaluate impact on readmission rates from baseline to PDSA2. **Results**: Following PDSA1 (May 2019 – Oct 2019), the 30-day readmission was 25.7%; PDSA2 was postponed due to COVID-19, however the 30-day readmission rate remained stable during the pandemic. Following PDSA2 (Sept 2021 – Dec 2021), the 30-day readmission rate was 18.2% corresponding to an absolute decrease of 34.3% which was statistically significant ($p \leq 0.05$). This was associated with a trend towards increased LOS, rate of ICU admission, and case-mix severity index although not statistically significant. There was no significant difference in inpatient mortality or transition to hospice (Table). **Conclusions**: Implementation of multidisciplinary discharge rounds and templated discharge communication resulted in a significant decrease in rate of 30-day readmissions for solid tumor oncology patients. There was a trend towards increased LOS and ICU admissions without increased inpatient mortality. Improvement in discharge email compliance and implementation of an urgent symptom clinic may further reduce the 30-day readmission rate. Research Sponsor: None.

	Baseline (n=424)	PDSA1 (n=1231)	PDSA2 (n=231)	P-value
30-day readmission rate (%)	27.7	25.7	18.2	0.046
Average LOS (days)	5.8	5.7	10.0	0.076
ICU admissions (%)	9.1	14.7	16.7	0.339
Inpatient mortality (%)	5.2	3.1	4.8	0.977
Transition to hospice (%)	15.6	16.0	16.7	0.845
Case mix index	1.66	1.68	1.94	0.287

Acceptability of a machine learning-powered clinical decision support system aiding serious illness conversation and its impact on clinical outcomes: A pilot study. *First Author: Teja Ganta, Tisch Cancer Institute, Division of Hematology and Medical Oncology, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Patients with advanced cancer that utilize end of life planning see benefits including better quality of life and medical care that is more consistent with their values. We developed a 30-day mortality predictive model using a machine learning algorithm and integrated it into a clinical decision support system (CDSS) that encourages clinicians to use the serious illness conversation (SIC) guide—a standardized questionnaire and conversational tool that facilitates end-of-life planning. The CDSS was piloted in the thoracic oncology clinic. We evaluated clinicians' use of this system and its impact on patient outcomes. **Methods:** Between 4/14/21-1/15/22, information about patients identified by the model was sent to clinical teams via the electronic health record (EHR) to assess eligibility for a SIC. We reviewed the EHR for patients identified, SIC completion, and level of agreement by oncologists with the model. We evaluated the SIC guide responses using descriptive statistics and assessed differences in rates of hospice referral, hospital visits, and 30-day mortality by SIC completion status. Chi-squared test was used for testing association. **Results:** 94 patients were evaluated for SIC eligibility. Of these, oncologists agreed with 48 (51%) model predictions and SIC was completed for 28 (58%) of those patients. A median of 2.5 SIC eligibility assessments per week were completed, with a median time of 4 days from prediction to assessment. Likewise, a median of 1 SIC per week was completed, with a median time of 20 days from SIC eligibility assessment to conversation. Regarding the responses to the SIC guide, out of 28 patients, 75% have an appropriate understanding of their illness; 64% want to be fully informed of their medical information while 21% prefer information to be limited. Common patient goals were "being comfortable" (54%), "being at home" (29%) and "being independent" (25%). The most prevalent patient fears were "family concerns" (29%) or "physical suffering" (25%). The clinician who performs the SIC most often recommended an "additional conversation with physician" (39%), "conversation with family" (36%), or "referral to palliative care" (18%). SIC completion was associated with an increased rate of enrollment in hospice (33% vs 14%, P= 0.03) on univariate analysis. SIC was not associated with a difference in 30-day mortality or hospital visits. Multivariable analysis is ongoing. **Conclusions:** The machine-learning powered CDSS was adopted by the oncology care team within a reasonable timeframe. However, even if an oncologist used and agreed with the CDSS, the rate of eventual completion of SIC was not 100%. Additional barriers to SIC will be studied to optimize the CDSS. SIC completion may lead to increased enrollment in hospice and should continue to be studied as a standard component of comprehensive cancer care. Research Sponsor: None.

Updated health-related quality of life of patients with TRK-fusion cancer treated with larotrectinib in clinical trials. *First Author: Shivaani Kummar, Stanford Cancer Center, Stanford University, Palo Alto, CA*

Background: *NTRK* gene fusions have been identified as oncogenic drivers in patients (pts) with TRK fusion cancer across multiple solid tumors. Larotrectinib, a highly selective, CNS-active TRK inhibitor has shown high response rates, durable disease control, and a favorable safety profile in pts with TRK fusion cancer and is approved in over 40 countries. Larotrectinib has demonstrated rapid health-related quality of life (HRQOL) improvement in a group of 57 adult and pediatric pts (Kummar et al, *Curr Prob Canc* 2021). Here, we report updated HRQOL results for larger group of pts treated with larotrectinib. **Methods:** HRQOL data were collected in two ongoing trials (NCT02576431, NCT02637687) of larotrectinib in pts with TRK-fusion cancer using the EORTC QLQ-C30, EQ-5D-5L questionnaires and were analyzed descriptively and longitudinally. Scores from the EORTC QLQ-C30 Global Health Status (GHS), EQ-5D-5L VAS range from 0 to 100, with higher scores indicating better QOL. We also calculated the proportion of pts with either below normal or normal and above normal HRQOL scores against values in the literature for the US general population. **Results:** By July 2021, 113 adults with TRK-fusion cancer had received larotrectinib and completed the baseline (BL) and ≥ 1 post-BL questionnaire. The majority of pts had clinically meaningful HRQOL improvements during treatment (Table). For EORTC QLQ-C30 GHS, most adults maintained or improved scores from BL at or above the normal population level category. HRQOL improvements (change from BL > 0) occurred after ~2 months of treatment in 75% of adults. Median duration of pts with sustained improvement in EORTC QLQ-C30 GHS, and EQ-5D-5L VASs was 12.5 months (range, 1.8-34.1), and 12.9 months (range, 1.8-34.0), respectively. HRQOL results were consistent across multiple data cuts. **Conclusions:** Patients with TRK-fusion cancer treated with larotrectinib continued to have rapid, clinically meaningful, and sustained improvements in HRQOL. Clinical trial information: NCT02576431, NCT02122913, NCT02637687. Research Sponsor: Bayer HealthCare and Loxo Oncology.

Readmission risk identification: Implementation of a patient-centered interview. *First Author: Raquel E. Reinbolt, The Ohio State University Comprehensive Cancer Center, Arthur G. James Cancer Hospital, Columbus, OH*

Background: Unplanned 30-day readmissions in the cancer population are common. There are few large studies describing cancer patients' readmission perspective. To better define predisposing factors associated with readmission, our Nurse Case Manager team implemented a patient-focused survey. **Methods:** Cancer patients readmitted to The James Cancer Hospital from May 2020-December 2021 were included. Readmission events were defined as an inpatient hospital readmission within 30 days of the patient's prior hospitalization. Team members conducted a 16-question survey immediately following readmission to evaluate the patients' perspective on factors that may have contributed to their readmission; results were recorded. **Results:** A total of 3,333 readmissions were unplanned, 109 planned, 22 listed as other; 3,464 patients completed interviews (Table). During their index admission, most patients reported receiving (90%) and understanding (89%) discharge education/instructions. Upon index discharge, most patients (62%) were discharged on a new medication; the majority reported filling their prescription (95%) and taking it as instructed (98%). Nearly all patients had a post-index hospitalization follow up appointment scheduled, but only 58% reported attending. The primary reason reported for not attending was readmission prior to the appointment. Just over 50% of patients received a post-index hospital stay phone call. Some patients (6% yes; 58% unanswered) felt services at discharge would have been helpful. Most patients (51%) contacted their provider regarding worrisome symptoms experienced prior to being readmitted. Pain (18%), fever (11%), and shortness of breath (10%) were the most commonly reported symptoms that prompted returning to the hospital. **Conclusions:** To our knowledge, this is the largest study to date of cancer patients' own perspective of their 30-day readmission. More immediate post-hospitalization follow up and increased deployment of tailored discharge services represent areas of opportunity identified to decrease readmission rates. Symptom-specific interventions may also be impactful. Due to the negative downstream effects readmissions have on the healthcare system, it is critical to develop risk mitigation strategies incorporating patient-reported experience. Research Sponsor: None.

Implementing proven methods in a community-based health system to improve breast cancer screening rates during the COVID-19 pandemic. *First Author: Celine Fadel, Northeast Georgia Medical Center, Gainesville, GA*

Background: There are reduced screening rates across the United States secondary to the COVID-19 pandemic; the additional anticipated deaths from breast and colorectal cancer, secondary to reduced screening, is approximated at 10,000 people. A study of thirty-two health systems in Georgia noted an 8% decrease in screening mammography compared to pre-pandemic rates. To help reverse the decline, Northeast Georgia Medical Center (NGMC) participated in the "Return to Screening" initiative, in conjunction with the American Cancer Society (ACS). A quality improvement project was performed at the community-based hospital system to increase breast cancer screening rates, using a multidisciplinary approach with a focus on health care disparities. **Methods:** The initial goal was to increase screening mammograms by 10% (n = 14,364) from June 1st to December 1st 2021. Interventions were selected by a multidisciplinary team of NGMC researchers, clinical providers, and oncology administrators. Interventions varied in category, encompassing unique patient and provider-specific approaches. The evidence-based interventions were tailored to address health care disparities in the local population. This included identification and quantification of cultural groups in the community to ensure quality patient access. Integrative collaboration consisted of intermittent meetings to certify consistent communication, project reflection and identification of barriers. The selected interventions were executed monthly, with simultaneous data tracking of mammography rates. **Results:** From June 1st to December 1st 2021, a total of forty evidence-based interventions were successfully implemented. Analysis of screening rates demonstrated a 15% increase across the allotted time period, corresponding to an average of 1,302 mammograms monthly (n = 15,284). This exceeded the initial anticipated goal of increasing screening by 10% (n = 14,364). Analysis of mammography results identified 331 new cases of breast cancer diagnosed within the allotted period, a 7% mean diagnosis rate increase. Certain planned interventions were unable to be conducted and required modification due to limitation of the ongoing pandemic; however, this solidified the use of social media and virtual participation as effective methods of community outreach. **Conclusions:** We identified key methods to engage the local community and successfully increased rates of screening mammography. Interventions were tailored to the local population, ensuring patient-centered tools and a personalized approach to medicine. The multidisciplinary, consistent collaboration with stakeholders ensured quality of care for the local patient population. This project demonstrates the importance of local community engagement to impact national cancer screening rates, and thus, ensure earlier detection of breast cancer. Research Sponsor: American Cancer Society.

Evaluation of inpatient chemotherapy among patients with cancer. *First Author: Giulia Petrone, Icahn School of Medicine/Mount Sinai Morningside-West Hospital, New York, NY*

Background: Administration of inpatient chemotherapy (IC) is associated with more aggressive end of life care, reduced use of palliative care (PC) and decreased quality of life (QOL). This study aims to identify risk factors associated with overutilization of IC. **Methods:** We conducted a retrospective chart review of all admissions where IC was administered at an academic center between January 2016 and December 2017. Patients (pts) were stratified by solid tumors (ST) versus hematologic malignancies (HM) and urgency for IC was assessed. We evaluated other variables which can impact patient care such as length of stay (LOS), reason for admission and for IC. Descriptive statistics and odds ratios (OR) were estimated from logistic regression models with mixed-effect taking into account correlations from multiple admissions per patient. All tests were two-sided and statistical significance was considered when p<.05. **Results:** We analyzed 880 admissions (17% ST). Table 1 summarizes outcomes. HM pts required frequent direct admission for IC compared to ST. ST pts (p<.0001), pts >65 years (p=0.004) and pts with KPS ≤50% (p<.0001) were most likely admitted for cancer complications rather than for IC. LOS (>7 days) was significantly longer in HM admissions (p=0.0001), among pts with stage 4 cancer (p=0.014) and KPS ≤50% (p=0.0001). ST (p=0.006) and pts with KPS ≤50% (p=0.0001) received IC for a non-urgent indication significantly more often than HM. In 20% of ST admissions, pts received IC because the admission coincided with a non-urgent planned cycle compared to 3% of HM. In the adjusted analysis, tumor type was the most important factor correlated with urgency of IC (OR 0.42, 95% CI: 0.25-0.72; p=0.001). ST pts (p=0.0001), older pts (p=0.004) and pts with KPS ≤50% (p=0.0001) were less likely to respond to chemotherapy. Only 15% of HM admissions and 46% of ST admissions had a PC consult. 60-day mortality was significantly higher in ST pts than HM (p=0.002). **Conclusions:** IC is associated with poorer outcomes for pts with advanced stage ST, pts with poor functional status and pts admitted for acute indications. Additionally, ST pts have a higher mortality after IC compared to HM. Utilization of IC should be standardized to account for different patient characteristics and to reduce the incidence of non-urgent administration. Based on this data, we created a standardized protocol to better assess the appropriateness of IC to improve patient care, QOL, and reduce chemotherapy and healthcare utilization at the end of life. Research Sponsor: None.

Lisocabtagene maraleucel (liso-cel) as second-line (2L) treatment (tx) for R/R large B-cell lymphoma (LBCL) in patients (pt) not intended for hematopoietic stem cell transplantation (HSCT): Patient-reported outcomes (PRO) from the phase 2 PILOT study. *First Author: Leo I. Gordon, Robert H. Lurie Comprehensive Cancer Center, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: PILOT (NCT03483103) evaluated liso-cel, an autologous, CD19-directed, CAR T cell product, as 2L tx in pts with R/R LBCL not intended for HSCT. We analyzed changes in health-related quality of life (QOL) with respect to functioning and symptoms in PILOT. **Methods:** Adults with R/R LBCL after first-line tx were eligible. Pts were deemed not candidates for high-dose chemotherapy and HSCT by their physician and met ≥ 1 frailty criteria: age ≥ 70 yr, ECOG PS = 2, DLCO ≤ 60%, LVEF < 50%, CrCl < 60 mL/min, or ALT/AST > 2 × ULN. Pts completed EORTC QLQ-C30, FACT-LymS, and EQ-5D-5L (health utility index [HUI] and VAS) at screening (baseline [BL]), pre-tx (within 7 days before lymphodepletion), preinfusion on day of liso-cel infusion (Day 1), post-tx on Days 29, 60, 90, 180, 270, 365, 545, and 730/end of study, or at PD. The PRO-evaluable set included all pts with BL and ≥ 1 post-BL assessments. Linear mixed-effects models for repeated measures assessed the least squares (LS) mean change from BL for visits with ≥ 10 pts. Meaningful change from BL was calculated using responder definitions (in points): 10 for EORTC QLQ-C30, 3 for FACT-LymS, 0.08 for EQ-5D-5L HUI, and 7 for EQ-VAS. **Results:** Among the PRO-evaluable set, completion rates were high (≥ 80%) across most visits for all measures. For EORTC QLQ-C30, mean BL fatigue was meaningfully worse than in a general noncancer population (difference of > 10 points). Overall LS mean changes through Day 545 showed significant improvements in EORTC QLQ-C30 fatigue and pain, FACT-LymS, and EQ-VAS (Table). Improvement for lymphoma symptoms was also clinically meaningful. Fatigue improvement was clinically meaningful with a more sensitive minimal important difference of 4 (Cocks et al, 2012). Significant worsening was not observed for any outcome. In individual patient-level analysis, 70% of pts demonstrated meaningful improvement in FACT-LymS at month 6. **Conclusions:** Liso-cel meaningfully improved fatigue and FACT-LymS scores without negatively impacting other QOL measures. These data support the clinical evidence of liso-cel as a potential new 2L tx in pts with R/R LBCL not intended for HSCT. Clinical trial information: NCT03483103. Research Sponsor: Juno Therapeutics, a Bristol-Myers Squibb Company.

Overall score changes for primary outcomes of interest.

Instrument	Outcome	LS mean change (95% CI)	*P* value
EORTC QLQ-C30 (n = 56)	Global health status/QOL[a]	2.77 (–0.36, 5.91)	0.082
	Physical functioning[a]	–1.67 (–4.88, 1.53)	0.298
	Role functioning[a]	–3.21 (–8.01, 1.60)	0.187
	Cognitive functioning[a]	–0.55 (–3.50, 2.41)	0.711

Polypharmacy and premature aromatase inhibitor (AI) discontinuation in older women with breast cancer. *First Author: Elizabeth Joyce, University of Michigan Health System, Ann Arbor, MI*

Background: Treatment with AI therapy for at least five years is recommended to reduce risk of cancer recurrence in postmenopausal women with hormone-positive breast cancer, but up to 50% prematurely discontinue their AI. Prior studies have demonstrated higher rates of nonadherence in older patients. Higher rates of comorbidities are also present in older patients, many of which require treatment with prescription medications. However, in prior studies, the impact of polypharmacy on AI persistence in older women has been variable. We evaluated the relationship between use of prescription and over-the-counter (OTC) medications and AI discontinuation in older women in a randomized controlled trial of AI therapy. **Methods:** In the Exemestane and Letrozole Pharmacogenetics (ELPh) trial, postmenopausal women with stage 0-III hormone-positive breast cancer were randomized to receive exemestane or letrozole and followed for two years. Prescription medication and OTC supplement usage was prospectively collected. Only enrolled participants at least 65 years of age were included in this analysis. Univariate and multivariable Cox proportional hazards models evaluated the association between baseline prescription medications, OTC medications, initial assigned AI medication, and time to discontinuation of initial AI. **Results:** 131 women at least 65 years old with baseline medication and OTC supplement information were identified. The average age was 70.4 (SD 5). 58 participants (44%) were randomized to exemestane and 73 (56%) to letrozole. 21% had previously received tamoxifen and 18% received taxane-based chemotherapy. The average number of prescription medications at AI initiation was 4.95, and 127 patients reported taking at least one. The average number of OTC medications was 3.23, and 107 patients reported taking at least one. There was no difference in number of prescription medications or OTC medications by study arm. As previously reported, exemestane was associated with premature discontinuation (HR 1.92 [95%CI 1.06-3.50], p = 0.032). Controlling for AI, the risk of discontinuation decreased by 12% for every additional prescription medication (HR 0.88 [95%CI 0.78-0.99], p = 0.038). OTC medication use was not significantly associated with AI duration. **Conclusions:** Increased prescription medication usage at AI initiation was associated with decreased risk of premature discontinuation of AI. Further research is needed to evaluate this interaction and identify characteristics that impact AI persistence in older women with breast cancer. Clinical trial information: NCT00228956. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

When and how to deliver oncology supportive care resources: An adolescent and young adult perspective. *First Author: Betty Roggenkamp, Independent Consultant, Chicago, IL*

Background: The Coleman Supportive Oncology Collaborative for Adolescents and Young Adults (CSOC AYA) is a multi-institution Chicago-based quality improvement collaborative consisting of representation from AYA-focused oncology teams at six hospitals and national patient advocacy organizations**.** Coping with cancer as an AYA is challenging given their complex and unique phases of life and dichotomy between pediatric and adult care. AYAs with cancer are a recognized underserved population within the cancer community and have unique supportive care needs that are often unmet. The CSOC AYA focuses on improving access to resources for supportive care. **Methods:** We implemented an online survey across six cancer treatment centers (5 academic, 1 community) engaging 50 AYAs. Participants were newly diagnosed (2), currently on treatment (18), or off treatment (30). Participant age range was representative of AYAs (< 18years: 2%, 18 – 24: 36%, 25 – 34: 55%, and 35-39: 7%). Reported race was 60% Caucasian, 10% Black, 18% Latino, 8% Asian, 2% American Indian, and 2% other. Questions were asked to inform which supportive resources were desired by patients, when the resources would be most useful during the care continuum, and the preferred methods to receive information. **Results:** Greater than 54% percent of respondents desire social/emotional resources and peer connection at diagnosis. During treatment and after treatment, > 71% and > 56% respectively, desire guidance regarding nutrition/diet and physical activity/exercise, in addition to social/emotional support and peer connection (See table). Preferred methods to receive information were identified: 72% via email or text, 60% in person, and 45% via a patient portal. **Conclusions:** The CSOC AYA survey identified the type of supportive care resources AYAs need, when they are wanted, and their preferred methods for receiving them. Optimizing accessibility and availability of supportive care resources can enable AYA self-management and has the potential to improve quality of life. These survey results will serve as the basis for a patient-facing online intervention implemented throughout the care continuum with the intent to improve supportive care access for AYAs with cancer. Research Sponsor: The Coleman Foundation.

At which point in your cancer care would these support resources be helpful?			
n = 50	% Diagnosis	% During Treatment	% Off Treatment
Nutrition/diet guidance	42	82	56
Physical activity/exercise guidance	40	76	64
Social/emotional support	65	78	69
Connecting to other AYAs	54	71	65

Changes in Functional Assessment of Cancer Therapy: General (FACT-G) to predict treatment response and survival outcomes in patients with metastatic gastrointestinal (GI) cancer. *First Author: Joy X. Jarnagin, Massachusetts General Hospital, Boston, MA*

Background: The FACT-G contains 27 questions within 4 subscale domains [Physical Well-Being, Social/Family Well-Being, Emotional Well-Being, Functional Well-Being] related to health-related quality of life (QOL) in the past 7 days, with higher scoring indicating better QOL. In this prospective cohort study, we assessed longitudinal FACT-G data with treatment response and survival outcomes among patients with metastatic GI cancer. **Methods:** From 5/2019-11/2021, we enrolled patients at Massachusetts General Hospital with metastatic GI cancer to study before their treatment start. We collected the FACT-G survey at baseline (start of treatment) and 1-month later. We then used regression models to assess associations of 1-month changes in FACT-G with treatment response and survival outcomes (progression-free survival [PFS] and overall survival [OS]). For treatment response, clinical benefit was defined as decreased or stable tumor burden versus progressive disease at the time of first scan. All models were adjusted for baseline values of each respective variable. **Results:** We enrolled 203 of 262 patients approached (77.5% enrollment); 160 had 1-month follow-up data (median age = 63.0 years [range: 28.0-84.0 years], 66.3% male, 45.6% pancreaticobiliary cancer). For treatment response, 66.3% experienced a clinical benefit and 33.8% had progressive disease at the time of first scan (mean time to first scan = 2.7 months). Increases in FACT-G Total were predictors for treatment response (OR = 1.05, p = 0.0028), and improved PFS (HR = 0.98, p = 0.026) and OS (HR = 0.98, p = 0.038). Increases in FACT-G Emotional were associated with clinical benefit at the time of first scan (OR = 1.18, p = 0.0024), improved PFS (HR = 0.94, p = 0.023), and improved OS (HR = 0.93, p = 0.012). Improvement in FACT-G Physical were predictors for clinical benefit at time of first scan (OR = 1.08, p = 0.038) and better PFS (HR = 0.96, p = 0.038), while increases in FACT-G Functional were associated with improved PFS (HR = 0.96, p = 0.034) and OS (HR = 0.96, p = 0.019). Finally, changes in FACT-G Social were only associated with treatment response (OR = 1.16, p = 0.011). **Conclusions:** We found that 1-month increases in FACT-G can predict for treatment response and improved survival outcomes in patients with metastatic GI cancers. Notably, the FACT-G Total and FACT-G Emotional subscore predicted for all three outcomes of interest, while the FACT-G Social only predicted for clinical benefit at first scan. These data support previous findings indicating the possible use of early changes in patient-reported outcomes as a biomarker for early treatment response while emphasizing the growing need to integrate more patient-centric interventions into clinical care for cancer patients. Clinical trial information: NCT04776837. Research Sponsor: Conquer Cancer Foundation of the American Society of Clinical Oncology.

Physician awareness of immune-related adverse events from checkpoint inhibitors. *First Author: Ahmed Bilal Khalid, Indiana University School of Medicine, Indianapolis, IN*

Background: Immune checkpoint inhibitors (ICIs) have been one of the most significant developments in Oncology over the last decade. Despite being very effective for certain patient subsets, they have a unique side effect profile different from conventional chemotherapy that can manifest as immune-related adverse events (IRAEs). With increasing ICI use, clinicians will increasingly encounter these adverse events and thus, adequate knowledge on recognition and management of IRAEs is very important. **Methods:** To assess physician knowledge on IRAEs of ICIs, an online survey was administered to resident physicians in internal medicine (IM), emergency medicine (EM) and family medicine (FM) as well as to faculty physicians in IM, and FM at 3 tertiary care hospitals in Indiana. **Results:** We sent the survey to 413 physicians out of which 155 responded with a response rate of 38%. Out of 155 physicians, 110 were residents and 45 were faculty (27 hospitalists and 17 primary care physicians). Pembrolizumab was identified as a checkpoint inhibitor correctly by 79% of physicians, nivolumab by 64% and ipilimumab by 55%. Twenty-five percent of physicians incorrectly believed infliximab and adalimumab were ICIs. Most physicians (93%) were able to identify the gastrointestinal tract as an IRAE site whereas only 57% and 67% were able to identify cardiovascular and renal systems as an IRAE site, respectively. Fifty-nine percent of physicians believed steroids negatively affect efficacy of ICIs and should be used with caution to treat IRAEs. Sixty-five percent of physicians incorrectly thought endocrinopathies due to IRAEs are usually reversible. Most physicians (79%) believed IRAEs most commonly manifest in the first 6 months of treatment. Forty-five percent of FM residents considered antibiotics as the mainstay of treatment in ICI associated immune mediated colitis; this was significantly different from EM (15%) and IM (8%) residents(p = 0.0004). When comparing between residency programs, on a scale of 0-100, IM residents felt significantly more comfortable identifying IRAEs secondary to ICIs (27.1±24.2) when compared to EM (12.2±12.7) and FM residents (9.4±13.8; p = 0.0009). There was no significant difference among IM (19.8±20.1), EM (11.9±13.6), and FM residents (11.6±18.9; p = 0.11) when comparing how comfortable they were in treating IRAEs. When asked what the best way would be to learn about IRAEs, 36% chose printed material and algorithms, 30% picked online teaching module and 30% chose one time in-person lecture from an Oncologist. **Conclusions:** Resident and faculty physicians in multiple specialties are not comfortable in the management and treatment of IRAEs due to ICIs. Given that most of these physicians are usually the first point of contact with patients, physician education on identification and treatment of IRAEs is needed. Early detection of these toxicities is critical for their resolution. Research Sponsor: None.

Implementation of a precision medicine thoracic (PREDICT) service using reflex testing in a large academic-community practice network. *First Author: Debora S. Bruno, Case Western Reserve University, Cleveland, OH*

Background: Broad genomic testing is necessary for treatment of patients with stage IV non-small cell lung cancer (NSCLC). This quality improvement initiative aims to implement a precision medicine service for NSCLC patients at a hybrid academic-community practice oncology network. **Methods:** Following IRB approval, network tumor registries were queried for retrospective newly diagnosed stage IV NSCLC from 01/2016 through 12/2018. PREDICT was implemented in 08/2021. It consists of: 1) system-wide reflex testing of newly diagnosed stage IV NSCLC patients by an in-house solid tumor focused assay (hybrid DNA/RNA next-generation sequencing (NGS) panel previously reported) and PD-L1 testing, 2) PREDICT navigator, 3) molecular tumor board (MTB), 4) integrated information portal for real-time updates on samples processing, results and treatment recommendations by the MTB. We compared prospective data (08/2021 through 01/2022) after PREDICT with retrospective practice assessment. Comparisons between the groups were conducted using independent samples t-test / Wilcoxon rank sum test for continuous variables and Chi-square test/Fisher's exact test for categorical variables. **Results:** Of 861 retrospective patients identified in the compiled registry of stage IV NSCLC, 626 were eligible. Since PREDICT launch in 08/2021, 103 eligible prospective patients have been identified. Prospective patients are slightly older (mean age 70.9 vs 68 years old; $p = 0.013$), with no other significant demographic or clinical differences identified. Rates of NGS testing obtained within 90 days of biopsy date (BxD) increased significantly (94.1% vs 60.8%; $p < 0.0001$) after PREDICT. Turnaround times (TAT) from BxD to test results were significantly shorter for both NGS (12 vs 18 days; $p < 0.0001$) and PD-L1 (7 vs 10 days; $p = 0.007$) after PREDICT. A trend towards higher rates of actionable alterations (EGFR, ALK, ROS1, RET, BRAF, MET14 skipping, NTRK1/2/3) was noted: 19.6% vs 13% ($p = 0.071$). Targeted therapy use increased from 6.8% to 15.6% ($p = 0.002$) in the overall cohort. No differences in time to treatment initiation (TTI) after PREDICT have been identified to this point, with a median of 34 and 35 days for the prospective and retrospective groups, respectively. **Conclusions:** Implementing a precision medicine service for thoracic oncology patients has led to significantly higher rates of NGS testing for patients with stage IV NSCLC in a large hybrid academic-community practice network. Launching of this initiative resulted in significantly shorter TAT for both NGS and PD-L1 test results. A trend towards higher rates of actionable alterations has been identified. Targeted therapy use has increased significantly overtime, potentially due to higher availability of precision medicine drugs in the current era. Research Sponsor: AstraZeneca/NCCN.

Association of modifiable factors with financial burden and health literacy among patients with cancer. *First Author: Betina Yanez, Northwestern University Feinberg School of Medicine, Chicago, IL*

Background: Cancer patients are at a higher risk of financial burden compared to those with other chronic illnesses and those without cancer. Additionally, cancer patients with low health literacy are at risk for poor health outcomes and poor self-management. Aside from factors such as education and insurance, there is limited information on the role of modifiable factors in predicting financial burden and health literacy. The aim of this study was to identify risk factors associated with financial burden and health literacy among cancer patients. **Methods:** Participants were 2,260 adult, English- or Spanish-speaking patients who were recruited from an NCI-designated cancer center in the Chicagoland area as part of a trial on symptom management. Participants completed measures on depressive symptoms and anxiety using the Patient-Reported Outcomes Measurement Information System (PROMIS). Financial burden was assessed using a Comprehensive Score for Financial Toxicity (COST FACIT) item (FT12) and health literacy was assessed by the Single Item Literacy Screener (SILS). Additional information on insurance and cancer diagnosis were extracted from medical records. The area deprivation index (ADI) was calculated using national percentile rankings for the patient's block group. All patient-reported outcomes were assessed at study baseline. Cross-sectional logistic regression models were fit with the FT12 item [dichotomized as high (somewhat/quite a bit/very much) vs. low (not at all/a little bit) financial burden] and SILS [dichotomized as high (quite a bit/extremely) vs. low (not at all/a little bit/somewhat) health literacy] as separate outcomes. The primary covariates of interest were anxiety and depressive symptoms T-scores (dichotomized reflect normal limits vs. elevated distress). Analyses were adjusted for socio-demographic and clinical characteristics. **Results:** After adjusting for covariates, significant associations of greater financial burden were PROMIS depression [odds ratio (OR): 1.63 (95% CI: 1.22-2.19)] and PROMIS anxiety (OR: 1.60; 95% CI: 1.22-2.10). In addition, higher ADI score, lower education, unemployment, and low health literacy were significantly associated with greater financial burden. PROMIS depression (OR: 2.15; 95% CI: 1.38-3.40) was associated with low heath literacy, along with disability/leave of absence, Medicare/Medicaid/uninsured and lower education. **Conclusions:** Modifiable factors are associated with financial burden and health literacy. These results support the systematic screening for financial burden and health literacy in addition emotional well-being. Interventions targeting the modifiable factors elucidated in this study may further efforts to provide quality and equitable comprehensive cancer care. Future work should evaluate the potential causal pathways between depression, health literacy, and financial burden. Research Sponsor: U.S. National Institutes of Health.

Standardized documentation of advanced care planning to facilitate goal-concordant care in a large gynecologic oncology practice. *First Author: Pamela T. Soliman, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Advanced care planning (ACP) involves sharing of knowledge related to prognosis, treatment options, and patient values/goals, among the patient, their caregivers, and the clinical care team. These goals of care (GOC) discussions are critical at different time points during the care of a cancer patient, but are not performed or documented consistently in most oncology practices. The American Society of Clinical Oncology recommends that documentation of advance directive discussions, a component of ACP, take place by the third office visit for patients with newly diagnosed invasive cancer. We implemented a quality improvement initiative to improve ACP discussion and documentation in our large gynecologic oncology practice. **Methods:** As part of an institution-wide effort called "Mind the Gap: bridging the gap between patients' perception of their oncologic situation and the reality thereof", we identified 3 critical timepoints for which a GOC discussion and ACP documentation was recommended in the outpatient setting. These time points included: (1) by the 3rd visit for new patients with an invasive cancer, (2) preoperative (within 30 days of surgery), and (3) at time of treatment/chemotherapy change. Providers were educated on the key components of ACP documentation including surrogate decision maker and goals of cancer treatment. Standard templates were used to document these discussions for easy identification in the electronic health record. Metrics for each faculty team were shared monthly with the entire department. The department goal was to reach a cumulative goal > 60% completion for all patients in each of the 3 clinical time points within 6 months. **Results:** The proposed plan and education on ACP standard documentation was presented to 22 gynecologic oncologists during a faculty retreat in 10/2020. Baseline data from 8/2020 was shared revealing that ACP documentation was completed in 24% of new patients, 1% of preoperative, and 19% at treatment change. At the 6-month assessment (5/2021), ACP documentation was completed in 83.6% of new patients, 79.8% of preoperative, and 63% of patients at the time of treatment change. At one year (10/2021), ACP documentation was completed on 88.6% of new patients, 70.3% of preoperative, and 59% of patients at the time of treatment change. There was variability among providers in documentation of ACP for new patients (range 50-100%), preoperative (range 0-100%) and treatment change (range 12.5-100%). **Conclusions:** Through a departmental initiative, we were able to successfully encourage more frequent goals of care discussions and their standardized documentation, which was maintained at 1 year. We are currently evaluating the impact of this program on end-of-life quality metrics including chemotherapy within 14 days, ICU stay within 30 days and multiple hospital admissions within 30 days of end of life. Research Sponsor: None.

Next-generation sequencing (NGS): How often is testing performed too late? *First Author: Meena Sadaps, Cleveland Clinic, Cleveland, OH*

Background: With the emergence of precision oncology over a decade ago, NGS and the utility of targeted therapies have readily been incorporated into standard-of-care (SOC) practices. Still in many cases, NGS is only done after patients (pts) have failed several lines of treatment and/or their performance status (PS) has declined. We aim to further evaluate the timing of NGS as it pertains to patients' clinical disease course. **Methods:** All patients with incurable solid tumor malignancies undergoing NGS testing at our institution from January 2020 to December 2021 were included. Our genomics team (including medical oncologists, bioinformaticians, and a genetic counselor) routinely reviews all NGS results on a biweekly basis to assess for actionable alterations that would be eligible for on-label therapy (tx), clinical trials, and/or off-label consideration for targeted tx that has been FDA approved in another histology. Baseline demographics for pts such as age and gender, in addition to oncologic history, performance status, and date of death were collected via in-depth chart review utilizing the electronic medical record system. **Results:** We reviewed NGS results for 1767 pts, of which 1455 (82.4%) had genomic tumor board (GTB) recommendations for an actionable alteration. Of the 1767 pts, 33 were deceased at time of results review. The most common histology amongst the deceased were lower gastrointestinal tract (24.2%), genitourinary (18.2%), lung and pancreatic (15.2% each). At time NGS was ordered, 11 (33.3%) had received no prior tx, 8 (24.2%) had received one line of systemic tx, and 14 (42.4%) had received 2 or more lines of systemic tx. The average time from when NGS was ordered to results being reported was 17.9 days. The median time from when NGS was ordered to date of death was 26 days. At time NGS was ordered, 39% of pts had an ECOG PS of 0-1, 34% had an ECOG PS of 2, and 27% had an ECOG PS of 3-4. All 33 of these pts had actionable alterations for which GTB recommendations were made. All of these pts were matched to at least one clinical trial while 21.9% were recommended for an on-label tx as well. 54.5% of these pts were receiving care at regional facilities while 45.5% were receiving care at main campus. **Conclusions:** In our experience, all patients who were deceased at time of NGS review had an actionable alteration, for which there was a treatment recommendation made. In a rapidly evolving field where novel targeted therapies are on the rise, the rate of actionability is increasing, and NGS is now SOC, we are still seeing pts get testing done only after the receipt of multiple lines of systemic tx and/or once their PS has declined. These pts may benefit from earlier NGS testing, which would have opened up additional therapies earlier on in the course of their disease, when their PS was also likely to be more optimal. Further work is necessary to determine if early NGS testing makes a significant clinical impact on survival. Research Sponsor: None.

An examination of translated content on NCI-designated cancer websites with a focus on breast and colorectal cancer. *First Author: Minira Aslanova, Mount Sinai Beth Israel, New York, NY*

Background: One unforeseen implication of the pandemic has been a greater reliance on health information sharing via the Internet. This is complicated by the fact that many healthcare websites and online resources fail to consider Limited English Proficiency (LEP) when designing websites that relay essential health information. We aimed to quantify the extent to which NCI-Designated Cancer Center websites provide language accessibility. **Methods:** Over the course of 2021, we performed a cross-sectional review of translation services and available languages on NCI-Designated Cancer Center websites. This study was particularly focused on both breast cancer and colorectal cancer portions of these websites. The primary out-comes were as follows: option of translated content, presence of more than one language, and method by which the translation was performed (written text vs. Google scholar). We referred to the 2015 US language map for the percentage of LEP by state. **Results:** Of the 71 NCI-Designated Cancer Centers, 56 (78.9%) were without translation, and 15 (21.1%) used either manual translation or displayed a link for Google translate. Of the 15 centers who offered translated content on their website, 15/15 (100%) had more than one language available in the drop down list. Spanish (100%) was the most common language available. In terms of Limited English Proficiency, 25 of 71 (35.21%) NCI-Designated Cancer Centers were located in states where greater than 10% of the population is defined as having LEP, and yet, only 5 of these centers (20.0%) had languages other than English featured. We observed no significant relationship between the state LEP percentile and the number of NCI-Designated Cancer Centers offering website translation services within that state. Additionally, no appreciable differences in language availability were observed between breast cancer and colorectal cancer. **Conclusions:** Overall, only a fraction of NCI-Designated Cancer Centers actually translate the content of their websites. In New York for example, despite having the highest percentage of residents with LEP at 19.345%, only one of ten NCI-Designated Cancer Centers within the state had a website with language translation. We believe this represents a missed opportunity as language inaccessibility may contribute to delays in care for non-English speaking patients, particularly in a post pandemic world, further exacerbating health care disparities among patient populations. Research Sponsor: None.

Contemporary real-world associations between performance status and clinical outcomes in patients with cancer: A retrospective cohort study. *First Author: Deepika Kumar, Hematology/Oncology Fellowship Program, Kaiser Permanente, San Francisco, CA*

Background: The ECOG-PS (Eastern Cooperative Oncology Group Performance Status) scale is often used to guide cancer care, but the degree to which it predicts contemporary real-world clinical outcomes, in general and within certain patient groups, is relatively unknown. This retrospective cohort study examined associations between ECOG-PS levels and adverse outcomes in cancer patients with diverse patient characteristics. **Methods:** Various patient characteristics and nurse-rated ECOG-PS scores (range: 0-4) were recorded for all 21,730 adult patients with cancer receiving intravenous systemic therapy between 01/01/2017 and 12/31/2019 at 18 Kaiser Permanente Northern California cancer centers. Differences in baseline characteristics by ECOG-PS scores were evaluated using chi-square tests for categorical variables and ANOVA for continuous variables. Univariable and multivariable Cox Proportional Hazard models were used to test the ability of ECOG-PS to predict the occurrence of adverse clinical outcomes, including 1-month emergency department (ED) visits and hospitalizations, and 6-month mortality. **Results:** Overall, 42.5% of patients had ECOG-PS = 0, 42.5% had ECOG-PS = 1, 10.5% had ECOG-PS = 2, 4% had ECOG-PS = 3 and 0.4% had ECOG-PS = 4. Most patients were women (58%), non-Hispanic White (61%), English speakers (93%) and married/domestic partners (63%). African Americans, men, older patients, and those with higher Charlson comorbidity index or Stage IV cancer were found to have higher ECOG-PS levels (all $p < 0.001$). In multivariable analysis, ECOG-PS of 3-4 were associated with higher ED visits (HR 3.85, 95% CI [3.47-4.26]), hospitalizations (HR 4.7, [4.12-5.36]) and mortality (HR 7.34, [6.64-8.11]), compared with ECOG-PS = 0. Upper gastrointestinal (GI) and Stage IV cancers were associated with a higher risk of ED (upper GI: HR 2.39, [2.12-2.68], (stage IV: HR 1.31, [1.21-1.42]), hospitalization (HR 2.67, [2.27-3.13], (HR 1.51, [1.35-1.68]), and mortality rates (HR 3.37, [2.97-3.81], (HR 1.82, [1.68-1.98]), compared to Breast and Stage I cancers; however, advanced age was not associated with these outcomes. Interactions between ECOG-PS and cancer type as well as ECOG-PS and age group were statistically significant ($p < 0.001$), such that ECOG-PS was more predictive of adverse outcomes in younger patients and those with breast cancer. **Conclusions:** In this contemporary real-world cohort, multivariable analysis showed that ECOG-PS, cancer type and stage were strong predictors of ED visits, hospitalizations and mortality; however, advanced age was not. These results also show that ECOG-PS is more predictive of clinical outcomes in certain patient groups. Our findings may have implications on the use of ECOG-PS for clinical decision making. Research Sponsor: None.

Overall survival (OS) of patients with TRK fusion–positive cancer receiving larotrectinib versus standard of care (SoC): A matching-adjusted indirect comparison (MAIC) using real-world data (RWD). *First Author: Carsten Bokemeyer, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Larotrectinib trials in Tropomyosin Receptor Kinase (TRK) fusion cancer population were single arm trials and therefore limited comparative effectiveness data with larotrectinib are available.MAIC is typically used to balance population characteristics to facilitate cross-study comparisons. The objective of this study was to use MAIC to compare efficacy of the highly specific TRK inhibitor larotrectinib vs. SoC. **Methods:** Individual patient data from larotrectinib trials (NCT02122913, NCT02637687, NCT02576431) were compared with published aggregate SoC data from patients with locally advanced/metastatic TRK fusion cancer identified in the Flatiron Health/Foundation Medicine clinico-genomic database (Demetri et al. Ann Oncol. 2021). Prior to matching, eligible patients were ^{3}18 years and had to have received ≤4 lines of prior therapy (LoPT). Patients were matched on available common baseline characteristics (Table). Overall survival was the only endpoint assessed and was defined as time from locally advanced/metastatic disease diagnosis to death. The analyses included: 1) a log-rank test of equality to test whether the two groups were similar before larotrectinib initiation; and 2) estimation of treatment effect of larotrectinib vs. SoC. Hazard ratios (HRs) were used to compare the 2 groups. MAIC assumes that all observed and unobserved prognostic factors are adjusted for in the analysis. **Results:** 85 larotrectinib patients and 28 SoC patients were included. After matching, log-rank testing suggested no difference between the 2 groups *(P*=0.26), and larotrectinib was associated with a 78% lower risk of death (adjusted HR: 0.22 [95% confidence interval: 0.09, 0.54]; *P*=0.001), compared to SoC. **Conclusions:** This analysis suggests longer overall survival with larotrectinib, compared to SoC, in adult patients with TRK fusion cancer. The current analysis was limited to the prognostic variables available in the RWD. Further data are warranted to confirm those results. Research Sponsor: Bayer.

Real-world trends of PARPi maintenance treatment uptake and progression-free survival (PFS) in patients (pts) with newly diagnosed advanced ovarian cancer (AOC) in the United States. *First Author: John K Chan, Palo Alto Medical Foundation, Palo Alto, CA*

Background: Since 2018, the FDA has approved 2 PARP inhibitors (PARPi), niraparib and olaparib, for first-line (1L) maintenance therapy for OC. Using real-world population data, we assessed trends of 1L PARPi maintenance treatment uptake and PFS of pts with newly diagnosed AOC. **Methods**: Pts diagnosed with AOC between January 1, 2017, and June 30, 2021, who completed 1L chemo were identified from the nationwide Flatiron Health electronic health record (EHR)-derived de-identified database. We calculated descriptive statistics describing pt demographics, clinico-pathological characteristics, and 1L treatment patterns. The use of PARPi or active surveillance (AS) was identified during a 120-day period after the last dose of 1L chemo. The end of the 1L treatment identification period was defined as the index date. Time to next treatment was used as a proxy for PFS and was defined as time from the index date to the next therapy, last clinical activity, end of study period, or death. Kaplan-Meier methods and Cox models were used to analyze the PFS endpoint. **Results**: A total of 705 pts were included in the study; 166 received PARPi monotherapy (PARPi mono) and 539 underwent AS after completion of 1L chemo. Median age was 68 y for AS vs. 65 y for PARPi mono (Table). Median time from last chemo to initiation of PARPi mono was 48.5 d. Median follow-up was 20.6 mo for AS and 10.9 mo for PARPi mono. In the overall group, median PFS (mPFS) was 9.53 mo for AS vs. not reached (NR) for PARPi mono. In those with *BRCA* mutations (*BRCA*m), corresponding mPFS was 11.4 mo vs. NR and for *BRCA* wild type (*BRCA*wt) was 9.1 mo vs. 13.5 mo. On multivariate analysis, 1L PARPi maintenance was an independent predictor for improved PFS when compared to AS in all pts (HR, 0.47; 95% CI, 0.34-0.63), *BRCA*m (HR, 0.17; 95% CI, 0.07-0.41) and *BRCA*wt (HR, 0.50; 95% CI, 0.35-0.72). Stage IV at initial diagnosis, no debulking surgery, residual disease, and *BRCA*wt status were associated with poorer PFS. Trends analysis over the 4-year study period showed PARPi mono use increased from 6% in 2017 to 53% in 2021. **Conclusions**: This real-world analysis shows that adoption of PARPi mono in the 1L maintenance setting in pts with newly diagnosed AOC has increased to 53% in 2021. PARPi use, when compared with AS, was associated with significantly improved mPFS in both pts with *BRCA*m and *BRCA*wt. Research Sponsor: GlaxoSmithKline.

Changes in cancer-related mortality during the COVID-19 pandemic in the United States. *First Author: Jingxuan Zhao, American Cancer Society, Atlanta, GA*

Background: The coronavirus disease 2019 (COVID-19) pandemic resulted in delayed medical care that may have led to increased death rates in 2020 among people with medical conditions such as cancer. This study examined changes in cancer-related mortality between 2019 and 2020. **Methods:** We used the US 2019-2020 Multiple Cause of Death database from the CDC WONDER to identify cancer-related deaths, defined as decedents with invasive or noninvasive cancer as a contributing cause of death (ICD-10 codes: C00-C97 and D00-D09). We compared age-standardized cancer-related annual and monthly mortality rates (per 100,000 person-years and person-months, respectively) in January-December 2020 (pandemic) versus January-December 2019 (pre-pandemic) overall and stratified by rurality and place of death. We calculated the 2020 excess death by comparing the numbers of observed death with the projected death based on age-specific cancer-related death rate from 2015 to 2019. **Results:** The number of cancer-related deaths was 686 054 in 2020, up from 664 888 in 2019, with an annual increase of 3.2%. Compared to the number of projected deaths for 2020 (666 286), the number of cancer-related excess deaths was 19 768 in 2020. Annual age-standardized cancer-related mortality rate (per 100,000 person-years) continuously decreased from 173.7 in 2015 to 162.1 in 2019, while it increased to 164.1 in 2020 (2020 vs 2019 rate ratio (RR): 1.013, 95% confidence interval (CI): 1.009 - 1.016). The cancer-related monthly mortality rate was higher in April 2020 (RR: 1.032, 95% CI: 1.020 – 1.044) when healthcare capacity was most challenged by the pandemic, subsequently declined in May and June 2020, and higher mortality rates were again observed each month from July to December 2020 compared to 2019. In large metropolitan areas, the largest increase in cancer-related mortality was observed in April 2020, while in non-metropolitan areas, the largest increases occurred from July to December 2020, coinciding with the time-spatial pattern of COVID-19 incidence in the country. Compared to 2019, cancer-related mortality rates were lower from March to December 2020 in medical facilities, hospice facilities, and nursing homes or long-term care settings but higher in decedent's homes. **Conclusions:** The COVID-19 pandemic led to significant increases in cancer-related deaths in 2020 versus 2019. Ongoing evaluation of the spatial-temporal effects of the pandemic on cancer care and outcomes is warranted, especially in relation to patterns in vaccine uptake and COVID-19 hospitalization rates. Research Sponsor: None.

Age-standardized cancer-related mortality rates in 2019 and 2020.

Frailty status derived from the electronic medical record to predict survival and health care utilization in veterans with lung and gastrointestinal cancers. *First Author: Sudha Yarlagadda, Baylor College of Medicine, Houston, TX*

Background: Frailty is associated with increased vulnerability to stressors. Although frailty is a predictor of survival, traditional frailty assessments are not feasible in clinical practice. Frailty indexes (FI) derived from the electronic medical record (EMR) are an alternate approach. There is limited data for the association between EMR-FI and cancer-related outcomes including survival and health care utilization. **Methods:** We identified a cohort of patients diagnosed with lung or gastrointestinal cancer from 2016-2020 using VA administrative files. We used the Veterans Affairs-FI (VA-FI), a validated 31-item cumulative deficit FI, to define three groups: robust (≤0.1), prefrail (0.1-0.2), frail (> 0.2). Cox proportional hazard analyses were conducted to evaluate survival. Logistic regression analyses were performed to examine healthcare utilization. All models were adjusted for age, gender, race, Charlson comorbidity index, and stage. **Results:** Among 37,439 patients (age: 70±8.6 years), the majority were prefrail (36.8%) or frail (24.1%). Prefrail patients had a 13% increased risk of death compared to robust patients (adjusted hazard ratio [aHR] 1.13; 95% CI 1.10-1.16), while frail patients had a 52% increased risk (aHR 1.52; 95% CI 1.47, 1.57). Pre-frail and frail patients had increased odds of 1-year ED visits (adjusted odds ratio [aOR] 1.33; 95% CI 1.27 - 1.40 and aOR, 1.88, 95% CI 1.77-2.00, respectively). Frailty status was associated with increased odds of 1-year all-cause hospitalization among prefrail (aOR 1.09; 95% CI 1.03-1.15) and frail patients (aOR 1.26; 95%CI: 1.18, 1.34). **Conclusions:** Frailty measured by EMR data is significantly associated with survival and healthcare utilization among patients with lung and gastrointestinal cancers, independent of stage. Further study is warranted to develop EMR-FI as a risk stratification tool for personalized cancer treatment decisions. Research Sponsor: Veterans Affairs.

What is driving declines in oncology-prescribed opioids? *First Author: Tarlise Townsend, NYU Grossman School of Medicine, New York, NY*

Background: Patients with cancer have experienced sharp declines in opioid prescribing during the past decade, raising concerns about insufficient pain management in a population with high rates of undertreated pain. It is unclear whether these declines are driven by certain oncology subspecialties, payors, or clinical guidelines regarding opioid prescribing released in/after March 2016. **Methods:** We conducted time series analyses using 2006-2019 IQVIA Longitudinal Prescription Data, which represents up to 92% of all U.S. prescription fills. Using log-linear regression stratified by group, we estimated annual percent change in opioid receipt by: subspecialty (medical oncology MO, radiation oncology RO, and surgical oncology SO); payor (third-party; Medicare, including Medicare Part D; Medicaid; cash/out-of-pocket); and pre- versus post-March 2016. Opioid receipt outcomes included: monthly fills of any opioid; monthly fills of extended-release/long-acting (ER/LA) opioids; and monthly number of patients receiving long-term opioid therapy (LTOT). Outcomes were per 1,000 survivors to account for temporal changes in cancer prevalence. **Results:** Between 2006 and 2019, 14,301,900 opioid fills were prescribed by oncologists to 3,476,354 distinct patients. Across all outcomes, MO had the highest levels of dispensing, followed by RO, then SO; for example, in 2006 MO dispensed 6.2 fills per 1,000 survivors (compared to 1.9 fills among RO, and 0.5 among SO). We observed substantial declines in all opioid outcomes. Per 1,000 survivors, there was an annual decline of: 5.7% (95CI: 5.1-6.3; total unadjusted decline 2006-2019=70.2%) in the rate of all opioid fills; 4.9% (95CI: 4.1-5.6; total unadjusted decline=66.8%) in ER/LA fills; 3.2% (95CI: 1.5-5.0; total unadjusted decline=56.2%) in LTOT fills, and 1.9% in average daily dose (95CI: 1.9-2.0; total unadjusted decline=29.8%). The annual decline in opioid fills prescribed by MO (7.1%, 95CI: 6.6-7.7) was sharper than for RO (5.9%, 95CI: 5.4-6.4) and SO (5.2%, 95CI: 4.7-5.7). Annual declines were steepest among fills paid out-of-pocket (14.5%, 95CI: 13.9-15.0), followed by those paid by Medicaid (13.1%, 95CI: 12.5-13.6), third-party payors (9.3%, 95CI: 8.7-9.9), and Medicare (2.4%, 95CI: 1.8-3.1). Declines in every outcome accelerated following clinical guidelines released in/after 2016. **Conclusions:** Opioids prescribed by oncologists declined dramatically across groups and outcomes. Medical oncologists were responsible for a disproportionate share of opioid fills in 2006, and for the sharpest declines. Out-of-pocket fills declined more sharply than fills covered by insurance and clinical guidelines may have contributed to accelerating declines. While de-escalation of opioid therapy may reduce risk of opioid-related harms to cancer survivors, care is needed to ensure cancer-related pain is appropriately treated. Analysis of genomic alterations and treatment landscape in patients with advanced tumors using real-world data for precision oncology. *First Author: Kubra Karagoz, Sema4, Stamford, CT*

Background: Analysis of real-world data is critical for clear understanding of treatment effectiveness. Here, we explore the clinical utility of next-generation sequencing (NGS) and the impact of mutational landscapes on targeted therapy and outcomes in almost 10,000 patients in real-world setting. **Methods:** We constructed a data analysis platform that integrated NGS results with machine and manually curated electronic medical records data from a single large healthcare system. We assessed eligibility for a targeted therapy based on the constellation of mutations detected by NGS, investigated whether a matched therapy was given and how this affected patient outcome. **Results:** The study comprised of 9848 patients with NGS results across 90 cancer types including lung (2208;22%), colorectal (1495;15%), multiple myeloma (1153;12%), breast (783;8%), and prostate (480;5%) and other remaining cancers (3,729; 38%) from 2011 to 2021. Overall, 95% of patients had a positive NGS result, of whom 6364 (65%) had a targetable mutation in 34 genes per any NCCN guidelines in any cancer type. Of these, 2930 (46%) were late-stage (3-4). 820 patients across 31 cancer types received any of 54 targeted therapies based on an NGS result; 605/820 (74%) were stage 3-4; overall 605/2930 (21%) of all tested stage 3-4 patients received targeted therapy. Overall stage 4 patients with a targetable mutation who were treated with a targeted therapy had better 5-year overall survival (OS) than patients who did not (HR = 0.71, 95% CI 0.57-0.89, p = 0.003). We further analyzed important biomarkers in specific cancers. Stage 4 lung cancer patients carrying *EGFR, ALK, ROS1* or *MET* alteration and receiving targeted therapy had better 5-year OS (HR 0.56, 95% CI 0.40-0.80, p = 0.001). We observed that multiple myeloma patients carrying *KRAS* and *NRAS* mutation received off-label Trametinib, however it did not improve their OS (HR 1.28, 95% CI 0.76-2.15, p = 0.4). Moreover, there are 665 patients with tumor mutational burden (TMB) across 64 cancer types. TMB has been categorized into high (55, 8%), intermediate (177, 27%) and low (433, 65%). OS was significantly longer in TMB-low patients compared to TMB-high and TMB-intermediate patients across all cancers (HR 0.63, 95% CI 0.43-0.92, p = 0.016). There are 5051 patients with microsatellite instability status across 72 cancers categorized into high (828, 16%), and low (4223, 84%) with no significant survival difference between groups. **Conclusions:** We show that real-world data offers important insights into clinical practice and patient outcome, with respect to genomic alterations and associated targeted therapies. Moreover, we have built an analytics platform which allows users to ask relevant clinical questions around outcome of patients treated with targeted therapy by genomics biomarker and potential to identify off-label use and clinical response in any cancer type. Research Sponsor: None.

Persistent high-risk opioid use in lymphoma survivors following treatment.

First Author: Katherine Ann Stafford, Mount Auburn Hospital, Cambridge, MA

Background: Opioid analgesia has an important role in treating cancer pain but can place survivors at risk for long-term adverse effects, including misuse, abuse, and overdose. While opioid use has been studied in surgical oncology patients, little is known about long-term use and outcomes for patients with hematologic malignancies who primarily receive non-surgical treatment. We evaluated the association between opioid use during lymphoma treatment and persistent high-risk opioid use. **Methods**: We conducted a retrospective cohort study using IBM Watson Health MarketScan Commercial Claims and Encounters Data from 2000-2019, containing claims for employer-sponsored privately insured individuals in the US. We identified opioid-naïve adults age 18-64 years at their first diagnosis of Hodgkin (HL) or Non-Hodgkin lymphoma (NHL) who had outpatient cancer therapy lasting 90-240 days (including ≥3 episodes of outpatient chemotherapy). Using outpatient pharmacy claims, we categorized each patient's opioid exposure during cancer treatment to no exposure, moderate [1-7 days supply], or high [> 7 days supply]. Follow-up began 60 days after patients' final cancer treatment and continued up to 365 days or until an outcome or censoring event. High-risk opioid use was defined as ≥120 days cumulative supply, ≥3 consecutive months of opioid prescriptions, or a prescription with ≥90 morphine milligram equivalents per day. We used time-to-event methods to estimate cumulative incidence and hazard ratios across exposure groups. **Results**: There were 4380 opioid-naïve lymphoma patients in the cohort. 42.5% had HL and 57.5% had NHL. Median age at diagnosis was 46 years (IQR 32-56) and median treatment duration was 147 days (IQR 112-166). 55.0% of patients were male. During cancer treatment, 42.8% of patients had no opioid exposure, 28.1% had moderate, and 29.1% had high. Among the no-opioid-exposure group, the 1-year cumulative incidence of high-risk opioid use was 1.7%. Compared to this no-exposure group, the hazard ratios for moderate and high exposure were 2.6 (95% CI 1.5-4.6) and 9.0 (95% CI 5.6-14.4), respectively, after adjustment for cancer treatment duration, age, cancer type, and calendar time. A sensitivity analysis comparing patients diagnosed 2000-2009 vs. 2010-2019 found that hazard ratios remained consistent between the two time periods; however, there was a decrease in the absolute incidence of high-risk opioid use by approximately half. **Conclusions:** In this cohort study of opioid-naïve lymphoma patients, higher opioid exposure during cancer treatment was associated with a higher likelihood for persistent high-risk opioid use in the year following cancer treatment. The absolute incidence of high-risk opioid use decreased over time and may be due to increased awareness of the opioid epidemic. Close clinical follow-up in the post-treatment period may be warranted for patients at high risk of adverse outcomes. Research Sponsor: None.

Time at home among older adults with acute myeloid leukemia based on treatment intensity: A SEER-Medicare analysis.

First Author: Daniel R. Richardson, University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Older adults with acute myeloid leukemia (AML) have identified time at home (TAH) as a critical outcome when deciding on treatment. No study to date has fully explored TAH for older adults with AML. **Methods**: We identified a cohort of adults age ≥66 years with a new diagnosis of AML from the SEER-Medicare linked database from 2004-2016. Individuals were stratified into high-intensity chemotherapy [HIC] v. hypomethylating agent [HMA] v. other using claims. The primary outcome was TAH, quantified by subtracting the total number of person-days spent in hospitals and skilled nursing facilities from the number of person-days survived. Demographics, comorbidities, frailty, and transfusion dependence were considered covariates. **Results**: 7,946 adults were included. 2,824 (36%) received HIC, 2,542 (32%) HMA, and 2,580 (33%) other. Mean age was 75 years (HIC: 73; HMA: 78; other: 76). The cohort was predominantly White (88%, Black 5%; Asian 3%; Hispanic 1%) and male (57%). Median survival was 7 months (HIC: 9; HMA: 8). Median total TAH was 151 days (Mean 426, Range 0-1825). Adults receiving HIC spent less time at home and more time hospitalized than those receiving HMAs each month in the first year (Table). Differences in TAH between HIC and HMA cohorts were most pronounced in the first 3 months (1st: 49.5% v. 86.5%; 2nd: 68.2% v. 84.1%; 3rd: 77.3% v. 86.8%). Total TAH over 12 months was lower for those receiving HIC v. HMA (51.7% [187 days] v. 56.9% [205 days]). Transfusion dependence (≥ 1/month) was associated with decreased TAH at 1 month (OR 0.81, p<0.001) and 12 months (OR 0.90, p=0.04). Other covariates were not associated with TAH. **Conclusions**: Although intensive chemotherapy resulted in slightly longer survival, older adults treated with HMAs had more time at home. Treatment decision-making should incorporate patient preferences for prolonging survival v. increasing time at home. The effect of new treatments (eg, venetoclax) on time at home should be evaluated in future studies. Research Sponsor: Lineberger Comprehensive Cancer Center.

Do publicly available OncoGenomic databases represent the population? A comparative analysis.

First Author: Danielle Brazel, UC Irvine Healthcare, Orange, CA

Background: Large publicly available databases are important repositories for analyses of clinicogenomic research used for identifying clinically relevant biomarkers. Diversity among individuals in these repositories is key for ensuring applicability of findings to patient populations. **Methods:** We compared two publicly available pancancer databases from academic institutions: The Cancer Genome Atlas (TCGA) and United States (US) institutions from the American Association for Cancer Research (AACR) Project GENIE version 11.0 (APG) with cancer incidence statistics from The US Cancer Statistics (USCS) in 2018, the most recently available data. We compared demographic data from key individual cancer types (Lung, Colorectal, Prostate, Breast, Gliomas, and Leukemias) for gender, race, and ethnicity. Frequencies are displayed as percentages and compared by Chi-Squared method. **Results:** The USCS includes 1,708,921 new cases in 2018 while the TCGA includes 12,958 cases and APG includes 109,041 cases. Women account for 49.5% of all cancer diagnosis and similarly 50.4% of all cases in AACR and 51.2% of TCGA cases. Table summarizes key demographic differences. Amongst all cancer types, 78% of all US cancers occur in White patients however 84% and 83% of patients were White in AACR and TCGA respectively. 16% of prostate cancer cases occur in Black patients, but only 9% (n = 328/3993) of AACR and 11% (n = 51/484) of TCGA cases were Black ($p < 0.01$). However, while Black patients are only 2% of all breast cancer diagnoses, they accounted for 9% (n = 841/9871) of AACR and 16% (n = 203/1343) of TCGA cases $p < 0.01$). Patients of Hispanic ethnicity were underrepresented amongst the population and all single tumor types with Hispanics accounting for 8% of cases in USCS but only 5% in the AACR and TCGA ($p < 0.01$). Pancreatic and lung cancers, which have historically short survivals, both had lower median ages at sequencing compared to the median age of diagnosis. Median age of sequencing for pancreatic cancers was 65 in both TCGA and AACR, while median age at diagnosis in US is 70. Median age at diagnosis of lung cancers is 71 years in US, however median age was 67 in both AACR and TCGA. **Conclusions:** Patients with advanced age and minority races are underrepresented in publicly available American databases. To make informed analyses from genomic databases, the diversity of the population must be reflected in these databases and efforts must be made to increase representation of underrepresented groups. Research Sponsor: None.

Real-world utilization and comparative effectiveness of treatment options in cancer-associated thrombosis: A propensity score weighed analysis.

First Author: Irbaz Bin Riaz, Mayo Clinic, Phoenix, AZ

Background: Real-world utilization and comparative effectiveness of direct oral anticoagulants (DOACs), low molecular weight heparin (LMWH) and warfarin for cancer-associated venous thromboembolism (VTE) treatment remains largely unexplored. **Methods:** De-identified administrative claims data (OptumLabs - Data Warehouse) for adult active cancer patients with acute VTE (1/1/2012-9/30/2019) were assessed for utilization patterns, recurrent VTE, and major bleeding differences between DOACs, LMWH, and warfarin. Patients were followed up till the end of treatment. Patients who crossed over to other anti-coagulants within the follow up period were excluded. Multinomial logistic regression was used to assess predictors of anticoagulant administration. Kaplan-Meier curves were used to evaluate the differences in time to medication discontinuation among the three groups. Propensity score (PS) and inverse probability of treatment weighting were used to balance baseline differences between groups. Standardized difference (SD) was used to assess the balance of covariates after weighting and SD < 10% was considered acceptable. Weighted Cox proportional hazards regression with a robust variance estimator was then used to assess outcomes in PS weighted groups. **Results:** A total of 5100 patients met the inclusion criteria; 49.3% filled DOACs (n = 2512), 29.2% LMWH (n = 1488), and 28.6% warfarin (n = 1460). Median treatment duration was around 3.2 months for DOACs and warfarin, and 1.8 months for LWMH (*P*-value < 0.01). Multinomial regression analysis showed that younger patients were more likely to be prescribed LMWH (OR 0.97 95% CI: 0.97-0.98) as compared to DOACs. Patients with lung (OR 2.07 95% CI: 1.12-3.65; OR 1.87 95% CI: 1.04-3.37), urological (OR: 1.94 95% CI:1.08-3.49; OR: 2.04 95% CI: 1.12-3.73), gynecological (OR 4.25, 95% CI: 2.31-7.82; OR 2.31 95% CI: 1.22-4.39) and colorectal cancer (OR 2.26 95% CI: 1.20-4.32; OR 2.51; 95% CI: 1.32-4.79) were more likely to be prescribed LMWH or warfarin respectively, compared to DOACs. VTE recurrences were more frequent for patients receiving LMWH (HR: 1.47; 95% CI: 1.14-1.90) or warfarin (HR: 1.46; 95% CI: 1.13-1.87) compared to DOACs. LMWH, but not warfarin, was associated with greater major bleeding rates compared to DOACs (HR: 2.27; 95% CI: 1.62-3.20). All-cause mortality rates were also significantly higher for patients receiving LMWH, but not warfarin compared to DOACs (HR: 1.61; 95% CI: 1.15-2.25). **Conclusions:** Patients with cancer associated VTE remain on anti-coagulation for a remarkably short duration in real-world clinical practice. DOACs and warfarin may offer better compliance than LMWH. Patients receiving DOACs have a lower risk of VTE recurrence, less major bleeding, and improved mortality. Warfarin may still be considered for patients with contraindications to DOACs and non-compliant to LMWH. Research Sponsor: Internal funding.

Comparison of outcomes for Hispanic and non-Hispanic patients with advanced renal cell carcinoma in the International Metastatic Renal Cell Carcinoma Database.

First Author: Kripa Guram, VA San Diego Healthcare System, San Diego, CA

Background: Epidemiologic studies suggest that Hispanic patients with renal cell carcinoma (RCC) have worse outcomes than non-Hispanic White patients (NHW). It is unclear if this disparity is related to inherent biological differences or patients' social determinants of health (SDOH). Utilizing the International Metastatic Renal Cell Carcinoma Database (IMDC) of patients with RCC primarily receiving care at academic medical centers, we investigated outcomes of Hispanic and NHW patients with advanced RCC. **Methods:** Eligible patients included patients who self-reported being non-Black Hispanic or NHW with locally advanced or metastatic RCC initiating systemic therapy. The primary endpoint was overall survival (OS) and secondary endpoint was time to treatment failure (TTF) for the first-line therapy. Kaplan Meier curves were constructed for OS and TTF. Cox regression was used to estimate hazard ratios (HR) adjusted for confounding variables. **Results:** The cohort included 1,563 patients, of which 181 (11.6%) were Hispanic. Most patients were male (74%) with clear cell histology (82%). IMDC risk groups were 18%, 58%, 24% for favorable, intermediate, and poor risk, respectively, and were similar by ethnic groups. Compared to NHW, Hispanic patients were younger at diagnosis (median 57 vs 59 years, p = 0.036), less likely to have > 1 metastatic site (61% vs 77%, p < 0.001) and bone metastases (24% vs 33%, p = 0.009). 1,178 patients (124 Hispanic vs. 1,054 NWH) received treatment before 2018, 385 patients (57 Hispanic vs. 328 NWH) received treatment during or after 2018. With regards to first line therapy, the majority received tyrosine kinase inhibitor (TKI) monotherapy (70%), 10% received immunotherapy (IO) + IO, 9% received TKI + IO, 4% received IO monotherapy, and 8% received other treatments. Median TTF was 7.8 months (95% Confidence Interval (CI): 6.2-9.0) in Hispanic patients and 7.5 months (95% CI: 6.9-8.1) in NHW patients. On multivariable analysis, there was no significant difference in TTF between Hispanic and NHW patients (HR 1.05, 95% CI: 0.89-1.25, p = 0.558). Significant predictors of TTF were presence of unfavorable site of metastases, histology, IMDC risk group, and therapy type. Median OS was 38.0 months (95% CI: 28.1-59.2) in Hispanic patients and 35.7 months (95% CI: 31.9-39.2) in NHW patients. On multivariable analysis, there was no significant difference in OS between Hispanic and NHW patients (HR 1.07, 95% CI: 0.87-1.32, p = 0.544). Significant predictors of OS were number of metastatic sites, presence of unfavorable metastasis, histology, IMDC risk group, and therapy type. **Conclusions:** In this analysis, we did not detect a difference in OS or TTF for Hispanic patients with RCC. Our data suggest that access to care (as available in a tertiary cancer hospital) can mitigate the historic difference in outcomes in Hispanic versus NWH patients. Research Sponsor: None.

Cost effectiveness of reduced intensity conditioning and transplantation of unrelated umbilical cord blood versus HLA haploidentical related bone marrow for adults with hematologic malignancies.

First Author: Lotte Maria Gertruda Steuten, Office of Health Economics, London, United Kingdom

Background: BMT CTN 1101 was a Phase III randomized controlled trial evaluating the comparative effectiveness of unrelated umbilical cord blood (UCB) versus HLA-haploidentical related donor bone marrow (haplo-BM) cell sources for hematopoietic cell transplantation (HCT) in patients with high-risk hematologic malignancies (leukemias, lymphomas). We report results of an economic evaluation conducted as part of the clinical trial. **Methods:** 368 patients (90% of planned accrual) enrolled from 33 centers in the U.S. were randomly assigned to unrelated UCB (n=186) or haplo-BM (n=182) transplant. Healthcare utilization and costs were estimated using propensity-score matched cohorts of BMT patients in the OptumLabs Data Warehouse for trial participants <65 years, and Medicare claims for trial participants ≥65 years. Cost-effectiveness was calculated from payer perspectives (commercial, Medicare) over a 20-year time horizon from time of transplant. Weibull models (best fit based on AIC/BIC) were used to extrapolate survival from 5-year trial follow-up data. Trial participant surveys (EQ-5D) were used to derive health state utilities for estimating Quality-Adjusted Life Years (QALYs). One-way and probabilistic sensitivity analyses were conducted to assess uncertainty in results. Outcomes were discounted at 3% annually. **Results:** At 5-year follow-up, overall survival was 42% for haplo-BM versus 36% for UCB (P=.06). Over a 20-year time horizon, haplo-BM is expected to be more effective and more costly for <65 year-olds and in ≥65 year-olds it is expected to be more effective and less costly. In one-way uncertainty analyses, for persons <65, the cost/QALY result was most sensitive to life years and health state utilities. For persons ≥65, life years were more influential than costs and health state utilities. Using probabilistic sensitivity analysis, for persons <65 there was a 43% chance that haplo-BM was cost-effective using a willingness to pay threshold of $150k/QALY and 52% at a $200K/QALY threshold. **Conclusions**: Results from a large national clinical trial indicate that compared to UCB, haplo-BM was moderately cost-effective for patients aged <65 years, and less costly and more effective for persons ≥65 years. Haplo-BM is a fair value choice for commercially insured patients with high-risk leukemia and lymphoma who require HCT. For Medicare enrollees, haplo-BM is a preferred choice when considering costs and outcomes. Research Sponsor: U.S. National Institutes of Health.

	LY	QALY	Cost	ICER (cost/LY gained)	ICER (cost/QALY gained)

A quantitative analysis of escalating antineoplastic medication price increases.

First Author: Michail Alevizakos, Beth Israel Deaconess Medical Center, Boston, MA

Background: Established antineoplastic medication prices are overall increasing, yet the yearly trend and additive cost of such increases relative to overall antineoplastic spending is often unclear. **Methods:** We accessed the yearly reimbursement files from Medicare Part B for parenteral antineoplastic agents (codes J8501-J9999) for the years 2010-2020 and adjusted all values to 2020 USD to account for inflation. We calculated an initial inflation-adjusted price-per-claim for every medication at the time of medication entry to the database and compared that price with the yearly price-per-claim that Medicare reimbursed. For medications whose price had increased beyond the initial inflation-adjusted price, we multiplied the annual differences with the total annual claims of the medication reimbursed in order to calculate the additional cost accrued by Medicare for every affected year. We only included medications with total annual cost >10 million USD/yr in our analysis. **Results:** Price increases were noted in 70.9% of already established medications annually (median 74.5%, range 52.17-81.48%). This led to an average additional extra cost of 311 million USD (range 156-492 million USD) annually, for a total of 3.1 billion USD over the 10 years of observation. This extra cost represented 4.6-9.3% of the total Medicare Part B spending for antineoplastic medications annually and this percentage rose yearly by a statistically significant 0.43% (95% CI 0.14%-0.73%, $P = 0.01$; R^2 0.59) in absolute terms (Table). Rituximab (1,003 million USD), trastuzumab (421 million USD), and bevacizumab (326 million USD) accumulated the highest extra costs. **Conclusions:** The majority of established parenteral antineoplastics are affected by escalating price increases beyond the rate of inflation. Year-by-year, these increases occupy a progressively larger part of overall Medicare Part B spending. Since Medicare does not negotiate medication price nor receives rebates but rather relies on average market prices, these increases likely affect other U.S. markets as well. Research Sponsor: None.

Price increases of Medicare Part B antineoplastic medications with cost >10 million USD/yr.

Cost effectiveness of adjuvant olaparib for BRCA-mutated, early-stage breast cancer.

First Author: Christie Zettler, Columbia University Medical Center, New York, NY

Background: An interim analysis of the OlympiA trial found that olaparib given in the adjuvant setting can improve distant disease-free and overall survival for patients with early-stage, BRCA-mutated breast cancer; however, the cost-effectiveness of adjuvant olaparib is unknown. This study aimed to evaluate the cost-effectiveness of adjuvant olaparib in patients with early-stage, BRCA-mutated breast cancer. **Methods:** We used a decision-analytic model to compare outcomes of treatment with and without one year of oral olaparib after completion of systemic therapy in 42-year-old women with BRCA-mutated, early-stage breast cancer. Olaparib's effectiveness was based on the OlympiA trial, and other model parameters were identified from the literature. We calibrated the model to reflect the 1-, 2-, and 3-year distant disease-free survival (DDFS) and overall survival (OS) observed in the OlympiA trial, and we assumed that olaparib reduced the risk of distant recurrence only in the first 3 years. Olaparib was estimated to cost $14,523 per month. Average lifetime costs were estimated from a health care system perspective in 2021 $ US, and incremental cost-effectiveness ratios (ICER) were estimated as $ per quality-adjusted life-year (QALY) gained. Costs, life-years, and QALYs were discounted by 3% annually. **Results:** Simulating the OlympiA trial, DDFS for the olaparib arm was 94.3% at 12 months, 90.0% at 24 months, and 87.5% at 36 months, compared to placebo with DDFS of 90.2%, 83.9%, and 80.4% respectively. Similarly, OS for the olaparib arm was 98.1%, 94.8%, and 92.0% compared to 96.9%, 92.3%, and 88.3% with placebo at 12, 24, and 36 months respectively. In the base case, adjuvant olaparib was associated with a 1.21-year increase in life expectancy and a 1.15-QALY increase at an incremental cost of $131,167 compared to placebo. The resulting ICER was about $114,500/QALY gained. At a willingness-to-pay threshold of USD$150,000/QALY, olaparib was cost effective at its current price. Results were sensitive to assumptions about the effectiveness of olaparib and its impact on quality of life. **Conclusions:** Adjuvant olaparib is cost-effective for women with early-stage, BRCA-mutated breast cancer at the current price of olaparib in the U.S. and at a willingness-to-pay threshold of $150,000. As such, clinicians and payers should consider adjuvant olaparib as a cost-effective option for this patient population. Research Sponsor: None.

Trends in low-value oncology care during the COVID-19 pandemic. *First Author: Ravi Bharat Parikh, University of Pennsylvania, Philadelphia, PA*

Background: Low-value services, which provide minimal patient benefit while entailing costs and risks, are prevalent in cancer care. Shifts in cancer care delivery during the COVID-19 pandemic to minimize exposure provided opportunities for health systems and clinicians to prioritize higher-value over low-value oncology services. **Methods:** In this retrospective cohort study, we investigated the association between the COVID-19 pandemic period and low-value cancer care practices using administrative claims from the HealthCore Integrated Research Environment, consisting of ~65 million members managed by 14 health plans across the US. We identified commercial or Medicare Advantage members diagnosed with breast, colorectal, or lung cancer between January 2015 and March 2021. Low-value cancer care practices were identified from peer-reviewed medical literature, including ASCO and ASTRO Choosing Wisely campaigns and evidence-based pathways. Five low-value practices were studied: (1) conventional fractionation instead of hypofractionation for early-stage breast cancer; (2) off-pathway systemic therapy; (3) non-guideline-based antiemetic use for minimal-, low-, or moderate-to-high-risk chemotherapies; (4) Positron Emission Tomography/Computed Tomography (PET/CT) instead of conventional CT for staging; and (5) aggressive end-of-life care (chemotherapy ≤14 days, multiple emergency department visits ≤30 days, ICU utilization ≤30 days, hospice initiation ≤3 days, and/or no hospice before death). We used linear probability models to evaluate the association between the COVID-19 period (March to December 2020) and the 5 outcomes, adjusting for patient, facility, geographic and temporal characteristics. **Results:** Among 204,581 members (mean age 63.1, 139,488 [68.1%] female), 83,593 (40.8%) had breast cancer, 56,373 (27.5%) had colon cancer, and 64,615 (31.5%) had lung cancer. Rates of low-value care were similar in pre-COVID vs. COVID periods: conventional radiotherapy: 22.1% vs. 9.4%; off-pathway systemic therapy: 36.7% vs. 43.2%; non-guideline-based antiemetics: 61.2% vs. 58.1%; PET/CT imaging: 39.9% vs. 41.3%; aggressive end-of-life care: 75.8% vs. 73.3%. In adjusted analyses, the COVID-19 period was associated with no changes in off-pathway therapy (adjusted percentage point difference [aPPD] 0.82, SD 0.08, p = 0.33), PET/CT imaging (aPPD 0.10, SD 0.005, p = 0.83), and aggressive end-of-life care (aPPD 2.71, SD 0.02, p = 0.16). Small changes in conventional radiotherapy (aPPD 3.93, SD 0.01, p < 0.01) and non-guideline-based antiemetics (aPPD -3.62, SD 0.006, p < 0.01), were noted. **Conclusions:** The shock of the COVID-19 pandemic did not meaningfully change several metrics of low-value cancer care. Broader changes to payment and incentive design should be considered to turn the tide toward higher-value cancer care. Research Sponsor: U.S. National Institutes of Health.

Systematic performance status assessment by primary care providers in patients with advanced cancer and its impact on referral to palliative care and cost in a value-based practice. *First Author: Roberto Enrique Ochoa, Chen Medical Centers, Miami, FL*

Background: Value Based (VB) Care model has been growing in the primary care (PrC) Medicare population, its role in oncology and integration with VB PrC has not been well defined. Key initiatives in VB include reducing hospitalizations by multidisciplinary management of chronic conditions. Earlier Palliative Care (PaC) has shown to favorably impact outcomes. Eastern Cooperative Oncology Group Performance Status (ECOG-PS) is a validated tool used for decision making. Poor PS is associated with worse outcomes and futile end of life care; Guidelines recommend using ECOG-PS to decide on involvement of PaC in patients (pts) with metastatic cancer (mCa). ECOG-PS is subject to significant variability among oncologists and rarely used by PrC providers (PCPs). We created a standardized system for ECOG-PS documentation and monitoring by PCPs in a VB model in a large Medicare Advantage (MA) population with the goal of increasing earlier PaC referrals. **Methods:** Pts with mCa managed by PCPs in a multi-state MA practice were identified via EMR from February 2021 to September 2021. At every visit, an automated alert asked PCPs to determine pts' ECOG-PS and for those ≥ 2, recommendation to refer to PaC. PCPs were trained on use of the tool and were given a script to discuss with pts the role of PaC. Hospital admissions as well as total cost of care was measured in pts comanaged by PCP's & PaC versus those managed by PCPs &Oncology without PaC. Statistical analysis between the groups was done using Pearson's Chi-squared test with Yates' continuity correction. **Results:** An ECOG-PS was measured in a total of 565 pts with mCa during the study period. Median age was 73 years, 40% were ≥75 yrs. 55% were female. Breast, Prostate, Lung, Colorectal and Gyn ca accounted for 75% cases. ECOG was documented in 97% of patients; 250 (44%) had ECOG ≥ 2, 124 (22%) had ECOG ≥ 3. Of those PaC referral was done by the PCP in 70%, in total 69 patients were comanaged by PC vs 181 who did not. Pts that had PaC involvement were 43% less likely (RR 0.57 [95%CI 0.33,0.98 p = 0.043]) to be admitted compared to patients without PC. Pts without PaC that were admitted had 238% higher admission days per 1,000 pts compared to pts comanaged by PaC. Total medical costs of pts comanaged by PaC was 86% lower after PaC involvement $18,541 3-months prior vs $2,742 3-months after PaC involvemen, driven by lower part A and part B costs (p=0.001) **Conclusions:** ECOG PS monitoring of pts with mCa by PCPs was very successful, easy to perform and implement in a PrC. Poor PS is common in this medicare advantage population. PaC involvement in pts with poor ECOG-PS was associated with lower admission rates at the end of life, and significantly lower total medical costs. Research Sponsor: None.

The financial toxicity order set: A simple intervention to better connect patients with resources. *First Author: Bridgette Thom, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Rising cancer care costs have led to significant hardship for patients and caregivers, defined as "financial toxicity." Prior research has focused on experiences of financial toxicity and identified risk factors, but there are limited interventions, despite a growing need for both patient-level and systems-based solutions. We present a novel electronic medical record (EMR) financial toxicity order that streamlines referrals for financial assistance and/or counseling for patients in need. **Methods:** A multidisciplinary team developed, tested, and implemented an EMR order set to refer patients directly to patient financial services, due to specific financial concerns. Following a 3-month service-based pilot, the order set was activated enterprise-wide March 2021. All team members could place the order, and referrals were tracked on an institutional dashboard. Order indications and frequency of orders across patient and provider demographics were evaluated. **Results:** From March-December 2021, 617 orders were placed for 580 unique patients, by 272 individuals across 49 services. Nurses placed 45% of orders, followed by advanced practice providers (20%) and attending physicians (14%). Primary indications for the order included high/outstanding balance or out-of-pocket costs (41%), difficulty meeting basic needs (i.e., transportation, food; 30%), co-payment assistance (28%), or out-of-network insurance (11%); 29% of referrals included multiple reasons. Most orders (69%) were placed for patients on active treatment. Compared to the distribution of institutional averages by age, more patients 30-39 years (8% of all orders vs. 5% of all patients), 50-59 years (22% of all orders vs. 19% of all patients), and 60-69 years (33% of all orders vs. 26% of all patients) received an EMR financial toxicity order. Compared to institutional race and ethnicity averages, Black patients (15% of all orders vs. 9% of all patients) and Hispanic patients (12% of all orders vs. 7% of all patients) were over-represented among orders. Disease sites over-represented among orders included breast (25% of orders vs. 21% of patients) and lung (10% of orders vs. 7% of patients); and Hodgkin's lymphoma (8% of orders vs. 5% of patients). More female patients received orders than their representation among patients (62% of orders vs. 57% of patients). **Conclusions:** Our findings represent a first step toward improving the process by which patients experiencing financial toxicity are referred to relevant counseling and tangible financial resources. Multilevel interventions are necessary to address financial toxicity, and hospital-based EMR interventions represent progress in empowering the care team to connect patients to available resources. Categorizing the amount and type of financial help provided as a result of the EMR order is next, and efforts to proactively screen patients for financial toxicity risk are underway. Longitudinal changes in financial burden in patients with colorectal cancer treated with curative intent: Primary results of EAQ162CD. *First Author: Sheetal Mehta Kircher, Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, IL*

Background: We prospectively assessed financial burden (FB) due to treatment costs among patients with colorectal cancer (CRC) recruited by NCI Community Oncology Research Program (NCORP) sites. **Methods:** Patients with newly diagnosed CRC treated with curative intent enrolled through NCORP sites and completed the FACIT Comprehensive Score for Financial Toxicity (COST) instrument at 0-, 3, 6, and 12 months. Higher COST score (range 0-44) indicates greater financial well-being. Effects of demographic, clinical, self-efficacy and safety net affiliation on FB were assessed using linear mixed modeling with compound symmetry covariance structure to account for measurement correlation from the same subject. **Results:** In 450 patients (mean age 61, 47% female, 84% white, 64% colon, 31% rectal) attrition was comparable across demographics, clinical variables and baseline FB. Higher COST score was linearly correlated with time. Increasing age, income less than $60,000 (vs. less than $29,999), higher self-efficacy, and higher neighborhood socioeconomic status (nSES) predicted a higher COST score; these effects were not moderated by time. Chemotherapy receipt, insurance type, and treatment at a safety net hospital did not predict COST score. **Conclusions:** Among those with CRC treated with curative intent in community settings, FB improves over the 12 months post diagnosis. Individual and neighborhood level social determinants of health are protective from financial fragility. Research Sponsor: U.S. National Institutes of Health.

National trends in post-launch cancer prescription drug prices and the impact of generic entry, 2014-2020. *First Author: Danielle Rodin, Princess Margaret Hospital Cancer Centre, Toronto, ON, Canada*

Background: The high prices of branded 'on patent' cancer prescription drugs and the impact of competition on them is of importance to patients, physicians, payers and policymakers. The objective of this study is to quantify trends in the prices of all currently approved cancer drugs and to evaluate the impact of loss of exclusivity and generic entry on prices using national and contemporaneous data. **Methods:** Observational study of cancer drug prices from the IQVIA National Sales Perspectives from January 2014 to December 2020. The compound annual growth rate (CAGR) of drug prices was calculated for branded and generic drugs by therapeutic class (chemotherapy, targeted therapy, and supportive therapy). An event study empirical strategy and ordinary least squares regression was used to determine the relationship between the natural logarithm of prices and loss of exclusivity and generic entry. **Results:** The study cohort included 184 cancer drugs (37% chemotherapy, 51% targeted therapy, and 12% supportive therapy), of which 105 were always branded, 18 were always generic and 18 underwent loss of exclusivity and generic entry during the study period. Prices of branded chemotherapies and targeted therapies increased by 2.24% (0.79% CPI-adjusted) and 2.83% (1.07% CPI-adjusted) annually, whereas generics decreased by 12.63% (-14.14% CPI-adjusted) and 20.15% (-21.57% CPI-adjusted), respectively. Prices of branded supportive therapies decreased by 0.73% (-2.40% CPI-adjusted), while generics increased by 1.28% but decreased with CPI-adjustment (-0.45). Loss of exclusivity and generic entry was associated with statistically significant decreases in generic drug prices, but increases in branded drug prices after CPI-adjustment; these effects are concentrated in chemotherapies and targeted therapies. **Conclusions:** We found that cancer drug prices increased, after adjusting for inflation, particularly among branded chemotherapies and targeted therapies. Generic entry mitigates these price increases, but only a handful of cancer drugs experienced competition in the study period. Drug prices are key determinants of cancer-related spending, and many cancer patients remain underinsured. Although this data reflects net prices before discounts to providers and pharmacies, patient out-of-pocket costs are based on the list price. Our findings are critical to informing current efforts to improve cancer treatment affordability. Research Sponsor: American Cancer Society.

Cost-effectiveness of adjuvant chemotherapy for patients with high-risk stage II and stage III colon cancer in South Africa. *First Author: Yoanna S Pumpalova, Columbia University Irving Medical Center, New York, NY*

Background: Colon cancer (CC) incidence is rising globally, and case fatality rates are greatest in low-income settings, such as South Africa (SA). Adjuvant chemotherapy is standard of care for high-risk stage II and stage III CC in the US. We evaluated the cost-effectiveness of adjuvant chemotherapy for CC in SA public hospitals. **Methods:** We developed a decision-analytic Markov model comparing lifetime costs and outcomes for 60-year-old high-risk stage II and stage III CC patients treated in a SA public hospital with no adjuvant chemotherapy, versus: capecitabine and oxaliplatin (CAPOX) for 3 or 6 months or capecitabine for 6 months. High-risk stage II was defined as ≥1 of: T4 disease; poorly differentiated tumor; lymphovascular/perineural invasion; <12 lymph nodes dissected, bowel obstruction/perforation. Transition probabilities were derived from clinical trials estimating toxicity, disease recurrence, and survival. Costs from a SA societal perspective and utility estimates were obtained from literature and local expert opinion. The primary outcome was the incremental cost-effectiveness ratio (ICER) in international dollars (I$) per disability-adjusted life year (DALY) averted, with a willingness-to-pay (WTP) threshold equal to 2021 GDP/capita of SA (I$13,764). **Results:** CAPOX for 3 months was the cost-effective strategy for stage III CC at a lifetime cost of I$5,284 and 5.55 DALYs averted, compared to no adjuvant treatment. All other strategies were absolutely dominated. For high-risk stage II CC, CAPOX for 3 months was the cost-effective strategy (ICER = I$711/DALY averted). No adjuvant chemotherapy was on the efficiency frontier, with a lower lifetime cost, but no DALYs averted. The results of one-way deterministic sensitivity analyses showed that the model is most sensitive to CC recurrence rate. In a probabilistic sensitivity analysis, CAPOX for 3 months was optimal in 88% of iterations for high-risk stage II CC and 79% of iterations for stage III CC. **Conclusions:** CAPOX for 3 months is the cost-effective adjuvant treatment for high-risk stage II and stage III CC in SA public hospitals. This strategy offers the highest quality of life benefit for the lowest cost and is well within the WTP threshold for SA. The optimal strategy in other settings will vary according to local WTP thresholds. Base case estimates of cost-effectiveness, in order of cost. Research Sponsor: U.S. National Institutes of Health.

Strategy	Cost (I$[a])	DALYs averted	Incremental DALYs averted	ICER[b]
High-Risk Stage II				
No Adjuvant Chemotherapy	3,517	0.00	0.00	0.00
CAPOX 3 months	4,598	1.52	1.52	711
Capecitabine 6 months	4,883	0.93	-0.59	Dominated
CAPOX 6 months	6,153	0.97	-0.55	Dominated
Stage III				
CAPOX 3 months	5,284	5.55	0.00	0.00
Capecitabine 6 months	5,594	4.01	-1.53	Dominated
CAPOX 6 months	6,668	5.28	-0.27	Dominated
No Adjuvant Chemotherapy	8,169	0.00	-5.55	Dominated

[a]I$1.00 = ZAR7.097; [b]In I$/DALY averted, relative to optimal strategy.

Oncologist consideration of patient health insurance coverage and out-of-pocket costs for genomic testing in treatment decision. *First Author: Kewei Shi, American Cancer Society, Atlanta, GA*

Background: Use of genomic testing, especially multi-marker tumor panels, is increasing in the United States. Not all tests and related treatments are covered by health insurance, which can result in substantial patient out-of-pocket (OOP) costs. Although most patients are concerned about OOP costs, little is known about oncologists' treatment decisions with respect to patient health insurance coverage and OOP costs for genomic testing. **Methods:** We identified 1,049 oncologists who reported using multi-marker tumor panels from the 2017 National Survey of Precision Medicine in Cancer Treatment. Separate multivariable ordinal logistic regression analyses were used to assess the associations of oncologist, practice, and patient characteristics and the oncologist ratings of the importance of health insurance coverage and OOP cost for genomic testing as part of treatment decisions. **Results:** Among oncologists, 47.3%, 32.7% and 20.0% reported that patient insurance coverage for genomic testing was very important, somewhat important, and a little/not important, respectively, in treatment decisions. 56.9%, 28.0%, and 15.2% reported patient OOP costs for genomic testing were very, somewhat, or a little/not important in treatment decisions, respectively. In adjusted ordinal logistic regression analyses, oncologists who used next-generation gene sequencing tests were more likely to report patient health insurance and OOP costs for testing as important (odds ratio (OR) = 2.0; 95% confidence interval (CI): 1.2, 3.5) and (OR = 2.1; 95%CI: 1.2, 3.7), respectively) in treatment decisions. Oncologists with more years of experience, who treated solid tumors (rather than only hematological cancers), worked in practices without molecular tumor boards for genomic tests, and with higher percentages of patients insured by Medicaid or self-paid/uninsured also reported insurance coverage or OOP costs for testing were important in treatment decisions (all $p < 0.05$). **Conclusions:** Physician, practice, and patient characteristics were associated with oncologists' ratings of the importance of patient health insurance and OOP costs in treatment decisions. Identifying factors that influence physicians' priorities in treatment decisions may inform the development and targeting of interventions to support patient and physician discussions about oncology care. Research Sponsor: None.

