Background: FOR46, a fully human antibody (ab) conjugated to monomethyl auristatin E (MMAE), targets a tumor selective epitope of CD46, which is highly expressed in mCRPC and treatment-emergent small cell neuroendocrine cancer (t-SCNC). CD46 is enriched in tumor cells upon treatment with androgen signaling inhibitors (ASI). Following dose escalation (Phase 1a), dose expansion was undertaken in 2 cohorts (Phase 1b): 1) Pts with *de novo* or t-SCNC and 2) pts with mCRPC without a t-SCNC component. Pts with adenocarcinoma enrolled in dose escalation and expansion are included in this analysis. **Methods:** Eligible pts had mCRPC, with progression on at least 1 ASI, with no prior chemotherapy for CRPC. Phase 1a pts received FOR46 0.1-3.0 mg/kg IV Q3 weeks (wks). The primary objectives in phase 1a were to assess adverse effects (AEs) and select the phase 1b dose; and in phase 1b to assess efficacy. For phase 1b, tumor biopsy in the CRPC setting for assignment to the 2 cohorts was required. CD46 expression was not required for inclusion in the expansion cohort, but was evaluated using a non-epitope specific CD46 polyclonal ab. Histology and CD46 expression were centrally reviewed. **Results:** Thirty-three pts were enrolled in phase 1a and 10 in phase 1b (including 6 treated in ph1a at the expansion dose or higher). Overall, 36 pts were treated at doses > 1.2 mg/kg. Following excess toxicity in pts with body mass indices > 30 (3 of 3 with Gr 4 neutropenia and 1 of 3 with Gr 3 fatigue at 2.4 mg/kg), further dosing was calculated using adjusted body weight (AJBW) rather than actual weight, allowing escalation to 3.0 mg/kg. The 2.7 mg/kg dose by AJBW was determined to be the MTD and phase 1b dose. The most common AEs at the 2.7 mg/kg dose were neutropenia (77% Gr 3 or 4), infusion reactions (37%, all < Gr 2), fatigue (31%, all < Gr 2) and peripheral neuropathy (24%, all < Gr 2)). Fourteen of 31 evaluable pts (45.2%) at > 1.2 mg/kg achieved a PSA_{50} response with 10 (32.3%) confirmed. Five pts were not evaluable for PSA response; 3 had no post-baseline PSA and 2 had baseline PSA < 1 ng/mL. The median duration of confirmed PSA_{50} response is >16 wks (range 6-48+ wks, with 4 ongoing at 12, 24, 25 and 48 wks). 18 pts had measurable lesions; 8 of 18 (44.4%) had tumor regression, with 4 (22.2%) confirmed partial responses (PR). The median duration of response is > 14 wks (range 9 -31+ weeks with 2 ongoing at 13 and 31 wks). Eight pts were evaluable for CD46 expression with a median H-score of 245 (range 0-300). Two pts with PRs had H-scores of 15 and 300; 4 with confirmed PSA_{50} had H-scores of 10, 15, 40 and 300. **Conclusions:** FOR46, a novel ADC targeting CD46, demonstrates clinical activity in mCRPC pts, with an acceptable safety profile, similar to other MMAE-containing ADCs. FOR46 merits further investigation in pts with mCRPC, alone and in combination with agents that enhance CD46 expression. Clinical trial information: NCT03575819. Research Sponsor: Fortis Therapeutics.

3002 **Oral Abstract Session**

Phase I, two-part, multicenter, first-in-human (FIH) study of DS-6000a in subjects with advanced renal cell carcinoma (RCC) and ovarian tumors (OVC). *First Author: Erika P. Hamilton, Sarah Cannon Research Institute/ Tennessee Oncology, PLLC, Nashville, TN*

Background: Cadherin 6 (CDH6) is part of the cadherin family, which is involved with cell-cell adhesion, organ development, and epithelial-mesenchymal transition. CDH6 is found to be overexpressed in various cancers, particularly RCC and OVC. DS-6000a is an antibody-drug conjugate, comprised of an humanized anti-CDH6 IgG1 monoclonal antibody attached to a topoisomerase I (TOP1) inhibitor payload via a cleavable linker. DS-6000a specifically binds to CDH6 on the surface of tumor cells and is internalized upon binding. The payload is then released, resulting in target cell apoptosis. In preclinical studies, DS-6000a inhibited tumor growth and induced tumor regression in CDH6-expressing RCC and OVC. Here, we report initial results from a phase I trial of DS-6000a in patients (pts) with advanced RCC and OVC (NCT04707248). **Methods:** This dose-escalation (Part A) and expansion (Part B) study will recruit pts with advanced RCC and OVC. DS-6000a is administered IV as monotherapy on Day 1 of 21-day cycles. Part A assesses safety, tolerability, and maximum tolerated dose or recommended dose for expansion (RDE) using Bayesian optimal interval design; additional pts are enrolled to examine safety and efficacy. The starting dose of DS-6000a is 1.6 mg/kg followed by 3.2, 4.8, 6.4, 8, and 9.6 mg/kg. Part B will assess safety, tolerability and efficacy at the RDE. **Results:** Part A interim results are presented. At data cutoff (19 NOV 2021), 22 pts had enrolled (7 RCC, 15 OVC). All RCC pts had received an immune checkpoint inhibitor and the majority of OVC had platinum resistant (Pt-R) disease; median age was 63.5 years (range, 41-78); median of 4 (range, 1-12) prior lines of therapy were administered; and median treatment duration was 8.0 wks (range, 3-33.14). Fifteen pts (68.2%) were ongoing at the cutoff date. Treatment-emergent adverse events (TEAEs) occurred in 19 pts (86.4%). Related TEAEs occurred in 17 pts (77.3%). The most common related TEAEs (>20%) were fatigue and nausea (45.5% each), and vomiting (27.3%). Grade ≥3 related TEAEs occurred in 4 pts (18.2%); the most common was neutropenia (13.6%). One patient (4.5%) had a Grade 3 febrile neutropenia. One dose-limiting toxicity of Grade 4 thrombocytopenia (9.6 mg/kg) occurred. There was no study drug discontinuation due to a TEAE. Among 15 evaluable pts, 2 partial responses (PRs; 1 confirmed in RCC and 1 unconfirmed PR in Pt-R OVC) were observed; 9 pts had stable disease. Moreover, 5 out of 11 OVC evaluable pts showed CA-125 responses using GCIG criteria and all CA-125 responders had Pt-R disease. **Conclusions:** The interim data from dose-escalation of this FIH study showed acceptable tolerability with early signals of efficacy in heavily pretreated pts with advanced RCC and Pt-R OVC, which support further clinical evaluation of DS-6000a in the planned dose-expansion cohorts in advanced RCC and OVC. Clinical trial information: NCT04707248. Research Sponsor: Daiichi Sankyo.

3003 **Oral Abstract Session**

First-in-human study of PC14586, a small molecule structural corrector of Y220C mutant p53, in patients with advanced solid tumors harboring a *TP53* Y220C mutation. *First Author: Ecaterina Elena Dumbrava, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The p53 tumor suppressor protein is a transcription factor that acts to maintain genome stability in response to cellular stress. Spontaneous mutation of the *TP53* gene leading to inactivation of the p53 protein is the most common mutational event across all human cancers. PC14586 is a novel, small molecule structural corrector that binds selectively to p53 Y220C mutant protein and restores the p53 wildtype conformation and transcriptional activity, resulting in potent preclinical antitumor activity. This Phase 1 multicenter dose escalation study assesses PC14586 safety, pharmacokinetics (PK), pharmacodynamics (PD) and preliminary efficacy in patients (pts) with advanced solid tumors that harbor the *TP53* Y220C mutation. **Methods:** Eligible adult pts with locally advanced or metastatic TP53 Y220C mutant solid tumors received increasing doses of oral PC14586 using the modified Toxicity Probability Interval design to estimate toxicity and to determine maximum tolerated dose and recommended phase 2 dose. Plasma PK was characterized using standard methods. Preliminary efficacy was assessed by RECIST v1.1. Reporting of interim results was approved by the study's Safety Review Committee. **Results:** As of 08 Feb 2022, 29 pts (62% female, median age 62 years) with a variety of *TP53* Y220C mutant solid tumor types (median number of prior lines of therapy 3; range 1 to 8) were treated in 7 dose cohorts of PC14586: 150 mg QD (3 pts), 300 mg QD (3 pts), 600 mg QD (4 pts), 1150 mg QD (5 pts), 2000 mg QD (7 pts), 2500 mg QD (4 pts) and 1500 mg BID (3 pts). PC14586 was generally well-tolerated; treatment-related AEs were observed in 79% of pts that were all Grade 1/2 in severity except 2 Grade 3 AEs (alanine aminotransferase increased and neutrophil count decreased). The most common AEs (≥15% of pts) were nausea (34%), vomiting (24%), fatigue (21%), and aspartate aminotransferase increased (17%). There were no dose limiting toxicities and enrollment continues. PK analysis showed dose proportional increases in Cmax and AUC. Amongst 21 efficacy evaluable pts, PRs were observed in 5 pts: 1 small cell lung and 1 breast with confirmed PR (cPR), both ongoing; 1 colorectal with unconfirmed PR (uPR), and 2 prostate with uPR and ongoing. In the 3 highest dose cohorts (total daily dose 2000 to 3000 mg), there were 3 PRs (2 uPR, 1cPR) and 7 SD out of 10 efficacy evaluable pts (all ongoing). Observations of decreasing p53 Y220C circulating tumor DNA and decreasing numbers of circulating tumor cells in pts further support on-target anti-tumor activity of PC14586. **Conclusions:** Enrollment to a Phase 1 study is feasible in a *TP53* mutation selective population. PC14586 is safe and tolerated up to 3000 mg daily. Preliminary efficacy was achieved in heavily pretreated pts. Additional safety, PK, PD and efficacy data will be reported at the annual meeting. Clinical trial information: NCT04585750. Research Sponsor: PMV Pharmaceuticals, Inc.