Price variability of pembrolizumab in New York City from 2016-2021. *First Author: Syed Hussaini, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: There is poor compliance among cancer centers with price transparency rules set forth by the CMS in 2021. Service charges higher than what a hospital reasonably expects to be reimbursed may both prevent competitive price shopping by the consumer and result in catastrophic financial toxicity for small payors and under/uninsured individuals. We investigated variability in the charged and reimbursed payments for pembrolizumab infusion within one metro area utilizing Medicare claims. **Methods**: Medicare claims data from 2016 through 2021 for all pembrolizumab (HCPCS J9271) infusions in a hospital outpatient department were selected from the Definitive Healthcare claims database for medical oncology providers in New York City (NYC). Average charges, reimbursements, and total claims were obtained for the 6 largest prescribers by volume. Annual percentage changes (APC) were calculated to evaluate trends during study period. Prices are presented as inflation adjusted numbers (charged and reimbursed; 2021 dollars). Analyses were performed in Excel (Microsoft Corp). **Results**: Our analysis included 5 NCI-designated cancer centers (NCI-A, NCI-B, NCI-C, NCI-D) of which 1 was PPS (Prospective Payment System)-exempt (NCI-PPS). One hospital was non-NCI and 4 hospitals were part of the discounted 340B Drug Pricing Program (NCI-A, NCI-B, NCI-D, Non-NCI). From 2016 to 2021, total Medicare claims increased 793 to 1537, and total payments to all centers increased from $5.4M to $16.3M. NCI-PPS comprised 61% of claims, and 65% of total payments in 2021. Average charge for pembrolizumab in 2021 ranged from $20,130 (NCI-PPS) to $155,825 (NCI-D/340B). During study period, APC ranged from +1.7% (NCI-A/340B) to +25.4% (NCI-D/340B). Despite wide variability in charged amounts for Medicare claims, reimbursed amounts were similar across centers (range: $6227-9623, 2021). **Conclusions**: There is significant variability in charges for pembrolizumab in Medicare claims with price increases outpacing the annual rate of inflation. Within NYC, the highest charges were from a 340B hospital; NCI-PPS had higher volume and total payments but consistently lower charged prices each year. Our study highlights extreme price variability, and has policy implications for price transparency requirements and uniform rate setting to establish payment levels and control rate of annual growth. Research Sponsor: U.S. National Institutes of Health.

Self-reported financial difficulties among patients with multiple myeloma and chronic lymphocytic leukemia: An Alliance for Clinical Trials in Oncology study. *First Author: Rena M. Conti, University of Chicago, Chicago, IL*

Background: Treatment advances have greatly improved survival and quality of life among blood cancer patients, yet significant financial costs are a growing concern. **Methods:** We conducted an observational, prospective survey in 2019-2020 to estimate the self-reported prevalence of financial difficulty among multiple myeloma (MM) and chronic lymphocytic leukemia (CLL) patients and identify sociodemographic correlates of financial difficulty. Patients with an MM or CLL diagnosis >/= 18 years of age were recruited from NCI NCORP sites of care. Financial difficulty was measured in a previously validated single question from the EORTC QLQ C30 and a composite measure of five questions from the EORTC QLQ C30. **Results:** 521 MM and CLL patients were registered to the study, 416 patients were administered all or part of the patient survey, for an overall response rate of 79.8%. 16.8% of respondents reported experiencing financial difficulty in response to the single item question and 58.6% reported experiencing financial difficulty in response to the composite measure. Respondents reporting financial difficulty to both measures had reported household incomes of less than $60,000, identified their highest education levels as a high school diploma or GED, had more than one medical comorbidity and used an expensive oral chemotherapeutic agent to treat their blood cancer. **Conclusions:** Blood cancer patients treated at NCI NCORP sites are experiencing financial difficulties. Results of this study aim to inform physician, site of care and policy efforts to improve access among cancer patients. Clinical trial information: NCT03870633. Research Sponsor: U.S. National Institutes of Health, Other Foundation.

Patient report of financial difficulty by selected sociodemographic and treatment characteristics.

	Total	Reported Financial Difficulty (Primary Endpoint)	Composite Score Financial Difficulty (Secondary Endpoint)

A randomized study to measure and enhance the health-related quality of life in patients with cancer receiving immune checkpoint modulators (ME-Q). *First Author: Marcos Aurelio Fonseca Magalhaes Filho, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Existing data demonstrate the impact of Immune checkpoint modulators (ICMs) on Health-Related Quality of Life (HRQOL), but this was from studies that used HRQOL tools developed for patients treated with chemotherapy and/or radiation. To address this gap, we developed a toxicity subscale to cover important immune-related adverse events (irAEs) to combine this subscale with the generic FACT-G to measure HRQOL in patients treated with ICMs, the FACT-ICM. This trial proposes to validate the use of the FACT-ICM as a tool for HRQOL measurement and simultaneously to assess the benefit of remote symptom monitoring and management using a new electronic platform developed specifically for patients receiving ICMs. **Methods:** Participants will be randomized (1:1) before starting their standard of care ICM therapy to either usual care or the monitoring arm. The ME-Q platform uses a web-based application to enable remote monitoring of patient symptoms and HRQOL, allowing all participants enrolled in both the usual care or monitoring arms to complete the FACT-ICM and other questionnaires (DART, Health Resource Utilization, Decision regret scale, post-study system usability questionnaire) at set time points. Patients on the monitoring arm will have their electronic responses sent automatically, and new or significant worsening symptoms of clinical concern will generate an alert to the advanced practicing nurse (APN) responsible for replying to the patient and acting on responses. Via phone or a video teleconference, the nurse will perform a targeted assessment and provide standardized clinical advice and interventions based on well-established clinical algorithms and international guidelines for the management of irAEs. The APN will inform the patient's clinical team about the patient's responses and obtain the treating team's input and agreement on a proposed treatment plan. Patients enrolled in the usual care arm will respond to the questionnaires; however, their responses are not transmitted to their clinical team. The primary objective will be to validate the PRO tool for HRQOL measurement, and the secondary objective is to improve HRQOL in cancer patients receiving ICMs by remote monitoring and symptom management using the ME-Q electronic platform. We estimate that a total sample size of 266 patients (divided into two arms) achieves 90% power to detect an effect size of 0.4 in mean score changes (from baseline to 4 months) between arms using a two-sample t-test with a two-sided significance level of 0.05. Enrolment is to be completed in 2 years. Research Sponsor: None.

TPS6604 **Poster Session**

Assessment of adolescent and young adult oncology patient and provider perspectives in Philadelphia (AYA-4P). *First Author: Christopher Terry, Sidney Kimmel Cancer Center, Philadelphia, PA*

Background: The overall cancer incidence continues to increase in adolescent and young adult patients (AYAs), defined by the National Cancer Institute as individuals diagnosed between the ages of 15-39. Both disease biology and psychosocial needs are unique for young adults living with cancer. AYAs are more likely to have challenges related to work, insurance, relationships, fertility and emotional distress. Studies demonstrate that specialized supportive care improves outcomes such as health-related quality of life, mental health, and physical functioning. Most AYA oncology programs are developed without patient input and affiliated with pediatrics. The Sidney Kimmel Cancer Center (SKCC) at Jefferson is an adult oncology group serving over 900 new patients annually between the ages of 18-39, but does not have a formal AYA program. With guidance from patient advocates and other validated tools, a unique survey-based needs assessment was created by SKCC to provide data for the development of a comprehensive, patient-centered model of care for AYAs. **Methods:** A one-time survey will be administered electronically to participants through Qualtrics. Solicitation from SKCC and the Young Adult Cancer Connection, a local patient advocacy group, will occur via social media and email aggregation. Eligible patients are those who received the majority of their cancer care within 30 miles of Philadelphia between the ages of 18-39. Eligible healthcare providers include current advanced practice providers or physicians who have practiced at SKCC for at least 1 year. There are no hypotheses being tested or primary outcome variables, therefore no sample size calculations were performed. A $10 Amazon card is offered as incentive for the patient-directed survey to improve response rates and reach at least 100 completed surveys. The provider survey includes no completion incentive. Each survey should take no longer than 20 minutes to complete and no follow-up is required. Surveys are multiple choice with a single open-ended, free response question at the end for additional comments. Categorical survey responses will be summarized using frequencies and percentages. Descriptive statistics and data visualization will be used to characterize the patient demographics and summarize awareness, experiences, and priorities of the participants. Primary objectives of the surveys are to assess AYAs' current perspective of age-specific medical services and psychosocial support in Philadelphia, as well as to assess the knowledge and perspective of providers of the current care and available services for AYAs at SKCC. The secondary objective is to identify patient preferences and areas for improvement. By using the data generated from the surveys, SKCC will be more informed in their patient-centric approach to program development in an effort to improve the overall care for Philadelphia's AYA oncology community. Research Sponsor: Sidney Kimmel Cancer Center Cancer Awareness, Research, Engagement and Support (CARES) Program.

Implementation of the Avera/Sema4 oncology and analytics protocol (ASAP). *First Author: Casey B. Williams, Avera Cancer Institute, Sioux Falls, SD*

Background: Precision medicine represents a new era in oncology and population health. Comprehensive molecular profiling and hereditary cancer testing are increasingly important in the routine management of many malignancies, yet may not be widely adopted in many practices and leads to patients not consistently receiving care recommended by current national guidelines such as NCCN and ASCO. In addition, available targeted DNA sequencing panels may be limited to only defined drivers and lack detection in precancerous conditions. Whole exome sequencing (WES) combined with whole transcriptome sequencing (WTS) represent an expanded testing approach that identifies additional genetic changes beyond standard commercial panel tests. Current evidence suggests that WES/WTS is feasible to carry out in routine clinical practice, with improved detection of somatic alterations compared to smaller panels, and the promise to enhance access to targeted therapies and clinical trials. The primary purpose of the ASAP study is to understand the breadth of molecular characteristics present in participants cared for in a large integrated community-based health system, by linking comprehensive molecular profiles with clinical data extracted and curated from the electronic medical record. **Methods:** Avera Health is a large, Midwestern, predominantly rural vertically integrated health system with six regional cancer centers and over 40 oncology outreach sites across South Dakota and surrounding states. The ASAP study was initiated in November 2021 in GYN and as of February, the study is enrolling in the Otolaryngology clinic and expected to open in medical oncology and hematology in March/April 2022. The study will expand to include additional cancer centers outside of Sioux Falls later in 2022 and is anticipated to be open for accrual for 5 years. Enrolled participants are expected to receive WES/WTS and proteomics on their primary tumor and metastatic sites were feasible as well as hereditary testing, pharmacogenomics (PGx) and microbiome profiling. Liquid biopsies will be performed every 3 months while on treatment or when treatment is changed, in follow up to coincide with scheduled radiographic testing, and as part of annual routine surveillance. For participants not diagnosed with cancer, each participant will receive hereditary testing, PGx, microbiome, and a liquid biopsy at least annually. Participants also consent to sharing their electronic health information. Future stages of this work will employ natural language processing (NLP) methods to develop algorithms to help identify opportunities to improve patient outcomes. Projected enrollment is 1000 participants in year 1, 1500 participants in year 2, and up to 3000 annually thereafter. Approximately 50 patients have consented as of February 1 2022. Clinical trial information: NCT05142033. Research Sponsor: Sema4, TheraLink.

NHS-Galleri Trial Design: Equitable study recruitment tactics for targeted population-level screening with a multi-cancer early detection (MCED) test.

First Author: Charles Swanton, Cancer Evolution and Genome Instability Laboratory, The Francis Crick Institute, London, United Kingdom

Background: Cancer is a leading cause of premature death globally. Early detection can reduce cancer mortality by reducing the number of cancers diagnosed at a late stage. A blood-based MCED test (Galleri) was developed that can detect cancer signals and predict cancer origin with a single blood draw. The NHS-Galleri trial is a randomized controlled trial (RCT) assessing the clinical utility of this MCED test in a targeted screening population alongside current screening programs. Screening adherence is lower among certain individuals (eg, those with lower socioeconomic status), despite healthcare being free at the point of access in England. NHS-Galleri utilizes innovative strategies to optimize equity in study recruitment, with the goal of enrolling a representative sample. **Methods:** This pragmatic, blinded RCT is currently enrolling 140,000 asymptomatic participants by inviting ~1.3 million residents aged 50-77 in select postcodes of England via the NHS DigiTrials service. Regions were selected to include areas of high cancer mortality, socioeconomic deprivation, and ethnic diversity; eligible participants will be identified from these regions. A variety of methods are employed to enroll a representative study population (defined as including a reasonable number of participants from all socioeconomic statuses and all major ethnic minority groups). These methods include the use of mobile phlebotomy clinics that facilitate access in economically deprived areas, monitoring of participant representativeness by postcode with dynamic adjustment of enrollment, providing interpreters and wheelchair accessibility, and targeted local campaigns. Blood will be collected at 3 annual visits (baseline, year 1, year 2) unless cancer is diagnosed. After baseline blood collection, participants will be randomized 1:1 to the intervention (blood sample analyzed by the MCED test) or control (blood sample stored for potential future MCED testing) arm. Only participants in the intervention arm with "cancer signal detected" will have results returned and be referred for investigations and possible treatment. Participants in the intervention arm without "cancer signal detected" and all in the control arm will remain blinded and return for annual visits. All participants will be reminded to continue guideline-based screening and report unusual/concerning symptoms to a doctor. The primary study objective is a significant reduction in the absolute numbers of stage III & IV cancers diagnosed in the intervention versus control arm 3.5 years after randomization. Cancer-specific mortality will be assessed during trial follow-up. Exploratory endpoints include assessing the primary objective by participant age, gender, socioeconomic status, and ethnicity. Clinical trial information: ISRCTN91431511. Research Sponsor: GRAIL, LLC.

Effects of age, obesity, and body surface area on asparaginase-associated toxicities during acute lymphoblastic leukemia induction therapy: A report from the Children's Oncology Group.

First Author: Etan Orgel, Childrens Hospital Los Angeles, Los Angeles, CA

Background: Asparaginase is integral to pediatric-inspired regimens (PIR) to treat acute lymphoblastic leukemia (ALL) in adolescents and young adults (AYA). However, asparaginase-associated toxicities (AAT) often preclude delivery of planned therapy. Older age, obesity and/or large body surface area (BSA) have been associated with higher risk of AAT in PIR, but data are conflicting, and the impact of dose modification based on these factors is unknown. **Methods:** We examined induction toxicity data from patients ages 1-30 years enrolled in the frontline Children's Oncology Group (COG) trials for high-risk B-ALL (AALL0232, 2004-2011) and T-ALL (AALL0434, 2007-2014). During Induction, patients received pegaspargase (2,500 IU/m^2 without prescribed dose-capping) plus daunorubicin, vincristine, and prednisone or dexamethasone. AAT were defined as CTCAE v4 hyperbilirubinemia (Grade ≥3), elevated alanine aminotransferase (ALT) (Grade ≥4), thrombosis (any), or pancreatitis (any, included consolidation phase). Obesity was classified using population norms as body mass index (BMI) ≥30 (or ≥95th percentile for age/sex). BSA was analyzed continuously and dichotomized at 1.5 m^2 (equivalent to pegaspargase 3,750 IU, the threshold for permissible dose-capping in PIR). The association of AAT with end-Induction minimal residual disease (MRD) ≥0.01% was assessed. **Results:** Among 4,925 patients, 25% were ≥15 years, 39% had BSA >1.5m^2, and 18% had obesity. Multivariable logistic analyses inclusive of BMI and BSA together found increased risk for any AAT in age groups ≥10 years (10-15y, odds ratio (OR) 2.0, 15-20y OR 2.2, ≥21 OR 3.3, p=0.002). Only patients with both obesity and high BSA (>1.5m^2) were at additional risk (OR 3.3, p<0.0001). Similarly, risks for hyperbilirubinemia, ALT elevations, and thrombosis were increased in patients with both high BSA and obesity (OR 3.5, 95% confidence interval [CI] 2.2-5.7), OR 3.3, 95%CI 1.7-6.6, and OR 3.1 95%CI 1.5-6.5, respectively), but not in those with high BSA without obesity. The risk of hyperbilirubinemia was greater with increasing obesity (p<0.0001) and was also higher in all age groups ≥10 years (OR 6.3-7.9, p<0.0001). Age was not associated with thrombosis or ALT elevation; risk for pancreatitis was associated with Hispanic ethnicity, but not with age, BMI, or BSA. AAT were not associated with pooled trial MRD ≥0.01%. **Conclusions:** We report here the largest dataset of AAT in children and AYAs receiving ALL Induction therapy without routinely prescribed dose-capping of pegaspargase. Risk for AAT was increased in patients >10 years and in those with obesity, but not high BSA alone. Dose capping may not be necessary for children and AYAs with high BSA without obesity. Prospective studies of AAT pharmacogenomics and modifiable risk factors will support safer dosing in PIR. Clinical trial information: NCT00075725, NCT00408005. Research Sponsor: U.S. National Institutes of Health.

7001 **Oral Abstract Session**

Efficacy and safety of intramuscular (IM) recombinant *Erwinia* asparaginase in acute lymphoblastic leukemia (ALL) or lymphoblastic lymphoma (LBL): The Children's Oncology Group (COG) AALL1931 study.

First Author: Luke Devon Maese, Huntsman Cancer Institute, University of Utah, Primary Children's Hospital, Salt Lake City, UT

Background: The inability to receive L-asparaginase (ASNase) therapy due to hypersensitivity is associated with inferior outcomes in patients with ALL or LBL. JZP458, a recombinant *Erwinia*-derived ASNase from a *Pseudomonas fluorescens* expression platform, is approved by the FDA for patients with ALL/LBL who have developed hypersensitivity to *E. coli*–derived ASNase. Here, we report the efficacy and safety of IM JZP458 from COG AALL1931, a phase 2/3, open-label, multicenter, pharmacokinetic (PK) study. **Methods:** Eligible patients with ALL/LBL had a grade ≥3 allergic reaction or silent inactivation to a pegylated *E. coli*–derived ASNase. Each remaining dose of pegylated *E. coli*–derived ASNase was replaced with 6 doses of IM JZP458 on Monday/Wednesday/Friday (M/W/F) over 2-weeks. Three dosing cohorts were enrolled: Cohort 1a, 25 mg/m^2 M/W/F; Cohort 1b, 37.5 mg/m^2 M/W/F; Cohort 1c, 25 mg/m^2 M/W and 50 mg/m^2 F. Efficacy was assessed by the proportion of patients who achieved the last 72-hour (primary endpoint) or 48-hour (key secondary endpoint) nadir serum asparaginase activity (NSAA) levels ≥0.1 IU/mL in the first treatment course. A population PK (PPK) model was developed based on SAA data from AALL1931 to characterize the PK of JZP458 and to inform dosing decisions. **Results:** 167 patients were enrolled for IM dosing (Cohort 1a, n = 33; Cohort 1b, n = 83; Cohort 1c, n = 51). The median (range) age was 10 (1, 25) years. The median (range) of JZP458 courses received was 5 (1, 14) for Cohort 1a, 5 (1, 15) for Cohort 1b, and 4 (1, 11) for Cohort 1c. Mean (95% CI) SAA levels (IU/mL) at 72-hour were 0.16 (0.12, 0.19) for Cohort 1a, 0.33 (0.27, 0.39) for Cohort 1b, and 0.47 (0.35, 0.59) for Cohort 1c; and 0.45 (0.37, 0.53), 0.88 (0.76, 1.01), and 0.66 (0.54, 0.77), respectively, at 48-hour. Simulated data from the PPK model matched the observed data well. For Cohort 1c, the proportions of patients (95% CI) achieving NSAA levels ≥0.1 IU/mL at the last 72- and 48-hour in Course 1 were 90% (81%, 98%) and 96% (90%, 100%), respectively, based on observed data; and were 92% (91%, 93%) and 94% (93%, 95%) based on modeled data. The Table shows the rates of treatment-related adverse events (TRAEs; all grades) of interest per cohort. Overall, TRAEs leading to discontinuation included pancreatitis (6%), drug hypersensitivity (4%), anaphylactic reaction (2%), increased alanine aminotransferase (1%), and hyperammonemia (1%). There were no TRAEs leading to death. **Conclusions:** The totality of the results from AALL1931 demonstrate the positive benefit-risk profile of the IM JZP458 dosing regimen of 25 mg/m^2 M/W and 50 mg/m^2 F with a safety profile consistent with other asparaginases. Clinical trial information: NCT04145531. Research Sponsor: Jazz Pharmaceuticals.

7002 **Oral Abstract Session**

MOMENTUM: Phase 3 randomized study of momelotinib (MMB) versus danazol (DAN) in symptomatic and anemic myelofibrosis (MF) patients previously treated with a JAK inhibitor.

First Author: Ruben A. Mesa, UT Health San Antonio, San Antonio, TX

Background: MMB, an oral JAK1/2 and ACVR1/ALK2 inhibitor, showed clinical activity on MF symptoms, RBC transfusion requirements (anemia), and spleen volume in the SIMPLIFY trials. This pivotal phase 3 study of MF patients (pts) previously treated with a JAK inhibitor (JAKi) tested MMB vs DAN on key symptom, anemia, and spleen volume endpoints at 24 weeks (wks). **Methods:** Eligibility: Primary or post-ET/PV MF; DIPSS high risk, Int-2, or Int-1; MF Symptom Assessment Form Total Symptom Score (MFSAF TSS) ≥10; Hgb <10 g/dL; prior JAKi for ≥90 days, or ≥28 days if RBC transfusions ≥4 units in 8 wks or Gr 3/4 thrombocytopenia, anemia, or hematoma; palpable spleen ≥5 cm. Stratification: TSS, palpable spleen, and RBC units transfused. JAKi taper and washout was ≥21 days. Randomization: 2:1 to MMB 200 mg QD plus DAN placebo or DAN 600 mg QD plus MMB placebo for 24 wks, after which pts could receive open-label MMB. Assessments: Pt reported symptoms using a daily eDiary and spleen volume by MRI or CT. The primary endpoint was TSS response (≥50% reduction from baseline [BL]) rate at wk 24. Secondary endpoints, assessed sequentially at wk 24, were RBC transfusion independence (TI) rate, splenic response rate (SRR; ≥25% reduction in volume from BL), change from BL in TSS, SRR (≥35% reduction from BL) and rate of zero transfusions since BL. **Results:** 94 of 130 (72%) MMB pts and 38 of 65 (58%) DAN pts completed the 24-wk randomized treatment (RT) phase. Median BL TSS were 28 (MMB) and 26 (DAN), Hgb were 8.1 (MMB) and 7.9 (DAN) g/dL, and platelets were 97 (MMB) and 94 (DAN) x10^9/L. BL TI was 13% (MMB) and 15% (DAN). Prior JAKi was ruxolitinib in 195 pts (100%) and fedratinib in 9 pts (5%). All primary and key secondary endpoints were met (Table). Most common Gr ≥3 TEAEs in the RT phase of the study were thrombocytopenia (MMB, 22%; DAN, 12%) and anemia (MMB, 8%; DAN, 11%). Gr ≥3 infections occurred in 15% of MMB and 17% of DAN pts. Peripheral neuropathy occurred in 5 (4%) of MMB (all Gr ≤2) and 1 (2%) of DAN (Gr ≤2) pts in the RT phase, and none discontinued study drug. Overall, TEAEs led to study drug discontinuation in 18% of MMB and 23% of DAN pts in RT phase. A trend toward improved OS up to wk 24 was seen with MMB vs DAN (HR=0.506, p=0.0719). **Conclusions:** In symptomatic and anemic MF pts, MMB was superior to DAN for symptom responses, transfusion requirements, and spleen responses with comparable safety and favorable survival. MMB may address a critical unmet need, particularly in MF pts with anemia. Clinical trial information: NCT04173494. Research Sponsor: Sierra Oncology, Inc.

Wk 24 Endpoint	Test	MMB	DAN	p-value

Rusfertide (PTG-300) treatment in phlebotomy-dependent polycythemia vera patients.

First Author: Ronald Hoffman, The Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Background: Polycythemia (PV) patients with hematocrit (HCT) levels > 45% are at an increased risk of thrombosis and are treated with therapeutic phlebotomy (TP) alone or in combination with cytoreductive agents. Current therapies are not effective in reaching a HCT < 45% or uniformly tolerated. Rusfertide (PTG-300) is a hepcidin mimetic being developed as a non-cytoreductive option to consistently control HCT at < 45% in PV patients. **Methods:** We report results from two Phase 2 trials investigating the activity of rusfertide in PV patients. The first (NCT04057040) was conducted in patients with excessive erythrocytosis despite TP (3 or more in the 6 months prior to enrolling) ± cytoreductive therapy with a HCT < 45% at study entry. This study comprised 1) a 28-week open-label dose finding phase; 2) a 12-week double-blind randomized (1:1) withdrawal; and 3) a 3-year open-label extension with all subjects receiving rusfertide. Rusfertide doses,10-120 mg, were self-administered SQ weekly and adjusted monthly to maintain HCT < 45%. The second study (NCT04767802) enrolled poorly controlled PV patients with HCT > 48% at study entry despite TP ± hydroxyurea. Rusfertide dosing was initiated as 40 mg twice weekly and reduced to once weekly dosing when HCT < 45% was reached. **Results:** As of December 2021, 63 subjects were enrolled in Study 1. TP alone was the most common treatment (n = 30). The mean number of TP in the 28 weeks prior to enrollment was 4.63 and was 0.43 after treatment. On rusfertide, patients consistently maintained HCT < 45%, essentially eliminating TP, had normalization of serum ferritin, MCV values and iron deficiency. Rusfertide-treated patients also reported a statistically significant improvement in symptom burden at week 28. 20 subjects were enrolled in Study 2. TP with hydroxyurea was the most common treatment (n = 12). Mean HCT was 50.7% pre-treatment and mean time to reach HCT < 45% without TP was 4.79 weeks with persistently well controlled HCT thereafter. Rusfertide significantly reduced erythrocyte counts by ~1.2x10^6/μL within 8 weeks of treatment. In both trials rusfertide did not result in changes in the number of WBC; clinically not meaningful transient increases in platelet numbers were noted. Rusfertide was well tolerated, with mostly grade 1-2 adverse events (AE). The most common AEs were injection site reactions. These were typically transient, manageable with topical therapies, and did not lead to study withdrawal. **Conclusions:** Rusfertide, when added to standard therapy, demonstrated robust activity in managing PV patients with sub-optimally controlled erythrocytosis in 2 trials, enrolling patients with HCT < 45% (Study 1), and HCT > 48% (Study 2). Taken together, these data show that the non-cytoreductive rusfertide, is a promising novel agent for PV patients which leads to sustained HCT control < 45%. A pivotal Phase 3 study is scheduled to begin in 2022. Clinical trial information: NCT04057040 and NCT04767802. Research Sponsor: Protagonist Therapeutics, Inc.

7004 **Oral Abstract Session**

Efficacy and safety results from ASCEMBL, a phase 3 study of asciminib versus bosutinib (BOS) in patients (pts) with chronic myeloid leukemia in chronic phase (CML-CP) after ≥2 prior tyrosine kinase inhibitors (TKIs): Week 96 update. *First Author: Delphine Rea, Hôpital Saint-Louis, Paris, France*

Background: Asciminib is the first BCR::ABL1 inhibitor to specifically target the ABL Myristoyl Pocket (STAMP). In the ASCEMBL primary analysis, asciminib had superior efficacy and better safety/tolerability than BOS in pts with CML-CP after ≥2 prior TKIs. After a median follow-up of 2.3 years (16.5 months' additional follow-up since primary analysis), we report efficacy and safety results (cutoff: October 6, 2021). **Methods:** Eligible pts were adults with CML-CP after ≥2 prior TKIs, with intolerance or lack of efficacy per 2013 European LeukemiaNet. Pts were randomized 2:1 to asciminib 40 mg twice daily or BOS 500 mg once daily, stratified by major cytogenetic response (MCyR) status (Ph+ metaphases ≤35%) at baseline. The key secondary endpoint was major molecular response (MMR) rate at wk 96. **Results:** 233 pts were randomized to asciminib (n=157) or BOS (n=76). At cutoff, treatment was ongoing in 84 (53.5%) and 15 (19.7%) pts, respectively; the most common reason for discontinuation was lack of efficacy in 38 (24.2%) and 27 (35.5%) pts, respectively. MMR rate at wk 96 (per ITT) was higher on asciminib (37.6%) than BOS (15.8%). The difference, adjusting for baseline MCyR, was 21.7% (95% CI, 10.5%-33.0%; 2-sided *P*=.001). More pts on asciminib than BOS, respectively, had *BCR::ABL1*^{IS} ≤1% (45.1% vs 19.4%) at wk 96. The probability of maintaining MMR and *BCR::ABL1*^{IS} ≤1% for ≥72 wk was 96.7% (95% CI, 87.4%-99.2%) and 94.6% (95% CI, 86.2%-97.9%), respectively, on asciminib and 92.9% (95% CI, 59.1%-99.0%) and 95.0% (95% CI, 69.5%-99.3%), respectively, on BOS. Median duration of exposure was 103.1 (range, 0.1-201.1) wk on asciminib and 30.5 (range, 1.0-188.3) wk on BOS. Despite the longer duration of asciminib exposure, safety/tolerability of asciminib continued to be better than that of BOS (Table). No new on-treatment deaths were reported since the primary analysis. Most frequent (>10%) grade ≥3 adverse events (AEs) on asciminib vs BOS were thrombocytopenia (22.4%, 9.2%), neutropenia (18.6%, 14.5%), diarrhea (0%, 10.5%), and increased alanine aminotransferase (0.6%, 14.5%). **Conclusions:** After >2 years of follow-up, asciminib continued to show superior efficacy and better safety/tolerability vs BOS. Responses were durable, with more pts on asciminib in MMR. Additionally, more pts on asciminib had *BCR::ABL1*^{IS} ≤1%, a milestone response in later lines associated with improved survival. These results continue to support the use of asciminib as a new CML therapy, with the potential to transform standard of care. Clinical trial information: NCT03106779. Research Sponsor: Novartis Pharmaceuticals Corporation.

Overview of AEs.

	Asciminib n=156[a]		BOS n=76	
n (%)	All grades	Grade ≥3	All grades	Grade ≥3
AEs	142 (91.0)	88 (56.4)	74 (97.4)	52 (68.4)
AEs leading to discontinuation	12 (7.7)	12 (7.7)	20 (26.3)	15 (19.7)

[a] 1 pt developed cytopenia after randomization and was not treated per investigator's decision.

Overall survival by *IDH2* mutant allele (R140 or R172) in patients with late-stage mutant-*IDH2* relapsed or refractory acute myeloid leukemia treated with enasidenib or conventional care regimens in the phase 3 IDHENTIFY trial. *First Author: Stéphane De Botton, Gustave Roussy, Villejuif, France*

Background: *IDH2* gene mutations (m*IDH2*) occur in up to ~20% of patients (pts) with acute myeloid leukemia (AML), most commonly as R140Q (in ~75% of cases) or R172K (~25%) point mutations. The functional effects and prognostic relevance of m*IDH2*-R140 and m*IDH2*-R172 can vary (Papaemmanuil 2016). In the randomized, phase 3 IDHENTIFY trial, enasidenib (ENA), an oral mIDH2 inhibitor, did not significantly improve overall survival (OS) vs conventional care regimens (CCR) as salvage treatment (Tx) for older pts with m*IDH2* relapsed/refractory (R/R) AML in ITT analysis, but a trend for improved OS with ENA was detected in pts with *IDH2*-R172 mutations. We further investigated OS and correlative biomarkers in IDHENTIFY pt subgroups defined by m*IDH2* variant (R140/R172). **Methods:** This open-label trial (NCT02577406) enrolled pts ≥ 60 years of age who had received 2 or 3 prior AML Tx. Pts were preselected to a CCR (azacitidine, intermediate- or low-dose Ara-C, or supportive care), and were then randomized 1:1 to ENA 100 mg/d or CCR in 28d cycles. Co-occurring gene mutations were identified by targeted next-generation sequencing (37-gene panel) of bone marrow mononuclear cell (BMMC) DNA. Total 2-HG levels were determined by LC/MS. **Results:** Of 319 pts enrolled, 88 pts (28%; 43 ENA, 45 CCR) had m*IDH2*-R172 and 229 (72%; 115 ENA, 114 CCR) had m*IDH2*-R140. Median baseline (BL) 2-HG levels were similar between Tx arms and m*IDH2* variant subgroups, as were *IDH2* variant allele frequencies. Pts with m*IDH2*-R172 had fewer median BL co-mutations (4 [range 2–8]) than did pts with m*IDH2*-R140 (5 [1–11]) ($P < 0.0001$). The most frequently co-occurring mutations were *SRSF2* and *RUNX1* in the R140 cohort (59% each) and *DNMT3A* in the R172 cohort (57%). Compared with the R172 cohort, the R140 group was enriched with *SRSF2, FLT3* (-ITD/-TKD), *NPM1, RUNX1,* and *JAK2* mutations, whereas *DNMT3A* and *TP53* mutations were more common in the R172 group. In Cox multivariate analysis including m*IDH2* variant (R140/R172), *DNMT3A* mutation status, and number of gene mutations at BL, m*IDH2*-R172 was significantly ($P = 0.04$) correlated with improved OS (vs. R140) in the ENA arm, whereas the number of BL gene mutations was significantly ($P < 0.01$) associated with OS in the CCR arm. Median OS in the R172 subgroup was 14.6 mo with ENA vs 7.8 mo with CCR (HR, 0.59 [95%CI 0.35-0.98]; $P = 0.039$) and 1-yr survival rates were 62% and 30%, respectively. In m*IDH2*-R140 pts, median OS was 5.7 mo in both Tx arms (0.93 [0.70-1.24]; $P = 0.61$), and 1-year survival rates were 29% and 25% with ENA and CCR, respectively. **Conclusions:** Mutational burden and co-mutational profiles differed between pts with m*IDH2*-R140 and m*IDH2*-R172 R/R AML. ENA improved survival outcomes for pts with *IDH2*-R172 mutations, with median OS and 1-year survival rate approximately double those in the CCR arm. Clinical trial information: NCT02577406. Research Sponsor: Celgene, a Bristol-Myers Squibb Company.

7006 **Oral Abstract Session**

Pre-MEASURE: Multicenter evaluation of the prognostic significance of measurable residual disease testing prior to allogeneic transplantation for adult patients with AML in first remission. *First Author: Chris S. Hourigan, Laboratory of Myeloid Malignancies, Hematology Branch, National Heart Lung and Blood Institute, National Institutes of Health, Bethesda, MD*

Background: Measurable residual disease (MRD) prior to allogeneic hematopoietic cell transplantation (alloHCT) is associated with increased relapse and death in patients with acute myeloid leukemia (AML) in cytomorphological complete remission (CR). We recently demonstrated AML MRD detected in pre-alloHCT blood by DNA-sequencing was associated with increased relapse and decreased overall survival in patients randomized to reduced intensity conditioning (RIC) versus myeloablative conditioning (MAC). The clinical utility of such ultra-deep next-generation sequencing (NGS-MRD) had not yet been reported in a large multi-center cohort. **Methods:** Patients aged 18 or older who underwent first alloHCT between 2013-2017 for AML in first CR (CR1), reported to be *FLT3, NPM1, IDH1, IDH2* and/or *Kit* mutated at diagnosis, with a pre-conditioning remission blood sample available in the CIBMTR biobank were eligible for this study. Ultra-deep anchored multiplex PCR-based NGS-MRD for the above mutations was performed on 500ng gDNA with error-corrected variant calling as previously described. The pre-specified statistical analysis plan was registered on OSF. **Results:** Of 457 patients with a sample available, 448 had sufficient clinical annotation and DNA for analysis. 147 of these 448 patients (33%) experienced relapse at a median of 5.6 months post-alloHCT. NGS-MRD was positive in 129 pre-alloHCT patient samples (29%), averaging 1.35 mutation(s)/patient (range: 1-4). 173 mutations were detected with a median VAF of 0.18% (range: 0.0054-62%), most frequently *FLT3-ITD* (n = 43 patients), *NPM1* (n = 48), and *IDH2* (n = 46). Testing positive by NGS-MRD prior to alloHCT was associated with a 3yr RFS of 36% (95% CI: 28-45%) compared with 56% (51-62%) in those testing negative ($p < 0.001$). Detection of *NPM1* and/or *FLT3-ITD* mutations prior to alloHCT was associated with a 3yr relapse probability of 55% (43-67%) and RFS of 26% (16-37%). NGS-MRD impact was modified by conditioning intensity: positive patients receiving RIC/NMA had the highest relapse of 57% at 3yr, testing negative followed by RIC/NMA had the same relapse rate at 3yr (35%) as those who tested positive but received MAC ($p < 0.001$). At three years, those positive for *FLT3-ITD* and/or *NPM1* mutations prior to RIC/NMA alloHCT had a relapse probability of 67% (50-83%) with a RFS of 19% (8-33%). HR for relapse if NGS-MRD positive pre-alloHCT in CR1 was 2.3 ($p < 0.001$, 95% CI 1.6-3.1) when adjusting for conditioning intensity and age group. **Conclusions:** In this largest cohort of NGS-MRD testing prior to alloHCT for AML reported to date, we confirm the ability to identify patients in CR1 but at high-risk of subsequent relapse. This evidence provides the foundation for future precision medicine approaches to reduce post-transplant AML relapse. Research Sponsor: U.S. National Institutes of Health.

7007 **Oral Abstract Session**

Long-term results of a phase 2 trial of crenolanib combined with 7+3 chemotherapy in adults with newly diagnosed FLT3 mutant AML. *First Author: Eunice S. Wang, Roswell Park, Buffalo, NY*

Background: Crenolanib is a potent type I FLT3 inhibitor active against FLT3- ITD, TKD and variant mutations. We report the long-term outcomes of a phase II trial evaluating crenolanib combination therapy in patients (pts) with newly diagnosed FLT3 mutant AML. **Methods:** Pts (≥ 18 yrs) with newly diagnosed FLT3-AML received 7+3 induction with cytarabine 100 mg/m^2/d for 7 days and daunorubicin (DNR) (<60 yrs: 90 mg/m^2; ≥60 yrs: 60 mg/m^2) or idarubicin (IDA 12 mg/m^2) for 3 days. Crenolanib 100 mg TID was administered starting on day 9 until 72 hrs prior to next chemotherapy. Re-induction was allowed. Up to 4 cycles of HiDAC consolidation (<60 yrs: 3 g/m^2; ≥60 yrs: 1g/m^2) was allowed. Eligible pts could proceed to transplant. Crenolanib maintenance therapy was offered for 1 yr after HiDAC or transplant. **Results:** 44 pts (22 male) with a median age of 57 yrs (range 19-75) were treated; 15 (34%) pts were >60 yrs. 7 pts had initial WBC >100,000/μL (2 had WBC >200,000). 4 pts had AML following MDS/MPN. 39 (89%) pts had intermediate risk cytogenetics, 3 (7%) had adverse risk, and 2 were unavailable. 33 (75%) pts had *FLT3-ITD*, 8 (18%) had *TKD*, and 3 (7%) had *ITD* and *TKD* mutations. 11 pts had concomitant *NPM1*/*DNMT3A* mutations, 11 pts had secondary AML-type mutations, and 2 pts had *TP53*. 28 pts received DNR/crenolanib; 16 pts received IDA/crenolanib. Overall CRc (CR + CRi) was 73% (32/44) after one induction cycle; 86% (38/44) after two cycles. CRc rates > 80% were noted in pts ≤ 60 yo, *FLT3-ITD* mutations, concomitant *FLT3/DMT3A/NPM1* mutations, intermediate risk cytogenetics, and WBC ≥ 100,000/μL. Median time to count recovery was 30 days. MRD-negative CRc was achieved in 94% of evaluable pts (17); 22 pts underwent HSCT. The most common treatment related adverse events (AE) were diarrhea (66%), nausea (57%) and febrile neutropenia (52%). Grade ≥3 AE included febrile neutropenia (50% pts), diarrhea (18%), nausea (6%), and rash (6%). No QTC prolongation was observed. 6 pts required crenolanib dose reduction during induction. High levels of serum crenolanib were achieved and maintained throughout therapy. With a median follow-up of 45 mos (4.4-54.9), the median OS for all pts has not been reached with 57% of pts alive. Median EFS for all pts was 45 mos. In younger pts (≤ 60 yo) OS was 69% and EFS 62%. Cumulative incidence of relapse was 15%. In older pts (61-75), 80% achieved CR/CRi, and median OS was 20 mos. Mutational analysis demonstrated clearance of multiple variant FLT3 mutations and no new FLT3 clones at relapse in pts completing protocol therapy. **Conclusions:** Long-term outcomes of a phase 2 trial of crenolanib combined with 7+3 induction and consolidation in adults with newly diagnosed *FLT3* mutant AML demonstrate high response rates (CRc 86%). With a median follow-up of 45 mos, median OS has not been reached. A phase 3 trial (NCT03258931) randomizing pts with newly diagnosed *FLT3* mutant AML to crenolanib vs midostaurin with 7+3 is ongoing. Clinical trial information: NCT02283177. Research Sponsor: Arog Pharmaceuticals, Inc.

7008 **Clinical Science Symposium**

Autologous CD19-directed CAR T cells produced by novel PrimeCAR manufacture platform exhibit safety, efficacy, and long persistence profiles in relapsed/refractory B-lineage acute leukemia (r/r B-ALL). *First Author: Shiqi Li, 920th Hospital of Joint Logistics Support Force of People's Liberation Army of China, Kunming, China*

Background: CD19 chimeric antigen receptor (CAR) T cell therapy has shown promising efficacy in the r/r B-ALL. However, the life-threatening side effects especially high grades of cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) limited its wide application. To overcome these limitations, we established a novel PrimeCAR platform based on moderate activation and short expansion to manufacture MC-1-50, an autologous CD19-directed CAR T cell. Our preclinical study showed that MC-1-50 exerted a great efficacy and less cytokines secretion. **Methods:** In this Phase I /II study (NCT04271410), CAR T cells were manufactured by PrimeCAR platform, which reduces manufacture periods to about 2 days. T cells were transducted with a lentiviral vector encoding a humanized CD19 specific scFv following 4-1BB and CD3ζ cytoplasmic domain. Patients (pts) received single-dose of MC-1-50 at dose level 1 (1×10^5 CAR+/kg), level 2 (3×10^5 CAR+/kg), and level 3 (1×10^7 CAR+ totally, ranged 1.67-3.85×10^5 CAR+/kg). Pts were pre-conditioned with fludarabine (25-30 mg/m^2) and cyclophosphamide (200-300 mg/m^2) daily for 3 days. Toxicity was graded by CTCAE , CRS and ICANS were graded by ASTCT criteria. **Results:** As of Feb 10, 2022, 13 pts with r/r B-ALL were infused with MC-1-50. Disease characteristics and outcomes are shown in the table. No DLTs were reported. Eleven pts (84%) experienced CRS, including 7 (54%) at grade 1 and 4 (30%) at grade 2, no ≥ 3 CRS were observed. One pts (7%) experienced grade 1 ICANS, no ≥ 2 ICANS occurred. The Tmax for IL-6 was detected around day 11 (123.3±165.16 pg/ml). There were similar low secretion features of other cytokines, which is consistent with low CRS and ICANS. In all dose levels, 13 pts finished 1M evaluation and the CR rate in 1M is 100%. Four pts finished 3M evaluation and the CR rate in 3M is 75%, 1 pts relapsed at the month 3 with CD19 mutation. One pts had a CR statue at the month 11. Cmax for CAR copy number in 3 dose levels are similar and the average number of Cmax of CAR is 275901.6 copies/ug genomic DNA. **Conclusions:** PrimeCAR platform could produce CAR T cells in very short time with high percentage of T_{scm}. Treatment of r/r B-ALL at very low dose resulted in excellent safety profile, while exhibited a promising efficacy. That make this PrimeCAR platform potential for outpatient administration in the future. Clinical trial information: NCT04271410. Research Sponsor: Chongqing Precision Biotech Co., Ltd.

A phase II trial of a chemotherapy-free combination of ponatinib and blinatumomab in adults with Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ ALL). *First Author: Nicholas James Short, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: Ponatinib and blinatumomab are highly active in Ph+ ALL. A chemotherapy-free combination of these agents may lead to durable remissions and reduce the need for stem cell transplant (SCT) in first remission. **Methods:** In this phase II study, adults with newly diagnosed (ND) Ph+ ALL, relapsed/refractory (R/R) Ph+ ALL, or CML in lymphoid blast phase (CML-LBP) received up to 5 cycles of blinatumomab. Ponatinib 30mg daily was given during cycle 1 and decreased to 15mg daily once a complete molecular response (CMR) was achieved. After completion of blinatumomab, ponatinib was continued for at least 5 years. All patients (pts) received 12 doses of prophylactic IT chemotherapy. **Results:** Between 2/2018 and 1/2022, 55 pts were treated (35 ND, 14 R/R and 6 CML-LBP). Baseline characteristics and responses are shown in Table. Among 23 pts with ND Ph+ ALL evaluable for response, 22 (96%) achieved CR/CRi; 1 pt had early death due to myelosuppression from prior chemotherapy. Among 13 evaluable pts with R/R Ph+ ALL, 12 (92%) achieved CR/CRi. The CMR rates for the ND, R/R and CML-LBP cohorts were 64%, 71%, and 17% after cycle 1 and were 85%, 79%, and 33% overall, respectively. In the ND cohort, 4/17 evaluable pts (24%) achieved CMR in the peripheral blood within 1 week, and 9/15 (60%) within 2 weeks. The median follow-up is 11 months (range, 1-46+ months). Among the 35 pts in the ND cohort, 33 pts (94%) are alive and in continuous remission. Only 1 pt in the ND underwent SCT in first remission (due to persistent MRD positivity), and no relapses have been observed. The 2-year EFS and OS rates in the ND cohort are 93%. Among the 13 responding pts in the R/R cohort, 6 (46%) underwent SCT. The 2-year EFS and OS rates for the R/R cohort are 42% and 61%, and for the CML-LBP cohort are 33% and 60%, respectively. Most side effects were grade 1-2 and were consistent with the known toxicity profile of the two agents individually. Two pts discontinued ponatinib due to toxicity (1 due to stroke and 1 due to DVT). One pt discontinued blinatumomab due to recurrent neurotoxicity. **Conclusions:** The chemotherapy-free combination of ponatinib and blinatumomab was safe and effective in Ph+ ALL and CML-LBP. Longer follow-up continues to demonstrate durable remissions, particularly in ND Ph+ ALL, even without SCT in first remission. Clinical trial information: NCT03263572. Research Sponsor: Amgen and Takeda.

7010 **Poster Discussion Session**

Two-year follow-up of KTE-X19, an anti-CD19 chimeric antigen receptor (CAR) T-cell therapy, in adult patients (Pts) with relapsed/refractory B-cell acute lymphoblastic leukemia (R/R B-ALL) in ZUMA-3. *First Author: Bijal D. Shah, Moffitt Cancer Center, Tampa, FL*

Background: Brexucabtagene autoleucel (KTE-X19) is an autologous anti-CD19 CAR T-cell therapy approved in the US to treat adult R/R B-ALL based on the ZUMA-3 study. The overall complete remission (CR) rate (CR + CR with incomplete hematologic recovery [CRi]) was 71% (95% CI, 57-82) after 16.4 mo median follow-up (N = 55; Shah et al. *Lancet* 2021). Here, we report updated outcomes with longer follow-up in these pts and in a larger pooled analysis of Phase (Ph) 1 and 2 pts who received the pivotal dose of KTE-X19. **Methods:** Eligible adults (≥18 years) had R/R B-ALL and received a single infusion of KTE-X19 at the pivotal dose (1×10^6 CAR T cells/kg) following leukapheresis and conditioning chemotherapy. The primary endpoint was CR/CRi rate by central review. **Results:** As of 23 July 2021, median follow-up was 26.8 mo (range, 20.7-32.6) for treated Ph 2 pts (N = 55). The CR/CRi rate per central review was 71% (95% CI, 57-82; 56% CR; 15% CRi). Eleven pts (20%; 8 CR and 2 CRi) proceeded to subsequent allogeneic stem cell transplant (alloSCT). Median duration of remission (DOR) censored at subsequent alloSCT was 14.6 mo (9.4-not estimable [NE]); not censored: 18.6 mo (9.6-NE); 6/39 responders (15%) had ongoing responses at data cutoff. Median (95% CI) relapse-free survival (RFS) was 11.6 mo (2.7-20.5) censored at subsequent alloSCT and 11.7 mo (2.8-20.5) not censored at subsequent alloSCT; 18-mo RFS rates (95% CI) were 35% (20.5-50.6) and 42% (28.0-55.0), respectively. Median (95% CI) overall survival (OS) was 25.4 mo (16.2-NE) among all KTE-X19-treated pts and not reached (25.4-NE) in pts with CR (n = 31). For Ph 1/2 pts (N = 78) who received the pivotal KTE-X19 dose (median follow-up: 29.7 mo; range 20.7-58.3), the CR/CRi rate by independent review was 73% (95% CI, 62-82). Medians (95% CI) for DOR, RFS, and OS were 18.6 mo (9.6-NE), 11.7 mo (6.1-20.5), and 25.4 mo (16.2-NE), respectively. A subgroup analysis revealed that in pts aged 18-39 (n = 36), 40-59 (n = 27), and ≥60 (n = 15) years, the CR/CRi rates (95% CI) were 69% (52-84), 70% (50-86), and 87% (60-98); 24-mo OS rates (95% CI) were 48% (30-64), 54% (33-71), and 57% (28-78), respectively. In pts with pre-KTE-X19 infusion marrow blast percentages > 25 to ≤50 (n = 12), > 50 to ≤75 (n = 14), and > 75 to 100 (n = 30), CR/CRi rates (95% CI) were 83% (52-98), 86% (57-98), and 57% (37-75); 24-mo OS rates (95% CI) were 58% (27-80), 55% (26-77) and 37% (19-55), respectively. There were no new safety signals; the proportion of treated Ph 2 pts with Gr ≥3 treatment emergent adverse events was unchanged since prior data cutoff. One pt had an ongoing neurologic event of Gr 1 finger numbness. **Conclusions:** With longer follow-up and an expanded data set by independent review, outcomes remain durable in adults with R/R B-ALL, most of whom were heavily pretreated, with median OS not yet reached in pts with CR. Long-term safety was favorable. Clinical trial information: NCT02614066. Research Sponsor: Kite, a Gilead Company.

7011 **Poster Discussion Session**

Updated results from a phase II study of mini-hyper-CVD (mini-HCVD) plus inotuzumab ozogamicin (INO), with or without blinatumomab (Blina), in older adults with newly diagnosed Philadelphia chromosome (Ph)-negative B-cell acute lymphoblastic leukemia (ALL). *First Author: Walid Macaron, MD Anderson Cancer Center, Houston, TX*

Background: INO and Blina improve overall survival (OS) in patients (pts) with relapsed/refractory B-ALL. The use of these agents in older adults in the frontline setting may allow for use of less chemotherapy and improve remission duration and OS compared to standard therapies. **Methods:** Pts ≥60 years with newly diagnosed Ph-negative B-cell ALL received mini-HCVD for up to 8 cycles. Initially, INO was given at 1.3-1.8mg/m^2 on day 3 of cycle 1 and 0.8-1.3mg/m^2 on day 3 of cycles 2-4. Rituximab (if CD20+) and prophylactic IT chemotherapy were given for the first 4 cycles. Responding pts received POMP maintenance for up to 3 years. Beginning with pt #50, INO was given in fractionated doses each cycle (0.6 mg/m^2 on day 2 and 0.3 mg/m^2 on day 8 of cycle 1; 0.3 mg/m^2 on day 2 and 8 of cycles 2-4) and 4 cycles of Blina were given following 4 cycles of mini-HCVD plus INO. Maintenance was with 12 cycles of POMP and 4 cycles of Blina (1 cycle of Blina after 3 cycles of POMP). **Results:** Characteristics of the 80 pts are shown in Table. 6 pts were in complete remission (CR) at enrollment. Among 74 evaluable pts, 73 (99%) responded (CR in 89%). MRD negativity by flow was achieved in 80% of pts after 1 cycle and in 94% overall. The 30-day mortality rate was 0%. Among 79 responders, 11 (14%) relapsed, 4 (5%) underwent SCT, 33 (42%) remain in ongoing continuous remission, and 31 (39%) died in remission. Notably, 6 pts (8%) developed veno-occlusive disease, 1 after subsequent SCT. With a median follow-up of 55 months, the 5-year continuous remission and OS rates were 76% and 47%, respectively. Age ≥70 and poor-risk cytogenetics were associated with worse outcomes. The inferior outcomes in pts ≥70 years was primarily due to higher rates of death in CR. The 5-year OS for pts age 60-69 years without poor-risk cytogenetics (n=37), age 60-69 with poor-risk cytogenetics (n=13), age ≥70 without poor-risk cytogenetics (n=24) and age ≥70 with poor-risk cytogenetics (n=6) were 69%, 39%, 36% and 0%, respectively. **Conclusions:** The combination of mini-HCVD plus INO, with or without Blina, in older adults with newly diagnosed Ph-negative ALL resulted in an overall response rate of 99% and a 5-year OS rate of 47%. Particularly favorable outcomes were seen in pts age 60-69 years without poor-risk cytogenetics (5-year OS: 69%). Chemotherapy-free regimens may improve outcomes in pts age ≥70 years, and novel agents/regimens are still needed for those with poor-risk cytogenetics. Clinical trial information: NCT01371630. Research Sponsor: Pfizer and Amgen.

Health inequities in survival of patients with acute lymphoblastic leukemia in Peru: A single tertiary institution experience.

First Author: Evelyn Pamela Espinoza-Morales, Universidad Privada San Juan Bautista, Lima, Peru

Background: Acute Lymphoblastic Leukemia (ALL) in Latino countries is characterized by high incidence and worst outcomes compare to other ethnicities. However, the actual epidemiological characterization of ALL in South America remains unknown. The lack of registries, uniform treatment and prospective protocols have been pointed out for these disparities. Also, biological, and social aspects of this disease play an important role that has not been well examined. We aimed to evaluate the survival of patients with acute lymphoblastic leukemia according to demographic characteristics with emphasis in the place of residence. **Methods:** We performed an analytical retrospective cohort study with subjects diagnosed and treated for ALL during the period 2016-2018 at the Peruvian national cancer center (INEN, Instituto Nacional de Enfermedades Neoplasicas). INEN is currently the main center dedicated to diagnosing and treat acute leukemias for patients without social neither private insurance. Also, INEN is located at the capital city (Lima-Peru). The calculated sample size was 378 patients. Patient data were obtained from the epidemiological registry and corroborated with the national registry of mortality (RENIEC, Registro Nacional de Identificacion y Estado Civil Overall survival probabilities according to demographic characteristics were estimated using the Kaplan-Meier curve; in addition, the Log-rank test and Cox regression were used. **Results:** A sample of 378 patients were included during the study period (N = 588), of which 212 (56.8%) were male, 42% were between 0-10 years, 24% in 46-65 years. Regarding the characteristics at diagnosis, 80% were Ph(-) BCP-ALL and 69% corresponded to high-risk groups. At 42 months of follow-up, the median survival of the patients was 29 months (95% CI: 23.3-34.6), and the overall survival at three years was 44.8%. Overall survival in males (48.8%) was higher than in females (39.5%). According to the range of age, the highest survival was in the group of 0-10 years (70%), followed by 11-20 years (36.8%) and the lowest survival was in 46- 65 years (12.5%). Furthermore, overall survival in Lima (51.5%) was higher than in the country-side (39.7%). There was a statistically significant association ($p < 0.05$) between survival and sex ($p = 0.042$), age range ($p = 0.000$) and place of residence ($p = 0.005$); according to the Log-rank test. **Conclusions:** We report a lower survival among all age groups in ALL compared to international working groups. Living in a country-side region represents a significant factor for dismal survival in our cohort. Specialized health care access to diagnosis and treatment should be warranted for patients with geographical limitations and programs to ensure it must be implemented. Research Sponsor: None.

Impact of socioeconomic status on survival after CD19 CART therapy.

First Author: Haley Newman, Children's Hospital of Philadelphia, Philadelphia, PA

Background: CD19-directed chimeric antigen receptor T cell (CART) therapy has dramatically improved survival for children with relapsed/refractory (r/r) B-cell acute lymphoblastic leukemia (B-ALL). While significant socioeconomic (SES) outcome disparities exist for children with newly diagnosed B-ALL, the impact of SES on CART access and outcomes is poorly described. Using the largest single-center pediatric CART experience, we investigated the hypothesis that poverty-exposed children would have inferior survival outcomes compared to unexposed children. **Methods:** Retrospective cohort study of US pediatric patients treated on CD19 CART clinical trials or with commercial tisagenlecleucel at Children's Hospital of Philadelphia from 2012-2020. Poverty was the primary exposure, defined at the household-level by insurance status (public vs private). Neighborhood opportunity was defined by census-derived Childhood Opportunity Index (COI) (low [q1-2] vs high [q3-4]). Overall survival (OS) and relapse-free survival (RFS) were evaluated by Kaplan Meier methods, and association with exposures by Cox regression models. **Results:** Among 206 patients, 36% were household poverty exposed, 24.9% low COI, 21.4% identified as Hispanic, 7.3% non-Hispanic Black, 63.6% non-Hispanic White, and 7.7% non-Hispanic Other. Household-poverty exposure was similar between local and referred patients (32.4% vs 36.7%). Patients unexposed to poverty at the household level or with high COI presented to CART with high disease burden (37.1% vs 26%, $p = 0.049$, 37.9% vs. 29.7%, $p = 0.002$). In multivariate analysis adjusting for age, race/ethnicity, disease burden, relapse status, and inotuzumab exposure, there were no significant differences in OS by householdverty (HR 0.86, 95%CI 0.50-1.48, $p = 0.575$) or low COI (HR 1.03, 95%CI 0.53-1.99, $p = 0.932$). Low COI was associated with inferior RFS (HR 2.26, 95%CI 1.34-8.80, $p = 0.002$). There was no significant difference in RFS by household-poverty (HR 0.84, 95%CI 0.48-1.44, $p = 0.520$). **Conclusions:** Household poverty was not associated with inferior survival outcomes in pediatric patients who received CART for r/r B-ALL. Patients with low neighborhood opportunity had increased hazard of relapse, a finding that requires investigation of the COI components underlying this association. Patients of higher proxied SES were more likely to have high disease burden, an access inequity potentially reflecting referral pattern bias or greater ability of advantaged families to advocate for CART. Future institutional and multi-center studies should utilize patient-reported social determinants of health to investigate mechanisms driving these disparities and guide care delivery interventions to improve equity in access and outcomes. Clinical trials: NCT01626495, NCT02435849, NCT02374333, NCT02228096, NCT02906371 Research Sponsor: None.

7014 **Poster Discussion Session**

Challenges and outcomes of treating acute myeloid leukemia (AML) in resource-constrained settings.

First Author: Sahitya Dangudubiyyam, All India Institute of Medical Sciences, New Delhi, India

Background: Acute myeloid leukemia (AML) is a heterogeneous disease. Improvement in supportive care, has considerably improved AML induction outcomes, decreasing induction deaths to <5% in recent studies. However, induction deaths during AML treatment in resource constraint settings remains as high as 25% in young adults. In this study we explore various challenges encountered in treating AML patients in one of the largest public sector teaching hospitals in India. **Methods:** Consecutive patients diagnosed with AML and registered in our clinic from January 1, 2018 to December 31, 2019, were included. **Results:** Of 316 patients diagnosed with AML, only 181 (57%) were able to get admitted to our institute for remission induction treatment. Median time from diagnosis to treatment initiation was 9.5 days (range, 0-232 days). Almost half (N=88; 49%) of admitted patients had infections at the time of admission. Among these, 31 (35%) had invasive fungal infection; 14 possible, 15 probable, and 2 proven. Fifty-two (29%) patients died prior to starting their remission induction therapy. Induction mortality in our cohort is 40%. Primary induction failure and primary refractory disease were noted in twenty (18%), and 5 (4%) patients respectively. Only 1 patient was able to get all three high dose cytarabine (HIDAC) consolidations on time. Median time to first HIDAC was 39.5 days (range, 28-91). Of 83 patients who were candidates for consolidative allogeneic hematopoietic cell transplantation (HCT), only ten (12%) patients were able to get transplanted. Median time to HCT from CR1 was 3.8 months (range, 1.89-12.8). The median event free survival (EFS) was 1.7 months (95%CI, 1.03-2.5) and median overall survival was 2.5 months (95%CI, 1.6-3.6). The median EFS in favourable risk, intermediate risk and adverse risk AML was 3.6 months, 3.7 months, and 3.4 months respectively. Likewise the median OS was 8.8 months, 11.8 months and 7.4 months in the three risk strata respectively. **Conclusions:** Outcomes of AML treatment in our cohort are discordant with that reported from the West. Our study identifies various challenges in treating AML in resource-constraint setting. Strategies need to be formulated to overcome these challenges. Research Sponsor: None.

Navitoclax plus ruxolitinib in JAK inhibitor-naive patients with myelofibrosis: Preliminary safety and efficacy in a multicenter, open-label phase 2 study.

First Author: Francesco Passamonti, Department of Medicine and Surgery, University of Insubria, Varese, Italy

Background: Ruxolitinib (RUX), a Janus kinase (JAK) 1/2 inhibitor, is the current standard of care for patients (pts) with myelofibrosis (MF) that improves splenomegaly and disease symptoms with limited impact on disease biology. Many pts lose response over time, highlighting an unmet need for novel therapies. Navitoclax (NAV) is an oral, small-molecule inhibitor of BCL-X_L and BCL-2 that has a synergistic effect when used in combination with JAK inhibitors to enhance apoptosis. This ongoing, open-label, multicenter, phase 2 trial (NCT03222609) is evaluating the efficacy and safety of NAV with/without RUX in pts with MF. Here, we report results from JAK inhibitor-naïve pts treated with NAV+RUX. **Methods:** Enrolled pts had primary or secondary MF with splenomegaly (DIPSS ≥INT-1) and did not receive prior JAK-2 therapy or bromodomain and extraterminal motif (BET) inhibitors. Pts initiated NAV at 100 mg QD or 200 mg QD if baseline (BL) platelet count was $\leq 150 \times 10^9$/L or $>150 \times 10^9$/L, respectively. RUX was given BID with starting dose based on BL platelet count per local label. The primary endpoint was spleen volume reduction of ≥35% (SVR_{35}) from BL at wk 24. Key secondary endpoints were ≥50% reduction in total symptom score (TSS_{50}), bone marrow (BM) fibrosis reduction, and anemia response. Adverse events (AEs) were monitored throughout the study. **Results:** As of Oct 04, 2021, 32 pts received NAV+RUX. Median duration of f/u was 6.1 (range, 1.9 18.6) mos. 28 (88%) pts received NAV 200 mg and 4 (13%) received 100 mg OD. Median age was 69 (44 83) yrs, and median spleen volume was 1889.08 cm^3 (645.6 7339.6). Median NAV and RUX exposures were 24.1 (5.1 80.9) and 20.1 (0.1 80.1) wks, respectively. 31 (97%) pts reported ≥1 AE (Grade ≥3 AEs, 25 [78%]; serious AEs, 6 [19%]). Most common Grade ≥3 AEs were anemia (34%), thrombocytopenia (31%), and neutropenia (19%). 3 (9%) and 2 (6%) pts reported an AE leading to NAV and RUX discontinuation, respectively, and 2 (6%; 1 PD, 1 cardiac disorder unrelated to NAV) AEs led to death ≤30 days after last NAV dose. SVR_{35} was achieved by 52% of evaluable pts at wk 24 (SVR_{35} in INT-2, 50%; HR, 33%) and by 76% at any time on treatment (Table). Median time to first SVR_{35} was 12.1 (11 47) wks. **Conclusions:** The combination of NAV+RUX was well tolerated and demonstrated early and robust reductions in spleen volume, anemia, and BM fibrosis in pts without prior JAK-2 inhibitor exposure. SVR_{35}, TSS_{50}, and BM fibrosis improved over time. Clinical trial information: NCT03222609. Research Sponsor: AbbVie.

Key endpoints.

	NAV+RUX n/N (%)
SVR_{35} at wk 24	11/21 (52)
SVR_{35} at any time post BL	16/21 (76)

TSS_{50} at any time post BL	9/16 (56)
Total anemia response[a]	6/11 (55)
Reduction in bone marrow fibrosis grade from BL by ≥1grade at any time post BL	6/20 (30)

BL, baseline [a]Total anemia response = transfusion independence (TI) in pts with BL Hb<10 g/dl with Hb increase ≥ 2g/dl + TI in those who were transfusion-dependent at BL.

7016 **Poster Discussion Session**

Phase 1/2a study of the IRAK4 inhibitor CA-4948 as monotherapy or in combination with azacitidine or venetoclax in patients with relapsed/refractory (R/R) acute myeloid leukemia or lyelodysplastic syndrome.

First Author: Guillermo Garcia-Manero, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: CA-4948 is a novel oral inhibitor of interleukin-1 receptor-associated kinase 4 (IRAK4) and FLT3. IRAK4 is critical in triggering inflammation, oncogenesis, and survival of cancer cells. Genetic mutations in the splicing factors *SF3B1* and *U2AF1* drive overexpression of a highly active long isoform of IRAK4 and have been associated with disease progression and poor prognosis of high-risk myelodysplastic syndrome (HR-MDS) and acute myeloid leukemia (AML). **Methods:** This is an open-label, phase 1/2a dose escalation and cohort expansion trial (NCT04278768). In phase 1 Dose Escalation, patients with R/R AML or HR-MDS are treated with CA-4948 monotherapy. Phase 1b includes 2 arms of combination therapy: CA-4948 + azacitidine (AZA) and CA-4948 + venetoclax (VEN). The primary objectives of this study are to assess the safety, clinical activity, and identify the Recommended Phase 2 Dose (RP2D) of CA-4948 as monotherapy or in combination with AZA or VEN in R/R AML or HR-MDS. The Phase 2a Dose Expansion includes patients for CA-4948 monotherapy: R/R AML with *FLT3* mutation, or AML and HR-MDS R/R to HMA with *U2AF1* or *SF3B1* mutations. **Results:** As of December 16th, 2021, 49 patients have been treated in the phase 1 portion, of whom 43 started by September 30th, allowing 2 on-study disease assessments. The median number of prior therapies was 2 (range 1-5). Four monotherapy dose levels of CA-4948 were tested (200 to 500 mg orally BID). No dose-limiting toxicities were observed at 200 mg and 300 mg BID. No Grade 4 or 5 treatment-related AEs (TRAEs) were reported, and all the TRAEs were manageable. Reversible, manageable Grade 3 rhabdomyolysis occurred in 1/26 (4%) patients at 300 mg BID, 2/17 (12%) at 400 mg BID, and 1/3 (33%) at 500 mg BID. RP2D was determined as 300 mg BID. Of 43 patients starting before Sept 30th, 2021, 14 had *SF3B1*, *U2AF1* or *FLT3* mutations and demonstrated more promising efficacy. In the 5 evaluable AML patients with spliceosome mutations, 40% reached CR/CRh (1 CR, 1 CRh), both with study duration >6 months. In the 7 spliceosome-mutated HR-MDS patients, 57% reached marrow CR, including 1 with RBC transfusion independence and 1 proceeding to HSCT. One of the three *FLT3*-mutated AML reached CR, and 2 became *FLT3*-negative. Among the 29 patients without *SF3B1/U2AF1/FLT3* mutations, 1 reached CR and 2 PR. Phase 1b and Phase 2a are ongoing. RNA-seq on selected samples showed decrease in relative expression of IRAK4-long isoforms with response to CA-4948. **Conclusions:** CA-4948 is well tolerated and effective in heavily pretreated AML and HR-MDS patients, especially in those with *U2AF1/SF3B1/FLT3* mutations. No dose-limiting myelosuppression was reported, suggesting CA-4948 may be a candidate for combination therapy. Accrual of Phases 1b and 2a is ongoing. Clinical trial information: 04278768. Research Sponsor: Curis.

Magrolimab in combination with azacitidine for untreated higher-risk myelodysplastic syndromes (HR-MDS): 5F9005 phase 1b study results.

First Author: David Andrew Sallman, Moffitt Cancer Center, Tampa, FL

Background: Magrolimab is a monoclonal antibody that blocks CD47, a "don't eat me" signal overexpressed on cancer cells. CD47 blockade by magrolimab induces macrophage-mediated phagocytosis of tumor cells and is synergistic with azacitidine (AZA) via upregulation of "eat me" signals. Here we report final Phase 1b data in patients (pts) with untreated HR-MDS (NCT03248479). **Methods:** Pts with previously untreated intermediate-/high-/very high-risk MDS per IPSS-R received magrolimab IV as a priming dose (1 mg/kg) followed by ramp-up to a 30 mg/kg weekly or Q2W maintenance dose. AZA 75 mg/m^2 was administered IV or SC on Days 1–7 of each 28-day cycle. Primary endpoints were safety/tolerability and complete remission (CR) rate. **Results:** 95 pts (median age 69 years [range 28, 91]) were treated. IPSS-R risk was intermediate, high, or very high in 27%, 52%, and 21%, respectively. MDS was therapy-related in 22%; 26% (n=25) had a *TP53* mutation and 62% had poor-risk cytogenetics (27% complex). Median (range) number of cycles was 6 (1, 27). The most common TEAEs included constipation (68%), thrombocytopenia (55%), anemia (52%), neutropenia (47%), nausea (46%), and diarrhea (44%). The most common Grade 3/4 TEAEs included anemia (47%), neutropenia (46%), thrombocytopenia (46%), and WBC count decreased (30%). 6 pts discontinued treatment due to AEs. 60-day mortality was 2%. Median Hb change from baseline (BL) at first post-dose sample was –0.7 g/dL (range –3.1, +2.4). CR and objective response (OR) rates were 33% and 75% with 31% of evaluable OR pts with abnormal cytogenetics at BL having cytogenetic CR. Median time to first OR, duration of CR (DCR), duration of OR, and PFS were 1.9, 11.1, 9.8, and 11.6 mos. OS rates at 12 and 24 mos were 75% and 52%, respectively (median NR with 17.1 mos follow-up for OS). For patients evaluated with sequential WES with a VAF cutoff of 5%, 3 of 3 pts with *TP53* mutation who achieved CR had TP53 VAF <5% by C5D1. Favorable outcomes were observed in both *TP53* mutant (40% CR, median OS 16.3 months) and wildtype pts (31% CR, median OS NR; Table). **Conclusions:** Magrolimab+AZA was well tolerated with promising efficacy in pts with untreated HR-MDS including those with *TP53*-mut and *TP53*-wt disease. A Phase 3 trial of magrolimab/placebo+AZA (ENHANCE: NCT04313881) is ongoing. Clinical trial information: NCT03248479. Research Sponsor: Gilead Sciences, Inc.

Outcome	All N=95*	*TP53*-wt MDS N=61	*TP53*-mut MDS N=25
Objective response rate, %†	75	79	68
CR, % (95% CI)	33 (23, 43)	31 (20, 44)	40 (21, 61)
Marrow CR, %	32	38	20
SD w/HI, %	11	10	8
DCR, median (95% CI) mos	11.1 (7.6, 13.4)	12.9 (8.0, NR)	7.6 (3.1, 13.4)
Marrow CR with HI/Any HI, %	17/59	20/61	12/56
Converted to RBC transfusion independence, %	14	10	24
PFS, median (95% CI) mos	11.6 (9.0, 14.0)	11.8 (8.8, 16.6)	11.0 (6.3, 12.8)
OS, median (95% CI) mos	NR (16.3, NR)	NR (21.3, NR)	16.3 (10.8, NR)

*9 pts included in all pts had missing TP53 status. †Defined as CR+ PR + marrow CR + SD w/HI. HI, hematologic improvement; NR, not reached; SD, stable disease.

7018 **Poster Discussion Session**

A phase Ib/II study of ivosidenib with venetoclax +/- azacitidine in IDH1-mutated hematologic malignancies.

First Author: Curtis Andrew Lachowiez, M.D. Anderson Cancer Center, Houston, TX

Background: Isocitrate dehydrogenase-1 mutations (*IDH1*$^+$) result in production of the oncometabolite 2-hydroxyglutarate, arrested differentiation, and increased dependence on the anti-apoptotic protein BCL-2, enhancing susceptibility to the BCL-2 inhibitor venetoclax (VEN). Herein, we report the completed P1b portion of the P1b/II study combining the IDH1 inhibitor ivosidenib (IVO; 500 mg PO daily D15-continous) with VEN (D1-14), with or without azacitidine (AZA; 75mg/m^2 D1-7 every 28 days). **Methods:** Eligible patients age 18 with *IDH1*$^+$ MDS, newly diagnosed (ND: de novo and secondary/treated secondary AML) or relapsed/refractory (R/R) AML were enrolled into 4 dose levels (DL): DL1 (IVO+VEN 400 mg), DL2 (IVO+VEN 800 mg), DL3 (IVO+VEN 400 mg+AZA), DL4 (IVO+VEN 800 mg+AZA). Primary objectives included safety and tolerability, and IWG defined overall response (ORR: CR+CRi+CRh+PR+ MLFS). **Results:** 31 patients (DL1: 6, DL2: 6, DL3: 13, DL4: 6) enrolled with a median follow-up of 26 months. Median age was 67 years (range: 44-84). 71% had AML (ND: N = 14, R/R: N = 8), 29% (N = 9) had MDS. ELN risk was intermediate and adverse in 19% (N = 6) and 55% (N = 17). Median baseline *IDH1*$^+$ VAF was 23% (5%-48%). Median time on study was 6.4 (range: 4 -not reached [NR]) months. The ORR was 94% (DL1: 67%, DL2-DL4: 100%); Composite CR (CRc: CR+CRi+CRh) was 87% (DL1: 67%, DL2: 100%, DL3: 85%, DL4: 100%). 63% of AML patients attained measurable residual disease negative CRc by multiparameter flow cytometry (ND-AML: 64%, R/R-AML: 60%). Addition of AZA increased MRD clearance in ND-AML compared to the doublet regimen (86% vs. 25%, p: 0.09). *IDH1*$^+$ mutation clearance by digital droplet PCR (sensitivity: 0.1-0.25%) was attained in 67% of patients (ND-AML: 83%, R/R-AML: 50%, MDS: 50%) following cycle 5. 35% of patients required dose reductions for cytopenias (DL2: 2 [33%], DL3: 6 [46%], DL4: 3 [50%]). Grade 3-5 adverse events (AEs) occurring in 10% of patients included febrile neutropenia (29%; one episode resulted in death in a R/R-AML patient relapsing on study) and pneumonia (23%). AEs of special interest (AESI) included grade 3 tumor lysis syndrome in two patients (dose-limiting toxicity in one), and differentiation syndrome in 4 (G2: N = 2, G3: N = 2) patients. All AESIs were transient and reversible. Median EFS and OS were 36 and 42 months. 24-month OS was 71% (95% CI: 55-91; [ND-AML: 67%, R/R-AML: 50%, MDS: 100%]). MRD-negative CRc improved OS (median NR vs. 8 months, p: 0.002) in ND and R/R-AML. 100% of patients (N = 4) relapsing after *IDH1*$^+$ clearance demonstrated no *IDH1*$^+$ at relapse. Based on efficacy and toxicity, DL3 (IVO+-VEN400+AZA) was the recommended phase 2 dose. **Conclusions:** IVO+VEN +/- AZA is an effective treatment for *IDH1*$^+$ myeloid malignancies with an expected toxicity profile and notable efficacy across disease groups. Single-cell sequencing and CyTOF correlatives will also be presented. Phase 2 enrollment is ongoing. Clinical trial information: NCT03471260. Research Sponsor: V foundation Award, LLS Career Scholar Award, Conquer Cancer Foundation of the American Society of Clinical Oncology.

7019 **Poster Discussion Session**

Molecular characterization of clinical response in patients with newly diagnosed acute myeloid leukemia treated with ivosidenib + azacitidine compared to placebo + azacitidine.

First Author: Stéphane De Botton, Institut Gustave Roussy, Villejuif, France

Background: Acute myeloid leukemia (AML) is a disease with a dynamic mutational landscape; 6–10% of patients (pts) have somatic mutations in isocitrate dehydrogenase 1 (*IDH1),* which can drive oncogenesis. Ivosidenib (IVO) is a potent oral targeted inhibitor of mutant IDH1 (mIDH1). IVO 500 mg QD + azacitidine (AZA) 75 mg/m^2 SC or IV for 7 days in 28-day cycles was shown to significantly improve event-free survival (HR = 0.33 [95% CI 0.16, 0.69], p = 0.0011), median overall survival (24.0 vs 7.9 months), and complete remission + partial hematologic recovery rates (CR/CRh; 52.8% vs 17.6%) vs placebo (PBO) + AZA in the double-blind phase 3 AGILE study (NCT03173248) in pts with newly diagnosed *IDH1*-mutated AML (ND-AML). *IDH1*-mutation clearance (*IDH1*-MC) and baseline co-mutation analysis from AGILE is reported. **Methods:** Genomic DNA from bone marrow mononuclear cells (BMMCs) or peripheral blood mononuclear cells (PBMCs), and/or bone marrow aspirate (BMA) were used for molecular studies. *IDH1*-MC analysis on BMMCs was performed by BEAMing digital PCR (limit of detection 0.02%-0.04%). BMA, BMMCs and PBMCs were utilized for co-mutational analysis by next-generation sequencing, ACE Extended Cancer Panel (detection limit 2%). **Results:** 146 pts were randomized: 72 to IVO+AZA; 74 to PBO+AZA. Median (range) baseline m*IDH1* variant allele frequency in BMMCs was 36.7% (3.1–50.5) in the IVO+AZA arm and 35.5% (3.0–48.6) in the PBO+AZA arm. Updated IDH1-MC data (October 2021) from 47 IVO+AZA and 32 PBO+AZA treated pts with at least 1 on-treatment sample demonstrated *IDH1*-MC in 21/35 (60%) IVO+AZA pts achieving CR/CRh vs 4/11 (36%) PBO+AZA pts. In CR/CRh pts with time points available after *IDH1*-MC, suppression of the m*IDH1* was durable and *IDH1*-MC maintained in all subsequent samples in 17/17 (100%) IVO+AZA treated pts and 1/3 (33%) PBO+AZA pts. Further analysis of baseline co-mutations on 120 pts (IVO+AZA: n = 58; PBO+AZA: n = 62) showed that *DNMT3A*, *SRSF2*, and *RUNX1* were the most frequent in both treatment arms. Importantly, comparison of CR/CRh and non CR/CRh responses by cohort did not identify any single gene or pathway associated with an inferior outcome in IVO+AZA pts compared to PBO+AZA pts ($p < 0.05$, Fisher's Exact test). Several genes (*DNMT3A*, *RUNX1*, *SRSF2*, *STAG2*) and pathways (Differentiation, Epigenetics, Splicing) were associated with improved outcomes with IVO+AZA, including the RTK pathway, which was previously reported to be associated with primary resistance to IVO monotherapy. Further analysis of patient subgroups, including R132 variants (i.e., R132C vs R132S), will be presented. **Conclusions:** These data suggest that improved clinical outcomes with IVO+AZA are associated with sustained clearance of the m*IDH1* clone including pts with disease that harbor mutations implicated in resistance to IVO monotherapy (e.g., with RTK pathway mutations). Clinical trial information: NCT03173248. Research Sponsor: Agios Pharmaceuticals, Inc. Servier Pharmaceuticals LLC has completed the acquisition of Agios' oncology business.

Tolerability and efficacy of the first-in-class anti-CD47 antibody magrolimab combined with azacitidine in frontline TP53m AML patients: Phase 1b results.

First Author: Naval Guastad Daver, Department of Leukemia, MD Anderson Cancer Center, Houston, TX

Background: Magrolimab is a monoclonal antibody blocking CD47, a "don't eat me" signal overexpressed on cancer cells such as acute myeloid leukemia (AML). This blockade induces phagocytosis of tumor cells and is synergistic with azacitidine (AZA) via upregulation of "eat me" signals. We report data from a Phase 1b trial of magrolimab+AZA in frontline *TP53*-mutant (*TP53*m) AML. **Methods:** Patients (pts) with frontline AML not suitable for intensive chemotherapy received IV magrolimab starting with a priming dose (1 mg/kg) followed by ramp-up to 30 mg/kg QW or Q2W as maintenance dose. AZA 75 mg/m^2 was given IV or SC on Days 1–7 of each 28-day cycle. Primary endpoints were safety/tolerability and complete remission (CR) rate by ELN 2017 criteria. **Results:** 72 *TP53*m AML pts were treated (Table). Common all-grade TEAEs were constipation (52.8%), diarrhea (47.2%), febrile neutropenia (45.8%), nausea (43.1%), fatigue (37.5%), decreased appetite (37.5%), thrombocytopenia (31.9%), peripheral edema (30.6%), and cough (30.6%). Most common Grade 3+ TEAEs were febrile neutropenia (37.5%), anemia (29.2%; Grade 3, 26.4%; Grade 4, 2.8%), thrombocytopenia (29.2%), pneumonia (26.4%), and neutropenia (20.8%). Objective response rate (ORR) by intent-to-treat was 48.6% (33.3% CR, 8.3% CR with incomplete hematologic recovery [CRi] / CR with partial hematologic recovery [CRh], 1.4% morphologic leukemia-free state [MLFS], 5.6% partial response). Stable disease was reported in 16.7%, progressive disease (PD) in 5.6%. 30- and 60-day mortalities were 8.3% and 18.1%, respectively. Response assessment was unavailable in 4.2% who discontinued due to AEs and 6.9% due to other, prior to the C3D1 assessment. Median time to CR/CRi was 2.2 months (mos; range 1.7–7.2) and to CR was 3.0 mos (range 1.8–9.6). 45.2% (14/31) of evaluable CR/CRi/CRh/MLFS pts achieved negative MRD by flow cytometry (investigator reported). Of 24 CR patients, 8 had a longitudinal *TP53* VAF assessment, and 5/8 (63%) had VAF decreased to ≤5%. Treatment was stopped due to SCT in 9 pts (12.5%), PD 26 (36.1%), death 8 (11.1%), AE 13 (18.1%), and other 14 (19.4%). Median durations of CR and CR/CRi were 7.7 mos (95% CI: 4.7, 10.9) and 8.7 mos (95% CI: 5.3, 10.9), respectively. Median overall survival (OS) for the 72 pts was 10.8 mos (95% CI: 6.8, 12.8) with median follow up 8.3 mos. **Conclusions:** In high-risk frontline *TP53*m AML pts unsuitable for intensive chemotherapy, magrolimab+AZA showed durable responses and encouraging OS in a single-arm study. A Phase 3 trial in *TP53*m AML (ENHANCE-2; NCT04778397) of this combination vs standard of care is ongoing. Clinical trial information: NCT03248479. Research Sponsor: Gilead Sciences, Inc.

Enrichment of high-risk innate immune cells in Hispanic and Black children with B-acute lymphoblastic leukemia.

First Author: Julie R. Gilbert, Aflac Cancer and Blood Disorders Center, Emory University and Children's Healthcare of Atlanta, Atlanta, GA

Background: Black and Hispanic children with B-acute lymphoblastic leukemia (B-ALL) experience worse outcomes compared to their non-Hispanic white (NHW) counterparts. Immune-based therapies have improved the outcomes of children with B-ALL, however, impact of racial/ethnic background on immune microenvironment is less studied. **Methods:** BM from 61 children with newly diagnosed B-ALL(Hispanic = 21, Black = 17, NHW = 23) was obtained via the Aflac Biorepository. High-dimensional analysis was performed utilizing single cell mass cytometry with 61 markers to characterize T, NK and myeloid cells. Data was analyzed using Cytobank and high-dimensional visualization platforms such as ViSNE. Clinical data including self-reported race/ethnicity and NCI-risk classification were obtained for all samples. **Results:** Multidimensional analysis was carried out for each cell population to dissect race/ethnicity-associated differences. ViSNE clustering of NK cells identified 3 different NK populations, including a distinct population of mature CD57+ NK cells with Tbet^{hi}, HLADR^{hi}, granzymeB^{hi}, CD27- phenotype. The distribution of NK subsets was highly impacted by race/ethnicity. Hispanic (H) patients had higher proportions of CD57+ mature NK cells when compared with other groups, (40 ± 4% vs 33 ± 2%; p = 0.03) with pronounced differences apparent within standard risk (SR) patients. H-SR had higher proportion of CD57+ NK cells compared to other SR patients (mean H-SR 43.4 ± 5.87% vs 26.3 ± 2.87% p = 0.0049). ViSNE clustering of myeloid cells identified 5 clusters based on patterns of cell surface markers, including a distinct CD11c+CD16+DR^{hi} inflammatory/non-classical myeloid population. Further analysis showed that NHW-SR patients have significantly lower proportions of CD16+DR+ myeloid cells compared to Hispanic, Black and NHW-HR patients (mean NHW-SR 3.67 ± 2.56% vs Others 10.8 ± 7.87% p = 0.0394). Notably, a phenotypically similar population has recently been implicated in leukemic progression in preclinical models (Witkowski et al, Cancer Cell 2020). In contrast to innate cells, T cell clusters were broadly comparable between different racial/ethnic groups. **Conclusions:** These studies provide detailed single-cell proteomic analysis and highlight the impact of racial/ethnic background on immune microenvironment in pediatric B-ALL. Our data identify differences in innate immunity with enrichment of high-risk immune-populations in Hispanic and Black children and depletion of inflammatory myeloid populations in NHW-SR children with B-ALL. These variations may contribute to the observed differences in outcomes and may impact application of immune therapies in racial/ethnic groups. Research Sponsor: Aflac Pilot Grant.

7022 **Poster Session**

Mutational landscape and clinical characterization of over 17,000 patients with myeloid malignancies using real-world data.

First Author: Taylor J. Jensen, Laboratory Corporation of America, Durham, NC

Background: Myeloid neoplasms represent a broad spectrum of hematological disorders for which somatic mutation status in key driver genes is important for diagnosis, prognosis and treatment. Here we summarize the findings from 17,181 clinical samples analyzed by a targeted next generation sequencing (NGS) laboratory developed test. Samples were analyzed comprehensively and as part of individual cohorts specific to acute myeloid leukemia (AML), myelodysplastic syndrome (MDS), and myeloproliferative neoplasms (MPN). **Methods:** Whole blood or bone marrow samples from patients with cause-for-testing for hematological symptoms were submitted for analysis by a referring clinician. DNA was extracted and assayed by a targeted, NGS panel to detect and report single nucleotide variants and small indels within 50 genes associated with myeloid malignancies and sequenced on Illumina DNA sequencers (Illumina, San Diego, CA). Results were reviewed, orthogonally confirmed unless previously validated, and reported by clinical laboratory directors. Disease status or symptoms were taken from test requisitions for each patient. **Results:** Overall, 34,581 Tier I, II, or III somatic variants were detected. The mean number of variants reported per patient was 1.98. This number increased with age ($p < 0.001$) and was highest in patients with AML. Mutations in genes associated with FDA-approved therapies (*FLT3*, *IDH1*, *IDH2*, *KIT*, and *JAK2*) were observed in 22.3% (3836) patients while 28.0% of samples had mutations considered diagnostically relevant by the WHO. Clinical trials are in progress for therapies targeting *TP53*, *NPM1*, and *CEBPA* mutations and were observed in 12.5% (2144) of samples. *FLT3, NPM1* and *RUNX1* mutation which are diagnostic for AML were found in 29.0% (646 of 2225) of AML samples. Pair-wise mutation analyses found 21 mutually exclusive pairs including between genes associated with RNA splicing (*SF3B1*, *SRSF2* and *U2AF1*; OR < 0.29, $p < 0.001$) suggesting possible candidates for targeted therapy. The clinically favorable co-mutation of *NPM1* with *FLT3* internal tandem duplicate was significantly enriched (OR = 7.4, $p < 0.001$) in the AML population. Co-occurrence of *ASXL1* with *RUNX1* mutations which independently confer adverse risk was also enriched in AML (OR = 3.9, $p < 0.001$). Some patients (1021; 6.3%) were tested at multiple time-points with 48.8% showing loss or gain of a mutation between sample dates, potentially the result of tumor evolution and/or therapeutic intervention. **Conclusions:** This study shows that parallel testing of multiple genes in addition to the canonical driver mutations encompasses the mutations contributing to the etiology of these diseases. Despite the breadth of different mutations observed for myeloid neoplasms, consistent patterns are routinely observed that can help the clinician tailor the treatment and chart the progression of these diseases for each patient. Research Sponsor: Laboratory Corporation of America.

Updated efficacy and safety report of a phase I trial of donor-derived CD7 CAR T cells for T-cell acute lymphoblastic leukemia.

First Author: Jing Pan, State Key Laboratory of Experimental Hematology, Department of Hematology, Beijing Boren Hospital, Beijing, China

Background: Results of a phase I trial of donor-derived CD7 chimeric antigen receptor (CAR) T cells for relapsed or refractory T-cell acute lymphoblastic leukemia (r/r T-ALL) (Pan et al. *J Clin Oncol* 2021;39:3340-3351) have been reported previously, and are updated now. **Methods:** The target dose is 1×10^6 (±30%) CAR T cells per kg of body weight. Patients with prior stem cell transplantation (SCT) received CAR T cells from prior SCT donors, while patients without SCT history received CAR T cells from new donors who also provided stem cells for transplantation post CAR T therapy. The primary endpoint was safety with efficacy secondary. Survival status were continuously followed up while severe adverse events (SAEs) were recorded until receiving other anti-leukemia therapy. **Results:** Nineteen (95%) of twenty enrolled patients responded and were followed up with a median time of 15.8 months (range 13-18.3) until Feb, 14th, 2022. Short-term adverse events included grade 3 or higher cytokine release syndrome (10%) and grade 1-2 graft-versus-host disease (GVHD, 60%), which were all reversible. Six late-onset (> 30 days post-infusion) severe adverse events (SAEs) occurred in 5 responders. Two had been reported previously. Four SAEs were newly observed, including a grade 4 intestinal GVHD at month 11 and a grade 5 pneumonia at month 12.3 in one patient, a grade 5 *Pseudomonas Aeruginosa* pneumonia at month 8.7 in one patient, and a grade 3 cytomegalovirus (CMV) encephalitis at month 11 which recovered at month 13.3 in another patient. All severe infections occurred in patients with no further therapy, and the total T cells in them reached a median count of 300.03/μL (range 121.46-512.83), which were substantially lower than normal levels despite steadily increasing. The objective response and complete remission rate was 95% and 85% at day 30 post-infusion. Of 19 responders that were followed up, two (11%) withdrew for other therapy at day 55 and 271 respectively. Of 10 (53%) patients who received no further therapy, all had continuously detectable CAR T cells until the last visit, three remained in remission, three had a relapse (one CD7+, and two CD7-), and four died of infection; Seven (37%) patients proceeded to SCT and no CAR T cells were detectable after SCT, and among them two remained in remission, four had a relapse (three CD7+, and one CD7-), and one died of transplant-related mortality. Patients relapsed at a median time of 6 (range 4-10.9) months. The one-year progressive-free survival (PFS) and overall survival (OS) rates were 51.6% (95% CI, 24.7-78.4%) and 72.5% (95% CI, 51.9-93.0%). **Conclusions:** Donor-derived CD7 CAR T cell therapy showed encouraging activity in treating r/r T-ALL. Relapse emerges as major issues impeding long-term outcomes. CD7-negative relapse was commonly observed under CAR T cell surveillance. Late onset GVHD and infections may occur and should be carefully managed. Clinical trial information: ChiCTR2000034762. Research Sponsor: the National Key R&D program.

Phase 1/2 study of SEL24/MEN1703, a first-in-class dual PIM/FLT3 kinase inhibitor, in patients with *IDH1*/*2*-mutated acute myeloid leukemia: The DIAMOND-01 trial.

First Author: Giovanni Martinelli, Istituto Romagnolo per lo Studio dei Tumori "Dino Amadori" (IRST)IRCCS, Meldola, Italy

Background: Mutations in the FLT3 tyrosine kinase are the most frequent ones that occur in adults with acute myeloid leukemia (AML) and can co-occur with mutations in *IDH1* or *IDH2* (collectively *IDH*m) in up to 30% of cases. SEL24/MEN1703 is an orally available, dual PIM/FLT3 kinase inhibitor. Preliminary results from the phase 1/2 first-in-human DIAMOND-01 trial (NCT03008187) evaluating single-agent SEL24/MEN1703 showed activity in adults with relapsed/refractory (R/R) *IDH*m AML, where 3/8 *IDH*m patients (pts) responded. Here we report the first safety and efficacy results from an additional expansion cohort of the DIAMOND-01 trial in 20 pts with R/R *IDH*m AML. **Methods:** Pts with IDHm R/R AML and no standard therapeutic options were eligible. The recommended dose of 125 mg SEL24/MEN1703 was given orally, once daily for 14 days over a 21-day cycle until disease progression or unacceptable toxicity. The primary endpoint was safety; adverse events (AEs) were graded according to NCI-CTCAE v4.03. The secondary endpoint was anti-leukemic activity including overall response rates (ORR). **Results:** As of 10 Jan 2022, 14 pts were enrolled in the IDHm cohort. Median age was 68 years (range 37-79). Four pts had AML secondary to myelodysplastic syndrome and 7 pts had intermediate cytogenetic risk. The median number of prior lines was 2 (range 1-3). Seven pts had IDH2, 1 had IDH1/2, and 4 had IDH1 mutations. Concomitant mutations in FLT3/ITD were detected in 2 pts. Median duration of treatment was 2 cycles (range 1-8). Safety data (N = 12) showed that serious treatment-emergent AEs (TEAEs; ≥5%) were pneumonia (33%), and skin infection and gastroenteritis clostridial (8% each). These were all unrelated to study drug. Drug-related TEAEs were liver injury, overdose, and hyponatremia (8% each). The drug-related liver injury occurred in a pt who was concomitantly receiving other drugs with known hepatotoxic potential. Grade ≥3 TEAEs (≥10%) were pneumonia (33%) and asthenia (17%), both unrelated to study drug. No differentiation syndrome was observed. Of the 7 pts who completed ≥1 treatment cycle and had ≥1 post-baseline assessment or clear disease progression, ORR was 28.6%; 1 pt achieved CRi at cycle (C) 3 and underwent hematopoietic stem cell transplant, 1 pt had PR at C4 (confirmed at C7 and still on treatment), 4 had disease progression, 1 discontinued for AE not drug-related. Among the 7 remaining pts, 3 discontinued before completion of C1 without progression or response, while 4 pts were ongoing and have not yet had any post-baseline assessment. **Conclusions:** Preliminary results in the IDHm cohort confirm that SEL24/MEN1703, a first in class, orally available, dual PIM/FLT3 inhibitor, has a manageable safety profile and single-agent activity in pts with R/R IDHm AML. Updated results will be presented at the congress. Clinical trial information: NCT03008187. Research Sponsor: Menarini Ricerche SpA.

BTX-1188, a first-in-class dual degrader of GSPT1 and IKZF1/3, for treatment of acute myeloid leukemia (AML) and solid tumors.

First Author: Aparajita Hoskote Chourasia, BioTheryX, Inc., San Diego, CA

Background: BTX-1188 is a first-in-class oral molecular glue that degrades GSPT1 and IKZF1/3 and is currently in phase 1 clinical trials for treatment of hematologic and solid malignancies. Targeted protein degradation of cereblon neosubstrates is clinically validated in the treatment (tx) of hematologic malignancies (Lu 2014, Zou 2020). **Methods:** Cell viability in BTX-1188-treated cells and patient samples was measured by CellTiter-Glo 2.0 assay (Promega). Substrate degradation and apoptosis profiles were analyzed by immunoblots of protein lysates from cells treated with DMSO or BTX-1188. Vehicle, or 30 or 40 mg/kg IP BTX-1188, was used in athymic nude mice AML xenograft models. **Results:** BTX-1188 is a rapid, deep, and potent degrader of GSPT1 and IKZF1/3 and inhibitor of Myc in several cancer cell lines (Table). Proteomics and immunoblot analysis of AML cell line, MV-4-11, shows significant degradation of GSPT1 and IKZF1 after 2 h tx with 100 nM BTX-1188 ($P<1x10^{-5}$) and 6 h tx with 3 nM BTX-1188 (>90% of GSPT1), respectively, indicating rapid and potent neosubstrate degradation. BTX-1188 also durably degrades GSPT1 where tx with 30 nM for 6 h followed by washout maintains significantly lower levels of GSPT1 and sustained apoptosis for up to 24 h. Owing to IKZF1/3 degradation, BTX-1188 has immunomodulatory properties as seen by inhibition of proinflammatory cytokines (IL-1β, IL-6, TNFα) and induction of IL-2 by LPS and αCD3-stimulated PBMCs, respectively. This approach is expected to improve clinical outcomes and reduce toxicities associated with pure GSPT1 degradation (CC-90009), thus expanding the therapeutic window of BTX-1188. Functionally, BTX-1188 is cytotoxic in various cancer cell lines such as Myc-driven lines (IC_{50} range: 0.5-10 nM) and primary human AML patient samples (IC_{50} range: 0.4-1.5 nM), including relapsed/refractory-, cytarabine- and venetoclax-resistant samples. The durability of GSPT1 degradation and sustained apoptosis in response to BTX-1188 tx is further reflected in in vivo efficacy models where daily or intermittent dosing of BTX-1188 results in potent and sustained antitumor activity. **Conclusions:** These preclinical data show that BTX-1188 is a promising drug candidate for AML and other tumor types. Its immunomodulatory properties owing to IKZF1/3 degradation may prevent systemic inflammatory dose-limiting toxicities associated with pure GSPT1 degradation (Uy 2019). BTX-1188 has entered phase 1 clinical studies for advanced solid tumors and AML. DC_{50} (nM) or inhibitory concentration (nM) of BTX-1188 at 6 h of Tx. Research Sponsor: BioTheryX, Inc.

Acute myeloid leukemia with *KMT2Ar* and association with risk of bleeding and early mortality.

First Author: Daniel Nguyen, University of Texas Health Science Center McGovern Medical School, Houston, TX

Background: Acute myeloid leukemia (AML) with rearrangement of *KMT2A* is characterized by chemotherapy resistance and high rates of relapse. However, additional causes of treatment failure or early mortality have not been well-defined in this entity. **Methods:** In a retrospective analysis, we compared causes and rates of early mortality following induction treatment between a cohort of adults with *KMT2Ar* AML (N=172) and an age-matched cohort of patients (pts) with normal karyotype (NK) AML (N=522). **Results:** The 30 and 60-day (60d) mortality in pts with *KMT2Ar* AML were significantly higher compared to those with NK AML, with rates of 10% (17/172 pts) and 15% (26/172 pts) in KMT2Ar AML vs 4% (20/522 pts) and 7% (38/522 pts) in NK AML, respectively (P=0.004). Among those who died within 60d, the most common contributing cause in *KMT2Ar* was respiratory failure without a clear infectious etiology in 38% (10/26 pts) vs 11% (4/38 pts) in NK AML (P=0.01). We found 42% (11/26 pts) with *KMT2Ar* AML who died within 60d were either diagnosed with or had high clinical suspicion for diffuse alveolar hemorrhage (DAH) that warranted empiric therapy vs 18% (7/38 pts) with NK AML (P=0.05). Given the high occurrence of DAH in *KMT2Ar* AML, we set out to quantify bleeding events and recorded major and minor bleeds as defined by the International Society of Thrombosis and Haemostasis. We found 65% (17/26 pts) with *KMT2Ar* AML had at least one bleeding event vs 32% (12/38 pts) with NK AML (P=0.01). There was a significantly higher frequent occurrence of major bleeds (rate ratio=6.22; P=0.005) and total bleeding events (rate ratio=4.5; P=0.001) in *KMT2Ar* AML vs NK AML. *KMT2Ar* was associated with disseminated intravascular coagulopathy (DIC), as 93% of evaluable pts (14/15 pts) vs 54% (7/13 pts) in NK AML had overt DIC before death. Longitudinal trajectories of DIC parameters of pts who died within 60d showed significantly higher prothrombin time levels (P=0.008) in *KMT2Ar*. In a multivariate analysis, *KMT2Ar* and a monocytic phenotypic were the only independent predictors of any bleeding event in pts who died within 60d (OR 3.5, 95% CI 1.4-10.4, P=0.03; OR 3.2, 95% CI 1.1-9.4, P=0.04). **Conclusions:** *KMT2Ar* AML is associated with higher early mortality and an increased risk of bleeding and coagulopathy compared with NK AML. Early recognition and aggressive management of DIC and coagulopathy are important considerations that could mitigate the risk of death during induction treatment. Research Sponsor: None.

Characteristics of bleeding events.

Characteristic	*KMT2Ar*	Normal Karyotype	*P*
60-day mortality	26/172 (15%)	38/522 (7%)	0.004
Respiratory failure, non-infectious	10/26 (38%)	4/38 (11%)	0.01
Diffuse alveolar hemorrhage	11/26 (42%)	7/38 (18%)	0.05
Pts with ≥1 bleeding event	17/26 (65%)	12/38 (32%)	0.01
Evaluable pts with overt DIC before death	14/15 (93%)	7/13 (54%)	0.03

A phase 1b/2 study of TP-0903 and decitabine targeting mutant TP53 and/or complex karyotype in patients with untreated acute myeloid leukemia ≥ age 60 years: Phase 1b interim results.

First Author: Alice S. Mims, The Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: TP-0903 is a multi-kinase inhibitor designed to target AXL, a receptor tyrosine kinase, and also inhibits cell cycle regulators such as Chk1/2 and other AML associated kinases. TP-0903 has shown prior anti-tumor activity at a safe dose in solid tumors. In pre-clinical AML studies, TP-0903 shows potent cytotoxicity in *TP53* mutant (*TP53*m) AML cell lines, an adverse prognostic genomic sub-group of AML. TP-0903 also had synergistic activity with decitabine (dec) in *TP53*m AML and prolonged survival in xenograft and genetically engineered mouse models. We report here on the initial safety and clinical results from the Leukemia and Lymphoma Society's ongoing Beat AML phase 1b/2 (Ph1b/2) trial of TP-0903 in combination with dec (ClinicalTrials.gov NCT03013998). **Methods:** Newly diagnosed AML pts ≥60 years with *TP53*m and/or complex karyotype (≥3 abnormalities) were selected for a Ph1b/2 dose escalation study of TP-0903 combined with dec. Seven Ph1b pts were given TP-0903 every 28-day cycle from days 1-21 (Dose level (DL) 1 = 37 mg/day) and dec IV days 1-10 (20 mg/m^2). A standard 3+3 design was used to evaluate the safety and tolerability. Nine additional patients enrolled onto Ph2 at DL1, but further assessments of safety, pharmacokinetics (PK) and correlative data was used to update the final recommended Ph2 dose (RP2D) of TP-0903 to DL-1 (25 mg/day) with dec. **Results:** At data cutoff (10Jan2022), 16 total pts were accrued. Ph1b treated 7 pts at DL1, 6 were DLT evaluable, and no DLTs were observed. Ph2 enrolled and treated 9 pts at DL1 before concerns of delayed count recovery led to the reduction of the Ph2 dose of TP-0903 to DL-1 (25 mg/day). For all 16 pts treated at DL1, 1 pt achieved CR, 4 pts CRh, and 1 pt CRi, for a composite CR (CR/CRh/CRi) rate of 37.5% (95% CI, 15.2-64.6), with 4 pts achieving MRD negativity by central flow cytometry. For the remaining 10 pts, 1 pt achieved MLFS (6%), 6 pts had stable disease (37.5%), 1 pt had treatment failure (6%), and 2 pts were not evaluable (12.5%) due to withdrawal of consent and death from early disease progression. Two pts (1 CR and 1 CRh) proceeded to stem cell transplantation. The most common grade 3 and above treatment-related AEs include decreased neutrophil counts (37.5%), platelet counts (31.3%), and anemia (18.8%). Finally, PK and correlative data analysis looking at soluble Axl and Gas6 also supported reduction to DL-1. **Conclusions:** Initial results with DL1 suggest that TP-0903/dec shows preliminary clinical activity in the prognostically poor *TP53*m/complex karyotype AML sub-group, with 4 pts achieving MRD negative status out of 6 patients who achieved a CR/CRh/CRi (66%). After further patients were treated on DL1, the toxicity profile and correlative data supported the de-escalation to DL-1 as the RP2D. The Ph2 study is ongoing to determine the clinical activity of this new RP2D (DL-1). Clinical trial information: NCT03013998. Research Sponsor: Sumitomo Dainippon Pharma Oncology, Leukemia & Lymphoma Society.

Phase I study of donor-derived CD5 CAR T cells in patients with relapsed or refractory T-cell acute lymphoblastic leukemia. *First Author: Jing Pan, State Key Laboratory of Experimental Hematology, Department of Hematology, Beijing Boren Hospital, Beijing, China*

Background: Despite the manageable safety and encouraging efficacy of donor-derived CD7 chimeric antigen receptor (CAR) T cells in relapsed or refractory T-cell acute lymphoblastic leukemia (r/r T-ALL) (Pan et al. *J Clin Oncol* 2021;39:3340-3351), a considerable proportion of responding patients eventually relapsed with CD7 antigen loss. CAR T cells targeting another antigen, CD5, which is expressed on blasts of over 80% T-ALL cases, may be capable of treating these patients. Here we present early safety and efficacy results of a phase I trial of donor-derived CD5 CAR T cells in T-ALL. **Methods:** CD5 CAR T cells that resist fratricide by deletion of CD5 gene (Preclinical data in Dai et al. *Mol Ther* 2021;29:2707-2722) were manufactured. Patients with prior stem cell transplantation (SCT) (group A) received CAR T cells from prior SCT donors, while patients without SCT history (group B) received CAR T cells from new donors who also provided stem cells for transplantation post CAR T therapy. The trial using bayesian optimal interval phase I/II design to explore optimal biological dose (OBD) from the initial dose of 1×10^6 (±20%) CAR T cells/kg in each group. If manufactured cells were not sufficient, patients could be treated at a low dose of 5×10^5 (± 20%)/kg. The primary endpoint was safety with efficacy secondary. **Results:** Five patients who had CD7-negative relapsed after CD7 CAR therapy were enrolled and received prior SCT donor-derived CD5 CAR T cells between Oct 8th, 2021 and Dec 14th, 2021. Four patients were on initial dose level, while one patient was on low dose level. This early report has approved by the Data and Safety Monitoring Committee, and indicated the OBD in group A was 1×10^6 (±20%) /kg. No DLT occurred. Adverse events within 30 days included grade 3-4 hematologic toxicity in all (100%) which already existed before enrollment, grade 1-2 cytokine release syndrome in 4 (80%), grade 1 graft-versus-host disease in 1 (20%), grade 2 rash maculo-papular in 3 (60%). One patient developed late grade 5 epstein-barr virus infection accompanied by hemophagocytic lymphohistiocytosis at 2.7 months post-infusion. All five patients achieved complete remission at day 30, and remained MRD-negative with a median follow-up time of 2.7 (range, 1.8-4.1) months. In three patients, low level of CD7 CAR T cells were still detectable for one month post-infusion, but CD5 CAR T cells dominated and persisted well until last visit. Patient CD5-positive healthy T cells were depleted, while CD5-negative T cells increased to a median count of 133 (range, 13-299)/μl at one month, although they were still much lower than normal level. **Conclusions:** We report the safety and efficacy of donor-derived CD5 CAR T cells in r/r T-ALL. And the depletion of CD5-positive healthy T cells was commonly observed. Longer follow-up assessment is needed to determine the durable remission and the functional immune system reconstitution. Clinical trial information: NCT05032599. Research Sponsor: the National Key R&D program.

Assessing eligibility for non-intensive chemotherapy (IC) randomized clinical trials (RCT) in patients (pts) with newly diagnosed (ND) AML from the Connect Myeloid Disease Registry. *First Author: Harry Paul Erba, Duke University, Durham, NC*

Background: Pts with AML in RCTs often do not reflect the population seen in clinical practice due to strict eligibility criteria. This study evaluated criteria from a recent RCT of non-IC against a broad cohort of real-world pts with AML from the Connect® Myeloid Disease Registry (NCT01688011). **Methods:** Pts were stratified into 3 groups based on the non-IC phase 3 VIALE-A trial eligibility criteria: 1) "eligible" pts who would have met all VIALE-A inclusion criteria; 2) "unfit" pts who would have been ineligible for VIALE-A due to ≥ 1 of the following: abnormal liver/kidney function, high ECOG, recent prior malignancy, comorbidities score ≥ 2 by ACE-27, hepatic grade ≥ 1, AIDS grade ≥ 1; 3) "fit" pts who would have been ineligible for VIALE-A because they would have qualified for IC (defined as: ≤ 74 y of age, low ECOG, no apparent cardiovascular/renal comorbidities, and did not meet any criteria in #2). Baseline characteristics were summarized by eligibility group. Overall survival (OS) by group was estimated using the Kaplan–Meier method. Induction regimens were categorized as IC (any regimens containing 7+3, MEC, CLAG, FLAG) or venetoclax (VEN)-based. Hazard ratios (HRs) for induction regimens among each group were estimated using Cox models adjusted for age, ELN risk, ECOG, frailty score, and comorbidity index. **Results:** Of 734 enrolled pts with AML (Dec 2021), most were male (61%) and white (84%); median age 71 y (range 55–97). Only 26% of pts (n = 192) were eligible for a non-IC RCT, 45% (n = 327) were ineligible due to unfitness, and 29% (n = 215) were ineligible due to overall fitness. The main reason for non-IC RCT ineligibility was high overall comorbidity grade (n = 265 [36%]). Fit pts intended to undergo transplant more often compared with unfit pts. Median OS for eligible, unfit, and fit pts were 14, 10, and 22 months, respectively. Among unfit pts, those receiving IC had significantly longer OS compared with pts receiving a VEN-based regimen (median OS 14 vs 6 months, respectively; HR: 0.51, 95% CI: 0.27–0.98, $P = 0.042$; Table). Eligible pts who received IC tended to have shorter median OS (13 months) vs pts who received VEN-based therapies (23 months; not sig.). **Conclusions:** The majority of pts with ND AML in the Registry would have been ineligible for a non-IC RCT due to being too fit or unfit. Pts ineligible for an RCT due to unfitness but who received IC maintained an OS benefit vs those receiving VEN-based therapies. This analysis suggests that non-IC RCTs may be excluding pts who appear unfit but can potentially tolerate IC and experience improved survival outcomes. Clinical trial information: NCT01688011. Research Sponsor: Bristol Myers Squibb.

Safety and efficacy of casein kinase 1α and cyclin dependent kinase 7/9 inhibition in patients with relapsed or refractory AML: A first-in-human study of BTX-A51. *First Author: Brian Ball, City of Hope, Duarte, CA*

Background: Inactivation of p53 and overexpression of Mcl1 are common mechanisms that cancer cells use to evade apoptosis. BTX-A51 is a novel, oral, direct inhibitor of casein kinase 1α (CK1α) and cyclin dependent kinase 7 and 9 that robustly increases p53 protein levels via CK1α inhibition while preferentially decreasing super-enhancer transcription of *Myc and Mcl1,* enabling selective apoptosis of leukemia cells. Here, we report the interim results of the first-in-human (FIH) study of BTX-A51 in patients (pts) with R/R AML. **Methods:** The study utilizes a hybrid accelerated titration with single pt cohorts and a Bayesian optimal interval design in dose escalation. The primary objective is to determine the maximum tolerated dose and recommended Phase 2 dose (RP2D) of BTX-A51. Secondary objectives include evaluating the anti-leukemic activity, pharmacokinetics (PK), and pharmacodynamics (PD). **Results:** As of 25 January 2022, 30 pts (28 with AML; 2 with HR-MDS) enrolled at dose levels between 1 and 42 mg; 2 pts remain on treatment. Monotherapy doses between 1 and 42 mg were administered orally 3 days/week (wk) (3 wk in a 28-day cycle) and at 21 mg (4 wk in a 28-day cycle). Baseline characteristics include median age 75 years, median number of prior therapies 3, 97% received prior treatment with venetoclax, 97% had prior HMA, and 43% had prior induction failure. The most common treatment-emergent AEs (TEAEs) were hypokalemia, nausea, vomiting, diarrhea, and hypotension. The most common Grade 3 or higher TEAEs were anemia, febrile neutropenia, platelet count decreased, and hypokalemia. DLTs included grade 3 hepatic failure at the 42 mg dose in 1 pt and grade 3 alkaline phosphatase elevation in 1 pt at the 21 mg dose. All events resolved after holding study drug. Plasma PK of BTX-A51 was roughly dose-proportional between 1 and 42 mg with accumulation based on AUC between Day 1 and Day 5. Estimated half-life was between 18 and 55 hours. Among the 30 pts with R/R AML and MDS, CR/CRi rate was 10% (3/30) with 1 pt at the 11 mg and 2 pts at the 21 mg dose levels attaining CRi. Bone marrow (BM) blast reduction > 50% occurred in 4 patients including the 3 responders, all at the 11 and 21 mg dose levels. All 4 pts with > 50% BM blast reduction had RUNX1 mutations; 9 pt with RUNX1 enrolled in the trial. The median duration of response for pts achieving CR/CRi was approximately 1.5 month. Responses were not observed in MDS pts. PD data will be provided in the full presentation. Based on the clinical data from dose escalation, the RP2D is 21 mg administered 3 days/wk for 4 wk of a 28-day cycle. **Conclusions:** In this FIH study, monotherapy BTX-A51 demonstrated an acceptable safety profile and promising antileukemic activity in pts with heavily pretreated R/R AML. The 21 mg dose administered 3x/wk for 4 wk was identified as the RP2D. RUNX1 mutations were enriched among responders and pts attaining > 50% BM blast reduction. Clinical trial information: NCT04243785. Research Sponsor: None.

7031 **Poster Session**

Lower-intensity CPX-351 + venetoclax for patients with newly diagnosed AML who are unfit for intensive chemotherapy. *First Author: Geoffrey L. Uy, Washington University School of Medicine, St. Louis, MO*

Background: CPX-351 (US: Vyxeos; Europe: Vyxeos liposomal) is a dual-drug liposomal encapsulation of daunorubicin and cytarabine in a synergistic 1:5 molar ratio. CPX-351 is approved for newly diagnosed, therapy-related AML or AML with myelodysplasia-related changes in patients (pts) who are candidates for intensive chemotherapy (IC) and aged ≥1 year in the US and adults in Europe. However, the appropriate dosage of CPX-351 in pts unfit for IC may be different from the label dosage. Venetoclax (VEN; BCL-2 inhibitor) + low-dose cytarabine has demonstrated efficacy in unfit pts with AML, and drug synergism/additivity in preclinical studies provided a rationale for combining CPX-351 + VEN clinically. Our study evaluates the safety and efficacy of lower-intensity CPX-351 + VEN in adults with newly diagnosed AML who are unfit for IC. **Methods:** This is an ongoing, open-label, phase 1b study (NCT04038437). Pts who achieve at least partial remission after 1 or 2 cycles may receive up to 4 similar cycles in the dose-exploration phase (DEP) or up to 8 similar cycles in the expansion phase (EP). Pts are assessed for response (morphology, measurable residual disease [MRD]) and monitored for safety and survival. **Results:** The data include 31 pts enrolled by 9/15/2021, with a data cutoff of 12/2/2021: 4 pts in DEP at dose level 1 (CPX-351 20 units/m^2 on Days 1 and 3 + VEN 400 mg on Days 2 to 21 of each cycle), 7 pts in DEP at dose level 2 (CPX-351 40 units/m^2 + VEN 400 mg), and a total of 20 pts in DEP and EP at dose level 1b (CPX-351 30 units/m^2 + VEN 400 mg; established as the recommended phase 2 dose). Pts were unfit for IC based on age ≥75 y (n = 15) or health (ECOG PS of 2 to 3 and/or comorbidities [n = 16]). Median age was 74 y (range: 60, 90); 65% were male; 77% had *de novo* AML; 58% had poor-risk disease; and 23% had a *TP53* mutation. Nonhematologic treatment-emergent adverse events (TEAEs) in ≥20% of pts were diarrhea (26%), cough (23%), dyspnea (23%), and nausea (23%). Hematologic grade ≥3 TEAEs were reported in 17 (55%) pts; no nonhematologic grade ≥3 TEAE was reported in > 10% of pts. There were no deaths by Day 30; mortality at Day 60 was 13%, with deaths due to myocardial infarction unrelated to therapy (n = 1), worsening lung infection (n = 1), and disease progression (n = 2). Median (IQR) recovery times were 30 d (22, 34.5) to neutrophils ≥500/μL and 21 d (21, 27) to platelets ≥50,000/μL. Complete remission (CR) or CR with incomplete neutrophil or platelet recovery (CRi) was achieved by 16/28 (57%) evaluable pts. All 16 of these pts achieved remission (CR or CRi) after the first cycle. MRD negativity was achieved by 12/16 (75%) pts with CR or CRi, primarily after Cycle 1 (Cycle 1: n = 8; Cycle 2: n = 2; Cycle 3: n = 1; Cycle 4: n = 1). Survival data are not yet mature. **Conclusions:** Lower-intensity CPX-351 + VEN was generally well tolerated in adults with newly diagnosed AML who are unfit for IC and showed promising initial efficacy, with CR or CRi in the majority of pts. Clinical trial information: NCT04038437. Research Sponsor: Jazz Pharmaceuticals.

Health-related quality of life (HRQoL) with enasidenib versus conventional care regimens in older patients with late-stage mutant-*IDH2* relapsed or refractory acute myeloid leukemia (R/R AML). *First Author: Courtney Denton Dinardo, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Enasidenib (ENA) is an oral inhibitor of mutant-IDH2 (mIDH2) proteins. In the phase 3 IDHENTIFY trial, ENA improved event-free survival (EFS), overall response, and complete remission rate vs conventional care regimens (CCR) ($P < 0.01$ for all) in patients (pts) ≥ 60 years of age with m*IDH2* R/R AML with 2 or 3 prior treatments (Tx) (DiNardo 2021). Pt-reported HRQoL was a secondary trial endpoint. **Methods:** IDHENTIFY is an open-label, randomized trial (NCT02577406). Pts were preselected to a CCR (SC azacitidine, intermediate- or low-dose Ara-C, or supportive care) and then randomized 1:1 to ENA 100 mg/d or CCR in 28-d cycles. Key HRQoL endpoints were mean changes from baseline (CFB) overall and by clinical response in the Global Health Status/QoL, Physical Functioning, Role Functioning, Fatigue, and Dyspnea domains of the EORTC QLQ-C30 questionnaire, and in EQ-5D-5L utility index (UI) and visual analogue scale scores. The QLQ-C30 and EQ-5D-5L were assessed on D1 of each Tx cycle (C) and at end of Tx. Minimally important differences (MIDs) in CFB scores within or between Tx arms were based on accepted thresholds. Sensitivity analysis using imputed data on CFB was conducted using pattern mixture modeling. **Results:** HRQoL-evaluable cohorts included 118/158 (74.7%) pts in the ENA arm and 80/161 (49.7%) in the CCR arm; 40 ENA pts and 81 CCR pts were not evaluable due to missing data at baseline (BL; 22 ENA and 51 CCR) and/or at ≥1 post-BL visit (26 ENA and 69 CCR). Pts ineligible for HRQoL analyses had lower response rates and worse EFS and overall survival than HRQoL-evaluable pts. Overall QLQ-C30 completion rates in the ENA and CCR arms were 79% and 65%, respectively ($P < 0.001$). While there was no meaningful improvement or worsening from BL (ie, exceeding MID) within either Tx arm in the key QLQ-C30 domains, scores worsened during initial Tx cycles and then improved with continued Tx. Mean EQ-5D-5L scores also worsened during early cycles in both Tx arms, with meaningful UI deterioration in the ENA arm from C2 through C7. However, between-group comparisons showed no consistent differences between ENA and CCR in mean CFB. Sensitivity analysis with imputation of missing CFB data showed worsened HRQoL compared with non-imputed data in the CCR arm but not with ENA. In the ENA arm, clinical responders reported relatively stable mean HRQoL scores over time, and non-responders showed no meaningful differences in CFB vs the CCR arm. **Conclusions:** HRQoL measures tended to worsen during early cycles in both Tx arms and gradually improved with continued Tx. Data should be interpreted with caution as only approximately one-half of pts in the CCR arm were HRQoL-evaluable. ENA improved clinical efficacy measures vs CCR without compromising HRQoL in older pts with R/R AML. Clinical trial information: NCT02577406. Targeting signaling pathways vulnerabilities for the treatment of IKZF1-deleted ph-negative B lymphoblastic leukemia. *First Author: Rohit Gupta, Baylor College of Medicine, Houston, TX*

Background: Approximately 20% of children diagnosed with B lymphoblastic leukemia (B-ALL) will suffer a relapse, and most adults with B-ALL have a poor prognosis. Genome-wide association studies of B-ALL patients have identified frequent deletions of the gene *IKZF1,* encoding the master regulator of lymphoid development, IKAROS. These deletions are associated with therapy resistance, increased risk of relapse, and inferior survival. Currently, how loss of IKAROS function contributes to therapy resistance and increased risk of relapse is not fully understood. We used CRISPR-Cas9 genome editing to develop human B-ALL cell lines with various *IKZF1* deletions that genetically and phenotypically recapitulate those occurring in patients. Using these isogenic cell lines, we have previously shown *IKZF1* deletion results in cell-intrinsic chemoresistance and increased activation of the JAK/STAT signaling pathway (Rogers, Gupta et al. 2021). **Methods:** Given JAK/STAT is often dysregulated in poor-prognosis leukemia, we investigated the potential mechanisms of aberrant JAK/STAT activation and the therapeutic potential of targeting JAK/STAT in our engineered cell lines. We treated our cells with SH-4-54 (STAT3/5 inhibitor) or tofacitinib (JAK1 inhibitor) alone and in combination with dexamethasone. To elucidate how loss of IKAROS mediates an increase in JAK-STAT activity, we also performed RNAseq of known pathway regulators, comparing *IKZF1* wild-type with *IKZF1* knockout. **Results:** The JAK/STAT negative regulator *Suppressor of Cytokine Signaling 2 (SOCS2)* was significantly downregulated with *IKZF1* deletion, validated by RTqPCR and immunoblotting. We further analyzed publicly-available RNAseq data from > 650 pediatric B-ALL samples, finding that *SOCS2* expression is significantly lower in patients with low *IKZF1*expression (likely corresponding to *IKZF1* deletion) compared to those with high *IKZF1* expression. When we treated our engineered cell lines with tofacitinib or SH-4-54, *IKZF1* wild-type cells were sensitive to each compound, suggesting JAK/STAT signaling plays a vital role in cell survival. In contrast, the *IKZF1*-deleted cells were relatively resistant to JAK/STAT inhibitors alone. However, in combination with dexamethasone, treatment of cells with sub-IC50 levels of SH-4-54 or tofacitinib resulted in re-sensitization to glucocorticoid-induced apoptosis. **Conclusions:** Our findings support that *IKZF1* deletion leads to a targetable upregulation of the JAK/STAT pathway that, when inhibited, results in relative re-sensitization to dexamethasone. JAK/STAT pathway upregulation in *IKZF1* deleted cells may be mediated by decreased expression of *SOCS2.* These results provide initial promise for targeting these vulnerabilities for the treatment of this poor-prognosis disease. 7034 **Poster Session**

A phase II study of hyper-CVAD with sequential blinatumomab (Blina), with or without inotuzumab ozogamicin (INO), in adults with newly diagnosed B-cell acute lymphoblastic leukemia (ALL). *First Author: Nicholas James Short, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: Blina and INO are highly effective in relapsed/refractory B-cell ALL and are associated with high rates of measurable residual disease (MRD) clearance. Use of these agents in the frontline setting may improve outcomes. **Methods:** Patients (pts) 14-59 years of age with newly diagnosed Philadelphia chromosome (Ph)-negative B-cell ALL, including pts who had received no more than 1 prior cycle of chemotherapy, were eligible. Pts received hyper-CVAD alternating with high-dose MTX/Ara-C for up to 4 cycles, followed by 4 cycles of Blina. Pts with CD20+ disease received 8 doses of an anti-CD20 antibody. Eight doses of IT chemotherapy were given. Maintenance was with alternating blocks of POMP (maintenance cycles 1-3, 5-7, 9-11, and 13-15) and Blina (maintenance cycles 4, 8, and 12). Beginning with pt #39, INO at a dose of 0.3 mg/m2 on day 1 and 8 was added to the 2 cycles of MTX/Ara-C and to 2 cycles of Blina (4 total cycles with INO). **Results:** Characteristics of the 58 treated pts (38 without INO and 20 with INO) are summarized in Table. Among 45 pts with active disease at study entry, 100% achieved CR. Overall, 76% achieved MRD negativity by flow cytometry after induction and 95% at any time over the course of therapy. The median follow-up of the entire cohort is 26 months (range, 3-61+ months). Overall, 5 pts (9%) relapsed, 18 (31%) underwent transplant in first remission (including an additional 2 pts who relapsed post-transplant), 2 (3%) died in CR, and 33 (57%) remain in continuous remission without transplant. All relapses occurred in pts with established poor-risk features and no relapses have occurred beyond 2 years. For the entire cohort, the estimated 3-year OS is 85% and the 3-year continuous remission duration is 84%. No relapses or deaths have occurred in the INO group, and the estimated 1-year OS is 100%. Treatment was overall well-tolerated. One patient discontinued Blina due to recurrent grade 2 neurotoxicity. No pts have discontinued INO due to toxicity and no cases of veno-occlusive disease have been observed. **Conclusions:** Hyper-CVAD with sequential Blina is highly effective as frontline treatment of Ph-negative B-cell ALL. The addition of INO to this regimen was safe and early results are encouraging, with no relapses observed to date. Clinical trial information: NCT01371630. Research Sponsor: Amgen and Pfizer.

Autologous CD7-targeted CAR T-cell therapy for refractory or relapsed T-cell acute lymphoblastic leukemia/lymphoma. *First Author: Liping Zhao, State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences &Peking Union Medical College, Tianjin, China*

Background: Refractory or relapsed (r/r) T-cell acute lymphoblastic leukemia/lymphoma (T-ALL/LBL) has a poor prognosis. Our previous report showed that donor-derived CD7 CAR-T cell therapy could induce remission of r/r T-ALL, but graft-versus-host disease (GVHD) occurred in some patients (Pan et al. J Clin Oncol 2021;39:3340-3351). We recently conducted a phase I trial to evaluate autologous CD7 CAR-T therapy in r/r T-ALL/LBL, which may avoid GVHD while showing the efficacy; here we report the early result with the approval of the Data and Safety Monitoring Committee and Institutional Review Board (IRB). **Methods:** The patients who had CD7$^+$ r/r T-ALL/LBL and no leukemia cells in peripheral blood were eligible for this phase I trial (NCT04840875). The CD7 CAR construct included an endoplasmic reticulum anchor domain fused to a CD7 binding domain to prevent CD7 expression on cell surface, which contributed to minimize CAR T cell fratricide. CAR T product was checked to ensure lack of tumor contamination before infusion. The trial followed a "3+3" dose escalation process. Adverse events and efficacy were primary and secondary endpoints. **Results:** A total of 5 patients (Pt1-5), with a median age of 3.8 years (range, 1.9-13), were enrolled between Sept 2021 and Jan 2022. At enrollment, Pt1 had mediastinal mass and blasts in pleural fluid; Pt4 was in central nervous system (CNS)-3 status; Pt2, 3 and 5 had marrow disease with a median burden of 1.35% (range, 0.07%-7.31%). Pt1, 2 and 3 received 5×10^5 (±20%) cells/kg; Pt5 received 1×10^6 (±20%) cells/kg; Pt4 received cells below the target dose. Three patients had cytokine release syndrome (CRS), including one grade 3; the median onset was on day 5 (range, 1-9) with the median duration of 4 days (range, 3-14). No patient had neurotoxicity, GVHD or infection. Grade 3-4 hematological toxicity occurred in all five patients, which recovered to grade 2 within 30 days. On one month post-infusion, four patients achieved complete remission, and one patient (Pt4) still had leukemia cells in the cerebrospinal fluid. With the median follow-up time of 62 days (range, 35-136), one patient (Pt1) underwent stem cell transplantation (SCT) on 2.9 months post-infusion, and had a CD7$^-$ relapse on 1.4 months post-SCT; the other three responders remained in MRD$^-$ CR. In the four patients who received target dose, the median peak CAR T cell count in peripheral blood was 4.27×10^2/uL (range, 2.49-5.61) by flow cytometry, and all five patients had detectable CAR transgene by PCR on their last visits. There was a decrease of CD7-positive normal T cells and an increase of CD7-negative counterparts in all responders. **Conclusions:** Autologous CD7 CAR T cell therapy was safe and effective in the induction of remission in r/r T-ALL/LBL patients, without signs of GVHD. Longer follow-up time of more cases will be used to further evaluate this therapy. Clinical trial information: NCT04840875. Research Sponsor: the National Key R&D Program of China (2019YFA0110200).

Quizartinib (QUIZ) with decitabine (DAC) and venetoclax (VEN) is active in patients (pts) with FLT3-ITD mutated acute myeloid leukemia (AML): A phase I/II clinical trial. *First Author: Musa Yilmaz, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: QUIZ, a potent 2nd generation FLT3 inhibitor (FLT3i) demonstrated synergy with VEN in AML cell lines and PDX models (Mali Haematologica 2020). We evaluated the safety and efficacy of DAC + VEN + QUIZ triplet in patients with newly diagnosed (ineligible for intensive induction chemotherapy) or relapsed/refractory (R/R; up to 5 prior chemotherapies) FLT3 ITD mutated AML. **Methods:** All pts received 10 days of DAC (20 mg/m2) in Cycle 1. Pts underwent day 14 bone marrow (BM) biopsy, and VEN (400 mg/day starting from day1) was put on hold in pts with BM blasts ≤ 5% or aplasia. Those with day14 BM blast >5% continued VEN for 21 days during cycle 1. In subsequent cycles, DAC was reduced to 5 days. QUIZ (30 or 40 mg/day) was administered daily continuously. **Results:** Overall, 28 pts were enrolled and evaluable at the time of this report. Of the 23 pts with R/R AML (median 3 [range 1-5] prior therapies, 78% with ≥1 prior FLT3i including prior gilteritinib (GILT) in 70%, and 39% had a prior ASCT), 78% achieved CRc (3 CR, 15 CRi) with 6/16 and 5/18 responders FLT3-PCR and multicolor flow cytometry (MFC) negative, respectively. Pts with RAS/MAPK mutations had the lowest response rates (Table). Interestingly, no emergent TKD mutations were noted at relapse after the triplet but 3/8 evaluable pts had emergent RAS/MAPK mutations. 60-day mortality rate was 5%. Of 5 patients with newly diagnosed AML (median age 69), all achieved CRc (2 CR, 3 CRi) with 4/5 and 2/4 responders FLT3-PCR and MFC negative, respectively. 60-day mortality was 0. 2 pts developed hematologic DLT with 40 mg/day QUIZ dose (grade 4 neutropenia with a <5% cellular BM lasting ≥42 days). Hence, QUIZ 30 mg/day dose was determined as RP2D for the triplet. Grade 3/4 non-hematologic toxicities included lung infections (42%) and neutropenic fever (30%). No QTcF prolongations >480 msec were noted. With a median follow-up (f/u) of 13 months, the median OS was 7.6 months in R/R cohort (1-year OS of 30%). 8/18 responding R/R pts (including 5/8 prior GILT exposed pts) underwent ASCT with a median OS of 19 vs 8 months in those who underwent ASCT versus not (p=0.26). Of the 5 frontline responding pts median OS was 14.5 months, 2 were alive in CR, 1 died in CR1 post-ASCT, 2 died due to relapsed disease at the last f/u. **Conclusions:** DAC + VEN + QUIZ is active in R/R FLT3-ITD mutated AML pts, with CRc rates of 78% and the median OS of 7.6 months. Interestingly, RAS/MAPK mutations but not emergent TKD mutations were associated with primary and secondary resistance to the triplet. Accrual continues, and updated clinical, NGS, and mass cytometry (CyTOF) data will be presented. Clinical trial information: NCT03661307. Research Sponsor: Daiichi-Sankyo.

7037 **Poster Session**

Phase 2 study of ASTX727 (cedazuridine/decitabine) plus venetoclax (ven) in patients with relapsed/refractory acute myeloid leukemia (AML) or previously untreated, elderly patients (pts) unfit for chemotherapy. *First Author: Farhad Ravandi, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ASTX727, is an oral formulation of the fixed dose combination of decitabine and cytidine deaminase inhibitor cedazuridine (100 mg/35 mg). We investigated whether a total oral therapy regimen of ASTX727+ven is feasible and safe. **Methods:** Pts aged ≥18 years (yrs) with relapsed/refractory AML (R/R) or pts with AML aged ≥ 75 or 18 -74 with comorbid conditions prohibiting intensive chemotherapy were eligible to participate (frontline-FL). Other eligibility criteria included adequate renal and hepatic function, and an ECOG performance status (PS) of≤2. ASTX727 is administered daily on days 1-5 of each cycle and ven on days 1-28 of the first cycle after a dose ramp up of 100-200-400 mg over 3 days (with tumor lysis prophylaxis precautions and with ven dose adjustments as needed). A bone marrow exam is performed on day 21±3 days and ven is held if blasts < 5% to allow count recovery. Cycles are repeated every 4-8 weeks and ven is administered for 21 days in subsequent cycles. **Results:** Between March 2021 and January 2022, 28 pts (15 FL and 13 R/R) have been treated on the study. The median age is 75 yrs (range, 47-90) with FL cohort 81 and R/R cohort 72. 9 FL pts (60%) were ≥80 and 5 (30%) 70-80 yrs. In R/R cohort 9 pts (69%) were 70-80 yrs. The median PS is 2 (range 0-3) and in the R/R cohort, the median number of prior treatments is 2 (range, 1-4). In the FL cohort 5 (33%) had normal and 6 (40%) a complex karyotype; 3 had other. In the R/R cohort, 15% had normal karyotype, 46% complex and 31% others. Mutations of note in the frontline cohort were RUNX1 (33%), ASXL1 (33%), DNMT3A (7%), TET2 (40%) and TP53 (20%). The overall response rate (ORR) including complete response (CR), CR with incomplete count recovery (CRi) and morphological leukemia free state (MLFS) in the FL cohort is 61% (4 CR, 4 CRi, 1 MLFS and 3 non-responders). 3 pts received only one day of therapy for severe adverse events unrelated to therapy (1 due to ischemic stroke, 1 septic shock and 1 debilitation) and were not evaluable for response. In the R/R cohort, the ORR was 45% (2 CR, 2 CRi, 2 MLFS with 5 non-responders and 2 not evaluable). The median number of cycles received is 2 (range, 1-5) for both cohorts. With a median follow-up of 5 months, the median survival for the FL cohort has not been reached (range, 0.6 – 7.3) and is 7.2 (range, 0.8-7.3) months for the R/R cohort. Grade 3 or higher adverse events directly attributable to therapy were mainly myelosuppression-related and included neutropenic infections in 3 (11%) and elevation of liver enzymes in 1 (4%) pt. **Conclusions:** Total oral therapy of ASTX727+ven is safe and feasible, particularly in the advanced elderly population, and demonstrates significant efficacy in pts unfit for chemotherapy both in the FL and R/R settings. Clinical trial information: NCT04746235. Research Sponsor: Taiho.

7038 **Poster Session**

Impact of induction approach on post-stem cell transplant (SCT) outcomes in older adults with newly diagnosed acute myeloid leukemia (AML). *First Author: Faustine Ong, The University of Texas MD Anderson Cancer Center, Department of Leukemia, Houston, TX*

Background: The optimal induction regimen for older patients (pts) with AML who are eligible for SCT is not well-established. **Methods:** This is a retrospective analysis of 127 pts age ≥60 years with newly diagnosed AML who underwent allogeneic SCT in first remission between 9/2012 and 7/2021 at our institution. Pts with previously treated secondary AML were excluded. Pts were divided according to induction therapy received: intensive chemotherapy (IC) (n = 44), lower-intensity therapy (LIT) without venetoclax (VEN) (n = 36), and LIT with VEN (n = 47). We compared overall survival (OS), relapse-free survival (RFS), cumulative incidence of relapse (CIR) and non-relapse mortality (NRM) according to the induction regimen received. **Results:** Pts who received IC were younger than those who received LIT with or without VEN (median age: 63 vs. 68 years; P < 0.0001) and were more likely to have an ECOG performance status of 0 at time of AML diagnosis (34% vs. 14%; P = 0.02). Cytomolecular risk was well-balanced between the 3 arms; the rates of adverse cytomolecular features in the IC, LIT without VEN and LIT with VEN groups were 43%, 50%, and 55%, respectively. Donor sources and degree of HLA matching were similar in the 3 groups. Most pts (92%) in the LIT with VEN group received reduced-intensity conditioning prior to SCT, compared with 54% and 58% in the IC and LIT without VEN groups, respectively. The majority of pts achieved CR/CRi prior to SCT (IC cohort:100%, LIT without VEN: 94%, LIT with VEN: 92%); the rest had MLFS as best response. The rate of measurable residual disease (MRD) negativity by flow cytometry prior to SCT was higher in the LIT with VEN group (69%), compared with IC (58%) and LIT without VEN (49%) (P = 0.14). The median number of cycles of chemotherapy prior to SCT was 3 in all groups. The median post-SCT follow-up was 37 months. The 2-year CIR was similar in pts who received IC or LIT with VEN (18% and 19%, respectively) and was highest in pts who received LIT without VEN (36%). The 2-year NRM was lowest in pts with LIT with VEN (11%), as compared with IC or LIT without VEN (27% and 22%, respectively) (P = 0.02 for IC vs. LIT with VEN). The 1-year post-SCT RFS for pts who received IC, LIT without VEN and LIT with VEN was 58%, 50%, and 75%, respectively, and the 2-year RFS was 54%, 42% and 62%. The 1-year post-SCT OS was 63%, 58%, and 84%, respectively, and the 2-year OS was 58%, 44% and 73%. OS was statistically superior for LIT with VEN compared with LIT without VEN (P = 0.02) and there was a trend towards superior OS with LIT with VEN compared to IC (P = 0.17). **Conclusions:** LIT with VEN was associated with similar rates of CIR and lower NRM compared with IC. Despite the older age of pts in the LIT with VEN cohort, their post-SCT survival outcomes were noninferior, and possibly superior, to those who received IC. These results suggest that LIT with VEN is a valid induction strategy for older SCT-eligible pts with newly diagnosed AML. Research Sponsor: None.

Donor-derived T cells specific for tumor antigen and multiple pathogens for prevention of relapse and infection after haemopoietic stem cell transplant (HSCT) for myeloid malignancies (the INTACT trial). *First Author: Wei Jiang, The Westmead Institute for Medical Research, The University of Sydney, Westmead, Australia*

Background: Disease relapse and infection cause significant morbidity and mortality after allogeneic HSCT for acute myeloid leukemia (AML) and myelodysplasia (MDS). Wilms' tumour 1 (WT1) and preferentially expressed antigen in melanoma (PRAME) are both commonly overexpressed in these conditions. We assessed the safety of a novel combination of tumour associated antigen (TAA) and multipathogen (MP) specific T cells administered prophylactically after HSCT in a phase 1 trial. **Methods:** Patients with overexpression of WT1 or PRAME by ddPCR on diagnostic tumour samples were eligible. TAA and MP specific T cells were *ex vivo* expanded from stem cell donors by stimulating apheresis derived mononuclear cells with tumour, viral or fungal peptides. T cells specific for CMV, EBV, Adenovirus (AdV) and Aspergillus (Asp) antigens were produced separately and pooled in equal parts into a MP product. Patients received 1 infusion of MP specific and up to 4 infusions of TAA specific T cells at 4-weekly intervals from 28 days post HSCT (cell dose $2x10^7/m^2$ per infusion). **Results:** Ten HSCT recipients have received a total of 38 infusions. Median age was 48 years (17-67), disease AML (n = 6) or high risk MDS (n = 4), DRI intermediate (n = 4) or high (n = 6), conditioning myeloablative (n = 8) or reduced intensity (n = 2), donor source sibling (n = 7) or matched unrelated (n = 3). Median expression of WT1 on diagnostic bone marrow was 1442 copies/10^4 copies ABL (0-3870), PRAME 131 copies/10^4 copies ABL (4-12300). Patients received WT1 (n = 4), PRAME (n = 5) or both WT1 and PRAME specific T cells (n = 1). Mean tumour antigen specificity in the TAA product was 1.4% and 13.3% of CD3+ cells for WT1 and PRAME respectively. Mean total pathogen specificity in the MP product was approximately 44% (CMV = 14.0%, EBV = 14.8% and AdV = 11.6% of CD3+ cells, Asp = 14.8% of CD4+ cells). All patients received MP specific T cells. No immediate infusion related adverse events were reported. At a median 540 days post transplant (80-1265), 8 of 10 patients remain alive and in complete disease remission. Two patients did not proceed after completing 3 of 5 infusions due to the development of graft versus host disease (GVHD); both are in remission. There were 2 deaths; one patient with progressive disease who had persistent high risk MDS pre and post HSCT, and one with multiorgan failure who had multiple post transplant complications (venoocclusive disease, sepsis, GVHD), both prior to infusion. Low level viral reactivations occurred (CMV n = 5, EBV n = 7, BKV n = 3, HHV6 n = 4, AdV n = 1), however none required treatment and there were no cases of viral tissue disease or EBV PTLD. There were no invasive fungal infections. **Conclusions:** Prophylactic infusions of donor derived WT1/PRAME and multipathogen specific T cells post HSCT are well tolerated and associated with low rates of infection and relapse. Clinical trial information: NCT02895412. Research Sponsor: Western Sydney Local Health District.

Long-term outcomes of newly diagnosed CRLF2 rearranged B-cell ALL.

First Author: Jayastu Senapati, Department of Leukemia, M.D. Anderson Cancer Center, Houston, TX

Background: CRLF2 rearranged B-ALL, a subtype of Ph-like ALL, constitutes a high-risk subset of B-ALL with poor outcomes with chemotherapy. Targeted therapies such as blinatumomab (blina) or inotuzumab (ino) may improve treatment outcomes for these patients (pts). **Methods:** We retrospectively analyzed pts with newly diagnosed B-ALL (diagnosed between 01/2001 and 12/2021) at our center who had documented CRLF2 overexpression. Initial therapy, including use of ino and blina in CR1 were noted. Outcomes measures included CR/CRi, MRD response, RFS and OS. **Results:** A total of 76 pts with a median age of 38 years (yrs) (range, 18-80) were identified, of which 70% were males and 81% were of Hispanic ethnicity. All pts had overexpression of CRLF2 documented by flow cytometry or gene expression profile. A subset of pts (n=37) had a concomitant CRLF2 FISH performed with all confirming CRLF2 rearrangement. Baseline disease parameters, treatment and outcomes are detailed in Table. Sixty-five pts (85%) received Hyper-CVAD based induction therapy (HCVAD, n=51; mini-HCVD, n=14) and 11 (15%) received augmented BFM. Among the HCVAD/mini-HCVD treated pts, 37% received blina in CR1 during consolidation at a median of 3.6 months after starting induction therapy, 34% received ino in CR1 (most commonly starting in cycle 1 as part of mini-HCVD + ino regimen) and 22% received both ino and blina in CR1. We focus on the outcomes of 65 pts treated with HCVAD/mini-HCVD. The median follow-up was 18 months (mos). CR/CRi rate after C1 among HCVAD/mini-HCVD treated pts was 52/65 (80%) with 25/47 (53%) MRD evaluable pts achieving MRD-neg post C1. The median RFS and OS was 17.6 and 26.6 mos, respectively. CR/CRp rate after C1 among pts who received mini-HCVD + ino in C1 was 100% (14/14) with 79% MRD-neg. On landmark analysis to the time to blina initiation, blina treated pts had similar RFS and trended for improved OS. A total of 19/65 (30%) had allo-SCT in CR1; all were MRD-neg prior to allo-SCT. Landmark analysis for OS based on time to allo-SCT (6 mos) favored SCT in CR1 (47.2 vs. 17.6 mos, p=0.04). **Conclusions:** Despite improvements in treatment options, CRLF2 overexpressed B-ALL continue to have inferior outcomes. Earlier initiation of targeted therapies might improve outcomes. Research Sponsor: None.

Decreasing HPK1 expression in CD19 CAR-T cells: A novel strategy to overcome challenges of cell therapy for adult (r/r) B-ALL.

First Author: Na Zhang, Department of Hematology, Xijing Hospital, Xi'an, China

Background: Since the FDA approved the first CD19 CAR T cell therapy (Kymriah) for pediatric and young adult patients with relapsed or refractory (r/r) B-cell acute lymphoblastic leukemia (ALL), cytokine release syndrome (CRS) has still been a life-threatening toxicity that limits the full therapeutic potential in adults [1,2]. So far, Tecartus was the first and only approved CAR-T cell therapy for adult r/r B ALL, which was based on results from ZUMA-3 study. CRS occurred in 92% patients, and neurologic toxicities occurred in 87% patients in ZUMA-3 study[3], suggesting that therapeutic developments are needed to ensure more safe options for adult B-ALL. Our preclinical data demonstrated that CAR-T cells with decreased HPK1 expression had enhanced antitumor effects and did not induce higher grade CRS [4]. Thus, the first-in-human clinical study is ongoing to test CD19 CAR-T cells with decreased HPK1 expression (XYF19 CAR-T cells) for adult (r/r) B-ALL (NCT04037566). **Methods:** Dose-escalation study was initiated to explore the safety and efficacy of XYF19 CAR-T cells in adult r/r B-ALL. 11 eligible adult r/r B-ALL patients were enrolled. The cell dosage of XYF19 was significantly lower than Tecartus and Kymriah, participants were infused with XYF19 CAR-T cells: 3 at low dose (2.0×10^5/kg), 5 at medium dose (5.0×10^5/kg), and 3 at high dose (1.0×10^6/kg). All patients received a conditioning regimen of IV fludarabine (30mg/m^2/d) for 4 days and cyclophosphamide (500mg/m^2/d) for 2 days. **Results:** 30 days after infusion with XYF19 CAR-T cells, 8 of the 11 (72.7%) patients had achieved complete remission (CR) or CR with incomplete count recovery (CRi). Considering the low dosage of XYF19 and that the CR/CRi rate is 71% with Tecartus [2] and 69% with Kymriah [3], the clinical response of XYF19 is similar or even the highest in these three studies. Strikingly, in this clinical trial, no patient has yet experienced dose-limiting toxicity. No grade 3 or higher CRS occurred in XYF19 treated patients, while Grade 3 or higher CRS was observed in 26% of patients with Tecartus [2], and 72% of patients with Kymriah[3]. No neurologic events occurred in the current study, while the incidence of neurological events was 51% with Tecartus [2] and 43% with Kymriah[3]. Thus, XYF19 is a strong potential novel treatment for CD19 CAR-T cell therapy in adult B-ALL. **Conclusions:** Treatment with XYF19 CAR-T cells promises a novel treatment that can alleviate some of the stern challenges of CD19 CAR-T cell therapy for adult patients with r/r B-ALL. In the current study, this treatment showed robust activity against adult (r/r) B-ALL without > Grade 2 toxicity. This efficacy and safety will be demonstrated in further trials with larger sample sizes. References: [1] Blood. 2021; 19;138 (7): 531–543. [2] Lancet.398(10299):491-502. [3] J. Biol. Hematologic improvements with ivosidenib + azacitidine compared to placebo + azacitidine in patients with newly diagnosed acute myeloid leukemia.

First Author: Hartmut Dohner, Ulm University Hospital, Ulm, Germany

Background: Ivosidenib (IVO) is a potent oral targeted inhibitor of mutant isocitrate dehydrogenase 1 (mIDH1). IVO plus azacitidine (AZA) significantly improved event-free survival (EFS), overall survival and complete remission + partial hematologic recovery rates compared with placebo (PBO) + AZA, in patients (pts) with newly diagnosed *IDH1*-mutant acute myeloid leukemia (AML) in the Phase 3 AGILE trial (NCT03173248). Here we report blood count recovery results from the AGILE trial. **Methods:** Pts were randomized 1:1 to IVO 500 mg QD + AZA 75 mg/m^2 SC or IV for 7 days in 28-day cycles (n = 72), or PBO+AZA (n = 74). Red blood cell (RBC)/platelet transfusion history were assessed at screening and follow-up. Bone marrow (BM) and peripheral blood samples were obtained at screening, and during weeks 9, 17, 25, 33, 41, 53, and every 24 weeks thereafter, and at end of treatment and during EFS follow up. Samples were analyzed at each local site according to ICSH guidelines. **Results:** In the IVO+AZA and PBO+AZA arms, 4.2% and 5.5% of pts, respectively, received concomitant granulocyte colony-stimulating factor. Hemoglobin levels steadily increased from baseline at a similar rate in both treatment arms. Mean platelet count recovered from baseline values in the IVO+AZA and PBO+AZA arms (71.0 and 92.6 x 10^9/L, respectively) as early as week 9 of treatment (171.1 and 155.1 x 10^9/L, respectively) and continued to steadily increase thereafter in the treated population. In pts receiving IVO+AZA, mean neutrophil counts rapidly increased from baseline (0.99 x 10^9/L) to week 2 (2.05 x 10^9/L) and week 5 (4.07 x 10^9/L), and then generally stabilized to within the normal range to study end (last available cycle value; ~2.0 x 10^9/L). Mean neutrophil counts initially declined with PBO+AZA before slowly recovering to near-normal levels after 36-40 weeks. The increased blood counts were accompanied by a rapid decrease in the mean BM blast percentage from 54.8% at baseline to 12.0% and 7.2% at week 9 and 17, respectively, in IVO+AZA treated patients and were maintained for 149 weeks. The decline in BM blasts was slower in the PBO+AZA arm (53.7%, 34.6% and 19.6% at baseline, week 9 and week 17, respectively). Among patients who were RBC/platelet transfusion-dependent at baseline (~54.0% in both groups), 46.2% in the IVO+AZA group achieved RBC/platelet transfusion independence compared with 17.5% in the PBO+AZA arm (1-sided p = 0.0032). Additionally, fewer adverse events of febrile neutropenia (28.2% vs 34.2%) and infections (28.2% vs 49.3%) were reported in the IVO+AZA arm compared to the PBO+AZA arm. **Conclusions:** IVO+AZA demonstrated a significant clinical benefit compared with PBO+AZA and this subanalysis demonstrated a rapidly improved recovery of blood counts and a reduced dependence on RBC and/or platelet transfusion. Moreover, rates of febrile neutropenia and infections were reduced with IVO+AZA. Clinical trial information: NCT03173248. Research Sponsor: Agios Pharmaceuticals, Inc. Servier Pharmaceuticals LLC has completed the acquisition of Agios' oncology business.

V-FAST master trial: Preliminary results of treatment with CPX-351 plus midostaurin in adults with newly diagnosed *FLT3*-mutated acute myeloid leukemia.

First Author: James K. McCloskey, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ

Background: CPX-351 (US: Vyxeos; Europe: Vyxeos liposomal), a dual-drug liposomal encapsulation of daunorubicin and cytarabine in a synergistic 1:5 molar ratio, is approved for newly diagnosed, therapy-related AML or AML with myelodysplasia-related changes in patients aged ≥1 year in the US and in adults in Europe. In a phase 3 study in older adults with newly diagnosed, high-risk/secondary AML, CPX-351 significantly improved overall survival and remission rates versus conventional 7+3, with a comparable safety profile. Preclinical data suggest CPX-351 may have synergistic activity with targeted agents, including the FLT3 inhibitor midostaurin (MID). Herein, we report preliminary results for the cohort of adults treated with CPX-351 + MID in the V-FAST (Vyxeos – First Phase Assessment with Targeted Agents) trial. **Methods:** V-FAST is an open-label, multicenter, multiarm, nonrandomized, phase 1b master trial (NCT04075747) to evaluate the safety and preliminary efficacy of CPX-351 combined with targeted agents (midostaurin, venetoclax, enasidenib). Eligible adults in the CPX-351 + MID cohort were aged 18 to 75 years, had newly diagnosed AML with a *FLT3* internal tandem duplication (ITD) or tyrosine kinase domain (TKD) mutation, were fit for intensive chemotherapy, and had an ECOG performance status of 0 to 2. The dose-exploration phase (3+3 design) determined a recommended phase 2 dose of CPX-351 100 units/m^2 (daunorubicin 44 mg/m^2 + cytarabine 100 mg/m^2) on Days 1, 3, and 5 + MID 50 mg BID on Days 8 to 21. There were no dose-limiting toxicities, and additional patients were enrolled in the expansion phase at this dose. **Results:** A total of 23 patients received CPX-351 + MID and had sufficient data to be included in the analysis (cutoff date: 1/20/2022). Patient baseline characteristics are shown in the Table. Treatment-emergent adverse events (TEAEs) in ≥40% of patients included febrile neutropenia (78%), nausea (65%), increased alanine aminotransferase (57%), leukopenia (57%), thrombocytopenia (57%), headache (43%), and hyponatremia (43%). All patients experienced a grade 3/4 TEAE, primarily hematologic events. Nonhematologic grade 3/4 TEAEs in ≥2 patients included pneumonia (17%), lung infection (13%), and hyperglycemia (9%). There were no grade 5 TEAEs and no deaths on or before Day 60. Complete remission was achieved by 18/22 (82%) evaluable patients after the first induction cycle. **Conclusions:** Preliminary results from the V-FAST trial suggest CPX-351 + MID is feasible, with a manageable safety profile and promising remission rates in adults with newly diagnosed AML who have a *FLT3* mutation. Clinical trial information: NCT04075747. Research Sponsor: Jazz Pharmaceuticals.

Efficacy and safety of venetoclax in combination with azacitidine or decitabine in an outpatient setting in patients with untreated acute myeloid leukemia.

First Author: Sudhir Manda, Arizona Oncology, The US Oncology Network, Tucson, AZ

Background: Venetoclax (Ven), a highly selective BCL-2 inhibitor, combined with hypomethylating agents (HMAs) azacitidine (Aza) or decitabine (Dec) is approved for the treatment of newly diagnosed acute myeloid leukemia (ND AML) in patients (pts) who are ineligible to receive intensive chemotherapy. Previous clinical studies initiated Ven + HMA in an inpatient setting due to concerns of tumor lysis syndrome (TLS). This Phase 3b, single-arm, multicenter, open-label study (NCT03941964) evaluated the efficacy and safety of Ven + HMA in a US community-based outpatient setting. **Methods:** Pts with ND AML who were ineligible to receive intensive chemotherapy, had no evidence of spontaneous TLS at screening, and were deemed an appropriate candidate for outpatient initiation of Ven + HMA by the investigator were eligible. Pts received Ven (400 mg) in combination with Aza (75 mg/m^2) or Dec (20 mg/m^2) for up to 6 cycles during the study period. Pts could continue receiving commercially acquired Ven after the study period. All pts received TLS prophylaxis. The primary endpoint was the composite complete remission (CR) rate (CR + CR with incomplete hematologic recovery [CRi]) per modified International Working Group criteria. Secondary endpoints included CR or CRi rates and transfusion independence (TI). TLS was assessed per Howard criteria (Howard. *N Engl J Med*. 2011;364:1844). **Results:** At the 19 Oct 2021 cutoff date, 60 pts were enrolled and treated (Ven + Aza, n=30; Ven + Dec, n=30). Efficacy outcomes are shown in the Table. The composite CR rate was 58%. CR and CRi rates were 13% and 45%, respectively. Most pts (>50%) maintained TI, and 41% and 57% of pts dependent on red blood cells or platelets, respectively, converted to TI. Bone marrow blast clearance was achieved in 42 pts (70%) at a median 26 days after treatment initiation. The most common (≥50%) AEs were anemia (75%), neutrophil count decrease (55%), white blood cell count decrease (52%), and nausea (50%). Serious AEs occurred in 67% of pts, most commonly (≥15%) febrile neutropenia (28%) and sepsis (15%). Two pts (3%) had TLS; neither event led to treatment discontinuation. Of pts who achieved blast clearance, 12/42 (29%) had a new event of myelosuppression post-blast clearance and prior to the next cycle. **Conclusions:** The results of this US community-based study indicate that Ven + HMA is an effective treatment option for pts with ND AML and, with appropriate TLS prophylaxis and monitoring, can safely be initiated in an outpatient setting. Clinical trial information: NCT03941964. Research Sponsor: AbbVie.

Incorporating patient-reported outcome data into a hematopoietic cell transplant survival calculator.

First Author: Bronwen E. Shaw, CIBMTR (Center for International Blood and Marrow Transplant Research), Department of Medicine, Medical College of Wisconsin, Milwaukee, WI

Background: The Center for International Blood and Marrow Transplant Research (CIBMTR) provides a validated 1-year Overall Survival (OS) calculator to estimate outcomes for individual patients prior to allogeneic Hematopoietic Cell Transplant (HCT) to inform risk. The calculator considers pre-HCT clinical and demographic characteristics, but not patient-reported outcome (PRO)s. Pre-HCT PRO scores have been associated with OS. We hypothesized that adding the baseline PRO score to the calculator will enhance its performance in predicting OS. **Methods:** In addition to established covariates,we considered pre-HCT PRO scores, collected on five (published) prospective randomized clinical trials performed through the Blood and Marrow Transplant Clinical Trials Network (BMT CTN). Measures used were the SF36 physical component score (PCS) and mental component score (MCS), and the FACT-BMT Trial outcome index (TOI). We also investigated inclusion of a single question from the SF36: In general, would you say your health is: excellent/very good/good vs fair/poor. Patients were ≥18. **Results:** 1,033 patients were included, 341 (33%) completed only the SF36, 339 (33%) only the FACT-BMT and 353 (34%) both, per study design. HCT occurred 2004-2014, and the population was diverse with respect to disease, stage, demographics, and transplant characteristics. When adjusted for clinical characteristics, the PCS was significantly predictive of mortality (HR=0.88, 95%CI 0.81-0.96, p=0.0021), while the MCS and TOI were not. The single general health question was also significantly associated with mortality (HR=0.52, 95%CI 0.35-0.74, p=0.0004). Addition of PRO scores to the calculator did not result in a significant change in the model's predictive ability as measured by Harrell's concordance statistic (Table). **Conclusions:** In this large analysis, we confirmed the significant, independent association of pre-HCT PRO scores with OS. We showed, for the first time in this setting, that a single general health question is as accurate as the full SF36 measure for predicting survival, but we did not find support for the hypothesis that adding PROs to the calculator improved its performance. Estimates of baseline PRO measure effect on mortality and model concordance statistics at 1-year post-HCT. Research Sponsor: U.S. National Institutes of Health, Other Government Agency.

Association of frailty with clinical and financial outcomes of allogeneic hematopoietic stem cell transplant.

First Author: Sara Sakowitz, David Geffen School of Medicine, UCLA, Los Angeles, CA

Background: Considered the only curative therapy for many hematological conditions, allogeneic hematopoietic stem cell transplantation (alloHSCT) is increasingly used in older patients. Yet, chronological age alone has been found to be an inaccurate predictor of posttransplant sequelae. More recently, the concept of frailty has emerged as a better marker of physiologic reserve. While formal frailty instruments have not been widely adopted due to their resource intensive nature, we applied a previously-validated coding-based approach to examine the association of frailty with in-hospital outcomes of alloHSCT. **Methods:** All adults (≥ 18 years) undergoing alloHSCT for hematological malignancies were identified in the 2010-2019 Nationwide Readmissions Database. The previously-validated binary Johns Hopkins Adjusted Clinical Groups indicator was used to classify patients as frail. In this algorithm, the presence of diagnoses across various domains, including malnutrition, dementia, and decubitus ulcer, constitute frailty. Regression models were developed to evaluate the independent association of frailty with in-hospital mortality, periprocedural complications, length of stay, hospitalization costs, and 30-day non-elective readmissions. **Results:** Of an estimated 48,161 patients, 9.8% were considered frail. Frail patients were not significantly older (51.8 ± 15.0 vs 51.6 ± 14.2, p = 0.685), but had higher Elixhauser scores (2.8 ± 1.3 vs 2.0 ± 1.3, p < 0.001). After adjustment, frailty was associated with increased odds of in-hospital mortality (AOR 2.22; 95% CI 1.68-2.94; P < 0.001), as well as infectious (AOR 1.44, 95% CI 1.18-1.76; P < 0.001) and respiratory (AOR 1.69, 95% CI 1.41-2.02; P < 0.001) complications. Frailty was also associated with greater risk of acute graft-vs-host disease (AOR 1.39, 95% CI 1.12-1.72; P = 0.003) and CMV (AOR 1.72, 95% CI 1.27-2.33; P < 0.001) or invasive fungal infection (AOR 1.49, 95% CI 1.07-2.06; P = 0.017). Further, frailty was linked to increased likelihood of non-home discharge (AOR 1.29, 95% CI 1.03-1.61; P = 0.026), 30-day non-elective readmissions (AOR 1.29, 95% CI 1.11-1.50; P = 0.001), and significant increases in length of stay (+6.05 days, 95% CI 4.41-7.69; P < 0.001) and costs (+$36,660, 95% CI 27,413-45,907; P < 0.001). **Conclusions:** Among patients undergoing alloHSCT, frailty, as measured by an administrative tool, was independently associated with increased in-hospital mortality, complications and overall resource use. Inclusion of frailty in risk models may better aid benchmarking efforts and inform shared-decision making. Research Sponsor: None.

Non-myeloablative allogeneic blood or marrow transplantation (AlloBMT) with post-transplant cyclophosphamide (PTCy) for peripheral T-cell lymphoma (PTCL): Improved outcomes with peripheral blood (PB) allografts and increased total body irradiation (TBI) to 400 cGV.

First Author: Cole Harris Sterling, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD

Background: The use of PTCy for graft-versus host-disease (GVHD) prophylaxis has revolutionized alloBMT, but there is limited published experience in PTCL. **Methods:** All patients with PTCL who received a non-myeloablative alloBMT using PTCy-based GVHD prophylaxis between January 2004 and December 2020 at Johns Hopkins Hospital were analyzed. Standard population statistics were used. **Results:** Sixty-five patients were identified. The median age was 59 years (range, 24-75 years). Lymphoma histology included PTCL-not otherwise specified (n=24), ALK-negative anaplastic large cell lymphoma (n=14), angioimmunoblastic T-cell lymphoma (n=7), enteropathy-associated T-cell lymphoma (n=6), hepatosplenic T-cell lymphoma (n=4), and other (n=10). Eleven patients were in first complete remission (CR1, 17%). The remaining patients were in first partial remission (PR1) or underwent salvage therapy to at least PR prior to transplant. Forty-eight patients received an alloBMT from a haploidentical related donor (74%), 10 from a fully matched donor (15%), and 7 from a mismatched unrelated donor (mMUD, 11%). All patients received non-myeloablative conditioning with fludarabine, cyclophosphamide, and TBI. The graft source was bone marrow (BM) in the first 46 patients (71%). Because of relatively high relapse rates, in 2018 we began using PB and increased TBI from 200 to 400 cGy; the remaining 19 patients (29%) received this regimen. GVHD prophylaxis was PTCy, mycophenolate mofetil, and a calcineurin inhibitor or sirolimus. With a median follow up of 2.8 years, the 3-year progression-free survival (PFS) for the entire cohort was 39% (95% confidence interval [CI] 28-54%), and the 3-year overall survival (OS) was 43% (95% CI 31-58%). The cumulative incidence (CuI) of relapse and non-relapse mortality (NRM) at 1 year was 25% (95% CI 14-35%) and 12% (95% CI 4-20%), respectively. Among 29 cases of GVHD (45%), 2 were grade 3-4 acute GVHD (3%) and 3 were severe chronic GVHD (5%). Univariate analysis including age, histology, mMUD, PB/400cGy, and CR1 revealed only PB/400 cGy TBI as a significant predictor of survival, relapse, or NRM. Outcomes by source. **Conclusions:** AlloBMT with non-myeloablative conditioning and PTCy is safe and well-tolerated in patients with PTCL. Our preliminary data suggest increasing TBI dose to 400 cGy and using PB allografts may offer improved disease control and better survival outcomes, though additional studies are needed to confirm these findings. Impact of prior solid tumor on outcomes of allogeneic hematopoietic stem cell transplantation for AML or MDS. *First Author: Aya Albittar, University of Washington, Seattle, WA*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) offers a definitive treatment of acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS). Prior solid tumor (PST) is felt to portend a worse post-transplant prognosis. The aim of this study was to evaluate the impact of PST history on allo-HSCT outcome. **Methods:** We retrospectively identified patients with AML or MDS who underwent first allo-HSCT at the Fred Hutchinson Cancer Research Center between 2010 and 2018. Cox regression analysis was used to identify factors associated with mortality among patients with PST, and to compare outcomes of patients with and without PST. Multivariable models were fit, adjusting for cytogenetic risk level, time from PST diagnosis to transplant, receipt of reduced-intensity conditioning (RIC), and age at transplant. Survival estimates were obtained using the Kaplan-Meier method. **Results:** 1198 patients were included for analysis, of which 101 had a history of PST. After a median follow up of 1301 days among survivors, there was a total of 558 deaths and 322 relapses among all patients. Patients with history of PST were older (62.5 vs 54.9 yrs) and a higher proportion received RIC (52.5% vs 27.3%). The most common PSTs included breast (38/101, 38%), prostate (13/101, 13%), colon (9/101, 9%), thyroid (8/101, 8%), and uterine (7/101, 7%). Among those with known staging (n = 66), stage 1 (28/66, 42%) was the most common, followed by stage 2 (17/66, 26%) then stage 3 (15/66, 23%). The most common therapies provided were surgery (95/101, 95%), cytotoxic chemotherapy (41/101, 41%), radiation (45/101, 45%), and endocrine therapy (25/101, 25%). The unadjusted hazard ratio (HR) of mortality in the PST group relative to the non-PST group was 1.10 (95% confidence interval [CI] 0.83-1.47, p = 0.52). After adjustment for patient age, disease, patient/donor CMV status, KPS, cytogenetic risk, source of stem cells, and donor type, the adjusted HR was 0.91 (95% CI 0.68-1.22, p = 0.59). The unadjusted HR for relapse was 1.15 (95% CI 0.79-1.67, p = 0.48), and adjusted HR was 1.11 (0.76-1.11, p = 0.61). Among patients with PSTs, high-risk cytogenetics were associated with increased mortality (adjusted HR = 2.21; 95% CI 1.16-4.2, p = 0.016) and relapse (adjusted HR = 1.91; 95% CI 1.01-3.60, p = 0.047). Longer time from PST diagnosis to transplant led to a numerically increased mortality in the unadjusted (HR = 1.05; 95% CI 1.00-1.11, p = 0.057) and adjusted (HR = 1.05; 95% CI 1.00-1.11, p = 0.69) models treating time as a continuous linear variable. **Conclusions:** In our study, a history of PST did not impact overall survival or relapse rate among patients who underwent first allo-HSCT for AML or MDS. As in the overall population, post-transplant outcomes were primarily driven by cytogenetic risk level. However, it is likely that selection of patients with PST for transplantation was biased based on overall risk assessment. Research Sponsor: None.

Bosutinib (BOS) in newly diagnosed chronic myeloid leukemia (CML): Gastrointestinal (GI), liver, effusion, and renal safety characterization in the BFORE trial. *First Author: Jorge E. Cortes, Georgia Cancer Center, Medical College of Georgia at Augusta University, Augusta, GA*

Background: Efficacy and safety of BOS vs imatinib (IMA) in patients (pts) with newly diagnosed chronic phase CML was assessed in the phase 3 BFORE trial. Here we characterize the safety profile of BOS after 5 yrs follow-up, with a focus on GI, liver, effusion and renal treatment-emergent adverse events (TEAEs). **Methods:** Pts who received ≥1 dose of BOS (n=268) or IMA (n=265) 400 mg/d in BFORE were included. Adverse events (AEs) of special interest were analyzed by selecting prespecified MedDRA terms to generate TEAE clusters. Final database lock: June 12, 2020. **Results:** Median duration of treatment (Tx) was 55 mo for pts receiving BOS or IMA; respective median (range) dose intensity was 393.6 (39–583) vs 400.0 (189–765) mg/d. Any grade TEAEs occurred in 98.9% and 98.9% of BOS- vs IMA-treated pts. Most common newly occurring TEAEs (any grade) after 12 mos were increased lipase (9.0%) with BOS, and diarrhea (8.3%) with IMA. In BOS- vs IMA-treated pts, 25.4% vs 14.3% had AEs leading to permanent Tx discontinuation; the majority discontinued in yr 1 (14.2% vs 10.6%). Most frequent AEs leading to discontinuation were increased ALT (overall, 4.9%; yr 1, 4.5%) with BOS vs thrombocytopenia (overall, 1.5%; yr 1, 1.5%) with IMA. GI, liver, effusion and renal TEAEs, respectively, occurred in 79.9%, 44.0%, 6.0% and 10.4% (maximum grade 3/4 [G3/4]: 9.0%, 26.9%, 1.1% and 2.2%) of BOS- vs 61.5%, 15.5%, 2.3% and 9.8% (G3/4: 1.1%, 4.2%, 0.4% and 0.8%) IMA-treated pts. One grade 5 renal TEAE occurred in the BOS arm and was not considered related to Tx. Cumulative rates per Tx yr are shown in the Table. Most common GI TEAEs were diarrhea (BOS vs IMA: 75.0% vs 40.4% [G3/4: 9.0% vs 1.1%]) with BOS, and nausea (37.3% vs 42.3% [G3/4: 0% vs 0%]) with IMA. In both arms, the most common liver, effusion and renal TEAEs, respectively, were increased ALT and/or AST (34.0% vs 8.3% [G3/4: 22.0% vs 2.3%]), pleural effusion (5.2% vs 1.9% [G3/4: 0.7% vs 0.4%]) and increased blood creatinine (6.7% vs 8.3% [G3/4: 0.4% vs 0.4%]). GI, liver, effusion and renal TEAEs infrequently led to Tx discontinuation (1.9%, 7.8%, 0.7% and 0.7% vs 1.1%, 0.8%, 0% and 0.4%). **Conclusions:** The safety profiles of BOS and IMA in BFORE were distinct, with no new safety signals identified after 5 yrs follow-up. Onset of TEAEs occurred primarily during yr 1 (eg, GI and liver), with an increased incidence of some TEAEs (eg, effusion and renal) in later yrs. Discontinuations due to AEs generally occurred early into Tx, with few due to GI, liver, effusion and renal AEs. These safety results support the use of first-line BOS as a standard of care in pts with CP CML. Clinical trial information: NCT02130557. Research Sponsor: Pfizer.

Cumulative rate of pts with GI, liver, effusion and renal TEAEs by yr.

	BOS n=268					IMA n=265				
%	Yr 1	2	3	4	5+	Yr 1	2	3	4	5+
GI	76.5	78.0	79.5	79.5	79.9	52.8	56.6	58.5	61.1	61.5

Treatment-free remission (TFR) in patients with chronic myeloid leukemia (CML) following the discontinuation of tyrosine kinase inhibitors. *First Author: Fadi Haddad, Department of Leukemia, University of Texas MD Anderson, Houston, TX*

Background: Tyrosine kinase inhibitors (TKIs) discontinuation in patients (pts) with CML is increasingly considered. We evaluated the outcome of pts with CML who discontinued TKIs and determined the factors associated with differences in the success rates of TFR. **Methods:** We reviewed data from 284 pts with CML treated with TKIs at our institution between October 1999 and February 2017 and who subsequently discontinued therapy. Major molecular response (MMR) was defined as a *BCR-ABL1/ABL1* transcripts ratio ≤0.1% as determined by real time (RT)-PCR, MR^4 as a ratio ≤0.01% IS, and $MR^{4.5}$ as a ratio ≤0.0032%. TFR failure was defined as the loss of MMR on any single test. We analyzed TFR rates according to duration and depth of response and conducted a multivariate analysis for factors associated with loss of MMR. **Results:** Median age was 63 years (range, 25-93). 199 pts (70%) had electively discontinued their TKI while 70 pts (24%) stopped therapy because of adverse events. 92 pts (32%) had switched ≥1 TKI prior to discontinuation due to drug intolerance or resistance. The median time from the initiation of frontline TKI to discontinuation was 117 months (range, 16-242). The median duration of MR^4 and $MR^{4.5}$ before TKI discontinuation was 74 months (range, 2-207) and 64 months (range, 0-207), respectively. At a median follow-up of 36 months (95% CI, 32-40) after TKI discontinuation, 53 pts (19%) lost MMR, translating into a 5-year TFR rate of 79%. 50 pts (94%) resumed TKI therapy and, among 47 evaluable pts, all but one pt regained MMR, with 41 pts (88%) achieving $MR^{4.5}$. The estimated 5-year TFR rates were 91%, 76% and 70% in pts achieving $MR^{4.5}$ for ≥6 years, between 5 and 6 years, and < 5 years, respectively (P < 0.0001). The estimated 5-year TFR rates were higher with MR^4 and $MR^{4.5}$ ≥5 years, compared with MR^4 < 5 years (87% vs 92% vs 64%; P < 0.0001). Pts who remained on their frontline TKI at the time of discontinuation had a 5-year TFR rate of 82%, compared with 75% and 72% among pts who switched to a second line TKI or beyond because of intolerance or resistance, respectively (P = 0.417). TFR rates did not vary according to the type of frontline TKI used (P = 0.761). By multivariate analysis, only durations in MR^4 or $MR^{4.5}$ ≥5 years before stopping treatment were associated with a lower risk of loss of MMR, with hazard ratios of 0.37 (95% CI, 0.18-0.76; P = 0.007) and 0.20 (95% CI, 0.09-0.45; P < 0.0001), respectively. We evaluated the impact of the frequency of molecular monitoring on the success rate of TFR. The estimated 5-year TFR rate was 79% for pts monitored monthly compared with 85% for pts monitored every 6-8 weeks following discontinuation (P = 0.263). **Conclusions:** Our findings suggest that achieving MR^4 for ≥5 years was associated with a very high probability of maintaining TFR, and that less frequent molecular monitoring could be more cost-effective without any negative impact on outcomes. Comparison of demographics, disease characteristics, and outcomes between African American patients and White patients with myelodysplastic syndrome: A population-based study. *First Author: Arnaud Lesegretain, Harvard Medical School, Boston, MA*

Background: Myelodysplastic syndrome (MDS) consists of a heterogeneous group of clonal myeloid neoplasms, classified as a malignancy since 2001. Previous studies have described inferior outcomes for African Americans (AA) versus Whites (W) in several solid tumors and hematological malignancies, including AML. We performed an analysis of the Survival, Epidemiology, and End Results (SEER) cancer registry to analyze baseline characteristics and various outcomes. **Methods:** Using SEER (18 Registries, 2000-2018, Nov 2020 submission), we included 37,564 patients (pts) with microscopically confirmed MDS, age > = 20, diagnosed between 2000-2013 based on ICO-03 codes. MDS sub-types were grouped into low, intermediate, and high-risk disease. We compared baseline characteristics, mortality rates per attributed cause of death (COD) and overall survival (OS). Multivariate Cox regression and Propensity Score analyses were conducted to reduce effect of confounding due to imbalance in baseline covariates. **Results:** We included 34,543 W (92%) and 3021 AA (8%) pts; There were more males (58%) among W vs AA (49%). At diagnosis the median age was 71 and 76 in AA and W subjects, respectively. Low and high risk MDS comprised 22.8% and 14.5% of cases among AA and 21.5% and 16.3% among W pts, respectively. 66.8% of AA were living in large metropolitan areas vs 60.2% for W pts. mOS was 33 months for AA and 26 months for W; HR for OS comparing W vs AA using a univariate Cox PH model was: 0. 79 (0.76- 0.82), p < 0.001. In a multivariate Cox-PH model, HR for OS after adjusting for sex, age at diagnosis, histology, urban-rural continuum, income group was: 0.90 (95%CI 0.86-0 .94), p < 0.001. HRs after stratified cox PH model and propensity score matching model for age, sex, histology and income group were 0.92 (0.88-0.96), p < 0.001 and 0.93(0.88-0.98), p = 0.01 respectively. Analysis by histology shows statistically significant association between race and OS for refractory anemia and MDS-unclassifiable while not significant for refractory anemia with ringed sideroblasts, refractory anemia with excess blasts and MDS with del(5q). Incidence rate ratio for AA vs W for death attributed to the two most frequent CODs were: MDS/Leukemia: 0.74 (0.69-0.81, p < 0.001); CVD: 1.07 (0.94-1.21, ns). **Conclusions:** In this large study of MDS cases reported to the SEER registry, we observed differences in age, sex, disease subtype, socio-economic factors, mortality rate per attributed COD, survival outcomes between AA and W. The finding of AA having better OS outcomes than W pts is unexpected and needs to be further investigated, specifically the contribution of the less well-defined low-grade risk forms of MDS. Although caution in the interpretation is necessary due to multiple limitations inherent to the SEER dataset, this data does raise intriguing questions for future study. Research Sponsor: None.

Anti–PD-1 antibody (sintilimab) plus decitabine as first-line treatment for patients with higher-risk myelodysplastic syndrome (MDS): Preliminary results from a single-arm, open-label, phase II study. *First Author: Jing Wang, Peking University People's Hospital, Peking University Institute of Hematology. National Clinical Research Center for Hematologic Disease, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China*

Background: Hypomethylating agents (HMAs) are the preferred treatment for untreated patients (pts) with higher-risk MDS, but the survival of pts after HMAs treatment is poor. It has been demonstrated that the PD-1/PD-L1 expression was upregulated by HMAs in MDS pts, providing a strong rationale for combining HMAs with PD-1 antibody for MDS treatment. Therefore, this single-arm, open-label, clinical trial was performed to evaluate safety and efficacy of Sintilimab plus decitabine for pts with higher-risk MDS (ChiCTR2100044393). **Methods:** Adult pts with higher-risk MDS by the IPSS-R were enrolled. Patients received decitabine 20mg/m^2 intravenously daily for 5 days and sintilimab 200mg IV starting on the first and 22nd day of a cycle every 42 days until unacceptable toxicity, relapse, or progression, for a maximum of 8 cycles. The primary endpoint was overall response rate (CR+PR+mCR). Simon's optimal two-stage design was employed.If five or more pts in stage I (13 pts) achieved ORR, the study would enroll 34 additional pts in stage II (47 pts). Secondary endpoints included safety, and survival outcomes. The relationship between expression levels of immune-checkpoint and efficacy of the combination therapy, as well as other potential biomarkers were also explored via genomic profiling. **Results:** At data cut-off (January 31, 2022), 21 pts were enrolled with a median follow-up time of 5.8 months. The median age of pts was 64 years (range 30-83), and the other characteristics are summarised in Table.The ORR was 62%,with six pts reaching complete response (CR),four pts reaching marrow CR and three pts achieved marrow CR+ hematologic improvement (HI). In addition,four pts reaching HI. The most common grade 3 TEAEs(> 10%) were febrile neutropenia (76.2%) and pulmonary infection (38.1%). No grade 4 TEAEs and treatment-related deaths occurred. A total of 12 pts (57.1%) experienced immune-related adverse event, including rash (28.6%), pneumonia (9.5%), hypothyroidism (9.5%), elevated serum bilirubin (4.8%) and transpeptidase (4.8%), which were all resolved by glucocorticoid. In these 21 pts, the most frequently mutated genes are ASXL1 (28.6%) , RUNX1 (14.3%) and TET2(14.3%). Updated biomarker data will be presented during the ASCO meeting. **Conclusions:** To the best of our knowledge, this is the first study to evaluate the efficacy and safety of sintilimab plus decitabine in pts with untreated higher-risk MDS. The preliminary results demonstrate that the combination therapy is relatively safe with anti-tumor activity. Clinical trial information: ChiCTR2100044393. Research Sponsor: Innovent Biologics.

Pts Characteristic		No. (%)/ Median (Range), n = 21

Ivosidenib in patients with *IDH1*-mutant relapsed/refractory myelodysplastic syndrome (R/R MDS): Updated enrollment and results of a phase 1 dose-escalation and expansion substudy. *First Author: David Andrew Sallman, Moffitt Cancer Center, Tampa, FL*

Background: Mutations in isocitrate dehydrogenase 1 (*IDH1*) occur in ~3% of patients (pts) with MDS and are associated with increased transformation to acute myeloid leukemia (AML). Ivosidenib (IVO), an oral, potent, targeted inhibitor of the mutant IDH1 (mIDH1) enzyme, is FDA approved for m*IDH1* R/R AML and m*IDH1* newly diagnosed AML in pts ≥75 years old or with comorbidities precluding the use of intensive induction chemotherapy. In the first-in-human study of IVO in pts with m*IDH1* advanced hematologic malignancies (NCT02074839), 12 pts with R/R MDS received IVO 500 mg once daily (QD). Based on encouraging safety and efficacy findings, including an investigator-assessed overall response rate (ORR) of 75%, with median response duration of 21.4 months, the FDA granted Breakthrough Therapy designation to IVO in m*IDH1* R/R MDS and the study was amended to enroll additional pts. We report updated results. **Methods:** This substudy of the single-arm, open-label study of IVO evaluated pts with R/R MDS after documented failure or relapse following prior standard therapy including intensive chemotherapy and hypomethylating agents. Other key eligibility criteria included: high disease burden based on IPSS or IPSS-R risk at baseline; an Eastern Cooperative Oncology Group performance status score of 0–2; and no prior IDH1 inhibitor therapy. Pts received IVO 500 mg QD orally on days 1–28 of 28-day cycles. **Results:** As of 08May2021, 16 pts with R/R MDS were enrolled: 5 (31%) pts remained on treatment and free from leukemic transformation; 11 (69%) had discontinued including 6 for disease progression, 1 for allogeneic stem cell transplantation, and 1 owing to an adverse event (AE) of sepsis (the only fatal AE; reported by investigator as not related to IVO). AEs are summarized in the Table. 2 pts each experienced differentiation syndrome (grade 2) and QTcF prolongation (grade 1 and 2). 7/16 pts achieved complete response (CR, 44%; 95% CI, 20%, 70%), 1 achieved partial response (6%), and 5 achieved marrow CR (31%), resulting in an ORR of 81% (95% CI, 54%, 96%). Hematologic improvement in ≥1 lineages was achieved by 11/16 (69%) pts. The Kaplan-Meier estimate of duration of CR+PR at 12 months was 60%. 3 pts experienced CRs lasting 24.0, 63.7, and 65.4 months, which remain ongoing. 5/7 pts (71%) who were transfusion dependent at baseline became independent of red blood cell or platelet transfusions for 56 or more consecutive days on treatment. Additional translational data are being analyzed. **Conclusions:** In pts with m*IDH1* R/R MDS, IVO monotherapy was tolerable and induced durable remissions and transfusion independence. These findings support the role of IVO as an effective, oral, targeted treatment for pts with m*IDH1* R/R MDS. Clinical trial information: NCT02074839. Research Sponsor: Stephanie Kapsalis.

Impact of magrolimab treatment in combination with azacitidine on red blood cells in patients with higher-risk myelodysplastic syndrome (HR-MDS). *First Author: James Yuhtyng Chen, Stanford University School of Medicine, Stanford, CA*

Background: Magrolimab is a monoclonal antibody that blocks CD47, a "don't eat me" signal expressed on cancer cells to escape immune surveillance and macrophage-mediated clearance. Prior preclinical studies have shown that CD47 is critical to RBC homeostasis, with CD47 deficiency decreasing RBC half-life. Fc-mediated opsonization also depletes RBCs, raising concerns for potential on-target anemia from anti-CD47 agents via multiple mechanisms. Notwithstanding, several clinical trials have demonstrated that magrolimab can be safely administered as a monotherapy with initial lower "priming" dose yielding transient anemia with compensatory reticulocytosis, with anemia not observed at subsequent higher maintenance doses. However, the mechanism underlying this observed protection has not been fully defined. Here we describe manageable anemia in patients (pts) with HR-MDS treated with magrolimab in combination with azacitidine (AZA) (NCT03248479) and further investigate these underlying mechanisms in preclinical models. **Methods:** In a multicenter prospective study, CBCs, peripheral blood, and bone marrow (BM) were collected at prespecified timepoints from HR-MDS pts (n = 57) treated with magrolimab in combination with AZA. CBCs were measured, and blood and BM samples were analyzed by flow cytometry for expression of CD47 on RBCs and WBCs. Magrolimab was initially dosed with a priming dose (1mg/kg) followed by an initial weekly maintenance dosing (30mg/kg) before transitioning to every 2 weeks maintenance dosing. AZA 75mg/m^2 was administered on days 1-7 of the 28-day cycle. Preclinical modeling studies were conducted with intact and Fc-deficient anti-mouse CD47 (MIAP410) and anti-human CD47 (magrolimab) antibodies in murine models, including C57BL/6J B-hSIRPA/hCD47 mice. **Results:** Combination treatment of magrolimab with AZA resulted in a tolerable anemia that correlated with rapid, near complete loss of CD47 from RBCs, but not WBCs. The initial 1mg/kg priming dose was sufficient for this CD47 loss, which persisted under subsequent 30mg/kg maintenance doses. Both findings are consistent with prior clinical observations in solid tumor pts with magrolimab monotherapy and lymphoma pts in combination with rituximab. Our preclinical studies with mouse models revealed that the CD47 removal is mechanistically independent of previously described RBC antigen modulation mechanisms and cellular compartments. Instead, this CD47 loss requires anti-CD47 crosslinking between RBCs and non-RBCs. **Conclusions:** Overall, these results support that on-target magrolimab mediated anemia is mitigated by a near complete loss of RBC CD47. HR-MDS patients treated with magrolimab in combination with AZA exhibit a tolerable anemia through priming and maintenance doses. Clinical trial information: NCT03248479. 7055 **Poster Session**

Hyperferritinemia as predictive biomarker of poor clinical outcomes in CMML. *First Author: Luis E. Aguirre, Moffitt Cancer Center, Tampa, FL*

Background: CMML is a heterogenous disease exhibiting features innate to MPN and MDS. Increasing evidence supports a close interplay between systemic inflammation and risk of myeloid malignancies, notably for those with history of infection or autoimmune disease. CMML has been associated with inflammation and end-organ damage related to CKD and CVD. Analysis of gene signatures from CMML-derived monocytes has shown them to be highly proinflammatory. High ferritin may serve as a practical biomarker of disease activity to help identify pts at higher risk of poor outcomes. **Methods:** Retrospective data was collected from a database of CMML pts treated at Moffitt Cancer Center. Pts were stratified in 2 cohorts based on ferritin levels (< 1000 or ≥1000 ng/mL). Hyperferritinemia was defined as ferritin > 1000 as seen at diagnosis or during follow-up. Kaplan–Meier was used to estimate OS. Cox regression was used for multivariate analysis. **Results:** Between August 1995 and October 2020 729 pts with CMML were identified. Median age at diagnosis was 71 (17-95). Out of 571 pts with available ferritin levels 29% (n = 168) developed hyperferritinemia vs 71% (n = 403) who did not. mOS was 32.4 mos (95%CI 30-35 mos). Pts with higher ferritin tended to present with CMML-2 (p = 0.001) and harbor a proliferative phenotype (p = 0.01). They presented with higher marrow cellularity (mean 83%, p = 0.08), PLT (mean 177k, p = 0.038), and lower Hb (mean 9.5, p < 0.05). There was no association with % circulating IMC, monocytes, WBC or ANC at baseline. Hyperferritinemia was associated with more profound fibrosis (p = 0.007), cytopenias (p < 0.05), % peripheral blasts (p < 0.05), RBC and PLT transfusion dependence (p < 0.05). Pts with hyperferritinemia had higher risk disease per IPSS-R, CPSS and all CMML models (p < 0.05); and had higher rates of AML transformation (p < 0.05). Pts were also more likely to require treatment earlier (within 3 yrs of diagnosis) (p < 0.05). ASXL1 (p = 0.002), EZH2 (p = 0.003), and SETBP1 (p = 0.019) mutations were more common among pts with hyperferritinemia. Conversely, TET2 (p = 0.001), CBL (p = 0.028) and SRSF2 (p = 0.003) mutations were less common. mOS for pts with hyperferritinemia was 23.9 mos (95%CI 19.9-27.9 mos), much lower than for those with ferritin < 1000 (mOS 40.5 mos, 95%CI 35.4-45.5 mos) (p < 0.05). In multivariate analysis, hyperferritinemia was a significant independent covariate for OS after adjusting for CPSS, transfusion dependence and disease phenotype (dysplastic vs proliferative) (HR = 0.69; 95%CI 0.53-0.89; p = 0.005). **Conclusions:** Almost 1/3 of pts with CMML will develop hyperferritinemia. This is associated with more aggressive disease and higher rates of AML transformation leading to dismal outcomes. ASXL1, EZH2, and SETBP1 MTs confer a higher risk of hyperferritinemia. Our findings indicate that hyperferritinemia is an independent prognostic biomarker that may serve as a surrogate representative of disease biology and comorbidities in CMML. Research Sponsor: None.