3004 **Oral Abstract Session**

A phase Ia/Ib, dose-escalation/expansion study of the MDM2–p53 antagonist BI 907828 in patients with solid tumors, including advanced/metastatic liposarcoma (LPS). *First Author: Mrinal M. Gounder, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: The highly potent MDM2–p53 antagonist BI 907828 showed antitumor efficacy *in vivo*, particularly in *TP53* wild-type, *MDM2*-amplified de-differentiated LPS (DDLPS) patient-derived xenografts and syngeneic models. This phase I study (NCT03449381) is assessing BI 907828 monotherapy in patients with advanced solid tumors, including LPS. In Part A (dose escalation), patients received one of two BI 907828 dosing schedules: Arm A, day 1 of 21-day cycles (q3w); Arm B, days 1 and 8 of 28-day cycles. Based on previously reported results from Part A (LoRusso ASCO 2021), the MTD was 60 mg q3w and the recommended dose for expansion (RDE) was selected as 45 mg q3w. **Methods:** In Part B (dose expansion), patients received BI 907828 45 mg q3w. The primary endpoint was PFS. Secondary endpoints/objectives included objective response rate, overall survival, the number of patients with grade ≥3 treatment-related AEs, and PK parameters. Here, we report overall safety data and efficacy data in the subgroup of patients with advanced LPS. **Results:** As of January 10, 2022, 90 patients had been enrolled; 49 (54.4%) were male, 55 (61.1%)/34 (37.8%) were ECOG PS 0/1, the median number of prior systemic therapies was 2 (range, 0–11), 44 had advanced LPS (28 DDLPS, 16 well-differentiated LPS [WDLPS]). At data cut-off, 31/90 patients (34.4%) had received treatment for ≥6 months. In the 41 evaluable patients with advanced LPS, best response of PR or SD was observed in 24/27 patients with DDLPS (88.9%) and 13/14 patients with WDLPS (92.9%). Two DDLPS and 4 WDLPS patients achieved a PR; all had MDM2-amplified disease. In Part A, 5/11 DDLPS patients and 4/8 WDLPS patients have achieved PFS ≥10.5 months. In the 42 patients who received the RDE of 45 mg q3w, 18 patients (42.9%) had grade ≥3 AEs; the most common grade ≥3 AEs were neutropenia (23.8%), thrombocytopenia (21.4%), and anemia (11.9%). Seven patients (16.7%) had SAEs; the most common were thrombocytopenia (4.8%) and pyrexia (4.8%). PK analysis showed that mean plasma exposures (C_{max} and $AUC_{0\text{-}inf}$) increased with dose and showed no significant deviation from linearity in the dose range 10–60 mg. A correlation was observed between exposure and GDF-15 levels in plasma, as a target engagement marker. **Conclusions:** BI 907828 showed a manageable safety profile, high plasma exposure, target engagement and encouraging signs of antitumor activity in patients with advanced DDLPS and WDLPS. The Part B dose expansion is ongoing. Clinical trial information: NCT03449381. Research Sponsor: Boehringer Ingelheim.

3005 **Oral Abstract Session**

A phase 1 study of TPST-1120 as a single agent and in combination with nivolumab in subjects with advanced solid tumors. *First Author: Mark Yarchoan, Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD*

Background: TPST-1120 is a first-in-class oral therapy that inhibits PPARα, a transcription factor that regulates fatty acid oxidation (FAO). TPST-1120 has diverse mechanisms of anti-tumor activity in preclinical studies, including inhibiting tumor proliferation, increasing the anti-angiogenic factor thrombospondin 1, and reducing T cell exhaustion. **Methods:** Subjects with advanced solid tumor malignancies received escalating doses of TPST-1120 as a single agent or in combination with nivolumab 480 mg IV every 4 weeks (combination cohort limited to RCC, cholangiocarcinoma [CCA] and HCC). Study objectives included evaluation of safety, pharmacokinetics, MTD, RP2D and anti-tumor activity as monotherapy and in combination with nivolumab. AEs were assessed per CTCAE v5 and efficacy per RECIST v1.1 **Results:** As of 14-Jan-2022, 35 subjects have been dosed (20 with TPST-1120 monotherapy at doses from 100 mg to 600 mg PO BID and 15 in combination with nivolumab at doses from 200 mg to 600 mg PO BID). Median prior lines of systemic therapy were 3 (2-11) in monotherapy and 2 (2-6) in combination cohorts. An MTD was not reached in monotherapy or combination, and the TPST-1120 RP2D was 600 mg PO BID for both cohorts. For TPST-1120 monotherapy, the most common treatment related AEs (TRAEs) were nausea (20%), fatigue (15%), and diarrhea (10%), all Grade 1-2. One monotherapy subject (5%) experienced a Grade 3 TRAE (hypertension). In the combination cohort the most common TRAEs related to either drug were fatigue (40%), diarrhea (27%) and nausea (20%), all Grade 1-2. Three combination subjects (19%) experienced Grade 3 TRAEs (one each arthralgia, hepatic enzyme increased, muscle spasms). A best response of stable disease was observed in 53% (10/19) of subjects treated with monotherapy. In combination, the ORR was 23% (3/13, all PRs) across all dose levels and 38% (3/8) at TPST-1120 dose levels ≥400 mg BID. These responses included 2 subjects with late-line RCC (2/2 RCC subjects enrolled, both with progression on prior anti-PD1 therapy) and one subject with heavily pre-treated CCA. At data cut off, 2 of 3 responding patients (CCA and one RCC) remained in PR and on study at 8.4 and 14 mo, respectively. **Conclusions:** TPST-1120 is a novel therapy designed to inhibit tumor proliferation and angiogenesis and stimulate anti-cancer immunity through inhibition of PPARα, a key regulator of FAO. The drug is well tolerated as a single agent and in combination with nivolumab. Promising objective responses have been observed in combination with nivolumab in subjects previously refractory to anti-PD-1 therapy, including 2/2 responders in late-line RCC, and a subject with heavily pretreated CCA, a tumor type generally not responsive to anti-PD-1 alone. Notably, all responders were treated at the two highest doses of TPST-1120 (ORR 38%). Updated study results including exploratory biomarkers will be presented. Clinical trial information: NCT03829436. Research Sponsor: Tempest Therapeutics.

3006 **Oral Abstract Session**

CRESTONE: Initial efficacy and safety of seribantumab in solid tumors harboring *NRG1* fusions. *First Author: Daniel R. Carrizosa, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: *NRG1* fusions are rare oncogenic drivers found in ~0.2% of all solid tumors. These fusions elicit ERBB3/HER3 overactivation to drive tumor growth and cancer cell survival. Currently there are no approved targeted therapies for *NRG1* fusion-positive tumors. Furthermore, patients (pts) with tumors harboring *NRG1* fusions have poor outcomes with standard therapies. Seribantumab is a fully human anti-HER3 IgG2 monoclonal antibody that suppressed tumor growth in *NRG1* fusion-driven preclinical models. Here, we present initial clinical data from the CRESTONE study (NCT04383210). **Methods:** CRESTONE is a Phase 2, global, multicenter, open-label study of seribantumab in adult pts with locally advanced or metastatic solid tumors harboring *NRG1* fusions. A dose ranging phase established the RP2D as a 3g once weekly (QW) intravenous dose administered until treatment discontinuation criteria are met. In the expansion phase, cohort 1 will enroll at least 55 pts who had received at least one prior therapy and are naïve to ERBB-targeted therapy. Exploratory cohorts 2 or 3 will enroll pts previously treated with ERBB-targeted therapies and/or tumors harboring additional molecular alterations. The primary endpoint is objective response rate (ORR) by independent central review per RECIST v1.1. Initial data from cohort 1 pts who received seribantumab 3g QW with investigator (INV)-assessed response per RECIST v1.1 are reported. **Results:** By JAN-13-2022, 12 pts have received seribantumab 3g QW in cohort 1. Median age was 65 years (range 44–76), 67% were female, and median number of prior therapies was 1 (range 1–5). 92% (11/12) of pts had non-small cell lung cancer (NSCLC); 5 different NRG1 fusion partners (*ATP1B1*, *CD74*, *ITGB1*, *SDC4*, *SLC3A2*) were reported by local next-generation sequencing tests. Among 10 pts evaluable for INV-assessed response, the confirmed ORR was 30%, and the disease control rate was 90% (1 complete response, 2 partial responses, 6 stable disease, 1 progressive disease). 58% (7/12) of pts remain on study treatment, including 2 pts with NSCLC who achieved objective responses with an ongoing duration of response of 6 and 8.5 months. Seribantumab 3g QW was well tolerated with no drug discontinuations or dose reductions. Across all cohorts (n = 29), the most frequently (≥20%) reported treatment-related adverse events (TRAEs) were diarrhea (38%), fatigue (34%), and rash (24%), all were grade 1 or 2. One grade 3 TRAE of vomiting occurred; there were no Grade 4 or 5 TRAEs. Efficacy analysis is ongoing and updated efficacy data from evaluable pts in cohort 1 will be presented. **Conclusions:** Initial data indicate seribantumab induced durable responses in advanced solid tumors harboring *NRG1* fusions and has a favorable safety profile. These data support the continued evaluation of seribantumab in *NRG1* fusion-positive solid tumors in the ongoing CRESTONE study. Clinical trial information: NCT04383210. Research Sponsor: Elevation Oncology, Inc.