7056 **Poster Session**

Long-term utilization and benefit of luspatercept in patients (pts) with lower-risk myelodysplastic syndromes (LR-MDS) from the MEDALIST trial. *First Author: Pierre Fenaux, Service d'Hématologie Séniors, Hôpital Saint-Louis, Assistance Publique-Hôpitaux de Paris and Université Paris 7, Paris, France*

Background: Luspatercept was previously shown to improve anemia in the phase 3 MEDALIST trial of pts with LR-MDS ineligible, intolerant, or refractory to erythropoiesis-stimulating agents (ESAs). Here, we report the long-term clinical value of luspatercept treatment (Tx) in pts from the MEDALIST study including dosing and rates of progression to acute myeloid leukemia (AML) and high-risk MDS (HR-MDS). **Methods:** Eligible pts were ≥ 18 y of age, had LR-MDS requiring regular red blood cell (RBC) transfusions, and were ineligible/intolerant or refractory to ESAs. Pts were randomized 2:1 to subcutaneous luspatercept or placebo every 3 wk for 24 wk. The primary endpoint was RBC transfusion independence (RBC-TI) ≥ 8 wk during wk 1–24. MEDALIST pts were eligible for enrollment into the long-term follow-up study. Median duration of Tx and cumulative duration of response were determined by Kaplan–Meier (KM) analysis. Total person-years for pts at risk of HR-MDS/AML progression was calculated from LR-MDS diagnosis to HR-MDS/AML diagnosis, or to last HR-MDS/AML follow-up date for pts who did not progress. **Results:** As of January 15, 2021, the median duration of Tx was 11.70 (95% CI, 8.97–16.33) mo for luspatercept pts and 5.52 (95% CI, 5.52–5.59) mo for placebo pts. Of those enrolled in MEDALIST, 106/153 (69.3%) pts receiving luspatercept and 64/76 (84.2%) receiving placebo escalated to the maximum dose of 1.75 mg/kg. During the entire Tx phase, RBC-TI ≥ 8 wk was observed in 74/153 (48.4%) and 12/76 (15.8%) pts in the luspatercept and placebo arms, respectively, with a median cumulative duration of response of 80.7 (95% CI, 53.71–154.14) wk and 21.0 (95% CI, 10.86–NE) wk, respectively. During the entire Tx period, RBC-TI ≥ 16 wk was observed in 48/153 (31.4%) and 6/76 (7.9%) pts in the luspatercept and placebo arms, respectively (Table). Among pts randomized to luspatercept, 13/153 (8.5%) progressed to HR-MDS/AML during the entire Tx period, compared with 5/76 (6.6%) for placebo. The total person-years for pts randomized to luspatercept at risk of progressing to HR-MDS/AML was 401.7 y vs 190.9 y for placebo. **Conclusions:** Pts receiving luspatercept had an extended period of clinical benefit and > 50% of pts continued to receive luspatercept for > 1 y, the majority of whom underwent dose escalations to achieve an optimal response. Pts experienced durable responses with luspatercept, with a median cumulative duration of RBC-TI response of approximately 20 mo. Pts receiving luspatercept also appeared to have a longer time to HR-MDS/AML progression than those receiving placebo. Research Sponsor: None.

Achievement of RBC-TI ≥ 16 wk.

	Luspatercept (N = 153)	Placebo (N = 76)
Number of pts who achieved RBC-TI ≥ 16 wk, n (%)	48 (31.4)	6 (7.9)
95% CI	24.12–39.39	2.95–16.40

Therapy related myeloid neoplasms (t-MNs) following PARP inhibitors (PARPi): Real-life experience. *First Author: Vincent Marmouset, Gustave Roussy, Villejuif, France*

Background: PARPi have shown promising results in several cancers, especially breast (BC) and ovarian cancer (OC), but may be associated with an increased risk of t-MNs. A careful monitoring of hematologic toxicity to exclude this risk is necessary. Here we described, in a real-life setting, the management of these adverse effect. **Methods:** First,we described, in a large cancer center, the profile of t-MN patients among OC patients treated with PARPi addressed in hematological consultation for cytopenias. Secondly, we compared t-MN post OC characteristics according to previous exposition to PARPi. Lastly, we described a large national observatory of 69 t-MNs post PARPi to decipher specific characteristics of these t-MNs. **Results:** From 2016 to 2021, among 373 PARPi treated patients for OC, 37 (10%) were explored for cytopenia's leading to 13 (3,5%) t-MNs diagnosis. No differences were seen in terms of age, BRCA1/2 status, type of PARPi, hemoglobin level but patients with t-MNs developed delayed cytopenias post-PARPi initiation (11 months vs to 4 months, p = 0.01), had a longer PARPi exposition (9 months vs 3 months, p = 0.01), lower platelets level (74 G/L vs 173 G/L, p = 0.0005), more cytopenias (2 vs 1, p = 0.0005). 77% of t-MNs patients had a *TP53* mutated t-MNs, 33% of patients w/o t-MNs had *TP53* mutated clonal hematopoiesis. In the last 20 years, 37 patients were addressed for t-MN post OC at our institute, with an increased incidence of 50% during the last 6 years. Compared to t-MN not exposed to PARPi, t-MN-PARPi patients had more *BRCA1/2* predisposition (61.5% vs 0% p = 0.03), their OC tended to be non-progressive (CR/PR/SD = 62.5% vs 38.5%, p = 0.3) and tend to have more *TP53* mutated t-MNs (77% vs 47%, p = 0.1). Median OS for t-MNs post PARPi was poor at 8.2 months (CI95% [2.03-18.7]) but not significantly different form other t-MNs (p = 0.8). We then studied 69 t-MNs-PARPi including 28 AML and 41 MDS in patient with history of OC (75%), BC (9%) or both (16%). Median age was 64 years, 80% received Olaparib, 72.5% had a *BRCA1/2* predisposition. Median time between cancer diagnosis and initiation of PARPi was 44 months and median duration of PARPi treatment was 14 months. History of haematological toxicity secondary to PARPi was reported in 51% of patients. Karyotype was often complex (61%) associated with a high rate of *TP53* mutation (70.5%). Median OS was 9.7 months (CI95%, 5.3-13.9). In multivariate analysis, a longer delay between the end of PARPi treatment and t-NM diagnosis (HR 1.046, p = 0.02), as well Olaparib treatment compared to others PARPi (HR 5.82, p = 0.003 and AML diagnosis (HR 2.485, p = 0.01) were associated with shorter OS. **Conclusions:** We describe in a large series a higher incidence of t-MNs post PARPi than previously reported. Unfavorable cytogenetic and molecular abnormalities associated with these t-MNS explained the poor OS. Early detection is crucial particularly in case of delayed appearance of cytopenias. Risk-adjusted safety analysis of pacritinib (PAC) in patients (pts) with myelofibrosis (MF). *First Author: Naveen Pemmaraju, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: PAC is a novel JAK2/IRAK1 inhibitor that has shown significant activity in pts with MF, including those with platelet (plt) counts $<50\times10^9$/L. Recently, JAK inhibitors have come under increased scrutiny due to specific, emerging toxicities with drugs in this class. This safety analysis focuses on these toxicities of interest for pts treated with PAC 200 mg BID and best available therapy (BAT), including ruxolitinib (RUX), on the Phase 3 PERSIST-2 and Phase 2 PAC203 studies. Data are presented as risk-adjusted incidences to account for differential time at risk for adverse events (AEs) between arms due to cross-over. **Methods:** Pts treated with PAC 200 mg BID on PERSIST-2 and PAC203, and those treated with BAT on PERSIST-2, were included. Risk-adjusted AEs, representing event rate per 100 patient-years (pt-yrs), were calculated for overall and fatal AEs, bleeding AEs (determined by Standardized Medical Dictionary for Regulatory Activities Query [SMQ]), cardiac AEs (by SMQ), major cardiac events (per major adverse cardiovascular events [MACE] classification), infections, thromboses, and secondary malignancies. **Results:** A total of 160 pts were analyzed as the pooled PAC group (n=106 in PERSIST-2; n=54 in PAC203) and 98 pts in the BAT group (44 on RUX). At baseline, median plt count was 57×10^9/L; 61% had prior JAK2 inhibitor therapy. The rate of AEs was higher on PAC versus BAT, while the rate of fatal AEs was lower (Table). Both bleeding and cardiac events occurred at slightly lower rates on PAC compared to BAT. There were no MACE events on PAC, whereas there were on BAT. Malignant neoplasms occurred at similar rates on PAC and BAT, though rate of non-melanoma skin cancers was lower in pooled PAC (3/100 pt-yrs) versus BAT (7/100 pt-yrs), including RUX (11/100 pt-yrs). Infection occurred more frequently on PAC, though fungal and viral infections occurred less frequently, as did herpes zoster reactivation (pooled PAC: 0/100 pt-yrs vs BAT: 2.4/100 pt-yrs, including RUX: 5.5/100 pt-yrs). Thrombosis occurred at similar rates on PAC and BAT. **Conclusions:** Risk-adjusted analysis demonstrates that the safety profile of PAC 200 mg BID is comparable or superior to BAT, including RUX. PAC 200 mg BID may represent a full-dose therapeutic option for pts with MF, including those with thrombocytopenia. Clinical trial information: NCT02055781; NCT04884191. Research Sponsor: CTI BioPharma.

Risk-adjusted treatment-emergent AEs (TEAEs) in PERSIST-2 and PAC203.

	PERSIST-2			PAC203	Pooled
≥1 TEAE (/100 pt-yrs)	PAC N=106	BAT N=98	BAT=RUX N=44	PAC N=54	PAC N=160

Evaluation of serum vascular endothelial growth factor as a biomarker in Erdheim-Chester disease. *First Author: Anais Roeser, Service de Médecine Interne 2, Hôpital Pitié Salpètrière, Assistance Publique Hôpitaux de Paris (AP-HP), Paris, France*

Background: Erdheim-Chester disease (ECD) is a rare histiocytosis characterized by tissue infiltration of $CD68^+$, $CD1a^-$ histiocytes, derived from cells of the mononuclear phagocyte system harboring recurrent mutations in the MAPK-signaling pathway. Vascular endothelial growth factor-A, also referred as VEGF, is a major regulator of angiogenesis, implicated in cancer pathophysiology. Mutation of the RAS oncogene induce the upregulation of VEGF gene expression. We hypothesized that VEGF could play a role in ECD pathophysiology. We aimed to determine if VEGF was expressed by ECD histiocytes, to assess levels of serum VEGF (sVEGF) in ECD patients, and determine if they were associated with patient's characteristics. **Methods:** We conducted a retrospective study, screening all ECD patients seen in the French National Reference Center for Histiocytoses (Pitié-Salpètrière Hospital) from 2009 to 2019. Patients were included if they had at least one sVEGF determination. Biopsies of patients with extreme sVEGF were centrally reviewed and an immunostaining for VEGF was practiced using 2 different antibodies (F/PU483-UP and VG-1). **Results:** We included 248 patients in the analysis. sVEGF were high (> 500pg/mL) at first determination in 123 patients (53%), and > 1000 pg/mL in 47 (19%). Median sVEGF was 843pg/mL in the high sVEGF group, 288pg/mL in the low sVEGF group. Sex, age, and *BRAF* status were not significantly different between the 2 groups. We analyzed 24 histological samples. Histiocytes had a VEGF staining in all samples analyzed, moderate (grade 2) in 5 and 1 cases and intense (grade 3) in 17 and 22 cases based on F/PU483-UP and VG-1 clone respectively. Control (4 biopsies of reactional sinusal histiocytoses) showed no histiocytic VEGF staining. Patients with high sVEGF had more frequently a vascular involvement (71% vs 48%, p = 0.0004) and a cardiac involvement (58% vs 41%, p = 0.008). Consecutive measurements of sVEGF were available for 183 patients (median interval: 24 months). sVEGF significantly decreased during follow-up (p < 0.0001). Consecutive cardiac MRI were available for 45 patients (median interval: 48 months). All patients had cardiac involvement: 6 achieved complete response, 25 partial response, 12 were stable, and 2 progressed. Mean variation of sVEGF (ΔsVEGF) of patients with complete response, partial response and stable disease were respectively - 591.3, -163.9, - 239.6 pg/mL and were significantly different from patients who progressed (mean ΔsVEGF + 555.5pg/mL). No patients in our cohort received a systemic anti-VEGF therapy for ECD or another indication. **Conclusions:** In our study, sVEGF was high in 53% of ECD patients, and its elevation associated with cardiac and vascular involvements. Variations of sVEGF were associated with responses of cardiac involvement under therapy. VEGF was at least partly produced by ECD histiocytes. sVEGF could help monitor cardiac involvement activity. Research Sponsor: None.

A phase 1, open-label, dose-escalation study of selinexor plus ruxolitinib in patients with treatment-naïve myelofibrosis.

First Author: Haris Ali, City of Hope, Duarte, CA

Background: Myelofibrosis (MF) is a myeloproliferative neoplasm characterized by unregulated, clonal proliferation of a hematopoietic stem cells in the bone marrow and is commonly associated with gene mutations in *JAK2, CALR*, or *MPL*. Front-line therapy may include the JAK1/2 inhibitor ruxolitinib (RUX), resulting in spleen volume reductions and improvement in MF-related symptoms. Despite the therapeutic effect of RUX, most patients (pts) eventually progress and thus novel combinations are required to increase responses and delay progression. Selinexor (SEL) is an oral selective inhibitor of nuclear export (SINE) compound, specifically inhibiting exportin-1 (XPO1), and currently approved for treatment of multiple myeloma and diffuse large B-cell lymphoma. Significant activity of SEL in combination with RUX has been shown in preclinical studies, and SEL monotherapy in MF refractory to JAK inhibitors demonstrated robust clinical activity and a tolerable safety profile (NCT03627403). Here, we present the initial results of a phase 1 dose escalation study of the combination SEL and RUX in treatment-naïve MF. **Methods:** The ongoing multicenter, open-label, Phase 1/2 study (NCT04562389) is evaluating the efficacy and safety of SEL plus RUX in JAKi-naïve MF pts. Two dose levels of SEL were evaluated, 40mg and 60mg once-weekly (QW) plus RUX twice daily (BID) as per label in 28-day cycles, using a 3+3 design. All pts received 5-HT3 antagonist for nausea prophylaxis. Primary objectives include safety, maximum tolerated dose (MTD), recommended Phase 2 dose (RP2D), and preliminary efficacy. Secondary objectives include spleen, symptom, and anemia response, and OS. **Results:** As of 31 Jan 2022, 10 pts have been dosed in 2 dose levels (40mg (n = 3), and 60mg (n = 7) SEL QW plus RUX). RUX starting dose was 20 mg in 8 pts, 15 mg in one patient and 10 mg in one patient. The median age was 64 (range 45-76). Seven pts had primary MF and 3 had post-ET MF. DIPSS risk category was int-1 (n = 4), int-2 (n = 4) and high risk (n = 2). No dose limiting toxicities have been reported at either dose levels of SEL. One patient required dose interruption due to dizziness and later discontinued treatment due to new onset of atrial fibrillation and pulmonary hypertension (unrelated to SEL and RUX) after 5 months of therapy. All other pts remain on study. There was no grade 3 neutropenia or thrombocytopenia observed. Hemoglobin level was maintained without any significant worsening. The most common treatment-emergent adverse event was low grade nausea (30%). All pts experienced improvement in their white blood cell count. Four of the first 5 evaluable pts demonstrated ≥35% spleen volume reduction at week 12. **Conclusions:** The combination of SEL and RUX has been well-tolerated and with a manageable side effect profile. No dose limiting toxicities were observed in pts with treatment-naïve MF in cohort 1 of once weekly oral SEL 40 and 60 mg with RUX. Clinical trial information: NCT04562389. Research Sponsor: Karyopharm Therapeutics.

7061 **Poster Session**

Thrombocytopenic myelofibrosis (MF) patients previously treated with a JAK inhibitor in a phase 3 randomized study of momelotinib (MMB) versus danazol (DAN) [MOMENTUM].

First Author: Aaron Thomas Gerds, Cleveland Clinic Taussig Cancer Institute and Case Comprehensive Cancer Center, Cleveland, OH

Background: MMB, an oral JAK1/2 and ACVR1/ALK2 inhibitor, showed clinical activity on MF symptoms, RBC transfusion requirements (anemia), and spleen volume in the SIMPLIFY trials, including in MF patients (pts) with thrombocytopenia. MOMENTUM is a pivotal phase 3 study of symptomatic and anemic MF pts previously treated with a JAK inhibitor (JAKi) testing MMB vs DAN. This analysis evaluated MOMENTUM pts with baseline (BL) platelet counts (PLT) ≤150 x 10^9/L. **Methods:** Eligibility: Primary or post-ET/PV MF; DIPSS high risk, Int-2, or Int-1; MF Symptom Assessment Form Total Symptom Score (MFSAF TSS) ≥10; Hgb <10 g/dL; prior JAKi for ≥90 days, or ≥28 days if RBC transfusions ≥4 units in 8 weeks (wks) or Gr 3/4 thrombocytopenia, anemia, or hematoma; palpable spleen ≥5 cm; PLT ≥25 x 10^9/L. JAKi taper and washout was ≥21 days. Randomization: 2:1 to MMB 200 mg QD plus DAN placebo or DAN 600 mg QD plus MMB placebo for 24 wks. Primary endpoint: TSS response (≥50% reduction from BL) rate at wk 24. Key secondary endpoints, assessed sequentially at wk 24: RBC transfusion independence (TI) rate, splenic response rate (SRR; ≥25% reduction in volume from BL), change from BL in TSS, SRR (≥35% reduction from BL) and rate of zero transfusions since BL. **Results:** 60 (74%) of 81 MMB pts and 25 (58%) of 43 DAN pts with BL PLT ≤150 x 10^9/L completed the 24-week randomized treatment (RT) phase. Median BL TSS were 29 (MMB) and 24 (DAN), Hgb were 7.9 (MMB) and 8.0 (DAN) g/dL, and PLT were 67 x 10^9/L (MMB) and 64 x 10^9/L (DAN). Prior JAKi was ruxolitinib in 124 pts (100%) and fedratinib in 6 pts (5%). Efficacy results are in Table. These results are consistent with the overall ITT analysis set (N=195). Most common Gr ≥3 TEAEs in the RT phase were thrombocytopenia (MMB, 31%; DAN, 16%) and anemia (MMB, 7%; DAN, 14%); Gr ≥3 bleeding events occurred in 9% of MMB and 5% of DAN pts. TEAEs led to study drug discontinuation in 15% of MMB and 19% of DAN pts in RT phase. A trend toward improved OS up to wk 24 was seen with MMB vs DAN [HR (95% CI)=0.490 (0.195, 1.235)]. Additional analyses of pts with BL PLT <100 x 10^9/L (N=100) and BL PLT <50 x 10^9/L (N=31) show similar treatment effects of MMB vs DAN. **Conclusions:** In thrombocytopenic MF pts who were symptomatic and anemic, MMB was superior to DAN for symptom responses, transfusion requirements, and spleen responses and showed comparable safety and favorable survival. MMB may address a critical unmet need in thrombocytopenic MF pts. Clinical trial information: NCT04173494. Research Sponsor: Sierra Oncology, Inc.

Wk 24 Endpoint in Subjects with PLT ≤150x10^9/L	MMB (N=81)	DAN (N=43)	Difference (95% CI)

Lisocabtagene maraleucel (liso-cel) as second-line (2L) therapy for R/R large B-cell lymphoma (LBCL) in patients (pt) not intended for hematopoietic stem cell transplantation (HSCT): Primary analysis from the phase 2 PILOT study.

First Author: Alison Sehgal, University of Pittsburgh Medical Center, Hillman Cancer Center, Pittsburgh, PA

Background: Pts with R/R LBCL after first-line (1L) treatment (tx) who are unable to undergo high-dose chemotherapy (HDCT) and HSCT have poor outcomes and limited tx options. PILOT (NCT03483103) evaluated liso-cel, an autologous, CD19-directed chimeric antigen receptor (CAR) T cell product, as 2L tx in pts with R/R LBCL not intended for HSCT. **Methods:** Eligible pts were adults with R/R LBCL after 1L tx who were not deemed candidates for HDCT and HSCT by their physician and met ≥ 1 frailty criteria: age ≥ 70 yr, ECOG PS = 2, DLCO ≤ 60%, LVEF < 50%, CrCl < 60 mL/min, or ALT/AST > 2 × ULN. Bridging tx was allowed. Pts received lymphodepletion with cyclophosphamide and fludarabine, followed 2–7 days later by liso-cel at a target dose of 100 × 10^6 CAR^+ T cells. Cytokine release syndrome (CRS) was graded per Lee 2014 criteria and neurological events (NE) per NCI CTCAE, version 4.03. Primary endpoint was ORR per independent review committee (IRC); all pts had ≥ 6 mo follow-up (f/u) from first response. **Results:** Of 74 pts leukapheresed, 61 received liso-cel and 1 received nonconforming product. Common reasons for pre-infusion dropout included death and loss of eligibility (5 each). For liso-cel–treated pts, median age was 74 yr (range, 53–84; 79% ≥ 70 yr) and 69%, 26%, and 5% met 1, 2, and 3 frailty criteria, respectively; 26% had ECOG PS = 2 and 44% had HCT-CI score ≥ 3. After 1L tx, 54% were chemotherapy refractory, 21% relapsed ≤ 12 mo, and 25% relapsed > 12 mo; 51% of pts received bridging chemotherapy. Median (range) on-study f/u was 12.3 mo (1.2–26.5). ORR and CR rate was 80% and 54%, respectively. Median DOR and PFS was 12.1 mo and 9.0 mo, respectively. Median OS has not been reached (Table). Most frequent tx-emergent AEs (TEAE) were neutropenia (51%), fatigue (39%), and CRS (38%), with grade (gr) 3 CRS in 1 pt (2%) and no gr 4/5 CRS. Any-grade NEs were seen in 31%, gr 3 in 5% (n = 3), and no gr 4/5 NEs; 7% received tocilizumab, 3% corticosteroids, and 20% both for tx of CRS/NEs. Overall, gr ≥ 3 TEAEs occurred in 79%, with gr 5 in 2 pts (both due to COVID-19). Two pts (3%) had gr 3/4 infections and 15 (25%) had gr ≥3 neutropenia at Day 29. **Conclusions:** In the PILOT study, liso-cel as 2L tx in pts with LBCL who met ≥ 1 frailty criteria and for whom HSCT was not intended demonstrated substantial and durable overall and complete responses, with no new safety concerns. Clinical trial information: NCT03483103. Research Sponsor: Bristol Myers Squibb.

TPS7063 **Poster Session**

An open-label, multicenter, phase 1b/2 study of navtemadlin (KRT-232) in patients with relapsed/refractory acute myeloid leukemia secondary to myeloproliferative neoplasms.

First Author: Raajit Rampal, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Patients with relapsed/refractory (R/R) acute myeloid leukemia (AML) secondary to myeloproliferative neoplasms (MPN) have limited treatment options, resulting in poor prognosis with median overall survival < 6 months (Dunbar 2020). Although conventional AML therapy can induce responses in a subset of patients, it does not prolong survival in AML secondary to MPN (Khan 2017). Navtemadlin is a potent, selective, orally available murine double minute 2 (MDM2) inhibitor that restores p53 activity to drive apoptosis in *TP53* wild-type (*TP53*^{WT}) malignancies. MDM2 is frequently overexpressed in AML with the majority being *TP53*^{WT}, suggesting that MDM2 inhibition may be a rational approach for the treatment of AML secondary to MPN (Rampal 2014; Carvajal 2018). Preclinically, navtemadlin had dose-dependent activity reducing leukemic cell burden and significantly prolonging survival in a murine MPN-blast phase, patient-derived xenograft model (Wang 2021). Evidence of clinical activity of navtemadlin monotherapy in R/R AML was observed among *TP53*^{WT} patients in a Phase 1b dose-escalation study (Erba 2019). In a Phase 2 study of intermediate-high risk R/R myelofibrosis patients, navtemadlin demonstrated clinical activity that correlated with disease-modifying effects (Al-Ali 2020; Vachhani 2021). Together, these studies provide biological and clinical support for evaluating navtemadlin in patients with R/R AML secondary to MPN. **Methods:** The open-label, multicenter Phase 1b/2 KRT-232-104 study (NCT04113616) is evaluating *TP53*^{WT} patients with R/R AML secondary to MPN (myelofibrosis, polycythemia vera, or essential thrombocythemia). Eligible patients are aged ≥18 years with ECOG performance status of 0-2 and adequate hepatic and renal function. Patients must have received ≥1 prior lines of therapy for AML secondary to MPN; prior treatment with a FLT3 or IDH1/IDH2 inhibitor is required if appropriate and available. Patients who have undergone allogeneic or autologous stem cell transplantation within 3 months or have active graft-versus-host disease prior to first study dose will be excluded. Patients (n = 12/arm) will be randomly assigned to receive oral navtemadlin once daily in Arm 1: 360 mg 7 days (D) on/21D off, Arm 2: 360 mg 7D on/21D off in Cycle 1 followed by 240 mg 7D on/21D off in subsequent cycles, or Arm 3: 180 mg 7D on/14D off until disease progression or unacceptable toxicity. The primary endpoint is Recommended Phase 2 Dose of navtemadlin. Secondary endpoints include rates of complete remission (CR; per modified 2017 European LeukemiaNet response criteria), CR with partial hematologic improvement, CR with incomplete hematologic recovery, overall response rate, duration of response, progression-free survival, overall survival, and safety. This trial is ongoing and will enroll patients at 65 global sites. Clinical trial information: NCT04113616. Research Sponsor: Kartos Therapeutics, Inc.

TPS7064 **Poster Session**

COVALENT-101: A phase 1 study of BMF-219, a novel oral irreversible menin inhibitor, in patients with relapsed/refractory (R/R) acute leukemia (AL), diffuse large B-cell lymphoma (DLBCL), and multiple myeloma (MM).

First Author: Farhad Ravandi, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Menin, a protein involved in transcriptional regulation, impacting cell cycle control, apoptosis, and DNA damage repair, plays a direct role in oncogenic signaling in multiple cancers. Inhibition of menin is therefore a novel approach to cancer treatment. Preclinical data of BMF-219, a highly selective, orally bioavailable, small-molecule irreversible inhibitor of menin, show sustained potent abrogation of menin-dependent oncogenic signaling in vitro and in vivo. BMF-219 exhibited a strong anti-proliferative effect on various menin-dependent acute myeloid leukemia (AML) cell lines, DLBCL lines representing Double/Triple Hit Lymphoma (DHL/THL) and Double Expressor Lymphoma (DEL), and MM cell lines with diverse mutational backgrounds. BMF-219 also showed high potency *ex vivo* in patient samples from MLL-rearranged and NPM1-mutant AML, THL and MYC-amplified DLBCL, and bone marrow mononuclear cells from treatment-naive and R/R MM. **Methods:** COVALENT-101 (NCT05153330) is an open-label, multi-cohort, non-randomized, multicenter Phase I study evaluating the safety, tolerability, and clinical activity of escalating doses of once daily oral BMF-219 in patients with R/R AL, DLBCL and MM who have received standard therapy. Utilizing an accelerated titration design, doses of BMF-219 will be escalated in single-subject cohorts independently for each indication until 1 subject experiences either a ≥ Grade 2 related-adverse event or dose limiting toxicity (DLT). At that point, the cohort will switch to a classical "3 + 3" design. Treatment will continue in 28-day cycles until progression or intolerability. Expansion cohorts for each indication will enroll patients to obtain further safety and efficacy data. Patients with R/R AL, R/R DLBCL ≥ 2 but ≤ 5 therapies, and R/R MM who received ≥ 3 therapies and failed or are ineligible for any standard therapies are eligible. Patients must have ECOG PS ≤ 2, and adequate organ function. Key exclusion criteria include known CNS disease involvement, prior menin inhibitor therapy, and clinically significant cardiovascular disease. The primary objective is to determine independently for each cohort/indication the optimal biological dose (OBD)/ recommended Phase 2 dose (RP2D) of BMF-219 oral monotherapy. Key secondary objectives include further evaluation of safety and tolerability, characterization of the pharmacodynamics and pharmacokinetics of BMF-219, and assessment of its antitumor activity based on best overall response rate (ORR), duration of response (DOR), progression-free survival (PFS), and time to progression (TTP) per disease-specific response criteria as assessed by the investigator. Food-effect studies will be performed in DLBCL and MM patients at certain dose levels. The enrollment commenced in January 2022. Clinical trial information: NCT05153330. Research Sponsor: Biomea Fusion, Inc.

TPS7065 **Poster Session**

Tamibarotene in combination with venetoclax and azacitidine in previously untreated adult patients selected for RARA-positive AML who are ineligible for standard induction therapy (SELECT AML-1).

First Author: Eytan Stein, Department of Medicine, Leukemia Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: RARA-positive (RARA+) AML is a novel genomically defined patient subset with an actionable biological target for treatment with tamibarotene, an oral and selective RARα agonist (McKeown 2017). RARA+ patients can be selected by a blood-based biomarker test, with approximately 30% of newly diagnosed (ND) AML patients being RARA+ (Vigil 2017). As a biologically targeted agent for patients with *RARA* overexpression, tamibarotene has the potential to provide benefit irrespective of mutation or cytogenetic risk classification. In RARA+ ND AML patients ineligible for standard induction therapy, tamibarotene plus azacitidine (aza) led to a CR/CRi rate of 61% and a rapid onset of response (de Botton 2020). Approximately one-third of patients with ND unfit AML do not respond to front-line standard of care venetoclax (ven)/aza (DiNardo 2020). Translational data suggest RARA positivity enriches for monocytic features reported to be associated with ven resistance (Fiore 2020, Pei 2020). This data suggests the RARA biomarker selects for patients who may respond to tamibarotene and may be less likely to respond to ven/aza. Given that tamibarotene plus aza has been generally well tolerated, with no increase in myelosuppression compared to single agent aza (de Botton 2020), it is anticipated that tamibarotene can be administered safely in combination with ven/aza. **Methods:** This is a Phase 2, open-label, multi-center study in the U.S. and France comparing the clinical activity of tamibarotene/ven/aza to ven/aza in treatment-naive RARA+ AML patients ineligible for standard induction chemotherapy. The primary objectives are to characterize the safety of the combination and to compare the CR/CRi rate of tamibarotene/ven/aza vs. ven/aza, with secondary objectives to compare CR rate, CR/CRh rate, duration of response, and time to response. The overall response rate using tamibarotene/ven/aza following ven/aza treatment failure will be explored. Clinical activity will be characterized by ELN criteria (Dohner 2017). This 3-part trial includes a safety lead-in, randomized efficacy study, and salvage arm. Following the safety lead-in, approximately 80 patients will be randomized 1:1 to receive tamibarotene/ven/aza or ven/aza. Response rates and 95% exact binomial confidence intervals will be calculated by treatment group. In the salvage arm, tamibarotene will be added for study patients randomized to ven/aza who experience progressive disease, relapse, or treatment failure. Patients will be treated with aza at 75 mg/m^2 IV/SC daily on days 1-7, ven on days 1-28 per VENCLEXA USPI, followed by tamibarotene at 6 mg twice per day by mouth on days 8-28 of each 28-day cycle. The SELECT AML-1 trial opened in July 2021 with ongoing enrollment. Clinical trial information: NCT04905407. Research Sponsor: Syros Pharmaceuticals.

TPS7066 **Poster Session**

Phase 1/2, open-label, dose-escalation, dose-expansion study of menin inhibitor DSP-5336 in adult patients with acute leukemia with and without mixed-lineage leukemia (*MLL*)-rearrangement (r) or nucleophosmin 1 (*NPM1*) mutation (m).

First Author: Naval Guastad Daver, Department of Leukemia, MD Anderson Cancer Center, Houston, TX

Background: DSP-5336, a menin *MLL* interaction inhibitor, elicited antitumor activity in *MLL*–r or *NPM1m* acute leukemia models *in vitro* and *in vivo*. An open-label, single-arm, phase 1/2 study (NCT04988555) will evaluate the safety and efficacy of DSP-5336 and determine the recommended phase 2 dose (RP2D) in patients with relapsed/refractory (R/R) acute myeloid leukemia (AML) or acute lymphocytic leukemia (ALL). **Methods:** Patients aged ≥18 y with R/R AML, ALL, or acute leukemia of ambiguous lineage after ≥1 line of standard therapy, ECOG PS 0–2, and adequate organ function are eligible. Patients will receive DSP-5336 twice daily for 28 d/cycle. In phase 1, there will be two parallel escalation cohorts: patients who do not receive concomitant azole antifungal medication and patients who receive antifungal azoles (ie, posaconazole, voriconazole, or fluconazole); 21–30 patients will be enrolled during phase 1 into multiple ascending dose levels. Dose escalation will use a Bayesian logistic regression model. Phase 2 will enroll two arms: R/R AML with *MLL*–r and R/R AML with *NPM1m* (10–20 patients/arm). Patients will be treated at the RP2D to evaluate clinical activity and safety. Clinical trial information: NCT04988555. Research Sponsor: Sumitomo Dainippon Pharma Oncology, Inc.

Study endpoints.

Endpoints	Phase 1 (R/R AML or ALL)	Phase 2 (R/R AML with *MLL*–r and/or *NPM1m*)
Primary	Safety DLTs; TEAEs, SAEs; changes in vital signs, PEs, clinical lab values, ECG & ECHO parameters Tolerability Dose interruptions, reductions, and/or discontinuations Biologic efficacy	Clinical Responses CR (MRD–), CR, CRh, CRi, PR, MLFS, CR + CRh, OR (=CR [MRD–] + CR + CRh + CRi + MLFS + PR), DOR, TTR, time to CR, TI, OS, EFS, RFS
Secondary	Pharmacokinetics Plasma DSP-5336 concentration-time profiles and PK parameters Clinical Responses CR (MRD–), CR, CRh, CRi, PR, MLFS, OR (=CR [MRD–] + CR + CRh + CRi + MLFS + PR), time to CR, DOR, TTR, TI, OS, RFS, EFS Cardiac Safety QT interval changes and morphology	Safety DLTs; TEAEs, SAEs; changes in vital signs, PEs, clinical lab values, ECG parameters Tolerability Dose interruptions, reductions, and/or discontinuations
Exploratory	Pharmacodynamics Changes in expression levels of leukemogenesis and myeloid differentiation genes	

Definitions: AE, adverse event; CR, complete response; CRh, complete remission with partial hematologic recovery; CRi, complete remission with incomplete hematologic recovery; DLT, dose-limiting toxicity; DOR, duration of response; ECG, electrocardiogram; ECHO, echocardiogram; EFS, event-free survival; MLFS, morphologic leukemia-free state; MRD, minimal residual disease; OR, objective response; PE, physical examination; PR, partial response; RFS, relapse-free survival; SAE, serious AE; TEAE, treatment-emergent AE; TI, transfusion independence; TTR, time to response.

Lemzoparlimab (lemzo) with venetoclax (ven) and/or azacitidine (aza) in patients (pts) with acute myeloid leukemia (AML) or myelodysplastic syndromes (MDS): A phase 1b dose escalation study.

First Author: Naval Guastad Daver, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Despite treatment advances, pts with AML or higher-risk MDS who are ineligible for standard intensive treatments still have poor survival, highlighting the need for novel therapies. Overexpression of CD47 is common in leukemic stem cells and AML blasts and correlates with poor clinical outcomes. Lemzo is an anti-CD47 antibody with red blood cell–sparing properties. Treatment with ven plus aza has shown favorable safety and efficacy in older/unfit pts with AML and higher-risk MDS. Blocking CD47 is hypothesized to hypersensitize AML cells to the antitumor activity of ven and aza. This study will evaluate the safety and dose-limiting toxicities (DLTs) of lemzo with ven + aza for pts with treatment-naïve AML, as well as lemzo with aza ± ven for treatment-naïve higher-risk MDS. **Methods:** This phase 1b, open-label, dose-escalation study (NCT04912063) is enrolling adults with: (1) treatment-naïve AML with adverse cytogenetic/molecular risk not suitable for induction therapy, with an Eastern Cooperative Oncology Group Performance Status (ECOG-PS) 0–2 (aged ≥75 years) or 0–3 (aged ≥18–74 years) excluding acute promyelocytic leukemia; or (2) treatment-naïve higher-risk MDS (Revised International Prognostic Scoring Score > 3) with < 20% bone marrow blasts, ECOG-PS 0–2, and no immediately planned stem cell transplant. For each 28-day cycle, aza is administered subcutaneously or intravenously (IV) daily for 7 days within the first 9 days (7-0-0 or 5-2-2 schedule); ven is administered orally daily on days 1–28 (AML, following dose ramp-up) or days 1–14 (ven-containing MDS cohorts). Lemzo is administered IV at a schedule that is to be determined in this study. Dose escalation has Bayesian optimal interval design and may be expanded to investigate alternate dosing for lemzo. Dose expansion will initiate at recommended phase 2 dose. Treatment discontinuation criteria are unacceptable toxicity, progressive disease, lack of partial/complete remission or clinical benefit within 6 cycles, or at physician's discretion. Pts who discontinue study treatment without progression will continue with posttreatment follow-up; pts who progress will enter survival follow-up. The primary endpoints are DLTs of lemzo. Secondary endpoints for both cohorts include best overall responses of complete remission, duration of response, event-free survival, and overall survival. Exploratory biomarker endpoints are included. Safety assessments include adverse event (AE, graded per National Cancer Institute Common Terminology Criteria for AEs v5.0) monitoring, physical examinations, vital signs, electrocardiograms, and laboratory tests. Response rates will be analyzed with estimates and 95% confidence intervals based on exact binomial distribution. Time-to-event endpoints will be analyzed using Kaplan–Meier methodology. Clinical trial information: NCT04912063. Research Sponsor: AbbVie.

TPS7068 **Poster Session**

Oral azacitidine plus venetoclax in patients with relapsed/refractory or newly diagnosed acute myeloid leukemia: The phase 1b OMNIVERSE trial. *First Author: Farhad Ravandi, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: For patients (pts) with acute myeloid leukemia (AML) who cannot undergo intensive chemotherapy (IC), lower-intensity treatment (Tx) regimens, including low-dose cytarabine (LDAC) and hypomethylating agents (HMAs; azacitidine [AZA], decitabine), are generally well tolerated but are associated with lower response rates than IC [Vey 2020]. Similarly, the BCL2 inhibitor, venetoclax (VEN), has shown antileukemic activity, although only modest clinical benefit as monotherapy [Konopleva 2016]. VEN + AZA shows synergistic activity in preclinical models, enhancing leukemic cell apoptosis in vitro and anti-tumor activity in vivo [Jin 2020]. In IC-ineligible pts with ND AML, VEN + injectable AZA significantly increased complete remission (CR)/CR with incomplete hematologic recovery (CRi) rates ($P < 0.001$) and prolonged overall survival (OS; $P < 0.001$) vs AZA only [DiNardo 2020]. VEN, in combination with an HMA or LDAC, is approved in the US for Tx of pts with ND AML ≥ 75 years (y) of age or who cannot undergo IC due to comorbidities. Oral-AZA (CC-486) is approved for Tx of pts with newly diagnosed (ND) AML in first CR or CRi after IC who cannot receive curative therapy (eg, HSCT). In the phase 3 QUAZAR AML-001 trial, maintenance Tx with Oral-AZA 300 mg QD for 14 days (d)/28-d Tx cycle improved OS and relapse-free survival vs placebo in older pts in CR/CRi after IC [Wei 2020]. Incorporation of AZA into DNA is S-phase-restricted; thus, extending AZA exposure over a longer duration by using an oral formulation increases the opportunity for cycling tumor cells to incorporate the drug to sustain therapeutic activity [Laille 2015]. Additionally, an all-oral combination regimen allows for outpatient administration to optimize pt convenience and reduce resource utilization. **Methods:** OMNIVERSE (NCT04887857) is an open-label, multicenter, 2-part phase 1b trial. The main goals are to evaluate safety and establish the maximum tolerated dose of Oral-AZA + VEN in pts ≥ 18 y of age with relapsed/refractory AML who are ineligible for further IC (*part 1*), and subsequently, in pts with ND AML ≥ 75 y of age, or pts 18–74 y of age with comorbidities that prevent use of IC or HSCT (*part 2*). Key eligibility criteria include ECOG performance status of 0–2 (ECOG 3 is allowed for pts 18–74 y of age with comorbidities) and unfavorable-risk cytogenetics for pts with ND AML. The Oral-AZA starting dose is 300 mg QD × 14 d/28-d cycle, which can be de-escalated to 200 mg QD × 14 d depending on dose-limiting toxicities; oral VEN 400 mg QD is taken continuously (or 21 d/cycle for dose level –2). A modified toxicity probability interval-2 design is used to evaluate dose levels. Sample size depends on the dose levels utilized (≤ 18 pts/part). Enrollment began in 2021. The trial is ongoing at clinical sites in the United States and Australia. Clinical trial information: NCT04887857. Research Sponsor: Bristol Myers Squibb.

TPS7069 **Poster Session**

Phase 1B/2A safety, pharmacokinetics, and pharmacodynamics study of fosciclopirox alone and in combination with cytarabine in patients with relapsed/refractory acute myeloid leukemia. *First Author: Tara L. Lin, University of Kansas Medical Center, Kansas City, KS*

Background: Fosciclopirox (F) is a γ-secretase inhibitor being developed for the treatment of acute myeloid leukemia (AML). Following intravenous (IV) administration, F is rapidly and completely metabolized to its active metabolite, ciclopirox (CPX). CPX binds to γ-secretase complex proteins Presenilin 1 and Nicastrin, which are essential for Notch activation. In HL60 cells, CPX inhibits Notch 1 and Notch 2 expression, reduces levels of γ-secretase complex proteins Presenilin 1 and Nicastrin, and decreases expression of the downstream Notch target gene Hes-1. Utilizing Notable Labs predictive precision medicine platform, bone marrow (BM) and peripheral blood (PB) samples obtained from 10 AML patients treated with CPX demonstrated significant blast count reductions. **Methods:** Study CPX-POM-003 (NCT04956042) is an open-label Phase 1B/2A, trial designed to characterize the efficacy, safety, and PK/PD of F alone and in combination with cytarabine (ara-C) in patients with relapsed/refractory AML (R/R AML). Eligible patients must be 18 years of age or older with relapsed AML after complete remission or with primary refractory AML refractory to at least two cycles of induction therapy. There will be up to three cohorts of patients, approximately 42 R/R AML patients, evaluated. If disease response to F alone (Cohort 1a) is observed in at least 4 of 14 patients, an additional 14 patients will be enrolled in Cohort 1b. If disease response is not observed following F alone, the study may be terminated or a second cohort, Cohort 2a, may be initiated to evaluate the combination of F + ara-C. If disease response to F + ara-C is observed in at least 4 of 14 patients, an additional 14 patients will be enrolled in Cohort 2b. If response to F + ara-C is not observed in at least 4 of 14 patients, the study will be stopped for futility. F is being administered as 900 mg/m^2 once daily as a 20-minute IV infusion on Days 1 to 5 of each 21-day treatment cycle. Ara-C is administered as 1 gm/m^2 once daily on Days 1 to 5 of each cycle. BM and PB samples are collected prior to and during Cycles 1 (C1) and 2 (C2) for disease response assessment and blast count determination. Additional BM and PB samples are obtained after every two cycles beyond C2 for patients continuing treatment. Disease response is determined based on Döhner et al, *Blood* 2017;129(4)424-447. Next Generation Sequencing (NGS) profiles will be determined prior to and at the end of C1, and thereafter as clinically indicated. Immunohistochemistry will be performed on BM samples to elucidate drug mechanism. *Ex vivo* Drug Sensitivity Screening (DSS) will be performed on BM and PB samples obtained prior to treatment as well as on C1 Days 8 and 21. The steady-state plasma pharmacokinetics of F are being characterized during C1. Enrollment began in October 2022 with four patients enrolled to date. Clinical trial information: NCT04956042. Research Sponsor: CicloMed LLC, Pharmaceutical/Biotech Company.

TPS7070 **Poster Session**

A phase 1 study of CD38-bispecific antibody (XmAb18968) for patients with CD38 expressing relapsed/refractory acute myeloid leukemia and T-cell acute lymphoblastic leukemia. *First Author: Guru Subramanian Guru Murthy, Division of Hematology/Oncology, Medical College of Wisconsin, Milwaukee, WI*

Background: Outcomes of adults with relapsed/refractory T-cell acute lymphoblastic leukemia (T-ALL) and acute myeloid leukemia (AML) have remained poor. CD38 is a transmembrane glycoprotein with several important functions including its role in immune escape of tumor cells [Chillemi A et al. Front Immunol 2017, Furano A et al. J Immunol 1990]. Several studies have demonstrated that CD38 is expressed in T-ALL and AML and is targetable with CD38 blocking agents [Naik J et al. Haematologica 2019, Bride KL et al. Blood 2018, Tembhare et al. J Immunother Cancer 2020]. XmAb18968 is a novel CD38-CD3 bi-specific T-cell engager with Fc domain modified to minimize Fcγ receptor binding and non-selective T-cell activation resulting in reduced cytokine release without compromising target cell killing. We hypothesize that targeting CD38 in relapsed/refractory T-ALL and AML would be safe and feasible using XmAb18968. **Methods:** This is an investigator-sponsored multi-institutional phase I study evaluating the safety and tolerability of XmAb18968. Patients aged 18 years or above with relapsed/refractory T-ALL or AML (including measurable residual disease relapse), CD38 expression ≥ 20% by flow cytometry, and adequate organ function will be eligible. Major exclusion criteria are hematopoietic cell transplantation within 6 months of enrollment, active acute graft-versus-host disease, and acute promyelocytic leukemia. The primary objective is to determine the recommended phase 2 dose (RP2D) and toxicity profile of XmAb18968. The secondary objectives include determination of response rates, duration of response, survival and pharmacokinetics. Exploratory objectives include correlation of responses with genomic profile, characterizing changes in serum cytokines and phenotypic expression of activated T-cells and leukemic cells, correlation of the phenotypic expression with changes in the transcriptome at the single-cell level, proteomics evaluation of cytokine secretion at the single-cell level and correlation of response with N-glycan profiling, quantitative site-occupancy and direct glycopeptide analysis. The study will follow 3+3 design. Dose escalation will proceed in two separate groups: Group A for subjects with T-ALL and Group B for subjects with AML. Patients will be entered sequentially to each dose level [0.8mg cohort, 1mg cohort, 1.3mg cohort, 1.5mg cohort). The observation period for dose-escalation will be 28-days. RP2D will be defined as the highest dose level at which none of the 3 treated subjects, or no more than 1 of the 6 treated subjects' experiences a dose limiting toxicity. A minimum of 24 and a maximum of 60 patients will be enrolled. The study is being conducted at 6 sites in United States and is currently open for enrollment. Clinical trial information: NCT05038644. Research Sponsor: Xencor Inc.

TPS7071 **Poster Session**

Phase 1 study of LP-108 as monotherapy and in combination with azacitidine in patients with relapsed or refractory myelodysplastic syndromes (MDS), chronic myelomonocytic leukemia (CMML), or acute myeloid leukemia (AML). *First Author: Alison R. Walker, The Ohio State University Wexner Medical Center, Columbus, OH*

Background: BCL2 inhibition as a means of targeting intrinsic apoptotic pathways that confer a survival advantage to leukemic blasts has become a key therapeutic strategy for patients with myeloid malignancies. LP-108 is an oral highly potent and selective inhibitor of BCL-2 with comparable or more potent *in vitro* inhibitory activity as compared to the FDA approved oral BCL-2 inhibitor venetoclax. We propose to investigate LP-108 as monotherapy and in combination with azacitidine in patients with relapsed or refractory (r/r) MDS, CMML or AML. **Methods:** The primary objectives of the trial are 1.) To determine the safety, tolerability and determine the maximum tolerated dose (MTD) and the recommended phase 2 dose / optimal biological dose (OBD) of LP-108 as a single agent (Arm 1) and in combination with azacitidine (Arm 2) in patients with relapsed/refractory MDS/CMML/AML; 2.) To characterize the pharmacokinetic profile of LP-108 as monotherapy and in combination with a fixed dose of azacitidine. The secondary objectives of the trial are 1.) To evaluate the objective response rate of LP-108 (monotherapy or combination therapy) in r/r MDS/CMML/AML as well as progression free survival, duration of response and overall survival. In Arm 1 patients will be enrolled according to a 3+3 design with escalating doses of LP-108 for a 28 day cycle (firs table). DLTs will be determined in the first 28 days. In Arm 2 patients will be enrolled according to a 3+3 design with escalating doses of LP-108 in combination with a fixed dose of azacitidine (second table). DLTs will be determined in the first 28 days. DLT for both arms is defined as some ≥ Grade 3 non-hematological toxicities or prolonged myelosuppression. Patients may continue treatment until disease progression, unacceptable toxicity, or per investigator discretion. Patients age ≥ 18 years with r/r MDS with excess or blasts or with high or very-high risk disease per the R-IPSS, or r/r MDS for Arm 2, r/r AML, or frontline older and/or unfit AML for Arm 2, or r/r CMML may enroll. Patients with prior hypomethylating agents or venetoclax exposure may enroll. The blast count at the time of starting therapy must be ≤ 30 x 10^9 cells/L. Hydroxyurea is allowed prior to and during treatment. Ejection fraction ≥ 50% is required. Calculated creatinine clearance shall be ≥ 30 mL/min. Strong CYP3A4 inducers and inhibitors are prohibited. Patients on weak/moderate azole antifungals were allowed to enroll. Enrollment to Arm 1 is complete and there have been no DLTs to date. Enrollment to Arm 2 is pending. Arm 1 Dose Escalation Scheme (LP-108 monotherapy). Clinical trial information: NCT04139434. Research Sponsor: Newave Pharmaceuticals.

Arm 2 dose escalation Scheme (LP-108 and azacitidine).

Cohort	LP-108 Dose
1	100 mg
2	200 mg
3	400 mg
4	600 mg

Cohort	LP-108 Dose	Azacitidine Days 1-7 or days 1-5, 8, 9
1	100 mg	75 mg/m2
2	200 mg	75 mg/m2
3	400 mg	75 mg/m2

TPS7072 **Poster Session**

Emotion and symptom-focused engagement (EASE): A multisite randomized controlled trial of an intervention for individuals with acute leukemia. *First Author: Kyle Fitzgibbon, Princess Margaret Cancer Centre - UHN, Toronto, ON, Canada*

Background: Acute leukemia (AL) is characterized by rapid symptom onset requiring urgent hospitalization and initiation of intensive treatment with high mortality. Despite this, there is scant research on its psychological and physical impacts and even less on interventions to alleviate them [Bryant 2016]. We conducted a longitudinal study showing substantial physical and psychological distress in these patients [Rodin 2013; Zimmermann 2013; Nissim 2013; Nissim 2014; Gheihman 2016; Rodin 2018a; Shaulov 2019]. Despite this distress, we observed a lack of referrals for specialized psychosocial and palliative care. Based on these findings, we developed an integrated psychosocial and early palliative care (symptom control) intervention, Emotion And Symptom-focused Engagement (EASE), for AL [Rodin 2015]. In a subsequent randomized phase II trial of EASE in patients newly diagnosed with AL, we demonstrated its feasibility and found preliminary evidence that it reduces physical and psychological distress compared to usual care [Rodin 2020]. EASE includes: i) an 8-week manualized psychotherapy intervention tailored to AL to prevent and treat psychological symptoms through: supportive counselling and trauma-focused cognitive-behavioural therapy; and emotional assessment and affect modulation; ii) 4-week systematic screening of physical symptoms with automatic referrals to palliative care for the management of moderate to severe symptoms. **Methods:** We are conducting a multi-centre randomized controlled phase III trial of 266 AL patients comparing EASE to usual care in collaboration with the Canadian Cancer Trials Group at Princess Margaret Cancer Centre, Sunnybrook Health Sciences, Kingston Health Sciences and the Ottawa Hospital in Ontario, Canada. Patients are newly diagnosed with acute myeloid leukemia or acute lymphoblastic leukemia and randomized within two weeks of hospital admission for induction chemotherapy with curative intent. Patients randomized to EASE will receive psychological support from a trained mental health clinician for 8 weeks and will be assessed for physical symptoms twice weekly until discharged from hospital. Moderate to severe physical symptoms will trigger a referral to a symptom-control team for symptom management. The symptom-control team consists of a physician and nurse with expertise in symptom control and other professionals as needed. All participants will be assessed for physical symptom severity, psychological distress, quality of life and satisfaction with care at baseline, 4, 8, 12 weeks, 6 and 12 months. Hypotheses will be tested using multilevel modeling (MLM) with maximum likelihood estimation, conducted as intention-to-treat analyses. The DMC last reviewed the trial in April 2021 and suggested that the trial continue as planned. Clinical trial information: NCT04224974. Research Sponsor: Canadian Institutes of Health Research, Other Foundation.

TPS7073 **Poster Session**

A phase II study of CPX-351 in younger patients < 60 years old with secondary acute myeloid leukemia: Trial in progress. *First Author: Mahesh Swaminathan, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Patients (pts) with secondary acute myeloid leukemia (s-AML) and therapy-related AML (t-AML) have poor long-term outcomes following standard induction 7+3 chemotherapy. CPX-351, a liposomal formulation of cytarabine and daunorubicin fixed at the synergistic ratio of 5:1, is indicated for the treatment of pts with newly diagnosed s-AML and t-AML based on the results of a phase III trial favorably comparing CPX-351 to 7+3. Although the trial only enrolled pts aged 60-75 years (Y), CPX-351 is approved by the United States Food and Drug Administration for all adult pts with t-AML and AML with myelodysplasia-related changes (AML-MRC). In a prior retrospective analysis of CPX-351 in pts <60 Y with s-AML, we noted that the outcomes of these younger pts appeared inferior to those reported in older pts (60-75 Y) in the phase III trial (Przespolewski et al. Blood 2018 p.2677). Therefore, we designed this prospective study to evaluate the efficacy of CPX-351 in pts <60 Y with untreated s-AML and t-AML. **Methods:** In this phase II single-arm multi-institutional study, pts aged 18-59 Y with untreated t-AML or AML-MRC, adequate organ function, and ECOG performance status ≤ 2 are eligible. Pts with active central nervous system disease and infections were excluded. CPX-351 will be dosed at 100 mg/m^2 cytarabine and 44 mg/m^2 daunorubicin on days 1, 3, and 5 during induction. Bone marrow biopsy will be performed between days 14-21 to assess response. If needed, re-induction CPX-351 dose will be 44 mg/m^2 daunorubicin/100 mg/m^2 cytarabine on days 1 and 3. Pts achieving a complete remission (CR) following induction can receive up to 2 cycles of consolidation CPX-351 dosed as cytarabine 65 mg/m^2 and daunorubicin 29 mg/m^2 on days 1 and 3. The primary endpoint of the study is overall response rates defined as CR and CR with incomplete blood count recovery (CRi)) within 45 days of beginning therapy. Secondary endpoints are duration of response, event-free survival, overall survival, rate of allogeneic stem cell transplant, and adverse events. A maximum of 46 pts will be enrolled at 4 U.S. sites with 5-year follow-up from the start of CPX-351.The study is open and has enrolled 4 pts to date. Clinical trial information: NCT04269213. Research Sponsor: U.S. National Institutes of Health.

TPS7074 **Poster Session**

A phase 1b study to evaluate safety, tolerability, pharmacokinetics, and efficacy of SER-155 in adults undergoing hematopoietic stem cell transplantation to reduce the risk of infection and graft versus host disease (NCT04995653). *First Author: Doris M. Ponce, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In patients undergoing allogeneic hematopoietic stem cell transplantation (HCT), loss of gastrointestinal microbial diversity is associated with risk of bloodstream infections (BSI), acute graft-versus-host disease (aGvHD), and death. SER-155 is a cultivated investigational microbiome therapeutic rationally designed to improve clinical outcomes in patients undergoing HCT by restoring colonization resistance to pathobionts, promoting epithelial barrier integrity, and reducing colonic inflammation. SER-155-001 is a Phase 1b study to evaluate the efficacy, safety, and pharmacokinetics (PK) of SER-155 in adults undergoing HCT. **Methods:**This study will enroll approximately 70 subjects $\geq$ 18 years in an open-label Cohort 1 (n = 10) followed by a double-blind, placebo-controlled Cohort 2 (n = 60) randomized 1:1 to SER-155 or placebo and stratified by conditioning regimen intensity. Exclusion criteria include history of severe colitis of any etiology or active inflammatory bowel disease or total colectomy, transplant using umbilical cord blood or *ex vivo* T-cell therapy, receipt of fecal microbiota transplant or any live microbial therapeutic within 3 months prior to screening, and evidence of relapse or progression of hematologic malignancy (minimal residual disease is allowed). Following screening, subjects in both cohorts will receive 2 treatment courses (before and after HCT), each comprised of microbiome conditioning with oral vancomycin or placebo followed by SER-155 or placebo, and a conditional 3rd treatment course if the subject receives antibiotics (Table). Safety outcomes will be followed through 52 weeks post HCT. The primary endpoint is to evaluate the incidence and severity of adverse events, serious adverse events, and adverse events of special interest. Secondary endpoints include rates of BSI, gastrointestinal infections, aGvHD, febrile neutropenia and overall survival in placebo vs SER-155 arms. Microbiome related endpoints include engraftment of SER-155 bacterial strains in the gastrointestinal tract (PK endpoint) and fecal microbiome diversity, composition and metabolites. Clinical trial information: NCT04995653. Research Sponsor: Seres Therapeutics.

	Microbiome conditioning regimen	Treatment course*
Cohort 1:	Oral vancomycin (125 mg, 4 times daily) for 4 days	2 capsules of SER-155 once daily for 10 days
Cohort 2:	Oral vancomycin (125 mg, 4 times daily)	2 oral capsules of SER-155 once daily for 10 days
	Placebo vancomycin 4 times daily	2 oral capsules placebo once daily for 10 days

*A third course will be administered without microbiome conditioning following completion of antibiotics for subjects who receive 3 days of systemic antibiotics following HCT.

TPS7075 **Poster Session**

A randomized, double-blind, placebo-controlled study of tamibarotene/azacitidine versus placebo/azacitidine in newly diagnosed adult patients selected for RARA+ HR-MDS (SELECT-MDS-1). *First Author: Amy Elizabeth Dezern, Johns Hopkins University, Baltimore, MD*

Background: A novel genomically defined subset of higher-risk MDS (HR-MDS) patients with an actionable target characterized by overexpression of *RARA* has been identified (McKeown 2017). Approximately 30% of HR-MDS patients are RARA-positive (RARA+) by a blood-based biomarker test (Vigil, 2017). Biologically targeted therapy with tamibarotene, an oral selective RARα agonist, has potential to provide clinical benefit for RARA+ HR-MDS patients, irrespective of mutation or cytogenetic risk. Initial clinical data in RARA+ R/R HR-MDS patients treated with tamibarotene showed myeloid differentiation, improved blood counts, and reduced bone marrow blasts, including one patient who achieved marrow complete remission with hematologic improvement (Jurcic 2017). Tamibarotene in combination with azacitidine (aza) showed high complete response rates (CR) with rapid onset of response in RARA+ newly diagnosed (ND) unfit AML patients, including those with low blast count ($\leq$ 30%) AML, and a majority of patients achieved or maintained transfusion independence (de Botton 2020). Tamibarotene/aza was generally well tolerated with no increase in myelosuppression compared to aza alone (de Botton 2020). Historical precedent demonstrating similar clinical outcomes in HR-MDS and AML, particularly low blast count AML (Estey 2021), supports further development of tamibarotene/aza in HR-MDS to improve clinical outcomes of standard of care treatment with hypomethylating agents (HMAs). **Methods:** This Phase 3, multi-center, randomized, double-blind, placebo-controlled study will compare activity of tamibarotene/aza to placebo/aza in RARA+ patients with ND HR-MDS. The primary objective is to characterize and compare the CR rate of tamibarotene/aza vs placebo/aza, with secondary objectives to characterize ORR, EFS, OS, transfusion independence rate, time to and duration of initial and complete responses, and safety. Approximately 190 patients will be randomized 2:1, providing 90% power to detect the difference in CR rates between the experimental and control arms, with a one-sided alpha of 0.025. Patients must be RARA+ based on the investigational biomarker test, ND with HR-MDS by WHO classification (Arber 2016), classified by IPSS-R risk category as very high, high, or intermediate risk with a blast count > 5% at study entry. Patients suitable for transplant at screening, or with prior treatment for MDS with any HMA, chemotherapy or transplant are excluded. Aza will be administered at 75 mg/m^2 IV/SC daily on days 1-7 (or 1-5, 8-9) followed by tamibarotene/placebo at 6 mg BID orally days 8-28 of each 28-day cycle. Response will be assessed per modified IWG MDS criteria (Cheson 2006). The SELECT-MDS-1 trial opened in February 2021, recruitment is ongoing, with sites located in North America, Israel, and Europe. Clinical trial information: NCT04797780. Research Sponsor: Syros Pharmaceuticals.

TPS7076 **Poster Session**

Phase II trial assessing safety and preliminary efficacy of high-dose intravenous ascorbic acid in patients with *TET2*-mutant clonal cytopenias of undetermined significance. *First Author: Zhuoer Xie, Mayo Clinic, Rochester, MN*

Background: Clonal cytopenias of undetermined significance (CCUS) is operationally defined as unexplained persistent cytopenias arising in the context of leukemia-associated somatic driver mutations in hematopoietic stem and progenitor cells, without morphologic evidence for an underlying hematological neoplasm. Patients with *TET2* mutant ($TET2^{MT}$) CCUS have a high probability of progression to myeloid neoplasms, with approximated 10-year cumulative rates of progression being 90%. To date, no FDA-approved treatment for CCUS has been established, and we have shown that these patients can have transfusion burdens akin to patients with myelodysplastic syndrome (MDS) (Li M et al. Blood Adv 2020). Thus there is an urgent and unmet need for therapies for these patients. Intravenous (IV) ascorbic acid (AA) dosed at pharmacologic concentrations could have anti-cancer activity via two mechanisms: (1) hydrogen peroxide-induced oxidative stress and (2) DNA demethylation mediated by TET activation (cofactor for TET1/2/3). TET2, the primary enzyme for catalyzing oxidative reactions, converts 5-methylcytosine to 5-hydroxymethylcytosine, a crucial step leading to iterative DNA demethylation. Our study hypothesis is that IV AA in $TET2^{MT}$ CCUS will restore hematopoiesis and limit clonal progression by stimulating TET2 (the unmutated allele) and TET3 activities. **Methods:** LS1781 (NCT03418038) is an investigator-initiated, prospective, single-arm, single-institution, phase II trial assessing the safety and preliminary efficacy of high dose of IV AA for patients with $TET2^{MT}$ CCUS (harboring ≥1 $TET2^{MT}$ or $TET2^{MT}$ combined with concurrent spliceosome MTs). IV AA (1g/kg, maximum 100g) is given 3 times weekly for 12 weeks through a central line with assessments being carried out before each cycle (4 weeks), at 12 weeks, and one year. The primary endpoint is the hematologic response rates determined by MDS IWG 2018 criteria. Secondary endpoints include safety and side effects. Exploratory endpoints include the impact of AA on $TET2^{MT}$ variant allele fraction, plasma cytokine levels, DNA methylation, and hydroxymethylation (as measured by Infinium MethylationEPIC array), and TET activity. Patients 18 years or older with $TET2^{MT}$ CCUS, and with any of the following laboratory criteria: (1) hemoglobin ≤10g/dL, (2) absolute neutrophil count (ANC) ≤1000/mm^3, (3) platelet count ≤100,000/mm^3 are eligible. Fifteen patients will be enrolled at Mayo Clinic Rochester and the Mayo Clinic Health System. Dose modifications have been established and will be considered based on adverse events. Treatment will be discontinued for disease progression or in the event of ≥Grade 3 adverse events that don't resolve promptly. Enrollment to the trial began in June 2021, with 7 patients enrolled at abstract submission. Clinical trial information: NCT03418038. Research Sponsor: U.S. National Institutes of Health.

TPS7077 **Poster Session**

A phase 1 study of NTX-301, an oral DNMT1 inhibitor, in patients with MDS and AML (trial in progress). *First Author: Pankit Vachhani, University of Alabama at Birmingham, Division of Hematology/Oncology, Department of Medicine, Birmingham, AL*

Background: Patients with relapsed and/or refractory (r/r) myelodysplastic syndrome (MDS), chronic myelomonocytic leukemia (CMML), and acute myeloid leukemia (AML) who are not candidates for stem-cell transplantation have dismal outcomes. Novel therapies are needed. The nucleoside analogue NTX-301 (5-aza-4'-thio-2'-deoxycytidine or Aza-TdC) is incorporated into DNA, where it engages the active site of DNA methyltransferase I (DNMT1), a maintenance methyltransferase that contributes to the hypermethylation and silencing of tumor suppressor genes. DNMT1 can become trapped in a covalent complex with DNA, thus depleting free enzyme and inhibiting the normal maintenance methylation of CpG sites, resulting in re-activation of tumor suppressor genes. Preclinical data suggest a correlation between NTX-301 activity in leukemia xenograft models and decreased levels of DNMT1. NTX-301 offers an improvement over traditional DNA methyltransferase inhibitors (azacitidine, decitabine) by virtue of a higher incorporation rate into DNA at lower levels of cytotoxicity. **Methods:** This is a phase 1, open-label, multi-center, dose-escalation study to assess the safety, tolerability, and recommended myeloid monotherapy dose of NTX-301 in patients with r/r myeloid neoplasms. Patients ≥ 18 years with r/r higher-risk MDS (intermediate, high, very-high risk by IPSS-R), high-risk CMML (int-2/high by CPSS or CPSS-mol), or AML (marrow blasts ≤ 30% or WBC < 20,000 cells/μL without leukoreduction) are eligible. Other key eligibility criteria: Eastern Cooperative Oncology Group performance status 0–2; adequate cardiac, renal, and liver function; and resolved acute effects of any prior therapy. Successive cohorts of patients will receive escalating doses of NTX-301 starting from 2 mg QD. Each cycle is 21 days in duration (treatment for 5 days/week x 2 weeks and 1 week off). The trial incorporates accelerated titration design for dose level 1 and 2 followed by traditional 3+3 dose escalation design (3-6 patients per cohort) from dose level 3. Intrapatient dose escalation is allowed. NTX-301 treatment will continue until disease progression or unacceptable toxicity, whichever occurs first. Primary endpoints: incidence and severity of adverse events, dose-limiting toxicities (DLTs), maximum tolerated dose (MTD), biologically effective dose (BED). Secondary endpoints: PK parameters of NTX-301, PD assessment through global hypomethylation assay and other markers in blood and marrow, and clinical efficacy [overall response rate (ORR), complete remission (CR), marrow CR (mCR), partial remission (PR), stable disease (SD), hematologic improvement (HI) per mIWG criteria]. After the MTD/BED is identified, the safety and efficacy of NTX-301 will be explored further in selected myeloid malignancies. The study began enrolling patients in January 2021 and is still recruiting. Clinical trial information: NCT04167917. Research Sponsor: Southern Research.

TPS7078 **Poster Session**

Pediatric and young adult leukemia adoptive therapy (PLAT)-08: A phase 1 study of SC-DARIC33 in pediatric and young adults with relapsed or refractory CD33+ AML. *First Author: Todd Michael Cooper, Seattle Children's Hospital, Cancer and Blood Disorders Center, Seattle, WA*

Background: The acute and late effects of acute myeloid leukemia (AML) therapy in children can be devastating, and relapse rates remain high. Targeted therapies are needed to decrease toxicity and improve cure rates. Most AML patients express CD33 on their leukemic blasts. CD33 is a viable target with CD33 targeted therapies approved for AML. CD33 targeted CAR T cell therapies are being developed, but safety and efficacy remain a challenge. Safety concerns include cytokine release syndrome, neurotoxicity and aplasia. Efficacy is limited, with antigen escape and T cell exhaustion proposed as mechanisms of treatment failure. Dimerizing Agent Regulated ImmunoReceptor Complex (DARIC) is a next-generation technology that utilizes a split receptor design separating the antigen binding and intracellular signaling subunits (Leung, 2019). These subunits remain inactive until the administration of rapamycin which allows for dimerization of the subunits, enabling T cell activation when antigen is present. Modulating CAR T cell activation may aid hematopoietic recovery, enhance CAR T cell function and persistence, and mitigate toxicity. We developed a DARIC T cell product, SC-DARIC33, that couples the DARIC technology with a lentiviral construct that incorporates the use of a novel humanized camelid nanobody for targeting the C2 splice isoform within the membrane proximal domain of CD33. **Methods:** Up to 18 patients will be enrolled in this phase 1 study (NCT05105152). Patients must have early first relapse of AML (≤ 6 months from diagnosis), first relapse refractory to at least one reinduction attempt, second or greater relapse, or refractory *de novo* AML. The first 3 patients must be ≥18 years, all patients who meet eligibility criteria must be ≤28 years. The primary objectives of this Phase I study (NCT05105152) are assessment of safety/toxicity and feasibility of manufacturing of SC-DARIC33. Secondary objectives include assessment of efficacy, on/off rate of DARIC expression, engraftment, expansion and persistence of SC-DARIC33. Also, the effect of cessation of rapamycin on activation state of SC-DARIC 33 and on hematopoietic recovery will be evaluated. Subjects receive lymphodepletion prior to a single dose of SC-DARIC33 T cells on Day 0 followed by initiation of rapamycin on Day +2 with the purpose of activating the T cells. Rapamycin continues until Day 21 and bone marrow evaluation occurs on Day 28. Subsequent cycles of rapamycin are allowed for patients who respond. The trial will implement a BOIN design with three possible dose levels (1 x 10^6, 5 x 10^6, and 10 x 10^6 $DARIC^+$ cells/kg) to determine the maximum tolerated dose (MTD). The trial is open for enrollment at Seattle Children's Hospital. Clinical trial information: NCT05105152. Research Sponsor: 270 Bio.

TPS7080 **Poster Session**

Phase II trial of luspatercept with or without hydroxyurea for the treatment of patients with myelodysplastic/myeloproliferative neoplasms with ring sideroblasts and thrombocytosis or unclassifiable with ring sideroblasts. *First Author: Abhishek Avinash Mangaonkar, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Myelodysplastic syndrome/myeloproliferative neoplasms (MDS/MPN) are classified as a distinct category under the World Health Organization (WHO) classification of myeloid neoplasms. MDS/MPN with RS and thrombocytosis (MDS/MPN-RS-T) and MDS/MPN, unclassifiable with > 15% bone marrow ring sideroblasts (MDS/MPN-U-RS) have similar clinical and pathological characteristics with symptomatic or transfusion-dependent anemia as the predominant morbidity. Luspatercept has been approved in myelodysplastic syndromes with ring sideroblasts (MDS-RS) and MDS/MPN overlap syndromes, based on the phase 3 MEDALIST clinical trial which primarily included MDS-RS patients with an objective erythroid response rate of approximately 40 per cent. In this trial, some MDS-RS patients also experienced an increase in neutrophil and platelet counts. This raises a safety concern for MDS/MPN patients with elevated platelet or WBC counts such as MDS/MPN-RS-T and MDS/MPN-U-RS. Previous studies have shown clinical and biological differences between MDS-RS and MDS/MPN-RS-T, with the latter group at a significantly elevated risk for thrombotic events. Additionally, several MDS/MPN-RS-T patients are on hydroxyurea which may blunt the erythroid response of luspatercept. Therefore, it is imperative to establish the safety and efficacy of luspatercept in this patient group. **Methods:** This is an investigator-initiated, prospective, phase II study of luspatercept in MDS/MPN overlap neoplasms with ring sideroblasts and thrombocytosis or unclassifiable with ring sideroblasts with 2 arms; hydroxyurea-independent (cohort A) and hydroxyurea-dependent (cohort B). Hydroxyurea and/or aspirin use is allowed as per investigator discretion. The primary goal is to study the efficacy and safety of luspatercept in MDS/MPN-RS-T or MDS/MPN-U-RS with symptomatic anemia. The primary endpoint is to assess erythroid response rate as per the 2015 International Working Group MDS/MPN response criteria. Secondary endpoints include response duration, time to acute myeloid leukemia (AML) transformation, thrombosis rate, AML-free and overall survival. Inclusion criteria include newly diagnosed or relapsed/refractory adult patients with WHO-defined diagnosis of MDS/MPN-RS-T or MDS/MPN-U-RS with symptomatic or transfusion-dependent anemia and unlikely to respond (EPO level > 200 IU/L) or intolerant to erythropoiesis stimulating agent (ESA) therapy. Prior therapy with lenalidomide, hypomethylating agents or immunosuppressive therapy is allowed. The overall plan is to enroll 54 patients across the three Mayo Clinic sites, Minnesota, Arizona and Florida. Enrollment to the trial began in January 2022 with 1 patient enrolled at the time of abstract submission. Clinical trial information: NCT05005182. Research Sponsor: BMS.

7500 **Oral Abstract Session**

Glofitamab in patients with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) and ≥ 2 prior therapies: Pivotal phase II expansion results. *First Author: Michael Dickinson, Peter MacCallum Cancer Centre, Royal Melbourne Hospital and The University of Melbourne, Melbourne, Australia*

Background: Glofitamab is a T-cell engaging bispecific antibody (Ab) with a novel 2:1 configuration that confers bivalency for CD20 (B cells) and monovalency for CD3 (T cells). In a Phase I/II study (NCT03075696), escalating glofitamab doses were highly active and well tolerated in pts with R/R B-cell lymphomas, with obinutuzumab pretreatment (Gpt) and Cycle (C) 1 step-up dosing providing effective CRS mitigation. For the first time, we present pivotal Phase II expansion results in pts with R/R DLBCL and ≥2 prior therapies. **Methods:** All pts had DLBCL (DLBCL NOS, HGBCL, PMBCL, or trFL) and had received ≥2 prior regimens including ≥1 anti-(a) CD20 Ab and ≥1 anthracycline. IV Gpt (1000mg) was given 7 days before the first glofitamab dose. IV glofitamab was then given as step-up doses on Day (D) 1 (2.5mg) and D8 (10mg) of C1 and at the target dose (30mg) on D1 of C2–12 (21-day cycles). The primary endpoint was CR rate (best response during initial treatment) assessed by Independent Review Committee (IRC) using Lugano 2014 criteria. CRS was assessed using ASTCT criteria. **Results:** As of Sep 14, 2021, 107 pts had received ≥1 dose of study treatment (median age: 66 yrs [21–90]; Ann Arbor stage III–IV disease: 74%; IPI score ≥3: 54%; DLBCL NOS: 74%). Median prior therapies was 3 (2–7); 59% had ≥3 prior therapies and 35% had received prior CAR T-cells (CAR-Ts). Most pts were refractory to a prior aCD20 Ab-containing regimen (85%) and to their most recent regimen (85%). Many were refractory to their initial therapy (59%) and to prior CAR-Ts (32%). After a median follow-up of 9 months (0.1–16), ORR and CR rates by IRC were 50.0% and 35.2%, respectively. CR rates were consistent in pts with and without prior CAR-Ts (32% vs 37%). Median time to CR was 42 days (95% CI: 41–48). The majority of CRs (33/38; 87%) were ongoing at data cut. An estimated 84% of complete responders and 61% of responders remained in response at 9 months. At data cut, the projected 12-month OS rate was 48%, and 92% of complete responders were alive. These results are consistent with earlier Phase I data in 100 pts treated with target glofitamab doses ≥10mg (CR rate: 34%; estimated 20-month CR rate in complete responders: 72%). CRS occurred in 68% of pts, was primarily associated with the initial doses, and was mostly Gr 1 (51%) or Gr 2 (12%); Gr 3 (3%) and Gr 4 (2%) events were uncommon. All but 2 CRS events were resolved at data cut. Glofitamab-related neurologic AEs potentially consistent with ICANS occurred in 3 pts (all Gr 1–2). No glofitamab-related Gr 5 (fatal) AEs occurred. Glofitamab-related AEs leading to discontinuation were uncommon (3 pts, 3%). **Conclusions:** Fixed-duration glofitamab induces durable complete remissions and has favorable safety in pts with R/R DLBCL and ≥2 prior therapies, including those with prior exposure to CAR-Ts. Glofitamab is a promising new therapy for pts with heavily pretreated and/or highly refractory DLBCL. Clinical trial information: NCT03075696. Research Sponsor: Third-party medical writing assistance, under the direction of all authors, was provided by Scott Malkin of Ashfield MedComms, an Ashfield Health company, and was funded by F. Hoffmann-La Roche Ltd.

7501 **Oral Abstract Session**

GEMSTONE-201: Preplanned primary analysis of a multicenter, single-arm, phase 2 study of sugemalimab (suge) in patients (pts) with relapsed or refractory extranodal natural killer/T cell lymphoma (R/R ENKTL). *First Author: Huiqiang Huang, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: R/R ENKTL is a rare and aggressive type of non-Hodgkin's lymphoma. Responses to chemotherapy after failure of prior asparaginase-based regimen were not durable with a median OS of < 7 months (mos) and 1-year OS rate of < 20% (Lim et al, Ann Oncol 2017; Bellei et al, Haematologica 2018). The only targeted therapy approved in China for R/R peripheral T cell lymphoma (ENKTL included) showed an ORR of 18.8% and a CR rate of 6.3% (Shi et al, Ann Oncol 2015). Here, we present the primary analysis from GEMSTONE-201, the largest registrational study reported to date to evaluate an anti-PD-L1 mAb in R/R ENKTL. Suge received breakthrough therapy designation from US FDA in 2021 for adult R/R ENKTL pts based on preliminary data of this study. **Methods:** Pts with ECOG PS of 0/1 and histologically confirmed ENKTL who failed prior asparaginase-based regimen were enrolled. Pts accepted suge at 1200 mg Q3W, iv, for up to 24 mos, until progression, death, or withdrawal from study. The primary endpoint was ORR (CR+PR) assessed by independent radiological review committee (IRRC) per Lugano 2014 criteria. Key secondary endpoints included investigator-assessed ORR, CR and PR rate, DoR assessed by IRRC and investigators, and safety. **Results:** As of the data cutoff date, Nov 10, 2021, 80 pts were enrolled and treated (median follow-up of 13.4 mos). Median age was 48 years (range 29-74); 64% were males; 74% had ECOG PS of 1 at baseline; 68% had stage IV disease; about half (49%) received ≥ 2 lines of prior systemic therapy. The median duration of treatment was 5.2 mos (range 0.7-37.4); 23 pts remained on treatment. Among the 78 evaluable pts as per IRRC, ORR was 46.2% (95% CI: 34.8%, 57.8%); 29 (37.2%) pts achieved CR; median DoR was not reached (NR); 12-mo DoR rate was 86%. Investigator's assessments in 79 evaluable pts were consistent with IRRC results, i.e. ORR of 45.6% (95% CI: 34.3%, 57.2%), 24 (30.4%) pts with CR, and median DoR of NR. The 1- and 2-year OS rates were 68.6% and 54.6%, respectively; median OS was NR (range 0.9-37.2^{+} mos). Of all pts, 96% (n = 77) had at least one AE. The most common AEs were pyrexia and WBC decreased (n = 24 each, 30%). Grade ≥ 3 AEs occurred in 31 (39%) pts. Suge-related AEs occurred in 61 (76%) pts and were mostly (60%) Grade 1/2. The most common irAE assessed by sponsor was hypothyroidism (n = 13, 16%). SAEs occurred in 18 (23%) pts; 5 (6%) pts had suge-related SAEs which had all been resolved (1 with sequelae). Fatal AEs occurred in 5 (6%) pts and none were suge-related as assessed by investigators. **Conclusions:** Suge has demonstrated deep and durable anti-tumor activity in R/R ENKTL pts, with a high CR rate and a promising OS benefit trend comparing to historical data. Suge had a well-tolerated safety profile and no new safety signals were detected. Primary analysis indicates that suge could provide a new treatment option to R/R ENKTL pts. Clinical trial information: NCT03595657. Research Sponsor: CStone Pharmaceuticals.

Primary results from the double-blind, placebo-controlled, phase III SHINE study of ibrutinib in combination with bendamustine-rituximab (BR) and R maintenance as a first-line treatment for older patients with mantle cell lymphoma (MCL). *First Author: Michael Wang, The University of Texas MD Anderson Cancer Center, Houston, TX*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

7503 **Oral Abstract Session**

First-line brentuximab vedotin plus chemotherapy to improve overall survival in patients with stage III/IV classical Hodgkin lymphoma: An updated analysis of ECHELON-1. *First Author: Stephen M. Ansell, Mayo Clinic, Rochester, MN*

Background: To date, an overall survival (OS) benefit from upfront treatment for new treatment combinations over existing approaches has rarely been shown in first-line classical Hodgkin lymphoma (cHL). With the introduction of newer active therapies for relapsed/refractory disease, demonstration of improved OS with first-line therapy has been challenging. In ECHELON-1 (NCT01712490), 5-year follow-up analyses supported the long-term progression-free survival (PFS) benefit with first-line brentuximab vedotin, doxorubicin, vinblastine, and dacarbazine (A+AVD) vs doxorubicin, bleomycin, vinblastine, and dacarbazine (ABVD) in patients (pts) with stage III/IV cHL, independent of interim positron emission tomography status. A+AVD had a manageable long-term safety profile, with numerically fewer second malignancies and a greater number of pregnancies reported vs ABVD (Connors et al, NEJM 2018; Straus et al, Lancet Haematol 2021). We report a prespecified OS analysis after approximately 6 years' follow-up (cut-off, June 1, 2021). **Methods:** Pts were randomized 1:1 to receive up to 6 cycles of A+AVD (n = 664) or ABVD (n = 670) on day 1 and 15 every 28 days. OS was the key secondary endpoint and was an event-driven, pre-specified, alpha-controlled analysis in the intention to treat population. **Results:** At a median follow-up of 73 months, 39 and 64 OS events occurred in A+AVD and ABVD arms, respectively: OS significantly favored A+AVD vs ABVD (HR 0.590; 95% confidence interval [CI] 0.396–0.879; p = 0.009). Estimated 6-year OS rates (95% CI) were 93.9% (91.6–95.5) vs 89.4% (86.6–91.7) with A+AVD vs ABVD, respectively. There was a consistent OS benefit for A+AVD vs ABVD across prespecified subgroups. The 6-year PFS estimate was 82.3% (79.1–85.0) vs 74.5% (70.8–77.7) with A+AVD vs ABVD, respectively (HR 0.678 [95% CI 0.532–0.863]). Overall, A+AVD had a comparable long-term safety profile to ABVD. Treatment-emergent peripheral neuropathy continued to resolve or improve in both arms, with 86% (379/443) and 87% (249/286) of cases in the A+AVD and ABVD arms either completely resolving (72% vs 79%) or improving (14% vs 8%) by last follow-up. Fewer second malignancies were reported in the A+AVD vs ABVD arm (23 vs 32). More female patients reported pregnancy (49 vs 28) or live births (42 vs 19 in females) in the A+AVD vs the ABVD arm; no stillbirths were reported. No new safety signals were identified. **Conclusions:** A+AVD treatment resulted in a statistically significant 41% reduction in the risk of death vs ABVD, with a manageable safety profile consistent with prior reports. These outcomes confirm A+AVD as a preferred option for pts with previously untreated stage III/IV cHL. Clinical trial information: NCT01712490. Research Sponsor: Takeda Development Center Americas, Inc. (TDCA).

Brentuximab vedotin and association with event-free survival (EFS) in children with newly diagnosed high-risk Hodgkin lymphoma (HL): A report from the Children's Oncology Group phase 3 study AHOD1331 (NCT 02166463).

First Author: Sharon M. Castellino, Emory University and Children's Healthcare of Atlanta, Atlanta, GA

Background: The anti-CD30 antibody drug conjugate, Brentuximab vedotin (Bv) is approved for adults with advanced stage HL but its use has not been established in children or adolescents. We compared the efficacy and safety of Bv with doxorubicin, vincristine, etoposide, prednisone and cyclophosphamide (Bv-AVE-PC) to the standard pediatric dose intensive regimen ABVE-PC, inclusive of bleomycin. **Methods:** This multicenter randomized, open-label phase 3 study enrolled patients 2-21 years (yrs) with previously untreated HL, stages IIB + bulk, IIIB, IVA, IVB. Patients were randomized to 5 cycles of either ABVE-PC or Bv-AVE-PC given every 21 days with granulocyte colony-stimulating factor support. Centrally reviewed PET-CT after 2 cycles (PET2) identified slow responding lesions (SRL) defined as Deauville score > 3. Involved site radiotherapy (ISRT) was given to bulky mediastinal adenopathy and SRL. The primary objective was 3-year EFS; events include relapse/progression, second malignant neoplasm (SMN) or death. Final data cutoff was 31 December 2021. **Results:** 600 participants were enrolled across 151 institutions from March 2015 to August 2019; 587 were eligible. Median age was 15.6 yrs (range 3.4-21). Patient and disease characteristics were balanced across study arms. Histology was nodular sclerosing in 76.5%. Stage distribution: 20.6% IIB-bulk; 19.3% IIIB; 28.5% IVA; 31.7% IVB. At a median follow-up of 42.1 mos (0.1-80.9), 3-year EFS (95%CI) by intent-to-treat analyses was 82.5% (77.4, 86.5) with ABVE-PC and 92.1% (88.4, 94.7) with Bv-AVE-PC (HR 0.41 (0.25, 0.67), p = 0.0002). Median time to 1st event was 9.4 months for both arms but the range differs by arm (3.6-57.8 ABVE-PC; 1.3, 25.8 Bv-AVE-PC). Relapse rate was 17% following ABVE-PC and 7% with Bv-AVE-PC. One SMN is noted in each arm: thyroid cancer at 57.8 mos and acute myeloid leukemia at 20.3 mos. 3-year overall survival (95%CI) was 98.5% (96.0, 99.4) for ABVE-PC and 99.3% (97.3, 99.8) for Bv-AVE-PC (p = 0.38). PET2 SRL rates were comparable (ABVE-PC 19% vs. Bv-AVE-PC 18%, p = 0.8). As-treated ISRT receipt did not differ (ABVE-PC 55.7% vs. Bv-AVE-PC 52.7%, p = 0.69). No difference in grade 3/4 adverse events was observed; myelosuppression, reflected in a 32% incidence of > grade 3 febrile neutropenia, did not differ by arm (p = 0.67). Only 19% of patients experienced > grade 2 neuropathy by the Balis pediatric neuropathy scale, with no difference between arms (p = 0.86). **Conclusions:** Brentuximab vedotin with AVE-PC in a dose intensive regimen has superior efficacy to ABVE-PC for pediatric patients with high-risk HL. A 59% risk reduction in EFS was achieved with no increase in toxicity and with fewer patients receiving ISRT compared to prior pediatric trials for high-risk HL. Clinical trial information: 02166463. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Racial disparities affecting Black patients with diffuse large B-cell lymphoma.

First Author: Daniel Arthur Ermann, Huntsman Cancer Institute-University of Utah Health Care, Salt Lake City, UT

Background: Diffuse Large B-cell Lymphoma (DLBCL) is the most common subtype of Non-Hodgkin Lymphoma, with the majority of patients (pts) achieving long-term survival due to the curative nature of frontline therapy. However, limited data exists regarding presentation and clinical outcomes for underrepresented minorities. In this study, we aimed to evaluate the influence of racial identity on overall survival (OS) outcomes for DLBCL pts. **Methods:** The National Cancer Database was used to identify DLBCL pts diagnosed from 2004-2018. Demographic and treatment characteristics were compared between racial groups. Kaplan-Meier and Cox regression analyses were used to compare OS between Black and white populations. Multivariate analysis and propensity score matching was performed with adjustment for age, stage, co-morbidity score, median income, and insurance status. **Results:** Of 223,709 DLBCL pts, 87% were white, 8% Black, and 5% other. As compared to white pts at diagnosis, Black pts were younger (mean 56 years [SD ± 16] vs. 66 years [SD ± 15]), more likely to have ≥1 co-morbidity (33% vs. 27%), be HIV-positive (26% vs. 5%), and have both B-symptoms (40% vs. 30%) and stage IV disease (42% vs. 37%) (All p<0.001). In terms of socioeconomic demographics, Black pts were more likely to be uninsured (8% vs. 3%) and be in the lowest median income quartile (43% vs. 15%), but were more likely to receive treatment at academic centers (50% vs. 36%) (all p<0.001). Both Black and white pts had similar IPI scores at diagnosis and were equally likely to receive multi-agent chemotherapy (77% vs. 77%, p<0.001). With a median follow up of 44.9 months, median OS for all treated HIV-negative DLBCL pts was 109 months (range 21-197). Compared to age-matched white pts, Black pts age ≤ 60 had worse median OS (46 vs. 76 months) along with 5- (73% vs. 75%) and 10-year OS (65% vs. 69%) (all p <0.001). Similar results were seen for Black and white pts between the ages of 61-79, but these differences were not demonstrated for pts ≥80 years old (Table). On multivariate analysis, Black race was independently associated with worse OS (HR 1.06, CI 1.01-1.10, p=0.02). Interestingly, the propensity matched analysis demonstrated no significant OS difference between Black and white pts (median 127 vs. 117 months; HR 1.0, CI 0.94-1.06; p=0.90). **Conclusions:** We present the largest study to date examining racial disparities in DLBCL. This data demonstrates that Black patients have significantly shorter OS compared to white patients, which persists on multivariate analysis. However, this disparity in survival became nonsignificant when patients are equally matched on surrogate markers of healthcare access such as insurance status and median income. Further studies into examining these racial differences are warranted to optimize care for all DLBCL patients. Research Sponsor: None.

Influence of racial and ethnic identity on overall survival in patients with chronic lymphocytic lymphoma.

First Author: Victoria Vardell, University of Utah, Salt Lake City, UT

Background: Chronic lymphocytic leukemia (CLL) is the most prevalent adult leukemia and results in highly variable clinical outcomes. Epidemiologically, CLL occurs in White ethnicity more frequently and thus, CLL outcomes among underrepresented minorities are not well studied. We sought to examine differences in treatment patterns and survival outcomes based on racial identity of CLL patients and how these have changed over time. **Methods:** The National Cancer Database was used to identify CLL patients diagnosed from 2004-2018. Demographic and treatment characteristics were compared between White, Black, Asian, Hispanic and other minority groups. Kaplan Meier and adjusted Cox regression survival analysis were used to compare overall survival (OS) between races. Survival analysis was repeated by year of diagnosis in Black and White populations. **Results:** Of 97,804 CLL pts identified, 90.7% of patients were White, 7.6% Black (N = 7,391), 2.6% Hispanic (N = 2,487), 0.6% Asian (N = 613), and 1.1% were other. Compared to White pts, Black pts were younger at diagnosis (median age 66 years [interquartile range 61-79] vs. 70 years [range 58-75], more likely to have ≥1 comorbidity (27.9% vs. 21.3%), and be uninsured (6.6% vs. 2.1%) (all p < 0.001). Black pts were more likely than White pts to have CLL directed treatment immediately after diagnosis (35.9% vs 23.6%; p < 0.001). With a median follow-up of 4.3 years, median OS for all CLL patients was 9.0 years (CI 8.9-9.1 years). Black pts had a shorter median OS of 7.0 years (CI 6.7-7.3 years) compared to White pts (9.14 years [CI 9.0-9.3]), p < 0.001), as well as inferior OS at 5-years (61% vs. 69%) and 10-years (36% vs. 46%), p < 0.001. On multivariate analysis adjusted for age and Charlson-Deyo score, Black race was independently associated with shorter OS (HR 1.51 [CI 1.46-1.57], p < 0.001). While OS lengthened with successive year of diagnosis for all races, the relative survival of Black compared to White pts did not improve over the observed time period. Referenced to the White population, Black pts diagnosed between 2004-2006 had a HR of 1.64 (CI 1.52-1.76) for mortality, and those diagnosed between 2016-2018 had a HR of 1.64 (CI 1.44-1.85). **Conclusions:** We present the largest study to date describing racial disparities in CLL. Black pts have significantly shorter OS compared to White pts, which is sustained when adjusted for the higher prevalence of comorbidities in the Black CLL population. Unfortunately, the survival gap between White and Black patients has not improved since 2004, highlighting the need for targeted research directed at improving survival in Black pts with CLL. Research Sponsor: U.S. National Institutes of Health.

	N	Median OS (Years)	95% CI	Adjusted HR	95% CI	P

A phase 1 study of ADI-001: Anti-CD20 CAR-engineered allogeneic gamma delta (γδ) T cells in adults with B-cell malignancies. *First Author: Sattva Swarup Neelapu, The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX*

Background: ADI-001 is a first-in-class allogeneic gamma delta (γδ) CAR T-cell therapy targeting the B-cell antigen CD20. ADI-001 also has both adaptive and innate cytotoxic effector functions to complement CAR targeting, potentially enhancing efficacy and reducing the possibility of tumor escape due to antigen loss. ADI-001 expresses MHC independent γδ T cell receptors, thus lowering the risk of graft versus host disease (GvHD) without the need for gene-editing. **Methods:** This phase 1 trial evaluates ADI-001 in adults with relapsed/refractory advanced B-cell lymphoma. Eligibility criteria included presence of measurable lesions, expression of CD20 and ≥ 2 prior systemic therapies. All patients received conditioning therapy with fludarabine and cyclophosphamide. ADI-001 is administered at 3 flat dose levels (DL; DL1:3E7, DL2:1E8, or DL3:3E8 cells) in a 3 + 3 dose-escalation scheme. Dose-limiting toxicities (DLT) were monitored during the initial 28-days post-treatment. Patients who completed the 28-day DLT period were considered evaluable. Treatment-emergent adverse events were graded by CTCAE v5.0, and immune effector cell toxicity assessment and grading were performed per ASTCT criteria. Objective response rates (ORR) were evaluated by independent radiographic review per Lugano 2014 criteria. **Results:** As of 14 February 2022, eight patients were enrolled and six were evaluable. Of these six patients, 2/6 were female (33%) and the median age was 62 years (range 45-75). The median number of prior therapies was 3.5 (range 2-5) and median IPI score was 3.5 (range 2-4). One patient received prior anti-CD19 CAR T cells therapy with lisocabtagene maraleucel. There were five patients with large B-cell lymphoma and one with mantle cell lymphoma. Among the six evaluable patients, three were treated on DL1 and three on DL2. Most related AEs (78%) were of grade 1/2. There were three AESI: two CRS (one grade 1 and one grade 2) and one grade 1 ICANS, and the only related SAEs were the grade 2 CRS and grade 1 ICANS. There was no reported GvHD and no protocol defined DLT events. At day 28, the ORR based upon PET/CT was 67% (4/6 patients) and the CR rate was 67% (4/6 patients). Both patients with ≥ 3 months post-treatment follow-up remained in CR. Additional data will be presented at the meeting. **Conclusions:** ADI-001 γδ CAR T cells were well tolerated, with a favorable safety profile and encouraging preliminary efficacy. Patients who achieved CR at day 28 appeared to be disease free during further follow-up at month-3. Clinical trial information: NCT04735471. Research Sponsor: Adicet Bio.