3007 **Oral Abstract Session**

Tumor agnostic efficacy and safety of erdafitinib in patients (pts) with advanced solid tumors with prespecified fibroblast growth factor receptor alterations (*FGFRalt*) in RAGNAR: Interim analysis (IA) results. *First Author: Yohann Loriot, Gustave Roussy, DITEP, Université Paris-Saclay, Villejuif, France*

Background: Erdafitinib (erda) is an oral selective pan-FGFR tyrosine kinase inhibitor approved to treat locally advanced or metastatic urothelial carcinoma (UC) in adults with susceptible *FGFR3/2alt* who have progressed during or after ≥ 1 line of platinum containing chemotherapy. *FGFRalt* are observed across a wide range of malignancies and may function as oncogenic drivers independent of the underlying tumor type. RAGNAR (NCT04083976) is an ongoing phase 2 open label, single arm tumor agnostic trial investigating the efficacy and safety of erda in pretreated adult and pediatric pts with advanced solid tumors and *FGFRalt*. Here, we report results from a planned IA of RAGNAR. **Methods:** Pts aged ≥ 6 y with advanced or metastatic solid tumors of any histology (except UC) with predefined *FGFR1-4alt* (mutations/fusions based on local/central test) and documented disease progression on ≥ 1 prior line of systemic therapy (tx) and no alternative standard tx received oral erda until disease progression or intolerable toxicity. The primary end point is objective response rate (ORR) by independent review committee (IRC). Secondary end points include investigator assessed ORR, duration of response (DOR), disease control rate (DCR), clinical benefit rate (CBR), PFS, OS, and treatment emergent adverse events (TEAEs). **Results:** As of the IA data cutoff, 178 pts were treated (median age 56.5 y [range 12-79], median 2 prior systemic tx). Only 9.0% of pts responded to last line of tx prior to study entry. ORR by IRC was 29.2% (95% CI, 22.7-36.5). Investigator assessed ORR was 26.4% (95% CI, 20.1-33.5). Responses were observed in 14 distinct tumor types, including gliomas, thoracic, gastrointestinal, gynecological, and rare tumors (Table). ORR in pts with *FGFR* mutations vs fusions was comparable (26.8% vs 27.0%, respectively). Median DOR, PFS, and OS were 7.1 mo (95% CI, 5.5-9.3), 5.2 mo (95% CI, 4.0-5.6), and 10.9 mo (95% CI, 7.9-14.3), respectively; DCR was 75.3% and CBR was 48.9%. All pts experienced TEAEs, including 69.1% with grade ≥ 3. Treatment-related serious TEAEs occurred in 7.3% of pts. **Conclusions:** RAGNAR data show, for the first time, evidence of efficacy for erda in heavily pretreated pts with a variety of hard to treat advanced *FGFR+* malignancies, including glioblastoma, pancreatic, and salivary gland cancers. Safety was consistent with the known erda safety profile. Clinical trial information: NCT04083976. Research Sponsor: Janssen Research & Development, LLC.

Cobimetinib plus vemurafenib (C+V) in patients (Pts) with solid tumors with BRAF V600E/d/k/R mutation: Results from the targeted agent and profiling utilization registry (TAPUR) study. *First Author: Funda Meric-Bernstam, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: TAPUR is a phase II basket study evaluating anti-tumor activity of commercially available targeted agents in pts with advanced cancers with genomic alterations. Results in a cohort of pts with solid tumors with *BRAF* V600E/D/K/R mutation (mut) treated with C+V are reported. **Methods:** Eligible pts had advanced solid tumors, no standard treatment (tx) options, measurable disease, ECOG performance status (PS) 0-2, and adequate organ function. Genomic testing was performed in CLIA-certified, CAP-accredited site selected labs. Pts matched to C+V had various solid tumors with *BRAF* V600E/D/K/R mut, or other *BRAF* mut if approved by the Molecular Tumor Board, and no *MAP2K1/2, MEK1/2, NRAS* mut. Recommended dosing was C, 60 mg orally daily for 21 days, 7 days off and V, 960 mg orally every 12 hours. Primary endpoint was disease control (DC), defined as complete (CR) or partial (PR) response or stable disease at 16+ wks (SD 16+) (RECIST v1.1). Low accruing histology-specific cohorts with the same genomic target and tx were collapsed into a single histology-pooled cohort for this analysis. For histology-pooled cohorts with sample size of 28, the results are evaluated based on a one-sided exact binomial test with a null DC rate of 15% vs. 35% (power = 0.84; $\alpha = 0.10$) and one-sided 90% confidence interval (CI). Other efficacy endpoint estimates are presented with two-sided 95% CIs. Secondary endpoints were progression-free survival (PFS), overall survival (OS) and safety. **Results:** 31 pts with solid tumors (13 histologies; 6/31 ovarian cancer) with *BRAF* muts were enrolled from Dec 2016 to Jan 2021 and collapsed into one histology pooled cohort for analysis. 3 pts were not evaluable due to lack of post-baseline tumor evaluation and excluded from efficacy analyses. Demographics and outcomes are summarized in the Table. Pts had tumors with *BRAF* V600E mut (N = 26), G469V mut (N = 1), K601E mut (N = 2), N581I (N = 1) and T599_V600insT (N = 1). 2 CR (breast and ovarian cancer; V600E), 14 PR (13 V600E, 1 N581I), and 3 SD16+ (2 V600E, 1 T599_V600insT) were observed for a DC rate of 68% (90% CI: 54%, 100%) and an objective response (OR) rate of 57% (95% CI: 37%, 76%). CR durations were 5.1 (ovarian cancer) and 108.9 wks (breast cancer) and median duration of PR was 20.5 wks (range: 8.0, 176.0). 19 pts experienced ≥1 Grade 1-5 AE/SAE at least possibly related to tx including 1 death attributed to tx-related kidney injury. **Conclusions:** C+V demonstrated evidence of anti-tumor activity in pts with advanced solid tumors with *BRAF* V600E and other muts. Clinical trial information: NCT02693535. Research Sponsor: Genentech, Pharmaceutical/Biotech Company.

Ulixertinib in patients with tumors with MAPK pathway alterations: Results from NCI-COG Pediatric MATCH trial Arm J (APEC1621J). *First Author: Kieuhoa Tran Vo, University of California, San Francisco, CA*

Background: The NCI-Children's Oncology Group (COG) Pediatric Molecular Analysis for Therapy Choice (MATCH) trial assigns patients age 1 to 21 years with relapsed or refractory solid tumors, lymphomas, and histiocytic disorders to phase 2 treatment arms of molecularly-targeted therapies based on genetic alterations detected in their tumor. Arm J evaluated the ERK1/2 inhibitor ulixertinib (BVD-523FB) in patients whose tumors harbored activating alterations in the MAPK pathway (*ARAF*, *BRAF*, *HRAS*, *KRAS*, *NRAS*, *MAPK1*, *MAP2K1*, *GNA11*, *GNAQ* hotspot mutations; *NF1*inactivating mutations; *BRAF* fusions). **Methods:** As there were no prior pediatric data, ulixertinib was initially tested in a dose escalation cohort using a rolling 6 design to establish the recommended phase 2 dose (RP2D) before proceeding with enrollment to the phase 2 cohort. Ulixertinib was administered at 260 mg/m^2/dose PO BID (dose level 1, DL1, n = 15) or 350 mg/m^2/dose PO BID (dose level 2, DL2, n = 5). Patients were treated on continuous 28-day cycles for up to 2 years, until disease progression or intolerable toxicity; response assessment occurred every 2-3 cycles. The primary endpoint was objective response rate; secondary endpoints included safety/tolerability and progression-free survival (PFS). **Results:** Twenty patients (median age 12 years; range 5-20) were enrolled between November 2018 and March 2021. All patients were evaluable for response. High-grade glioma (HGG, n = 7) was most common, with CNS tumors comprising 55% (11/20) of diagnoses; all CNS tumors except one (HGG with *KRAS* and *NF1* mutations) harbored *BRAF* fusions or V600 mutations. Rhabdomyosarcoma (n = 5) was the most frequent non-CNS diagnosis, with *NRAS* mutations detected in 4 tumors. DL1 was declared the RP2D after first-cycle dose limiting toxicities (DLTs) occurred in 1/6 DLT-evaluable patients at DL1 and 2/5 patients at DL2 in the dose escalation cohort. Any-cycle DLTs in 8 patients in the dose escalation and primary cohorts included fatigue, anorexia, rash, nausea, vomiting, diarrhea, dehydration, increased creatinine, hypoalbuminemia, hypernatremia, and hip fracture. No objective responses were observed. Six-month PFS was 37% (95% CI: 17%, 58%). Three patients with CNS tumors achieved stable disease > 6 months (HGG with *BRAF* fusion, 15 cycles; glioneuronal tumor with *BRAF* V600E, 9 cycles; low-grade glioma with *BRAF* fusion, 7 cycles). Analyses of correlative studies, including pharmacokinetics and circulating tumor DNA, are ongoing. **Conclusions:** The pediatric RP2D of ulixertinib was established as 260 mg/m^2/dose PO BID. There were no objective responses in this cohort of children and young adults with treatment-refractory tumors with activating MAPK alterations. Clinical benefit of prolonged disease control was observed in 3 patients with *BRAF*-altered gliomas and glioneuronal tumors. Clinical trial information: NCT03698994. Research Sponsor: U.S. National Institutes of Health.