Zanubrutinib plus obinutuzumab (ZO) versus obinutuzumab (O) monotherapy in patients (pts) with relapsed or refractory (R/R) follicular lymphoma (FL): Primary analysis of the phase 2 randomized ROSEWOOD trial. *First Author: Pier Luigi Zinzani, Institute of Hematology "Seràgnoli", University of Bologna, Bologna, Italy*

Background: FL is the most common type of indolent non-Hodgkin lymphoma. Approved treatment options are limited for pts with R/R FL. In a phase 1b trial (*Blood Adv.* 2020;4(19):4802-4811), ZO was found to be tolerable and associated with early signal of efficacy. ROSEWOOD (BGB-3111-212) is a phase 2, randomized study designed to assess efficacy and safety of ZO vs O in pts with R/R FL. **Methods:** Pts with R/R FL who received ≥2 lines of therapy, including an anti-CD20 antibody and an alkylating agent, were randomized 2:1 to receive either ZO or O. O was given in both arms on Days 1, 8, and 15 of Cycle 1, Day 1 of Cycles 2-6, and then every 8 weeks up to 20 doses maximum. Z (160 mg twice daily) was given until progressive disease (PD) or unacceptable toxicity; Pts with confirmed PD in the O arm were allowed to crossover to ZO. Primary endpoint was overall response rate (ORR) by independent central review. Secondary endpoints included complete response rate (CRR), duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety. Exploratory endpoint included ORR by investigator after crossover. Primary analysis cutoff was October 8, 2021. **Results:** A total of 217 pts were randomized to ZO (n = 145) or O (n = 72). Median study follow-up was 12.5 mo; median age was 64 yrs. Incidence of high FL International Prognostic Index score was 53% (ZO) and 51% (O). Pts received a median of 3 prior lines of therapy, with 28% (ZO) and 25% (O) of pts receiving > 3 lines. Proportion of pts refractory to rituximab, refractory to the most recent line of therapy, or with PD within 24 mo of initiation of first-line immunochemotherapy was 54%, 32% and 28% with ZO and 50%, 40% and 32% with O, respectively. The study met its primary endpoint: ORR was 68.3% with ZO vs 45.8% with O (p= 0.0017). CRR was 37.2% (ZO) vs 19.4% (O); 18-mo DOR rate was 70.9% (ZO) vs 54.6% (O); and median PFS was 27.4 mo (ZO) vs 11.2 mo (O; hazard ratio [HR], 0.51 [95% CI, 0.32-0.81], p= 0.0040). Median time to new anti-lymphoma therapy or crossover was not evaluable (NE; ZO) vs 12.1 mo (O; HR, 0.37 [95% CI, 0.23-0.60], p< 0.0001). ORR for 29 pts who crossed over to ZO was 24.1%. Median OS was NE; 18-mo OS probability was 85.4% (ZO) vs 72.6% (O). Most common any grade AEs in the ZO arm were thrombocytopenia (34.3%), neutropenia (27.3%), diarrhea (16.1%), fatigue (14.0%), constipation (13.3%), cough (11.9%), pyrexia (11.2%), and dyspnea (10.5%). Grade ≥3 AEs with incidence > 5% with ZO were neutropenia (22.4%) and thrombocytopenia (14.0%); incidence of atrial fibrillation was 0.7% and major bleeding was 1.4%. Incidence of treatment-emergent AEs leading to death was 5.6% (ZO) and 9.9% (O). **Conclusions:** ZO demonstrated superior efficacy to O in treatment of pts with R/R FL. ZO had a favorable benefit-risk profile and represents a potential combination therapy for pts with R/R FL. Clinical trial information: NCT03332017. Research Sponsor: BeiGene USA, Inc.

7511 **Poster Discussion Session**

Efficacy and safety of zandelisib administered by intermittent dosing (ID) in patients with relapsed or refractory (R/R) follicular lymphoma (FL): Primary analysis of the global phase 2 study TIDAL. *First Author: Andrew David Zelenetz, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Zandelisib, a PI3Kδ inhibitor with high target-binding affinity, is administered by intermittent dosing (ID) on days 1-7 of 28-day cycles to potentially enable regulatory T-cell repopulation and lower the risk of immune adverse events (irAEs) seen with continuous PI3Kδ inhibition. In a phase 1b study in 37 patients (pts) with R/R FL, zandelisib daily for two 28-day cycles for tumor debulking then on ID achieved an overall response rate (ORR) of 87% (78% single agent and 95% with rituximab) with < 10% irAEs (Pagel et al. ICML 2021; #113). We conducted the TIDAL study to further evaluate zandelisib in R/R indolent lymphomas (NCT03768505). **Methods:** Eligible pts ≥18 years with FL Grade I-IIIA, progressive disease after ≥2 prior therapies, and no prior PI3K inhibitor, gave consent and received zandelisib 60 mg daily for 2 cycles then on ID. Not reported here are an arm randomizing pts to zandelisib daily continuously, closed to enrollment early, and an actively enrolling arm in R/R marginal zone lymphoma (MZL). The planned FL sample size was 120 pts on ID, with the primary efficacy population (PEP) pre-defined as the first 91 pts treated. The primary efficacy endpoint was ORR by the Lugano criteria in the PEP as assessed by independent review and analyzed after a minimum 6-month follow-up. **Results:** 121 FL pts were enrolled. In the PEP (N = 91), the median number of prior therapies was 3 (range 2-8), 21 pts (23%) had received prior stem cell transplant, 42 (46%) had disease refractory to last therapy, 31 (34%) had tumors ≥5 cm, and 51 (56%) were POD24. Overall response rate was 70.3% (n = 64) (95% CI 59.8-79.5%) and complete response rate was 35.2% (n = 32) (95% CI 25.4-45.9%). Responses occurred early with 87.5% (n = 56) of responses observed at the end of Cycle 2 and 75% (n = 24) of CRs at the end of Cycle 4. The data are still immature to estimate accurately the duration of response (DOR). With a median follow-up of 9.4 months (range 0.8-24) for all 121 pts, 12 pts (9.9%) discontinued therapy due to any drug-related AE. Grade 3 AEs of special interest (AESI) were diarrhea in 6 pts (5%), colitis in 2 (1.7%), rash in 4 (3.3%), stomatitis in 3 (2.5%), and 1 (0.8%) each for AST and ALT elevation, and non-infectious pneumonitis. Grade 3 AESIs primarily (15 of 18, 83%) occurred in cycles 1-3, during daily dosing. **Conclusions:** Zandelisib on ID achieved high ORR and CR rate in heavily pretreated FL pts, and was associated with < 10% of discontinuations due to drug-related AEs and grade 3 AESI, results comparable to the Phase 1b study. Longer follow-up is needed to estimate median DOR. This profile supports evaluation of zandelisib alone and in combination in various B-cell malignancies, both in relapsed disease and earlier lines of therapy. Zandelisib plus rituximab vs chemoimmunotherapy is being studied in the phase 3 trial COASTAL in R/R FL and MZL (NCT 04745832). Clinical trial information: NCT03768505. Research Sponsor: MEI Pharma, Inc.

7512 **Poster Discussion Session**

Subcutaneous rituximab induction followed by short rituximab maintenance to improve progression-free survival in patients with low-tumor burden follicular lymphoma: Final results of FLIRT phase III trial, a LYSA study. *First Author: Guillaume Cartron, CHU de Montpellier, Montpellier, France*

Background: In low–tumor burden follicular lymphoma (FL), maintenance rituximab (MR) has been shown to improve progression-free survival (PFS) when compared with observation. RESORT study (Kahl et al. 2014) clearly showed that Rituximab (R) retreatment strategy provided similar time to treatment failure that maintenance strategy with less rituximab use. It is not known whether short MR using sub-cutaneous (sc) route could improve PFS while reducing R infusions. **Methods:** Patients with the diagnosis of low-tumor burden FL (GELF criteria) within the last 4 months before signing informed consent were randomly assigned to either Iv-Arm : 4-weekly iv infusions of R 375 mg/m^2 or Sc-Arm: one iv infusion of R (D1, 375 mg/m^2) followed by 3 sc infusions of R (1400 mg, on days 8, 15 and 22) followed by Rsc maintenance on months (M) 3, 5, 7 and 9. The primary endpoint was PFS and secondary endpoints included safety, response rates (M3, M12), duration of response (DOR), time to next anti-lymphoma treatment (TTNTL) and overall survival (OS). **Results:** A total of 202 patients were included, 102 in Iv-Arm and 100 in Sc-Arm and constitute the intent to treat population. The median uses of R were 4 infusions (range: 1-4, Iv-Arm) and 8 infusions (range: 2-8, Sc-Arm). With a median follow-up of 50.2 months (95% CI: 48.3-54.5), 4-year PFS was 41.2% (95% CI: 30.6%; 51.6%) in Iv-Arm and 58.1% (95% CI: 47.5%; 67.4%) in Sc-Arm. Median PFS was then 36.1 months (95% IC: 23.9-52.6) in Iv-Arm and 73.8 months (95% CI: 39.4-NA) in Sc-Arm (Fig 1.) (HR: 0.58; 95% CI: 0.39-0.87; P = 0.0076). Patients with at least one AE grade ≥ 3 were 8 (7.8%) and 12 (12.4%) in Iv-Arm and Sc-Arm, respectively. According to Cheson criteria, ORR at M3 were: 83% and 80% including 38% and 29% of CR/CRu, in Iv-Arm and Sc-Arm, respectively. According to Lugano criteria, 36.3% (Iv-Arm; 95% CI: 27.0%. 46.4%) and 59.0% (Sc-Arm; 95% CI: 48.7%; 68.7%) were in CMR at M12. The median DOR was 32.7 months (95% IC: 20.6-49.7) and 70.8 months (36.4-NR) (HR: 0.56; 95% IC: 0.37-0.84) in Iv-Arm and Sc-Arm, respectively. 4-year TTNLT was 54% (95% CI: 42.9%; 63.8%) in Iv-Arm and 61.8% (95% CI: 50.8.6%; 71.0%) in Sc-Arm (HR: 0.81, 95% IC: 0.53-1.24). 4-year TTNLT chemotherapy was 60.8 % (95% CI: 49.6%; 70.3%) in Iv-Arm and 71.4% (95% CI: 60.7%; 79.8%) in Sc-arm (HR: 0.69, 95% IC: 0.42-1.12) (Fig 2.). OS was not different according to treatment arm, 4-year OS was 95.0% (95% CI: 88.5%; 97.9%) in Iv-Arm and 96.7% (95% CI: 89.9%; 98.9%) in Sc-Arm. **Conclusions:** This phase III study met its primary endpoint and demonstrated that Rsc induction followed by a short MRsc improves PFS of patients with low-tumor burden. MRsc did not however improved TTNLT. R in low-tumor burden FL allowed to avoid cytotoxic use in most patients 6 years after treatment initiation. Clinical trial information: NCT02303119. Research Sponsor: LYSA, Pharmaceutical/Biotech Company.

7513 **Poster Discussion Session**

Interim results of a phase II multicenter study with the oral histone deacetylase inhibitor abexinostat in patients with relapsed/refractory follicular lymphoma. *First Author: Lin Gui, National Cancer Center/ National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, Beijing, China*

Background: Follicular lymphoma (FL) is generally considered incurable with patients (pts) often experiencing multiple relapses requiring varying lines of subsequent treatments. Abexinostat (Abx) is a novel potent oral pan- Histone Deacetylase Inhibitor (HDACi) with a pharmacokinetic profile that allows maintenance of sufficient drug concentrations for anti-tumor activity with twice daily (BID) dosing. In prior phase 1/2 studies, Abx was shown to be well-tolerated with significant clinical activity and durable responses in patients with Relapsed/Refractory (R/R) FL. **Methods:** This open label, single arm study is being conducted to assess the efficacy and safety of Abx in pts with R/R FL. Adults with histologically confirmed grade 1, 2 or 3a FL who have previously received at least 2 lines of therapies, and ECOG PS of 0-2 are being recruited. Abx is administered orally at 80 mg BID 4 hours apart in "one week on, one week off" schedule (Days 1 to 7 & 15 to 21 of a 28-day cycle). Pts undergo efficacy assessment by enhanced CT/MRI every 8 weeks for the first 24 weeks, and every 12 weeks thereafter, and PET-CT at weeks 12 and 24 and to confirm a complete response, in accordance with the Lugano 2014 criteria. The primary endpoint is overall response rate (ORR) assessed by independent review committe (IRC), defined as the % of pts who achieve complete response (CR) or partial response (PR). Secondary endpoints include duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety. In a planned interim futility analysis conducted with the first 37 pts, if <12/37 (32%) responded (CR or PR), the study was to be terminated. **Results:** Between June 17, 2020 and Jan 28, 2022, 41 pts received Abx. 37 pts underwent at least one post baseline tumor assessment. Median age was 55 (range 34 – 79), 46% of pts were male, 70% had stage IV disease and 24% had >3 FLIPI-2. Pts had a median of 3 prior lines of therapy (range 2-6), and 22% were refractory to the last prior treatment. As of the data cutoff date on Jan 31, 2022, of 37 pts evaluable for efficacy, the ORR was 70% (26/37 pts), 16% CR (6/37) and the disease control rate was 92% (34/37). The median time to response was 10.8 weeks. The study has met the pre-defined stage I criteria and has entered stage II, aiming to enroll up to 81 evaluable pts. Of 41 pts evaluable for safety, the most common treatment emergent adverse events (TEAEs) (≥ 30%) were thrombocytopenia (85%), diarrhea (61%), neutropenia (54%), leukopenia (49%), asthenia (39%), nausea (37%), and anemia (34%). Grade ≥ 3 TEAEs (≥ 5%) included thrombocytopenia (41%), neutropenia (27%), leukopenia (7%), lymphopenia (7%), prolonged QT (7%), and anemia (5%). One pt discontinued treatment due to AEs. **Conclusions:** Oral Abx demonstrated promising efficacy and was well tolerated in patients with R/R FL. Clinical trial information: NCT03934567. Research Sponsor: Xynomic Pharmaceuticals, Inc.

7514 **Poster Discussion Session**

Real-world outcomes of brentuximab vedotin maintenance after autologous stem cell transplant in relapsed/refractory classical Hodgkin lymphoma: Is less enough? *First Author: Charlotte Wagner, Huntsman Cancer Institute-University of Utah, Salt Lake City, UT*

Background: The AETHERA trial demonstrated improvement in PFS with 16 cycles of brentuximab vedotin (BV) after autologous stem cell transplant (ASCT) in BV-naive patients with high-risk relapsed/refractory classical Hodgkin lymphoma (r/r cHL). However, in real world, patients are rarely able to complete all 16 cycles of BV at full dose. We performed a multicenter retrospective study to assess the impact of cumulative dose on toxicity and 2-year PFS. **Methods:** Patients from 11 institutions across the US who had received at least one cycle of BV maintenance after ASCT for r/r cHL with one of these features were included: primary refractory disease (PRD), extra-nodal disease (END), or relapse < 12 months of diagnosis (RL<12). PFS was compared between the three cohorts based on a total cumulative dose of 28.8 mg/kg (1.8 mg/kg x 16 cycles): C1, those that received >75% (21.7 to 28.8 mg/kg) cumulative dose of BV, C2, those that received between 51% -75% (14.5 to 21.6 mg/kg) dose and C3, those that received ≤ 50% (≤ 14.4 mg/kg) dose. **Results:** Between July 2015-June 2019, 100 patients with a median age of 34 years (19-70) underwent ASCT for r/r cHL. At relapse, 44% had PRD, 47% had RL<12, 39% had END and 45% had received BV as initial (1%) or salvage (44%) therapy. 71% had CR before ASCT and 23% received >1 line of salvage (>1 SLT). There was no difference in baseline characteristics between the cohorts. Thirty-six patients were in C1, 27 in C2, and 37 in C3. Only 14% of patients received full cumulative dose of BV. The median number of cycles completed was 12. Fifty-seven patients discontinued early: 39 for toxicity, 7 for progression, 5 for patient preference, 2 for cost and 4 for other reasons. Six of the patients who stopped early for progression were in C3. Grade ≥3 adverse events for neuropathy, neutropenia, and infections were 16%, 7%, and 5% respectively. There was no difference in severity of neuropathy in patients who had received BV prior to ASCT (p=.37). The median follow up was 3.37 years (.4–6.35). The 2-year PFS was 85% for all subjects, 94% for C1, 84% for C2, and 72% for C3 (p=.079) (Table). Patients in C3 had worse PFS compared to C1 (p=.035); this difference remained significant after adjusting for five other factors. There was no difference in PFS between C1 and C2 (p=.29). **Conclusions:** The majority of patients discontinued BV maintenance early due to toxicity. 2-year PFS was robust regardless of cumulative dose of BV. We conclude that total cumulative dose of 28.8 mg/kg of BV maintenance is not necessary and 51%-75% of total BV dose may still attain a similar PFS advantage. Research Sponsor: None.

Outcomes of classic Hodgkin lymphoma, relapsed within one year of diagnosis, in the era of novel agents. *First Author: Sanjal Desai, University of Minnesota, Minneapolis, MN*

Background: Primary refractory disease (PRD) and early relapse (ER) are predictors of poor prognosis in classic Hodgkin lymphoma (cHL). In this multicenter retrospective study, we describe outcomes of PRD and ER in pts with relapsed/refractory (R/R) cHL treated with salvage therapy (ST) and autologous stem cell transplant (ASCT). **Methods:** Of 14 sites, adult patients with R/R cHL who received ST and underwent ASCT were enrolled. PRD was defined as progression on frontline chemoimmunotherapy or within 6 months of diagnosis. ER was defined as relapse from 6 months-1 yr of diagnosis. Pts who relapsed >1 yr of diagnosis were called late relapses (LR). Study objectives were Overall response rates (ORR), CR rates, PFS, and OS. **Results:** Of 986 total pts, 160 had PRD, 365 had ER and 461 had LR. Significantly higher number of pts with PRD, but not ER, had bulky disease (41% vs 27%, p<0.01) and B symptoms (53% vs 38%, p<0.001) than LR. Higher proportions of pts with PRD and ER required >1 line of ST (44% vs 30% vs 23%, p<0.001) before ASCT and received BV maintenance (25% vs 24% vs 16%, p<0.05). When adjusted for B symptoms and Bulky disease, PRD and ER had significantly lower ORR (65% vs 76% vs 84%, p<0.001) and CR (37% vs 46% vs 57%, p<0.001) to first ST than LR. Pts with PRD and ER had significantly lower PFS (56.3%, 61.4%, vs 77.6%, p<.0001) and OS (93% vs 89% vs 94%, p=0.01) than LR. In pts with ER, Brentuximab/bendamustine (BBV) and brentuximab vedotin/nivolumab (BV/nivo) had a trend towards higher ORR (92% vs 92% vs 75%) but significantly higher CR (79.2% vs 76% vs 42%, p<0.01) than platinum based chemotherapy (PBC). In pts with PRD, BBV and BV/Nivo had a statistically insignificant trend towards higher ORR and CR than PBC. The table shows 2 yr PFS by type of ST in PRD, ER, LR. There was no difference in PFS by time to relapse in BV/nivo, CPI and miscellaneous agents. BV/Nivo had a significantly higher PFS than PBC in PRD (88% vs 48%, p<0.05) and ER (95% vs 57%, p<0.05). There was no difference in PFS of PBC and other ST in PRD, ER or LR. OS was not significantly associated with type of ST in either group. **Conclusions:** PRD and ER are associated with lower response to ST and survival after ASCT compared to late relapse. In pts with PRD and ER, BV/Nivo has high ORR and CR and leads to significantly higher PFS comparable to pts with late relapse and may be preferable ST regardless of time to relapse. Research Sponsor: None.

Favezelimab (anti–LAG-3) plus pembrolizumab in patients with anti–PD-1–naive relapsed or refractory (R/R) classical Hodgkin lymphoma (cHL): An open-label phase 1/2 study. *First Author: Nathalie A. Johnson, Jewish General Hospital, Montréal, QC, Canada*

Background: PD-1 inhibitors are a standard of care in pts with R/R cHL but new approaches are still needed to deepen and lengthen responses. Dual blockade of PD-1 and LAG-3 has demonstrated antitumor activity in preclinical models. The multicohort phase 1/2 MK-4280-003 study (NCT03598608) evaluated the safety and efficacy of favezelimab (MK-4280), a humanized IgG4 LAG-3 inhibitor, plus pembrolizumab (pembro; a PD-1 inhibitor) in pts with R/R hematologic malignancies. This analysis focused on anti–PD-1–naïve pts with R/R cHL (cohort 1). **Methods:** This study included a safety lead-in phase (part 1) to determine the recommended phase 2 dose (RP2D) followed by a dose-expansion phase (part 2). Eligible pts in cohort 1 must have R/R cHL after autologous stem cell transplantation (ASCT) or be ineligible for ASCT and have had no prior anti–PD-1 therapy. In part 1, patients from all cohorts received pembro IV 200 mg Q3W and favezelimab IV 200 mg or 800 mg Q3W. Dose escalation followed the mTPI design. In part 2, pts received pembro + favezelimab at the established RP2D for up to 35 cycles. Primary end point was safety. Secondary end point was ORR. DOR, PFS, and OS were exploratory end points. **Results:** Only 1 dose-limiting toxicity (DLT; autoimmune hepatitis [grade 4]) was identified among the first 6 pts from all cohorts in part 1 at the favezelimab 200 mg dose; thus, the dose was escalated to 800 mg. No DLTs were observed in the 15 additional pts treated at the 800 mg dose. The RP2D for the combination was defined as 800 mg Q3W + pembro 200 mg Q3W. In cohort 1, 30 pts were enrolled; median age was 40 years, 53% had ECOG PS 0, and 80% had ≤3 prior lines of therapy. After a median follow-up of 13.5 mo, ORR for cohort 1 was 73% (95% CI, 54-88; CR, 7 pts [23%]; PR, 15 pts [50%]). 28 of 30 pts (93%) had reduction from baseline in target lesions. Median DOR was not reached (NR; 95% CI, 0+ to 23+ mo); 6 pts (51%) had response ≥12 mo. Median PFS was 19 mo (95% CI, 8-NR); 12-mo PFS rate was 57%. Median OS was NR (95% CI, NR-NR); 12-mo OS rate was 94%. As of the database cutoff (Nov 1, 2021), 9 of 30 pts had discontinued (3 AEs; 6 PD). Treatment-related AEs (TRAE) occurred in 26 pts (87%); most common (≥10%) were hypothyroidism (27%), fatigue (20%), infusion-related reactions (20%), headache (17%), and arthralgia, hyperthyroidism, myalgia, and nausea (10% each); grade 3 or 4 TRAEs occurred in 6 pts (20%). 10% of pts discontinued due to TRAEs. No treatment-related deaths occurred. **Conclusions:** Favezelimab 800 mg + pembrolizumab 200 mg Q3W demonstrated a tolerable safety profile and effective antitumor activity in pts with anti–PD-1–naïve R/R cHL. Further studies will be useful to compare its activity to that of pembrolizumab alone. Clinical trial information: NCT03598608. Outcomes by BCL2 and MYC expression and rearrangements in untreated diffuse large B-cell lymphoma (DLBCL) from the POLARIX trial.

First Author: Franck Morschhauser, Lille University Hospital Center, Lille Cedex, France

Background: Overexpression of BCL2 and MYC, and translocation of *MYC*, *BCL2*, and *BCL6*, are associated with poorer outcomes in patients (pts) with DLBCL (Horn et al. Blood 2013). We previously reported progression-free survival (PFS) from POLARIX in subgroups of pts with DLBCL receiving Pola-R-CHP or R-CHOP, including pts with double expressor lymphoma (DEL; favoring Pola-R-CHP: hazard ratio [HR] 0.64, 95% confidence interval [CI] 0.42–0.97), and double- or triple-hit lymphoma (DHL/THL; favoring R-CHOP: HR 3.81, 95% CI 0.82–17.64) (Tilly et al. NEJM 2022). In this prespecified exploratory analysis, we further analyzed immunohistochemistry (IHC) expression status of BCL2, MYC, and rearrangements (R) of *BCL2*, *BCL6* and *MYC* as independent prognostic markers. We also explored the prognostic impact of DEL within treatment arms. **Methods:** BCL2 and MYC protein expression were assessed by IHC and identified as IHC+ (≥50% [BCL2]/≥40% [MYC]) or IHC−; *MYC*-R, *BCL2*-R, and *BCL6*-R were detected by fluorescence in situ hybridization (Tilly et al. NEJM, 2022). Exploratory multivariate Cox regression models were adjusted for treatment, stratification factors (IPI, bulky disease, geographic region), age >60 years, cell of origin, and biomarker evaluated, as appropriate. **Results:** The prevalence, univariate HR, and 2-year (yr) PFS estimates of BCL2+/MYC+ and *BCL2*-R/*MYC*-R/*BCL6*-R subgroups are presented (Table) except for *BCL6*-R, because all 4 PFS events in this subgroup were with Pola-R-CHP. Multivariate analyses results for Pola-R-CHP vs R-CHOP in pts with BCL2+ (HR 0.60, 95% CI 0.43–0.86) and in pts with MYC+ (HR 0.63, 95% CI 0.45–0.89) were similar to results of univariate analyses. Multivariate analyses of other subgroups were not performed due to the low pt number with *BCL2*-R/*MYC*-R/*BCL6*-R. While pts with DEL treated with Pola-R-CHP had improved PFS vs pts treated with R-CHOP (HR 0.64, 0.42–0.97), the prognostic impact of DEL vs non-DEL was more pronounced with R-CHOP (univariate HR 1.53, 95% CI 1.06–2.21; multivariate HR 1.29, 95% CI 0.88–1.91) vs Pola-R-CHP (univariate HR 1.10, 95% CI 0.72–1.69; multivariate HR 1.42, 95% CI 0.89–2.28). **Conclusions:** Multivariate analyses support the benefit of Pola-R-CHP in pts with BCL2+ and MYC+ DLBCL. The poor prognostic impact associated with DEL appears reduced in Pola-R-CHP- vs R-CHOP-treated pts. Clinical trial information: NCT03274492. Research Sponsor: POLARIX is sponsored by F. Hoffmann-La Roche Ltd and Genentech, Inc. Third-party medical writing assistance, under author direction, was provided by Carla Smith of Ashfield MedComms, and was funded by F. Hoffmann-La Roche Ltd.

Three-year follow-up of outcomes with KTE-X19 in patients with relapsed/refractory mantle cell lymphoma in ZUMA-2.

First Author: Michael Wang, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Brexucabtagene autoleucel (KTE-X19) is an autologous anti-CD19 chimeric antigen receptor (CAR) T-cell therapy approved for the treatment of patients (pts) with relapsed/refractory (R/R) mantle cell lymphoma (MCL). In ZUMA-2, a 93% objective response rate (ORR; 67% complete response [CR] rate) was reported with KTE-X19 in pts with R/R MCL (median follow-up: 12.3 mo; 60 efficacy-evaluable pts; Wang et al. *N Engl J Med*. 2020). Here, we present updated outcomes with 2 years of additional follow-up. **Methods:** Adult pts (≥18 years) with R/R MCL underwent leukapheresis and conditioning chemotherapy followed by a single infusion of KTE-X19. Minimal residual disease (MRD) was an exploratory endpoint (sensitivity 10-5) evaluated in peripheral blood using next-generation sequencing. Updated results are reported for all 68 treated pts. **Results:** After 35.6 mo median follow-up, the ORR (CR + partial response) was 91% (95% CI, 81.8-96.7), with a 68% CR rate (95% CI, 55.2-78.5). The median duration of response (DOR) was 28.2 mo (95% CI, 13.5-47.1), with 25 of 68 treated pts (37%) still in ongoing response (all CR) at data cutoff. Late relapse > 24 mo post-infusion was infrequent (n = 3). The medians for progression-free survival (PFS) and overall survival (OS) were 25.8 mo (95% CI, 9.6-47.6) and 46.6 mo (95% CI, 24.9-not estimable), respectively. MRD was analyzed in 29 pts total; 24 of 29 were MRD-negative at mo 1, and 15 of 19 with available data were MRD-negative at mo 6. At data cutoff, the medians for DOR, PFS, and OS in the 15 MRD-negative pts were all not reached, vs 6.1, 7.1, and 27.0 mo, in the 4 MRD-positive pts, respectively. MRD-negative status at mo 1, 3, and 6 was associated with durable response, with 55%, 71%, and 69% of MRD-negative pts at those timepoints remaining in ongoing CR at data cutoff. Circulating tumor DNA analysis of MRD at mo 3 and 6 was predictive of relapse (AUC 0.80 and 0.75, respectively). No new safety signals were observed. Only 3% of treatment-emergent adverse events (AEs) of interest occurred since the primary report. The most frequent Grade ≥3 AE was neutropenia (1 [1%] Grade 3; 7 [10%] Grade 4). Two pts had KTE-X19-related Grade 3 serious infections: pneumonia and upper respiratory tract infection (n = 1); influenza (n = 1). There were no new cytokine release syndrome AEs and 1 new serious neurologic AE of Grade 3 encephalopathy (13.0 mo post-infusion) that was considered not related to study treatment. Three new Grade 5 AEs occurred, none of which were considered related to study treatment: *Salmonella* bacteremia (24.9 mo post-infusion), myelodysplastic syndrome (25.2 mo post-infusion), and acute myeloid leukemia (37.5 mo post-infusion). **Conclusions:** These data represent the longest follow-up of CAR T-cell therapy in pts with MCL to date and suggest that KTE-X19 induces durable long-term responses with manageable safety and low late relapse potential in R/R MCL. Clinical trial information: NCT02601313. Research Sponsor: Kite, a Gilead Company.

7519 **Poster Discussion Session**

Fixed-duration (FD) ibrutinib (I) + venetoclax (V) for first-line (1L) treatment (tx) of chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL): Three-year follow-up from the FD cohort of the phase 2 CAPTIVATE study.

First Author: William G. Wierda, Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: CAPTIVATE (PCYC-1142) is a multicenter phase 2 study of 1L I+V in CLL. The primary analysis (PA) evaluating FD tx with I+V was previously presented (Ghia et al., ASCO 2021). Here we present 3-y follow-up results from the FD cohort. **Methods:** Patients (pts) aged ≤70 y with previously untreated CLL/SLL received 3 cycles of I then 12 cycles of I+V (I 420 mg/d orally; V ramp-up to 400 mg/d orally). Responses were investigator assessed per iwCLL 2008 criteria. Undetectable minimal residual disease (uMRD; $<10^{-4}$) was measured by 8-color flow cytometry. Serious AEs (SAEs) deemed related to I reported >30 d after last dose of study drug were collected. **Results:** 159 pts were enrolled (median age 60 y), including pts with high-risk features of del(17p)/*TP53* mutation (17%), unmutated IGHV (uIGHV; 56%), and complex karyotype (19%). 147 (92%) and 149 (94%) pts completed tx with I and V, respectively. With 1 y of additional follow-up since PA, median time on study was 39 mo (range 1-41). ORR was 96% and was consistent (96%-97%) in pts with high-risk features (Table).The primary endpoint of complete response (CR) including CR with incomplete bone marrow recovery (CRi) rate in pts without del(17p) (n=136) increased nominally from 56% (95% CI, 48-64) to 58% (95% CI 50-66); in all pts, CR rate increased from 55% (95% CI 48-63) to 57% (95% CI 50-65). In pts achieving CR, 93% had durable responses lasting ≥12 mo post-tx. Of pts with uMRD in peripheral blood at 3 mo post-tx, 66/85 (78%) evaluable pts maintained uMRD through 12-mo post-tx. At 36 mo, PFS was 88% (95% CI 82–92) and OS was 98% (95% CI 94–99); similar rates were seen in pts with high-risk features (Table). All pts are off tx; no new SAEs of any kind have occurred since the PA. Available data on relevant mutations in *BTK*, *PLCγ2*, or *BCL-2* at time of PD will be presented. As of January 2022, 12 pts were retreated with single-agent I after PD (tx duration range 3-29 mo); of evaluated pts, 7/9 had partial responses and 2/9 had stable disease. **Conclusions:** Fixed duration I+V continues to provide deep, durable responses and clinically meaningful PFS, including in pts with high-risk disease features, representing an all-oral, once-daily, chemotherapy-free FD regimen for previously untreated pts with CLL/SLL. With an additional 1 y of follow-up, no OS events or SAEs occurred. Manageable safety profile is unchanged as previously reported. To date, successful single-agent I retreatment responses are observed. Clinical trial information: NCT02910583. Research Sponsor: Pharmacyclics LLC, an AbbVie Company.

Phase 1/2 study of zilovertamab and ibrutinib in mantle cell lymphoma (MCL) or chronic lymphocytic leukemia (CLL).

First Author: Hun Ju Lee, The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX

Background: Zilovertamab (Zilo) is a humanized monoclonal antibody that inhibits the tumor promoting activity of ROR1 and has demonstrated additive/synergistic activity with many anticancer agents, including ibrutinib (Ibr). **Methods:** Patients (Pts) with relapsed or refractory (RR) MCL or treatment-naïve (TN) or RR CLL were enrolled. In Part 1 (Dose Escalation), multiple doses were examined. Zilo 600 mg IV starting q2wks x3 then q4wks + Ibr qD was selected as the recommended dosing regimen for use in Part 2 (Expansion) and Part 3 (CLL only, Zilo+Ibr vs. Ibr alone). **Results:** As of 18Jan2022 data cutoff, 26 evaluable RR MCL pts, including pts who received prior Ibr (5) or auto-SCT (7), and 34 evaluable CLL pts (12 TN and 22 RR) were enrolled into Parts 1&2. In Part 3, 22 evaluable pts were randomized (2:1) to receive either Zilo+Ibr (15) or Ibr (7). Safety: Treatment-emergent adverse events (TEAEs) (≥30%, N = 84), regardless of relationship, included fatigue (41.7%), contusion (39.3%), and diarrhea (38.1%). Most common (≥5%) Grade ≥3 TEAEs included hypertension (10.7%), pneumonia (7.1%), atrial fibrillation, fatigue, and neutropenia (all 6.0%). Grade ≥3 neutrophil decrease observed in 9.4% or 17.6%, platelet decrease in 12.5% or 2.9%, or hemoglobin decrease in 9.4% or 0% of pts with MCL or CLL, respectively in Parts 1&2. Investigators scored TEAEs as due to Ibr in 78.1% or 85.3%, or to Zilo in 15.6% or 23.5% of pts with MCL or CLL, respectively. Efficacy (MCL): Objective response rate (ORR) was 80.8% (34.6% CR, 46.2% PR). ORR for pts with prior Ibr was 80% (2CR, 2PR) and median duration of response (mDOR) was 13.7 months (M) (95%CI: 11.93, NE). ORR was 100% in pts who had prior SCT+/- CAR-T (5CR, 2PR), and mDOR was 34.1 M (95% CI 13.84, NE). Overall median PFS (mPFS) was 35.9 M (95% CI: 17.3, NE) at median follow-up of 15.0 M. For MCL pts with *TP53* aberrancy (6), Ki67 > 30% (13), ≥ 3 prior lines of therapies (4), blastoid histology (3), bulky disease ≥5 cm (4), intermediate MIPIb (6), or high MIPIb (11), the mPFS (in M) was 17.3 (95% CI: 2.85, NE), Not Reached (NR) (95% CI: 2.85, NE), 35.9 (95% CI: 16.52, NE), NR (min 9.18, max 27.87), 26.6 (95% CI: 0.03, NE), 35.9 (min 8.30, max 35.9) or 16.5 (95% CI: 2.72, NE). Efficacy (CLL): In Parts 1&2 ORR was 91.2% (8.8% CR, 82.3% PR/PR-L), and 8.8% had stable disease (SD). At median follow-up of 31.4 M, mDOR was 33.5 M and mPFS was NR (95% CI: 36.3, NE); the mPFS (in M) for pts with 1, 2, or ≥ 3 prior therapies was NR (min 19.3, max 41.3), NR (min 31.3, max 36.8) or 36.3 (95% CI: 15.7, NE). At median follow-up of 21.1 M in Part 3, mPFS was NR for TN or RR in both Zilo+Ibr and Ibr arms. **Conclusions:** Zilo+Ibr is well-tolerated. Striking responses were observed in MCL pts, with mPFS of 35.9 M (95% CI: 17.3, NE) and CR of 34.6%, which compares favorably to mPFS of 12.8 M (95% CI 8.5, 16.6) and CR of 20% reported for single agent Ibr (Rule 2017). For CLL, ORR and PFS compare very favorably to Ibr monotherapy data (Byrd 2019). Clinical trial information: NCT03088878. Research Sponsor: Oncternal Therapeutics, Inc., Other Foundation.

7521 **Poster Discussion Session**

ASPEN: Long-term follow-up results of a phase 3 randomized trial of zanubrutinib (ZANU) versus ibrutinib (IBR) in patients with Waldenström macroglobulinemia (WM).

First Author: Constantine Si Lun Tam, Peter MacCallum Cancer Centre, Melbourne, Australia

Background: ASPEN is a randomized, open-label, phase 3 study comparing ZANU, a potent and selective Bruton tyrosine kinase inhibitor (BTKi), with the first-generation BTKi IBR in patients with WM. We present data with a median follow-up of 43 months. **Methods:** Patients with *MYD88* mutations were assigned to cohort 1 and randomized 1:1 to receive ZANU 160 mg twice daily or IBR 420 mg once daily. Randomization was stratified by *CXCR4* mutational status and lines of prior therapy (0 vs 1-3 vs > 3). Patients without *MYD88* mutations were assigned to cohort 2 and received ZANU 160 mg twice daily. The primary endpoint was proportion of patients achieving complete response or very good partial response (CR+VGPR). **Results:** A total of 201 patients (ZANU arm, n = 102; IBR arm, n = 99) were enrolled in cohort 1 and 28 patients were enrolled in cohort 2. A larger proportion of patients in the ZANU arm of cohort 1 vs IBR had *CXCR4* mutations by next-generation sequencing (32% vs 20%, or 33 of 98 vs 20 of 92 with data available) and were aged > 75 years (33% vs 22%). Median duration of treatment was 42 months (ZANU) and 41 months (IBR), with 67% and 58% remaining on treatment, respectively. The CR+VGPR rate by investigator was 36% with ZANU vs 22% with IBR (p= 0.02) in cohort 1, and 31% in cohort 2. One patient achieved CR (cohort 2). In patients with wild type or mutant *CXCR4* from cohort 1, CR+VGPR rates with ZANU vs IBR were 45% vs 28% (p= 0.04) and 21% vs 5% (p= 0.15), respectively. Median progression-free survival and overall survival were not yet reached. Rates of atrial fibrillation, diarrhea, hypertension, localized infection, hemorrhage, muscle spasms, pneumonia, and adverse events leading to discontinuation or death were lower with ZANU vs IBR (Table). Exposure-adjusted incidence rates of atrial fibrillation/flutter and hypertension were lower with ZANU vs IBR (0.2 vs 0.8 and 0.5 vs 1.0 persons per 100 person-months, respectively; p< 0.05). Rate of neutropenia was higher and rate of grade ≥3 infection was lower with ZANU vs IBR. Safety outcomes of ZANU were similar between cohorts 1 and 2. **Conclusions:** ASPEN is the largest phase 3 trial with head-to-head BTKi comparison in WM. At a median follow-up of 43 months, ZANU was associated with higher CR+VGPR rate and demonstrated clinically meaningful advantages in long-term safety and tolerability vs IBR. Clinical trial information: NCT03053440. Research Sponsor: BeiGene USA, Inc.

AE (all grade), % of treated patients	Cohort 1 ZANU (n = 101)	Cohort 1 IBR (n = 98)	Cohort 2 ZANU (n = 28)
AE, grade ≥3	74.3	72.4	71.4
AE leading to discontinuation	8.9	19.4	14.3
Atrial fibrillation / flutter[a]	7.9	23.5	7.1
Diarrhea	21.8	34.7	32.1

Phase 1/2 study of anbalcabtagene autoleucel, novel anti-CD19 CAR-T cell therapy with dual silencing of PD-1 and TIGIT in relapsed or refractory large B-cell lymphoma.

First Author: Won Seog Kim, Samsung Medical Center, Seoul, South Korea

Background: Anbal-cel is a novel 2nd generation autologous CD19 CAR-T cell therapy which has been knock-downed for PD-1 and TIGIT using OVIS platform. Anbal-cel demonstrated the eradication of CD19 positive tumor cells *in vitro* and *in vivo* better than conventional CD19 CAR-T cells. The knock-down of PD-1 and TIGIT at CD19 CAR-T cells exerts the superior T-cell functionality by delaying the exhaustion of CAR-T cells. **Methods:** This phase 1 dose escalation part (NCT04836507) was evaluated the safety and preliminary efficacy in patients with r/r LBCL. Anbal-cel was manufactured at GMP facility with fresh leukapheresis product. Patient was administered as a single intravenous dose at dose level 1 ($2x10^5$ cells/kg), DL2 ($7x10^5$ cells/kg) or DL3 ($2x10^6$ cells/kg). Lymphodepletion with cyclophosphamide (500mg/m^2) and fludarabine (30mg/m^2) was performed for 3 days prior to Anbal-cel infusion. **Results:** As of Jan 17 2022, 9 patients with r/r DLBCL were infused with Anbal-cel; 4pts at DL1, 3pts at DL2 and 2pts at DL2. Median age was 54 (range 26-71); all patients received 2 or more prior lines of therapy and 44% (4/9) received ≥4 prior line of treatment before the study. 78% (7/9) patients were refractory to their last treatment. 67% (6/9) of patients were at IPI 3-4 and 44% (4/9) of patients had bulky disease. No patient experienced DLT during the study. Of the 9 patients, 5 (56%) experienced CRS; 4 (44%) were grade 1 or 2 and one patient experienced grade 3 CRS. Median time to onset of CRS was 7 days (range, 1-16) with median duration of 4 days (range, 0-18). One patient dosed at DL3 experienced grade 2 ICANS, time to onset of ICANS was 7 days and lasted for 13 days. This patient had prior CNS involvement history before the study. Most commonly reported grade 3/4 AEs were neutrophil count decrease (6/9, 67%), anemia (5/9, 56%), thrombocytopenia (2/9, 22%), platelet count decrease (2/9, 22%) and no infection was reported. Complete response rate (CRR) was 78% and complete responses were observed at the lowest dose level and from patients expressing less than 10% CD19 at IHC; 3 complete responses (CR) at DL1, 2 CRs at DL2 & DL3 respectively. Dose-dependent CRC01 expansion was observed; median T_{max} was 15.4, 15.8, 11.0 days at DL1, DL2 & DL3 each; median C_{max} was 18,003, 30,103, 53,688 copies/ug gDNA at DL1, DL2 & DL3 each; median $AUC_{0\text{-}28day}$ was 679,125, 1,110,108, 2,852,235 copies/ug gDNA at DL1, DL2 & DL3 respectively. **Conclusions:** Anbal-cel demonstrated promising efficacy and tolerable safety profile in this dose escalation study. Based on this phase 1 study, phase 2 patient enrollment will be commenced in Mar 2022 to evaluate the response rate, duration of response of CRC01 as well as safety. In addition, various biomarker studies are planned to investigate the differential mode of action of Anbal-cel during phase 2 study. Clinical trial information: NCT04836507. Research Sponsor: Curocell Biotherapeutics.

First-line treatment (Tx) with subcutaneous (SC) epcoritamab (epco) + R-CHOP in patients (pts) with high-risk diffuse large B-cell lymphoma (DLBCL): Phase 1/2 data update.

First Author: Lorenzo Falchi, Lymphoma Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Outcomes of pts with newly diagnosed DLBCL with high/poor risk according to the revised International Prognostic Index (IPI) treated with immunochemotherapy (IC) remain suboptimal, with a 4-year survival rate of 55% (Sehn et al, *Blood* 2007). SC epco is a well-tolerated bispecific antibody with single-agent activity in the relapsed/refractory (R/R) aggressive B-cell NHL setting. The mechanism of action and safety profile of epco are distinct from IC, and epco is well suited for use in combinations and in earlier lines of therapy. Addition of a novel agent to standard of care IC may overcome the adverse prognosis of high-risk pts. Presented here are updated results of epco + rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) in previously untreated DLBCL pts with IPI 3–5 (EPCORE NHL-2 arm 1; NCT04663347). **Methods:** Adults with previously untreated CD20$^+$ DLBCL and IPI ≥3 received SC epco (every week, cycle [C] 1–4; every 3 weeks, C5–6) + R-CHOP for 6 cycles (21 d) followed by single-agent epco every 4 weeks up to 1 y (in cycles of 28 d). To mitigate CRS, epco step-up dosing and corticosteroid prophylaxis were required. Response was assessed by PET-CT with contrast per Lugano 2014 criteria. **Results:** As of Dec 1, 2021, 33 pts (median age, 66 y; range, 19–82) received epco + R-CHOP (epco 24 mg, n = 4; 48 mg, n = 29). Median time from diagnosis to first dose was 25 d (range, 5–70). All pts had IPI ≥3 and ≥24% had double- or triple-hit DLBCL. Median follow-up was 3 mo (range, 0–9.7); median number of total cycles initiated was 5 (1–13). Overall, 94% of pts (31/33) remained on Tx. Tx-emergent adverse events (TEAEs) in ≥30% of pts were neutropenia (48%; febrile neutropenia in 9% of all pts), CRS (45%), infections (42%), anemia (39%), injection-site reactions (36%), nausea (33%), constipation (30%), and pyrexia (30%). No TEAEs led to epco discontinuation. AEs of special interest included CRS (42% grade [G] 1/2, 3% G3) and ICANS (3% G2); 1 pt had tumor lysis syndrome (3% G3). Most CRS events occurred in C1 and resolved after a median of 2 days (1–11); 4 pts with CRS received tocilizumab. No fatal TEAEs were reported. In efficacy-evaluable pts, the overall response rate (ORR) was 96% (24/25); 68% (17/25) had complete metabolic response (CMR). For the 10 pts who received 6 cycles of R-CHOP and had a subsequent response assessment, the ORR and CMR rate were 100% and 90%, respectively. As of the data cutoff, all of these 10 pts remained in response, with the longest duration of response 7.1+ mo and ongoing. Updated data will be presented. **Conclusions:** Epco is the first SC bispecific antibody assessed in combination with standard of care in previously untreated DLBCL. The safety profile of epco + R-CHOP is manageable. CRS events were mostly of low grade and did not lead to Tx discontinuation. ORR and CMR rate were high with no relapses as of the data cutoff date. Clinical trial information: NCT04663347. Research Sponsor: Genmab A/S and AbbVie.

Subcutaneous epcoritamab with rituximab + lenalidomide (R^2) in patients (pts) with relapsed or refractory (R/R) follicular lymphoma (FL): Update from phase 1/2 trial.

First Author: Lorenzo Falchi, Lymphoma Service, Memorial Sloan Kettering Cancer Center, New York, NY

Background: R/R FL is associated with poor prognosis and less frequent, shorter responses with each line of treatment (Tx). Although R^2 is an effective regimen in R/R FL with an acceptable safety profile, FL remains incurable; thus, better Tx options are needed. Subcutaneous epcoritamab is a bispecific antibody that simultaneously binds to CD3 on T cells and CD20 on malignant B cells. In the dose-escalation part of the phase 1/2 EPCORE NHL-1 trial, single-agent epcoritamab (0.76–48 mg) resulted in an overall response rate of 90% and a complete response rate of 50% in R/R FL. The distinct mechanisms of action of epcoritamab and R^2 may combine to increase antitumor response, with generally non-overlapping toxicity profiles. We present updated data for epcoritamab with R^2 in R/R FL (EPCORE NHL-2 arm 2; NCT04663347). **Methods:** Adults with R/R CD20$^+$ FL received epcoritamab + R^2 for 12 cycles (C) of 28 d; epcoritamab was administered at 24 or 48 mg in dose escalation and 48 mg in expansion. During C1, step-up epcoritamab dosing and corticosteroids were required to mitigate CRS. Response was assessed by PET-CT. The epcoritamab regimen for these pts was: Q1W, C1–3; Q2W, C4–9; Q4W, C≥10 up to 2 y. **Results:** As of December 1, 2021, 30 pts (median age, 68 y) had received epcoritamab + R^2 (24 mg, n=3; 48 mg, n=27), 21 pts (70%) had stage IV disease, and 20 pts (67%) had FLIPI scores 3–5. Median (range) number of prior lines of therapy was 1 (1–5), 30% had primary refractory disease, and 40% had disease progression within 24 mo after starting first-line Tx (20% within 24 mo after starting immunochemotherapy). At a median (range) follow-up of 5.1 mo (0.8–12.3), 25 pts (83%) remained on Tx; 5 pts discontinued Tx due to progression (n=2), AEs (n=2), or consent withdrawal (n=1). Common Tx-emergent AEs (TEAEs) of any grade (G) included infections (57%), injection-site reactions (50%), constipation (37%), fatigue (37%), and neutropenia (37%). CRS was seen in 15 pts (50%; G1/2 43%, G3 7%), with most events in C1. All CRS events resolved with standard management, including tocilizumab in 3 pts, and 1 pt discontinued Tx due to CRS. One pt experienced G2 ICANS. No fatal TEAEs occurred. Antitumor activity is shown in the Table. As of the data cut, all responders remained in response, with the longest duration of response being 7.0+ mo and ongoing. **Conclusions:** Subcutaneous epcoritamab+ R^2 exhibits promising efficacy, including a high CMR rate, in pts with R/R FL. The safety profile was consistent with prior data, and CRS events were generally low grade and in C1. Updated data with an additional 30 pts will be presented. Clinical trial information: NCT04663347. Research Sponsor: Genmab A/S and AbbVie.

SHR2554, an enhancer of zeste homolog 2 (EZH2) inhibitor, in relapsed or refractory (r/r) mature lymphoid neoplasms: A first-in-human phase 1 study. *First Author: Yuqin Song, Key Laboratory of Carcinogenesis and Transitional Research (Ministry of Education), Department of Lymphoma, Peking University Cancer Hospital and Institute, Beijing, China*

Background: Dysregulation of histone methyltransferase EZH2 plays critical roles in lymphomagenesis. Emerging evidence shows that EZH2 also contributes to tumor immune evasion. SHR2554 is an oral, small-molecule inhibitor exhibiting potent selectivity for EZH2. We initiated a first-in-human study to assess SHR2554 across a broad spectrum of lymphoid neoplasms that had relapsed or was refractory to standard systemic therapies, including B-cell lymphomas, T-cell lymphomas, and classical Hodgkin lymphoma (cHL). **Methods:** This multicenter, phase 1 study was composed of 3 parts: dose escalation phase according to mTPI-2 design, dose expansion phase, and clinical expansion phase in selected tumor subtypes. Dose was escalated at 50, 100, 200, and 400 mg BID, and then de-escalated at 300 and 350 mg based on the observed toxicities. Two dose levels (300 and 350 mg) were expanded. Subsequently, follicular lymphoma (FL), peripheral T-cell lymphoma (PTCL), and cHL were selected for clinical expansion at RP2D. Primary endpoints were to assess the safety and determine the MTD and RP2D. Key secondary endpoint included clinical activity at RP2D in different subtypes. **Results:** As of Sep 10, 2021, 113 heavily pretreated pts were enrolled, with 53 (46.9%) having received ≥3 lines of prior systemic therapies. In dose escalation phase, DLTs occurred in 2 of 3 pts at 400 mg and 1 of 6 pts at 350 mg; thus, 350 mg BID was the MTD. Combined with the safety, tolerability, PK/PD, and preliminary efficacy findings observed in dose escalation and expansion phases, RP2D was determined to be 350 mg BID. As of cutoff date, 41 FL, 22 PTCL, and 21 cHL pts who received SHR2445 at 350 mg BID completed at least one post-baseline efficacy assessment. ORR in FL was 58.5% (95% CI 42.1-73.7); majority of responses (66.7%) were still ongoing, and the estimated median DoR was 9.3 mos (95% CI 5.6-NR). *EZH2*^{mut} FL pts showed a slightly higher ORR than *EZH2*^{WT} FL pts (62.5% vs 55.2%). *EZH2* mutations were not detected in pts with PTCL or cHL. ORR in PTCL was 63.6% (95% CI 40.7-82.8); majority of responses (71.4%) were still ongoing, and the estimated median DoR was 7.4 mos (95% CI 2.9-NR). All cHL pts had received prior chemotherapy and anti-PD-1/PD-L1 antibodies. Shrinkage in target lesions was shown in 76.2% of cHL pts; ORR was 19.0% (95% CI 5.4-41.9); majority of responses (75.0%) were still ongoing, and the median DoR had not been reached yet. Grade ≥3 treatment-related AEs occurred in 38 of the 113 pts (33.6%), with the most common being decreased platelet count (17.7%), decreased neutrophil count (8.8%), decreased white blood cell count (8.0%), and anemia (6.2%). **Conclusions:** SHR2554 showed a manageable safety profile and promising anti-tumor activity in pts with r/r lymphomas, supporting further explorations in FL, PTCL, and cHL. Clinical trial information: NCT03603951. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Characterization of CD20 expression loss as a mechanism of resistance to mosunetuzumab in patients with relapsed/refractory B-cell non-Hodgkin lymphomas. *First Author: Stephen J. Schuster, Lymphoma Program, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: Mosunetuzumab (M) is a bispecific antibody targeting CD20 and CD3 that redirects T cells to engage and eliminate malignant B cells being developed for relapsed or refractory (R/R) B-cell non-Hodgkin lymphomas (B-NHL). CD20 is an optimal target, with uniform expression across B-NHL histologies and minimal receptor turnover. We characterized CD20 loss as a potential mechanism of resistance to M in patients (pts) on a Phase I/II trial (NCT02500407) receiving M monotherapy for the treatment (tx) of R/R B-NHL. **Methods:** Pts with R/R B-NHL received M intravenously in 3-week cycles, for eight to 17 cycles depending on tumor response. At baseline (BL), biomarker-evaluable (archival or fresh) biopsies were collected from 293 pts. Biopsies from 62 pts were collected at additional time points during tx with M and/or at disease progression (PD). The proportion of CD20+ and PAX5+ tumor cells was determined by immunohistochemistry (IHC) using dual-staining with anti-CD20 (clone L26, VENTANA) and anti-PAX5 (clone DAK-PAX5, DAKO) antibodies. Expression of *MS4A1,* the gene encoding CD20, was measured by RNA-sequencing (RNA-seq); *MS4A1* mutation profiling was performed by whole exome sequencing (WES). Levels of CD20 expression were assessed relative to response rates. Correlative analyses were performed and assessed centrally (IHC, RNA-seq, and WES) and locally (IHC). **Results:** CD20 levels were consistently high (> 75% CD20+PAX5+ cells) in the majority of BL biopsies and generally comparable across histologies (FL, DLBCL, tFL, MCL, and RT). BL CD20 loss (≤5% CD20+PAX5+ cells) was seen in 16/293 pts (5.5%), more commonly in aggressive NHL, and responses to M were not seen in these pts. Among 62 pts with BL and on-tx/at-PD biopsies, BL CD20 levels were ≤5% in 7/62 pts (11%) (6/7 pts [86%] progressed before completing Cycle 2). CD20 levels were maintained in on-tx biopsies from 23/24 pts (96%). At PD, biopsies showed CD20 loss in 7/26 pts (27%). For five pts with BL, on-tx and at-PD biopsies, all pts maintained CD20 while on-tx and 1/5 pts (20%) had CD20 loss at PD. There was no clear association between CD20 reduction and histology. Data from 185 BL biopsies showed generally concordant levels of CD20 gene and protein expression (r = 0.72). In 10/185 pts (5%), *MS4A1* was expressed without detectable CD20 protein expression; DNA sequencing revealed novel mutations in *MS4A1*, including mutations leading to truncation of the protein. CD20 transmembrane and extra-cellular domain mutations were also observed but do not block CD20 expression. **Conclusions:** In pts with R/R B-NHL treated with M, low BL CD20 expression is associated with lack of response to M. During M tx, loss of tumor cell expression of CD20 is one mechanism of acquired resistance; however, CD20 expression is maintained in most pts with PD, implying alternative mechanisms for acquired M resistance. Clinical trial information: NCT02500407. Hoffmann-La Roche Ltd.

7527 **Poster Session**

Epcoritamab (epco) with gemcitabine + oxaliplatin (GemOx) in patients (pts) with relapsed or refractory (R/R) diffuse large B-cell lymphoma (DLBCL) ineligible for autologous stem cell transplant (ASCT) induces high response rate even in pts failing CAR T therapy. *First Author: Joshua Brody, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Pts with R/R DLBCL who fail or are ineligible for ASCT have very poor outcomes with standard palliative chemotherapy. Rituximab + GemOx had a complete response rate of 33% (Cazelles et al, *Leuk Lymphoma* 2021); novel approaches are needed. Epco is a subcutaneously administered bispecific antibody targeting CD3 on T cells and CD20 on B cells. In the EPCORE NHL-1 dose-escalation trial, epco had manageable safety and antitumor activity in heavily pretreated B-cell NHL including DLBCL. EPCORE NHL-2 is a phase 1/2 trial evaluating epco + standard B-cell NHL therapies; shown here are results from arm 5 (NCT04663347). **Methods:** Adults with R/R CD20^{+} DLBCL who failed or were ineligible for ASCT received epco (QW, cycle [C] 1–3; Q2W, C4–9; Q4W, C≥10) and GemOx (Q2W, C1–4) until disease progression or unacceptable toxicity (28 d/C). Step-up epco dosing and prophylactic corticosteroids were required in C1 to mitigate CRS. Response was assessed by PET-CT per Lugano 2014 criteria. **Results:** As of Dec 1, 2021, 27 pts (median age, 71 y; range, 47–87 y) had received epco + GemOx (epco 24 mg, n=3; 48 mg, n=24). Most were stage IV (56%), primary refractory (56%), and refractory to last therapy (70%). Median number of prior therapies was 2 (range, 1–13). Median follow-up was 6.0 mo (range, 1.0–11.1), with treatment (Tx) ongoing in 16 pts (59%). The most common Tx-emergent AEs were CRS (70%), thrombocytopenia (70%), neutropenia (56%), anemia (52%), and infections (52%). CRS events were all grade (G) 1/2, with most cases occurring in C1; all cases resolved. One pt had ICANS (G3); 1 pt had tumor lysis syndrome (G3). Six pts (22%) had G5 AEs; investigator could not rule out contribution of epco in 2 pts: small bowel perforation in pt (72 y) with transformed DLBCL and extensive gastrointestinal involvement (had complete metabolic response [CMR]); acute hepatitis/multiorgan failure in pt (68 y) with transformed DLBCL and liver involvement (had CMR). Of 4 pts with fatal AEs unrelated to epcoritamab by investigator, 2 (87 y) had primary refractory disease and 2 (74 y) had multiple comorbidities. Response is shown in the Table. At the time of data cut, 65% of responders remained in response with the longest duration of response 6.9 mo. All 3 pts with prior CAR T remained on Tx and in response (2 CMR and 1 partial metabolic response [PMR]). **Conclusions:** When considering individual safety profiles of epco or GemOx, no unexpected safety findings were observed for epco + GemOx. In this R/R population with high unmet need, these initial data are encouraging and warrant further clinical evaluation. Clinical trial information: NCT04663347. Subcutaneous epcoritamab + R-DHAX/C in patients (pts) with relapsed or refractory (R/R) diffuse large B-cell lymphoma (DLBCL) eligible for autologous stem cell transplant (ASCT): Preliminary phase 1/2 results. *First Author: Pau Abrisqueta, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: Current standard of care for pts with R/R DLBCL eligible for ASCT includes salvage immunochemotherapy, such as rituximab, dexamethasone, cytarabine, and oxaliplatin or carboplatin (R-DHAX/C), followed by consolidation with high-dose therapy (HDT) and ASCT. However, salvage therapy fails in many pts, and novel treatment (Tx) options are needed to improve response and long-term outcomes. Epcoritamab, a bispecific antibody targeting CD3 on T cells and CD20 on B cells, had a manageable safety profile and meaningful single-agent antitumor activity in pts with heavily pretreated B-cell non-Hodgkin lymphoma (NHL) in the dose-escalation part of the EPCORE NHL-1 trial. Here we present initial results from arm 4 (epcoritamab + R-DHAX/C) of the EPCORE NHL-2 phase 1/2 trial (NCT04663347). **Methods:** Adults with R/R CD20^{+} DLBCL who were eligible for HDT-ASCT were enrolled. Pts received standard R-DHAX/C with subcutaneous epcoritamab (QW, 21-d cycle [C] 1–3). If HDT-ASCT was postponed, pts could continue epcoritamab monotherapy (28-d C: QW, C4; Q2W, C5–9; Q4W, C≥10) until disease progression or unacceptable toxicity. Step-up epcoritamab dosing and corticosteroids were required to mitigate CRS in C1. Response was determined by PET-CT per Lugano criteria. **Results:** As of Jan 26, 2022, 27 pts (median age, 59 y; range, 30–75) had received epcoritamab + R-DHAX/C. Of these, 74% had received 1 prior line of therapy, the remainder (26%) 2–3 prior therapies; 3 pts had prior CAR T. The majority of pts (70%) had primary refractory disease. The most common Tx-emergent adverse events (any grade [G]) were thrombocytopenia (67%), neutropenia (48%; febrile neutropenia, 19% in all pts), infections (37%), nausea (37%), and anemia (33%). Adverse events of special interest were CRS in 8 pts (30%; all G1/2) and ICANS in 1 pt (G2; discontinued epcoritamab, pt with prior CAR T). No clinical tumor lysis syndrome was observed. CRS events occurred early in Tx; median time to resolution was 2 d. Of the 23 evaluable pts, 11 pts underwent ASCT; among these, overall response rate (ORR) was 100% prior to ASCT (82% [9/11] complete metabolic response [CMR]; 18% [2/11] partial metabolic response [PMR]). In 12 pts, HDT-ASCT was postponed/canceled and epcoritamab monotherapy continued; of these, 5 (42%, including 2 with prior CAR T) had CMR and 3 (25%) had PMR. The CMR and PMR rates for the entire evaluable population were 61% (14/23) and 22% (5/23), respectively. **Conclusions:** Subcutaneous epcoritamab in combination with R-DHAX/C in pts with R/R DLBCL had a manageable safety profile. CRS events were of low grade and resolved with standard management. ORR and CMR rate were high. At the time of data cutoff, 70% of pts had either received ASCT or continued epcoritamab Tx in CMR. Clinical trial information: NCT04663347. Research Sponsor: Genmab A/S and AbbVie.

Two-year follow-up result of RELIANCE study, a multicenter phase 2 trial of relmacabtagene autoleucel in Chinese patients with relapsed/refractory large B-cell lymphoma. *First Author: Zhitao Ying, Department of Lymphoma, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital & Institute, Beijing, China*

Background: RELIANCE study is the first pivotal CD19 CAR-T study that got IND approval by the authority in China (NCT04089215). Initial findings of this study demonstrated high response rates and low rates of CAR-T–associated toxicity with Relmacabtagene autoleucel (Carteyva, also known as Relma-cel, JWCAR029) treatment in heavily pretreated patients with Relapsed/Refractory (r/r) large B-cell lymphoma (LBCL) (Ying *et al.* Cancer Med, 2020). Here we provide 2-year follow-up result of RELIANCE study. **Methods:** 59 adults (age ≥18 years) with ≥2 prior therapies r/r LBCL were randomized to receive lymphodepletion chemotherapy followed by a single infusion of Carteyva at a dose of 100×10^6 or 150×10^6 CAR+T cells, patients were evaluated for efficacy using Lugano criteria (Cheson 2014), for toxicity using CTCAE v4.03 and for cytokine release syndrome (CRS) using Lee *et al.* criteria (Blood 2014). Primary endpoint was 3-month objective response rate (ORR); key secondary endpoints included complete response rate (CRR) at 3 months, duration of response (DOR), progression-free survival (PFS), overall survival (OS) and treatment-emergent adverse event (TEAE) profile. **Results:** The cutoff date was December 22, 2021. All 59 patients (median age 56.0 years, range 18–75 years) were post-treatment with Carteyva, among of them 26 patients completed trial, 8 patients on study, 25 patients withdrew. Among the modified intent-to-treat (mITT) population of 58 efficacy-evaluable patients, best ORR and CRR was 77.6% and 53.5%, respectively. The median follow-up was 24 months(95% CI 23.9-24.1), median PFS and DOR was 7 months (95% CI 4.76–24.15) and 20.3 months (95% CI 4.86–NA), median OS was NA (95% CI NA–NA). 2-year PFS, DOR and OS rates were 38.3%, 38.1% and 69.0%, respectively. 91.5% patients reported treatment–related TEAEs with 72.9% patients had Grade ≥3, among this, the most common Grade ≥3 AE were neutropenia (42.4%) and leukopenia (22%). CRS and NT of any grade occurred in 47.5% and 20.3% of patients (Grade 3–4 CRS, 5.1%; Grade 3–4 NT, 3.4%). Median onset of CRS and NT was 4 (1–10) days and 8.5 (2–11) days, After Day 90, 6(10.2%) patients reported AEs Grade ≥3, the most common were lymphocytopenia 2(3.4%), neutropenia 2(3.4%) and leukopenia 1(1.7%). Grade ≥ 3 infections occurred in 2(3.4%) patients, which was gastroenteritis and herpes zoster. 17 (28.8%) patients died in this study, 12(20.3%) due to disease progression. **Conclusions:** As the longest follow-up term of CD19+ CAR T cell study in heavily pretreated patients with r/r LBCL in China, Carteyva demonstrated durable responses with a high 2-year OS rate, the median OS not yet reached for responding patients, and a manageable safety profile. These data continue supporting the compelling clinical benefit-risk profile of Carteyva for r/r LBCL patients. Clinical trial information: NCT04089215. Research Sponsor: None.

Demographics and treatment outcomes in patients with EBV$^+$ PTLD treated with off-the-shelf EBV-specific CTL under an ongoing expanded access program in Europe: First analyses. *First Author: Sylvain Choquet, Hôpital de la Pitié-Salpêtrière, Paris, France*

Background: Patients undergoing allogeneic hematopoietic cell transplant (HCT) or solid organ transplant (SOT) are at risk of developing Epstein–Barr virus driven post-transplant lymphoproliferative disorder (EBV$^+$ PTLD), a rare hematologic malignancy, which is often aggressive and life-threatening. Patients with relapsed or refractory (r/r) EBV$^+$ PTLD have few treatment options with poor outcomes, demonstrating a clear unmet medical need. Tabelecleucel is an investigational, off-the-shelf, allogeneic EBV-specific T-cell immunotherapy being studied in patients with serious EBV$^+$ diseases (NCT04554914 & NCT03394365) that has demonstrated clinical benefit and favorable safety profile in the treatment of EBV$^+$ PTLD after failure of rituximab (R) ± chemotherapy (Prockop, EBMT 2021, ATC 2021, ASH 2021). **Methods:** Atara Biotherapeutics supports an ongoing expanded access program (EAP) in Europe for patients with EBV$^+$ diseases who have no other treatment options. Here we report demographics, efficacy and safety results of r/r EBV$^+$ PTLD patients following SOT or HCT who presented between Jul 2020 and Nov 2021 and consented to research. **Results:** A total of 48 EAP requests from 9 countries for patients with EBV$^+$ diseases were received. Twenty-two patients from 7 countries consented to this research: 16 EBV$^+$ PTLD and 6 EBV$^+$ non-PTLD. Of the 16 PTLD patients 15 received at least one dose of tabelecleucel. Overall, 9 out of 15 (60%) patients achieved a response as assessed by the treating physician, with 6 complete responses and 3 partial responses. Eight out of nine responses were seen after the first cycle. No adverse events were reported as related to tabelecleucel by the treating physician. **Conclusions:** The successful execution of this European EAP demonstrates the feasibility to deliver an off-the-shelf allogeneic EBV$^+$ T-cell therapy in time-sensitive clinical situations when no other treatment options exist. These data show clinically meaningful outcomes for patients with r/r EBV$^+$PTLD post-SOT or post-HCT treated with tabelecleucel consistent with previously reported favorable safety and efficacy profile (Prockop, ASH 2021). Research Sponsor: Atara Biotherapeutics.

Molecular disease monitoring in patients with relapsed/refractory B-cell non-Hodgkin lymphoma receiving anti-CD19 CAR T-cell therapy. *First Author: Meryl D. Colton, University of Colorado School of Medicine, Aurora, CO*

Background: Chimeric antigen receptor (CAR) T-cell therapy has improved the historically poor outcomes for relapsed and refractory (R/R) B-cell non-Hodgkin's lymphoma (NHL). However, nearly 60% of patients will either fail to respond or relapse after CAR T-cell therapy. Currently, PET/CT scans are used to assess response. Cell-free circulating tumor DNA (ctDNA) is released by tumor cells into the peripheral blood and can be measured for minimal residual disease (MRD) assessment. **Methods:** In this retrospective, IRB approved pilot study, archived lymphoma tissues and ctDNA from peripheral blood samples on day 0, 14, 28, 56, 80, 180, and 365 after CAR T-cell infusion from 10 patients with R/R NHL were collected for next-generation sequencing (NGS) of clonal variable-diversity-joining (VDJ) rearrangements [Adaptive biotechnologies (Seattle, WA)]. Response was assessed by PET/CT on days 30, 60, 90, 180 and 365 and graded according to the Lugano 2014 criteria. The primary endpoint was to determine the feasibility of detecting ctDNA to monitor disease response after anti-CD19 CAR T-cells. The secondary endpoint was to compare the sensitivity/specificity of MRD assessment from ctDNA to PET/CT imaging. **Results:** Nine out of 10 patients with a trackable sequence [median age 69 (range: 56-76); 55.6% male; median LDH 224], were included in this study. Each received tisagenlecleucel CAR T-cell therapy after median two prior treatments (range: 2-4). 7/9 patients had R/R diffuse large B-cell lymphoma (DLBCL), and 2/9 had transformed follicular lymphoma. At a median follow up of 12.7 months (range: 1.5-30 months), four patients were alive. By day 90, three patients (33.3%) achieved a radiographic complete response (CR) whilst six patients (66.6%) had progressive disease (PD). MRD and radiographic response are outlined in the Table. Detectable MRD on day 14 or day 28 had 83% sensitivity and 100% specificity for radiographic progression at any time before one year. For patients with PD, the median (interquartile range) MRD at day 0, 14, and 28 were 17.31 (1.01, 96.84), 9.12 (0.30, 18.8), and 23.77 (8.01, 137.53) copies per milliliter (mL), respectively. For patients with detectable MRD at day 28, mOS and mPFS were 205 and 38 days, respectively. **Conclusions:** Our pilot study demonstrated that monitoring MRD was a sensitive and specific method to detect disease response and relapse. In addition, MRD can be monitored more frequently, thus allowing for earlier detection of relapse. MRD and PET/CT identified progressive disease (PD) or complete response (CR) by day 90 in nine patients (A-I) with R/R NHL post CAR T-cell infusion. Research Sponsor: Novartis.

MRD on day 0-365 is ctDNA (copies per mL).

ID	PET/CT outcome	Day 0	Day 14	Day 28	Day 56	Day 80	Day 180	Day 365

Autologous hematopoietic stem cell transplantation in tandem with anti-CD30 CAR T-cell infusion in relapsed/refractory CD30$^+$ lymphoma. *First Author: Xiuxiu Yang, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*

Background: Long-term outcome is unfavorable for patients with relapsed/refractory (r/r) classical Hodgkin lymphoma (cHL) who are resistant to salvage chemotherapy, even followed by autologous stem cell transplantation (ASCT). Long-term survival is most likely achieved in patients who are sensitive to salvage therapy and have a complete response (CR) before ASCT, while outcome is poor in patients with residual disease. Although CD30-directed chimeric antigen receptor (CAR30) T-cell therapy induces high response rates in these patients, the duration of response is limited. **Methods:** We conducted an open-label, single-center and single-arm pilot study to explore the safety and efficacy of ASCT in tandem with CAR30 T-cell infusion in r/r CD30$^+$ lymphoma (Chinese Clinical Trial Registry, number ChiCTR 2100053662). Patients will receive BEAM as preconditioning. HSCs are infused at day zero and followed by the infusion of 3rd generation CAR30 T cells in the next week. Between June 1, 2019 to May 1, 2021, 6 patients enrolled, including 5 with cHL and 1 with anaplastic lymphoma kinase-negative anaplastic large cell lymphoma (ALCL). The median age was 24 years. No patient had a prior history of ASCT. Three patients (50.0%) relapsed ≥ 2 times and 3 patients (50.0%) had primary refractory diseases. All had a Deauville score of 4 or 5, and 5 patients (83.3%) had a stable or progressive disease (SD/PD) to previous treatments at enrollment. **Results:** CD34$^+$ cells were infused at day zero with a median dosage of 3.9 (IQR, 3.2-6.1) $\times$ 10^6 /kg and followed by the infusion of CAR30 T cells with a median dosage of 7.6 (IQR, 5.5-9.7) $\times10^6$ /kg at +2 to +6 days. Cytopenias represented the most commonly severe advers events (≥ grade 3). The engraftments of neutrophil or platelet occured at a median time of 13.5 (IQR,12.3-14.0) days or 11.5 (IQR, 11.0-12.8) days, respectively, suggesting rapid multilineage engraftments post-ASCT. Cytokine release syndrome (CRS) was observed in 5 (83.3%) patients, all of which were grade 1. No neurotoxicity or severe infection was observed. At month 3 after HSC infusion, all patients achieved objective responses, including 5 (83.3%) with a CR and 1 with a patial response (PR). With a median follow-up of 18.2 (range, 9.9-32.1) months, the median PFS and OS were not reached. At January 31, 2022, the data-cutoff date, all patients maintained their responses and remained alive without disease relapse or progression. Of note, responses were sustained in all 5 patients who had a SD/PD at enrollment. **Conclusions:** Our work demonstrates tandem administration of ASCT and CAR30 T-cell therapy was well-tolerated and highly active in r/r HL and ALCL, even in PET-positive or chemorefractory patients who were expected to have inferior outcome after ASCT, although further large-scale validation in prospective clinical trial is warranted. Clinical trial information: ChiCTR2100053662. Research Sponsor: National Natural Science Foundation of China.

Standard chemotherapy followed by allogeneic or autologous transplantation: The role of allogeneic transplantation in the AATT study. *First Author: Norbert Schmitz, Department of Medicine A, Haematology and Oncology, University Hospital Muenster, Münster, Germany*

Background: Prognosis of relapsed and refractory T-cell lymphoma patients (pts) is devastating. Early results of the AATT study (Autologous or Allogeneic Transplantation in T-cell lymphoma, Schmitz et al. ASCO 2019; NCT00984412) showed that standard chemotherapy followed by allogeneic transplantation (alloSCT) compared to autoSCT did not improve outcome of poor-risk patients. We wanted to investigate the long-term clinical course of AATT patients (pts) focusing on pts receiving alloSCT off study. **Methods:** AATT was a randomized trial comparing alloSCT with autoSCT in younger pts (18-60 yrs) with newly diagnosed PTCL who achieved stable disease or better after 4 courses of CHOEP and 1 course of DHAP. Pts were to receive BEAM/autoSCT or myeloablative conditioning/alloSCT from matched related or unrelated donors for consolidation. Local investigators gave updated detailed reports on all further therapy until last follow up or death in order to report long-term EFS and OS focusing on patients receiving alloSCT off study and after failing autoSCT. **Results:** 103 pts (median age 50 years) randomized to autoSCT (n = 54) or alloSCT (n = 49) formed the full analysis set (FAS), 67 pts (65%) actually received autoSCT (n = 41) or alloSCT (n = 26) (per protocol set, PPS). Median observation time for EFS (OS) was 80 (84) months in the FAS and PPS population. At 7 years EFS and OS were 36% [95%CI: 27% - 46%] and 58% [48-68] for all 103 pts; EFS and OS for patients randomized to autoSCT vs. alloSCT were 34% [22-47] vs. 38% [25-52] and 61% [47-74] vs. 55% [41-69]. For patients actually transplanted 7-year-EFS and -OS were 50% [34-66] vs. 61% [42-80] and 72% [58-86] vs. 61% [42-80]. None of these survival rates differed significantly. TRM was 0/41 (0%) after autoSCT and 8/26 (31%) after alloSCT. Relapse rates were 15/36 (42%) vs. 1/21 (5%) for patients auto- or allografted. Overall, 26/ 50 pts received alloSCT off study because of early relapse/ progression before transplantation or after failing autoSCT. 7-year-OS for these pts is 62% (43-80). Ten of 15 pts relapsing after autoSCT received alloSCT as next therapy. Eight of these pts remain alive 39 – 94 mos after transplantation 5-year-OS of 24 pts who did not receive alloSCT was 17% (2-32). **Conclusions:** Seven-year OS-rates for the FAS- and the PPS cohort are remarkably high (58% and 68%) reflecting the high rate of long-term survivors after alloSCT also in pts with early relapse and after autoSCT. Pts not undergoing alloSCT had a dismal outcome. For T-cell lymphoma pts with early progression/ relapse after first-line therapy or failing autoSCT alloSCT offers cure in a significant portion of pts and should therefore be the preferred option for all transplant-eligible pts. Clinical trial information: NCT00984412. Research Sponsor: BMBF (Bundesminisiterium fuer Bildung und Forschung) (Germany), Other Government Agency.

First-in-human phase I study of a ROR1-targeting bispecific T-cell engager (NVG-111) shows evidence of efficacy in patients with relapsed/refractory CLL and MCL. *First Author: Parag Jasani, Royal Free London NHS Foundation Trust, London, United Kingdom*

Background: NVG-111 is a first in class, humanized, tandem scFv ROR1xCD3 bispecific T cell engager that mediates potent killing of ROR1$^+$ tumours by engaging an epitope on the Frizzled domain of ROR1 and redirecting T cell activity via the CD3 binder. **Methods:** This phase I/II study is evaluating NVG-111 in patients with relapsed/refractory (R/R) CLL and MCL who have received ≥2 prior systemic therapies and have achieved a stable, or partial response to the last line of therapy. NVG-111 was delivered as continuous intravenous (cIV) infusion over 21 days per cycle, with each patient typically receiving 3 cycles of treatment. The first 3 single patient cohorts were subjected to accelerated dose titration (ADT) over a range of 0.3-30μg/day. Dose-escalation steps in the subsequent, multi-patient, cohorts were determined using a continuous reassessment method with overdose control. The primary endpoints are safety and determination of MTD/RP2D. Secondary objectives are pharmacokinetics, pharmacodynamics, immunogenicity and anti-tumor activity, assessed by multicolor flow cytometry to quantitate minimal residual disease (MRD4). **Results:** As of January 2022, six patients (all males, median age 60 years) had been enrolled to the study; three into each of the ADT cohorts and the remaining into a 30 μg/day flat dosing cohort. Five patients had CLL, and one had MCL, with all subjects remaining on ibrutinib whilst receiving NVG-111. The most common adverse events were Grade 1 lethargy, headaches, nausea, vomiting and thrombocytopenia. All 3 patients exposed to a flat dose of NVG-111 at 30μg/day suffered Grade 1 cytokine release syndrome (CRS) during week 1 of cycle 1. This did not require tocilizumab or dose interruption except in one patient who developed transient, grade 3 immune effector cell–associated neurotoxicity syndrome-like symptoms (ICANS). CRS or ICANS was not observed in subsequent cycles of treatment at this dose level. Response was observed in all 5 evaluable patients who had completed efficacy assessment after 3 cycles of NVG-111. Amongst these, 2 patients had undetectable MRD in the blood with one being MRD negative in the bone marrow. Dose escalation is ongoing, including exploration of step-up dosing. **Conclusions:** Early data with NVG-111 shows promising efficacy with a predictable and manageable safety profile. Clinical trial information: NCT04763083. Research Sponsor: NovalGen Ltd.

Real-world analysis of safety and efficacy of CAR T-cell therapy in patients with lymphoma with decreased renal function. *First Author: Omar Mamlouk, University of Texas MD Anderson Cancer Center, Department of Nephrology, Houston, TX*

Background: Chimeric antigen receptor T-cell therapy (CART) is approved for treatment of relapsed and refractory large B cell lymphoma (r/r LBCL), however eligibility for patients (pts) treated on clinical trials included normal kidney function (NKF). There is a gap in knowledge regarding the safety and efficacy of CART in pts with reduced kidney function (RKF), despite the prevalence of chronic kidney disease in lymphoma pts. **Methods:** This is a single-center retrospective analysis of adult pts with r/r LBCL who received CART between 2017-2021. RKF was defined as estimated glomerular filtration rate (GFR) of < 60 ml/min and NKF defined as GFR ≥ 60 ml/min, at time of lymphodepletion chemotherapy (LDC). Increased length of ICU stay define as > 3 days. Kaplan-Meier method used to estimate the time-to-event endpoints including progression free survival (PFS), and overall survival (OS). **Results:** We identified 210 pts who received CART, of those 169 (80.5%) had NKF and 41(19.5%) had RKF (15-59 ml/min, 27% < 45). Median age of pts was 60 and 63% of RKF pts were older than 60 vs 45% in NKF group (p = 0.03). Median Hematopoietic cell transplantation-specific comorbidity index (HCT-CI) score of pts with RKF was higher than NKF (3 vs. 1, P = 0.004). Pts with RKF had significantly longer ICU length of stay (29.3% vs. 13.6%; p = 0.01). There was no difference in grade 3 hematological toxicity (82.9% vs. 84.5%, p = 0.80) or infection within 30 days of CART (51.2% vs. 37.9%, p = 0.11) between RKF and NKF pts, respectively. CART specific toxicity including grade and frequency of cytokine release syndrome and neurotoxicity was also not related to renal function. After a median follow-up of 22.9 months (95% CI: 21.1-25.6 months), there was no significant difference in PFS and OS when comparing pts with RKF vs. NKF; PFS at 1 year of 31% (19-50%) vs. 33% (26-41%), p = 0.97, and OS at 1 year was 47% (34-67%) vs. 44% (37-57%), p = 0.45, and respectively. However, pts with RKF had a significant increase in non-relapse mortality (NRM) at 3 months (19.5% vs. 8.3%, p = 0.03), and at 6 months (22% vs. 9.5%, p = 0.02), respectively. **Conclusions:** In this retrospective single center study we observed reassuring durable remission rates in pts with r/r LBCL and RKF who received CART, without significantly different PFS or OS. Interestingly our analysis found that increased ICU length of stay and higher rates of NRM early after CART were associated with RKF. While our data shows RKF does not preclude pts from receiving CART for r/r LBCL, it does suggest that patients with RKF may need closer monitoring and multidisciplinary management. Research Sponsor: Cancer Center Support Grant (CCSG).

7537 **Poster Session**

Cost-effectiveness of CD19 chimeric antigen receptor T-cell (CAR-T) therapy versus autologous stem cell transplantation (ASCT) for high-risk diffuse large B-cell lymphoma (DLBCL) in first relapse. *First Author: Amar Harry Kelkar, Dana-Farber Cancer Institute, Boston, MA*

Background: The recently reported ZUMA-7 and TRANSFORM trials demonstrate superior event-free survival among patients with primary refractory or early relapsed DLBCL compared to salvage chemotherapy with ASCT. However, given a cost of >$370,000, it is not known whether second-line CAR-T is cost-effective compared to ASCT. Thus, we developed a state-transition microsimulation model to simulate clinical outcomes and costs associated with therapy for DLBCL patients in first relapse, using ZUMA-7 and TRANSFORM data. **Methods:** The model begins at initiation of second-line therapy comparing salvage chemotherapy with ASCT or CAR-T therapy. We examined a three-year time horizon, including crossover to the alternative strategy therapy in the third line, as well as subsequent lines of therapy, using open-source Amua 0.3.0 software. Base case analysis was performed using 1000 first-order Monte Carlo simulations and probabilistic sensitivity analysis (PSA) was performed with 1000 simulations to test model uncertainty. Conditional probabilities of survival and disease progression were extracted from Kaplan-Meier curves from pivotal clinical trials using the WebPlotDigitizer tool. Costs were estimated from public sources in US Dollars ($) and effects were estimated in quality-adjusted life years (QALY) using published utility values. **Results:** Median overall survival was 15 months (95% confidence interval [CI] 13-19 months) with ASCT and 21 months (95% CI 17-29 months) with CAR-T. The PSA demonstrated costs and effectiveness per patient of $243,581 and 1.06 QALYs with ASCT and $470,150 and 1.22 QALYs with CAR-T with an incremental cost-effectiveness ratio (ICER) of $1,383,320/QALY. Incremental net monetary benefit of CAR-T versus ASCT, based on a willingness-to-pay (WTP) threshold of $200,000/QALY, was -$193,812. The break-even price for CAR-T and all subsequent therapies, based on a one-way sensitivity analysis, was $170,489. **Conclusions:** The model demonstrated improved survival and QALYs for the second-line CAR-T therapy, but was not cost-effective, as the ICER exceeded $1,000,000/QALY, which is higher than most accepted WTP thresholds. A limitation of these early data is that they only assess outcomes over three years. To estimate the full effect of these therapies, we will extrapolate the Kaplan-Meier curves for additional analyses. Clinical outcomes of second-line CAR-T are promising, but prices would need to be considerably lower to enable equitable access and affordability. Research Sponsor: None.

Cost-effectiveness table.

Strategy	Cost	Cost 95% CI	QALY	QALY 95% CI	ICER	Notes
ASCT Strategy	$ 243,581	$221,774-$265,460	1.06	0.90-1.22	—	Baseline
CAR-T Strategy	$ 470,150	$460,764-$480,997	1.22	1.02-1.43	$ 1,383,320/QALY

Acalabrutinib versus rituximab plus idelalisib or bendamustine in relapsed/refractory chronic lymphocytic leukemia: ASCEND results at 4 years of follow-up.

First Author: Wojciech Jurczak, Maria Sklodowska-Curie National Research Institute of Oncology, Krakow, Poland

Background: Acalabrutinib (acala) is a next-generation, highly selective, covalent Bruton tyrosine kinase (BTK) inhibitor approved for patients (pts) with chronic lymphocytic leukemia (CLL). In the primary analysis of ASCEND (median follow-up 16.1 mo), acala showed superior efficacy with an acceptable tolerability profile vs idelalisib (Id) plus rituximab (R) (IdR) or bendamustine (B) plus R (BR) in pts with relapsed/refractory (R/R) CLL (Ghia et al. *J Clin Oncol*. 2020;38:2849-2861). We report the results of the ASCEND study at ~4 years of follow-up. **Methods:** In this multicenter, randomized, open-label, phase 3 study (NCT02970318), pts with R/R CLL received oral (PO) acala 100 mg BID until progression or unacceptable toxicity or investigator's (INV) choice of IdR (Id: 150 mg PO BID until progression or unacceptable toxicity; R: 375 mg/m^2 x1 then 500 mg/m^2 IV [8 total infusions]) or BR (B: 70 mg/m^2 IV; R: 375 mg/m^2 x1 then 500 mg/m^2 IV [6 cycles]). Progression-free survival (PFS), overall survival (OS), overall response rate (ORR), and safety were assessed. **Results:** A total of 310 pts (acala, n=155; IdR, n=119; BR, n=36) were randomized (median age 67 y; del(17p) 15%, unmutated IGHV 74%, Rai stage 3/4 42%). At median follow-up of 46.5 mo (acala) and 45.3 mo (IdR/BR), acala significantly prolonged INV-assessed PFS vs IdR/BR (median not reached [NR] vs 16.8 mo; *P*<0.0001); 42-mo PFS rates were 62% for acala vs 19% for IdR/BR. In pts with del(17p), median PFS was NR (acala) vs 13.8 mo (IdR/BR; *P*<0.0001). In pts with unmutated IGHV, median PFS was NR (acala) vs 16.2 mo (IdR/BR; *P*<0.0001). Median OS was NR in both arms; 42-mo OS rates were 78% (acala) vs 65% (IdR/BR). ORR was 83% (acala) vs 84% (IdR/BR) (ORR + partial response with lymphocytosis: 92% [acala] vs 88% [IdR/BR]). AEs led to drug discontinuation in 23% of acala, 67% of IdR, and 17% of BR pts. Events of clinical interest (acala vs IdR/BR) included all-grade atrial fibrillation/flutter (8% vs 3%), all-grade hypertension (8% vs 5%), all-grade major hemorrhage (3% vs 3%), and grade ≥3 infections (29% vs 29%). **Conclusions:** At ~4 years of follow-up, acala maintained efficacy compared with standard-of-care regimens and a consistent tolerability profile in R/R CLL. Clinical trial information: NCT02970318. Research Sponsor: AstraZeneca.

Acalabrutinib ± obinutuzumab versus obinutuzumab + chlorambucil in treatment-naïve chronic lymphocytic leukemia: Five-year follow-up of ELEVATE-TN.

First Author: Jeff Porter Sharman, Willamette Valley Cancer Institute and US Oncology Research Center, Eugene, OR

Background: For ELEVATE-TN (NCT02475681), we previously reported superior efficacy of acalabrutinib (A) ± obinutuzumab (O) vs O + chlorambucil (Clb) in patients (pts) with treatment-naive (TN) chronic lymphocytic leukemia (CLL) at 28.3 and 46.9 months (mo) median follow-up. Now, we report results from a 5-y update. **Methods:** Pts were randomized to A+O, A, or O+Clb. Pts who progressed on O+Clb could cross over to A monotherapy. Investigator-assessed (INV) progression-free survival (PFS), INV overall response rate (ORR), overall survival (OS), and safety were evaluated. **Results:** A total of 535 pts (A+O, n=179; A, n=179; O+Clb, n=177) had a median age of 70 y. At a median follow-up of 58.2 mo (range, 0.0–72.0; data cutoff Oct 1, 2021), median PFS was not reached (NR) (hazard ratio [HR]: 0.11) for A+O and A (HR: 0.21) vs 27.8 mo for O+Clb (both *P*<0.0001). Estimated 60-mo PFS rates were 84% (A+O), 72% (A), and 21% (O+Clb). Median OS was NR in any treatment arm, and significantly longer in the A+O vs O+Clb arms (HR: 0.55; *P*=0.0474); estimated 60-mo OS rates were 90% (A+O), 84% (A), and 82% (O+Clb). ORR was significantly higher with A+O (96%; 95% CI 92–98) and A (90%; 85–94) vs O+Clb (83%; 77–88; *P*<0.0001 [A+O], *P*=0.0499 [A]). Complete response (CR)/CR with incomplete hematologic recovery (CRi) rates were higher with A+O (29%/3%) vs O+Clb (13%/1%); 13%/1% had CR/CRi with A; CR increased since the interim analysis (previously 21% [A+O] and 7% [A]). Adverse events (AEs) and treatment exposure are shown in the Table. Treatment is ongoing in 65% (A+O) and 60% (A) of pts; the most common reasons for treatment discontinuation were AEs (17% [A+O], 16% [A], 14% [O+Clb]) and progressive disease (6%, 10%, 2%, respectively). Crossover from O+Clb to A occurred in 72 (41%) patients; 25% of these pts discontinued A (10% due to AEs and 11% due to progressive disease). **Conclusions:** After a 5-y follow-up, efficacy and safety of A+O and A monotherapy were maintained, with significantly longer OS in the A+O arm compared with O+Clb. Clinical trial information: NCT02475681. Research Sponsor: AstraZeneca.

Four-year follow-up from a phase 2 study of obinutuzumab, ibrutinib, and venetoclax in CLL.

First Author: Kerry Anne Rogers, Division of Hematology, The Ohio State University, Columbus, OH

Background: Targeted agent combinations for chronic lymphocytic leukemia (CLL) have resulted in safe regimens with improved progression-free survival (PFS) compared to chemoimmunotherapy. The optimal regimen and long-term outcomes remain unknown. We conducted a phase 2 study of obinutuzumab (OBIN), ibrutinib (IBR), and venetoclax (VEN) in relapsed/refractory (RR) and treatment-naïve (TN) CLL patients (pts) and report extended follow up on two previously reported cohorts (RR, TN 1) and a new cohort of identically treated TN pts (TN 2). **Methods:** Pts with TN or RR (≥1 prior treatment) CLL requiring treatment were eligible. Treatment was given for 14 28-day cycles (C). OBIN was started C1, IBR C2, and VEN C3 with standard dose escalation. Response was assessed 2 months (mos) after C14 (EOT) by iwCLL 2008 criteria. Minimal residual disease (MRD) was measured by 10-color flow cytometry with a cutoff of $< 1x10^{-4}$. The primary endpoint was complete remission (CR) with undetectable MRD (uMRD) in blood and bone marrow at EOT. A sample size of 25 pts per cohort achieves 90% power to test the null hypothesis of 10% against 30% with 1-sided α of 10%. The Kaplan-Meier method was used to estimate PFS and overall survival (OS). **Results:** 75 pts were treated in 3 cohorts (Table). Data are as of 1/3/2022. In the TN 2 cohort, the overall response rate (ORR) at EOT was 96% (95% CI: 80-100) and CR with uMRD was 20% (95% CI: 7-41). The ORR for TN 1 and TN 2 combined was 90% (95% CI: 78-97) and CR with uMRD was 24% (95% CI: 13-38). Median follow up was 56 (0-65), 57 (7-63), and 30 (24-35) mos, respectively, for RR, TN 1, and TN 2. There were 3 deaths (RR = 1, TN 1 = 1, TN 2 = 1) and 6 disease progressions (RR = 4, TN 1 = 2, TN 2 = 0). Estimated 48-month PFS for TN 1 and RR cohorts were both 96% (95% CI: 72-99) and OS was 85% (95% CI: 60-95) and 100%, respectively. The estimated 24-month PFS and OS for TN 2 were both 96% (95% CI: 75-99). The most frequent adverse events were neutropenia (95%, 73% grade ≥3), leukopenia (95%, 45% grade ≥3), lymphopenia (93%, 40% grade ≥3), and thrombocytopenia (91%, 28% grade ≥3). The only grade ≥3 non-hematologic toxicity occurring at ≥20% was hypertension (85%, 39% grade ≥3). Atrial fibrillation occurred in 11% of pts. **Conclusions:** At extended follow-up, remissions remain durable after fixed duration OBIN, IBR, and VEN. The efficacy and acceptable safety justify further study and are being compared to IBR and OBIN in 2 phase 3 US cooperative group trials. Clinical trial information: NCT02427451. Research Sponsor: Genentech.

Preclinical activity of irreversible Menin inhibitor, BMF-219, in chronic lymphocytic leukemia.