3010 **Poster Discussion Session**

Phase II study of vismodegib in patients with *SMO* or *PTCH1* mutated tumors: Results from NCI-MATCH ECOG-ACRIN Trial (EAY131) Subprotocol T. *First Author: Anne S. Tsao, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: NCI-MATCH (EAY131) is a platform trial enrolling patients (pts) with solid tumors, lymphomas, or multiple myeloma to targeted therapies based on matching genomic alterations (NCT02465060). Subprotocol Arm T evaluated vismodegib (GDC0449), a hedgehog signaling pathway inhibitor with anti-tumor activity in pts with tumors harboring *PTCH1* and *SMO* mutations. **Methods:** Pts whose tumors had *SMO* or *PTCH1* mutations were eligible; results were confirmed by NCI-MATCH central labs if possible. Pts received oral vismodegib (150 mg daily) for 4-week cycles until progression/toxicity. Tumor response was assessed every 2 cycles. Primary endpoint was ORR; secondary endpoints included PFS, 6-month PFS, OS, and predictive biomarkers. Cutaneous basal cell carcinomas were excluded. **Results:** Of 34 pts enrolled (6/20/16 – 9/22/20); 2 were ineligible and 1 did not start therapy. The 31 analyzable pts' demographics were primary tumor sites/histology [gastrointestinal (n = 9), skin/soft tissue (n = 7), gynecologic (n = 5), lung (n = 4), unknown primary (n = 4), ductal breast (n = 1), meningioma (n = 1)]; median age 64 (range 19-81); 48.4% women; 61.3% (19/31) > 3 lines of prior therapy; 74% (23/31) > 1 co-occurring mutation [median 2 co-alterations (range 1-20)]. 8/31 > 4 co-occurring alterations. 9 pts had *SMO* mutant tumors (all SNVs); 5/9 had > 1 co-occurring gene alterations. 22 pts had *PTCH1* alterations (7 SNVs and 15 indels); 18/22 pts had > 1 additional gene alteration. Of 31 analyzable pts, 22 were MATCH-confirmed (i.e. had central confirmation of tumor *PTCH1/SMO* mutations). MATCH-confirmed pts had ORR 9.1% (2/22) while all analyzable pts had ORR 6.5% (2/31). 2 PRs were seen in pts with a skin/soft tissue sarcoma (*PTCH*) and a meningioma (*SMO*) with a median duration of response 14 months. The 6-month PFS rate was similar in MATCH-confirmed and analyzable pts (22.4% and 23.2% respectively) and median PFS was identical at 1.8 months. Median OS was 9.1 months in MATCH-confirmed and 7.3 months in analyzable pts. Within analyzable *SMO* variants: 1 PR, 3 SD, 4 PD, and 1 unevaluable responses were documented. Within analyzable *PTCH1* variants: 1 PR, 7 SD, 10 PD, and 4 unevaluable responses were seen. 4 pts (12.9%) discontinued therapy due to AE. Among 33 pts starting therapy, 18 (54.5%) had grade 1-2 toxicity, while 2 (6.1%) had grade 3 treatment-related toxicity. Most common toxicities: grade 1-2 fatigue (n = 11), anorexia (n = 8), weight loss (n = 7), alopecia (n = 7), and dysgeusia (n = 6). There were 4 on-study deaths, but none were treatment related. **Conclusions:** Although the primary endpoint was not reached, vismodegib was well-tolerated with mostly grade 1-2 toxicities and substantial responses were seen in patients with SMOPro641Ala and PTCHGlu947Ter alterations. Further study of the impact of concomitant molecular alterations may yield additional insights into vismodegib mechanisms of response. Clinical trial information: NCT02465060. Research Sponsor: U.S. National Institutes of Health, This study was coordinated by the ECOG-ACRIN Cancer Research Group (Peter J. O'Dwyer, MD and Mitchell D. Schnall, MD, PhD, Group Co-Chairs) and supported by the National Cancer Institute of the National Institutes of Health under award numbers: U10CA180820, U10CA180794, UG1CA233302, UG1CA233180, UG1CA233290, UG1CA233341, UG1CA233193, and UG1CA233329.

3011 **Poster Discussion Session**

A multicenter, open-label, single-arm, phase 1 dose-escalation study to evaluate the safety, tolerability, and anti-tumor activity of FCN-159 in adults with neurofibromatosis type 1. *First Author: Xiaojie Hu, Shanghai Ninth People's Hospital, Shanghai Jiao Tong University, School of Medicine, Shanghai, China*

Background: Neurofibromatosis type 1 (NF1) is an autosomal-dominant genetic disease that increases susceptibility to malignant tumors. Up to 50% of patients with NF1 present with plexiform neurofibroma (PN). Surgery, a common treatment strategy for patients with PN, has limited efficacy. NF1 is caused by mutations in the gene that encodes neurofibromin; the NF1 mutation then leads to tumorigenesis via dysregulation of the Ras/Raf/MEK/ERK pathway. FCN-159 is anti-tumorigenic via highly potent, selective inhibition of MEK1/2. This study aims to assess the safety of FCN-159 in patients with NF1-related PN. **Methods:** This is a multicenter, open-label, single-arm, phase 1 dose-escalation and phase 2 dose-expansion study (NCT04954001). Patients with NF1-related PN that was not completely resectable or not suitable for surgery were enrolled in the study; they received FCN-159 monotherapy continuously in 28-day cycles. Here, we report safety and clinical efficacy data from adults enrolled in phase 1. **Results:** As of the data cutoff of December 1, 2021, 19 adults from 3 hospitals in China have been enrolled in the phase 1 dose-escalation study, 3 in 4 mg, 4 in 6 mg, 8 in 8 mg, and 4 in 12 mg. The most common neurofibroma-related complications were disfigurement and pain, occurring in 10 patients (52.6%) and 4 patients (21.1%) at baseline, respectively. Four patients experienced dose-limiting toxicity; G3 folliculitis was reported in 1 patient (16.7%) receiving the 8-mg dose and 3 (100%) patients receiving the 12-mg dose. The maximum tolerated dose was determined to be 8 mg. Study-drug-related treatment-emergent adverse events (TEAEs) were observed in all 19 patients (100%); the majority were grade 1 or 2 in severity. Nine (47.4%) patients reported grade 3 study drug-related TEAEs; 4 patients experienced paronychia and 5 experienced folliculitis, which were the most common causes of dose reduction (42.1%) and drug interruption (21.2%). One patient experienced a serious adverse event of rhegmatogenous retinal detachment, but this was considered unrelated to the study drug as it was preexisting at baseline. Of the 16 patients with at least 1 post-baseline tumor assessment, all (100%) had reduced tumor size and 6 (37.5%) had a reduction in tumor size of > 20%. Three out of 6 patients with a second tumor assessment result had further tumor shrinkage; tumor volumes in the remaining 3 patients were similar to those at first assessment. The largest reduction in tumor size was 84.2%. **Conclusions:** Overall, FCN-159 at 8 mg is well tolerated, with easy to manage adverse events, and showed promising anti-neurofibroma activity in phase 1; this warrants further investigation in a phase 2 study on efficacy and safety in this indication. Clinical trial information: NCT04954001. Research Sponsor: Fosun Pharmaceutical Development Co., Ltd.

3012 **Poster Discussion Session**

NCI 9938: Phase I clinical trial of ATR inhibitor berzosertib (M6620, VX-970) in combination with irinotecan in patients with advanced solid tumors. *First Author: Liza C Villaruz, University of Pittsburgh Medical Center, Hillman Cancer Center, Pittsburgh, PA*

Background: Ataxia telangiectasia and Rad3 related (ATR) is activated in response to replication stress from topoisomerase 1 inhibitors. Selective ATR inhibition with berzosertib potentiates the efficacy of irinotecan in colorectal mouse xenograft models. We hypothesized that berzosertib in combination with irinotecan is well tolerated, modulates the DNA damage repair response to irinotecan, and the combination is associated with clinical activity. **Methods:** This phase I study utilized a modified Storer's up and down dose escalation design. Dose Levels (DLs) combined berzosertib 60 to 270 mg/m^2 with irinotecan 180 mg/m^2, every 2 weeks in a 4-week cycle. The primary endpoint was identification of the maximum tolerated dose (MTD) and recommended phase II dose (RP2D). Activity, pharmacokinetics (PK), and pharmacodynamics (PD) were secondary endpoints. The identification of molecular subpopulations sensitized to the combination was exploratory. **Results:** Between July 2016 and July 2021, 51 patients (pts) enrolled, of whom 50 received treatment. Pts most commonly had colorectal cancer (CRC, 39%), pancreatic cancer (24%), small cell lung cancer (SCLC, 6%) and non-small cell lung cancer (6%). The median number of prior lines of therapy was 4 (range, 2 to 11). In Stage I, 1 of 3 evaluable pts experienced dose-limiting toxicity (DLT) of grade 3 lung infection at DL3 (berzosertib 180 mg/m^2 - irinotecan 180 mg/m^2), and Stage II was initiated enrolling cohorts of 5 pts. In Stage II, 4 of the first 11 pts treated at DL4 (berzosertib 270 mg/m^2 - irinotecan 180 mg/m^2) were unable to complete the DLT evaluation period due to clinically significant toxicity not meeting DLT criteria: grade 2 diarrhea (1 pt), grade 3 diarrhea (1 pt), and grade 3 neutrophil decrease (2 pts). The protocol was amended to limit dose escalation beyond DL4. At DL4, 1 of 21 evaluable pts experienced DLT (grade 4 febrile neutropenia). Most common treatment-related grade ≥ 3 toxicities were neutrophil decrease (34%), lymphocyte decrease (30%), WBC decrease (28%), anemia (20%), diarrhea (16%), fatigue (8%) and hypokalemia (8%). 2 partial responses were observed, occurring in pts with pancreatic cancer and *ATM* alterations: 32% decrease in an ATM E11828/ATM K1109* tumor lasting 15.3 months and 68% decrease in an ATM R3008H/germline ATM R1882* tumor ongoing at 11 months. An additional pt with ATM S214fs*40 mutant colorectal cancer (CRC) experienced a 26% decrease lasting 7.5 months. **Conclusions:** Berzosertib 270 mg/m^2 - irinotecan 180 mg/m^2 was declared the RP2D. The combination is associated with manageable side effects and promising disease activity in ATM mutant solid tumors. PK and PD studies are in process. Tumor biopsy studies are planned in a 15 pt dose expansion cohort at DL4, enrolling pts with CRC, pancreatic cancer, SCLC and DNA damage repair deficient tumors. Clinical trial information: NCT02595931. Research Sponsor: U.S. National Institutes of Health.

3013 **Poster Discussion Session**

First-in-human, phase I study of TT-00420, a multiple kinase inhibitor, as a single agent in advanced solid tumors. *First Author: Sarina Anne Piha-Paul, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: TT-00420 is a spectrum-selective multi-kinase inhibitor that targets cell proliferation, angiogenesis, and immune-oncology pathways by inhibiting Aurora kinases A/B and Janus kinases (JAK) involved in cytokine signaling and receptor tyrosine kinases (FGFRs and VEGFRs) involved in the tumor microenvironment. TT-00420 has demonstrated anti-tumor activity in both *in vitro* and *in vivo* preclinical models of solid tumors, including triple-negative breast cancer (TNBC) and cholangiocarcinoma (CCA). **Methods:** This phase I, first-in-human, dose escalation and expansion study of TT-00420 (NCT03654547) enrolled adult patients with advanced or metastatic solid tumors. Capsules in 1 mg or 5 mg formulation were administered orally once daily in 28-day cycles. Dose escalation was guided by Bayesian modeling with overdose control. The primary safety endpoints were to determine dose limiting toxicities (DLTs) and a dose recommended for dose expansion (DRDE). Secondary endpoints included pharmacokinetics (PK) and preliminary efficacy evaluated per RECIST v1.1 criterion. **Results:** As of February 7, 2022, 48 advanced solid tumor patients were enrolled in the study, and received at least one dose of TT-00420 in 7 dose levels: 1 mg *q.d.* (N = 1), 3 mg *q.d.* (N = 1), 5 mg *q.d.* (N = 4), 8 mg *q.d.* (N = 10), 10 mg *q.d.* (N = 6), 12 mg *q.d.* (N = 20), and 15 mg *q.d.* (N = 6). DLTs were observed in 3 out of 40 DLT-evaluable patients, including 1 patient at 8 mg *q.d.* who had Grade (Gr) 3 palmar-plantar erythrodysaesthesia syndrome and 2 patients at 15 mg *q.d.* who both had Gr 3 hypertension. Among the twenty (20) safety evaluable patients treated at 12 mg, the DRDE, drug-related TEAEs included hypertension (n = 11, 55.0%; Gr 3: n = 6, 30%); diarrhea (n = 7, 35%, Gr 3: n = 1, 5%); mucosal inflammation (n = 7, 35%; Gr 3: n = 1, 5%); palmar-plantar erythrodysaesthesia syndrome (n = 6, 30%; Gr 3: n = 0, 0%); and vomiting (n = 4, 20%; Gr 3: n = 0, 0%). No grade 4 suspected adverse events were reported. Out of 42 patients who had at least one post-baseline scan, 7 (16.7%) had a best response of partial response (PR) and 22 (52.4%) had stable disease (SD). Among 7 PRs, 3 were CCA patients (one for each treated at 8 mg, 10 mg, or 12 mg), 2 were TNBC patients (one for each at 10 mg, or 12 mg), 1 was HER2-negative BC patient at 12 mg, and 1 was CRPC patient at 12 mg. Sustainable stable disease for six months or longer was observed in patients with colon cancer (n = 1), head and neck cancer (n = 1), and peritoneal mesothelioma (n = 1). **Conclusions:** TT-00420 monotherapy was well tolerated and had favorable PK characteristics. The TEAEs observed in dose escalation and dose expansion cohorts were manageable with concomitant treatment and/or dose interruptions of TT-00420 and reversible upon the discontinuation of TT-00420 treatment. Taking safety, efficacy and clinical PK into consideration, 10 mg *p.o. q.d.* was recommended for phase II study of TT-00420 in patients with advanced CCA. Clinical trial information: NCT03654547. Research Sponsor: TransThera Sciences (Nanjing), Inc.

3014 **Poster Discussion Session**

Efficacy proof-of-concept from a phase 1 study of a novel therapeutic peptide, ST101, targeting the oncogenic transcription factor C/EBPβ in patients with refractory solid tumors. *First Author: T.R. Jeffry Evans, University of Glasgow, Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom*

Background: The oncogenic transcription factor CCAAT/enhancer-binding protein β (C/EBPβ) promotes tumor survival and proliferation and inhibits differentiation. ST101 is a peptide antagonist of C/EBPβ, with anti-tumor activity in prostate cancer (PC), glioblastoma (GBM), breast cancer (BC), melanoma, and other pre-clinical models. **Methods:** This phase 1 study enrolled patients (pts) with refractory solid tumors with varying histologies. The primary objective was to evaluate safety/tolerability of ST101 and to determine the recommended phase 2 dose (RP2D). Secondary and exploratory objectives included pharmacokinetics (PK), preliminary efficacy (RECIST 1.1), and pharmacodynamic (PD) evaluation. The study used a 3+3 dose-escalation design, with once-weekly IV infusion dosing of ST101 at 0.5, 1, 2, 4, 6, 9 mg/kg or a flat dose of 500 mg. **Results:** Enrollment in phase 1 was completed in November 2021 with a total of 25 pts with multi-metastatic disease that were refractory to standard therapy. As of February 15, 2022, five pts remain on study with a median treatment duration of 27 weeks' (16-77). There were no DLTs, dose modifications, or serious adverse events (SAEs) related to ST101. The only AEs of note were G1-2 histaminergic infusion-related reactions (IRRs), largely pruritis and urticaria, managed with antihistamines, montelukast, and interruption/slowing of infusion. IRRs affected 93% of pts on the first dose at ≥4mg/kg and led to prolongation of infusion time. Intensity and frequency of IRRs decrease with repeat dosing. No other AEs were consistently reported. There was no evidence of accumulation upon continued exposure of ST101 and no anti-drug antibodies. Tumor immunohistochemistry showed dose-proportionate staining for ST101 and decreased tumor proliferation in several pts represented by decreased Ki67 expression. Population PK analysis supported flat dosing in phase 2. Five pts continue on treatment with one confirmed partial response in a patient with cutaneous melanoma lasting >42 weeks and four pts with ongoing stable disease. **Conclusions:** ST101 demonstrated safety at all doses explored and evidence of efficacy across dose levels, particularly higher doses and in pts with melanoma. PK and PD support a dose relationship for efficacy and selection of 500 mg as the RP2D. Pts are now enrolling in phase 2 cohorts to assess response in cutaneous melanoma, GBM, castrate-resistant PC, and HR$^+$ BC. Clinical trial information: NCT04478279. Research Sponsor: Sapience Therapeutics.

Phase 1 pts demonstrating clinical benefit (SD, PR, CR).

Dose (mg/kg)	Tumor type	Response	Duration (weeks)
0.5	Signet ring adenocarcinoma	SD	77+
2	Small bowel adenocarcinoma	SD	18
2	Abdominal sarcoma	SD	9
4	Cutaneous melanoma	PR	42+
6	Hepatocellular carcinoma	SD	18
6	Esophageal adenocarcinoma	SD	9
9	Cutaneous melanoma	SD	27+
Flat dose (mg)			
500	Uveal melanoma	SD	16+
500	Mucosal melanoma	SD	16+

+indicates ongoing treatment.

3015 **Poster Discussion Session**

Expanding clinical actionability in individual patient profiles with the Molecular Oncology Almanac. *First Author: Brendan Reardon, Dana-Farber Cancer Institute, Boston, MA*

Background: The clinical care of oncology patients is routinely informed by tumor and inherited genetic profiles. This is accomplished by molecular pathologists synthesizing the growing body of clinical guidelines and scientific evidence that associates cancer genome alterations and therapeutic response, and applying that knowledge during case reviews. Many academic medical centers formalize this process in the form of molecular tumor boards. As the number of cases for review and literature continue to increase, there is opportunity to leverage clinical interpretation algorithms to computationally prioritize molecular features and both enhance and automate the sample contextualization process. Here, we present the Molecular Oncology Almanac (MOAlmanac) to enable the rapid assessment of tumor actionability. **Methods:** Molecular Oncology Almanac is an open source clinical interpretation algorithm and paired knowledge base for precision cancer medicine. It is used to rapidly characterize and identify genomic features related to therapeutic sensitivity and resistance and of prognostic relevance. This is performed by assessing not only individual genomic features (e.g. somatic variants, copy number alterations, germline variants, and fusions) but also interactions between these events as well as secondary features such as mutational burden, mutational signatures, MSI status, and aneuploidy. MOAlmanac summarizes all clinically relevant findings into a web-based actionability report. The underlying knowledge base can be accessed through our API endpoints and web browser, and entries may be recommended through either Github or our browser extension. In addition, we developed a cloud-based web portal on top of the Terra framework to increase accessibility. **Results:** A total of 32,108 samples from 30,607 patients across 66 cancer types received targeted sequencing to characterize somatic variants, copy number alterations, and fusions from PROFILE's Oncopanel and were evaluated with MOAlmanac. Based on Oncopanel's tier 1 and tier 2 criteria for clinical actionability, we observed that 8,285 samples (26%, 0 - 69% by cancer type) of patients harbored at least one alteration suggesting therapeutic sensitivity based on FDA approvals or clinical guidelines. Actionability increases to 18,117 samples (56%, 0 - 85% by cancer type) when considering an expanded set of evidence to include relationships captured from clinical trials, clinical, preclinical, and inferential evidence; consequently providing at least one therapeutic hypothesis to otherwise variant-negative patients. **Conclusions:** Clinical actionability of molecular tumor data was increased in individual patients by expanding the set of evidence considered. Source code and a web portal for this project are available at moalmanac.org. Research Sponsor: U.S. National Institutes of Health.