First Author: Priyanka Somanath, Biomea Fusion, Inc., Redwood City, CA

Background: Menin is a scaffold protein that drives oncogenic function through transcriptional modulation directed by its various cofactors. A previous report demonstrated that menin regulates a distinct set of gene targets independent of its function with the MLL proteins in hematopoiesis and is essential for B-cell maturation (Li et al.*Blood.*2013;122(12):2039-46.). Chronic Lymphocytic Leukemia (CLL) is a disease of malignant B lymphocytes, for which standard-of-care agents are generally well tolerated; however, CLL patients with certain genetic backgrounds demonstrate inferior outcomes to these regimens. A major driving feature of CLL is overexpression of the anti-apoptotic marker, BCL2. We previously reported the ability of BMF-219, a selective, irreversible menin inhibitor, to downregulate the expression of BCL2 in acute leukemia cells. Additionally, we have reported the synergy of BCL2-targeted agent, venetoclax, with BMF-219 in potent cell killing of diffuse large B-cell lymphoma (DLBCL) preclinical models, prompting our exploration of BMF-219 activity in CLL. Here, we provide the first preclinical evidence for menin as a therapeutic target in CLL, by demonstrating high potency of BMF-219 against a diverse collection of CLL patient specimens. **Methods:** A comprehensive panel of CLL samples isolated from patients with Rai Stage 1 to 3 disease, including relapsed or refractory disease, were cultured *ex vivo* in the presence of BMF-219 or clinical reversible menin inhibitors to assess the antileukemic activity of the compounds. Samples were analyzed for differential gene expression of select targets in response to treatment. **Results:** BMF-219 demonstrated high potency, achieving > 98% cell lethality at 1 μM exposure in all patient samples tested, with IC_{50} values in the range of 0.1 to 0.38 μM. Specimens isolated from patients with clinical profiles of high-risk genetic backgrounds associated with inferior outcomes to standard therapy, such as mutations in TP53 and NOTCH1, and chromosomal aberrations such as del(13q), trisomy 12 and complex karyotype, exhibited high sensitivity to BMF-219 treatment. BMF-219 was also highly effective against patient samples with clinical profiles of resistance to bendamustine, ibrutinib and venetoclax therapy. In comparison, clinical reversible menin inhibitors demonstrated no significant activity across all patient samples tested, with incalculable IC_{50} values and < 15% reduction in cell viability at 1 μM exposure. Expression of select target genes in treated CLL cell lines was explored and will be reported. **Conclusions:** Collectively, our data demonstrate the potent preclinical activity of BMF-219 against CLL patient specimens harboring various mutational and cytogenetic backgrounds, including categories of high-risk. These data highlight the unique potential of irreversible menin inhibition as a novel therapeutic option for patients with CLL. Research Sponsor: None.

Racial and socioeconomic disparities among patients with chronic lymphocytic leukemia: Analysis of Surveillance, Epidemiology, and End Results program data. *First Author: Adam Kittai, Division of Hematology, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Therapy for chronic lymphocytic leukemia (CLL) has changed dramatically over the past 20 years. With the cost of new therapies and rapid practice changes, it is unclear if patients (pts) are benefiting equally from this progress. We assessed Surveillance, Epidemiology, and End Results (SEER) program data to determine how race and socioeconomic status (SES) affect survival for pts with CLL. **Methods:** CLL cases reported to 18 SEER Program registries from 2006 – 2018 were included. Pt characteristics such as age at diagnosis (dx), sex, year (yr) of dx, race, and SES as determined by rural/urban census tract residence (RUCA), and neighborhood (as represented by the Yost Index, a composite measure of 7 variables assessing different aspects of the SES of a census tract) were collected and analyzed. Multivariable cox regression (MVA) was used to determine adjusted odds of survival. Two separate databases were utilized, one which included data to 2018, and another which contained SES data but only had data available to 2016. **Results:** 46,605 cases from 2009 – 2018 were identified without SES data. The median age was 70 yrs, 60% were male, and there was an even distribution of patients diagnosed with CLL annually from 2009 – 2018. Of the cases with race reported, 89.9% were white, 7.3% Black, 2.4% Asian/Pacific islander, and 0.3% American Indian/Alaska Native. After a median follow up of 47 months, the median 3, 5, and 10 yr overall survival (OS) was 79.5%, 69.5%, and 48.8%, respectively. MVA showed Black race (HR 1.5, 95% CI 1.4 – 1.6) as the strongest independent prognostic variable for worse OS controlling for yr of dx, suggesting race was a significant factor in OS in the era of modern therapies. Using the linked RUCA and Yost tertiles for SES, 47,867 cases of CLL from 2006 – 2016 were analyzed. Median age, sex, and race distribution were similar to the prior analysis. MVA showed American Indian/Alaska Native, and Black race as independent prognostic variables for worse OS, and Yost group 2 and 3, representing higher SES, were found to be significant independent prognostic variables for improved OS (Table 1). In this analysis, race remained an independent variable for worse OS after controlling for SES. **Conclusions:** Black race and low SES are prognostic of OS in CLL. Further research is needed to determine whether this is due to access to therapy, quality of care, social determinants of heath, or disease biology. Research Sponsor: None.

A phase Ib/II study of lisaftoclax (APG-2575), a novel BCL-2 inhibitor (BCL-2i), in patients (pts) with relapsed/refractory chronic lymphocytic leukemia or small lymphocytic lymphoma (R/R CLL/SLL). *First Author: Jianyong Li, Jiangsu Province Hospital, Nanjing, China*

Background: B-cell malignancies evade apoptosis by overexpressing BCL-2 proteins. Approved BCL-2i venetoclax requires a slow dose ramp-up to limit risk of tumor lysis syndrome (TLS) and has been associated with severe neutropenia. Investigational single-agent lisaftoclax is a novel, oral BCL-2i active against hematologic malignancies (HMs), with potentially synergistic antitumor effects when combined with other agents in B-cell malignancies. **Methods:** The aim of this multicenter open-label study was to evaluate dose-limiting toxicity (DLT), maximum tolerated dose (MTD), recommended phase 2 dose (RP2D), efficacy, pharmacokinetics (PK), and pharmacodynamics of lisaftoclax in pts with R/R CLL/SLL (per 2008 iwCLL NCI-WG guidelines). Lisaftoclax was administered orally once daily at 3 dose cohorts (400, 600, or 800 mg) every 28 days, with 15 pts in each cohort. **Results:** As of the data cutoff date of January 25, 2022, 45 pts had been enrolled, with a median (range) age of 58 (38-80) years. DLT and MTD were not observed. The preliminary PK profile showed that exposures increased with lisaftoclax doses from 400 to 800 mg (average half-life: 4.2-6.6 hours). A total of 42 pts experienced any-grade treatment-related adverse events (AEs), including neutropenia (55.6%); anemia (42.2%); decreased leukocyte count (40%); thrombocytopenia (37.8%); lowered lymphocyte count (17.8%); hyperuricemia (31.1%); hypokalemia (24.4%); increased blood bilirubin (22.2%); hypertriglyceridemia (20%); diarrhea (20%); hyperphosphatemia, hypocalcemia, and decreased weight (15.6% each); increased AST (15.6%) and blood LDH (13.3%); pyrexia; and increased ALT and blood creatinine (11.1% each). A total of 28 (62.2%) pts experienced grade ≥ 3 AEs and 13 (28.9%) serious AEs. Of these, 25 (55.6% of total) and 9 (20%) were related to lisaftoclax, and 14 (31.1%) led to treatment discontinuation. One clinical TLS was reported. With a median (range) treatment of 7 (1-17) cycles and median (range) time to response of 1 (1-13) cycles, 1 of 41 evaluable pts with CLL experienced complete response (CR) and 27 with CLL/SLL achieved partial response (PR), for an objective response rate (ORR) of 68.29%. The RP2D of lisaftoclax as monotherapy was determined as 600 mg. **Conclusions:** BCL-2i lisaftoclax was well tolerated up to 800 mg/day. There were no significant new or unmanageable safety findings, and the ORR was 68.29%. Lisaftoclax may offer a treatment alternative for pts with R/R HMs, with a daily ramp-up schedule that may be more convenient and "user friendly." Clinical trial information: NCT04494503. Research Sponsor: Ascentage Pharma Group Corp Ltd (Hong Kong).

7544 **Poster Session**

Survival outcomes in patients with chronic lymphocytic leukemia treated at academic centers. *First Author: Victoria Vardell, University of Utah, Salt Lake City, UT*

Background: Chronic lymphocytic leukemia (CLL), the most prevalent leukemia in western countries, is associated with highly variable clinical outcomes. This study aims to evaluate whether patients with CLL treated at Commission on Cancer accredited academic centers (ACs), which offer high clinical volume, clinical trial access, and postgraduate physician education, have improved survival compared to non-academic centers (NACs). **Methods:** The National Cancer Database (NCDB) was used to identify CLL patients diagnosed between 2004-2018. Demographic and treatment characteristics were compared between center categories with binary logistic regression for odds of receiving CLL treatment at an AC. Survival analysis was completed with Kaplan Meier and multivariate Cox regression, adjusted for the only available disease-related characteristics in the NCDB, age and Charlson-Deyo comorbidity score, to compare overall survival (OS). **Results:** Of the 98,186 patients identified, 33.3% were treated at ACs. Patients treated at ACs were younger than those treated at NACs (median age 67 vs. 71 years, p<0.001). ACs were more likely to treat Black and other minority patients, with Black patients representing 9.7% vs. 6.3% of AC vs NAC patients (p<0.001). ACs were more likely than NACs to treat privately insured (39.1% vs. 30.3%), uninsured (3.2% vs.2.0%) and patients on Medicaid (4.1% vs. 2.9%) (p<0.001), as well as patients from the highest quartiles of income (OR 1.46), and education (OR 1.12), when referenced to lowest quartiles (p<0.001). ACs were more likely to manage patients with surveillance versus NACs (53.7% vs. 45%, p<0.001). With a median follow up of 4.3 years, median OS at ACs was significantly improved when compared to NACs, with a median OS of 11.0 years (CI 10.5-11.3) vs. 8.2 years (CI 8.1-8.3), respectively (p<0.001). Survival benefit was maintained at both 5-years (73% vs. 66%) and 10-years (53% vs. 43%) (both p<0.001). On multivariate analysis adjusted for age and comorbidity, management of CLL patients at ACs was an independent factor for improved OS (HR 0.87, CI 0.85-0.89, p<0.001). **Conclusions:** In this study of a large population of CLL patients, there is significant demographic and socioeconomic variation between CLL patients treated at ACs and NACs. While our study is limited by the available disease and treatment level data available, the improved OS benefit of CLL patients managed at ACs suggests possible differences in treatment and clinical trial availability, and supportive care management. Further investigations into the factors contributing to such disparities would be beneficial to help standardize care and improve outcomes. Research Sponsor: U.S. National Institutes of Health.

Favezelimab (anti–LAG-3) plus pembrolizumab in patients with relapsed or refractory (R/R) classical Hodgkin lymphoma (cHL) after anti–PD-1 treatment: An open-label phase 1/2 study. *First Author: John Timmerman, UCLA Medical Center, Los Angeles, CA*

Background: PD-1 inhibitors are a standard of care for R/R cHL but optimal therapy after anti–PD-1 therapy failure is yet to be defined. LAG-3/PD-1 coblockade has demonstrated antitumor activity in preclinical models. This multicohort phase 1/2 study (NCT03598608) evaluated the safety and efficacy of favezelimab (MK-4280), a humanized IgG4 LAG-3 inhibitor, plus the PD-1 inhibitor pembrolizumab (pembro) in pts with R/R hematologic malignancies. Cohort 2 focused on pts with R/R cHL refractory to anti–PD-1 therapy. **Methods:** This study included a safety lead-in phase (part 1) to determine recommended phase 2 dose (RP2D) followed by a dose-expansion phase (part 2). Eligible pts in cohort 2 had R/R cHL, relapsed after or were ineligible for autologous stem cell transplantation (ASCT), and progressed after ≥2 doses of anti–PD-1 therapy (within 12 weeks of last dose). In part 1, pts from all cohorts received pembro IV 200 mg Q3W and favezelimab IV 200 mg or 800 mg Q3W. Dose-finding based on occurrence of dose-limiting toxicities (DLT) was determined using an mTPI design. In part 2, pts received pembro + favezelimab at the established RP2D for up to 35 cycles. Primary end point was safety. Secondary end point was ORR. DOR, PFS, and OS were exploratory. **Results:** Only 1 DLT (autoimmune hepatitis [grade 4]) was observed among the first 6 pts from all cohorts in part 1 at the favezelimab 200 mg dose; thus, the dose was escalated to 800 mg. No DLTs were observed in 15 additional pts at the 800 mg dose. Favezelimab RP2D was defined as 800 mg Q3W + pembro 200 mg Q3W. In cohort 2, 33 pts were enrolled; median age was 37 yrs, 64% had ECOG PS 0, and 94% had ≥4 prior lines of therapy. After a median follow-up of 16.5 mo, ORR for pts receiving favezelimab 800 mg (n = 29) was 31% (95% CI, 15-51; CR, 2 [7%]; PR, 7 [24%]); 66% of responders had an anti–PD-1–based regimen as most recent line of therapy at study entry. 23 of 29 pts (79%) had reduction from baseline in target lesions. Median DOR for pts who received favezelimab 800 mg was not reached (NR; 95% CI, 0+ to 14+ mo). For all pts in cohort 2, median PFS was 9 mo (95% CI, 5-15); 12-mo PFS rate was 39%. Median OS was 26 mo (95% CI, 26-NR); 12-mo OS rate was 91%. At database cutoff (Nov 1, 2021), 20 pts discontinued treatment (7 AEs, 11 PD/clinical progression, 2, withdrawal/physician decision). TRAEs occurred in 28 pts (85%); most common (> 10%) were hypothyroidism (18%), nausea and fatigue (15% each), and arthralgia and diarrhea (12% each); grade 3 or 4 TRAEs occurred in 6 pts (18%); 18% discontinued treatment due to TRAEs. No treatment-related deaths occurred. **Conclusions:** Favezelimab 800 mg + pembro 200 mg Q3W showed a tolerable safety profile and effective antitumor activity in heavily pretreated pts with R/R cHL whose disease had progressed after anti–PD-1 therapy, suggesting that the combination may reinduce a response in these pts. Clinical trial information: NCT03598608. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Polatuzumab vedotin with dose-adjusted etoposide, cyclophosphamide, doxorubicin, and rituximab (Pola-DA-EPCH-R) for upfront treatment of aggressive B-cell non-Hodgkin lymphomas. *First Author: Ryan C Lynch, University of Washington/Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: The phase 3 POLARIX trial demonstrated the superiority of polatuzumab vedotin (Pola) over vincristine in the R-CHOP regimen for large B-cell lymphomas. However, it is unknown if Pola can be safely incorporated into intensified regimens typically utilized for the highest risk histologies. To address this question, we conducted a prospective trial (NCT04231877) evaluating Pola with dose adjusted etoposide, cyclophosphamide, doxorubicin, and rituximab (Pola-DA-EPCH-R). **Methods:** This is a single center, open label, investigator-initiated clinical trial of 6 cycles of Pola-DA-EPCH-R in aggressive large B-cell lymphomas where DA-EPOCH-R is considered standard (eg. HGBCL, PMBCL, and select DLBCL-NOS). Pola is given at 1.8 mg/kg on day 1 without intra-patient dose escalation. All other components of the regimen including escalation of chemotherapy dosing based on neutrophil and platelet nadirs from the previous cycle are given according to Dunleavy et al NEJM 2013. The primary objective is to estimate the safety of Pola-DA-EPCH-R as measured by the rate of dose-limiting toxicities (DLTs) in the first 2 cycles with pre-specified suspension rules if the lower limit of an 80% confidence interval cannot exclude a DLT rate of > 20%. Efficacy, survival, and correlative analyses will also be performed. **Results:** 18 patients enrolled on study and as of Feb 15, 2022, 3 patients remain on study treatment. Median age was 64 years (range 41-74). With only 3 DLTs, the study met its primary endpoint for safety. Five SAEs were observed, including one grade 5 sepsis/typhlitis (during cycle 1), 3 episodes of febrile neutropenia, and a grade 3 perforation of a colonic diverticula which required a treatment delay of 12 days before completing all expected study therapy. Other grade 3+ non-heme AEs in more than one pt. include hyperglycemia (17%), oral mucositis (17%), incidental asymptomatic pulmonary embolism (17%), abdominal pain (11%), and hypokalemia (11%). Grade 1 peripheral sensory neuropathy was uncommon (22%), no grade 2+ neuropathy was observed. One patient required a decrease in Pola dosing due to a platelet nadir at dose level 1. Among those with at least 2 cycles of treatment, 94% were able to increase chemotherapy to at least dose level 2 (Table). Post cycle 2 interim overall response rate (ORR) and complete response (CR) rate was 88% and 24%, respectively. EOT ORR and CR was 93% and 71%, respectively, with one PD. Updated data will be presented at the meeting. **Conclusions:** Using Pola at 1.8 mg/kg to replace vincristine in the DA-EPOCH-R regimen appears feasible and met its primary safety endpoint. These data support the further evaluation and use of this approach in histologies where the potential benefit of both an intensified regimen and Pola may be desired. Clinical trial information: NCT04231877. Research Sponsor: Genentech.

Phase 1 dose escalation study of MH048, a novel and non-covalent BTK inhibitor in patients with relapsed or refractory B-cell malignancies. *First Author: Guoqing Cao, Minghui Pharmaceutical (Shanghai) LTD, Shanghai, China*

Background: Despite impressive clinical response of covalent Bruton's tyrosine kinase (BTK) inhibitors in multiple B cell malignancies, treatment failure often occurs through drug resistance most commonly due to BTK cysteine-481 (C481) mutation or intolerance due to off-target toxicities. We evaluated the safety, pharmacokinetics (PK) and preliminary antitumor efficacy of MH048, an orally bioavailable, potent, and reversible inhibitor of both wild type and C481S-mutant BTK, in selected patients with relapsed or refractory (R/R) B-cell malignancies. **Methods:** Eligible patients with R/R B-cell malignancies were enrolled in a Phase 1, multicenter, open-label, dose escalation study. The primary objectives were to assess the safety and tolerability of MH048, and to determine the maximal tolerated dose (MTD) and the recommended dose for expansion. The secondary objectives were to assess the PK profile and preliminary evidence of anti-tumor activity. **Results:** Twelve patients were treated with MH048 across six dose levels (5 mg, 15 mg, 45 mg, 90 mg, 135 mg, 200 mg QD) in fast state. No dose-limiting toxicities were observed and the MTD was not reached. The most common drug-related TEAEs (Any grade) that occurred in > 2 patients were platelet count decrease (n=5), anemia (n=4), neutrophil count decrease (n=4), lipase increase (n=3), and white blood cell count decrease (n=3). Drug-related grade 3 TEAEs included platelet count decrease, neutrophil count decrease, lipase increase, and hypertension (one patient for each). Plasma exposure of MH048 and its active metabolite (M3) increased in a dose-proportional manner from 5 to 200 mg dose levels. Sign of efficacy was observed starting from 15 mg. Among eleven efficacy-evaluable patients (one patient in 200 mg cohort is yet to be evaluated), one complete response (CR) and four partial responses (PRs) were achieved in ≥90 mg cohorts, including patients with MZL (n=1, CR), MCL (n=2), SLL (n=1) and DLBCL (n=1). Of the two MCL patients with PRs, one was heavily pretreated including ibrutinib prior to the enrollment. The recommended doses for expansion were selected as 135 and 200 mg. **Conclusions:** MH048 was well-tolerated and efficacy in heavily pre-treated patients with B-cell malignancies was observed. Pharmacokinetics studies suggest once-daily dosing. The dose expansion study is ongoing at 135 and 200 mg QD for CLL and MCL patients. Clinical trial information: NCT04689308. Research Sponsor: Minghui Pharmaceutical.

Clinical and patient (pt)-reported outcomes (PROs) in a phase 3, randomized, open-label study evaluating axicabtagene ciloleucel (axi-cel) versus standard-of-care (SOC) therapy in elderly pts with relapsed/refractory (R/R) large B-cell lymphoma (LBCL; ZUMA-7). *First Author: Jason Westin, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Elderly pts with R/R LBCL are at risk of inferior outcomes, increased toxicity, and inability to tolerate second-line (2L) SOC treatment (Tx) (Di M, et al. *Oncologist.* 2021). Further 2L SOC Tx is often associated with poor health-related quality of life (QoL) (Lin V, et al. *J Clin Oncol.* 2020;38:e20070). In the pivotal Phase 3 ZUMA-7 study, we assessed outcomes, including PROs, of 2L axi-cel (an autologous anti-CD19 CAR T-cell therapy) versus SOC in elderly pts with R/R LBCL. **Methods:** Pts aged ≥65 y were assessed in a planned subgroup analysis. Pts with ECOG PS 0-1 and R/R LBCL ≤12 mo after 1L chemoimmunotherapy (CIT) were randomized 1:1 to axi-cel or SOC (2-3 cycles of platinum-based CIT; pts with partial or complete response [CR] proceeded to HDT-ASCT). PRO instruments, including the EORTC QLQ-C30 (Global Health [GH] and Physical Functioning [PF]) and the EQ-5D-5L VAS, were administered at timepoints including baseline (BL; prior to Tx), Day (D) 50, D100, D150, and Month (M) 9, then every 3 mo up to 24 mo or time of event-free survival event (EFS), whichever occurred first. The QoL analysis set included all pts who had a BL PRO and ≥1 completed measure at D50, D100, or D150. A clinically meaningful change was defined as 10 points for each EORTC QLQ-C30 score, 7 points for EQ-5D-5L VAS score. **Results:** As of 03/18/2021, 51 and 58 elderly pts were randomized to the axi-cel and SOC arms, respectively, with median ages (range) of 70 y (65-80) and 69 y (65-81). At BL, more axi-cel versus SOC pts had high-risk features, including 2L age-adjusted IPI 2-3 (53% vs 31%) and elevated LDH (61% vs 41%). EFS was superior with axi-cel versus SOC (HR, 0.276, P< 0.0001), with higher CR rates (75% vs 33%). Grade ≥3 Tx-emergent adverse events (AEs) occurred in 94% and 82% of axi-cel and SOC pts, respectively, and Grade 5 Tx-related AEs occurred in 0 and 1 pt. In the QoL analysis set comprising 46 axi-cel and 42 SOC pts, there were statistically significant and clinically meaningful differences in mean change of scores from BL at D100 favoring axi-cel for EORTC QLQ-C30 GH (P<0.0001) and PF (P=0.0019) and EQ-5D-5L VAS (P<0.0001). For all 3 domains, scores also favored (P<0.05) axi-cel over SOC at D150. The mean estimated scores numerically returned to or exceeded BL scores earlier in the axi-cel arm (by D150) but never equaled or exceed BL scores by M15 in the SOC arm. **Conclusions:** Axi-cel demonstrated superiority over 2L SOC in pts ≥65 y with significantly improved EFS and a manageable safety profile. Compared with SOC, axi-cel also showed meaningful improvement in QoL over SOC, measured by multiple validated PRO instruments, with suggested faster recovery to pre-Tx QoL. The superior clinical outcomes and pt experience with axi-cel over SOC should help inform Tx choices in 2L R/R LBCL for pts ≥65 y. Clinical trial information: NCT03391466. Research Sponsor: Kite, a Gilead Compnay.

Acalabrutinib in patients with relapsed/refractory (R/R) marginal zone lymphoma (MZL): Results of a phase 2, multicenter, open-label trial. *First Author: L Elizabeth Budde, City of Hope National Medical Center, Duarte, CA*

Background: MZL is a rare indolent B-cell malignancy considered incurable at recurrent stage. Bruton tyrosine kinase (BTK) inhibitors have produced durable responses in patients (pts) with R/R MZL. Acalabrutinib (acala) is a potent next-generation BTK inhibitor with high selectivity for BTK. We report data for acala monotherapy from the R/R MZL cohort (phase 2) of a phase 1b/2 clinical trial (NCT02180711). **Methods:** Pts with histologically confirmed MZL, ECOG performance status ≤2, and ≥1 prior therapy (including ≥1 CD20-directed regimen) received oral acala 100 mg twice daily until disease progression or unacceptable toxicity ± R. The primary objective was overall response rate (ORR; Lugano criteria as assessed by the investigator). Secondary objectives were duration of response (DOR), progression-free survival (PFS), overall survival (OS), and safety. Data were analyzed descriptively (no formal hypothesis testing). **Results:** Forty-two pts received acala (median age 69 y [range 42–84]; median 2 prior systemic regimens [range 1–4]). MZL subtypes were extranodal (43%), nodal (31%), and splenic (26%). At data cutoff (Oct 15, 2021), median follow-up duration was 10.7 mo (range 0.4–42.8). Sixteen (38%) pts discontinued acala, most commonly due to disease progression (26%). Among pts evaluable for response (n = 37; 3 pts had not reached the first assessment timepoint and 2 pts exited the study without response assessment), ORR was 54% (95% CI 37%–71%) with 6 complete (16%) and 14 partial (38%) responses; 17 (46%) pts had stable disease. ORRs in extranodal, nodal, and splenic subtypes were 65%, 44%, and 45%, respectively. Median time to initial response was 3.0 mo; median DOR was 19.3 mo (95% CI 8.4–not estimable). Median PFS was 27.4 mo with a 12-mo PFS rate of 66%. Four pts died (disease progression, n = 2; transformation to diffuse large B-cell lymphoma after stopping treatment, n = 1; adverse event [AE], n = 1 [septic shock unrelated to treatment]); median OS was not reached. Treatment was well tolerated with most AEs being grade 1 or 2. Sixteen pts (38%) had grade ≥3 AEs, most commonly (in ≥2 pts) anemia, dyspnea, neutrophil count decrease (n = 3 each), fatigue, thrombocytopenia, and neutropenia (n = 2 each). AEs led to treatment discontinuation in 2 pts (grade 3 hypotension and grade 1 myalgia). Among AEs of clinical interest, hypertension was reported in 2 pts (both grade 2); no cases of atrial fibrillation/flutter or major hemorrhage were reported. **Conclusions:** These early results indicate that acala is efficacious and well tolerated in pts with R/R MZL. The AE profile is consistent with the known safety profile of acala. Clinical trial information: NCT02180711. Research Sponsor: AstraZeneca.

Impact of bone marrow involvement in patients with peripheral T-cell lymphoma undergoing autologous stem cell transplant. *First Author: Robert Stuver, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Nodal-based T-cell lymphomas (PTCL) are treated with induction therapy and consideration for autotransplant (autoSCT) in first remission. The impact of bone marrow (BM) involvement at diagnosis and at autoSCT is unclear. **Methods:** We performed a retrospective review of consecutive patients with PTCL-NOS, AITL, and ALCL who received autoSCT in first remission at Memorial Sloan Kettering Cancer Center from 1997-2021. For BM involvement at baseline, patients were classified as positive (≥5% by histology), any involvement (by histology and/or at least 1 high-sensitivity [HS] assay, referring to flow or clonal TCR gene rearrangement), or negative (no involvement by histology and at least 1 negative HS assay). Patients with no baseline BM biopsy were excluded. At end of therapy (EOT, after induction but prior to autoSCT), BM involvement was considered positive (≥5% by histology), minimal residual disease positive (MRD+, no histological involvement but at least 1 positive HS assay), and MRD- (no histological involvement and at least 1 negative HS assay). Patients with no EOT BM but negative baseline BM were included as a separate cohort. Patients with no baseline BM and no EOT BM were excluded, as were those with baseline BM involvement and no EOT BM. The Kaplan-Meier method was used to estimate survival and compared using log-rank tests. **Results:** A total of 135 patients were included. Median follow-up after autoSCT for survivors was 56 months. The 5-year PFS/OS for the entire cohort was 45% and 65%, respectively. By histology, 5-year PFS/OS for PTCL-NOS (N = 27), AITL (N = 78), ALK+ (N = 8) and ALK- (N = 21) ALCL was 36%, 37%, 75%, 74% (p = 0.005), and 51%, 59%, 100%, 85% (p = 0.01). Among those with adequate baseline BM evaluation (N = 98), 31 were positive, 52 had any involvement, and 44 were negative. Five-year PFS and OS in the positive, any involvement, and negative groups was 46%, 42%, 44% (p = 0.82), and 63%, 61%, 74% (p = 0.27). Of those with adequate EOT BM evaluation (N = 72), 1 was positive, 17 were MRD+, and 43 were MRD-; 32 patients had no EOT BM but negative baseline BM. Five-year PFS and OS by the EOT positive, MRD+, MRD-, and no EOT BM but negative baseline groups was 0%, 37%, 45%, 45% (p = 0.86), and 0%, 92%, 59%, 71% (p = 0.39). Of the 17 patients with MRD+ EOT BM, 14 (82%) had AITL. Two-year PFS/OS in the AITL only cohort by EOT BM was 0%, 54%, 48%, 33%, and 0%, 90%, 75%, 72%, for the positive, MRD+, MRD-, and no EOT BM but negative baseline groups (PFS: p = 0.4; OS: p = 0.3). **Conclusions:** In patients treated with upfront induction and autoSCT in first remission, neither BM involvement at diagnosis nor the presence of MRD at the time of autoSCT resulted in worse survival outcomes compared to those with no BM involvement. For patients with PTCL-NOS, AITL, or ALCL in first remission, baseline BM involvement or pre-autoSCT BM MRD+ should not dissuade use of autoSCT consolidation. Research Sponsor: None.

7551 **Poster Session**

Initial safety run-in results of the phase III POLARGO trial: Polatuzumab vedotin plus rituximab, gemcitabine, and oxaliplatin in patients (pts) with relapsed/refractory diffuse large B-cell lymphoma (R/R DLBCL). *First Author: Matthew J. Matasar, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Transplant-ineligible pts with R/R DLBCL have a poor prognosis (Gisselbrecht C, et al. Br J Haematol 2018). Several treatment options are available including platinum-based chemotherapies such as oxaliplatin plus rituximab and gemcitabine (R-GemOx). Adding polatuzumab vedotin to R-GemOx (Pola-R-GemOx) may improve outcomes for pts with a continued unmet medical need. The safety of polatuzumab vedotin and platinum-based therapy combinations must be considered as both are associated with neuropathy. POLARGO (NCT04182204; MO40598) is a Phase III, multicenter, open-label, randomized trial evaluating the safety and efficacy of Pola-R-GemOx vs R-GemOx in pts with R/R DLBCL. **Methods:** Results from the safety run-in stage of POLARGO are presented. The primary endpoint is the safety and tolerability of polatuzumab vedotin (1.8 mg/kg) + R-GemOx (R, 375 mg/m^2; Gem, 1000 mg/m^2; Ox, 100 mg/m^2) given every 21 days for up to 8 cycles. Safety was assessed by the incidence, nature, and severity of adverse events (AEs; NCI CTCAE v5.0), with a focus on peripheral neuropathy (PN). Dose interruptions and reductions were used to assess tolerability. Granulocyte-colony stimulating factor was given as primary prophylaxis with each cycle (C) of therapy; anti-infective prophylaxis for pneumocystis and herpes virus was mandatory. **Results:** As of October 26, 2021, 15 pts were enrolled and 11 (73%) pts received ≥4 cycles of Pola-R-GemOx. Median age was 76 (range 47–87) years, 10 (67%) pts had an IPI score of 3–5, 7 (47%) had ≥2 prior therapy lines, and 8 (53%) were refractory to last treatment. Grade (Gr) 3–4 AEs were reported in 5 (33%) pts: thrombocytopenia (20%) and neutropenia (13%) were the most common. Two (13%) pts had serious AEs (Gr 3 febrile neutropenia and Gr 3 infection [n = 1 each]). There were no Gr 5 AEs or AEs leading to drug discontinuation. Eight (53%) pts had Gr 1 or 2 PN; there were no cases of Gr >3 PN. Three (20%) pts had drug interruptions due to PN. Two (13%) pts had a dose reduction of polatuzumab vedotin and oxaliplatin due to PN at C5 and C8, respectively; one pt (7%) had a dose reduction of polatuzumab vedotin due to Gr 4 thrombocytopenia at C2. End-of-treatment (EOT) objective response rate was 40% (95% CI: 16–68) and complete response rate was 27% (95% CI: 8–55); 7 (47%) pts had progressive disease at EOT. Ten (67%) pts received subsequent therapies following Pola-R-GemOx, including CAR-T cell therapy (n = 3) and stem-cell transplant (n = 1). **Conclusions:** In the safety run-in stage, Pola-R-GemOx was safe and tolerable. PN was manageable with dose interruptions and reductions; no cases of Gr ≥3 PN were observed. The toxicity of this combination did not compromise delivery of subsequent treatments. POLARGO is currently enrolling pts to receive Pola-R-GemOx vs R-GemOx; results will be presented at a future meeting. Clinical trial information: NCT04182204. Research Sponsor: POLARGO is sponsored by F. Hoffmann-La Roche Ltd and Genentech, Inc. Third-party editorial assistance, under author direction, was provided by Cheryl Wright and Stephanie Cumberworth of Ashfield MedComms, and was funded by F. Hoffmann--La Roche Ltd.

Tislelizumab, a PD-1 inhibitor for relapsed/refractory mature T/NK-cell neoplasms: Results from a phase 2 study. *First Author: Emmanuel Bachy, Hematology Department, Lyon Sud Hospital and Claude Bernard University Lyon 1, Lyon, France*

Background: Effective treatment choices for patients (pts) with relapsed/refractory (R/R) mature T/NK-cell neoplasms after failure of standard therapies are limited. Tislelizumab (TIS), a humanized anti-PD-1 mAb, demonstrated outstanding efficacy and favorable safety in pts with R/R classical Hodgkin lymphoma or solid tumors. We present safety and efficacy of the phase 2 study of TIS in pts with R/R mature T/NK-cell neoplasms. **Methods:** Pts were enrolled into 3 cohorts stratified by the type of T/NK-cell neoplasm to receive TIS 200 mg intravenously every 3 weeks until disease progression or intolerable toxicity. Eligible pts had ≥1 prior systemic therapy, disease progression during/after most recent therapy completion or refractory disease, ECOG ≤2, and life expectancy ≥6 mo. Primary endpoint was investigator-assessed overall response rate (ORR). Secondary endpoints included duration of response (DoR), complete response (CR) rate, progression-free survival (PFS), overall survival (OS) in cohorts 1 and 2, and safety. **Results:** 77 pts were treated. Cohort 1: R/R extranodal NK/T-cell lymphoma (n = 22); cohort 2: R/R mature T-cell neoplasms (n = 44; 21 peripheral T-cell lymphoma not otherwise specified; 11 angioimmunoblastic T-cell lymphoma; 12 anaplastic large cell lymphoma); cohort 3: R/R cutaneous T-cell lymphomas (CTCL; stage ≥1B; n = 11; 8 mycosis fungoides and 3 Sézary syndrome). Of all pts, 76.6% had advanced-stage disease, 51.9% had refractory disease, and 49.4% had ≥3 prior systemic regimens. Median treatment cycles for cohorts 1, 2, and 3 were 5 (range, 1-37), 4.5 (range, 1-38), and 17 (range, 3-25), respectively. Cohort 3 had promising efficacy (median follow-up [FU] 16.6 mo): ORR 45.5%; CR 9.1%; median DoR 11.3 mo (95% CI: 2.76-11.30); median PFS 16.8 mo; median OS not reached (NR). Modest efficacy was reported in cohort 1 (median FU 8.4 mo): ORR 31.8%; CR 18.2%; median DoR NR (95% CI: 2.66-not estimable [NE]); median PFS 2.7 mo; median OS 8.8 mo and also in cohort 2 (median FU 9.3 mo): ORR 20.5%; CR 9.1%; median DoR 8.2 mo (95% CI: 2.50-NE); median PFS 2.7 mo; median OS 13.3 mo. Most frequent adverse events (AEs) were pyrexia (32.5%), anemia (18.2%), arthralgia (18.2%), and diarrhea (15.6%); most frequent grade ≥3 AEs were anemia (7.8%), pneumonia (6.5%), and neutropenia (5.2%). Any grade immune-mediated AEs occurred in 22 (28.6%) pts, most frequently hypothyroidism (10.4%), hyperglycemia (5.2%), and rash (5.2%); and grade ≥3 in 4 (5.2%) pts (blood creatine phosphokinase increased, hepatitis, hypothyroidism, rash, and urticaria [1 pt each]). No treatment-related AEs led to death. **Conclusions:** TIS was well tolerated, achieving modest efficacy in R/R mature T/NK-cell neoplasms, with some long-lasting remissions particularly in CTCL. Further studies are warranted to determine the biologic features associated with response and explore optimal combination therapies. Clinical trial information: NCT03493451. Research Sponsor: BeiGene USA, Inc.

7553 **Poster Session**

Long-term outcomes and circulating tumor DNA analysis from a phase I/II study of lenalidomide and obinutuzumab with CHOP for newly diagnosed diffuse large B-cell lymphoma. *First Author: Hua-Jay Jeffery Cherng, MD Anderson Hematology/Oncology Fellowship, Houston, TX*

Background: Diffuse large B-cell lymphoma (DLBCL) can be cured with rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone (RCHOP), but a third of patients (pts) experience treatment failure. Randomized trials comparing RCHOP with modified regimens, including replacing R with obinutuzumab (O, CD20 antibody, Vitolo JCO 2017) and adding lenalidomide (L) to RCHOP (Nowakowski JCO 2021), have not significantly improved outcomes. The combination of L and O may have synergy via an enhanced NK-cell mediated antibody dependent cellular cytotoxicity. We hypothesized combining L and O with CHOP (LOCHOP) would be an effective and well tolerated treatment of DLBCL. **Methods:** In this single center phase Ib/II study (NCT02529852) pts with untreated CD20+ DLBCL received 6 cycles of CHOP with O 1000mg IV on days (D) 1, 8, and 15 during cycle 1 and D1 during cycles 2-6, and L 15 mg orally on D1-14 of each cycle. Growth factor and thromboembolism prophylaxis were mandated. The primary objectives were to determine the maximum tolerated dose (MTD) of L and efficacy of LOCHOP. Plasma samples were collected for circulating tumor DNA (ctDNA) analysis. **Results:** Fifty-three pts were enrolled, 6 in phase Ib and 47 in phase II. No dose limiting toxicities were experienced in phase Ib at an MTD of 15 mg of L. Median age was 62 years, 35 (66%) pts had stage III/IV disease, 12 (23%) an IPI > 2, and 26 (49%) and 22 (42%) were germinal center (GC) and non-GC subtype (5 not classified) by Hans algorithm. At end of therapy, 50 pts were evaluable, overall response: 49 (98%), complete response: 45 (90%). Median follow up was 4.5 years and 4-year progression free and overall survival rates were 87.4% and 91.3%. No characteristics were associated with differences in outcomes. Any grade and grade 3-4 adverse events (AEs) were experienced by 100% and 70% of pts. Grade 3-4 AEs included neutropenia (38%), thrombocytopenia (17%), fatigue (13%), neutropenic fever (13%), and infection (9%). Four (8%) pts developed venous thromboembolism. At study entry, 31/33 (94%) profiled pts had detectable ctDNA with CAPP-Seq, 24% had high ctDNA (> log 2.5 hGe/ml) and 24/31 (77%) were evaluable by LymphGen classifier: molecular subtypes included EZB (5, 21%), ST2 (5, 21%), MCD (4, 17%), and other (9, 38%). All 5 EZB and 4/5 ST2 pts were GC subtype while 2/4 MCD pts were non-GC (1 GC, 1 not classified). With LOCHOP, 13/18 (72%) and 11/15 (73%) pts achieved early and major molecular response (Kurtz JCO 2018). By PhasED-Seq (Kurtz Nat Biotechnol 2021), 16/18 (89%) had no detectable ctDNA after ≥5 cycles. **Conclusions:** LOCHOP demonstrates high efficacy and tolerability in newly diagnosed DLBCL, leading to a high rate of undetectable minimal residual disease by ctDNA. Noninvasive molecular subtyping is feasible as a supplement to tissue diagnosis and should be incorporated in future studies aiming to improve on RCHOP. Clinical trial information: NCT02529852. Research Sponsor: Celgene/BMS and Genentech.

Treatment patterns and real-world effectiveness of rituximab maintenance in older patients with mantle cell lymphoma: A population-based analyses. *First Author: Mengyang Di, Yale University School of Medicine, New Haven, CT*

Background: In the clinical trial setting, rituximab maintenance (RM) improved survival of older adults with mantle cell lymphoma (MCL) compared to maintenance interferon following RCHOP. However, given the considerable shift away from the use of RCHOP for MCL, real-world effectiveness of RM is now uncertain for MCL in older adults. We used SEER-Medicare, a large population-based data set, to evaluate MCL treatment patterns and assess effectiveness of RM following standard chemoimmunotherapy in older patients. **Methods:** We selected adults ≥66 years old, diagnosed with MCL 2007-2017, with continuous Medicare A/B/D coverage, who received MCL therapy. We captured 1st and 2nd line regimens, defining RM as rituximab (R) given as a single agent after R-based multi-agent induction regimen, with treatment gap ≤200 days (d) prior, for ≥2 consecutive doses and lasting ≥ 28d. We examined the benefits of RM in patients who received bendamustine-R (BR) or RCHOP as 1st line with no consolidative stem cell transplant (SCT). We limited our control group to those who survived ≥ 200d (if no 2nd line given) or had a gap ≥ 200d between completion of induction and initiation of 2nd line treatment to reduce potential immortal time bias. We used propensity score matching (PSM) based on age, sex, race, marital status, Medicaid dual coverage, residence, poverty, frailty, comorbidities, year of diagnosis, extranodal disease, stage, 1st line regimen, and duration of 1st line therapy. We used Cox regression model to compare all-cause mortality (AM) and reported hazard ratio (HR) with 95% confidence interval (CI). We conducted competing risk analysis for mortality from MCL (MFM; competing event [CE]: non-lymphoma mortality [NLM]) and initiation of 2nd line therapy (CE: AM), respectively, reporting sub-HR (sHR). **Results:** Of 1579 older adults treated for MCL, BR (37%) and RCHOP (17%) were the most common 1st line regimens. Among those receiving BR/RCHOP, 44% received RM. Only 3% received SCT. Use of RCHOP decreased substantially over time (2007: 31%, 2017: 5%, *P* for time trend<0.001), with an increase for BR (2007:1%, 2017: 41%, *P*<0.001). We included 386 patients who received either RCHOP (83) or BR (303) (post-PSM; median age: 75, 67% men, 95% White) to examine effectiveness of RM, and all covariates were well balanced. Compared to patients not receiving RM, AM (HR: 0.59, 95% CI: 0.42-0.84), MFM (sHR: 0.53, 95% CI: 0.35-0.81) and initiation of 2nd line therapy (sHR: 0.60, 95% CI: 0.44-0.82) were all significantly lower in patients receiving RM. NLM was similar between RM and non-RM groups, suggesting that PSM worked well. **Conclusions:** Our population-based real-world analyses showed significant benefits of RM in survival and disease control among older patients with MCL who did not receive SCT, despite the shift from RCHOP to BR as 1st line induction regimen. Quality-adjusted time without symptoms or toxicities (Q-TWiST) analysis of ZUMA-7, a randomized controlled trial of axicabtagene ciloleucel versus standard of care for second-line large B-cell lymphoma. *First Author: Marie José Kersten, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands*

Background: Quality of life (QoL) post cancer therapy is increasingly important. We conducted a Q-TWiST analysis to compare the quality-adjusted survival of axicabtagene ciloleucel (axi-cel, a chimeric antigen receptor T-cell therapy) versus standard of care (SOC) among relapsed/refractory (R/R) large B-cell lymphoma (LBCL) patients enrolled in ZUMA-7 (NCT03391466), a Phase 3, randomized, open-label, multicenter study. ZUMA-7 met its primary endpoint of event-free survival; events were defined as death, progression, or new lymphoma therapy. **Methods:** Overall survival (OS) in the intention-to-treat (ITT) cohort was partitioned into 3 mutually exclusive health states as measured through a median follow-up duration of 23.5 months (m): time with grade 3/4 adverse events (AE) before an event (TOX); time without symptoms from events or toxicity (TWiST); and time after event (REL). Q-TWiST was calculated as the average time spent in each state, weighted by state-specific QoL utility (u, ranging from 0 to 1), assuming a base case u(TOX)=0.5, u(REL)=0.5, u(TWiST)=1. Threshold analyses assessed the mean Q-TWiST differences between axi-cel and SOC by varying u(TOX) and u(REL) from 0 to 1. Relative gains for axi-cel (axi-cel Q-TWiST gain divided by mean SOC OS) ≥15% were considered "clearly clinically important" using published norms. Nonparametric bootstrap 95% confidence intervals (CI) were computed. Subgroup analyses were performed for relapse status and age. Sensitivity analyses varying the follow-up duration from 3 to 37.7m were explored. **Results:** For the ITT cohort (n=359), mean time spent in TOX and TWiST was significantly longer for the axi-cel cohort compared to SOC, and mean time spent in REL was significantly shorter for axi-cel (Table). Using the base case, quality-adjusted survival was significantly longer for axi-cel by 3.7m, representing a 21.9% relative gain. In threshold analyses, the difference in Q-TWiST ranged from 1.2m (u(TOX)=0, u(REL)=1) to 6.2m (u(TOX)=1, u(REL)=0) in favor of axi-cel. Q-TWiST gains favored axi-cel across all subgroup analyses. Q-TWiST gains from axi-cel increased with longer follow-up. **Conclusions:** Axi-cel was associated with statistically significant and "clearly clinically important" gains in quality-adjusted OS vs. SOC in R/R LBCL, regardless of the relative decline in QoL associated with treatment toxicity, disease progression, or additional cancer treatment. Research Sponsor: Kite Pharma.

Mean (95% CI) months in health states and Q-TWiST, over 23.5m of follow-up.

State	Axi-cel	SOC	Difference (Axi-cel − SOC)
TOX	1.16 (0.83, 1.48)	0.74 (0.51, 0.94)	0.42 (0.04, 0.82)
TWiST	11.18 (9.73, 12.61)	5.39 (4.21, 6.56)	5.79 (4.07, 7.62)
REL	6.02 (4.9, 7.15)	10.66 (9.42, 11.93)	-4.64 (-6.39, -3.09)
Q-TWiST	14.8 (13.6, 15.9)	11.1 (10, 12.1)	3.7 (2.3, 5.2)

In-field recurrences in relapsed/refractory (R/R) B-cell non-Hodgkin lymphoma (NHL) bridged with radiation prior to CD19 chimeric antigen receptor T-cell therapy (CART). *First Author: Omran Saifi, Mayo Clinic Department of Radiation Oncology, Jacksonville, FL*

Background: The majority of R/R NHL progressions after CART involve pre-existing sites, suggesting a promising role for bridging radiotherapy (bRT). We assessed the local control rate of disease sites bridged with radiotherapy prior to CART and identified predictors of in-field recurrence. **Methods:** We retrospectively reviewed 35 patients with aggressive B-cell NHL who received bRT between leukapheresis and CART infusion between 2018 and 2021 at a multi-site single institution. bRT local control rate (LC), calculated based on the total number of irradiated sites, was defined from bRT end date. Progression-free survival (PFS) and overall-survival (OS) were defined from the date of CART infusion. In-field recurrence was defined as disease relapse occurring within the radiation planning target volume. Kaplan-Meier plots and cox regression modeling were used to estimate the desired output. **Results:** Median age of the cohort at time of CART infusion was 59 (range 19-73). The median equivalent 2 Gy dose (EQD2) administered was 23.3 Gy (range 4-41 Gy). The median time from end of bRT to CART infusion was 14 days (range 6-42). Five (14%) patients also received bridging chemotherapy with bRT. Among the 34 evaluable patients, 30 (88%) achieved an objective response (59% complete response and 29% partial response). At a median follow-up of 12 months, 1-year PFS was 48% and 1-year OS was 72%. No progression occurred beyond 240 days. On review of treatment plans and pre-treatment PET/CT scans, 59 sites were identified that received bRT prior to CART infusion. The median size and SUVmax of the irradiated sites were 8.7cm (range 1.5-22) and 13 (range 4-46), respectively. Of the 59 irradiated sites, 8 sites (13.6%) in 7 patients had in-field local recurrence, translating to 1-year LC of 84%. No in-field recurrence occurred beyond 180 days. Moreover, no local recurrence occurred in patients who received radiation to all known sites of active disease to EQD2> 30 Gy (n = 4 patients); these patients remained in remission except for 1 who experienced progression outside the bRT field. On univariate analysis, triple hit lymphoma (THL) (OR 22.8, 95% CI: 3.8-138.3; p < 0.001), tumor size (OR 1.25, 95% CI: 1.1-1.4; p < 0.001), specifically ≥ 9cm (OR 9.4, CI: 1.2-77.3; p = 0.036) and SUVmax (OR 1.1, CI: 1.02-1.15; p = 0.008), specifically ≥ 20 (OR 5.6, CI: 1.3-23.7; p = 0.018), were significantly associated with increased risk of in-field recurrence. On multivariate analysis, THL (OR 32.9, CI: 3.2-336.0; p = 0.03) and tumor size (OR 1.3, CI: 1.1-1.6; p = 0.01) retained significant association with in-field recurrence. **Conclusions:** Bridging radiotherapy prior to CART provides excellent and durable in-field local control for R/R B-cell NHL. Patients with triple hit histology and bulky disease are likely at higher risk of in-field recurrence and may benefit from higher doses of bRT. Research Sponsor: None.

Asia subpopulation analysis from the phase III POLARIX trial. *First Author: Yuqin Song, Key Laboratory of Carcinogenesis and Transitional Research (Ministry of Education), Department of Lymphoma, Peking University Cancer Hospital and Institute, Beijing, China*

Background: In the pivotal Phase III POLARIX trial, Pola-R-CHP demonstrated significantly improved progression-free survival (PFS) compared with R-CHOP, with a similar safety profile in patients with previously untreated DLBCL (Tilly et al. 2022). An Asia subpopulation analysis was included as part of the trial design; patients enrolled in Asia were analyzed for the purpose of registration in China of POLARIX (NCT03274492). **Methods:** Patients from mainland China, Hong Kong, Japan, South Korea, and Taiwan (enrolled during the global phase), and from the China extension cohort were included in the Asia subpopulation. POLARIX methods were previously described (Tilly et al. 2022). Briefly, patients with untreated DLBCL were randomized 1:1 using the same stratification factors to receive six cycles of Pola-R-CHP or R-CHOP, plus two cycles of rituximab alone. The purpose of this analysis was to evaluate consistency of PFS (defined as ≥50% risk reduction in PFS) in the Asia subpopulation with the global population. **Results:** Overall, 281 patients (intent-to-treat population; 150, 85, 31 and 15 patients in mainland China, Japan, South Korea and Taiwan, respectively) were analyzed (141 received Pola-R-CHP and 140 received R-CHOP); 160 patients from the global population and 121 from the China extension cohort. Median age was 63 (range 19–79) years, and most patients had an International Prognostic Index of 3–5 (61.9%). At the data cut-off of June 28, 2021, (median follow-up of 24.2 months) PFS was superior with Pola-R-CHP vs R-CHOP (hazard ratio [HR] 0.64; 95% confidence interval [CI]: 0.40–1.03) and met the consistency definition with the global population. The 2-year PFS rate was 74.2% (95% CI: 65.7–82.7) with Pola-R-CHP vs 66.5% (95% CI: 57.3–75.6) with R-CHOP. Other key efficacy results were similar to the global study results (Table). The safety profile was generally comparable for Pola-R-CHP vs R-CHOP, including rates of grade 3–4 adverse events (AEs; 72.9% vs 66.2%), serious AEs (32.9% vs 32.4%), grade 5 AEs (1.4% vs 0.7%), AEs leading to discontinuation of any study treatment (5.0% vs 7.2%), and incidence of peripheral neuropathy (all grades, 44.3% vs 50.4%), respectively. Key efficacy results. CR, complete response. **Conclusions:** The results from the Asia subpopulation of POLARIX were consistent with the global study, with a clinically meaningful improvement in PFS (risk of disease progression, relapse or death reduced by 36%) following treatment with Pola-R-CHP vs R-CHOP, and a comparable safety profile in Asian patients with previously untreated DLBCL. Clinical trial information: NCT03274492. Research Sponsor: POLARIX is sponsored by F. Hoffmann-La Roche Ltd and Genentech, Inc. Third-party editorial assistance, under author direction, was provided by Tracey McManus of Ashfield MedComms, and was funded by F. Hoffmann-La Roche Ltd.

Outcome	Pola-R-CHP (n=141)	R-CHOP (n=140)

Brentuximab vedotin in combination with lenalidomide and rituximab in patients with relapsed/refractory diffuse large B-cell lymphoma: Safety and efficacy results from the safety run-in period of the phase 3 ECHELON-3 study. *First Author: Nancy L. Bartlett, Washington University School of Medicine, St. Louis, MO*

Background: Patients (pts) with relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL) who relapse after or are ineligible for hematopoietic stem cell transplant (HSCT) or chimeric antigen receptor T cell (CAR-T) therapy generally have poor outcomes. Preclinical data provide the rationale for combining brentuximab vedotin (BV), lenalidomide (len), and rituximab for the treatment of R/R DLBCL. BV+len showed promising clinical activity in a Phase 1 trial with a 57% overall response rate (ORR), 10.2-month median progression-free survival, and 14.3-month overall survival (Ward 2021). We report the results of the open-label safety run-in that was conducted prior to the randomized portion of the study. **Methods:** ECHELON-3 (NCT04404283) is a randomized, double-blind, placebo-controlled, active-comparator, multicenter Phase 3 study. Prior to randomization, an open-label safety run-in was conducted; pts received BV (1.2 mg/kg) and rituximab (375 mg/m^2) both q3w, and len 20 mg qd. Pts must have received ≥2 prior lines of therapy and be previously treated with or were ineligible for HSCT or CAR-T, ECOG score ≤2, and PET-avid, bidimensional measurable disease (> 1.5 cm by CT). Pts with negligible CD30 expression (< 1%) were eligible. Response was assessed by the investigator according to the Lugano Classification Revised Staging System (Cheson 2014). **Results:** 10 pts with R/R DLBCL were enrolled. Median age was 70.5 years, 7 pts were male, and all had an ECOG ≤1. Median prior lines of therapy was 3 (range, 2 to 6); no pts received prior HSCT and 6 pts received prior CAR-T. At a median follow-up of 6.9 months (range, 2.3 to 14.1), the most common treatment emergent adverse events (TEAE) were fatigue (n = 5), anemia (n = 4) and constipation (n = 4). Grade ≥3 events were experienced by 8 pts, most commonly anemia and pneumonia (n = 3 each), and neutropenia and thrombocytopenia (n = 2 each). Serious adverse events were observed in 7 pts. Seven pts each had BV and rituximab dose modifications, and 6 pts had a len dose modification. The most common reasons for any dose modification were anemia (n = 3), neutropenia, peripheral neuropathy, or pneumonia (n = 2 each). 4 pts discontinued treatment due to an AE, 2 of which were treatment related (n = 1 each of Grade 2 fatigue; Grade 3 anemia). There was 1 death due to a TEAE that was not treatment related. The ORR (best response) was 70%, including 4 pts with a complete metabolic response, 2 pts with a partial metabolic response, and 3 pts with progressive disease. Responses were seen in both CD30 (+) and (-) pts, as well as in 4 pts who received prior CAR-T. **Conclusions:** This novel triplet regimen appears active in R/R DLBCL with an acceptable safety profile. The randomized portion of the study is currently enrolling. Clinical trial information: NCT04404283. Research Sponsor: Seagen Inc.

7560 **Poster Session**

Subgroup analysis in RE-MIND2, an observational, retrospective cohort study of tafasitamab plus lenalidomide versus systemic therapies in patients with relapsed/refractory diffuse large B-cell lymphoma (R/R DLBCL). *First Author: Grzegorz S. Nowakowski, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Tafasitamab (tafa) + lenalidomide (LEN) demonstrated efficacy in adult patients (pts) with R/R DLBCL ineligible for autologous stem-cell transplant in the pivotal Phase II study L-MIND (NCT02399085) and received accelerated approval in the United States in 2020 and conditional marketing authorization in Europe and Canada in 2021 in this setting. RE-MIND2 (NCT04697160), an observational, retrospective cohort study, compared pt outcomes from L-MIND with matched pt cohorts treated with other NCCN/ESMO recommended therapies. **Methods:** Methodology for RE-MIND2 has been presented previously. Hypothesis-generating analyses were conducted for pt subgroups of number of extranodal sites (ENS) (0–1 vs ≥2) and elevated lactate dehydrogenase (LDH) (yes vs no) in matched cohorts of pts receiving tafa + LEN vs systemic therapies pooled (STP), polatuzumab vedotin + bendamustine + rituximab (pola-BR), rituximab + LEN (R2), and CD19 CAR-T therapies (CAR-T). The primary endpoint was overall survival (OS). **Results:** Of 3,454 pts enrolled, 961, 106, 106, and 149 were treated with STP, pola-BR, R2, and CAR-T, resulting in 76, 24, 33, and 37 matched pairs for pts receiving tafa + LEN, respectively. Hazard ratios (HR) for OS show a trend toward favoring tafa + LEN in most pt subgroups (Table). Conclusion: These analyses suggest that tafa + LEN may be associated with improved OS vs selected systemic therapies for certain pts with high-risk disease and may further inform physicians' treatment choices for pts with R/R DLBCL. These analyses are not powered for statistical comparison; small sample sizes in some subgroups result in wide confidence intervals (CI) and so results must be interpreted with caution. Data for other treatment cohorts, pt subgroups, and endpoints will be presented. Funding: MorphoSys AG. Clinical trial information: NCT04697160. Research Sponsor: MorphoSys AG.

Analysis of peripheral neuropathy (PN) using clinician- and patient-reported outcomes (ClinRO and PRO) in the POLARIX study. *First Author: Marek Trneny, Charles University General Hospital, Prague, Czech Republic*

Background: PN is an identified risk of anti-microtubule agents, including polatuzumab vedotin and vincristine. POLARIX (NCT03274492), a Phase III randomized, double-blind, placebo-controlled study comparing Pola-R-CHP with R-CHOP, demonstrated improved progression-free survival (PFS) with Pola-R-CHP (Tilly et al. NEJM 2022). Here, we evaluate the impact of Pola-R-CHP vs R-CHOP on PN using ClinRO and PRO data. **Methods:** Patients with previously untreated diffuse large B-cell lymphoma (DLBCL) received Pola-R-CHP or R-CHOP. ClinRO data were based on PN grading according to the NCI CTCAE v4.0. PRO data were generated from assessment of patient-reported PN symptoms at baseline and Day 1 of each cycle using the Functional Assessment of Cancer Therapy/Gynecologic Oncology Group – Neurotoxicity (FACT-GOG/NTX) subscale, ranging from 0–44, with higher scores representing lower levels of PN (minimal clinically important difference: 1.38–3.68 [Cheng et al. Health Qual Life Outcomes 2020]). **Results:** At baseline, ClinRO and PRO symptom scores showed low PN burden (Table). Overall incidence of PN was comparable between treatment arms (Pola-R-CHP: 52.9%; R-CHOP: 53.9%); most events were grade 1, and incidence of grade 2 (Pola-R-CHP: 12.2%; R-CHOP: 15.5%) and grade 3 (Pola-R-CHP: 1.6%; R-CHOP: 1.1%) events were comparable between treatment arms. FACT-GOG/NTX survey completion was high in both arms (96% at baseline; >80% at other timepoints). When evaluated by cycle, ClinRO and PRO demonstrated that more patients experienced earlier onset PN with R-CHOP than with Pola-R-CHP (Table), with ~10% more R-CHOP- than Pola-R-CHP-treated patients having clinician-reported PN in Cycle (C) 2–5, and a ~+1-point difference (i.e. fewer symptoms) in PRO symptom scores in C3–6 with Pola-R-CHP vs R-CHOP; by C8+, and during follow up, rates and symptoms of PN were similar. PN symptoms resulted in fewer dose reductions (3.9% vs 8.2%) and drug discontinuations (0.7% vs 2.1%) with Pola-R-CHP vs R-CHOP. Duration of PN was similar for both treatments. **Conclusions:** In the POLARIX study, Pola-R-CHP did not result in different rates or severity of PN vs R-CHOP. According to ClinRO and PRO data, PN occurred later following initial exposure to Pola-R-CHP than to R-CHOP, and there were fewer dose modifications with Pola-R-CHP than with R-CHOP. Overall, the risk of PN was manageable. Clinical trial information: NCT03274492. Research Sponsor: POLARIX is sponsored by F. Hoffmann-La Roche Ltd. Third-party medical writing assistance, under the direction of the authors, was provided by Carla Smith of Ashfield MedComms, an Ashfield Health company, and was funded by F. Hoffmann-La Roche Ltd.

Methylated DNA markers in early detection of lymphoma: Discovery, validation, and clinical pilot. *First Author: Thomas E. Witzig, Division of Hematology, Mayo Clinic, Rochester, MN*

Background: Lymphoma is the 6th most common cancer and a top 10 cause of cancer deaths. To date, there are no blood test approaches to population screening, and accurate surveillance markers are limited. Methylated DNA markers (MDMs) are broadly informative for early detection of cancer but have not been extensively studied for lymphomas. We sought to discover and validate MDMs in DNA extracted from lymphoma tissue, then test these MDMs in archival blood plasma specimens. **Methods:** Reduced representation bisulfite sequencing (RRBS) was performed on DNA extracted from a discovery set of frozen tissues of classic Hodgkin lymphoma (CHL, n=24), non-Hodgkin lymphoma (NHL, n=78: T-cell-TCL (8); diffuse large B-cell-DLBCL (18); follicular-FL (12); mantle cell-MCL (20); marginal zone-MZL (15)), and lymphoma cell line samples (27); controls included benign lymph node (n=11) and healthy donor buffy coat (n=30). 30 MDMs were ranked by fold-change and AUC and used to design methylation-specific PCR assays for biological validation on independent DNA samples extracted from FFPE tissue from 13 normal lymph node and 63 lymphoma samples and 36 buffy coats from healthy patients. Target enrichment long-probe quantitative-amplified signal assays were developed for 16 MDMs and then assayed in plasma-extracted, bisulfite-converted DNA samples from 390 independent treatment-naïve lymphoma patients (100 CHL and 290 NHL:100 DLBCL, 73 FL, 41 MCL, 41 MZL, 35 TCL), and 210 controls without cancer. Lymphoma plasma samples and 159 controls were provided by the Lymphoma SPORE (CA97274); 51 controls came from a 7-county population archive. Classification of lymphoma cases vs controls was modeled with random forest method and cross-validated across 500 bootstrap samples of each dataset. **Results:** For MDMs tested in DNA from independent biological validation samples, cross-validated random forest models identified 60/63 cases (95% sensitivity) and 12/13 normal controls (92% specificity). In plasmas, a panel of 16 MDMs (*ZNF503, VWA5B1, HOXA9_5195, GABRG3, ITGA5, MAX_chr17_793, BNC1_2407, CDK20, MAX_chr4_184, TPBG, DNAH14, SYT2, CACNG8, FAM110B, and NRN1*) detected 78% (95% CI, 74-82%) of lymphoma cases at 90% specificity. Excluding MZL and TCL, sensitivity increased to 84% (80-88%) including 26/49 (53% (38-67%)) of stage I and 59/71 (83% (71-90%)) of stage II cases. **Conclusions:** MDMs show promise to detect lymphoma. These markers could be evaluated as part of multicancer early detection testing and could also be evaluated as response markers to treatment and subsequent surveillance. Research Sponsor: Exact Sciences (Madison WI), U.S. National Institutes of Health.

A phase I/II study of golidocitinib, a selective JAK1 inhibitor, in refractory or relapsed peripheral T-cell lymphoma. *First Author: Won Seog Kim, Samsung Medical Center, Seoul, South Korea*

Background: Peripheral T cell lymphoma (PTCL) is a group of heterogeneous T cell lymphomas. Patients who relapse from or are refractory to 1st line therapy face dismal prognosis. The response rates to commonly used 2nd line agents such as histone deacetylase inhibitors are below 30%. Immunotherapies, such as anti-PD1 antibodies, may induce hyperprogression in certain PTCL subtypes. Hence, r/r PTCL patients urgently need better therapies. Preclinical data shows JAK/STAT pathway may mediate the pathogenesis of PTCL, making it a promising target. Golidocitinib (DZD4205) is an orally available, potent, JAK1 specific inhibitor, demonstrating profound anti-tumor activities in T lymphoma cells *in vitro* and tumor xenograft *in vivo*. Here we report the preliminary data from an ongoing phase I/II study (NCT04105010) of Golidocitinib in r/r PTCL. **Methods:** The study included two parts: Part A (dose escalation) and Part B (dose expansion). In Part A, patients with r/r PTCL were enrolled and received Golidocitinib at different doses (150 mg or 250 mg, QD) to determine the recommended phase II dose (RP2D). Evaluation of safety and efficacy were performed by investigators per CTCAE and Lugano criteria, respectively. Part B is a single-arm, pivotal study, where patients with r/r PTCL will receive Golidocitinib at the RP2D till disease progression or intolerance. **Results:** As of May 31, 2021, a total of 51 patients enrolled in Part A and received Golidocitinib at 150 mg (n = 35) or 250 mg (n = 16). Patient characteristics: median age (range): 61.0 years (29-79); median prior systemic therapies (range): 2 lines (1-8). Ten patients (19.6%) had undergone hematopoietic stem cell transplantation. Fifteen patients (29.4%) had bone marrow involvement at baseline. Histological subtypes included PTCL-NOS (41.2%), AITL (39.2%), ALCL ALK- (7.8%), NKTCL (7.8%), and MEITL (3.9%). At the data cut-off (DCO), 49 patients completed at least one post-treatment Lugano assessment, of whom 21 (42.9%) achieved tumor response, including 11 complete responses (CRs, 22.4%) and 10 partial responses (20.4%). Tumor response was observed in various subtypes, including AITL (13/20), PTCL-NOS (5/19), ALCL ALK- (2/4) and NKTCL (1/4). At the DCO, the median duration of response (DoR) was not reached, and the longest DoR was > 14 months. Forty-eight patients (94.1%) experienced treatment emergent adverse events (TEAEs), of whom 30 (58.8%) experienced ≥ grade 3 TEAEs. Per investigators' assessment, 20 patients (39.2%) experienced ≥ grade 3 TEAEs possibly related to the drug. The most common (≥ 10%) ≥ grade 3 TEAEs were neutropenia (29.4%), thrombocytopenia (15.7%) and pneumonia (11.8%). The majority of TEAEs were reversible or clinically manageable with dose modifications. **Conclusions:** Golidocitinib shows good safety and promising anti-tumor efficacy in r/r PTCL, indicating its potential as a therapeutic option for this unmet medical need. Association of pretreatment (preTx) tumor characteristics and clinical outcomes following second-line (2L) axicabtagene ciloleucel (axi-cel) versus standard of care (SOC) in patients (pts) with relapsed/refractory (R/R) large B-cell lymphoma (LBCL). *First Author: Frederick L. Locke, Moffitt Cancer Center, Tampa, FL*

Background: The Phase 3 randomized ZUMA-7 trial in 2L R/R LBCL showed axi-cel superiority to SOC (salvage chemotherapy and HDT-ASCT) in event-free survival (EFS; hazard ratio [HR], 0.398; *P*< .0001; Locke et al. *N Eng J Med.* 2021). We report results of exploratory analyses of tumor characteristics, including preTx tumor burden (TB), tissue hypoxia-related lactate dehydrogenase (LDH) level, and tumor microenvironment (TME). **Methods:** TB was calculated as the sum of product diameters of ≤6 reference lesions (Locke et al. *Blood Adv.* 2020). Serum LDH was assessed. PreTx tumor samples were assessed for RNA expression by the NanoString IO 360™ panel and prespecified immune contexture indexes related to T-cell involvement (Immunosign 15 [IS15] and 21 [IS21]; Galon et al. ASCO 2020. #3022). ZUMA-1 data were used for comparison to 3L R/R LBCL. CD19 protein expression was assessed by immunohistochemistry (H-score). Associations between biomarkers and clinical outcomes were assessed using descriptive statistics (*P*< .05 was significant). **Results:** Axi-cel EFS was superior to SOC for both high and low TB (HR, 0.29 and 0.49, respectively; *P*< .001 for both) and elevated and nonelevated LDH (HR, 0.32 and 0.5, respectively; *P*< .001 for both). EFS in axi-cel pts was not associated with preTx TB (HR, 1.01 [95% CI, 0.88-1.16]; *P*= .89) or LDH (HR, 0.98 [95% CI, 0.74-1.29]; *P*= .86), but was worse in SOC pts with higher preTx TB (HR, 1.17 [95% CI, 1.03-1.32]; *P*= .01) or higher LDH (HR, 1.29 [95% CI, 1.02-1.63], *P* =.03). PreTx TB was lower in SOC pts with ongoing response vs nonresponders and pts who relapsed (*P*= .07), but not in axi-cel pts (*P*= .99). Non-germinal center B-cell (GCB) cell-of-origin subtypes is a poor prognostic factor for EFS in SOC (EFS was significantly worse in SOC pts with non-GCB vs GCB; HR, 1.82 [95% CI, 1.12-2.96]; *P*= .02) but not in axi-cel. In IO360 analysis, gene expression of B-cell lineage antigens (CD19, CD20, BCMA) and markers highly expressed by tumor cells (CD45RA, IRF8, BTLA) positively associated with objective and durable responses to axi-cel. While axi-cel remained superior to SOC with high (> median) or low CD19 expression level, the probability of an ongoing response increased with a higher CD19 H-score. PreTx TME IS15 and IS21 scores were generally higher in 2L vs 3L. **Conclusions:** Axi-cel was superior to SOC in all subgroup analyses, including higher TB and LDH. Durable responses with axi-cel were greatest in tumors with prominent B-cell features, but were superior to SOC regardless of these features. Axi-cel intervention in 2L is supported by durable response rates not impacted by high TB, as seen in 3L axi-cel or 2L SOC. Higher preTx immune involvement in 2L vs 3L tumors suggests high TB may be overcome with axi-cel in patients with a more favorable immune contexture. Clinical trial information: NCT03391466. Bendamustine rituximab (BR) versus ibrutinib (Ibr) as primary therapy for Waldenström macroglobulinemia (WM): An international collaborative study. *First Author: Jithma P. Abeykoon, Mayo Clinic, Division of Hematology, Rochester, MN*

Background: Parenteral limited-duration BR chemoimmunotherapy and continuous orally administered Ibr, a Bruton tyrosine kinase inhibitor, dominate the treatment landscape of WM, a rare B cell lymphoma. No trials have assessed the comparative effectiveness of these 2 vastly different approaches. We conducted a multiinstitutional, international, collaborative study to compare BR and single-agent Ibr in patients (pts) with treatment naïve (TN) WM. **Methods:** Data from 347 pts with active TN WM, seen between 2011 and 2021 in the US and Europe, were analyzed. The pts on rituximab maintenance were excluded. The modified IWWM-6 criteria (based on IgM alone) were used for response assessment. All time-to-event analyses were performed from the frontline therapy initiation, using the Kaplan-Meier method. **Results:** The median age of the pts treated with BR (n=208) and Ibr (n=139) was 66 (range 40-86) years (y) and 69 (39-97) y, respectively, (p=0.005). With a median follow up of 4.2 y (95% CI 3.8-4.5), the 4-y progression free survival (PFS) was 73% in each group, p=0.6, and 4-y overall survival (OS) was 94% (95% CI 91-98) in the BR group versus (*v*) 82% (95% CI 75-90) in the Ibr group, p=0.01. In a bivariate analysis adjusting for age and the treatment type, only age emerged as a predictor for OS (HR 7.2, p=0.0001). Therefore, a 1:1 age-matched analysis of 246 pts who received Ibr (n=123) or BR (n=123) was performed. Pts with a known *MYD88*^{WT} status who had received Ibr and their age matched controls on BR were excluded. The international prognostic scoring system (IPSS) WM was comparable between the 2 groups (Table**).** A higher proportion of pts on BR attained very good partial or deeper response (≥VGPR) as the best response in comparison to the pts on Ibr (Table). The 4-y PFS for the BR and Ibr groups was similar [72% (95% CI 63-82) *v* 78% (95% CI 70-87), p=0.14] and 4-y OS was 95% (95% CI 91-99) with BR *v* 86% (95% CI 80-93) with Ibr (p=0.3). Premature discontinuation, during active treatment, due to adverse effects (AEs) or lack of response was noted in 13% and 33% of pts on BR and Ibr, respectively. A detailed assessment of the AEs will be presented at the meeting. **Conclusions:** Both BR and Ibr lead to comparable outcomes in pts with TN WM, although deeper responses are attained with BR. These findings require confirmation in prospective studies. For pts who harbor *MYD88*^{L265P} mutation, selection between the 2 approaches should be dictated by their potential toxicities, pt comorbidities, pt/clinician preference (parenteral fixed-duration *v* continuous oral) and access to therapies. Axicabtagene ciloleucel (axi-cel) in combination with rituximab (Rtx) for the treatment (Tx) of refractory large B-cell lymphoma (R-LBCL): Outcomes of the phase 2 ZUMA-14 study. *First Author: Paolo Strati, The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX*

Background: Despite the success of axi-cel, ≈60% of patients (pts) have no response or relapse within ~2 y after Tx (Jacobson C, et al. ASH 2021. #1764), highlighting the need for more therapeutic strategies. In preclinical studies, Rtx augmented CD19 CAR T-cell function and increased tumor reduction and survival in murine models via synergistic targeting with CAR T-cells (Mihara K, et al. *Br J Haematol*. 2010). Here, we report outcomes of ZUMA-14, a Phase 2, multicenter study of axi-cel in combination with Rtx in pts with R-LBCL after ≥2 lines of systemic therapy. **Methods:** Eligible pts were ≥18 y with R/R LBCL. Pts received one Rtx dose (375 mg/m^2) on Day -5, a conditioning regimen of cyclophosphamide and fludarabine on Days -5, -4, and -3, and a single axi-cel infusion of 2×10^6 CAR T cells/kg on Day 0. Starting on Day 21 post–axi-cel infusion, pts received 1 Rtx dose every 28 d for up to 5 doses. The primary endpoint was investigator-assessed complete response (CR) rate. Secondary endpoints included objective response rate (ORR), duration of response (DOR), progression-free survival (PFS), overall survival (OS), safety, and biomarker assessments. The analysis reported here occurred after all treated pts had ≥12 mo of follow-up. **Results:** As of 12/2/21, 27 pts were enrolled, and 26 received axi-cel and ≥1 Rtx dose (15 pts received all 6 Rtx doses); 1 pt discontinued Tx due to an adverse event (AE). Median age was 63 y (range, 38-82), 54% of pts were male, 81% had stage III/IV disease, 62% had extranodal disease, 38% had elevated LDH, and 85% had an aaIPI ≥1 (35% aaIPI 2). The CR rate was 65% (95% CI, 44-83), and the ORR was 88% (95% CI, 70-98). With a median follow-up of 17 mo, 65% of the pts had ongoing response, with 57% ongoing in CR. Medians for DOR, PFS and OS were not reached. The estimated DOR and PFS rates at 12 mo were 64% and 56%, respectively. The estimated 12 mo OS rate was 76%, and 6 pts (23%) died of progressive disease. Most pts (92%) experienced Grade ≥3 AEs. Grade ≥3 cytopenias were reported in 85% of pts, with 38% ongoing on Day 30. Grade ≥3 neurologic events (NEs) occurred in 4 pts (15%), and there was no Grade ≥3 cytokine release syndrome (CRS). Median times to onset of CRS and NEs were 4 d (range, 1-7) and 6 d (range, 3-32), respectively, with median durations of 5 d (range, 2-15) and 7 d (range, 1-39). No pts experienced myelodysplastic syndrome. Median peak CAR T-cell levels were comparable to the ZUMA-1 pharmacokinetic profile. Immune-modulating cytokines, including granzyme B, IL-6, CXCL10, IFN-g and IL-2, were induced in pts following axi-cel and Rtx infusion and were more prominently elevated in responders vs non-responders. Peak Rtx levels were also elevated in responders vs non-responders. **Conclusions:** Results from ZUMA-14 demonstrated that axi-cel in combination with Rtx elicited a high CR rate with no new safety signals detected in pts with R-LBCL. Clinical trial information: NCT04002401. Research Sponsor: Kite, A Gilead Company.

Cost effectiveness of polatuzumab vedotin in combination with chemoimmunotherapy (Pola-R-CHP) in previously untreated diffuse large B-cell lymphoma. *First Author: Swetha Kambhampati, City of Hope, Duarte, CA*

Background: In patients with treatment naive diffuse large B-cell lymphoma (DLBCL), the POLARIX study demonstrated a 6.5% improvement in the 2-year (yr) progression-free survival (PFS) with no difference in overall survival or safety using polatuzumab vedotin + R-CHP compared to standard RCHOP. We evaluated the cost effectiveness of pola-R-CHP for DLBCL. **Methods:** We modeled a hypothetical cohort of US adults (mean age, 58 yrs) with treatment naïve DLBCL by developing a Markov model with a 1-month cycle and 20-yr horizon. The cost-effectiveness of two strategies were directly compared (pola-R-CHP, RCHOP) using a range of plausible long-term outcomes. A patient with DLBCL in remission after treatment could develop subsequent progression or relapse, death, or alternative toxicity. Progression rates and overall survival were estimated from POLARIX study. Outcome measures were reported in incremental cost-effectiveness ratios (ICERs), with a willingness-to-pay (WTP) threshold of $150,000/quality-adjusted life-yr (QALY). **Results:** Assuming a 5-yr PFS of 69.6% with pola-R-CHP and 62.6% with RCHOP, pola-R-CHP was more effective (0.81 incremental QALYs) but more costly ($66,218) and was cost-effective at a WTP of 150,000 (ICER $82,220/QALY). Its cost effectiveness was highly dependent on the 5-yr PFS of pola-R-CHP with it no longer being cost effective if the 5-yr PFS was < 65%. One way sensitivity analysis demonstrated that pola-R-CHP is cost effective up to a cost of $270,506 at a WTP of $150,000. Probabilistic sensitivity analysis was derived from performing 10,000 Monte-Carlo model iterations and demonstrated that pola-R-CHP was the cost-effective strategy in 61.3% of iterations with RCHOP being cost-effective in 38.6% of iterations at a WTP of $150,000. **Conclusions:** If the absolute benefit in PFS is maintained over time, frontline pola-R-CHP for treatment of DLBCL would be cost effective at its current cost when compared to RCHOP at a WTP of $150,000/QALY. However, its cost effectiveness is highly sensitive to changes in long-term PFS and the cost of pola-R-CHP. If pola-R-CHP is adopted as frontline therapy for the 29,108 incident cases of DLBCL annually in the US, this will lead to an additional 1.8 billion dollars in healthcare expenditures. This highlights the importance of decreasing the cost of pola-R-CHP and identifying sub-populations that derive the highest benefit from it. Research Sponsor: None.

Cost-effectiveness of Pola-R-CHP (compared to R-CHOP).

Treatment	Clinical Outcomes				Cost-Effectiveness				
	2-yr OS	2-yr PFS	5-yr OS	5-yr PFS	QALYs	Incr QALY	Cost	Incr Cost	ICER
R-CHOP	88.4%	70.2%	77.7%	62.6%	12.55	–	350566	–	
Pola-R-CHP	88.6%	76.6%	81.8%	69.6%	13.35	0.81	416785	66,218	82,220
5-yr PFS with Pola-R-CHP

Prospective evaluation of the prognostic value of circulating tumor DNA in patients with follicular lymphoma: A pilot study. *First Author: Ismael Fernández-Miranda, Instituto de Investigación Sanitaria Puerta de Hierro-Segovia de Arana, Hospital Universitario Puerta de Hierro-Majadahonda, Majadahonda, Spain*

Background: Follicular lymphoma (FL) is the most frequently occurring indolent non-Hodgkin lymphoma, with generally favorable outcomes but a variable clinical course. Around 20% of patients suffer progression of disease within 24 months (POD24) of chemoimmunotherapy. In this prospective study, we examined the prognostic value of circulating tumor DNA (ctDNA), before and during treatment, to predict response and POD24 in FL patients. **Methods:** We collected 110 plasma samples from 39 patients diagnosed with FL, prospectively enrolled in 8 Spanish hospitals and treated with Chemotherapy-Rituximab regimen from April 2017 to November 2020 with a median follow-up of 41 months (m). Samples were collected before treatment (basal), mid-treatment (3m), at the end of treatment (EOT) (6m) and relapse or follow-up. We performed targeted deep sequencing in cell-free DNA and paired genomic DNA from 30 formalin-fixed paraffin-embedded tumoral (FFPET) samples with the same gene panel. **Results:** Before treatment, ctDNA levels, measured as haploid genome equivalents per milliliter of plasma (hGE/mL), were detected in 17/30 patients. Basal ctDNA levels were higher in patients without complete response (CR) than in CR patients [18 *vs* 14 $\log_2$(hGE/mL); Mann-Whitney P = 0.007] and in patients with POD24 compared to those not-POD24 [18 *vs* 13 $\log_2$(hGE/mL); P = 0.005]. None of the 13 patients with zero basal ctDNA levels, experienced POD24. Patients with at least one mutation detected in basal ctDNA had an inferior 24-months PFS than patients without alterations (64 *vs* 100%, log-rank test P = 0.027). In addition, basal ctDNA levels were detected in one patient with low FLIPI, but partial response and POD24, and by contrast, no ctDNA was detected in another patient with CR and no progression event but high FLIPI. From the alterations detected in FFPET samples, 66% were also identified in basal ctDNA. No alterations were detected in basal ctDNA from 7 patients with CR and 3 patients with watch-and-wait strategy. Dynamic analysis showed that ctDNA levels decreased after treatment for every patient (3 mo), but the reduction at EOT was higher in patients achieving CR than in non-CR patients (12 *vs* 3 log-reduction) and in not-POD24 patients compared to those with POD24 (10 *vs* 8). Furthermore, patients with at least one mutation detected in ctDNA at EOT had a shorter 24-months PFS than those without alterations (50 *vs* 90%). The sensitivity to detect alterations in ctDNA at EOT was 94% in patients not achieving a CR and no mutation was detected in patients with CR. **Conclusions:** In a real-life, prospective-based population, we showed that pre-treatment and dynamic molecular response measured by ctDNA, could be useful to stratify patients and predict response to treatment and early relapse in FL patients. Research Sponsor: Gilead (GLD18/00019), AECC, CAM (PEJ-CAM & S2017/BMD-3778), AES-ISCIII-MINECO (PI17/00272 & PI20/00591.

The utility of the novel optimized HLH inflammatory (OHI) index for predicting the risk for mortality and causes of death in lymphoma. *First Author: Adi Zoref Lorenz, Division of immunobiology, Cincinnati Children's Hospital Medical Center and Meir Medical Center, Sackler School of Medicine, Tel Aviv, Israel*

Background: Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening inflammatory syndrome that may complicate hematologic malignancies (HM). We recently developed a simplified diagnostic and prognostic index termed the 'optimized HLH inflammatory' (OHI) index comprising the combined elevation of sCD25 (> 3,900 U/mL) and serum ferritin (> 1,000 ng/mL), which in HM patients both identifies HLH and predicts mortality more accurately than conventional criteria for HLH. In this study, we examined whether mortality in our cohort is directly related to progressive malignancy vs. HLH-associated causes in OHI+ and OHI- patients. **Methods:** We performed a multicenter, retrospective study of patients with newly diagnosed lymphoma from Israel, the USA, and Japan for whom sCD25 and ferritin levels were measured either as routine surveillance or during investigation for HLH and classified patients by their OHI status. The International Prognostic Index, International Prognostic Score, and Follicular Lymphoma International Prognostic Index were used to estimate the predicted prognosis of T/B cell non-Hodgkin's lymphoma (NHL), Hodgkin's lymphoma, and follicular lymphoma, respectively. Predicted five-year overall survival was calculated based on the relevant prognostic index and was compared between OHI+ and OHI- patients using the unpaired t-test. The actual survival at five years/last follow-up was recorded, as was the cause of death. The odds ratios (ORs) for observed vs. predicted mortality, and for HLH- vs. malignancy-related death were calculated using the Chi-square test. **Results:** 100 lymphoma patients were studied: 65% with B cell NHL, 18% with natural killer/ T cell lymphoma, 17% with Hodgkin's lymphoma; 37 were OHI+, and 63 were OHI-. The disease-relevant international prognostic index-predicted five-year survival did not differ between OHI + and OHI- patients (a mean of 58% n OHI+ and 57% in OHI- p = 0.62). However, the observed five-year survival in OHI+ patients was lower (12%) than predicted, reflecting a mortality incidence that was four times higher than predicted by the relevant prognostic score (OR 3.9; CI 1.3-12.1). By contrast, OHI- patients had better survival (79%) than predicted by their prognostic scores (OR 0.15; CI 0.07-0.34). More than half of the OHI+ patients died from non-malignant causes (39% multi-organ dysfunction or HLH, 18% infection), while most OHI- patients (92%) died from progressive malignancy. The likelihood of dying from multi-organ dysfunction or HLH was 26 times higher in OHI+ vs. OHI- patients (OR 26.2; CI 4.1-286.7). **Conclusions:** OHI index status strongly correlated with mortality in patients with lymphoma within our cohort, and death in OHI+ patients was largely due to causes other than progressive malignancy. The OHI index appears to identify a harmful inflammatory state and deserves further prospective study. Research Sponsor: U.S. National Institutes of Health.

Real-world outcomes of axicabtagene ciloleucel (Axi-cel) for the treatment of large B-cell lymphoma (LBCL) by race and ethnicity. *First Author: Frederick L. Locke, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: In clinical trials of CAR T-cell therapies and real-world studies published to date, there is a paucity of data on outcomes by race and ethnicity. Here, we examined outcomes by race and ethnicity among LBCL pts who received axi-cel in the real-world setting. **Methods:** A total of 1389 pts with LBCL were identified from a non-interventional post-authorization safety study with pts receiving commercial axi-cel between 10/2017 and 08/2020. Race (African American or Asian vs White) and ethnicity (Hispanic vs non-Hispanic) were self-reported by pts. Pts with rescinded consent, enrolled in trials, having prior non-HCT cellular therapy, primary CNS lymphoma, unknown comorbidity or data in query were excluded. Median follow-up was 12.7 mo. Outcomes included ORR, CR rate, DOR, PFS and OS, grade ≥ 3 CRS (Lee 2014 criteria) and ICANS (ASTCT consensus grade). ORR and CR were evaluated in pts with ≥ 180 days of follow-up. Kaplan-Meier estimates were calculated for PFS and OS. Multivariable analyses comparing race and ethnicity were conducted via logistic and Cox regression. **Results:** Among all, 1127 (81%) were White, 70 (5%) African American and 81 (6%) Asian; 152 (11%) were Hispanic including 104 White, 2 Black, and 1 Asian Hispanic. African Americans, compared to White, were younger (median age 55.5 vs 62.8 years), more likely to have pulmonary impairment (41% vs 28%) and tended to have longer time from diagnosis (≥ 12 mo 71% vs 59%). Hispanic pts were younger (median age 58.5 vs 62.6 years) than non-Hispanic pts. ORR was 74% (CR 57%, 12-mo PFS and OS 48% and 63%) for White, 57% (CR 45%, 12-mo PFS and OS 36% and 62%) for African American, 67% (CR 53%, 12-mo PFS and OS 55% and 65%) for Asian and 73% (CR 55%, 12-mo PFS and OS 50% and 65%) for Hispanic pts. Grade ≥ 3 CRS and ICANS occurred in 7% and 18% of African American, 10% and 19% of Asian, and 8% and 27% of White pts, respectively. Hispanic pts had lower rates of grade ≥ 3 CRS and ICANS (4% and 15%) vs non-Hispanic (9% and 27%). African American race was associated with inferior ORR (OR 0.40; 95% CI, 0.24-0.69) and CR rate (OR 0.55; 95% CI 0.32-0.93) vs White. Asian pts had favorable DOR compared to both White (HR 0.46; 95% CI 0.24-0.87) and African American (HR 0.39; 95% CI 0.17-0.88). No statistical differences were found in OS and PFS across races, nor in any efficacy outcome between Hispanic and non-Hispanic pts. Asian (OR 0.52; 95% CI 0.29-0.96 vs White) and Hispanic pts (OR 0.51; 95% CI 0.31-0.85 vs non-Hispanic) had lower risk of grade ≥ 3 ICANS. **Conclusions:** Overall, axi-cel showed favorable OS, PFS and safety profile regardless of race and ethnicity in the real-world setting. No notable differences in outcomes were observed for Hispanic or Asian pts. Lower response rates in African American pts noted here warrant further investigation including any underrepresentation not explained by a lower incidence rate for DLBCL (SEER), access to care, and disease burden. Updated interim analysis of the randomized phase 1b/3 study of tazemetostat in combination with lenalidomide and rituximab in patients with relapsed/refractory follicular lymphoma. *First Author: Connie Lee Batlevi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Tazemetostat (TAZ), an enhancer of zeste homolog 2 (EZH2) inhibitor, showed antitumor activity as monotherapy in patients with relapsed or refractory (R/R) follicular lymphoma (FL) who received ≥2 prior lines of therapy. In clinical studies in patients with R/R FL, lenalidomide and rituximab (R^2) demonstrated an objective response rate (ORR) of 73%–78% and median progression-free survival (PFS) of 36–39 months. This global, multicenter phase 1b/3 study is designed to determine the recommended phase 3 dose (RP3D), efficacy, and safety of TAZ + R^2 in patients with R/R FL after ≥1 prior therapy. We report an updated interim analysis of the phase 1b safety run-in where we assess the clinical activity and pharmacokinetics (PK) of TAZ when administered with R^2 in patients with R/R FL. **Methods:** Phase 1b evaluated TAZ at 3 dose levels (400, 600, and 800 mg orally twice daily) in 28-day cycles with standard-dose R^2 (NCT04224493). In addition to PK and safety, preliminary efficacy analysis was performed on the response-evaluable population, including best overall response, PFS, and duration of response (DOR) per investigator assessment according to Lugano 2014 response criteria. **Results:** As of January 22, 2022, 43 patients were enrolled and receiving TAZ + R^2 (400 [n = 4], 600 [n = 18], and 800 mg [n = 21]). These patients had a median age of 67 years (range, 39–83) and received a median of 1 prior therapy (range, 1–4). Overall, 15/43 (34.9%) patients were refractory to rituximab, 10/39 (25.6%) had POD24, and 6/41 (14.6%) had mutant-type *EZH2*. Median duration of treatment exposure was 32.0 weeks (range, 4.1–68.1). Mean C_{max} and AUC_{0-t} of TAZ 800 mg + R^2 at steady state were similar to those found for TAZ as monotherapy. PK of TAZ was not altered by concomitant administration of daily oral lenalidomide 20 mg, and PK of lenalidomide was not altered by concomitant administration of TAZ. No dose-limiting toxicities were observed in phase 1b, and no new safety signals were identified as of the January 2022 data cutoff. Serious treatment-emergent adverse events (TEAEs) were observed in 14 (32.6%) patients. Grade 3–4 TEAEs were observed in 24 (55.8%) patients; the most common grade 3–4 TEAE was neutrophil count decrease (n = 13; 30.2%). Of 38 patients evaluable for tumor assessment, 19 (50.0%) had a complete response, 17 (44.7%) had a partial response, and 2 (5.3%) had stable disease. ORR was 94.7% (n = 36). With a median follow-up of 5.8 months, median PFS and DOR were not reached and appeared to be similar, regardless of mutation status. **Conclusions:** TAZ + R^2 combination demonstrates consistent and unaltered PK for TAZ and lenalidomide as well as a favorable safety profile and efficacy trend. The 2-arm randomized phase 3 portion will further explore the efficacy and safety of TAZ RP3D 800 mg + R^2 in ≈500 patients with R/R FL. Clinical trial information: NCT04224493. Research Sponsor: Epizyme, Inc.

7573 **Poster Session**

Therapy for patients with POD24 follicular lymphoma: Treatment patterns and outcomes from the Lymphoma Epidemiology of Outcomes (LEO) Consortium. *First Author: Carla Casulo, University of Rochester Medical Center-James P. Wilmot Cancer Center, Rochester, NY*

Background: While most patients (pts) with follicular lymphoma (FL) usually have favorable outcomes, those with refractory disease after first-line anti-CD20 based immunochemotherapy (IC), or progression within 24 months of diagnosis (POD24) have higher risk of premature death. There are no standard approaches for treating this vulnerable group and studies testing novel agents are ongoing in this setting. We sought to investigate clinical practice treatment choices and efficacy for pts with POD24 that align with eligibility criteria for the randomized SWOG1608 which compares IC with novel agents in this population. **Methods:** This was a multicenter observational cohort study from the LEO Consortium. Eligible pts had grade 1-3a FL diagnosed between 1/1/2002 and 2/1/2019, and initiated therapy after POD24 to first-line bendamustine or CHOP (cyclophosphamide, doxorubicin, vincristine, prednisone) based IC. Observation, radiotherapy, or rituximab monotherapy were permitted prior to IC and pts with transformation prior to the subsequent therapy after IC were excluded as per S1608. Outcomes of interest were overall and complete response rate (ORR/CR), progression-free survival (PFS), and overall survival (OS). **Results:** We identified 196 eligible pts with early progression to IC (39% antiCD20 Benda; 61% antiCD20 CHOP) who received subsequent therapy. Median age at post IC treatment was 57 years, 78% grade 1-2 FL. Treatments for pts with POD24 included CHOP- or Benda-based in 31%, salvage/hematopoietic stem cell transplant (HSCT) in 27%, novel therapies in 10% (including phosphatidylinositol 3-kinase inhibitors), antiCD20 monotherapy in 9%, and lenalidomide-based treatment in 8% (table); 21% of pts were treated on clinical trials. Across all treatments, ORR (CR) was 63% (37%) (95% CI: 55-70). At a median follow up of 6.2 years, 2 year PFS was 22% (95% CI: 17%-29%) and 5 year OS was 71% (95% CI: 65-79). Outcomes by regimen are shown in the table. **Conclusions:** Pts with FL experiencing POD24 following first-line IC are treated heterogeneously, with many pts still receiving IC as subsequent therapy. Despite modest CR rates and low 2-year PFS, 5-year OS appear to be improving compared to historical outcomes. This supports the ongoing need to investigate novel treatments in this population. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Post POD24 therapy (%)	ORR (95%CI)/CR %	2 yr PFS % (95%CI)	5 yr OS %

A phase II, multicenter, single-arm study of parsaclisib, a PI3Kδ inhibitor, in relapsed or refractory follicular lymphoma in China: Updated data from the study. *First Author: Zhong Zheng, Shanghai Institute of Hematology, State Key Laboratory of Medical Genomics, National Research Center for Translational Medicine at Shanghai, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

Background: For Follicular lymphoma (FL) patients (pts) of 3rd or higher line, treatment options are limited. Parsaclisib is a potent, highly-selective, next-generation PI3Kδ inhibitor. Initial safety and efficacy data were previously presented (Zhong Zheng et al. ASH 2021; NCT04298879). Here, we report safety, efficacy and survival data of the multicenter, open-label phase 2 study of parsaclisib in 3rd or higher line FL pts in China. **Methods:** Key eligibility included, age ≥ 18 years, histologically confirmed FL grade 1, 2, or 3a, ≥ 2 prior systemic therapies, ECOG PS ≤ 2, and ineligible for hematopoietic stem cell transplantation (HSCT). Pts received parsaclisib 20 mg once daily (QD) for 8 weeks followed by 2.5 mg QD, till disease progression (PD), unacceptable toxicity, death or withdrawn consent. Prophylaxis for Pneumocystis jirovecii pneumonia (PJP) was required. Primary endpoint was objective response rate (ORR) evaluated by an Independent Review Committee (IRC) according to Lugano 2014 criteria, secondary endpoints included: duration of response (DOR), PFS, OS, and safety and tolerability. **Results:** As of the data cutoff date (Dec 12, 2021), 61 pts (median age: 50yr; male [n = 35, 57.4%]) were enrolled. Forty-eight pts remained on treatment and 13 pts had discontinued study treatment mainly due to PD (n = 11). With a median follow-up time 9.5 months (range 6.0-19.7months), the median duration of treatment was 251.0 days (range: 23.0-589.0 days). All 61 pts were evaluable for response, the ORR and complete response rate (CRR) were 86.9% (n = 53, 95% CI: 75.8-94.2%) and 31.1% (n = 19, 95% CI: 19.9-43.3%), respectively. The median time to response (TTR) was 8.0 weeks (95% CI: 7.9-8.0%), and the median DOR was not reached (95% CI: 9.2 months-NC), and 43 of 53 pts with CR or PR still retained CR or PR. As data cutoff, eleven (17.9%) pts had disease progression, the median PFS was not achieved. Three pts died data as data cutoff, the median OS was not achieved. Among the 61 treated pts, 48 (95.1%) pts experienced at least 1 treatment-emergent adverse events (TEAEs), with the most common TEAEs being neutrophil count decreased (49.2%), white blood cell count decreased (32.8%). Twenty-seven patients (44.3%) experienced grade ≥ 3 TEAEs, the most common grade ≥ 3 TEAEs was neutrophil count decreased (n = 10, 16.4%). **Conclusions:** Parsaclisib demonstrated promising efficacy, and acceptable safety profile. These results suggest that parsaclisib could benefit 3rd or higher line Follicular lymphoma patients. Clinical trial information: NCT04298879. Research Sponsor: Innovent Biologics Inc.