3016 **Poster Discussion Session**

Genomic landscape of acquired resistance to targeted therapies in patients with solid tumors: A study from the National Center for Precision Medicine (PRISM). *First Author: Arnaud Bayle, Gustave Roussy Cancer Center, Villejuif, France*

Background: Despite the effectiveness of the various targeted therapies currently approved in solid tumors, acquired resistance remains a persistent problem that limits the ultimate effectiveness of these treatments. Polyclonal resistance to targeted therapy has been described in multiple solid tumors through high throughput analysis of multiple tumor tissue samples from a single patient. However, biopsies at the time of acquired resistance to targeted agents may not always be feasible and may not capture the genetic heterogeneity that could exist within a patient. We used here sequencing of circulating tumor DNA (ctDNA) to characterize the landscape of secondary resistance mechanisms in a large cohort of patients with solid tumors. **Methods:** This study enrolled patients with advanced cancer from two institutional molecular profiling program STING (NCT04932525, sponsor: Gustave Roussy) or BIP (NCT02534649sponsor: Institut Bergonié). Genomic analysis was performed for each patient by using the Foundation One Liquid CDx Assay (324 genes, tumor mutational burden [TMB], microsatellite instability status). **Results:** 3435 patients with metastatic disease entered the study. Among them 992 patients (29%) received a targeted therapy matched to a specific molecular alteration before ctDNA. The main tumor types were: prostate cancer (349, 35%), luminal breast cancer (236, 24%), oncogene-addicted non-small cell lung cancer (129, 13%), *KRAS*-wild type colorectal cancer (126, 13 %). The most frequent class of targeted agents were androgen receptor pathway inhibitor (n = 350, 35%), aromatase inhibitor (236, 24%), anti-*EGFR* monoclonal antibodies (166, 17%), anti-*EGFR* tyrosine kinase inhibitors (83, 8%). ctDNA sequencing revealed DNA aberrations involved in secondary resistance in 308 patients (31%). The most frequent aberrations were *AR* mutations/amplifications, *ESR1* point mutations, *KRAS* point mutations, *EGFR* point mutations. Among patients with resistance mutation, polyclonal aberrations were identified in 123 patients (40%). The median number of polyclonal aberrations per patient was 2 (range: 2-16). Polyclonal aberrations involved at least 2 different genes in 32 patients (10%). Preliminary results suggest that patients with polyclonal aberrations had worse outcome in comparison with patients with one or no detected aberration and final data will be presented at the time of the congress. **Conclusions:** We report here the first comprehensive landscape of genomic aberrations in ctDNA involved in resistance to targeted therapies in cancer patients. Polyclonal secondary genomic aberrations represent a frequent clinical resistance mechanism that may explain the poor rate of sustained complete remission observed with targeted therapies and must guide the development of future combinatorial strategies. Research Sponsor: None.

3017 **Poster Discussion Session**

Dual tissue and plasma testing to improve detection of actionable variants in patients with solid cancers. *First Author: Matthew Mackay, Tempus Labs, Inc., Chicago, IL*

Background: Next generation sequencing (NGS) of tumor tissue and plasma (circulating tumor DNA [ctDNA]) are used clinically to identify actionable genomic alterations, with implications for treatment selection and disease surveillance. Early studies have observed that solid tumor tissue and ctDNA testing may capture both overlapping and complementary alterations. Using the Tempus database, we examined whether dual tissue and ctDNA testing, "dual testing", improved identification of actionable variants compared with either modality alone. **Methods:** We used Tempus Lens to retrospectively analyze 3153 de-identified stage 4 patients (breast [N = 644], colorectal [N = 841], non-small cell lung cancer (NSCLC) [N = 1232], and prostate [N = 436]). Each patient had dual testing—Tempus xF (ctDNA, 105 panel genes) and Tempus xT (tumor tissue, 595-648 panel genes), representing 6306 total samples. Samples were defined as concurrent if biopsied ≤30 days apart and longitudinal if plasma was collected between 31–365 days after tissue biopsy. All analyses were limited to single nucleotide variants and insertions/deletions that met the limit of detection criteria for both assays (104 genes). Indication matched actionable variants were defined by OncoKB Level 1 and 2 evidence, or R1 within both xF and xT (13 genes). **Results:** Of the 3153 patients with dual testing, 37% (1168) had actionable variants identified by at least one test. 94% (1100/1168) of these patients had variants identified via solid tumor profiling alone, 73% (856) had variants identified via ctDNA profiling alone, and 64% (745) had perfectly concordant variants. Thus, dual testing identified additional variants in 36% (423/1168) of these patients compared to any singular test. Of the 423 patients who had additional actionable alterations discovered through dual testing, ctDNA revealed unique alterations—which were not found in solid tissue testing—in 22% (95/423) of patients. Of these patients, 72% (68/95) had all actionable variants identified solely from ctDNA. Of the 251 patients with additional alterations identified by concurrent dual testing, 24% (61/251) had unique alterations identified in plasma. Similarly, of the 172 patients with additional alterations identified by longitudinal dual testing, 20% (34/172) had unique alterations identified in ctDNA alone. **Conclusions:** In the largest study of its kind, we show that dual tumor tissue and ctDNA testing—with samples collected either concurrently or longitudinally—identified more patients with actionable alterations than single modality testing alone and therefore should be considered as part of routine NGS testing. Additional studies to explore the genetic and intra-patient tumor heterogeneity of these variants as well as the impact of time between tissue and plasma sampling assessments and implications for timing of therapeutic recommendations are underway. Research Sponsor: None.

3018 **Poster Discussion Session**

Differential diagnosis of hematologic and solid tumors using targeted transcriptome and artificial intelligence. *First Author: Hong Zhang, Genomic Testing Cooperative, Irvine, CA*

Background: Diagnosis and classification of tumors is becoming increasingly dependent on biological and molecular biomarkers. RNA expression profiling using next generation sequencing (NGS) provides information on various biological and molecular changes in the cancer and in the microenvironment. We explored the potential of using targeted transcriptome and artificial intelligence (AI) in the differential diagnosis and classification of various hematologic and solid tumors. **Methods:** RNA from hematologic neoplasms (N = 2606) and solid tumors (N = 2038) as well as normal bone marrow and lymph node control (N = 806) were sequenced by NGS using a targeted 1408-gene panel. The hematologic neoplasms included 20 different subtypes. Solid tumors included 24 different subtypes. Machine learning is used for comparing two classes at a time. Geometric Mean Naïve Bayesian (GMNB) classifier is used to provide differential diagnosis across 45 diagnostic entities with assigned ranking. **Results:** Machine learning showed high accuracy in distinguishing between two diagnoses with AUC varied between 1 (Sarcoma vs GIST) and 0.841 (MDS vs normal control) (examples in Table). For differential diagnosis between all 45 different diagnoses, we used 3045 samples for training the GMNB algorithm and 1415 samples for testing. Correct first choice diagnosis was obtained in 100% of ALL, 88% of AML, 85% of DLBCL, 82% of colorectal cancer, 88% of lung cancer, 72% of CLL, and 72% of follicular lymphoma. The algorithm had difficulty in typically overlapping diagnoses and diagnosed as first choice 19% of MDS, 46% of normal, and 12% of MPN. Diagnosis improved significantly when second choice was considered. **Conclusions:** Targeted RNA profiling with proper AI can provide highly useful tools for the pathologic diagnosis and classification of various cancers. Additional information such as mutation profile and clinical information can improve these algorithms, reduce subjectivity, and minimize errors in pathologic diagnoses. Research Sponsor: None.

Two classes	AUC	% Sensitivity	% Specificity	Leave one out AUC
Normal (N) vs AML	0.971	95.2	91	0.967
N vs ALL	0.98	95.5	98.7	0.984
N vs CLL	0.988	97	97.3	0.998
N vs MPN	0.925	90.9	83	0.894

AI-enabled identification prediction of homologous recombination deficiency (HRD) from histopathology images. *First Author: Gowhar Shafi, iNDX.Ai, Cupertino, CA*

Background: Homologous recombination deficient (HRD) tumors are highly responsive to platinum-based chemotherapy and poly (ADP-ribose) polymerase inhibitor (PARPi) therapy. Pathogenic BRCA-1 and BRCA-2 (BRCA1/2) alterations are key members of the HR DNA repair pathway but genomic instability status, including loss of heterozygosity, telomeric allelic imbalance and large scale state transitions across the genome are also predictive of HRD. HRD testing is currently performed by next generation sequencing which can take 2-4 weeks for results, has a high failure rate, requires significant tissue and is costly. We developed and tested the ability of an AI enabled platform to predict HRD status from the analysis of whole slide imaging of the diagnostic H&E slide. This platform, iPREDICT-HRD is rapid, precise, and cost effective. **Methods:** The AI engine was trained on 120 H&E slides that were used to identify tumor prior to manual microdisseection for HRD assessment by NGS. Histopathological features were extracted, followed by feature mapping to predict HRD status based on the results of NGS testing. ResNet AI algorithm was trained to segment, annotate and predict HRD status. 10 lac tiles of 256x256 size at 40x magnification were generated per pathological class. 70% of the data set was used for training and 30% for validation of the AI model. **Results:** Using single blinded clinical samples, iPREDICT-HRD tool detected HRD + ve samples with 99.3% accuracy with 100% sensitivity and 99% specificity in the test set. Patch-level predictions of HRD status demonstrated intra-tumor heterogeneity within the H&E slides. Visual inspection of the heatmap suggested the presence of patches with high predictive ability of HRD status and this outperformed an average HRD score for slides with heterogeneity. **Conclusions:** AI-enabled prediction of HRD status can be accurately performed on diagnostic H&E slides potentially yielding results quickly and afforadably, even when limited tissue is available for testing. 3020 **Poster Discussion Session**

A clinical AI-driven multiplex immunofluorescence imaging pipeline to characterize tumor microenvironment heterogeneity. *First Author: Dmitry Zarubin, BostonGene, Waltham, MA*

Background: Understanding the underlying heterogeneity of the tumor microenvironment (TME) on a single-cell level is becoming increasingly important to predict a patient's response to immunotherapy. Conventional imaging methods can help reveal tissue heterogeneity, but are not optimal for identifying multiple cellular subpopulations or cellular interactions from a single slide image, limiting their use in clinical settings. Here, we present a clinical artificial intelligence (AI)-driven multiplex immunofluorescence (MxIF) imaging pipeline based on novel cell segmentation and cell typing methods to evaluate tumor cellular heterogeneity, immune cell composition, and cell-to-cell interactions. **Methods:** A machine learning (ML)-based cell segmentation algorithm was trained on a manually annotated dataset created from 219 different regions of interest (ROIs) that contained 85,991 cells from various tissues (colon, kidney, lung, lymph node, tonsil, and ureter). A dataset containing 58,676 cells from 146 ROIs was used for validation and accuracy was determined between automated and manually annotated images; accuracy was further evaluated by calculating the f1-score using available methods (DeepCell and Stardist). Marker stains with a low signal-to-noise ratio were automatically enhanced, allowing for adequate cell-to-cell interaction analysis. **Results:** An automated MxIF image processing workflow was developed. Validation of the trained cell segmentation model showed high accuracy (0.80 f1-score), demonstrating superior performance compared to other methods (DeepCell and Stardist - 0.55 and 0.78 f1-score, respectively). The pathologist-determined accuracy (0.84 mean f1-score) indicated a near-human performance of the developed method. Normalized expression values obtained from the cell typing model allowed automated cell recognition. We analyzed cellular heterogeneity across 3 regions of colorectal cancer (CRC), gastric cancer (GC), and non-small cell lung cancer (NSCLC) samples. While proportions of immune cells varied, proportions of malignant epithelial cells were stable across all regions of each sample, as concordant percentages of Ki67+ cells were identified (CRC-19%; GC-21%; NSCLC-5%). Analysis of cell-to-cell interactions and immune communities identified tumor-, immune-, and stromal-enriched communities in all tumor samples that were stable across regions. **Conclusions:** By analyzing complex tumor tissue at single-cell resolution with high accuracy, this AI-driven MxIF imaging technology is able to characterize tumor and microenvironment heterogeneity across cancer types. This novel AI-based tool is currently being integrated into several ongoing prospective clinical studies to aid in the development of predictive and prognostic biomarkers. Research Sponsor: None.

First-in-human, phase I study of AK109, an anti-VEGFR2 antibody, in patients (pts) with advanced or metastatic solid tumors. *First Author: Nong Xu, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China*

Background: AK109 is a fully-human monoclonal antibody that specifically binds to vascular endothelial growth factor receptor 2 (VEGFR2), thereby block vascular endothelial growth factor (VEGF)/VEGFR2 signaling pathway to inhibit angiogenesis, endothelial cell migration and proliferation of tumor cells. This phase I study is the first-in-human trial of AK109, which was designed to evaluate safety, tolerability of AK109, to determine the maximum tolerated dose (MTD), recommend phase II dose (RP2D) and to gain preliminary data on pharmacokinetics (PK), pharmacodynamics, immunogenicity and clinical activity for AK109 in pts with advanced or metastatic solid tumors resistant to standard therapies (NCT04547205). **Methods:** This open-label, multi-center, phase I study included a dose escalation phase (part 1) using a 3+3 design to determine MTD and potential RP2D (n = 36 max), with planned dosing of 2, 4, 8, 12 and 18 mg/kg q2w and 15mg q3w, followed by a dose expansion phase (part 2), at 2 potential RP2Ds in q2w or q3w respectively (n = 24-30) . The PK characteristics, dose limiting toxicity (DLT), adverse events per CTCAE 5.0 and efficacy (ORR, DCR, DoR, PFS per RECIST v1.1, OS, etc.) of AK109 were evaluated. **Results:** As of December 30th, 2021 (median follow-up: 6.0 months), 40 pts (median age: 59.5 years) were enrolled, 16 pts in part 1 and 24 pts in part 2. No DLT was observed AK109 in part 1. Tumor types included gastric cancer (n = 9), non-small cell lung cancer (n = 8), hepatocellular carcinoma (n = 8), colorectal cancer (n = 5), pancreatic carcinoma (n = 2) and oesophagus cancer (n = 2), etc. Preliminary PK analyses showed systemic exposure in C_{max} and AUC_{last} increased dose proportionally at doses of 8 mg/kg and above, with a mean half-life of 8.5 to 10 days. 12mg/kg q2w and 15mg/kg q3w were selected as RP2Ds. Average exposure of AK109 was 6.9 cycles. Eight pts received over 10 cycles of AK109 . Treatment related adverse events(TRAE) occurred in 38 (95%) of all pts. Grade 3 and 4 TRAE occurred in 16 (40%) of all pts. The most common TRAEs were proteinuria (22/40, 55%), hypertension (13/40, 32.5%) and AST increased (11/40, 27.5%). Serious adverse event (SAE) occurred in 11 (27.5%) pts, 2 (5%) of which were AK109 related. ORR and DCR were 10.0% and 62.5%, respectively. The median PFS of non-small cell lung cancer (n = 8) and gastric cancer (n = 9) were 5.6 months (95% CI, 1.3, NE) and 5.5 months (95% CI, 1.4, NE), respectively. **Conclusions:** AK109 showed manageable safety and promising anti-tumor activity. Two phase II studies of AK109 combined with AK104 (anti PD-1/CTLA-4 bi-specific antibody) are ongoing to evaluate the efficacy of AK109 combined with AK104 in patients with multiple solid tumors (NCT05142423, NCT04982276). Clinical trial information: NCT04547205. Research Sponsor: Akeso Biopharma, Inc.

3022 **Poster Session**

Safety of the cyclin dependent kinase 9 (CDK9) inhibitor FIT039 for cervical intraepithelial neoplasia (CIN) 1 or 2 in a phase I/II trial. *First Author: Junzo Hamanishi, Kyoto University Graduate School of Medicine, Department of Gynecology and Obstetrics, Kyoto, Japan*

Background: Human papillomaviruses (HPVs) infect uterine cervical epithelial cells, leading to cervical intraepithelial neoplasia (CIN) and cervical cancer. However, there is no treatment for HPV infection in the uterine cervix prior to vaccination. We recently reported that cyclin dependent kinase 9 (CDK9) plays a critical role in viral RNA transcription of DNA viruses such as HPVs in host cells, and that FIT-039, a specific inhibitor of CDK9, suppresses the proliferation of several DNA viruses. Here, we evaluated the safety and antiviral effect of a FIT039-releasing vaginal tablet (FIT039CT) for CIN1 or 2 (CIN1/2). **Methods:** A multi-institutional, single-blind, placebo-controlled randomized phase I/II clinical trial involving 2 cohorts was designed to evaluate the safety of transvaginal FIT039CT for CIN1/2 as follows:. In the first cohort, 8 healthy women were randomized into FIT039CT (50mg/day or 100mg/day) or control group. In the second cohort, 14 women with a primary diagnosis of CIN1/2 were randomized into either FIT039CT (100mg/day) or control group. The primary endpoints were adverse events and plasma concentrations of FIT039. **Results:** 22 patients (8 volunteers, 11 CIN1 and 3 CIN2) were enrolled. There were no serious adverse events. Adverse events considered related to treatment were mild (vaginal discharge Grade 1: FIT039CT 16/17 women [94%] vs placebo 2/6 [33%]) and self-limiting in both cohorts. No patient discontinued this study due to adverse events. Maximum concentration (C max) and terminal elimination half-life (t 1/2) of serum FIT039 concentrations after single transvaginal treatment of FIT039CT were similar between the two doses as follows; C max (mean ± standard deviation) was 4.5 ± 0.5 ng/mL (50mg/day) and 4.4 ±1.4 ng/mL (100mg/day) at 6-7 hours; mean t1/2 was 14.8 ± 2.1 hours (50mg/day) and 12.1 ± 2.6 hours (100mg/day) hours. **Conclusions:** This study demonstrated the safety and validity of transvaginal FIT039CT once a day and may contribute to the development of an antiviral agent that can cure CIN1/2, and supports the design of the ongoing phase 2 clinical study. Clinical trial information: jRCT2051180201. Research Sponsor: Japan Agency for Medical Research and Development (AMED, 20lk0201081h0003), Pharmaceutical/Biotech Company.

A phase I study to evaluate the safety, tolerability, and pharmacokinetics of MSB0254 in Chinese patients with solid tumors. *First Author: Tianshu Liu, Zhongshan Hospital of Fudan University, Shanghai, China*

Background: MSB0254 is a humanized vascular endothelial growth factor receptor 2 (VEGFR-2) monoclonal antibody. MSB0254 inhibits angiogenesis induced by either VEGF-A or –C. This trial is a phase I study to evaluate MSB0254's safety, tolerability and PK profiles, as well as early anti-cancer activities in Chinese patients with advanced solid tumors. **Methods:** In this phase I study (NCT04381325), locally advanced or metastatic solid tumor patients failed previous standard treatments were enrolled. In the dose escalation phase, following 3+3 rules, MSB0254 was given intravenously Q2W (every 2 weeks) at 4mg/kg , 8mg/kg, 12mg/kg, 16mg/kg, and Q3W at 20mg/kg. In the dose expansion phase, patients with selected tumor types will be treated with MSB0254 at 16mg/kg Q2W or 20mg/kg Q3W. Primary objectives were to evaluate the safety and tolerability and to identify maximum tolerable dose (MTD) and/or Recommended Phase 2 Dose (RP2D). Secondary objectives included the assessment of pharmacokinetics, immunogenicity, and preliminary efficacy per RECIST1.1. **Results:** As of 10th Jan, 2022, a total of 22 Chinese patients have been enrolled into the dose escalation phase and treated with MSB0254 at different dose levels from 4-16mg/kg Q2W or 20mg/kg Q3W. MTD was not reached. One DLT was reported in 12mg/kg Q2W dose cohort. A subject with intra-cholangial carcinoma developed G3 (grade 3) upper gastrointestinal hemorrhage on the C1D13. The adverse event was resolved after symptomatic treatment. The most common treatment-emergent adverse events (TEAEs) (>10%) included: hypertension (27.3%), AST increased (27.3%), γ-GGT increased (22.7%), neutrophil count decreased (18.2%), proteinuria (18.2%), WBC count decreased (13.6%), platelet count decreased (13.6%) and anemia (13.6%). Three subjects (13.6%) experienced G3 TEAEs: 1 upper gastrointestinal hemorrhage, 1 anemia and 1 Hypertriglyceridemia. No G4/5 TEAE was observed. And three subjects (13.6%) experienced 3 SAEs: 1 upper gastrointestinal hemorrhage, 1 G2 intestinal obstruction caused hospitalization and 1 G2 fatigue caused hospitalization. MSB0254 displayed a dose proportional pharmacokinetic profile between 4-16 mg/kg Q2W with calculated $T_{1/2}$ of 6-9 days. Eighteen subjects had at least one tumor assessment per RECIST 1.1 after MSB0254 treatment. Eleven subjects (61.1%) had best response of stable disease (SD). Four of them had stable disease for more than 6 months, including a neuroendocrine tumor (NET), a gastric cancer, an epithelioid hemangioendothelioma (EHE) and a submaxillary gland carcinoma patient. **Conclusions:** MSB0254 demonstrated a manageable safety profile and preliminary antitumor activity in patients with advanced solid tumors. 16mk/kg Q2W is recommended as RP2D. 20mg/kg Q3W is still under investigation. The study of MSB0254 on the expansion phase in selected tumor patients is ongoing. Clinical trial information: NCT04381325. Research Sponsor: Suzhou Transcenta Therapeutics Co., Ltd.