Open-label, dose-escalation, and expansion trial of CA-4948 in combination with ibrutinib in patients with relapsed or refractory hematologic malignancies.

First Author: Erel Joffe, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

Background: CA-4948 is a novel oral inhibitor of interleukin-1 receptor-associated kinase 4 (IRAK4), which is essential for toll-like receptor (TLR) and interleukin-1 receptor (IL-1R) signaling in B cell proliferation. IRAK4 forms a Myddosome complex with MYD88 adaptor protein and drives overactivation of nuclear factor-kappa B (NF-κB), causing inflammation and tumor growth. CA-4948 has been reported to be well tolerated and active as monotherapy in heavily pretreated patients with relapsed/refractory (R/R) non-Hodgkin lymphoma (NHL). Preclinical studies demonstrated that tumor resistance and survival via IRAK4 activation could be delayed or reversed. CA-4948 crossed the blood-brain barrier in a murine PDX model of pCNS lymphoma, resulting in tumor response and prolonged survival. In combination with Bruton tyrosine kinase (BTK) inhibitors, CA-4948 showed *in vivo* synergy in B-cell NHL. Here we will present an update on the preliminary efficacy data of CA-4948+ibrutinib in R/R hematologic malignancies. **Methods:** This is an ongoing open-label trial (NCT03328078) of CA-4948 as monotherapy and in combination with ibrutinib. Part A1 (completed) dose escalation of CA-4948 as monotherapy; the recommended phase 2 dose (RP2D) is 300 mg BID with continuous oral dosing. Part A2 (dose escalation in combination with ibrutinib), and Part B (a basket design of 4 expansion cohorts of CA-4948 and ibrutinib: BTK-naïve MZL, DLBCL, or PCNSL and NHL with adaptive resistance to ibrutinib). The primary endpoints of Parts A1 and A2 include safety, tolerability, and RP2D. The primary endpoints of Part B include CR or ORR, with key secondary endpoints of DOR, DCR, PFS and OS following treatment of CA-4948 at dose levels of 200 (DL1) or 300 mg BID (DL2) with ibrutinib at full prescribed dose. **Results:** As of December 7th, 2021, 35 heavily pretreated NHL patients have received CA-4948 monotherapy (median age 66 years, range 50-87), of which six patients have been on CA-4948 for approximately 1 year or longer, suggesting CA-4948 has a long-term acceptable safety and tolerability profile at RP2D (dose level of 300 mg BID). In Part A2, 10 patients are treated with CA-4948+ibrutinib (median age 65 years, range 56-82). Median number of prior lines of anti-cancer therapies is 3 (range 1-8). No DLTs were observed at 200 or 300 mg dose levels to date. The preliminary efficacy data of seven evaluable patients with combination therapy showed 1 CR (MCL), 2 PR (MCL and MZL), 3 SD, and 1 PD, 3 of whom had failed prior ibrutinib. The preliminary data indicate the combination therapy may overcome ibrutinib resistance. **Conclusions:** CA-4948 as a monotherapy and in combination with ibrutinib is well tolerated with an acceptable long term safety profile and promising efficacy. Part A2 is transitioning to Part B basket cohorts of MZL, ABC-DLBCL, PCNSL and NHL with adaptive resistance to ibrutinib. Clinical trial information: 03328078. Research Sponsor: Curis.

DLBCL cell of origin typing and whole transcriptome analysis using single slides with HTG EdgeSeq.

First Author: Matthew Loya, Genmab US, Inc., Plainsboro, NJ

Background: Diffuse large B-cell Lymphoma (DLBCL) is a highly heterogenous disease. Gene microarrays were initially used to classify DLBCL into germinal center B-cell-like (GCB) or activated B-cell-like (ABC) Cell of Origin (COO) subtypes. ABC is associated with shorter overall survival. In newly diagnosed patients, COO classification by RNA profiling is a validated prognostic. A simpler immunohistochemical (IHC) staining of CD10, MUM1 and BCL6 is a proxy used in clinical practice in lieu of transcriptomics due to its expense, complexity and tissue requirements. Recent advances in the HTG EdgeSeq platform allow genome-scale profiling with minimal tissue. We successfully applied this novel technology to perform simultaneous COO classification, immune cell enrichment and tumor pathway analysis using a single FFPE slide. **Methods:** Accuracy of the HTG EdgeSeq panel (19,000 genes) was assessed in a head-to-head comparison with RNAseq using FFPE tumor samples (n = 8). DLBCL resections and core needle biopsies were commercially sourced and COO typed using Han's algorithm into GCB or non-GCB (n = 65). Tumor locations included: lymphoid organs, gastrointestinal tract, testes, and the pleural cavity. EdgeSeq was performed on single slides with an average tissue area of 40mm^2. Transcriptomic COO classification was performed using a linear combination of genes as described in Wright et al., *PNAS* 2003, substituting HTG platform-specific weights. Validated COO gene sets from literature and commercial diagnostic assays were tested. Immune cell gene signature enrichment analysis was performed using xCell (Aran et al., *Genome Biol* 2017); pathway analysis was performed with GSEA (Subramanian et al., *PNAS* 2005). **Results:** Gene expression levels estimated from whole transcriptome EdgeSeq on single slides were highly correlated to whole transcriptome RNAseq. Differential expression analysis of GCB vs non-GCB showed that key prognostic genes were detectable and enriched in the expected subtypes. Using these pre-established signatures, subtyping accuracy was ~93% on the training set and 89% on the test set. Immune cell enrichment analysis identified class-switched memory B-cells as more prevalent in non-GCB subjects. This is consistent with emerging evidence that memory B-cells are the primary source of ABC DLBCL and not plasma cells (Venturutti & Melnick, *Blood* 2020). Pathway analysis identified genes regulated by the oncogene ic transcription factor *MYC* were enriched in non-GCB samples; *MYC* protein was found to be overexpressed in ABC in a large study (Hu et al., Blood 2013). **Conclusions:** Combined COO typing and whole transcriptome analysis from a single slide efficiently uses precious patient tissue. Longitudinal core needle sampling may yield insights into tumor evolution and therapeutic mechanisms of action across the DLBCL treatment landscape. Research Sponsor: Genmab A/S.

Impact of sex on outcomes in patients with hairy cell leukemia (HCL): An HCL Patient Data Registry (PDR) analysis.

First Author: Narendranath Epperla, The Ohio State University, Columbus, OH

Background: HCL is a rare indolent leukemia that is more common in men, with a 4:1 male predominance. To date, no studies have characterized the potential difference in outcomes of HCL between male and female patients. Hence, we sought to evaluate the outcomes of female HCL patients using the HCL-PDR. **Methods:** The HCL Foundation sponsored the development of HCL-PDR to characterize the clinical features and outcomes of this rare leukemia. HCL-PDR is an international multicenter PDR that includes patient, disease and treatment information abstracted from medical records. Adult patients enrolled in the HCL-PDR were included in the study. Female patients with HCL were the study population, with males as the comparator. The primary endpoint was the time to next treatment (TTNT) in females compared to males. Secondary endpoints included response rates (RR) and predictors of TTNT. Responses were categorized as: complete response (CR) including CR/CRu (CR unconfirmed)/HR (hematologic response), and partial response (PR), which included PR/PRu (PR unconfirmed)/pHR (partial HR). CRu was defined as no disease in bone marrow (BM) without available blood counts and HR as blood counts meeting criteria for HR, but no available BM. Cox proportional hazard models were used to estimate the hazard ratios for TTNT risk. **Results:** 357 patients were included: 265 males and 92 females. Table shows baseline characteristics stratified by sex. Among the patients who had disease status assessed after first treatment (n=224, males 169 and females 55), there was no significant difference in RR. However, females had significantly longer median TTNT (17.6 years) relative to males (8 years, HR 0.54, 95% CI 0.32-0.91, p=0.02) that remained significant after adjusting for other variables (RR and BRAF mutation) in multivariable analysis (HR 0.32, 95% CI 0.11-0.97, p=0.04). Factors predictive of longer TTNT include female sex and CR (HR.0.26, 95% CI 0.11-0.57, p=0.001). **Conclusions:** This is the first study to date reporting the clinical characteristics and outcomes in female HCL patients. The significantly longer TTNT in females compared to males may be related to factors such as underlying molecular features or hormonal influences. This finding needs to be explored further. Research Sponsor: HCL Foundation.

Phase I study of the anti-BTLA antibody icatolimab as a single agent or in combination with toripalimab in relapsed/refractory lymphomas.

First Author: Jun Ma, Department of Hematology & Oncology, Harbin Institute of Hematology & Oncology, Harbin, China

Background: The B- and T-lymphocyte attenuator (BTLA) is an inhibitory receptor expressed on B, T and NK cells. Using PBMC derived from melanoma patients, co-blockade of the BTLA and PD-1 pathways improved antigen specific T cell response compared to either blockade alone. Icatolimab (JS004 or TAB004) is a humanized IgG4 monoclonal antibody with a hinge mutation (S228P) that binds BTLA and blocks its interaction with its ligand HVEM. In this first-in-human study, we report the preliminary safety and anti-tumor activity of icatolimab as a single agent or in combination with toripalimab (anti-PD-1) in patients with relapsed /refractory (R/R) lymphoma. **Methods:** Eligible patients with R/R lymphoma were enrolled in this open-label, multicenter study (NCT04477772). Icatolimab was administered as a monotherapy at escalating doses of 1, 3 and 10 mg/kg intravenously Q3W and followed by 3 mg/kg and 200 mg monotherapy dose expansion until disease progression or intolerable toxicity. During combination dose escalation, patients received ascending doses of icatolimab (100mg and 200mg) plus toripalimab (240mg). Dose-limiting toxicity (DLT) was evaluated by a safety monitoring committee. Study objectives included safety, pharmacokinetics, and efficacy. **Results:** A total of 31 patients were enrolled, including 9 in the monotherapy dose escalation, 16 in the monotherapy dose expansion and 6 in the combination dose escalation. The lymphoma subtypes included 15 Hodgkin's lymphoma and 16 non-Hodgkin's lymphoma. The median age was 40 (range 21-70) years with 20 (64.5%) male patients. The median prior line of therapy was 4 with 19 (61.3%) received prior anti-PD-1/L1 therapy. By the cutoff date of January 31 2022, the median follow-up was 22.7 weeks. No DLT was observed in either monotherapy or combination dose escalation. Twenty-nine (93.5%) patients experienced treatment emergent adverse event (TEAE), with 6 (19.4%) experienced grade 3 or above TEAEs. The most common TEAEs were anemia (29.0%) and fever (22.6%). Four treatment-related adverse events led to discontinuation of the study drug. 10 (40.0%) and 6 (100%) patients experienced immune related AE in the monotherapy and combination subgroups respectively, but all were grade 1 or 2. Among 22 evaluable patients receiving monotherapy, 1 PR (follicular lymphoma) and 7 SD were observed per Lugano criteria. By the cutoff date, among 5 evaluable patients receiving the combination (all progressed upon prior anti-PD-1 therapy), 2 PR (ORR 40%) and 1 SD were observed. BTLA receptor was fully occupied in all doses evaluated. The mean half-life of icatolimab was 13.3 days. Biomarker analysis indicated HVEM positivity was associated with favorable response. **Conclusions:** Icatolimab alone or in combination with toripalimab were well tolerated in all doses evaluated and showed preliminary clinical efficacy in patients with R/R lymphoma. Clinical trial information: NCT04477772. Research Sponsor: Shanghai Junshi Biosciences Co., LTD.

KITE-363: A phase 1 study of an autologous anti-CD19/CD20 chimeric antigen receptor (CAR) T-cell therapy in patients with relapsed/refractory (R/R) B-cell lymphoma (BCL). *First Author: Loretta J. Nastoupil, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: One mechanism by which B-cell tumors can resist the effects of CD19-targeted CAR T-cell therapy is through CD19 antigen escape (Neelapu et al. ASH 2019). Recent analyses in large B-cell lymphoma (LBCL) demonstrated that approximately one-third to two-thirds of relapses after infusion of CAR T-cell therapy were CD19 negative (Plaks et al. *Blood.* 2021; Spiegel, Dahiya et al. *Blood.* 2021; Spiegel et al. *Nat Med.* 2021). KITE-363 is an autologous CAR T cell transduced with a bicistronic vector with resultant expression of a CD19 CAR with a CD28 costimulatory domain and a CD20 CAR with a 41BB costimulatory domain. In preclinical studies, KITE-363 recognized and eliminated tumor cells expressing CD19 and/or CD20. KITE-363 CAR T-cell therapy has the potential to rescue CD19-negative relapsing patients with BCL as well as prevent CD19 antigen escape by minimizing selective pressure through upfront therapeutic dual targeting. This Phase 1, first-in-human, open-label, multicenter study (NCT04989803) will evaluate the safety and preliminary efficacy of KITE-363 in patients with R/R BCL. **Methods:** The Phase 1 design includes a 3+3 dose-escalation portion (1A), with 5 planned CAR T-cell levels, and a dose expansion portion (1B). Patients may receive optional corticosteroid bridging therapy following leukapheresis. Patients will then receive conditioning chemotherapy (cyclophosphamide and fludarabine) on Day –5 to Day –3 followed by KITE-363 infusion on Day 0. The primary endpoint for Phase 1A is the incidence of adverse events defined as dose-limiting toxicities. The primary endpoint for Phase 1B is investigator-assessed objective response rate per Lugano criteria (Cheson et al. *J Clin Oncol.* 2014). Secondary endpoints include complete response rate, time to next treatment, duration of response, progression-free survival, overall survival, safety, and levels of CAR T cells in blood and cytokines in serum. Eligible adult patients have histologically confirmed BCL, including LBCL, indolent non-Hodgkin lymphoma, nodular lymphocyte-predominant Hodgkin lymphoma (HL), and BCL, unclassifiable (with features intermediate between diffuse LBCL and classical HL), that is R/R after ≥2 lines of therapy (patients with LBCL may have primary refractory disease). Other key inclusion criteria are adequate bone marrow and organ function and ECOG performance status 0–1. Key exclusion criteria are central nervous system (CNS) involvement from lymphoma, active infection including hepatitis B and C, and clinically significant CNS disorder. This study is currently open and accruing patients. Clinical trial information: NCT04989803. Research Sponsor: Kite, a Gilead Company.

TPS7580 **Poster Session**

CRC-403: A phase 1/2 study of bbT369, a dual targeting CAR T-cell drug product with a gene edit, in relapsed and/or refractory B-cell non-Hodgkin lymphoma (NHL). *First Author: Frederick L. Locke, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Although CD19 directed CAR T cell therapies have improved outcomes for non-Hodgkin's lymphoma (NHL) patients, only about 30-40% of 3L+ patients obtain long term remission after this treatment (Neelapu et al. 2017; Schuster et al. 2019). bbT369, a next generation, dual targeted (CD79a/CD20), gene edited (CBLB gene knock out) autologous CAR T cell therapy was devised to overcome hypothesized mechanisms of CD19 CAR T cell treatment failure including loss/downregulation of target antigen, loss of co-stimulation pathways on tumor cells, exhaustion of CAR T cells, and CAR T cell dysfunction due to an immunosuppressive microenvironment (Shah and Fry 2019). bbT369 uses an OR gated design to limit antigen escape and contains split costimulatory domains (CD28 and 41BB) to enhance T cell activation. **Methods:** CRC-403 (NCT05169489) is a non-randomized, open label, multi-site phase 1/2 study enrolling relapsed and/or refractory B cell non-Hodgkin's lymphoma (NHL), including diffuse large B cell lymphoma (DLBCL), high-grade B cell lymphoma (HGBCL), primary mediastinal (thymic) large B cell lymphoma (PMBCL), follicular lymphoma (FL) 3b, and DLBCL transformed from FL (tFL). Patients must have relapsed after ASCT or at least 2 prior lines of therapy. Patients with tFL must be relapsed after receipt of ASCT or at least 2 prior therapies after documentation of transformation. Patients with previous exposure to non-investigational CD19 directed CAR T cell therapy who did not experience disease progression within 6 weeks of initial CAR T cell infusion are eligible for enrollment. Approximately 50 patients will be enrolled in the phase 1 portion. The primary endpoints of the phase 1 portion are determination of the MTD, determination of recommended phase 2 dose (RP2D) and safety. Secondary endpoints include overall response rate, complete response rate, time to response and time to next anti-lymphoma treatment. Exploratory endpoints include DOR, PFS, OS, CAR+ T cell expansion and correlations between clinical response and T cell phenotype or antigen expression on tumor cells. The starting dose of bbT369 will be $50x10^6$ CAR+ T cells and a BOIN design will be used for dose escalation/de-escalation decisions during the study. Upon establishment of the RP2D, the phase 2 portion will begin enrollment. Clinical trial information: NCT05169489. Research Sponsor: 2seventy bio.

TPS7581 **Poster Session**

A first-in-human phase 1 trial of NX-2127, a first-in-class oral BTK degrader with IMiD-like activity, in patients with relapsed and refractory B-cell malignancies. *First Author: Anthony Mato, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Bruton's tyrosine kinase inhibitors (BTKi) have received regulatory approvals and are standard of care for patients with chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL), mantle cell lymphoma (MCL), marginal zone lymphoma (MZL), and WaldenstrÖm macroglobulinemia (WM). However, BTKi-resistant disease remains a clinical challenge with limited options for subsequent therapy. Immunomodulatory drugs (IMiDs, e.g., lenalidomide) are approved as monotherapy for follicular lymphoma (FL), MZL, and MCL, in combination with other therapies for diffuse large B-cell lymphoma (DLBCL) and have shown synergy with BTK-targeted therapy. Dual activity of BTK protein degradation with IMiD-like activity offers a unique approach to overcome known resistance to BTKi. NX-2127 is an oral small molecule that induces BTK degradation via recruitment of cereblon, an adaptor protein of the E3 ubiquitin ligase complex. NX-2127 has shown preclinical activity similar to IMiDs by catalyzing the ubiquitination of Ikaros (IKZF1) and Aiolos (IKZF3), ultimately leading to increased T-cell activation. NX-2127 was shown to degrade both wild-type (WT) and C481-mutated (ibrutinib-resistant) BTK protein in vitro. Robust BTK degradation was also shown in non-human primate studies. Further, NX-2127 demonstrates potent tumor growth inhibition in BTK-dependent mouse xenograft tumor models expressing either WT or ibrutinib-resistant C481S BTK-mutant protein. This dual activity of BTK degradation and IMiD-like activity offers a promising treatment for patients who have failed prior therapy. **Methods:** NX-2127-001 is a first-in-human, dose escalation (Phase 1a) and cohort expansion (Phase 1b) study designed to evaluate the safety, tolerability, and preliminary efficacy of NX-2127 in adult patients with relapsed/refractory B-cell malignancies with once daily oral dosing. Dose escalation will proceed using a modified Fibonacci design with 1 patient per cohort, proceeding to a standard 3 + 3 design based on protocol specified criteria. There will be up to 5 expansion cohorts in Phase 1b enrolling patients with CLL/SLL, DLBCL, FL, MCL, MZL, and WM. Key eligibility criteria include >2 two prior lines of therapy (>1 prior for WM); measurable disease; and an Eastern Cooperative Oncology Group performance status of 0 or 1. Approximately 130 patients (30 in Phase 1a, 100 in Phase 1b) will be enrolled and treated until disease progression or unacceptable toxicity. The primary objectives are to evaluate safety and tolerability and to determine the maximum tolerated dose (Phase 1a), and to evaluate the early clinical activity of NX-2127 in expansion cohorts (Phase 1b). The Phase 1a part of this study is currently enrolling in the United States. Clinical trial information: NCT04830137. Research Sponsor: Nurix Therapeutics.

TPS7582 **Poster Session**

A first-in-human phase 1 study of oral LOXO-338, a selective BCL2 inhibitor, in patients with advanced hematologic malignancies (trial in progress). *First Author: Lindsey Elizabeth Roeker, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: B-cell lymphoma 2 (BCL2) is a key regulator of apoptosis and provides protection from cell death in many hematologic malignancies. LOXO-338 is an orally bioavailable small molecule inhibitor of BCL2, developed to achieve selectivity over BCL-xL and thus avoid dose-limiting thrombocytopenia associated with BCL-xL inhibition. In preclinical studies, LOXO-338 showed a favorable pharmacological profile, selectively inhibited BCL2, and was well-tolerated *in vivo*. LOXO-338 also demonstrated dose-dependent tumor growth inhibition in various murine xenograft models and showed improved efficacy in combination with pirtobrutinib, a highly selective, non-covalent (reversible) BTK inhibitor (Brandhuber et al. *Cancer Res* 2021 81 (13 Suppl) 1258). **Methods:** LOXO-BCL-20001 is a global open-label, first-in-human phase 1 study of oral LOXO-338 in patients (pts) with advanced hematologic malignancies who have received prior therapy. The study will be conducted in 2 parts. Part 1 will evaluate LOXO-338 as monotherapy and will explore different dosing strategies. Part 2 will evaluate LOXO-338 in combination with pirtobrutinib. Part 1 dose escalation will follow an i3+3 design. Each cycle will be 28 days. Eligible pts include those with CLL/SLL, mantle cell lymphoma, and Waldenström macroglobulinemia (WM) who received standard therapy. Pts with other B-cell non-Hodgkin lymphomas (NHL) who received standard therapy, are not candidates for available therapy, or have no options with proven benefit are also eligible. Pts with active or suspected Richter transformation, transformed low grade lymphoma, Burkitt or Burkitt-like lymphoma, and multiple myeloma are also eligible. Pts with AL amyloidosis are eligible in monotherapy dose expansion; all other pts are eligible in both monotherapy and combination dose expansion. Pts must not have progressed while receiving prior BCL2 inhibitor; those with WM or AL amyloidosis must not have received a prior BCL2 inhibitor. Key exclusion criteria include history of CNS involvement, stem cell transplant or CAR-T therapy <60 days, concurrent anticancer therapy, and clinically significant cardiovascular disease. Primary objective is to determine the recommended phase 2 dose of oral LOXO-338 in pts who were previously treated for CLL/SLL and other B-cell NHL, administered alone or in combination with pirtobrutinib. Determining anti-tumor activity in pts with WM and AL amyloidosis is an additional primary objective of part 1 monotherapy. Secondary objectives include determining the safety profile, PK, and preliminary efficacy of LOXO-338 administered alone and in combination with pirtobrutinib. Antitumor activity will be evaluated based on overall response rate (ORR), progression-free survival (PFS), time to progression (TTP) and duration of response (DOR) according to disease-specific response criteria. Clinical trial information: NCT05024045. Research Sponsor: Loxo Oncology at Lilly.

TPS7583 **Poster Session**

inMIND: A phase 3 study of tafasitamab plus lenalidomide and rituximab versus placebo plus lenalidomide and rituximab for relapsed/refractory follicular or marginal zone lymphoma. *First Author: Laurie Helen Sehn, BC Cancer Centre for Lymphoid Cancer and University of British Columbia, Vancouver, BC, Canada*

Background: Most patients with the indolent non-Hodgkin lymphoma (NHL) subtypes follicular (FL) or marginal zone (MZL) respond to first-line treatment but relapse is common, and there is no single standard treatment for patients (pts) with relapsed/refractory (R/R) FL or MZL. Tafasitamab (TAFA) is an Fc-engineered humanized monoclonal antibody (mAb) against CD19 which is broadly expressed in FL and MZL, and regulates B-cell proliferation via B-cell receptor signaling. In preclinical studies, TAFA has shown activity against NHL cell lines in combination with rituximab (anti-CD20 mAb) and lenalidomide (LEN). Monotherapy with TAFA has shown promising clinical activity in a phase 2a study in pts with R/R NHL (NCT01685008), with an ORR of 29% (n/N = 10/34) in pts with FL and 33% (n/N = 3/9) in pts with MZL. In an ongoing phase 2, single-arm study (L-MIND, NCT02399085), TAFA + LEN followed by TAFA alone demonstrated an ORR of 57.5% (n/N = 46/80) in pts with R/R diffuse large B-cell lymphoma (FDA approved indication). These preclinical and clinical observations from phase 2 trials suggest a potential clinical benefit of TAFA + LEN and rituximab for pts with R/R FL or MZL. **Methods:** This phase 3 double-blind, placebo-controlled, randomized study is designed to investigate whether TAFA + LEN and rituximab provides improved clinical benefit compared with LEN and rituximab in pts with R/R FL or R/R MZL. Pts will be randomized 1:1 to receive TAFA (12 mg/kg IV on days 1, 8, 15, and 22 of a 28-day cycle [cycles 1–3], then days 1 and 15 [cycles 4–12]) + LEN (20 mg PO QD, days 1–21/cycle for 12 cycles) and rituximab (375 mg/m^2 IV on days 1, 8, 15, and 22 of cycle 1, then day 1 of cycles 2–5), or placebo (0.9% saline solution IV) + LEN and rituximab. Stratified randomization will be performed separately for pts with R/R FL and R/R MZL. The primary study endpoint is PFS (investigator assessed [INV] by Lugano 2014 criteria) for pts with FL. Key secondary endpoints are PFS (INV) in overall population (FL and MZL), PET-CR rate (INV) at end of treatment (90 days after last treatment) and OS in pts with FL. Inclusion criteria include age ≥18 y, histologically confirmed FL (grade 1, 2, or 3a) or MZL (nodal, splenic, or extranodal), documented R/R disease, ≥1 prior systemic anti-CD20 therapy (including pts with anti-CD20 refractory disease), ECOG PS ≤2, adequate systemic organ function, and high tumor burden (per GELF criteria). Exclusion criteria include prior rituximab + LEN treatment, history of radiotherapy for other diseases (≥25% of bone marrow), nonhematologic malignancy, congestive heart failure (LVEF < 50%), active systemic infection, known CNS lymphoma, or severe immunocompromised state. inMIND (NCT04680052, EudraCT2020-004407-13) is currently enrolling pts; planned enrollment is 528 pts with R/R FL and 60–90 pts with R/R MZL across North America, Europe, and Asia Pacific. Clinical trial information: NCT04680052 / EudraCT2020-004407-13. Research Sponsor: Incyte Corporation, Wilmington, DE, USA.

TPS7584 **Poster Session**

Sequential pembrolizumab (pembro) and chemotherapy (chemo) in newly diagnosed, early unfavorable, or advanced-stage classical Hodgkin lymphoma (cHL): The phase 2 KEYNOTE-C11 study. *First Author: Jane N. Winter, Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago, IL*

Background: PD-1 and PD-L1 inhibitors are standard of care therapies for relapsed/refractory cHL. A recent study of the anti–PD-1 antibody pembro followed by conventional chemotherapy has shown clinical benefit in the first-line setting for cHL (Allen PB et al. *Blood* 2020;137[10]:1318-1326). KEYNOTE-C11 (NCT05008224) is an open-label phase 2 study that is evaluating safety and efficacy of sequential pembro monotherapy and chemo followed by pembro consolidation in newly diagnosed early unfavorable or advanced-stage cHL. **Methods:** Eligible patients (pts) are adults with newly diagnosed and histologically confirmed early unfavorable (Ann Arbor stage I/II plus ≥1 NCCN unfavorable risk factor) or advanced-stage (Ann Arbor stage III/IV) cHL. Pts must have measurable disease per Lugano 2014 criteria and have not received prior radiation therapy, chemotherapy, immunotherapy, or other systemic therapy for cHL. All pts will receive pembro 200 mg IV Q3W for 3 cycles followed by PET to determine response. After pembro induction, all pts will receive 2 cycles of doxorubicin, vinblastine and dacarbazine (AVD day 1 and day 15 Q4W) and undergo another PET assessment (PET3). Pts with negative findings on PET3 (≤3 on the FDG-PET 5-point scale) will receive 2-4 additional cycles of AVD, depending on stage and bulk of disease; those with nonbulky early unfavorable disease will receive 2 cycles, and all others will receive 4 cycles. Pts with positive findings on PET 3 (≥4 on the FDG-PET 5-point scale) and aged < 60 years will transition to 2-4 cycles of escalated therapy with bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine and prednisone, depending on bulk and stage of disease; those with nonbulky early unfavorable disease will receive 2 cycles, and all others will receive 4 cycles. Pts aged ≥60 years will continue to receive AVD for 4 cycles. All pts will then receive 4 cycles of pembro 400 mg Q6W as consolidation therapy. Treatment will continue until disease progression, unacceptable toxicity, investigator's decision, or maximum duration of treatment is reached. Adverse events will be graded per CTCAE version 5.0. Primary end point is complete response (CR) by BICR per Lugano 2014 response criteria. Secondary end points include CR by investigator review per Lugano 2014 response criteria, rate of PET negativity by BICR according to the FDG-PET 5-point scale, duration of CR by BICR per Lugano 2014 response criteria, and safety and tolerability. Exploratory end points include 2-year modified PFS by BICR per Lugano 2014 response criteria and OS. Efficacy and safety will be evaluated in all pts who received ≥1 dose of pembrolizumab. CR rate with 95% CI will be reported per the Clopper-Pearson exact binomial method. Duration of CR, PFS, and OS will be estimated using the Kaplan-Meier method. Planned enrolment is 140 pts. Clinical trial information: NCT05008224. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS7585 **Poster Session**

KEYNOTE B68: Open-label phase 2 study of the efficacy and safety of pembrolizumab administered every six weeks in patients with relapsed or refractory classical Hodgkin lymphoma or primary mediastinal B-cell lymphoma. *First Author: Philippe Armand, Dana-Farber Cancer Institute, Boston, MA*

Background: Classical Hodgkin lymphoma (cHL) and primary mediastinal B-cell lymphoma (PMBCL) frequently harbor amplifications at 9p24.1, leading to overexpression of PD-L1 and PD-L2, suggesting a genetically driven vulnerability to programmed death 1 (PD-1) blockade. The PD-1 inhibitor pembrolizumab, dosed at 200 mg every 3 weeks (Q3W), demonstrated strong antitumor activity and acceptable safety that led to approvals for adult and pediatric patients with relapsed or refractory (R/R) cHL and R/R PMBCL. Efficacy, safety, and pharmacokinetic (PK) results from studies in solid tumors have since led to accelerated approval for the pembrolizumab 400 mg Q6W regimen for all indications in adults; however, further efficacy and safety data are needed for hematologic indications. The open-label, single-arm, multisite, global, phase 2 KEYNOTE-B68 study (NCT04875195) evaluates the safety, efficacy, and PK profile of pembrolizumab 400 mg Q6W in patients with R/R cHL or PMBCL. **Methods:** Patients must have histologically confirmed R/R cHL (cohort 1) or R/R PMBCL (cohort 2) per WHO classification and radiographically measurable disease per the Lugano 2014 classification criteria and must not have previously received treatment with anti–PD-1 therapy. Eligible patients must have failed to respond to or relapsed after receiving an autologous stem cell transplant (ASCT) or must be ineligible for ASCT and must have failed to respond or relapsed after ≥1 (cHL) or ≥2 (PMBCL) prior lines of therapy; patients with PMBCL must have received ≥1 line of therapy containing rituximab. Approximately 60 patients will be enrolled. They will receive pembrolizumab 400 mg IV Q6W for up to 18 cycles. Disease assessments will occur Q12W by investigator per the Lugano 2014 response criteria. Local radiographic assessments will be collected by computed tomography Q12W and by positron emission tomography at weeks 12 and 24 and to confirm complete response. Adverse events will be monitored and assessed by investigators throughout the study, and their severity will be graded per NCI Common Terminology Criteria for Adverse Events, version 5.0 guidelines. Patients who receive an allogeneic SCT within 2 years of the last dose of study treatment will be monitored for 18 months after SCT for events of clinical interest. The primary end point (assessed per cohort) is objective response rate by investigator per the Lugano 2014 classification criteria. Secondary end points (assessed per cohort) include duration of response by investigator assessment, characterization of the PK profile and immunogenicity for pembrolizumab 400 mg Q6W, and safety. Exploratory end points assessed per cohort include overall survival, progression-free survival per the Lugano 2014 criteria, and molecular biomarker analyses. Clinical trial information: NCT04875195. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS7586 **Poster Session**

A novel microbial-derived peptide therapeutic vaccine (EO2463) as monotherapy and in combination with lenalidomide and rituximab, for treatment of patients with indolent non-Hodgkin lymphoma (SIDNEY). *First Author: Pier Luigi Zinzani, Institute of Hematology "L. e A. Seràgnoli", University of Bologna, Bologna, Italy*

Background: EO2463 is a therapeutic vaccine designed to activate existing commensal bacteria-specific memory T cells that cross-react with B cell markers in order to drive anti-tumor immune activity against B-cell malignancies. The four microbial-derived, synthetically produced peptides contained in EO2463 (OMP72, OMP64, OMP65, and OMP66), correspond to cytotoxic CD8 T cell HLA-A2 restricted epitopes, and exhibit molecular mimicry with the B cell markers CD20, CD22, CD37, and CD268 (BAFF-receptor), respectively. In pre-clinical models, these peptides can generate strong immune responses and specifically stimulate cross-reactive cytotoxic CD8 T cells to recognize the chosen B cell targets. EO2463 also contains a CD4 helper peptide referred to as universal cancer peptide 2, derived from the human telomerase reverse transcriptase catalytic subunit. The present study is a first-in-human clinical trial of this microbiome-derived peptide therapeutic cancer vaccine approach in patients with follicular lymphoma (FL) and marginal zone lymphoma (MZL). **Methods:** This four-cohort phase 1/2 trial will investigate EO2463 monotherapy, and combinations of EO2463/lenalidomide (EL), EO2463/rituximab (ER), and EO2463/lenalidomide/rituximab (ER^2), for treatment of patients with FL and MZL. Cohort 1 is a safety lead-in dose-finding in patients with relapsed/refractory (RR) disease, with a 3-by-3 design to establish the recommended phase 2 dose (RP2D) for EO2463 monotherapy and to confirm the safety of the RP2D for combination schedules of EL, and ER^2. After the recommended EO2463 monotherapy dose is established, cohorts 2, 3, and 4 will open to accrual. Cohort 2 will investigate EO2463 monotherapy in patients with newly diagnosed FL/MZL who are not in need of treatment; cohort 3 will investigate EO2463 monotherapy, followed by ER in patients with limited tumor burden who need treatment, and cohort 4 will further investigate EL, followed by ER^2 in the RR setting. EO2463 will be administered SC 4 times at 2-week intervals, followed by continued booster administrations every 4 weeks for 9 (Cohorts 2 and 3) or 12 (Cohorts 1 and 4) months. Inclusion/exclusion criteria, and the design and schedule of the intense immune and safety monitoring will be presented. The safety lead-in dose-finding is currently ongoing, and no safety concerns have been observed thus far. Clinical trial information: NCT04669171. Research Sponsor: Enterome.

TPS7587 **Poster Session**

Frontline treatment of follicular lymphoma with atezolizumab and obinutuzumab, with and without radiotherapy (The FLUORO study). *First Author: Eliza Anne Hawkes, Austin Health, Heidelberg, Australia*

Background: Follicular lymphoma (FL) is the commonest indolent lymphoma, comprising 20% of non-Hodgkin Lymphoma, with approximately 80% of patients (pts) requiring therapy. At present, advanced stage is incurable; most pts require >1 treatment. Overall response rates (ORR) to standard chemoimmunotherapy (bendamustine or CHOP with rituximab or obinutuzumab) approximate 85% with considerable toxicity (grade 3-5 in 69-75%) (Hiddemann 2018). With the FL population predominantly >65 years, 10-year median survival and need for further therapy, efficacious treatments with low toxicity are desirable. PD1/PDL1 axis inhibitors are active in FL. A phase I study of obinutuzumab (O) + atezolizumab (A) induced 57% ORR in pts with rituximab-refractory FL (Palomba 2017). Our phase II '1st FLOR' study, combining nivolumab + rituximab in treatment naïve FL yielded 92% ORR, (54% Complete Response, CR). Toxicity profiles compared favourably with conventional chemotherapy: 41% grade 3-5 events (Hawkes 2021). FL is sensitive to low dose radiotherapy (RT), with abscopal effects reported, and potential to improve treatment efficacy with minimal additional toxicity when combined with PD1/PDL1 inhibitors (Sharabi 2015). This investigator initiated, multicentre single-arm phase II PET-adapted trial aims to assess the response of O + A +/- RT for treatment-naïve FL, reducing treatment-related toxicity using a chemotherapy-free, multi-modality, synergistic regimen. **Methods:** Eligible pts are >18 years, ECOG 0-2 with untreated, biopsy proven, grade 1-3A stage II-IV FL. Exclusions are significant compressive symptoms, autoimmune disease, pneumonitis and treatment urgency. All pts receive 6 cycles (q21 days) of O 1000mg + A 1200mg (plus O given on days 8 & 15 of cycle 1). Interim PET-CT is performed post cycle 2. Pts with less than CR will undergo RT (4Gy) to residual disease after cycle 3. At end of induction, responding patients will receive maintenance O (up to 12 cycles, 1000mg Q8W). Pts with significant progression will be taken off study. Total follow-up is 2 years post treatment. Primary endpoint is CR rate following 6 x O&A +/- RT. Secondary endpoints include ORR, PFS, OS and adverse events. PET centres are ARTnet accredited with central analysis. An extensive exploratory biomarker substudy is planned. Sample size is 46 according to a Simon's 2-stage design. If ≥5 positive responses (CR +/- PR) without prohibitive toxicity are seen in the first 15 pts, 31 further pts will be recruited**.**The trial has currently enrolled 7 pts from 4 Australian sites. Clinical trial information: NCT04962126. Research Sponsor: Roche Australia, Victorian Comprehensive Cancer Center.

TPS7588 **Poster Session**

CELESTIMO: A phase III trial evaluating the efficacy and safety of mosunetuzumab plus lenalidomide versus rituximab plus lenalidomide in patients with relapsed or refractory follicular lymphoma who have received ≥ 1 line of systemic therapy. *First Author: Loretta J. Nastoupil, Emory University, Atlanta, GA*

Background: Despite significant progress with first-line immunochemotherapy, most patients with follicular lymphoma (FL) will eventually relapse with increasing refractoriness and decreasing duration of response to subsequent therapy lines (Rivas-Delgado et al. 2019). Mosunetuzumab (M) is a CD20xCD3 bispecific antibody that engages and redirects T-cells to eliminate malignant B cells (Sun et al. 2015). In an ongoing, pivotal Phase I/II trial of M monotherapy, patients with relapsed/refractory (R/R) FL who have received ≥2 prior treatment lines achieve deep and durable responses (NCT02500407; Budde et al. ASH 2021). Preliminary data from a Phase Ib study have suggested favorable safety and promising activity of M in combination with lenalidomide (Len), a potent immunomodulatory agent that has shown additive/synergistic activity with an anti-CD20 antibody in R/R indolent lymphoma (Leonard et al. 2019), in patients with R/R FL who have received ≥1 prior therapy (NCT04246086; Morschhauser et al. ASH 2021). The chemotherapy-free M-Len combination may represent a promising outpatient therapy option for future management of patients with R/R FL. The randomized, multicenter Phase III study has been initiated. **Methods:** CELESTIMO (NCT04712097) is a randomized, multicenter, open-label Phase III study evaluating the efficacy and safety of M-Len versus rituximab plus Len (R-Len) in patients with previously treated R/R FL. Patients must have histologically documented CD20+ FL (Grades 1–3a) requiring systemic therapy and have received ≥1 prior line of systemic therapy. Patients are randomized (1:1) to receive M-Len (M intravenously [IV] on Days [D] 1, 8 and 15 of Cycle [C] 1 [21-day cycle] and D1 of C2–12 [28-day cycles], plus Len orally [PO] on D1–21 of C2–12) or R-Len (R IV on D1, 8, 15 and 22 of C1 then on D1 of C3, 5, 7, 9, and 11, plus Len PO on D1–21 of C1–12 [all 28-day cycles]), and stratified by disease progression within 24 months of initial treatment (yes/no), number of prior lines of therapy (1 versus ≥2), and refractoriness to anti-CD20 therapy (refractory/non-refractory). The primary endpoint is progression-free survival (PFS) assessed by independent review committee; secondary endpoints include investigator-assessed PFS, complete and objective response, overall survival, and safety. Biomarkers predictive of response to M-Len and R-Len will also be investigated as exploratory endpoints. The study started recruitment in 2021 and plans to enroll ~400 patients from approximately 16 countries and 150 sites globally. Clinical trial information: NCT04712097. Research Sponsor: Sponsored by F. Hoffmann-La Roche Ltd. Third-party medical writing assistance was provided by Helen Cathro, PhD, on behalf of Ashfield MedComms, an Ashfield Health company, and was funded by F. Hoffmann-La Roche Ltd.

TPS7589 **Poster Session**

Brentuximab vedotin and nivolumab alone and then combined with rituximab, cyclophosphamide, doxorubicin, and prednisone for frontline therapy of patients with primary mediastinal large B-cell lymphoma. *First Author: Raphael Eric Steiner, The University of Texas MD Anderson Cancer Center, Department of Lymphoma/Myeloma, Houston, TX*

Background: Primary mediastinal large B-cell lymphoma (PMBL) is a rare and distinct subtype of diffuse large B-cell lymphoma and affects primarily young adults. PMBL has a unique genomic profile that has similarities to classic Hodgkin lymphoma with CD30 expression and genomic alterations in the programmed T-cell death-ligand 1 (PD-L1) locus 9p24.1. The trial CheckMate-436, including relapsed/refractory PMBL patients treated with nivolumab (antibody that binds to immune checkpoint PD-1) and brentuximab vedotin ((BV) anti-CD30 antibody-drug conjugate) showed an overall response rate (ORR) of 73% and complete response rate (CRR) of 43% (Zinzani et al. JCO 2019). Although most PMBL patients can be cured with frontline chemoimmunotherapy with or without radiotherapy, the outcome of patients having rr-PMBL treated with intensive regimens is generally unfavorable. The discovery of new frontline regimens to decrease chemoresistance and toxicities represents an urgent unmet clinical need for PMBL patients. **Methods:** We are conducting a phase II, open-label, single-center clinical trial combining BV-Nivolumab alone and then combined with rituximab, cyclophosphamide, doxorubicin, and prednisone (R-CHP) for patients with previously untreated PMBL Patients 18 years or older with previously untreated PMBL, stage I to stage IV disease are eligible. However, patients with an urgent need for cytoreductive treatment will be excluded. Patients will receive BV 1.8 mg/Kg IV and Nivolumab 240 mg flat dose IV day 1 for cycles 1 and 2, in a 21-day cycle. During cycles 3 and 4, R-CHP will be added to BV-Nivolumab. Patients who have achieved complete response (CR) at PET/CT before cycle 5 will receive 2 more cycles of BV-Nivolumab+R-CHP (cycle 5 and 6) and BV-Nivolumab only for cycles 7 and 8. In case of CR on PET/CT after cycle 8, therapy will be considered completed. Patients in PR on PET/CT before cycle 5 will receive 4 more cycles of BV-Nivolumab+R-CHP (cycles 5-8). The primary endpoint is CRR at the end of therapy (EOT). The maximum sample size for the PMBL cohort is 40 patients, with a target CRR at EOT of 70%. The null hypothesis is that the true CRR at EOT is 50%, and the alternative hypothesis is that the true CRR at EOT is 70%. The Simon's optimal two-stage design controls the one-sided type I error rate at 0.06 and yields the power of 0.8. The secondary endpoints will include the response rate of BV-Nivolumab+R-CHP at the end of the immune lead-in, landmark survival outcomes, the safety of the combination, and patient-reported outcome. Exploratory analyses include assessing molecular response by sequencing cell-free DNA and Multiplexed ion beam imaging to analyze the tumor microenvironment. The trial is actively accruing at MD Anderson Cancer Center, and 2 out of 40 patients have been enrolled. Clinical trial information: NCT04745949. Research Sponsor: Seagen, Pharmaceutical/Biotech Company.

TPS7590 **Poster Session**

frontMIND: A phase III, randomized, double-blind study of tafasitamab + lenalidomide + R-CHOP versus R-CHOP alone for newly diagnosed high-intermediate and high-risk diffuse large B-cell lymphoma. *First Author: Umberto Vitolo, Candiolo Cancer Institute, Torino, Italy*

Background: Up to 40% of patients relapse or are refractory (R/R) to R-CHOP, the current standard of care for diffuse large B-cell lymphoma (DLBCL), indicating an unmet need, particularly in patients with high-intermediate and high-risk disease (IPI 3–5). POLARIX (NCT03274492) evaluated a modified regimen substituting polatuzumab vedotin for vincristine (pola-R-CHP), demonstrating modest improvement in PFS with no OS benefit between treatment arms. The addition of lenalidomide (LEN) to R-CHOP improved both PFS and OS in the ECOG-ACRIN E1412 trial but not in the Phase III ROBUST study, in which a lower dose of LEN was used, despite a positive trend toward 2-year PFS in a subgroup analysis. The chemo-free immunotherapy tafasitamab + LEN has received accelerated approval in the United States (2020), and conditional marketing authorization in Europe and Canada (2021) in adult patients with R/R DLBCL ineligible for ASCT based on L-MIND (NCT02399085). The primary analysis of First-MIND (NCT04134936), a Phase Ib randomized safety study of R-CHOP + tafasitamab ± LEN in patients with previously untreated and newly diagnosed DLBCL, demonstrated that adding tafasitamab + LEN does not impair dosing and scheduling of R-CHOP, with toxicities similar to those expected with R-CHOP alone (ASH 2021; #3556). frontMIND (NCT04824092) will investigate the efficacy and safety of R-CHOP + tafasitamab + LEN vs R-CHOP alone in previously untreated patients with high-intermediate and high-risk DLBCL. **Methods:** frontMIND is a Phase III, multicenter, randomized, double-blind, placebo-controlled study. Approximately 880 patients are planned to be randomized at ~350 centers in North and South America, Europe, and Asia-Pacific. Eligible patients aged 18–80 years with previously untreated local biopsy-proven, CD20+ DLBCL with IPI score 3–5 (age-adjusted IPI 2–3 if ≤60 years), and ECOG PS 0–2 will be enrolled. Patients with transformed lymphoma (except double or triple hit lymphoma) are excluded. Patients will be randomized 1:1 to receive six 21-day (D) cycles of either R-CHOP + tafasitamab (12 mg/kg intravenously, D 1, 8, and 15) + LEN (25 mg orally, D1–10) or R-CHOP + tafasitamab and LEN placebos. Patients will be followed for up to 5 years after the end of treatment. The primary endpoint is investigator-assessed PFS. Secondary endpoints include investigator-assessed event-free survival, OS, safety, and tafasitamab serum concentration (trough and C_{max} levels). Sensitivity and specificity of minimal residual disease for early detection of disease progression is an exploratory endpoint; further MRD parameters may also be investigated. The study is funded by MorphoSys AG and conducted with the scientific support of members of the Fondazione Italiana Linfomi and the German Lymphoma Alliance. Clinical trial information: NCT04824092. Research Sponsor: MorphoSys AG.

TPS7591 **Poster Session**

Phase 3 randomized study of loncastuximab tesirine in combination with rituximab (Lonca-R) versus immunochemotherapy in patients with R/R DLBCL (LOTIS-5). *First Author: Mehdi Hamadani, BMT & Cellular Therapy Program, Medical College of Wisconsin, Milwaukee, WI*

Background: Patients (pts) with refractory or relapsed (R/R) diffuse large B-cell lymphoma (DLBCL) have poor outcomes with standard treatment. Loncastuximab tesirine (loncastuximab tesirine-lpyl; Lonca), an antibody-drug conjugate (ADC) comprising a humanized anti-CD19 monoclonal antibody conjugated to a pyrrolobenzodiazepine dimer toxin, is approved in R/R DLBCL based on data from the phase 2 LOTIS-2 trial (Caimi et al. *Lancet Oncol* 2021). Rituximab (R) is part of standard immunochemotherapy for DLBCL, both as frontline therapy and in subsequent treatments. Preclinical evidence suggests that the addition of rituximab to anti-CD19 ADC therapy may result in prolonged tumor control (Ryan et al. *Blood* 2017). LOTIS-5 aims to evaluate Lonca-R vs. standard immunochemotherapy of R + gemcitabine + oxaliplatin (R-GemOx) in pts with R/R DLBCL. **Methods:** This is a phase 3 randomized open-label, two-part, two-arm multicenter study of Lonca-R in pts with R/R DLBCL (NCT04384484). A review of safety data from the nonrandomized safety run-in (Part 1), comparing the safety of Lonca-R to previous Lonca safety data, was completed in January 2022. The trial is now continuing to the randomized phase (Part 2). In Part 2, approximately 330 pts will be randomized 1:1 to receive Lonca-R or R-GemOx. The primary objective of the study is to evaluate the efficacy of Lonca-R versus R-GemOx. The primary endpoint is progression-free survival by independent central review (ICR). Secondary endpoints include overall survival, overall response rate (by ICR using 2014 Lugano classification), complete response rate by ICR, duration of response by ICR, frequency and severity of adverse events, changes from baseline in safety laboratory and clinical variables, concentration and pharmacokinetic parameters of Lonca (conjugated and total antibody and unconjugated warhead), immunogenicity, and changes in patient-reported outcomes. The time to event endpoints will be analyzed based on the intent-to-treat population using a stratified log-rank test. The dosing regimen for Lonca-R: Lonca at 0.15 mg/kg + rituximab at 375 mg/m^2 every 3 weeks (Q3W) for 2 cycles and then Lonca at 0.075 mg/kg + rituximab at 375 mg/m^2 Q3W for up to 6 cycles. The dose regimen of R-GemOx: rituximab at 375 mg/m^2, gemcitabine at 1000 mg/m^2 Gem, and oxaliplatin at 100 mg/m^2 every 2 weeks for up to 8 cycles. Key inclusion criteria include age ≥18 years, pathologic diagnosis of DLBCL (including pts with DLBCL transformed from indolent lymphoma) or high-grade B-cell lymphoma with *MYC* and *BCL2* and/or *BCL6* rearrangements, ≥1 line of prior systemic therapy, not being a candidate for stem cell transplantation, and measurable disease per the 2014 Lugano classification. The randomized part of LOTIS-5 commenced in January 2022, and recruitment is ongoing. Funding: ADC Therapeutics SA; medical writing: CiTRUS Health Group. Clinical trial information: NCT04384484. Research Sponsor: ADC Therapeutics.

TPS7592 **Poster Session**

Open-label, active-control, phase 2/3 study of zilovertamab vedotin plus standard of care in patients with relapsed or refractory diffuse large B-cell lymphoma. *First Author: Patrick Wayne Cobb, St. Vincent Healthcare Cancer Centers of Montana, Billings, MT*

Background: Consensus treatment guidelines are unavailable for patients with diffuse large B-cell lymphoma (DLBCL) whose disease progresses after first-line therapy. The receptor tyrosine kinase-like orphan receptor 1 (ROR1) is a transmembrane protein that is overexpressed in multiple cancers, including hematological malignancies. Zilovertamab vedotin (ZV; MK-2140, previously known as VLS-101), an antibody-drug conjugate comprising a humanized IgG1 monoclonal antibody, a proteolytically cleavable linker, and the antimicrotubule cytotoxic agent monomethyl auristatin E, targets ROR1 and has shown promising efficacy and tolerability in hematological malignancies, including DLBCL. This 2-part (part 1, dose confirmation; part 2, dose expansion), open-label, randomized, active-control, phase 2/3 study (NCT05139017) will assess safety and efficacy of ZV + standard of care in patients with relapsed/refractory (R/R) DLBCL. **Methods:** Eligible adult patients must have histologically confirmed DLBCL per WHO classification, ineligible for or have failed autologous stem cell transplantation and chimeric antigen receptor T cell therapy, R/R DLBCL after ≥1 line of prior therapy (cohort A) or ≥2 lines of prior therapy (cohort B), measurable disease per Lugano 2014 criteria, and Eastern Cooperative Oncology Group performance status ≤2. Approximately 420 patients will be enrolled in the study (cohort A, n = 230; cohort B, n = 190). In the part 1 dose confirmation phase, 30 patients from cohort A will receive ZV (at increasing doses: 1.5, 1.75, 2.0, 2.25, and 2.5 mg/kg; starting at 1.75 mg/kg) plus gemcitabine-oxaliplatin + rituximab (R-GemOx) to establish the recommended phase 2 dose using the mTPI design. A safety run-in phase of part 2 will include 30 patients from cohort B and will receive ZV + bendamustine and rituximab (BR). Approximately 360 patients will be included in the part 2 dose expansion phase (cohort A, n = 200; cohort B, n = 160). Patients from cohort A will be randomly assigned 1:1 to 6 cycles of either ZV + R-GemOx or R-GemOx. Patients from cohort B will be randomly assigned 1:1 to 6 cycles of either ZV + BR or BR. Disease response assessments by CT and PET scans will occur every 12 weeks until disease progression or study discontinuation. Adverse events (AEs) will be monitored throughout the study and graded per NCI CTCAE version 5.0. In part 1, the primary end point is safety, including DLTs, AEs, and discontinuation due to AEs. The primary end point for cohorts A and B in the dose expansion phase of part 2 will be progression-free survival by blinded independent central review per Lugano 2014 criteria. Key secondary end points in the dose expansion phase of part 2 for both cohorts include objective response rate (including complete response and partial response) and duration of response, both per Lugano 2014 criteria and overall survival. Clinical trial information: NCT05139017. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS7593 **Poster Session**

Alliance A059102: A randomized phase II U.S. intergroup study of CHO(E)P versus CC-486-CHO(E)P versus duvelisib-CHO(E)P in previously untreated, CD30-negative, peripheral T-cell lymphomas. *First Author: Neha Mehta-Shah, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: While PTCL is treated for curative intent, 5-year (yr) overall survival (OS) remains 20-25% with CHOP based therapy. For pts <60 yrs old, the addition of etoposide to CHOP has been associated with improved outcomes. Brentuximab vedotin in combination with chemotherapy demonstrated an OS benefit in PTCL with CD30 >10% by immunohistochemistry, and most significantly improved outcomes in anaplastic large cell lymphoma. This served as proof of principle that biomarker driven therapy can lead to improved outcomes in this rare disease (Horwitz et al Lancet 2019). Duvelisib is a gamma delta PI3 kinase inhibitor with a 50% overall response rate in PTCL and a trend toward a higher response rate in PTCL with a T-follicular helper (TFH) phenotype (Brammer et al. Blood 2021). Azacitidine is a hypomethylating agent that has shown a 75% overall response rate (ORR) in PTCL with TFH phenotype. CC-486, oral azacitidine, has been safely combined with CHOP and showed a 75% ORR with a higher ORR in PTCL with TFH phenotype (Ruan et al. Blood 2021). **Methods:** A051902 is a 3 arm randomized phase II US intergroup study in previously untreated PTCL with CD30 expression <10% comparing standard chemotherapy (CHOP or CHOEP) to CHOP/CHOEP with duvelisib 25mg PO BID or CHOP/CHOEP with azacitidine 300mg PO. Pts will be stratified by age (>60, ≤60) and TFH phenotype. Pts over age 60 will receive CHOP and those ≤60 will receive CHOEP. Prior to the randomized study, there is a safety lead-in study for the first 12 pts combining duvelisib 15mg BID with CHOP/CHOEP. The primary endpoint of the phase II study is complete remission (CR) rate by the Lugano 2014 criteria. The phase II study is powered for a 25% improvement in CR rate (45% vs 70%) in an experimental arm compared to CHOP/CHOEP with a 90% power and type I error rate of 10%. The phase II will enroll 159 pts (53 per arm). Key eligibility: 1. untreated PTCL (nodal T-cell lymphoma with TFH phenotype, follicular T-cell lymphoma, PTCL-NOS, angioimmunoblastic T-cell lymphoma, enteropathy associated T-cell lymphoma, monomorphic epitheliotropic intestinal T-cell lymphoma) with CD30 expression <10%, 2. Stage I-IV, PS 0-2. Pts with transformed mycosis fungoides or anaplastic large cell lymphoma are excluded. Standard CHOP and CHOEP are administered every 21 days with growth factor support. Azacitadine 300mg will be taken on days -6 to -1 prior to cycle 1 and then on days 8 to 21 for cycles 1-5. Duvelisib 25mg BID will be taken continuously. Correlative studies include evaluation of TFH phenotype (by immunohistochemistry, gene expression profiling and DNA sequencing) and cell free DNA evaluation to predict outcomes as well as patient reported outcomes. The study was activated 7/30/2021 and the safety lead-in portion is currently enrolling. Support: U10CA180821, U10CA180882. Clinical trial information: NCT04803201. Research Sponsor: U.S. National Institutes of Health.

TPS7594 **Poster Session**

A phase I study of duvelisib in combination with oral azacitidine (CC-486) in relapsed lymphoid malignancies. *First Author: Hayder Saeed, Univ of Kentucky, Lexington, KY*

Background: Phosphoinositide 3-kinase (PI3K) inhibitors have shown promising activity in lymphoid malignancies such as mature T cell lymphoma, diffuse large B cell lymphoma, and mantle cell lymphoma. Duvelisib's PI3K-δ and PI3K-γ activity in T cell lymphoma is promising as a single agent (Horwitz, Koch et al. 2018). While the safety profile can generally be managed, certain autoimmune adverse events may limit its adaptation in clinical practice. Azacitidine, a pyrimidine nucleoside analog of cytidine, is active in T cell lymphoma (Saillard, Guermouche et al. 2017) as well as in DLBCL (Martin, Bartlett et al. 2018). Hypomethylators could enhance the activity of PI3K inhibitors through increasing PTEN expression (Spangle, Roberts et al. 2017), and upregulation of tumor suppressor genes (Zuo, Liu et al. 2011). Duvelisib's immune mediated adverse events may be related to shifts in T cell differentiation towards Th17 phenotype and decreases in T reg differentiation that found to be more pronounced in patients with higher immune related toxicity (Gadi, Kasar et al. 2019). Studies have shown that T regs can be induced from Cd4+CD25- T cells using DNA methyltransferase inhibition with azacitidine (Fagone, Mazzon et al. 2018). Thus, the intermittent administration of azacytidine can potentially restore the balance by increasing T regs to decrease the autoimmune toxicity while maintaining Th17 phenotype that enhances tumor killing as shown in myelodysplastic syndrome (Jia, Yang et al. 2020). **Methods:** This is a 3+3 phase I dose escalation study designed to determine the maximum tolerated dose (MTD) of CC-486 in combination with duvelisib in patients with lymphoid malignancies. The MTD is defined as the highest dose with an observed incidence of dose limiting toxicity (DLT) in no more than one out of six patients treated at a particular dose level. Secondary endpoints include best overall response, disease control rate and duration of response. Exploratory end points will be biomarker driven with focus on the composition of different T cell compartments during the administration of the combination. Efficacy biomarkers will include measuring the phosphorylation of AKT in peripheral CD3+ T cells. Oral duvelisib will be given continuously with the dose escalation maintained during the first 2 cycles while CC-486 schedule will be 14 days on/14 days off. The first cohort of patients are enrolled, and are in the DLT testing period. Clinical trial information: NCT05065866. Research Sponsor: SecuraBio, BMS.

TPS7595 **Poster Session**

TTI-622-01: A phase 1a/1b dose-escalation and expansion trial of TTI-622 in patients with advanced hematologic malignancies, including diffuse large B-cell lymphoma (DLBCL). *First Author: Krish Patel, Swedish Cancer Institute, Seattle, WA*

Background: CD47 is an innate immune checkpoint that binds signal regulatory protein alpha (SIRPα) and delivers a "don't eat me" signal to suppress macrophage phagocytosis. Overexpression of CD47 on cancer cells serves as a mechanism of immune surveillance evasion, and is associated with poor prognosis in both hematologic and solid malignancies. TTI-622 is a fusion protein consisting of the CD47-binding domain of human SIRPα linked to the Fc region of human IgG4. It is designed to enhance phagocytosis and antitumor activity by preventing CD47 from delivering its inhibitory signal as well as generating a moderate pro-phagocytic signal via IgG4 Fc. Importantly, unlike many CD47-blocking agents, TTI-622 does not bind to human red blood cells. Preclinical studies demonstrate that TTI-622 induces macrophage-mediated phagocytosis of different malignant cell lines, including DLBCL cells, decreases tumor growth and improves survival in a DLBCL xenograft tumor model. Anti-CD47 antibody enhances rituximab stimulated macrophage-mediated phagocytosis of non-GCB DLBCL cell lines (Bouwstra et al, Cancer Immunol Res. 2019). The ongoing phase 1a part of this study has been previously described. Here we describe 2 cohorts within the phase 1b part of the study that are intended to determine the safety and preliminary efficacy of TTI-622 when given in combination with anti-CD20 targeting agent in patients with CD20+ relapsed/refractory (RR) DLBCL. **Methods:** TTI-622-01 is a multi-center Phase 1a/1b study. Phase 1a was designed to determine the MTD, pharmacokinetics (PK), pharmacodynamics, and preliminary antitumor activity of QW, Q2W, and Q3W single-agent TTI-622 in R/R lymphoma using a 3+3 dose escalation schema. Phase 1b, ongoing, will determine the safety, recommended dose and preliminary efficacy of TTI-622 in combination with select approved anticancer treatments for patients with hematological malignancies including, but not limited to anti-CD20 therapy in patients with CD20+ RR DLBCL. Secondary objectives are to further characterize safety, PK and immunogenicity of TTI-622 when combined with approved therapies. Patients will be enrolled in 2 cohorts exploring different doses of TTI-622 in combination with anti-CD20 therapy. Cohorts will open in a staggered manner. In each cohort 3 patients will be dosed and followed for 28 days before expanding enrolment to additional 27 patients per cohort. Key eligibility criteria include: age ≥18 years; relapsed and/or refractory disease after ≥1 prior line of therapy; not eligible for or have progressed after high dose chemotherapy (HDT)/auto-SCT; ≥1 site of measurable disease (Lugano 2014 classification); ECOG PS ≤2; adequate organ functions, no known CNS involvement; no prior anti-CD47 or anti-SIRPα therapy. Patient recruitment is planned or ongoing at 40 sites worldwide. Clinical trial information: NCT03530683. Research Sponsor: Trillium Therapeutics Inc., which was acquired by Pfizer, Inc. in November 2021.

TPS7596 **Poster Session**

Trial in progress: A phase 1b study evaluating the safety, tolerability, and preliminary anti-tumor activity of NT-I7 (efineptakin alfa), a long-acting human IL-7, post-tisagenlecleucel in subjects with relapsed/refractory large B-cell lymphoma. *First Author: Armin Ghobadi, Washington University School of Medicine, St. Louis, MO*

Background: CD19-directed chimeric antigen receptor T-cell (CAR-T) therapy with tisagenlecleucel (Kymriah) is standard of care (SOC) for patients with relapsed/refractory large B-cell lymphoma (r/r LBCL). CAR-T expansion is a strong predictor of response to this therapy. NT-I7 (efineptakin alfa) is a first in-class, long-acting human IL-7 previously shown clinically in solid tumor studies to increase the number and functionality of T-cells in peripheral blood and within tumors. In a $CD19^+$ lymphoma xenograft mouse model that received anti-CD19 universal CAR-T infusion, NT-I7 treatment prolonged survival and enhanced CAR-T gene expression of functional markers, proliferation, persistence, and tumor killing. We hypothesize that NT-I7 administration after tisagenlecleucel SOC for subjects with r/r LBCL may increase expansion and persistence of CAR-T, leading to increased tumor response rate and improved clinical outcomes without safety concerns. **Methods:** This phase 1b study consists of a dose-escalation phase followed by a dose expansion. In dose escalation, subjects receive tisagenlecleucel infusion on Day 0 and a single dose of NT-I7 on Day 21, at 7 dose levels (DLs 1-7): 60, 120, 240, 360, 480, 600, and 720 μg/kg. DLs 1 and 2 will enroll 1 subject each, followed by a 3+3 design for the remaining DLs. Up to 42 subjects will be enrolled for the dose-escalation phase and up to 15 subjects in the dose-expansion phase, treated at the recommended phase 2 dose (RP2D). Eligible subjects are ≥18 years of age with biopsy-proven diagnosis of r/r LBCL after ≥2 lines of systemic therapy, including diffuse LBCL (DLBCL) not otherwise specified (NOS), high-grade B-cell lymphoma, and DLBCL arising from follicular lymphoma. Subjects must be eligible for tisagenlecleucel as SOC. Subjects who have received prior CD19-directed therapy are ineligible. Primary objectives are to evaluate safety and tolerability and determine the maximum tolerated dose (MTD) and/or RP2D for NT-I7 with this regimen. Secondary objectives are to explore the anti-tumor activity of this regimen for r/r LBCL. The effect of NT-I7 after tisagenlecleucel infusion on the safety profile regarding Grade ≥3 Cytokine Release Syndrome (CRS) and Immune Effector Cell-Associated Neurotoxicity Syndrome (ICANS) will also be evaluated. Exploratory objectives are to assess pharmacokinetic parameters of tisagenlecleucel with NT-I7 administration, and correlative studies will evaluate the effects of this regimen not limited only to the expansion of lymphocytes and serum cytokines. As of January 3, 2022, 2 subjects have received NT-I7 in the dose-escalation phase at DL1 and DL2. Clinical trial information: NCT05075603. Research Sponsor: NeoImmuneTech.

8001 **Oral Abstract Session**

ATLAS: A phase 3 randomized trial of carfilzomib, lenalidomide, and dexamethasone versus lenalidomide alone after stem-cell transplant for multiple myeloma. *First Author: Dominik Dytfeld, Poznań University of Medical Sciences, Poznan, Poland*

Background: Treatment following autologous stem cell transplantation (ASCT) for multiple myeloma (MM) remains an area of active investigation. We have shown that extended post-ASCT treatment with carfilzomib, lenalidomide, and dexamethasone (KRd) after KRd induction improved the depth and duration of response (Jasielec et al, Blood 2020), suggesting a benefit of post-ASCT KRd therapy. Here we directly compare that strategy to standard lenalidomide (R) maintenance. **Methods:** This international open-label phase 3 randomized trial recruited newly-diagnosed MM patients (pts) who received any induction therapy for up to 12 months (mo) followed by single ASCT and achievement of at least stable disease within 100 days afterward. Pts were randomized to receive either KRd or R, stratified by post-transplant response (≥VGPR vs < VGPR) and cytogenetic risk [standard risk (SR) vs high [HR: presence of t(4;14), t(14;16), or del(17p)]. Pts randomized to KRd received carfilzomib 36 mg/m^2 on days (D) 1,2,8,9,15,16 for 4 cycles (C) then D1,2,15,16 starting C5; R 25 mg D1-21, and dexamethasone 20 mg D1,8,15,22 in 28-day cycles. KRd pts with SR who reached IMWG-defined MRD-negativity after C6 de-escalated therapy to R alone after C8 (KRd- > R); the rest continued KRd through C36 followed by R alone until progression. Pts randomized to R received lenalidomide 10 mg C1-3 and then 15 mg daily. The primary objective was to compare progression free survival (PFS) rate between the two arms. Based on historical PFS rates, a sample size of 180 Pts was calculated to provide 85% power with 2-sided alpha 0.05. **Results:** 180 pts were enrolled (R n = 87; KRd n = 93) through 10/21/20; data cutoff was 12/31/21. Pt characteristics in the KRd and R arms were balanced for median age (58 vs 59 yrs), >VGPR (88% vs 92%), and HR (23% vs 21%). After 6 cycles, 47% pts in the KRd arm and 29% in the R arm achieved MRD-negativity (p = 0.017). 34 KRd pts eligible for de-escalation converted to R alone after C8 and were analyzed on the KRd arm per intention-to-treat. At median follow-up of 33.8 mo, 23 pts (25%) on the KRd arm and 38 pts (44%) on the R arm progressed; estimated median PFS was 59.0 mo for KRd vs 41.4 mo for R (Hazard Ratio 0.56, logrank p = 0.026). At cutoff, 90% of KRd and 87% of R pts were alive; no deaths were treatment-related. All-grade toxicities were generally comparable between arms. The most common grade 3+ AEs and those of special interest were neutropenia (KRd 47%; R 59%), thrombocytopenia (KRd 13%; R 7%), infections (KRd 15%; R 6%), cardiovascular toxicities (KRd 4%, R 5%), and secondary malignancies (KRd 2, R 2). **Conclusions:** This is the first randomized phase 3 trial demonstrating superior PFS with extended post-transplant KRd therapy compared to R maintenance. Therefore, MRD/risk-adapted post-ASCT extended KRd treatment may represent a new standard of care. Clinical trial information: NCT02659293. Research Sponsor: Amgen, Pharmaceutical/Biotech Company.

8002 **Oral Abstract Session**

Daratumumab carfilzomib lenalidomide and dexamethasone as induction therapy in high-risk, transplant-eligible patients with newly diagnosed myeloma: Results of the phase 2 study IFM 2018-04. *First Author: Cyrille Touzeau, University Hospital Hôtel-Dieu, Nantes, France*

Background: High-risk (HR) cytogenetic is associated with poor outcome in transplant eligible (TE) newly diagnosed myeloma multiple myeloma (NDMM). The triplet combination carfilzomib lenalidomide and dexamethasone (KRD) plus transplantation demonstrated high efficacy with favorable safety profile in TE-NDMM patients (FORTE). The addition of daratumumab (Dara) to frontline therapy also improved response rate and progression free-survival in TE-NDMM patients (CASSIOPEIA, GRIFFIN). Double transplant also improved outcome of HR TE NDMM patients (EMN02, STAMINA). The phase 2 trial 2018-04 from the Intergroupe Francophone du Myelome (IFM) is evaluating an intensive strategy with Dara-KRD induction and consolidation plus double transplant in HR TE NDMM (NCT03606577). **Methods:** HR MM was defined by the presence of del17p, t(4;14) and/or t(14;16). Stategy includes Dara-KRD induction (6 cycles), autologous stem cell transplantation (ASCT), Dara-KRD consolidation (4 cycles), second ASCT, Dara-lenalidomide maintenance. The primary endpoint was the feasibility of this intensive strategy. Here, we report efficacy and safety analysis of Dara-KRD induction. **Results:** Fifty patients with previously untreated NDMM were included from july 2019 to march 2021 in 11 IFM centers Median age was 57 (range 38 -65). ISS stage 3 was present in 12 (24%) patients. Based on inclusion criteria, all patients had HR cytogenetic, including 17p deletion (n = 20, 40%), t(4;14) (n = 26, 52%) or t(14;16) (n = 10,20%). Forty-six patients completed Dara-KRD induction. Two patients discontinued treatment due to severe adverse event (COVID-19 infection, n = 1 ; drug-induced hepatitis, n = 1) and 2 patients discontinued treatment due to disease progression. Grade 3-4 treatment related adverse event (> 5% of patients) were neutropenia (38%), anemia (14%), thrombocytopenia (8%), infection (6%), renal insufficiency (6%) and deep-vein thrombosis (6%). Two patients (6%) experienced stem-cell collection failure. Overall response rate was 96%, including 92 % > very good partial response. Among 37 (/46) evaluable patients post induction, Minimal Residual Disease negativity rate (NGS, 10-^{5}) was 62%. **Conclusions:** Dara-KRD as induction prior ASCT is safe and allows deep responses in TE NDMM patients with high-risk cytogenetic profile. IFM 2018-04 study is ongoing and longer follow-up is needed to evaluate safety and efficacy of the overall strategy with Dara-KRD induction and consolidation plus double transplant in this subset of HR patients. Clinical trial information: NCT03606577. Research Sponsor: Celgene/BMS, Amgen, Janssen.

8003 **Oral Abstract Session**

Phase 1 study of CART-ddBCMA in relapsed or refractory multiple myeloma. *First Author: Matthew J. Frigault, Massachusetts General Hospital Cancer Center, Boston, MA*

Background: Chimeric Antigen Receptor (CAR) T cell therapies targeting B-cell maturation antigen (BCMA) have demonstrated benefit in patients (pts) with relapsed and/or refractory Multiple Myeloma (RRMM). CART-ddBCMA is an autologous anti-BCMA CAR T cell therapy that utilizes a novel, synthetic binding domain, called a D-Domain, instead of a typical scFv binder. The objective of this first-in-human trial is to assess the safety and efficacy of CART-ddBCMA. **Methods:** This is a Phase 1, multi-center, open label, dose escalation trial for pts with RRMM who have received ≥3 prior regimens or are triple-refractory. After apheresis, bridging therapy is allowed during manufacturing. Pts receive fludarabine and cyclophosphamide (30/300 mg/m^2/day) days -5 to -3 and CART-ddBCMA infusion on day 0. Dose escalation was performed at 100 (DL1) and 300 (DL2) x 10^6 (± 20%) CAR+T cells, followed by expansion of DL1. The primary endpoint is incidence of adverse events (AEs), including dose-limiting toxicities (DLTs). Additional endpoints are depth and duration of response (IMWG Criteria), minimal residual disease (MRD, clonoSEQ), progression-free (PFS) and overall survival (OS). Pts with 1- and 3-months follow-up were eligible for safety and efficacy analysis, respectively. **Results:** As of January 25, 2022, 25 pts received CART-ddBCMA, with median age 66 (range: 44-76), after a median of 5 prior lines of therapy (3-16), including 10 (40%) with extramedullary disease (EMD). Median follow-up was 9.8 (2-23.7) months. Overall, 25 pts (19 DL1; 6 DL2) were evaluable for safety and 24 (18 DL1; 6 DL2) for efficacy analysis. All pts experienced CRS, but only 1 pt (in DL2) had grade (gr) 3 CRS. All other CRS cases were gr ≤2, with no cases of gr ≥3 CRS in DL1. Four pts experienced ICANS (2, gr ≤2; 2, gr 3), with 1 gr 3 case in each of DL1 (5%) and DL2 (17%). Standard management resulted in resolution of CRS/ICANS within 30 days in all cases without sequelae. The ORR = 100%, sCR/CR rate = 67%, and ≥VGPR rate = 88%. Conversion to CR/sCR has occurred with longer follow-up, as late as month 9 in this trial. At time of data-cut 5 pts in DL1 with PR/VGPR have < 9 months follow-up, with 4 (of 4 evaluable) negative at ≥10^{-5} for MRD. Overall, 17 of 20 (85%) evaluable pts have achieved best MRD response of ≥10^{-5}. In the dose escalation pts (i.e., those with longest follow-up, n = 12), the ORR and CR/sCR rate was 100% and 75%, respectively, despite 58% (7/12) EMD in this group. Of the first 6 pts dosed in DL1, 4 (67%) continue in ongoing sCR beyond 18 months, including 3 with EMD. Median duration of response, PFS and OS were not evaluable at the time of data-cut because 19 of 24 evaluable pts (79%) remain in ongoing response. **Conclusions:** CART-ddBCMA administration, to date, has demonstrated clinical activity, including 100% ORR with rates of CR/sCR and ≥VGPR of 67% and 88%, respectively. Durable responses beyond 18 months have been observed, including in pts with EMD. Clinical trial information: NCT04155749. Research Sponsor: Arcellx.

8004 **Oral Abstract Session**

Phase I open-label single arm study of GPRC5D CAR T-cells (OriCAR-017) in patients with relapsed/refractory multiple myeloma (POLARIS). *First Author: He Huang, Department of Hematology, The First Affliated Hospital, Zhejiang University, Hangzhou, China*

Background: GPRC5D, a type-C 7-pass transmembrane receptor protein, is predominantly expressed on malignant plasma cells from MM patients. The autologous GPRC5D-directed CAR-T cell (OriCAR-017), owning to an additional proprietary Ori element, is the 2nd generation CAR-T cell with improvement in expansion and durability. **Methods:** The primary objective of this study was to evaluate safety and tolerability of OriCAR-017. Key enrolment criteria included measurable MM adults, R/R or intolerant to established therapies. Patient received lymphodepleting chemotherapy with fludarabine 30mg/m^2/d and cyclophosphamide 300mg/m^2/d for 3 days followed by a single infusion of OriCAR-017. The trial followed 3+3 design with 1×10^6/kg, 3×10^6/kg and 6×10^6/kg CAR$^+$ T cells cohorts. **Results:** Eleven patients were enrolled and underwent apheresis during June 9, 2021 and January 31, 2022. 9pts have completed infusion and 8pts available for efficacy and safety evaluation, the 9th pt completed infusion at January 23, 2022. 2 pts were suspended infusion due to rapid disease progression. Of the 9 infused pts , median age 65 years (range41-71) and a median of 6 (range3-17) prior therapy lines; 3 (33.0%)/1 (11.0%) triple-class/penta-drug exposed; 2 (22.0%)/1 (11.0%) triple-class/penta-drug refractory; 4 (44.0%) prior BCMA CART therapy. Five out of 6pts had high-risk cytogenetic profiles including 2pts with del(17p). No dose-limiting toxicities occurred. The most common TEAEs were neutropenia (G3/4 100%), thrombocytopenia (G3/4 100%), leukopenia (G3/4 100%), lymphopenia (G3/4 100%) and anemia (G3/4 87.5%). All pts experienced CRS with 7pts in G1, 1pt in G2. All CRSs were rapidly relieved after conventional intervention(tocilizumab and steroids). The median onset time was 3 days (range0-8), median duration 6 days (range5-8). No neurologic toxicities were reported. No nail disorders were reported. 8pts avaliable for efficacy evaluation, median follow up time was 109.5 days (range32-195 days). A 100.0% ORR were observed with 3pts CR/sCR, 2pts VGPR, 3pts PR. Three out of 4pts with prior BCMA CAR-T therapy were available for efficacy evaluation-1sCR, 1VGPR, 1PR. After infusion, 8pts were MRD negative in the bone marrow by flow cytometry (10^{-5}) at day 28, 5pts continued at month 3 and 1pt at month 6. Robust OriCAR-017 expansion in peripheral blood by using qPCR for 8pts, median peak was 507,463.6copies/ml (range152093.7 – 1121996.9), median time to peak expansion was 10 days (range7-14). **Conclusions:** In this phase I study, OriCAR-017 was showed safe and impressive efficacy in RRMM patients. Majority of AEs were transient and manageable. 100% ORR and 100% MRD negative rate, along with favorable safety support OriCAR-017 to be a competitive therapy for RRMM. Furthermore, patients who had relapsed from BCMA CAR-T therapy may still benefit from OriCAR-017. Clinical trial information: NCT05016778. Research Sponsor: Oricell Therapeutics Co., Ltd.

8005 **Oral Abstract Session**

Updated results of a multicenter first-in-human study of BCMA/CD19 dual-targeting fast CAR-T GC012F for patients with relapsed/refractory multiple myeloma (RRMM). *First Author: Juan Du, Changzheng Hospital, Shanghai, China*

Background: GC012F is a B cell maturation antigen (BCMA)/CD19 dual-targeting CAR-T developed on the novel FasT CAR-T platform with overnight manufacturing and designed to improve depth of response and efficacy. Data was presented at ASCO and EHA 2021 for initial 19 pts. We present updated data for study (NCT04236011; NCT04182581) with longer follow up and 9 additional pts treated (n = 28) in 3 different dose levels. **Methods:** From October 2019 to November 2021, 28 heavily pretreated RRMM pts (age 27-76) median of 5 prior lines (range 2-9) were treated on a single-arm, open label, multicenter Investigator Initiated Trial receiving a single infusion of GC012F. 89.3% (25/28) were high risk (HR- mSMART), 8 pts had EM disease, 3 had never achieved a CR including after transplant, 1 pts presented with plasma cell leukemia, 24/28 pts were refractory to last therapy, 3 pts primary refractory. 9/28 pts had received prior anti-CD38, 27/28 pts prior IMiDs. 26/28 pts were refractory to PI, 26/28 pts to IMiDs. After lymphodepletion over 2-3 days (30 mg/m^2/d, 300mg/ m^2/d Flu/Cy) GC012F was administered as single infusion at 3 dose levels: 1x10^5/kg (DL1) n = 2, 2x10^5/kg (DL2) n = 10 and 3x10^5/kg (DL3) n = 16. **Results:** As of Jan 26th 2022, 28 pts - median follow-up (f/u) 6.3 mths (1.8-29.9) - had been evaluated for response. Overall response rate (ORR) in DL1 was 100% (2/2)- DL 2 -80% (8/10) DL 3 -93.8% (15/16) with 27 pts MRD negative by flow cytometry (sensitivity 10^{-4}-10^{-6}). 100% of MRD assessable pts (27/27) achieved MRD negativity. One patient out of 28 could not get assessed. At d28, 21/24 assessable patients were MRD negative (81.5%), 4/28 pts could not get d28 MRD assessment f/u due to COVID-19 restrictions however were assessed at a later timepoint. To date best response is MRD- sCR in 21/28 patients(75.0%) across all dose levels. Some pts after short f/u show responses that are still deepening. Cytokine Release Syndrome (CRS) was mostly low grade: gr 0 n = 3 (10.7%), gr 1-2 n = 23 (82.1%), gr 3 n = 2 (7.1%) – no gr 4/5 CRS and no ICANs were observed (Graded by ASBMT criteria). Median duration of CRS was 3 d (1-8 d). PK results showed no difference amongst dose levels DL1 to DL3. Overall, CAR-T median Tmax was 10 d (range 8-14 d), median peak copy number (Cmax) was 97009 (16,011-374,346) copies /μg DNA with long duration of persistence of up to d793 (data cut-off). CAR-T geometric mean $AUC_{0\text{-}28}$ for DL1, DL2 and DL3 were 468863, 631540 and 581620 copies/μg DNA$\times$day, respectively. Pts continue to be monitored for safety and efficacy including DOR. **Conclusions:** BCMA-CD19 dual FasT CAR-T GC012F continues to provide deep and durable responses with a favorable safety profile in additional RRMM pts across all dose levels demonstrating a very high MRD negativity rate including in pts refractory to anti-CD38, PI and IMIDs. GC012F is currently being studied in earlier lines of therapy as well as additional indications. Clinical trial information: NCT04236011; NCT04182581. Research Sponsor: Gracellbiotechnologies.

8006 **Oral Abstract Session**

Initial safety results for MagnetisMM-3: A phase 2 trial of elranatamab, a B-cell maturation antigen (BCMA)-CD3 bispecific antibody, in patients (pts) with relapsed/refractory (R/R) multiple myeloma (MM). *First Author: Alexander M. Lesokhin, Division of Hematology and Oncology, Memorial Sloan Kettering Cancer Center/Weill Cornell Medical College, New York, NY*

Background: Elranatamab (PF-06863135) is a humanized bispecific antibody that targets both BCMA-expressing MM cells and CD3-expressing T cells. MagnetisMM-3 (NCT04649359) is an open-label, multicenter, non-randomized, phase 2 study to evaluate the safety and efficacy of elranatamab monotherapy in pts with R/R MM. Initial safety results are presented. **Methods:** MagnetisMM-3 enrolled pts who are refractory to at least 1 proteasome inhibitor, 1 immunomodulatory drug, and 1 anti-CD38 antibody. Pts were assigned to 1 of 2 independent, parallel cohorts: those naïve to BCMA-directed therapies (Cohort A) and those with previous exposure to BCMA-directed antibody-drug conjugates or CAR-T cells (Cohort B). Pts received subcutaneous elranatamab 76 mg QW on a 28-d cycle with a 2-step-up priming dose regimen administered during the first week. Dose modifications were permitted for toxicity. Treatment-emergent adverse events (TEAEs) were graded by CTCAE (v5.0), and cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) by ASTCT criteria. **Results:** As of the data cutoff on Dec 31, 2021, 60 pts in Cohort A had received ≥1 dose of elranatamab; the last pt's first dose was ~2 months prior to the cutoff. Median age was 69.0 y (range, 44–89), 48.3% were male, 63.3% were white, 18.3% were Asian and 11.7% were Black/African American. At baseline, 60.0% of pts had an ECOG performance status 1–2 and pts had received a median of 5 (range, 2–12) prior therapies. Median duration of elranatamab treatment was 9.57 wks (range, 0.1–46.1); median relative dose intensity was 87.4% (range, 23.1–101.4). TEAEs were reported in 100% (Grade [G] 3/4, 75.0%) of pts. Most common (≥30%) hematologic TEAEs were neutropenia (36.7% [G3/4, 35.0%]), anemia (36.7% [G3/4, 30.0%]) and thrombocytopenia (30.0% [G3/4, 21.7%]). Among pts who received the 2-step-up priming regimen (n = 56), CRS and ICANS, respectively, were reported in 58.9% (G3/4, 0%) and 3.6% (G3/4: 0%); of those pts, 57.6% (n = 19/33) and 100% (n = 2/2) received tocilizumab and/or steroids. Most common (≥30%) non-hematologic TEAE, other than CRS/ICANS, was fatigue (31.7% [G3/4, 3.3%]). Infections were reported in 46.7% (G3/4: 18.3%) of pts; most frequently reported were upper respiratory tract infections (11.7% [G3/4: 0%]). Discontinuations due to adverse events were reported in 5.0% of pts. No pts permanently discontinued treatment due to CRS or ICANS. There were 10 deaths; causes were MM progression (n = 8), septic shock (n = 1) and unknown (n = 1). Data will be updated at the time of presentation to include ~90 pts. **Conclusions:** Preliminary results of MagnetisMM-3 in pts with R/R MM and no prior BCMA-targeted treatment suggest that 76 mg QW elranatamab with a 2-step-up priming regimen is well tolerated, with no G ≥3 CRS or ICANS observed. Clinical trial information: NCT04649359. Research Sponsor: Pfizer.

8007 **Oral Abstract Session**

Teclistamab, a B-cell maturation antigen (BCMA) x CD3 bispecific antibody, in patients with relapsed/refractory multiple myeloma (RRMM): Updated efficacy and safety results from MajesTEC-1. *First Author: Ajay K. Nooka, Emory University, Winship Cancer Institute, Atlanta, GA*

Background: The BCMA $\times$ CD3 bispecific antibody teclistamab (tec; JNJ-64007957) redirects CD3+ T cells to mediate T-cell activation and subsequent lysis of BCMA-expressing myeloma cells. The multicohort, open-label, phase 1/2 MajesTEC-1 study is investigating safety/efficacy of tec in patients (pts) with RRMM who previously received ≥3 lines of therapy (LOT). In phase 1, the recommended phase 2 dose (RP2D) of tec was identified as a weekly subcutaneous dose of 1.5 mg/kg preceded by step-up doses of 0.06 and 0.3 mg/kg. Initial results from pts treated with the tec RP2D in phase 1/2 (no prior exposure to an anti–BCMA-targeted treatment), demonstrated that tec was well tolerated with encouraging efficacy. Here we present updated results from pts treated at the RP2D, including additional pts and longer follow-up. **Methods:** Eligible pts were aged ≥18 years, had documented MM (per IMWG criteria), and had received ≥3 prior LOT including a proteasome inhibitor, an immunomodulatory drug, and an anti-CD38 antibody. Prior BCMA-targeted therapy was not permitted in Phase 1. Pts received tec at the RP2D. The primary endpoint was overall response rate (assessed per IMWG 2016 criteria). Adverse events (AEs) were graded per CTCAE v4.03 (cytokine release syndrome [CRS] and ICANS graded per ASTCT guidelines). Data cutoffs for safety and efficacy (N = 165) were Sep 7 and Nov 9, 2021, respectively. **Results:** Median pt age was 64 y (range 33–84); 58% were male, and median prior LOT was 5 (range 2–14); 100% were triple-class exposed, 70% were penta-drug exposed, 78% were triple-class refractory, and 30% were penta-drug refractory. ORR was 64% (95% CI 56–72), with a complete response or better achieved in 30% of pts. Responses were durable and deepened over time; median duration of response (DOR) was not reached. The 12-mo DOR rate was 66% (95% CI 49–79). The majority of pts who responded to treatment in the first cycle had a reduction in soluble BCMA. The most common hematologic AEs were neutropenia (65%; grade 3/4: 57%), anemia (50%; grade 3/4: 35%), thrombocytopenia (38%; grade 3/4: 21%), and lymphopenia (34%; grade 3/4: 32%). Infections occurred in 104 pts (63%; grade 3/4: 35%). The most common nonhematologic AE was CRS (72%; grade 3: 0.6%; no grade 4/5); median time to CRS onset (range) was 2 days (1–6) and median duration was 2 days (1–9). Five pts (3%) reported a total of 9 ICANS events (all grade 1/2; 7 were concurrent with CRS; all resolved). There were no treatment-related deaths. No pts required a teclistamab dose reduction due to AEs. **Conclusions:** Current data with ~9 months of follow-up reaffirm the deep and durable responses that have been observed with tec in pts with highly refractory MM, with no new safety signals. Additional data with longer follow-up, including subgroup analyses and PFS, will be presented. Clinical trial information: NCT04557098. Research Sponsor: Janssen Research & Development, LLC.

8008 **Oral Abstract Session**

Major risk factors associated with severe COVID-19 outcomes in patients with multiple myeloma: Report from the National COVID-19 Cohort Collaborative (N3C). *First Author: Amit Kumar Mitra, Department of Drug Discovery and Development, Harrison College of Pharmacy, Auburn University, Auburn, AL*

Background: Patients with multiple myeloma (MM), an age-dependent neoplasm of antibody-producing plasma cells, have compromised immune systems due to multiple factors that may increase the risk of severe COVID-19. The NCATS' National COVID Cohort Collaborative (N3C) is a centralized data resource representing the largest multi-center cohort of ~12M COVID-19 cases and controls nationwide. In this study, we aim to analyze risk factors associated with COVID-19 severity and death in MM patients using the N3C database. **Methods:** Our cohort included MM patients within the N3C registry diagnosed with COVID-19 based on positive PCR or antigen tests or ICD-10–CM. The outcomes of interest include all-cause mortality (including discharge to hospice) during the index encounter, and clinical indicators of severity (hospitalization/ED visit, use of mechanical ventilation, or extracorporeal membrane oxygenation/ECMO). **Results:** As of 09/10/2021, the N3C registry included 690371 cancer patients, out of which 17791 were MM patients (4707 were COVID-19+). The mean age at diagnosis was 65.9yrs, 57.6% were >65yo, 46.4% were females, and 21.8% were Blacks. 25.6% had a Charlson Comorbidity Index (CCI) score of ≥2. 55.6% required an inpatient or ED visit, and 3.65% required invasive ventilation. 11.4% developed acute kidney injury during hospitalization. Multivariate logistic regression analysis showed histories of pulmonary disease (OR 2.2; 95%CI: 1.7-2.8), renal disease (OR 1.8; 95%CI: 1.4-2.4), and black race (p<0.001) were associated with higher risk of severity. Interestingly, smoking status was significantly associated with a lower risk of severity (OR 0.7; 95%CI: 0.5-0.9). Further, protective association was also observed between COVID-19 severity and blood or marrow transplant (BMT) (OR 0.52; 95%CI: 0.4-0.7), daratumumab therapy (OR 0.64; 95%CI: 0.42-0.99) and COVID-19 vaccination (OR 0.28; 95%CI: 0.18-0.44). IMiDs were associated increase in the risk of COVID-19 severity (OR 2.1; 95%CI: 1.6-2.7). 2.3% of N3C-myeloma COVID-19+ patients died within the first 10 days, while 4.95% died within 30 days of COVID-19 hospitalization. Overall, the survival probability was 90.5% across the course of the study. Multivariate cox proportional hazard model showed that CCI score ≥2 (HR 4.4; 95%CI: 2.2-8.8), hypertension (HR 1.6; 95%CI: 1.02-2.4), IMiD (HR 2.6; 95%CI: 1.8-3.8) and proteasome inhibitor (HR 1.6; 95%CI: 1.1-2.5) therapy were associated with worse survival. COVID-19 vaccination (HR 0.195; 95%CI: 0.09-0.45) and BMT (HR 0.65; 95%CI: 0.4-0.995) were associated with lower risk of death. **Conclusions:** We have identified previously unpublished potential risk factors for COVID-19 severity and death in MM as well as validated some published ones. To the best of our knowledge, this is the largest nationwide study on multiple myeloma patients with COVID-19. Research Sponsor: None.

8009 **Clinical Science Symposium**

Phase II study of umbilical cord blood–derived natural killer (CB-NK) cells with elotuzumab, lenalidomide, and high-dose melphalan followed by autologous stem cell transplantation (ASCT) for patients with high-risk multiple myeloma (HRMM). *First Author: Samer Ali Srour, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Despite the introduction of several novel agents over the past decade, patients with HRMM continue to have relatively poor outcomes. In a first-in-human study, we previously showed the feasibility of using CB-NK cells up to a dose of 1 x 10^8 cells/kg in MM patients undergoing high-dose melphalan (200 mg/m^2; Mel200) plus lenalidomide and ASCT (NCT01729091). Lenalidomide enhances NK cell function and antibody-mediated cell toxicity against tumor targets. Our preclinical data showed that *ex vivo* expanded NK cells demonstrated higher elotuzumab-mediated cytotoxicity against myeloma targets than non-expanded cells, and the addition of elotuzumab to lenalidomide augmented the CB-NK cell ADCC against MM1.S myeloma targets. Hence, we aimed from this expansion part of the phase 2 clinical trial to determine the efficacy of CB-NK cells combined with elotuzumab/lenalidomide for HRMM undergoing ASCT. **Methods:** Patients with HRMM, ages 18-75 years, were eligible. HRMM defined as: disease relapse within 18 months of ASCT; fluorescence in situ hybridization (FISH) showing t(4:14), t(14:16), t(14:20), deletion (del) 17/17p or gain (amp) 1q; del(13) by conventional cytogenetic analysis; high-risk signatures as determined by the GEP-70 or EMC-92 gene expression profiles. With day 0 defined as day of stem cell infusion, treatment consisted of IV elotuzumab 10 mg/kg (days -15 and -8), oral lenalidomide 10 mg (days -8 to -2 prior to ASCT), Mel200 on day -7, and CB-NK cells on day -5. The primary endpoints were best response rate (≥VGPR) and minimal residual disease (MRD) at 3 months after ASCT, as defined per the IMWG criteria. MRD was tested by using 8-color multiparametric flow cytometry validated to a sensitivity level of 0.001% (1 cell in 100,000). **Results:** Thirty patients, with a median age of 63 (range, 40-72) years, were enrolled between 03/2018 and 01/2021. 97% had R-ISS stages 2/3, 40% had ≥2 high-risk genetic abnormalities, and 23% had del TP53. Most (80%) received induction therapy with bortezomib or carfilzomib + lenalidomide + dexamethasone, 1 patient had prior ASCT, and 4 received >1 prior line of therapy. Before ASCT, 73% had VGPR or better (40% in CR/sCR) and 40% had negative MRD. At 3 months after transplant, 97% achieved ≥VGPR (76%, CR/sCR) and 75% had negative MRD. At median follow-up of 26 (range, 12-44) months, only 4 patients progressed (3 had positive MRD after ASCT). The 2-year PFS and OS rates were 83% and 97%, respectively. No unexpected serious adverse effects attributable to NK cells were noted. **Conclusions:** CB-derived expanded NK cells plus elotuzumab/lenalidomide combined with Mel200 and ASCT results in excellent and durable hematologic and MRD responses in HRMM patients. Furthermore, PFS and OS rates compare favorably to published outcomes for HRMM patients. Clinical trial information: NCT01729091. Research Sponsor: Moonshot Program, Pharmaceutical/Biotech Company.

8000 **Oral Abstract Session**

Ixazomib and daratumumab without dexamethasone (I-Dara) in elderly frail RRMM patients: A multicenter phase 2 study (IFM 2018-02) of the Intergroupe Francophone du Myélome (IFM). *First Author: Xavier Leleu, Centre Hospitalier Universitaire de Poitiers, Poitiers, France*

Background: Frail patients with multiple myeloma have an inferior outcome, especially in the relapse setting. This adverse prognosis is mainly related to a high discontinuation rate due to treatment (Tx) related adverse events. The aim of this phase 2 study is to evaluate efficacy and tolerability of Ixazomib-Daratumumab (I-Dara) without Dexamethasone in elderly frail patients with relapsed myeloma (RRMM) (NCT03757221). **Methods:** Ixa-Dara naïve RRMM patients received oral Ixazomib (4 mg: days 1, 8, 15), IV Daratumumab (16 mg/kg; days 1, 8, 15, 22, cycles 1-2; days 1, 15, cycles 3-6; days 1, cycles 7+) and IV Methylprednisolone before Daratumumab (100 mg at day 1, 8, cycle 1 and then 60 mg). They were enrolled after 1 or 2 prior therapy if their frailty score was ≥ 2 by IMWG score. The primary endpoint was ≥ very good partial response rate (VGPR) at one year. Secondary endpoints included ORR, PFS, OS & toxicity according to NCI-CTCAE version 5. **Results:** Sixty-three patients were screened and 55 enrolled between 03/2018 and 09/2021. Patient were at first (n = 36) or second relapse (n = 19). Thirty-three patients (60%) were previously exposed to bortezomib, 37 (67%) were previously exposed to lenalidomide (Len) and 20 (36 %) were refractory to Len. Median age was 82 (72-93). All patients had a frailty score ≥2 and 13 (24 %) had a 3 or 4 frailty score. In 41 patients ISS at diagnosis was stage I (n = 11), II (n = 18) or III (n = 12). Seventeen (36%) patients harbored high-risk (HR) cytogenetic, including t(4;14) (n = 8) or del17p (n = 10). The median duration of Tx among 28 pts with ongoing Tx was 10 months [5-32] at data cutoff (February, 2)]. The median duration of Tx among 27 pts who stopped Tx was 6 months [0-18]: 18 had progressive disease. Nine patients died during the study: Daratumumab-related bronchospasm (D1C1); Ixazomib-related overdose (C2); sepsis (n = 4), progressive disease (n = 3). Regarding toxicity, 27 pts had a ≥grade 3 AE (49%). The most common grade 3-4 toxicities were thrombocytopenia (n = 9), other cytopenias (n = 4), infection (n = 8), hypertension (n = 3) and gastrointestinal disorders (n = 3). Fourteen out of 28 were SAE including 5 infections, 1 bronchospasm, 1 acute respiratory failure and 2 ixazomib overdoses. Overall response rate, including minimal response, was 86 % with a ≥VGPR rate of 32 % in the whole group. In Len refractory patients the ORR was 82 % and ≥VGPR 41%, in HR cytogenetic patients ORR was 85 % and ≥VGPR 46%. With a median follow-up of 11.6 months median PFS is 16 months and median OS NR (76% estimated at one year). **Conclusions:** In this elderly frail population Ixa-Dara is a feasible combination with favorable efficacy profile even in Len refractory and HR cytogenetic patients. Early toxicity remains a concern in this population eventhough more manageable with Dara SC. Clinical trial information: NCT03757221. Research Sponsor: Janssen and Takeda companies.

8011 **Poster Discussion Session**

Daratumumab (DARA) + lenalidomide, bortezomib, and dexamethasone (RVd) in transplant-eligible newly diagnosed multiple myeloma (NDMM): A post hoc analysis of sustained minimal residual disease (MRD) negativity from GRIFFIN. *First Author: Cesar Rodriguez, Wake Forest University School of Medicine, Winston-Salem, NC*

Background: In the primary analysis of the phase 2 randomized GRIFFIN study, DARA + RVd (D-RVd) improved the stringent complete response (sCR) rate by end of consolidation for transplant-eligible NDMM (42.4% vs 32.0%; 1-sided $P = 0.068$). With longer follow-up (median, 38.6 mo), D-RVd vs RVd improved MRD-negativity (10^{-5}) rates in clinically relevant subgroups (ISS stage III, 71% vs 36%; high cytogenetic risk, 44% vs 29% [del17p, t(4;14), or t(14;16)]; revised high cytogenetic risk, 55% vs 32% [del17p, t(4;14), t(14;16), t(14;20), or gain 1q]). Here we present a post hoc analysis of sustained MRD negativity (median follow-up, 38.6 mo) in the same subgroups and in patients (pts) with ≥CR. **Methods**: Transplant-eligible NDMM pts were randomized 1:1 to 4 D-RVd/RVd induction cycles, ASCT, 2 D-RVd/RVd consolidation cycles, and 2 years of maintenance therapy with lenalidomide (R) ± DARA. For induction/consolidation (21-day cycles), pts received R (25 mg PO Days [D] 1-14), V (1.3 mg/m^2 SC D1, 4, 8, 11), and d (40 mg PO weekly) ± DARA (16 mg/kg IV D1, 8, 15 of Cycles 1-4 and D1 of Cycles 5-6). In maintenance (28-day cycles), pts received R (10 mg PO D1-21; if tolerated, 15 mg in Cycles 10+) ± DARA (16 mg/kg IV Q8W/Q4W or 1800 mg SC per protocol amendments). The primary endpoint was sCR rate by end of consolidation. **Results**: The following features were balanced among randomized pts (D-RVd, n = 104; RVd, n = 103): high cytogenetic risk (16; 14), revised high cytogenetic risk (42; 37), gain 1q (34; 28), and ISS stage III (14; 14). Sustained MRD-negativity rates at 10^{-5} lasting ≥6 and ≥12 months were higher for D-RVd vs RVd among all high-risk subgroups (Table). D-RVd was superior to RVd for rates of sustained MRD negativity lasting ≥12 months for pts with ≥CR (53.7% vs 20.3%) and sCR (59.1% vs 17.4%; Table). Among all pts with sustained MRD negativity, only 1 D-RVd pt subsequently had disease progression, and 1 RVd pt died. Additional data on MRD at 10^{-6} and PFS will be presented. **Conclusions**: MRD data in GRIFFIN show that the addition of DARA to RVd induction/consolidation and R maintenance may lead to durable MRD-negativity (10^{-5}) rates in pts with transplant-eligible NDMM with high cytogenetic risk, ISS stage III, and those who achieve ≥CR or sCR, however larger studies are needed. Clinical trial information: NCT02874742. Research Sponsor: Janssen Oncology, AFT (https://acknowledgments.alliancefound.org).

Sustained MRD negativity (10^{-5} by NGS), n/N (%)	D-RVd ≥6 mo	D-RVd ≥12 mo	RVd ≥6 mo	RVd ≥12 mo
Overall (ITT)	50/104 (48.1)	46/104 (44.2)	15/103 (14.6)	13/103 (12.6)
High cytogenetic risk	4/16 (25.0)	3/16 (18.8)	2/14 (14.3)	2/14 (14.3)

8012 **Poster Discussion Session**

A phase II study of daratumumab with weekly carfilzomib, pomalidomide, and dexamethasone in relapsed and refractory multiple myeloma. *First Author: Andrew J Yee, Massachusetts General Hospital Cancer Center, Harvard Medical School, Boston, MA*

Background: Daratumumab (dara), carfilzomib (K), pomalidomide (P), and dexamethasone (d) are established in relapsed multiple myeloma (MM) with activity in 3-drug combinations including: dara Kd; dara Pd; and KPd. The paradigm in relapsed/refractory disease is moving towards more intensive and well-tolerated combinations to achieve deeper and more durable responses while ensuring tolerability. Quadruplet regimens are now becoming standard in newly diagnosed MM, and we explored a 4-drug regimen in relapsed disease. Preliminary results of a phase 2 study of dara KPd with a twice/week schedule of K showed an ORR of 86% in pts with a median of 1 prior line (Jasielec et al., ASH 2020). Here we report an ongoing study of dara with *weekly* KPd (dara wKPd) to improve the accessibility of this regimen. **Methods:** This phase 2 study (NCT04176718) will enroll up to 43 pts with relapsed/refractory MM who have received at least 1 prior therapy, including both lenalidomide and a proteasome inhibitor. Prior therapy with dara, K, or P was permitted except for K and P given together as last line of therapy. Dara wKPd was given on a 28-day schedule. Dara was given according to the dara Pd schedule. An initial cohort received dara 16 mg/kg iv (with first dose split over two days); the trial was amended to dara 1800 mg sc. K 56 mg/m^2 iv was given weekly on days 1, 8, 15; for C1D1, dose was 20 mg/m^2. P 4 mg was given po on days 1-21. Dex 40 mg was given weekly with the dose split over two days. Treatment was until progression or unacceptable toxicity. The primary endpoints are overall response and the safety profile of dara wKPd. Secondary endpoints include PFS. **Results:** At time of data cutoff, 24 pts were enrolled; median age was 65 (range 42-73), and median number of prior regimens was 2 (range 1-3). All pts were refractory to their last line of therapy and had prior lenalidomide and bortezomib. Additional prior therapies included: pomalidomide (54%), carfilzomib (13%), ixazomib (46%), cyclophosphamide (4%), auto SCT (29%). High risk FISH was present (out of 24 pts): del 17p (13%); t(14;16) (8%); gain of 1q (46%). Median follow up was 8.4 months. 2 pts came off study due to neutropenia leading to delay in treatment. Grade 3-4 hematologic AEs included neutropenia (46%) and thrombocytopenia (25%). There was 1 episode of febrile neutropenia. Common non hematologic AEs (all; grade 3-4) included fatigue (42%; 0%); dyspnea (38%; 4%); increase in ALT/AST (29%; 8%); insomnia (21%; 0%); neuropathy (17%; 0%). 22 pts were evaluable for response, with an overall response rate of 95% (PR 23%, VPGR 68%, CR 5%). Median PFS at 12 months was 86.2% (95% CI, 70%-100%). **Conclusions:** Dara wKPd shows some of the highest response rates (95%) reported to date in relapsed/refractory MM. This likely reflects the incorporation of 4 active drugs in 1 regimen and builds on the efficacy of dara-based triplet regimens, with manageable toxicity and convenience of weekly K. Clinical trial information: NCT04176718. Research Sponsor: Amgen, Janssen.

8013 **Poster Discussion Session**

Efficacy and safety of teclistamab (tec), a B-cell maturation antigen (BCMA) x CD3 bispecific antibody, in patients (pts) with relapsed/refractory multiple myeloma (RRMM) after exposure to other BCMA-targeted agents. *First Author: Cyrille Touzeau, University Hospital Hôtel-Dieu, Nantes, France*

Background: Tec (JNJ-64007957) is a BCMA x CD3 bispecific antibody (Ab) that redirects CD3+ T cells to mediate T-cell activation and subsequent lysis of BCMA-expressing myeloma cells. MajesTEC-1 is a multicohort, open-label phase 1/2 study of tec in pts with RRMM who previously received ≥3 prior lines of therapy (LOT). Results from a pooled analysis of phase 1 and phase 2 cohort A (median follow-up 7.8 mo) demonstrated an overall response rate (ORR) of 62.0% in pts with no prior anti-BCMA treatment (tx). We present initial results from cohort C, in which pts had prior exposure to an anti-BCMA tx. **Methods:** Eligible pts (age ≥18 y) had documented MM per IMWG criteria and had received ≥3 prior LOT including a PI, an IMiD, an anti-CD38 Ab, and an anti-BCMA tx (chimeric antigen receptor T [CAR-T] or Ab drug conjugate [ADC]). Pts were enrolled into a Simon's stage design, receiving weekly subcutaneous tec 1.5 mg/kg preceded by step-up doses of 0.06 and 0.3 mg/kg. Primary endpoint was ORR (per IMWG 2016 criteria). AEs were graded per CTCAE v4.03; cytokine release syndrome (CRS) and immune effector cell–associated neurotoxicity syndrome (ICANS) were graded per ASTCT guidelines. **Results:** As of Sep 7, 2021, 38 pts in cohort C received tec (63% male; median age 63.5 y [range 32–82]; median prior LOT 6 [range 3–14]). 32 (84%) pts were refractory to last LOT; 25 (66%) were refractory to an anti-BCMA tx. Of 25 pts evaluated for efficacy, 16 (64%) had prior ADC, 11 (44%) prior CAR-T (2 pts received both). With median follow-up of 6.9 mo (range 0.7–8.7), ORR was 40% (95% CI 21–61). 5 pts (20%) achieved a complete response or better. The ORR (95% CI) was 38% (15–65) in ADC-exposed pts and 45% (17–77) in CAR-T–exposed pts. Most responses occurred rapidly; 7/25 pts had responses that deepened over time. Median time (range) to first and best response was 1.2 mo (0.2–4.9) and 2.1 mo (1.1–5.7), respectively. Median duration of response was not reached. The safety profile was comparable with that observed in BMCA tx-naive pts, with no new safety concerns. 16 pts (42%; grade 3/4 26%) had infections. Most common AEs (n = 38) were CRS (63%; all grade 1/2; median [range] time to CRS onset: 3 d [2–6], duration of CRS: 2 d [1–4]), neutropenia (55%; grade 3/4 50%), thrombocytopenia (42%; grade 3/4 29%), anemia (39%; grade 3/4 29%), and lymphopenia (40%; grade 3/4 37%). One pt had grade 3 ICANS that resolved with supportive care; pt remains on tx. No pts developed anti-tec Abs. Baseline BCMA expression was comparable with that observed in BCMA tx-naive pts. Updated efficacy and safety data will be presented for 40 pts. **Conclusions:** Initial results of serial targeting of BCMA with tec following ADC or CAR-T tx suggest a promising ORR with responses occurring early and deepening over time. A well-tolerated safety profile was observed in pts previously treated with anti-BCMA tx. Clinical trial information: NCT04557098. Research Sponsor: Janssen Research & Development, LLC.

Elranatamab, a BCMA-targeted T-cell redirecting immunotherapy, for patients with relapsed or refractory multiple myeloma: Updated results from MagnetisMM-1. *First Author: Andrzej J. Jakubowiak, Department of Medicine, University of Chicago Medical Center, Chicago, IL*

Background: Elranatamab (PF-06863135) is a bispecific molecule that activates and redirects the T-cell mediated immune response against multiple myeloma (MM), a plasma cell dyscrasia characterized by expression of B-cell maturation antigen (BCMA). MagnetisMM-1 (NCT03269136), the ongoing Phase 1 first-in-human study for elranatamab, was designed to characterize safety, pharmacokinetics (PK), pharmacodynamics, and efficacy for patients (pts) with relapsed or refractory MM. **Methods:** Elranatamab was given subcutaneously (SC) at doses from 80 to 1000μg/kg either weekly or every 2 weeks (Q2W). Treatment-emergent adverse events (TEAEs) were graded by Common Terminology Criteria for Adverse Events (v4.03) and cytokine release syndrome (CRS) by American Society for Transplantation and Cellular Therapy criteria. PK, cytokine and soluble BCMA profiling, and lymphocyte subset analyses were performed. Response was assessed by International Myeloma Working Group (IMWG) criteria. Minimal residual disease (MRD) was assessed by next generation sequencing at a sensitivity of 1×10^{-5} in accordance with IMWG criteria. **Results:** A total of 55 pts received single-agent elranatamab SC at a dose ≥215μg/kg as of 1-Nov-2021. Median age was 64 (range 42-80) years, and 27% of pts were Black/African American or Asian. Median number of prior regimens was 6 (range 2-15), 91% were triple-class refractory, 56% had prior stem cell transplantation, 27% had high cytogenetic risk, and 22% received prior BCMA-targeted therapy. The most common TEAEs regardless of causality included CRS, neutropenia, anemia, injection site reaction, and lymphopenia. With pre-medication and a single priming dose (600μg/kg or 44mg), the overall incidence of CRS at the recommended dose (1000μg/kg or 76mg) was 67% and limited to Grade 1 (33%) or Grade 2 (33%), with no events Grade 3 or higher. Exposure was dose dependent and Q2W dosing achieved exposure associated with anti-myeloma efficacy. Cytokine increases occurred with the first dose and were reduced by pre-medication. Soluble BCMA decreased with disease response, elranatamab therapy was associated with increased peripheral T cell proliferation, and median time to response was 36 days (range 7-73). With a median follow-up of 8.1 months (range 0.3-21) and including only IMWG confirmed responses, 31% of pts achieved complete response or better and the overall response rate was 64% (95% CI 50-75%). For responders (n = 35), median duration of response was not yet reached, but the probability of being event-free at 6 months was 91% (95% CI 73-97%). Single-agent elranatamab induces durable clinical and molecular responses, and updated data including MRD assessment will be presented. **Conclusions:** Elranatamab shows a manageable safety profile and achieves durable clinical and molecular responses for pts with relapsed or refractory MM. Clinical trial information: NCT03269136. Research Sponsor: This study was sponsored by Pfizer.

8015 **Poster Discussion Session**

Efficacy and safety of talquetamab, a G protein-coupled receptor family C group 5 member D x CD3 bispecific antibody, in patients with relapsed/refractory multiple myeloma (RRMM): Updated results from MonumenTAL-1. *First Author: Monique C. Minnema, University Medical Center Utrecht, Utrecht, Netherlands*

Background: G protein-coupled receptor family C group 5 member D (GPRC5D), which has limited expression in normal human tissue but is highly expressed on malignant plasma cells, is a promising target for multiple myeloma (MM) immunotherapy. Talquetamab (JNJ-64407564) is a first-in-class, bispecific IgG4 antibody that binds to both GPRC5D and CD3 receptors, mediating T-cell–activated lysis of GPRC5D+ MM cells. Here we report updated results with additional patients (pts) and longer follow-up from MonumenTAL-1, a phase 1 trial of talquetamab in RRMM (NCT03399799). **Methods:** Eligible pts had RRMM or were intolerant to standard therapies; prior B-cell maturation antigen-directed therapies were permitted. The primary objectives were to identify the recommended phase 2 doses (RP2Ds) (part 1) and assess talquetamab safety and tolerability at the RP2Ds (part 2). Collective safety, efficacy, PK, and PD data supported 2 RP2Ds for talquetamab: 405 μg/kg SC QW (n = 30) and 800 μg/kg SC Q2W (n = 44). Step-up dosing was used to mitigate against severe cytokine release syndrome (CRS); required premedications were limited to step-up doses and the first full dose of talquetamab. Adverse events (AEs) were graded by CTCAE v4.03 with CRS events graded per Lee et al 2014 criteria. Investigators assessed responses per International Myeloma Working Group criteria. **Results:** As of Jan 17, 2022, pts in the 405 μg/kg/800 μg/kg groups, respectively, received a median of 6 /5 prior lines of therapy, 100%/98% were triple-class (TC) exposed, 77%/75% were TC refractory. Median follow-up (range) was 11.7 (1.0–21.2)/4.2 (0.7–13.7) months. Most AEs were grade 1 or 2. The most common AEs were cytopenias and CRS. Cytopenias (including neutropenia [67%/36%; grade 3/4: 53%/23%]) were reversible, mostly confined to step-up and cycle 1–2 doses, and generally resolved within 1 week. Infections occurred in 47%/34% (grade 3/4: 7%/9%) of pts. CRS (77%/80%; grade 3: 3%/0%) mostly occurred during step-up dosing. Skin-related and nail disorder AEs occurred in 83%/75% of pts (most commonly skin exfoliation: 37%/39% [all grade 1 and 2]). Dysgeusia (63%/57%) was generally mild and managed with dose adjustments. The overall response rates in response-evaluable pts were 70% (21/30 pts)/64% (28/44 pts); very good partial response or better rate: 57%/52%; median time to first confirmed response (range): 0.9 (0.2–3.8)/1.2 (0.3–6.8) months. Median duration of response will be reported. No pts died due to drug-related AEs. The PK and PD profiles of both RP2Ds appear comparable. **Conclusions:** These data show that both RP2Ds of talquetamab have comparable safety, efficacy, and pharmacokinetic profiles and confirm talquetamab as a novel, first-in-class therapy with highly promising efficacy in a heavily pretreated RRMM pt population. Clinical trial information: NCT03399799. Research Sponsor: Janssen Research & Development, LLC.

8016 **Poster Discussion Session**

Comparative efficacy of teclistamab (tec) versus current treatments (tx) in real-world clinical practice in the prospective LocoMMotion study in patients (pts) with triple-class exposed (TCE) relapsed/refractory multiple myeloma (RRMM). *First Author: Niels W.C.J. van de Donk, Amsterdam University Medical Center, Vrije Universiteit Amsterdam, Amsterdam, Netherlands*

Background: Pts with TCE RRMM who have been exposed to ≥3 lines of therapy (LOT) have a poor prognosis and limited tx options. Tec is a B-cell maturation antigen × CD3 bispecific antibody being evaluated in MajesTEC-1 (NCT04557098), a single-arm, phase 1/2 study in pts with RRMM who were TCE to an immunomodulatory drug, a proteasome inhibitor, and an anti-CD38 antibody and received ≥3 LOT. Since MajesTEC-1 lacks a control arm, we assessed the comparative efficacy of tec vs tx currently used in real-world clinical practice (RWCP) by creating an external real-world control arm from LocoMMotion (NCT04035226), a prospective study of RWCP efficacy and safety outcomes in pts with TCE RRMM who received ≥3 LOT. **Methods:** An external control arm for MajesTEC-1 was created from pts in LocoMMotion (248 pts, clinical cutoff May 21, 2021) who met MajesTEC-1 eligibility criteria. Individual pt-level data from MajesTEC-1 were included from 150 pts treated with tec (1.5 mg/kg weekly) at a clinical cutoff of Sep 7, 2021. Inverse probability of tx weighting with average tx effect on the treated was used to adjust for imbalances in baseline covariates of prognostic significance (refractory status, International Staging System stage, time to progression on prior LOT, extramedullary disease, number of prior LOT, time since diagnosis, average duration of prior LOT, age, hemoglobin, lactate dehydrogenase, creatinine clearance, Eastern Cooperative Oncology Group performance status, gender, type of MM, and prior transplant). Comparative efficacy of tec vs RWCP was estimated for overall response rate (ORR), very good partial response (VGPR) rate, complete response or better (≥CR) rate, duration of response (DOR), progression-free survival (PFS), and overall survival (OS). For binary endpoints (ORR, VGPR rate, and ≥CR rate), relative effect of tec vs RWCP was estimated with an odds ratio, transformed into a response-rate ratio (RR) and 95% confidence interval (CI), derived from weighted logistic regression. A weighted Cox proportional hazards model was used to compute hazard ratios (HRs) and 95% CIs for time-to-event endpoints (DOR, PFS, and OS). **Results:** Baseline characteristics were well balanced between the 2 cohorts after reweighting the external RWCP cohort. Pts treated with tec had improved outcomes vs tx used in RWCP: ORR (RR 2.31; 95% CI 1.75–2.87; $P<0.0001$), VGPR rate (RR 5.54; 95% CI 3.38–7.70; $P<0.0001$), ≥CR rate (RR 91.50; 95% CI 12.66–661.43; $P<0.0001$), DOR (HR 0.17; 95% CI 0.08–0.36; $P<0.0001$), PFS (HR 0.47; 95% CI 0.34–0.67; $P<0.0001$), and OS (HR 0.69; 95% CI 0.46–1.05; $P=0.08$). **Conclusions:** Tec showed significantly improved efficacy over RWCP for almost all outcomes, highlighting its potential as a highly effective tx option for pts with TCE RRMM who have been exposed to ≥3 LOT. Research Sponsor: Janssen Global Services, LLC.

8017 **Poster Discussion Session**

Safety and clinical activity of belantamab mafodotin with lenalidomide plus dexamethasone in patients with relapsed/refractory multiple myeloma (RRMM): DREAMM-6 arm-A interim analysis. *First Author: Hang Quach, University of Melbourne, St. Vincent's Hospital Melbourne, Melbourne, VIC, Australia*

Background: Belantamab mafodotin (belamaf; BLENREP) is a B-cell maturation antigen-targeting antibody–drug conjugate approved for patients (pts) with RRMM as monotherapy at 2.5 mg/kg Q3W. Preclinical data demonstrate synergy between belamaf and lenalidomide (Len), suggesting added benefit when combined with standard of care such as Len + dexamethasone (Dex). DREAMM-6 (NCT03544281) Arm A is evaluating belamaf in combination with LenDex in pts with RRMM. **Methods:** This ongoing, two-part, two-arm, open-label study included pts with RMMM previously treated with ≥1 line of therapy (LOT). Pts received 4 belamaf doses/schedules (1.9 mg/kg Q8W or Q4W; 2.5 mg/kg Q4W or Q4W SPLIT dose [50% on Days (D)1, 8] IV) in combination with Len (20 mg PO D1–21) and Dex (20 mg PO/IV D1, 8, 15, 22). Primary objectives were safety (including treatment-related [TR]AEs related to the combination belamaf and LenDex), tolerability, and efficacy (including overall response rate [ORR] defined as ≥partial response). **Results:** As of this interim analysis (data cut: July 23, 2021), 45 pts received ≥1 dose (12 at 1.9 mg/kg Q8W; 4 at 1.9 mg/kg Q4W; 16 at 2.5 mg/kg Q4W; 13 at 2.5 mg/kg Q4W SPLIT). Across cohorts, the median age was 68 y (range: 36–80). Thirteen pts (29%) had high-risk cytogenetics and 6 (13%) had extramedullary disease. Median prior LOT was 3 (range: 1–11) and 26 (58%) had prior Len treatment. The median duration of follow-up and ORR ranged across cohorts (Table). The median duration of response was only reached in the 1.9 mg/kg Q4W cohort (11.1 mo [95% CI: 3.7–not reached [NR]). At the time of data cut, median progression-free survival was not reached in the 1.9 mg/kg Q8W or 2.5 mg/kg Q4W cohorts. Gr ≥3 TRAEs occurred in 42–85%. Gr ≥3 keratopathy occurred in 0 pts in 1.9 mg/kg Q8W, 1 pt (25%) in 1.9 mg/kg Q4W, 8 pts (50%) in 2.5 mg/kg Q4W, and 6 pts (46%) in 2.5 mg/kg Q4W SPLIT cohorts. **Conclusions:** Belamaf + LenDex had a tolerable safety profile, with no new safety signals identified in pts with RRMM. AEs, including keratopathy, were common but manageable with dose modifications. Encouraging clinical activity is observed with this combination in pts with RRMM. Follow-up/correlative studies are ongoing. Funding: GSK (Study 207497); drug linker technology licensed from Seagen Inc.; mAb produced using POTELLIGENT Technology licensed from BioWa. Clinical trial information: NCT03544281. Research Sponsor: GlaxoSmithKline.

Safety and clinical activity of belantamab mafodotin with pembrolizumab in patients with relapsed/refractory multiple myeloma (RRMM): DREAMM-4 Study. *First Author: Attaya Suvannasankha, Indiana University Simon Cancer Center and Roudebush VAMC, Indianapolis, IN*

Background: Belantamab mafodotin (belamaf; BLENREP), a B-cell maturation antigen (BCMA) targeted antibody–drug conjugate approved for adult patients with RRMM, has a multimodal mechanism that eliminates myeloma cells via direct cytotoxicity and a systemic anti-tumor immune response, which may be augmented by an immune checkpoint inhibitor. DREAMM-4 (NCT03848845) assessed safety and clinical activity of belamaf with pembrolizumab (pembro) in RRMM. **Methods:** This was a Phase I/II, single-arm, open-label study of adults with RRMM after ≥3 lines of therapy (LOT, including anti-CD38 monoclonal antibody, proteasome inhibitor, and immunomodulator). Part 1 established the dose of belamaf 2.5 mg/kg with pembro 200 mg, both IV Q3W up to 35 cycles, for the Part 2 expansion. Primary efficacy endpoint was investigator-assessed overall response rate (ORR, ≥partial response [PR] per IMWG criteria by investigator). Secondary endpoints included duration of response (DoR), progression-free survival (PFS), adverse events (AEs) per NCI-CTCAE v4.03, and pharmacokinetics (PK). **Results:** This primary analysis of all treated pts (as of Oct 18, 2021) included 34 pts (6 in Part 1 and 28 in Part 2). In both parts, median prior LOT was 5 (range 3–13); 10 pts (29%) had high-risk cytogenetics and 9 (26%) had extramedullary disease. ORR was 47%, with most responses (10/16 pts) ≥ very good PR (VGPR, Table). Median follow-up was 14.7 months (mo); median (95% CI) DoR was 8.0 (2.1–not reached) mo; median PFS was 3.4 (1.4–5.6) mo. Most pts had ≥1 AE (any grade [Gr]: 97%; Gr ≥3: 74%) and treatment-related AE (TRAE, any Gr: 97%; Gr ≥3: 65%). Most common (≥35%) AEs were keratopathy (any Gr: 76%; Gr ≥3: 38%), vision blurred (any Gr: 38%; Gr ≥3: 0%), and thrombocytopenia (any Gr: 35%; Gr ≥3: 29%). AEs led to dose delays (65%) and dose reductions (32%), but not discontinuation. Nine pts had a serious AE (SAE); 4 pts had ≥1 SAE related to study treatment. Two pts had immune-related AEs of Gr 1 (gout and autoimmune hypothyroidism). Preliminary PK and soluble BCMA data were consistent with single-agent belamaf therapy. **Conclusions:** Belamaf + pembro demonstrated a favorable ORR compared with single-agent belamaf in heavily pre-treated RRMM. No new TRAEs were identified; AE frequency and severity were similar to single-agent belamaf. Correlative biomarker studies are ongoing. Clinical trial information: NCT03848845. Research Sponsor: GSK (205207), Pharmaceutical/Biotech Company.

8019 **Poster Discussion Session**

Synergistic effects of low-dose belantamab mafodotin in combination with a gamma-secretase inhibitor (nirogacestat) in patients with relapsed/refractory multiple myeloma (RRMM): DREAMM-5 study. *First Author: Sagar Lonial, Emory University, Winship Cancer Institute, Atlanta, GA*

Background: Preclinical data demonstrate that nirogacestat, a gamma-secretase inhibitor, may increase cell-surface levels of a B-cell maturation antigen (BCMA) and reduce soluble BCMA levels, which could enhance anti-BCMA agent activity in multiple myeloma. In the DREAMM-5 (NCT04126200) Phase I/II platform trial belantamab mafodotin (belamaf; BLENREP), a BCMA-targeting antibody-drug conjugate, is being evaluated in combination with nirogacestat to determine if the combination can result in similar efficacy and an improved ocular safety profile compared to the currently approved belamaf schedule (single agent dose 2.5 mg/kg Q3W) in patients with RRMM which showed a 31% overall response rate (ORR) and 44.5% Gr3/4 keratopathy (BLENREP US prescribing information). **Methods:** This cohort within the DREAMM-5 nirogacestat combination sub-study has a sequential dose-exploration (DE) phase evaluating 0.95 mg/kg Q3W belamaf with 100 mg BID nirogacestat continuously, followed by a randomized cohort expansion (CE) comparing the combination to a belamaf 2.5 mg/kg Q3W arm. **Results:** Preliminary results from the 10 patients (pts) in the DE cohort with low-dose belamaf + nirogacestat are presented in this abstract. Pts had a median (range) of 4.5 (3–10) prior lines of therapy. At time of data cut-off (Nov 15, 2021), pts received a median (range) of 7 cycles (1–26). The ORR was 60% (n=6/10) and 20% (n=2) achieved a very good partial response (Table). The key emergent adverse events (AEs) included ocular events (n=7 [70%]; ≥Grade [Gr] 3, n=2 [20%] of which Gr 3 keratopathy was reported in 1 pt [10%]), diarrhea (n=7 [70%]; Gr 3, n=1 [10%]) and hypophosphatemia (n=7 [70%]; Gr 3, n=1, [10%]). There were 2 Grade 5 AEs, neither of which were related to study treatment. No pt permanently discontinued study due to treatment related AEs. **Conclusions:** Encouraging clinical activity and a manageable safety profile is observed with low dose belamaf (0.95 mg/kg Q3W) + nirogacestat (100 mg BID continuously) in pts with RRMM. This ongoing sub-study is actively recruiting patients and will continue to evaluate belamaf + nirogacestat efficacy and safety. Updated results will be reported at the congress. Biological correlative analyses and updated clinical data of ciltacabtagene autoleucel (cilta-cel), a BCMA-directed CAR-T cell therapy, in lenalidomide (len)-refractory patients (pts) with progressive multiple myeloma (MM) after 1–3 prior lines of therapy (LOT): CARTITUDE-2, cohort A. *First Author: Hermann Einsele, Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Würzburg, Germany*

Background: Cohort A of the multicohort phase 2 CARTITUDE-2 (NCT04133636) study is evaluating cilta-cel safety and efficacy in pts with MM who received 1–3 prior LOT and were len-refractory – a difficult-to-treat population with poor prognosis. We present updated results. **Methods:** Pts had progressive MM after 1–3 prior LOT, including a PI and IMiD, were len-refractory, and had no prior exposure to BCMA-targeting agents. A single cilta-cel infusion (target dose 0.75×10^6 CAR+ viable T cells/kg) was given post lymphodepletion. Safety and efficacy were assessed, and the primary endpoint was MRD negativity at 10^{-5}. Management strategies were implemented to minimize risk of movement/neurocognitive AEs (MNTs). Pharmacokinetic (PK) analyses (C_{max} and T_{max} of CAR+ T-cell transgene levels in blood) are being conducted, as well as analyses of levels of CRS-related cytokines (eg, IL-6) over time, peak levels of cytokines by response and CRS, association of cytokine levels with ICANS, and CAR+ T cell CD4/CD8 ratio by response, CRS, and ICANS. **Results:** As of January 2022 (median follow-up [MFU] 17.1 mo [range 3.3–23.1]), 20 pts (65% male; median age 60 y [range 38–75]) received cilta-cel. Pts received a median of 2 (range 1–3) prior LOT, and a median of 3.5 y (range 0.7–8.0) since MM diagnosis. 95% were refractory to last LOT, and 40% were triple-class refractory. ORR was 95%, 90% achieved CR or better, and 95% had ≥VGPR. Median times to first and best response were 1.0 mo (range 0.7–3.3) and 2.6 mo (range 0.9–13.6), respectively. 16 pts were MRD-evaluable, all of whom achieved MRD negativity at 10^{-5}. Median DOR was not reached and 12-mo event-free rate was 79%. The 12-mo PFS rate was 75%. Median time to onset of CRS was 7 d (range 5–9) and occurred in 95% of pts (gr 3/4: 10%), with median duration of 3 d (range 2–12). Neurotoxicity occurred in 30% of pts (5 gr 1/2; 1 gr 3/4). 3 pts (15%) had ICANS (all gr 1/2); 1 pt had gr 2 facial paralysis. No MNTs were seen. 1 death occurred due to COVID-19 (assessed as tx-related by the investigator), 2 due to progressive disease, and 1 due to sepsis (not related to tx). Preliminary PK analyses indicate that peak expansion of CAR-T cells occurred at d 10.5 (range 8.7–42.9) and median persistence was 153.5 d (range 57.1–336.8). **Conclusions:** At a longer MFU of 17.1 mo, a single cilta-cel infusion led to deepening and durable responses in pts with MM who had 1–3 prior LOT and were len-refractory. Follow-up is ongoing. Updated and in-depth PK, cytokine, and CAR-T subset analyses and clinical correlation will be presented and provide novel insights into biological correlates of efficacy and safety in this pt population. This pt population is being further evaluated in the CARTITUDE-4 study (NCT04181827), which has concluded enrollment. Clinical trial information: NCT04133636. Research Sponsor: Janssen Research & Development, LLC, Pharmaceutical/Biotech Company.

Correlative analysis to define patient profiles associated with manufacturing and clinical endpoints in relapsed/refractory multiple myeloma (RRMM) patients treated with idecabtagene vicleucel (ide-cel; bb2121), an anti-BCMA CAR T cell therapy.

First Author: Julie Rytlewski, Bristol Myers Squibb, Princeton, NJ

Background: The anti-BCMA autologous CAR T cell therapy ide-cel has achieved deep and durable responses in RRMM patients (Munshi, N Engl J Med 2021). Prior studies have described the correlation between patient characteristics and clinical outcomes from CD19 CAR T cell therapy (Finney, J Clin Invest 2019; Fraietta, Nat Med 2018). We sought to define patient profiles correlated with manufacturing and clinical endpoints in RRMM patients treated with ide-cel in clinical trials using unsupervised clustering and multivariate machine learning across multiple key variable domains. **Methods:** Clinical and manufacturing data were harmonized across 164 RRMM patients treated with ide-cel in KarMMa (NCT03361748) and KarMMa-2 cohort 1 (NCT03601078). Based on individual multivariate importance, 10 selected peripheral blood mononuclear cell (PBMC), drug product (DP), and in-process cell growth variables were used to define patient clusters. Random forest classifiers were generated to identify patient characteristics associated with manufacturing and clinical endpoints. Wilcoxon rank sum and Kruskal-Wallis tests were used to compare 2 and 3+ categorical groups; Cox proportional hazards were used to compare groups with time-to-event data. **Results:** Using an unsupervised method, 4 patient clusters were identified that represented 10%, 57%, 15%, and 18%, respectively, of the total 164 patients. Cluster 4 was the most favorable and was characterized by a higher frequency of T cells in PBMCs; increased T-cell size during manufacturing; higher DP T-cell transduction, potency, and vector copy number; and ultimately a > 3-fold higher CAR T cell yield compared with the least favorable cluster 1. Cluster 2 contained most patients and was associated with intermediate manufacturing endpoints. Patients in cluster 4 had a higher complete response rate, longer progression-free survival, and were defined by lower tumor burden, higher absolute lymphocyte count (ALC), and longer washout period after alkylator treatment, among others (Table). **Conclusions:** The current study identified patient profiles in RRMM using accessible laboratory or medical history data that correlated with longitudinal outcomes. These findings may inform patients likely to achieve improved outcomes with CAR T cell therapy. Clinical trial information: NCT03361748. Prognostic value of early bone marrow MRD status in CAR-T therapy for myeloma.

First Author: Radhika Bansal, Division of Hematology, Mayo Clinic, Rochester, MN

Background: Bone marrow (BM) assessment of minimal residual disease (MRD) is being considered as a surrogate endpoint in clinical trials and is prognostic for survival in multiple myeloma (MM). Timing of BM assessment is variable across Chimeric Antigen Receptor T cell (CART) therapy trials and differs from standard of care practice. BM myeloma cell clearance can be detected by month 1 post CART, even before serum immunofixation becomes negative. BM is still hypocellular at month 1, thus prognostic value of MRD negative (MRDneg) at this timepoint is unclear. We examined impact of Day 30 MRD status in patients (pts) who received CART at Mayo Clinic. **Methods:** Medical records were reviewed retrospectively for MM pts who received CART between 8/2016 and 6/2021. PFS and OS were plotted by Kaplan-Meier method. **Results:** Sixty MM pts received CART and had BM biopsy at month 1. Median age was 62 yrs, 53% were male, and 78% were BM MRDneg by flow cytometry. Baseline demographics were similar between MRDneg and MRD+ (Table). Overall, 85% (40/47) who were month 1 BM MRDneg had i/u FLC<normal. Patients who achieved CR/sCR had higher rates of BM MRDneg (100% vs 61%, p<0.001) and i/u FLC< normal (89% vs 58%, p<0.001). At month 1, 24/60 (40%) pts had hypocellular BM. Serial BM samples at month 3 (n=35), 6 (n=28) and 12 (n=23) showed MRDneg rate of 93% (25/27), 56% (9/16) 58% (7/12), respectively. . Rate of hypocellularity was 54% (19/35), 32% (9/28) and 30% (7/23), respectively. Among the MRDneg/hypocellular pts at month 1, hypocellular BM was seen in 8/11 (73%) pts at month 3 and 2/4 (50%) pts at month 6 and 12. Compared to MRD+, pts who had BM MRDneg at months1 had longer PFS (Table). PFS was not statistically significantly different between pts who had BM MRDneg and were either hypocellular or not. MRDneg pts with i/u FLC<normal at months1 had better median PFS compared to those who did not. (MRD+:2.9 months (1.2-NR). MRDneg/FLC>normal: 4.9 months (2.3-NR). vs MRDneg/FLC<normal:17.9 months (11.8-NR), p<0.0001). **Conclusions:** Hypocellular BM is common in the 3 months post CART. Regardless of BM cellularity, BM MRDneg at month 1 correlates with deep response and prolonged PFS. Majority of BM MRDneg pts at month 1 also had FLC<normal. BM MRDneg status and FLC normalization were associated with longer survival. Our data support the continued evaluation of BM early post CART infusion as a prognostic tool. Research Sponsor: None.

Association of socioeconomic status with adherence to oral agents in patients with multiple myeloma.

First Author: Wilbur Rutter, CVS Health, Lincoln, RI

Background: The introduction of novel oral immunomodulatory drugs has improved the overall survival rates of patients with multiple myeloma (MM). Poor adherence to oral therapies may lead to drug resistance, poor response to treatment and other downstream effects. It is unknown if socioeconomic status (SES) mediates adherence to oral MM agents. **Methods:** This is a retrospective review of newly diagnosed adult patients with MM with drug coverage through a large pharmacy benefit manager (PBM) who received oral MM agents between September 1, 2016 and September 1, 2020. Patients were excluded if they were not eligible for PBM benefits for the 6 months prior to or the 12 months after the index date and if they had a stem cell transplant based on a proxy signal. Adherence was defined as an annual medication possession ratio between 0.8 and 1.2. An SES composite index was developed using ZIP code level factors in a K-means clustering algorithm. Multivariable logistic regression for adherence was conducted using the SES-index and controlled for other patient-specific demographics. **Results:** In total, 6,602 patients were enrolled in the study, of which, 4,211 (64.5%) were defined as adherent. There were significant unadjusted differences in age (67.89 vs 64.06, p<0.00001), ZIP code-based SES index (p=0.00049), census region (p<0.00001) and insurance plan type (p<0.00001). Results from multivariable logistic regression are shown in table. Patients residing in Very Low SES ZIP codes were significantly less likely to be adherent to oral MM agents compared to those residing in Very High SES locations. Odds of adherence increased as patient's age increased. Increasing polypharmacy was negatively associated with oral MM agent adherence. **Conclusions:** Aside from patients residing in Very Low SES ZIP codes, ZIP code-based SES measures were not associated with worse adherence. Other mediating factors include younger age and number of co-prescribed medications. Further investigations of adherence to oral MM agents with clinically relevant outcomes are warranted. Research Sponsor: None.

Pomalidomide, bortezomib, and dexamethasone in lenalidomide-pretreated multiple myeloma: A subanalysis of OPTIMISMM by frailty.

First Author: Albert Oriol Rocafiguera, Hematology Department, Institut Català d'Oncologia, Carretera de Canyet s/n, Barcelona, Spain

Background: Patients (pts) with multiple myeloma (MM) are likely to be older adults, and advanced age is associated with lower survival rates, in part due to comorbidities and frailty. Results from the phase 3 OPTIMISMM trial (NCT01734928) demonstrated that pomalidomide (P) in combination with bortezomib + dexamethasone (Vd) significantly improved progression-free survival (PFS) in lenalidomide (LEN)-pretreated pts with relapsed/refractory MM (RRMM) vs Vd, irrespective of age and Eastern Cooperative Oncology Group performance status (ECOG PS). Here, we report results from a post hoc analysis assessing outcomes of PVd vs Vd in pts with RRMM by frailty status. **Methods:** Pts with MM and 1–3 prior lines of therapy (including a LEN-containing regimen) who had been randomized 1:1 to PVd or Vd were assessed for frailty. Frailty scores were calculated using age (≤ 75 yr = 0; 76–80 yr = 1; > 80 yr = 2), the Charlson Comorbidity Index (≤ 1 = 0; > 1 = 1) and ECOG PS (0 = 0; 1 = 1; ≥ 2 = 2). Pts were classified as non-frail (NF; combined score: 0 or 1) or frail (F; combined score: ≥ 2). PFS, overall response rate (ORR), and safety outcomes were assessed by treatment group and frailty status. **Results:** In the intent-to-treat population (N = 559) (data cutoff Oct 26, 2017), 93/281 (33.1%) pts who received PVd and 93/278 (33.5%) who received Vd were frail. Baseline characteristics were similar between treatment groups within each frailty subgroup. Median PFS was longer with PVd vs Vd in NF ($P = 0.001$) and F ($P = 0.006$) subgroups (Table). ORR was higher with PVd vs Vd in NF ($P < 0.001$) and F ($P < 0.001$) subgroups. Incidence of grade ≥ 3 (G3) treatment-emergent adverse events (TEAEs) was higher with PVd vs Vd in NF (88.1 vs 61.3%) and F (96.8 vs 87.9%) subgroups; peripheral neuropathy, acute renal failure, and hypertension were the most common. Treatment discontinuation due to G3 TEAEs was greater with PVd vs Vd in NF (19.2 vs 18.5%) and F (30.1 vs 20.9%) subgroups. PVd had a longer median treatment duration vs Vd in NF (8.8 vs 5.7 mo) and F (8.9 vs 4.3 mo) subgroups. **Conclusions:** Frail pts with RRMM who received PVd had longer PFS and higher ORR than pts who received Vd, consistent with the overall OPTIMISMM results. Frail pts experienced more G3 TEAEs and treatment discontinuations with PVd vs Vd, but treatment duration was longer with PVd vs Vd. Clinical trial information: NCT01734928. Research Sponsor: Celgene, a Bristol-Myers Squibb Company.

Efficacy outcomes for pts in OPTIMISMM who received PVd vs Vd, by frailty level.

Subcutaneous (SC) isatuximab administration by an on-body delivery system (OBDS) in combination with pomalidomide-dexamethasone (Pd) in patients with relapsed/refractory multiple myeloma (RRMM): Interim phase 1b study results. *First Author: HANG QUACH, St. Vincent's Hospital, University of Melbourne, Melbourne, VIC, Australia*

Background: Intravenous (IV) isatuximab (Isa) + Pd is approved for the treatment of RRMM patients (pts). SC delivery would optimize convenience of administration. Prior results showed that SC Isa administered by syringe pump has efficacy and safety profiles comparable to IV Isa; the recommended Phase 2 dose (RP2D) was 1400 mg (IMW21 P-207). **Methods:** This multicenter Phase 1b study evaluated safety, PK and efficacy of SC vs IV Isa + Pd in RRMM pts after ≥2 prior treatment lines. Pts were randomized 2:1 to SC1000 mg or IV 10 mg/kg and to SC1400 mg or IV. An expansion cohort was later implemented with SC Isa administered at the RP2D via OBDS, a wearable bolus injector applied to the abdomen by a healthcare professional. Primary endpoints (EPs) were safety, including injection site reactions (ISRs), and PK. Main secondary EPs were overall response rate (ORR) and progression-free survival (PFS). **Results:** 56 pts were randomized and treated: 12 Isa IV, 12 Isa SC1000, 10 Isa SC1400 and 22 OBDS pts. At study entry, ISS stage II–III was 67% in IV, 33% in SC1000, 60% in SC1400 and 50% in OBDS pts. On Jan 20, 2022, 33% IV, 25% SC1000, 50% SC1400 and 86% OBDS pts remained on treatment. Due to sequential accrual, median follow-up (FU) was longer in IV (20.6 mo) and SC1000 (23.8 mo) than SC1400 (18.1 mo) and OBDS (6.5 mo) pts. Infusion reactions (IRs) were infrequent (≤10% in each cohort, all Grade [G] 2), only at first IV or SC infusion/injection, with no IRs in OBDS. Local tolerability of OBDS was very good, with 5 (22.7%) pts experiencing 7 ISR episodes, all G1, out of 305 administrations (2.3%): 5 injection site erythemas, 1 injection site hemorrhage, and 1 injection site induration. Median duration of OBDS injection was 10 min. Incidence of G4 neutropenia was lower in SC1000 (42%) vs the other cohorts (55–60%). The lower % of ≥G3 treatment-related AEs in OBDS (77%) vs the other cohorts (≥80%) may be due to shorter FU. Best overall responses are shown in table; longer FU is needed for OBDS pts. Median PFS was 22 mo in IV, 12.5 mo in SC1000 and not reached in SC1400 and OBDS pts. PK and CD38 receptor occupancy results in OBDS pts are consistent with those observed in SC1400 with pump. **Conclusions:** SC Isa administered by OBDS shows a safety profile consistent with IV administration with no IRs and excellent local tolerability. Efficacy in the SC cohorts was comparable to the Phase 3 ICARIA results. Isa SC administration by OBDS is well tolerated, requires a short duration of injection and provides a convenient hands-free option. Clinical trial information: NCT04045795. Research Sponsor: Sanofi.

Efficacy.

Safety and efficacy of daratumumab use in patients with renal impairment and hemodialysis. *First Author: Mateusz Niewinski, NYU Langone Health - Long Island, Mineola, NY*

Background: Targeting CD38 in multiple myeloma (MM) using daratumumab-based regimens can prolong remission in both the newly diagnosed and relapsed settings. However clinical trials have excluded patients with creatinine clearances (CrCl) <30 mL/min, warranting real-world analysis of daratumumab use in MM patients with renal insufficiency. **Methods**: Following IRB approval, we performed a retrospective chart review of relapsed MM patients at our institution who had reduced CrCl and received at least one dose of either daratumumab between October 2018 and January 2022. All subjects received IV daratumumab, 52% went on to receive SQ. Outcomes included change in CrCl during treatment, adverse events, and survival. Survival was estimated using product-limit estimates. CrCl groups at daratumumab initiation of more or less than 30 were compared using the chi-square test or Fisher's exact test, as deemed appropriate, for categorical variables and the two-sample t-test or Mann-Whitney test for continuous data (SAS Institute Inc., Cary, NC). **Results**: 101 MM patients were included, with median age of 74 (54-92); 46 (45.5%) were female. 14% were on hemodialysis. Patients had a median of 2 prior lines of therapy. Distribution of R-ISS stages were I (20%), II (35%), and III (45%). High-risk cytogenetics were present in 20%. A median of 23 daratumumab infusions (1-60) were delivered over a median of 18 months (median IV=16, SQ=10). Daratumumab regimens included DRD (32%), DPD (35%), DKD (13%), and DVD (35%). Median CrCl at MM diagnosis and at daratumumab initiation was 45 (7.3-101) and 40 (5.3-107), respectively, with 33% having CrCl <30. Following 3, 6, and 12 months (n = 95, 89, 69) on daratumumab-based regimens, median CrCl were 45, 43, and 41, respectively. There were no differences in renal function in patients who went on to receive SQ daratumumab. 16 patients had died at the time of data collection, and the median survival was 63 months. Of the 101 patients, 16 subjects were deceased at the time of data collection, and 23% of subjects had gone on to subsequent treatments. Analysis showed that there was a progression-free survival of 54% at 5 years. The most common adverse events reported were anemia (37%) and neutropenia (15%). Infusion-related reactions were reported in 19% of patients. **Conclusions**: This is the largest real-world assessment of outcome for MM patients treated with daratumumab-containing regimens in the setting of renal insufficiency. There was no significant impact of the treatment on renal function at 12 months. Compared to published data on patients treated with CrCl>30, there does not appear to be a detriment to survival or an increase in adverse events when using daratumumab regimens in patients with more advanced renal insufficiency. Characteristics of long-surviving patients with multiple myeloma: Over 12 years of follow-up in the Connect MM Registry. *First Author: Howard R. Terebelo, Providence Cancer Institute, Southfield, MI*

Background: The Connect MM Registry is a large, US, multicenter, prospective observational cohort study of pts with newly diagnosed multiple myeloma (NDMM) and one of the largest, longest running MM registries. Long-term survivors (LTS), defined as patients (pts) who have ≥ 8 years of follow-up, comprise a large portion of the Connect MM Registry. The purpose of this analysis was to assess LTS demographic and clinical characteristics. **Methods**: Adult pts with NDMM (N = 3011) were enrolled from 250 community, academic, and government sites: Cohort 1 from 2009 – 2011 and Cohort 2 from 2012 – 2016. As 99% of LTS were enrolled in Cohort 1, only pts from Cohort 1 were included in this analysis. Pt data were unevaluable if there were missing treatments, disease assessments, or large gaps in activity during follow-up (n = 28). Baseline characteristics, treatment patterns, and quality of life (QoL) form completion rates were examined. **Results**: At data cutoff (5/17/21), of the 1493 pts in Cohort 1 with evaluable data, 279 were LTS and 1186 were non-LTS. LTS were generally younger and had better performance status at enrollment (Table). Most (66%) LTS received stem cell transplants and few experienced progression within the first 6 months (3%). Top first-line (1L) regimen for LTS was lenalidomide/bortezomib/dexamethasone (31%) vs bortezomib/dexamethasone (22%) in non-LTS. At data cutoff, 73% of LTS were still on treatment at their most recent visit. LTS underwent disease assessments more frequently (2.0 vs 1.3 per year) and had a higher QoL completion rate by year 5 (58% vs 46%). This analysis showed an estimated 8-year survival of 36% vs an observed 8-year survival of 39% from the SEER database. Additional analyses are ongoing. **Conclusions**: LTS were younger and healthier than non-LTS. Most LTS received triplets at induction, stem cell transplants in 1L, and were less likely to relapse within the first 6 months of treatment than non-LTS. These findings are consistent with what has been observed in MM clinical trials. Further, this analysis demonstrates the value of longitudinal data in the CONNECT MM Registry and provides insights on long surviving pts with MM. Clinical trial information: NCT01081028. Research Sponsor: Bristol Myers Squibb.

Phase 1b/2 study of ciltacabtagene autoleucel, a BCMA-directed CAR-T cell therapy, in patients with relapsed/refractory multiple myeloma (CARTITUDE-1): Two years post-LPI. *First Author: Saad Zafar Usmani, Myeloma Service, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Ciltacabtagene autoleucel (cilta-cel), a chimeric antigen receptor T (CAR-T) cell therapy with 2 B-cell maturation antigen (BCMA)–targeting single-domain antibodies, led to early, deep, and durable responses in the phase 1b/2 CARTITUDE-1 study (NCT03548207) in heavily pretreated patients (pts) with relapsed/refractory multiple myeloma (RRMM). At ~1-year (y) median follow-up (MFU), overall response rate (ORR) was 97%; 67% of pts achieved stringent complete response (sCR). 1-y progression-free survival (PFS) and overall survival (OS) rates were 77% and 89%, respectively (Berdeja 2021). Updated results 2-y post last patient in (LPI) will be presented (~30-month total MFU). Here, we report CARTITUDE-1 results at 21.7-month MFU. **Methods:** Eligible pts with RRMM received ≥3 prior lines of therapy (LOT) or were refractory to a proteasome inhibitor (PI) and immunomodulatory drug (IMiD) and had received a PI, IMiD, and anti-CD38 antibody. Bridging therapy was permitted after apheresis. Pts received a single cilta-cel infusion (target dose 0.75×10^6 CAR+ viable T cells/kg) 5–7 days after lymphodepletion. Primary objectives were to evaluate cilta-cel safety and efficacy. Response was assessed per International Myeloma Working Group criteria by independent review committee and minimal residual disease (MRD) negativity at 10^{-5} by next-generation sequencing. **Results:** As of July 22, 2021, 97 pts (59% male; median age 61 y) received cilta-cel. Pts had a median of 6 (range 3–18) prior LOT; 84% were penta-drug exposed, 88% were triple-class refractory, 42% were penta-drug refractory, and 99% were refractory to last LOT. ORR was 97.9% (95% CI 92.7–99.7), 94.9% achieved very good partial response, and 82.5% achieved sCR. Median times to first response, best response, and ≥CR were 1.0, 2.6, and 2.9 months (m), respectively; median duration of response was not reached (NR). Of 61 pts evaluable for MRD, 92% were MRD negative (10^{-5}), sustained for ≥6 m in 44% (27/61) and ≥12 m in 18% (11/61). 2-y PFS was 60.5% (95% CI 48.5–70.4). Median PFS and OS were NR. 2-y PFS rates in pts with sustained MRD negativity for ≥6 m and ≥12 m were 91% and 100%, respectively. There were no new safety signals or new events of CAR-T cell neurotoxicity, movement and neurocognitive treatment-emergent adverse events, or treatment-related deaths since 1-y MFU. 15 second primary malignancies were reported in 11 pts over ~2-y MFU. **Conclusions:** At ~2-y MFU, a single cilta-cel infusion led to deepening and durable responses in heavily pretreated pts with RRMM with a manageable safety profile. Follow-up is ongoing, and landmark 2-y post LPI data (~8 m additional follow-up; ~30 m total MFU) will be presented. Further investigations of cilta-cel are ongoing in earlier LOT and outpatient settings across the CARTITUDE program (NCT04133636, NCT04181827, NCT04923893). Clinical trial information: NCT03548207. Research Sponsor: Janssen Research & Development, LLC, Pharmaceutical/Biotech Company.

8029 **Poster Session**

Biological correlative analyses and updated clinical data of ciltacabtagene autoleucel (cilta-cel), a BCMA-directed CAR-T cell therapy, in patients with multiple myeloma (MM) and early relapse after initial therapy: CARTITUDE-2, cohort B. *First Author: Niels W.C.J. van de Donk, Amsterdam University Medical Center, Vrije Universiteit Amsterdam, Amsterdam, Netherlands*

Background: In cohort B of the multicohort phase 2 CARTITUDE-2 (NCT04133636) study, the efficacy and safety of cilta-cel are being evaluated in patients (pts) with MM who had early relapse after initial therapy. These pts have functionally high-risk disease, with early relapse post autologous stem cell transplantation (ASCT) being a poor prognostic factor and representing an unmet medical need. We present updated results. **Methods:** Eligible pts had MM, received 1 prior LOT (PI and IMiD required), had disease progression per IMWG (either ≤12 mo after ASCT or ≤12 mo after start of anti-myeloma therapy for pts who did not undergo ASCT), and were tx-naive to CAR-T/anti-BCMA therapies. A single cilta-cel infusion (target dose 0.75×10^6 CAR+ viable T cells/kg) was given post lymphodepletion. Safety and efficacy were assessed, and the primary endpoint was MRD negativity at 10^{-5}. Management strategies were implemented to minimize risk of movement/neurocognitive AEs (MNTs). Pharmacokinetic (PK) analyses (C_{max} and T_{max} of CAR+ T-cell transgene levels in blood) are being conducted, as well as analyses of levels of CRS-related cytokines (eg, IL-6) over time, peak levels of cytokines by response and CRS, association of cytokine levels with ICANS, and CAR+ T cell CD4/CD8 ratio by response, CRS, and ICANS. **Results:** As of January 2022, 19 pts (median age 58.0 y [range 44–67]; 74% male; median follow-up 13.4 mo [range 5.2–21.7]) received cilta-cel. 79% of pts received prior ASCT. ORR was 100.0%, 90% achieved CR or better, and 95% achieved ≥VGPR. Median time to first response and best response were 0.95 mo (range 0.9–9.7) and 5.1 mo (range 0.9–11.8), respectively. Of pts who were MRD-evaluable (n = 15), 14 (93%) achieved MRD 10^{-5} negativity during this study. Median DOR was not reached and 12-mo event-free rate was 88.9%. The 12-mo PFS rate was 90%. Median time to onset of CRS was 8 d (range 5–11) and occurred in 16 (84.2%) pts (1 gr 4). CRS resolved in all pts. ICANS (gr 1) occurred in 1 pt; MNT (gr 3) occurred in 1 pt, previously reported. 1 pt died post cilta-cel due to PD at d 158. Preliminary PK analyses indicate that peak expansion of CAR-T cells occurred on d 13.1 (range 8.96–209.9) and median persistence was 76.9 d (range 40.99–221.8). **Conclusions:** A single cilta-cel infusion led to deep and durable responses in a functionally high-risk pt population who experienced early clinical relapse/tx failure to initial therapy, with a manageable safety profile. In this pt population with ineffective or insufficient response to ASCT, cilta-cel led to responses. Responses continue to deepen, and follow-up is ongoing. Updated and in-depth PK, cytokine, and CAR-T subset analyses and clinical correlation will be presented and provide novel insights into biological correlates of efficacy and safety in this pt population. Clinical trial information: NCT04133636. Research Sponsor: Janssen Research & Development, LLC, Pharmaceutical/Biotech Company.

Health-related quality of life (HRQoL) in patients with relapsed/refractory multiple myeloma (RRMM) receiving real-life current standard of care (SOC) in the LocoMMotion study. *First Author: Michel Delforge, University of Leuven, Leuven, Belgium*

Background: Evaluation of patient (pt)-reported outcomes provides insight into how real-life SOC treatments (tx) affect HRQoL for pts with RRMM. LocoMMotion (NCT04035226) is the first prospective, multinational study of real-life SOC in triple-class exposed pts with RRMM. Here, we present measures of symptoms, functioning, and overall HRQoL. **Methods:** LocoMMotion is a prospective, noninterventional study across 76 sites (63 European; 13 US). Pts had received ≥3 prior lines of therapy (LOT) or were refractory to PI and IMiD; received PI, IMiD, and anti-CD38 mAb; and had disease progression during/after last LOT. Real-life SOC tx were defined as those used in local clinical practice. The questionnaires were EORTC QLQ-C30, 4 single items from EORTC QLQ-MY20, and EQ 5D-5L. HRQoL was assessed at baseline (BL), day 1 of each tx cycle, end of tx visit, and during the follow-up period (every 4 weeks). Improvement compared to BL health status was evaluated using established thresholds. Within-group change was assessed using mixed models for repeated measures. **Results:** Questionnaire completion for pts in the LocoMMotion study (N=248; 54.4% male; median age 68 yrs; median 4.0 [range, 1–20] cycles of SOC) was 75.6% during SOC tx. Most pts did not achieve meaningful improvement in PRO scores, defined by a literature-based minimally important difference of 10 points in mean score. This was most pronounced in pain symptoms (62% of pts had no meaningful improvement during the first 3 months of tx; 55% had no improvement during full tx duration). For the overall population, the least square (LS) mean changes from BL during SOC tx and subsequent LOT are described (Table). Pts who achieved very good partial response and better during SOC tx had greater improvement in PRO scores, including in LS mean change for pain score (-14.9 [95% confidence interval (CI): -22.9, -7.0]). **Conclusions:** In this first prospective study of real-life current SOC in triple-class exposed pts, limited gains in HRQoL were reported, most notably in pain symptoms. There is an urgent need for effective therapies that can help pts achieve deep responses and delay disease progression, as these are associated with improved HRQoL. Clinical trial information: NCT04035226. Research Sponsor: Janssen Research & Development, LLC, Pharmaceutical/Biotech Company.

Subgroup analyses in patients with relapsed/refractory multiple myeloma (RRMM) receiving real-life current standard of care (SOC) in the LocoMMotion study. *First Author: Hermann Einsele, Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Würzburg, Germany*

Background: Patients (pts) with RRMM who are triple-class exposed (proteasome inhibitor [PI], immunomodulatory drug [IMiD], and anti-CD38 monoclonal antibody [mAb]) have an urgent and currently unmet clinical need. LocoMMotion (NCT04035226) is the first prospective multinational study of real-life SOC in triple-class exposed pts with RRMM. Here we present efficacy in subgroups of pts treated with SOC therapies in the LocoMMotion study. **Methods:** LocoMMotion is a noninterventional study across 76 sites (63 European; 13 US). Eligible pts had received ≥3 prior lines of therapy (LOT) or were double refractory to a PI and an IMiD; received a PI, an IMiD, and anti-CD38 mAb; and had disease progression during/after their last LOT. Real-life SOC treatments were defined as those used in local clinical practice. Responses and disease progression were assessed by response review committee, per IMWG criteria. Subgroups were defined by baseline (BL) characteristics: age, Eastern Cooperative Oncology Group performance status (ECOG PS), renal function, ISS stage, presence of extramedullary plasmacytoma, LDH level, % of bone marrow plasma cells, number of prior LOT, triple-class or penta-drug exposure, and refractoriness. **Results:** As of May 21, 2021 (median follow-up 11.0 mo), 248 pts were enrolled and treated with median 4.0 (range, 1–20) cycles of SOC therapy. Evaluation of efficacy outcomes in subgroups demonstrated that refractoriness to 3 classes of anti-myeloma therapy, presence of extramedullary plasmacytomas, high LDH, and ECOG PS ≥1 were associated with generally worse outcomes, compared with pts who did not have these characteristics (Table). Overall response rate (ORR) ranged from 20.0–43.1% across all subgroups. Age and number of prior LOT did not have an impact on efficacy outcomes. **Conclusions:** Subgroup analyses of this first prospective study of real-life SOC tx in triple-class exposed pts with RRMM indicate that specific pt and disease characteristics were associated with poor outcomes. Triple-class refractory and non-triple-class refractory pts had poor outcomes, although the latter had longer median progression-free survival (PFS). These findings should be considered when planning bridging strategy for CAR-T therapy. Clinical trial information: NCT04035226. Research Sponsor: Janssen Research & Development, LLC, Pharmaceutical/Biotech Company.

Efficacy in select subgroups of pts in LocoMMotion.

Pts	N	Median OS, months	Median PFS, months	ORR, n, %	Median DOR,[a] months

A novel, immunotherapy-based approach for the treatment of relapsed/refractory multiple myeloma (RRMM): Updated phase 1b results for daratumumab in combination with teclistamab (a BCMA x CD3 bispecific antibody). *First Author: Paula Rodríguez-Otero, Clínica Universidad de Navarra, Madrid, Spain*

Background: Teclistamab (tec; JNJ-64007957) is a BCMA × CD3 T-cell redirecting bispecific antibody under investigation in patients (pts) with RRMM. Daratumumab (dara) is a CD38 mAb with direct on-tumor and immunomodulatory actions. Initial clinical data from the phase 1b multicohort TRIMM-2 study support the combination of tec + dara for the treatment of RRMM, with tolerable safety, no overlapping toxicities, and promising efficacy. We present updated results with additional pts and longer follow-up. **Methods:** Eligible MM pts aged ≥18 y had received ≥3 prior lines of therapy (LOT; including a proteosome inhibitor [PI] and immunomodulatory drug [IMiD]) or were double-refractory to a PI and IMiD. Pts treated with anti-CD38 therapy ≤90 d prior were excluded. Pts received dara SC 1800 mg per approved schedule and tec SC 1.5–3 mg/kg QW or Q2W. Primary objectives were to identify the recommended phase 2 dose of tec for combination therapy and evaluate safety of the combination. Responses were assessed by IMWG criteria. AEs were graded per CTCAE v5.0; cytokine release syndrome (CRS) and immune effector cell–associated neurotoxicity syndrome (ICANS) were graded per ASTCT guidelines. **Results:** At data cutoff (Jan 13, 2022; safety population: N=46), median follow-up was 7.2 mo (range 0.1–16.6; median age 67 y [range 50–79]; 52% female). Pts received a median of 6 prior LOT (range 2–17; 74% triple-class exposed; 63% penta-drug exposed; 15% anti-BCMA exposed). 91% of pts had ≥1 AE (grade 3/4 78%), most commonly CRS (61%; all grade 1/2; median time to onset 2 d; median duration 2 d), neutropenia (54%; grade 3/4 50%), anemia (46%; grade 3/4 28%), thrombocytopenia (33%; grade 3/4 28%), and diarrhea (33%; grade 3/4 2%). Infections occurred in 29 pts (63%; grade 3/4 28%). One pt had grade 1 ICANS that fully resolved. Among 37 response-evaluable pts, ORR was 78% (29/37); 27 pts (73%) had very good partial response (VGPR) or better (Table). Median time to first response across dosing cohorts was 1.0 mo (range 0.9–2.8); median duration of response was not reached. Upregulation of $CD38^+/CD8^+$ T cells and proinflammatory cytokines was observed with tec + dara, supporting potential synergy of the combination in pts with prior anti-CD38 exposure. Updated results will be presented. **Conclusions:** Tec + dara provides a novel immunotherapy approach for the treatment of RRMM that may yield improved clinical efficacy in heavily pretreated pts. Clinical trial information: NCT04108195. Research Sponsor: Janssen Research & Development, LLC.

Health-related quality of life in patients with relapsed/refractory multiple myeloma (RRMM) treated with teclistamab, a B-cell maturation antigen (BCMA) x CD3 bispecific antibody: Patient-reported outcomes in MajesTEC-1. *First Author: Thomas G. Martin, UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: As multiple myeloma (MM) negatively affects patients' (pts) health-related quality of life (HRQoL), assessment of patient-reported outcomes (PROs) in addition to clinical outcomes is important. Teclistamab (tec; JNJ-64007957) is an off-the-shelf bispecific antibody that redirects CD3+ T cells to mediate T-cell activation and subsequent lysis of BCMA-expressing MM cells. Initial results from the pivotal cohort of the phase 1/2 MajesTEC-1 study demonstrated that tec was well tolerated with encouraging efficacy in pts who received ≥3 prior lines of treatment (LOT; including a proteasome inhibitor, an immunomodulatory drug, and an anti-CD38 antibody). Here we report PROs from this cohort. **Methods:** Pts (aged ≥18 years) had documented RRMM (International Myeloma Working Group criteria), progressive/measurable disease, and had previously received ≥3 prior LOT; prior anti-BCMA treatment (tx) was not allowed. Pts received weekly subcutaneous tec at the recommended phase 2 dose (1.5 mg/kg with step-up doses of 0.06 and 0.3 mg/kg). PROs were assessed at screening and every even cycle (cycles 2–8 reported here) using the EORTC QLQ-C30 (range: 0–100; higher scores indicate better global health status [GHS] but greater symptom severity [symptom scales]) and the EuroQol 5-dimensional descriptive system (visual analog scale [VAS] range: 0 [worst imaginable health state] to 100 [best imaginable]). Tx effect was assessed by a mixed-effects model with repeated measures; the proportion of pts with meaningful improvement was defined as a change ≥10 points. Time to worsening was determined using the Kaplan-Meier estimate. **Results:** A total of 110 pts were included (median follow-up: 7.8 mos). Overall PRO compliance rates were high (baseline [BL]: 85–90%; cycles 2–8: 80–94%). Tec improved overall HRQoL as evidenced by improvements in GHS scores (cycles 2–8) and reduction in pain (-4.2 [cycle 2] to -15.1 [cycle 8]; Table), with no overall change in physical functioning and fatigue. The proportions of pts with meaningful improvements from BL at cycle 8 were GHS: 50%; physical functioning: 35%; pain: 65%; fatigue: 73%; 50% of pts reported meaningful improvement in their overall health (VAS). Median time to improvement from baseline was ~1.5 months (with nausea/vomiting and fatigue taking longer to improve), while median time to worsening (all symptoms) ranged from 2 months to not estimable. **Conclusions:** Consistent with clinical outcomes, pts treated with tec reported rapid, clinically meaningful improvements in HRQoL. Clinical trial information: NCT04557098. Research Sponsor: Janssen Research & Development, LLC.

BL and least squares (LS) mean change from baseline in PRO measures.

	GHS	Physical functioning	Pain	Fatigue	VAS
BL (mean)	58.0	71.3	43.6	39.6	61.2

Indirect treatment (tx) comparison of teclistamab (tec) in MajesTEC-1 versus physician's choice of therapy in the long-term follow-up of the CASTOR, POLLUX, EQUULEUS, and APOLLO trials in patients (pts) with triple-class exposed (TCE), relapsed/refractory multiple myeloma (RRMM). *First Author: Maria-Victoria Mateos, University Hospital of Salamanca/IBSAL/CIC/CIBERONC, Salamanca, Spain*

Background: Tec is a B-cell maturation antigen × CD3 bispecific antibody currently being evaluated in the single-arm, phase 1/2 MajesTEC-1 trial (NCT04557098) in pts with RRMM who had received ≥3 prior lines of therapy (LOT) and were TCE to an immunomodulatory agent, a proteasome inhibitor, and an anti-CD38 monoclonal antibody. The aim of this study is to evaluate the comparative efficacy of tec versus physician's choice of therapy, as no head-to-head trials have been conducted. **Methods**: An external control arm for MajesTEC-1 was created from pts in the long-term follow-up of 4 clinical trials of daratumumab (CASTOR, POLLUX, EQUULEUS, and APOLLO) who met the eligibility criteria for MajesTEC-1. These pts (N = 427) were subsequently treated with physician's choice of therapy after discontinuing trial txs, and disease progression and best tx response were based on the investigator's assessment. Individual pt-level data from MajesTEC-1 pts who received tec (1.5 mg/kg weekly) at a clinical cutoff of Sep 7, 2021 were included. Inverse probability of tx weighting (IPTW) with average tx effect on the treated population was used to adjust for imbalances in baseline covariates of prognostic significance: refractory status, progression on last LOT, cytogenetic risk, International Staging System stage, number of prior LOT, extramedullary plasmacytoma, time since diagnosis, age, and hemoglobin. Overall response rate (ORR), rate of complete response or better (≥CR), rate of very good partial response or better (≥VGPR), progression-free survival (PFS), time to next tx (TTNT), and overall survival (OS) were assessed. For binary endpoints (ORR, ≥CR rate, ≥VGPR rate), the relative effect of tec vs physician's choice of therapy was estimated with an odds ratio (OR) and 95% confidence interval (CI) derived from a weighted logistic regression analysis. A weighted Cox proportional hazards model was used to compute hazard ratios (HRs) and 95% CIs for time-to-event endpoints (PFS, OS, and TTNT). Several sensitivity analyses were conducted. **Results**: After IPTW, baseline characteristics were comparable between the 2 cohorts. Pts treated with tec had improved outcomes vs physician's choice of therapy: ORR (OR 4.58; 95% CI 2.83–7.53; $P < 0.0001$); ≥CR rate (OR 12.62; 95% CI 5.20–38.55; $P< 0.0001$); ≥VGPR rate (OR 11.64; 95% CI 6.49–21.98; $P< 0.0001$); PFS (HR 0.62; 95%CI 0.45–0.84; $P= 0.0024$); TTNT (HR 0.38; 95% CI 0.27–0.52; $P< 0.0001$); and OS (HR 0.47; 95% CI 0.32–0.69; $P= 0.0001$). Results were similar for all sensitivity analyses. **Conclusions**: Tec showed improved efficacy versus physician's choice of therapy in all clinical outcomes, highlighting its therapeutic potential to address unmet needs in pts with TCE RRMM who received ≥3 prior LOT. Research Sponsor: Janssen Global Services, LLC.

8035 **Poster Session**

Matching-adjusted indirect treatment comparison (MAIC) of teclistamab (tec) versus belantamab mafodotin (belamaf) for the treatment of patients (pts) with triple-class exposed (TCE), relapsed/refractory multiple myeloma (RRMM). *First Author: Philippe Moreau, Hematology Clinic, University Hospital Hôtel-Dieu, Nantes, France*

Background: Pts with RRMM who are TCE to immunomodulatory drugs, proteasome inhibitors, and anti-CD38 antibodies have limited treatment options. While there is no standard of care for treatment of pts with TCE RRMM, belamaf is a recently approved, novel therapeutic option. MajesTEC-1 (NCT04557098) is a single-arm phase 1/2 study evaluating tec, a B-cell maturation antigen × CD3 bispecific antibody in pts with TCE RRMM who received ≥3 prior lines of therapy (LOT). Given the absence of a control arm in MajesTEC-1, we compared efficacy outcomes of pts who received tec at the recommended phase 2 dose in MajesTEC-1 with those of pts treated with belamaf in the phase 2 DREAMM-2 trial (NCT03525678). **Methods:** An unanchored MAIC was performed using individual pt-level data (IPD) from MajesTEC-1 (tec 1.5 mg/kg weekly; N = 150) at a clinical cutoff of Sep 7, 2021, and published summary-level data from pts who received the approved dose of belamaf in DREAMM-2 (2.5 mg/kg every 3 weeks; N = 97). The DREAMM-2 eligibility criteria were applied to pts from the intent-to-treat population of MajesTEC-1. IPD from MajesTEC-1 were weighted to match the aggregated DREAMM-2 baseline pt characteristics. Baseline characteristics of prognostic significance (refractory status, cytogenetic profile, International Staging System stage, presence of extramedullary disease, and number of prior LOT) were adjusted for in the analysis. Comparative efficacy of tec vs belamaf was estimated for overall response rate (ORR), complete response or better (≥CR) rate, progression-free survival (PFS), overall survival (OS), and duration of response (DOR). For binary endpoints (ORR and ≥CR rate), the relative effects of tec vs belamaf were quantified using an odds ratio (OR) and 95% CI derived from a weighted logistic regression analysis, while time-to-event endpoints (DOR, PFS, OS) were estimated using a weighted Cox proportional hazards model. **Results:** After adjustment, the effective sample size (ESS) of the MajesTEC-1 cohort was 33 and baseline characteristics for the reweighted MajesTEC-1 population were balanced with the DREAMM-2 population. Pts treated with tec had an improved ORR (OR 2.05; 95% CI 0.92–4.57; $P= 0.0786$), ≥CR rate (OR 2.13; 95% CI 0.80–5.65; $P= 0.1283$), PFS (HR 0.63; 95% CI 0.34–1.15; $P= 0.1338$), OS (HR 0.95; 95% CI 0.47–1.92; $P= 0.8897$), and DOR (hazard ratio [HR] 0.19; 95% CI 0.05–0.73; $P= 0.0149$) compared with belamaf. The reduced ESS following adjustment may account for the lack of statistical significance for most outcomes. **Conclusions:** These analyses demonstrated statistically improved DOR for tec vs belamaf and numerically favorable results for other outcomes, highlighting its potential as a treatment for pts with TCE RRMM who received ≥3 prior LOT. Research Sponsor: Janssen Global Services, LLC.

Comparative effectiveness of teclistamab versus real-world treatments for patients with triple-class exposed (TCE), relapsed/refractory multiple myeloma (RRMM). *First Author: Amrita Y. Krishnan, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Teclistamab is a B-cell maturation antigen × CD3 bispecific antibody currently being evaluated in MajesTEC-1 (NCT04557098), an open-label, single-arm, phase 1/2 trial in patients with RRMM who had received ≥3 prior lines of therapy (LOT) and were TCE to an immunomodulatory agent, a proteasome inhibitor, and an anti-CD38 monoclonal antibody. Given the absence of a control arm in MajesTEC-1, we assessed the comparative effectiveness of teclistamab versus treatment regimens using an external control arm from a real-world database. **Methods**: An external control arm for MajesTEC-1 was created from eligible patients in the nationwide de-identified electronic health record-derived Flatiron Health multiple myeloma cohort database who started a new line of therapy (physician's choice) following triple-class exposure between January 2011 and August 2021, received ≥3 prior LOT, and satisfied key MajesTEC-1 eligibility criteria. Individual patient data from MajesTEC-1 included patients who received teclistamab (1.5 mg/kg weekly) at a clinical cutoff of Sep 7, 2021. Inverse probability of treatment weighting (IPTW) was used to adjust for imbalances in baseline covariates of prognostic significance: refractory status, progression on last LOT, cytogenetic risk, International Staging System stage, number of prior LOT, time since diagnosis, age, and hemoglobin. Outcomes of interest included progression-free survival (PFS), time to next treatment (TTNT), and overall survival (OS); these outcomes were analyzed as time-to-event data using IPTW adjusted Kaplan-Meier estimates and a weighted Cox proportional hazards model. Several sensitivity analyses were conducted. **Results**: After IPTW, baseline characteristics were comparable between the 2 cohorts. Patients treated with teclistamab had improved PFS (hazard ratio [HR] 0.43; 95% confidence interval [CI] 0.32–0.59; $P< 0.0001$), TTNT (HR 0.42; 95% CI 0.31–0.58; $P< 0.0001$), and OS (HR 0.73; 95% CI 0.48–1.09; $P= 0.13$) versus assessed real-world treatments. Results were similar for all sensitivity analyses. **Conclusions**: Teclistamab showed improved effectiveness for PFS, TTNT, and OS, compared with real-world treatments used in patients with TCE RRMM who received ≥3 prior LOT. These findings highlight the therapeutic potential of teclistamab in patients with RRMM who have limited treatment options. Research Sponsor: Janssen Global Services, LLC.

Circulating tumor DNA analysis and association with relapse in patients with primary refractory multiple myeloma receiving secondary salvage therapy.

First Author: Sridurga Mithraprabhu, Alfred Hospital / Monash University, Melbourne, Australia

Background: Multiple myeloma (MM) is an incurable plasma cell malignancy with a 5 year-median overall survival (OS) in newly diagnosed (ND) patients. Real-world data reveals that 23% of transplant eligible (TE) ND MM patients relapse within 12 months of starting first-line bortezomib (1LB) based therapy and of these ~50% will fail secondary therapy and die within 18 months. It is currently impossible to identify these high-risk patients and genomic studies could potentially inform alternative secondary therapeutic options. We propose that circulating tumour DNA (ctDNA) analysis could provide a more holistic approach to determine genomics of high-risk patients than bone marrow (BM) tumour DNA analysis in this genetically heterogenous multi-site malignancy. **Methods:** Peripheral blood plasma and BM samples (n = 186) were obtained at baseline, cycle 3 day 1 (C3D1), end of the study (EOS) and/or relapse, whichever appeared earlier, from a Phase II multicentre single arm study of carfilzomib-thalidomide-dexamethasone (KTd) in 50 TE ND MM patients who were refractory or registered suboptimal response to 1LB (Australasian Leukaemia and Lymphoma Group - MM17 trial). Somatic variants were identified in BM or ctDNA with ultra-sensitive targeted amplicon sequencing of 22-genes known to be mutated in MM. Mutational spectrum was correlated to standard MM risk factors including International Staging System (ISS), response to 1LB and KTd, cytogenetics/FISH, lactate dehydrogenase (LDH) levels, progression-free survival (PFS) and OS. **Results:** Our initial analysis of ctDNA mutational proportions between patients who did not or did experience relapse on KTd revealed a significantly higher proportion of *RAS/RAF* (3% vs 25%), or *ATM/ATR/TP53* (17% vs 41%; $p < 0.0001$), respectively, in relapse patients. Subsequently, we correlated ctDNA *RAS/RAF* and/or *ATM/ATR/TP53* mutational presence to standard MM risk factors. We identified a shorter PFS and OS for ISS Stage 2 and 3 compared to Stage 1 patients ($p = 0.002$ and $p = 0.02$, respectively) and a significantly higher proportion of *RAS/RAF* or *ATM/ATR/TP53* mutations in patients with refractory as compared to sub-optimal response to 1LB therapy ($p = 0.0002$). Patients with *RAS/RAF* or *ATM/ATR/TP53* mutations in ctDNA at the time of starting salvage therapy also had a shorter PFS and OS on KTd ($p = 0.003$ and $p = 0.02$, respectively). Sequential ctDNA analysis discovered that in 87.5% of patients, one or more of the dominant mutations present at the time of relapse were already present at the start of salvage therapy. **Conclusions:** Our analysis reveals that *RAS/RAF* and *ATM/ATR/TP53* mutations in ctDNA could be prognostic biomarkers of response to secondary salvage therapy in primary refractory patients thus providing the opportunity to design targeted salvage treatment paradigms in high-risk MM patients. Prevalence of ocular comorbidities in patients with multiple myeloma: An analysis of U.S. claims data.

First Author: Sikander Ailawadhi, Mayo Clinic, Jacksonville, FL

Background: Multiple myeloma (MM) predominantly affects older patients (pts) (median age at diagnosis 69 yrs) in whom comorbidities must be considered to manage the disease appropriately. Some anti-MM therapies can be associated with ocular toxicities and require careful attention when used among pts with pre-existing ocular comorbidities (OC). In 2018, 41% of Medicare enrollees had OC. Despite the potential implication on treatment decisions, information on pre-existing OC (e.g., disorders of lens, glaucoma) in MM pts is limited. This study aims to describe the prevalence of OCs among real-world pts with MM in 2011-2020 in the US. **Methods:** Adults with newly diagnosed MM (NDMM) with or without treatment, with 1L systemic therapy, and with relapsed/refractory MM (RRMM) who received up to 4 lines of systemic therapies (LOT) for MM were identified in the IQVIA PharMetrics Plus data. The index date was the date of initial MM diagnosis or a LOT initiation date. The prevalence of OC in each group was defined as the presence of any OC ICD 9/10 diagnosis codes in the 12 months prior to the index date. OCs (e.g., disorders of conjunctiva, lens, choroid, retina, glaucoma) were considered a potentially MM-related disease manifestation or MM treatment-related toxicity based on published literature and clinical expert opinion. **Results:** The median age at initial MM diagnosis was 64 yrs overall (N=49,814), and 63 yrs among treated pts (N=22,963). The median age was 63 yrs at 1L initiation and 64 yrs at 2L, 3L, and 4L initiation. The prevalence of OC at initial MM diagnosis was 39.0% overall and 35.2% among treated pts (Table). The OC prevalence was 35.8% prior to 1L initiation and higher in RRMM pts (42.1%, 44.9%, and 45.7% prior to 2L, 3L, and 4L initiation, respectively). This trend was observed across all OC categories, among MM-related OCs, and across all age groups. The prevalence of OC by MM stage was stable over the years. **Conclusions:** Approximately 40% of NDMM pts have a pre-existing OC, and the prevalence increases with the number of LOT in RRMM. While some OC may be due to aging, the impact of OC on treatment decisions for MM should be explored. Research Sponsor: Regeneron Pharmaceuticals, Inc.

Prevalence of pre-existing ocular comorbidities during 12-month baseline by cohort.

Factors associated with dose adjustment for the bortezomib, lenalidomide, dexamethasone regimen among patients with newly diagnosed multiple myeloma.

First Author: Tao Ran, Janssen Scientific Affairs, LLC, Horsham, PA

Background: VRd (bortezomib/lenalidomide/dexamethasone) has become one of the established treatment regimens in the US for multiple myeloma (MM). Due to toxicities, dose adjustments are often required for VRd. This real-world study described the patient characteristics and factors associated with dose adjustment among MM patients treated with VRd as first line (1L) therapy. **Methods:** Adult MM patients treated with 1L VRd were selected from the Optum Clinformatics database (Nov 1, 2015-Sep 30, 2020). Patient characteristics were evaluated during a 6-month baseline period. Dose adjustments were defined based on lenalidomide (len) dose received during 1L. Receipt of > 15mg len was categorized as VRd regular, ≤15mg len as VRd lite, and initial len dose > 15mg reduced to ≤15 mg over treatment period as VRd reduced. Baseline factors associated with different VRd dose categories were studied using multinomial logistic regression. **Results:** Among the 1497 patients identified, the mean (SD) age was 69 (9.5) years (52% ≥70), 51% were male, 59% were White, 37% were frail, and 67% with Medicare. Baseline Charlson Comorbidity Index was 4.2, with hypertension (70%), hyperlipidemia (56%), renal impairment (26%), and CVD (25%) being the most prevalent comorbidities. Over half of the patients received an adjusted dose, VRd lite (33%) and VRd reduced (22%). Overall, for patients treated with 1L VRd, median follow-up was 16.2 months; median duration of 1L was 4.9 months (among those with confirmed end of therapy); and median TTNT was 14.5 months. Compared to VRd regular, use of VRd lite was over 6 times more likely to be associated with patients ≥75 years of age, about 2 times more likely to be associated with females, and about 40% less likely to be associated with commercial insurance vs. Medicare; VRd reduced was 1.3 times more likely to be associated with females, and 1.5 times more likely to be associated with frail patients (table). No differences were observed among different races. **Conclusions:** Over half of the MM patients treated with 1L VRd in the real-world were > 70 years of age and over one-third were frail. A large proportion of patients received a modified dose of VRd. Receipt of VRd lite dose was highly associated with older age (≥75 years), and receipt of VRd reduced dose was associated with frailty. These dose adjustments may potentially result in reduced efficacy of the VRd regimen in the real-world relative to controlled clinical trials, which needs to be assessed in future studies. Research Sponsor: Janssen Scientific Affairs, LLC.

Patient factors	VRd lite vs. VRd regular (ref.) Odds ratio (95% CI)	VRd reduced vs. VRd regular (ref.) Odds ratio (95% CI)
65 to < 70 vs. < 65	1.0 (0.6–1.7)	0.9 (0.6–1.5)
70 to < 75 vs. < 65	2.2 (1.3–3.8)	1.2 (0.7–2.0)
≥75 vs. < 65	6.2 (3.6–10.5)	1.6 (0.9–2.8)
Female vs. male	1.8 (1.4–2.4)	1.3 (1.0–1.8)
Commercial vs. Medicare	0.6 (0.4–0.9)	0.8 (0.5–1.3)
Frailty index > 0.2 vs. ≤0.2	1.3 (0.9–1.8)	1.5 (1.1–2.2)

B-PRISM (Precision Intervention Smoldering Myeloma): A phase II trial of combination of daratumumab, bortezomib, lenalidomide, and dexamethasone in high-risk smoldering multiple myeloma.

First Author: Omar Nadeem, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA

Background: Early therapeutic intervention with lenalidomide has shown to be effective in delaying progression in patients with high-risk smoldering multiple myeloma (HR-SMM) (Lonial J Clin Oncol 2020). Quadruplet regimen of daratumumab, bortezomib, lenalidomide and dexamethasone (D-RVD) has demonstrated significant activity in multiple myeloma, achieving high rates of minimal residual disease (MRD) negativity (Voorhees Blood 2020). Thus, we proposed to examine the activity and safety of D-RVD in patients with HR-SMM. **Methods:** This is a phase II single center, single-arm, open label study evaluating the combination of D-RVD in HR-SMM. Eligibility included high risk per Mayo 2018 "20-2-20" model and other previously established criteria including Mayo 2008 criteria, presence of immunoparesis, evolving type of SMM, and high risk FISH. Primary objective is rate of sustained MRD negativity at 2 years. Secondary objectives include PFS, response rates and safety. Treatment duration with modified D-RVD is for total of 2 years (24 cycles). Daratumumab is administered subcutaneously (SQ) per standard dose and schedule, bortezomib given weekly on days 1, 8, 15 for cycles 1-6 and then biweekly until completion of cycle 24. Lenalidomide is administered on days 1-21 and dexamethasone is administered weekly. All eligible patients will undergo stem cell collection after 6 cycles of therapy. **Results:** At the time of data cut off, 20 patients have been enrolled with a median follow up of 6 months. The median age is 58 years old (range 40-73). Sixteen out of 20 (80%) patients met high risk criteria per Mayo 2018 model with median plasmacytosis of 20%, median M protein value of 2.6 g/dl and median FLC ratio of 28.2. Seven patients had high-risk FISH: 5 with 1q duplication, 2 with t(4;14). Most common toxicities of any grade included neutropenia (65%), WBC decreased (55%) insomnia (50%), constipation (45%) and hypophosphatemia (45%). Most common grade 3 toxicities included neutropenia (15%), ALT increased (5%), thrombocytopenia (5%), hyperglycemia (5%), hypertension (5%), diarrhea (5%), syncope (5%). No patients discontinued therapy due to toxicity. The overall response rate is 90% with 40% PR, 25% VGPR and 25% CR. All patients have achieved at least a MR and 50% achieved VGPR or greater with responses deepening over time. No patients have progressed on treatment. MRD was evaluable in 16 patients and 8 patients have undergone MRD testing, with MRD negativity rate of 50% (4/8) and 25% (2/8) at thresholds of 10^{-5} and 10^{-6}, respectively. Stem cells were successfully collected in all patients with mean stem cell yield of 5.78×10^6 CD34+/kg cells. **Conclusions:** D-RVD is well tolerated in patients with HR-SMM demonstrating significant early activity. Responses continue to deepen over time with patients achieving MRD negative disease. Clinical trial information: NCT04775550. Research Sponsor: Janssen.