VEGF inhibitors (VEGFi) activity in liver metastases (mets) regardless of primary cancer type: Meta-analysis and systematic review. *First Author: Ines Esteves Domingues Pires Da Silva, Melanoma Institute Australia, The University of Sydney, Sydney, Australia*

Background: Liver metastasis is a poor prognostic factor in several cancers and is associated with poor response to immunotherapy (IO) in melanoma and lung cancer. VEGFi have activity in hepatocarcinoma (HCC) and is hypothesized to be due the hypoxic microenvironment. Whether this is also true for liver mets is unknown. We sought to assess the efficacy of VEGFi in liver mets utilizing randomized-controlled clinical trials (RCTs) testing the efficacy of VEGFi, regardless of primary cancer site. **Methods:** Systematic searches of PubMed, Cochrane CENTRAL, and Embase were conducted from January 1, 2000, to January 1, 2022. All RCTs that compared a backbone of systemic therapy (chemotherapy [chemo] and/or IO and/or targeted therapy [TT]) or best supportive care (BSC) with vs without VEGFi in patients (pts) with liver mets from any cancer were selected. HCC trials were excluded. Study design, cancer type, number of pts, lines of treatment, study drugs and hazard ratios (HRs) with 95% CIs for overall survival (OS) and progression-free survival (PFS) were extracted. Pooled effects of VEGFi in pts with liver mets across different cancer types were estimated using random effect model with inverse variance. Heterogeneity between studies was assessed by I^2 statistics. Sensitivity analyses were performed considering prespecified subgroups of trials. **Results:** 3170 pts with liver mets from 19 RCTs were included in this meta-analysis: 8 colorectal cancer, 4 non-small cell lung cancer, 4 renal cell cancer & urothelial cancer, 1 pancreatic cancer, 1 GIST and 1 gastric cancer. Backbone systemic therapy in these trials included: chemo (11), TT (2), IO (2), chemo+IO (1), chemo+TT (1); and 2 BSC trials. Moderate heterogeneity between studies for both PFS (I^2= 55%) and OS (I^2= 46%) was seen. The addition of VEGFi to standard systemic therapy or BSC was associated with superior PFS (HR = 0.61; 95% CI, 0.50-0.74; p < 0.0001) and OS (HR = 0.86; 95%CI, 0.76-0.99; p = 0.0334) in pts with liver mets, regardless of whether pts had only liver mets or concurrent other sites of mets. In the subset of RCTs with data on pts without liver mets, the benefit with VEGFi was more pronounced in patients with liver mets (HR = 0.56) vs those without liver mets (HR = 0.64) for PFS, but not for OS. **Conclusions:** The addition of VEGFi to standard management improved survival outcomes in pts with liver mets across different cancer types and warrants further investigation. VEGFi added to IO may be effective in pts with resistant liver mets. Research Sponsor: None.

3025 **Poster Session**

Dose-finding and -expansion studies of trastuzumab deruxtecan in combination with other anti-cancer agents in patients (pts) with advanced/metastatic HER2+ (DESTINY-Breast07 [DB-07]) and HER2-low (DESTINY-Breast08 [DB-08]) breast cancer (BC). *First Author: Fabrice Andre, Gustave Roussy, Université Paris-Sud, Villejuif, France*

Background: Trastuzumab deruxtecan (T-DXd), an antibody-drug conjugate composed of a humanized anti-HER2 monoclonal antibody and a topoisomerase I inhibitor payload, is approved for pts with unresectable or metastatic HER2+ BC with ≥2 prior anti-HER2–based therapies. T-DXd showed improved progression-free survival vs trastuzumab emtansine (T-DM1) as an earlier-line treatment (tx) for pts with HER2+ metastatic BC in the phase 3 DESTINY-Breast03 trial (Cortes J, et al. *Ann Oncol*. 2021;32:S1283-S1346. Abstract LBA1). Preliminary antitumor activity of T-DXd was shown in heavily pretreated pts with HER2-low advanced/metastatic BC in the phase 1 DS8201-A-J101 trial (Modi S, et al. *J Clin Oncol*. 2020;38:1887-1896). We report preliminary results from the dose-finding phase of 2 trials investigating T-DXd combination tx in HER2+ or HER2-low metastatic BC. **Methods:** DB-07 (phase 1b/2; NCT04538742) and DB-08 (phase 1b; NCT04556773) are 2-part, modular, open-label, multicenter trials of T-DXd combined with other anticancer tx in pts with advanced/metastatic BC that is HER2+ (DB-07) or HER2 low (DB-08). Part 1 of each study is an ongoing dose-finding phase; pts must have ≥1 prior tx for metastatic BC. Part 2 of each study is a dose-expansion phase; pts must have no (DB-07) or ≤1 (DB-08) prior tx for metastatic BC. We report preliminary results from the T-DXd + pertuzumab module of DB-07 part 1 (data cutoff: Oct 15, 2021) and T-DXd + anastrozole and T-DXd + fulvestrant modules of DB-08 part 1 (data cutoff: Sep 27, 2021); pts in the DB-08 modules must be hormone receptor positive. The part 1 primary objective was to assess safety and tolerability and determine the recommended phase 2 dose (RP2D) according to the modified toxicity probability interval-2 algorithm. Pts were followed up beyond the 21-day dose-limiting toxicity (DLT) period (28 days for T-DXd + fulvestrant) for safety events. **Results:** In DB-07, 7 pts were enrolled and received T-DXd 5.4 mg/kg + pertuzumab 420 mg (loading dose: 840 mg) every 3 wk (q3w; not evaluable for DLTs, n = 1). In DB-08, 6 pts were enrolled and received T-DXd 5.4 mg/kg q3w + anastrozole 1 mg daily (not evaluable for DLTs, n = 1); another 6 pts were enrolled and received T-DXd 5.4 mg/kg q3w + fulvestrant 500 mg every 4 wk (loading dose: 500 mg cycle 1 days 1 and 15). For all 3 modules, no DLTs were reported in any DLT-evaluable pts; the dose levels used in part 1 were approved to be the RP2Ds for use in the dose-expansion part of each corresponding module. No deaths on study or cases of interstitial lung disease/pneumonitis were reported to date. **Conclusions:** The RP2Ds for the T-DXd combinations were the standard doses for BC of each individual drug. These studies are ongoing, with additional T-DXd combinations being evaluated and further follow-up underway. Clinical trial information: NCT04538742; NCT04556773. Research Sponsor: This study is funded by AstraZeneca Pharmaceuticals. In March 2019, AstraZeneca entered into a global development and commercialization collaboration agreement with Daiichi Sankyo for trastuzumab deruxtecan (T-DXd; DS-8201).

3026 **Poster Session**

Safety, pharmacodynamic, and clinical response evaluation of nilotinib and paclitaxel in adults with refractory solid tumors. *First Author: Sarah Shin, Developmental Therapeutics Clinic/Early Clinical Trials Development Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD*

Background: The combination of the BCR-Abl kinase inhibitor nilotinib and the anti-tubulin agent paclitaxel was identified in the NCI-ALMANAC study to have greater-than-additive activity in the NCI-60 cell line panel and greater-than-single-agent antitumor activity in xenograft models, in which this combination induces tumor epithelial-mesenchymal transition (EMT). A phase 1 study was initiated to establish the safety, tolerability, and recommended phase 2 dose (RP2D) of this combination in patients (pts) with advanced solid tumors and to examine the pharmacokinetic (PK) and pharmacodynamic (PD) effects of the combination to understand the mechanism of action (NCT02379416). The dose escalation phase established the RP2D as 300 mg oral nilotinib twice daily and 80 mg/m^2 intravenous paclitaxel on days (D) 1, 8, and 15 of each 28-day cycle. Here, we report the safety, preliminary PD, and efficacy data for this combination. **Methods:** Nilotinib and paclitaxel were administered as noted above, with a 1-day (escalation cohort) or 2-day (expansion cohort) paclitaxel-only run-in during the first cycle to enable comparison of the PK and PD effects of the combination vs. single-agent paclitaxel. Paired biopsies to assess tumor molecular response were collected from expansion cohort pts at baseline, cycle (C) 1 D2, and C1D28, with an optional biopsy at progression; accrual continued until ≥ 12 sufficient-quality paired biopsies were obtained. Blood specimens to assess molecular responses in circulating tumor cells (CTCs) were obtained at several timepoints during C1 and longitudinally every cycle thereafter. EMT biomarkers were measured in tumor and CTC specimens using quantitative immunofluorescence microscopy assays. **Results:** A total of 44 pts were enrolled. Three pts had partial responses (PR), and 1 had an unconfirmed PR (9%); 23 pts (52%) had a best response of stable disease (SD), including 7 pts on study for ≥ 10 cycles. The most common grade (Gr) 3-4 treatment-related adverse events were hematologic and hypophosphatemia. No pts experienced Gr ≥ 3 peripheral neuropathy. The median time on treatment was 67 days. Two pts with granulosa cell ovarian carcinoma had durable responses, completing 74+ and 64 cycles. Multiple patient biopsies and corresponding CTC specimens exhibited treatment-induced EMT. Longitudinal analysis of CTC EMT phenotypes in the 2 pts with extended PR revealed a substantial increase in mesenchymal-like CTCs prior to progression for the pt on study for 64 cycles; such increases were not observed in the pt still on study after 74+ cycles. Further PD analyses are ongoing. **Conclusions:** The combination of nilotinib and paclitaxel demonstrates promising disease control with durable response in select patients. Tumor PD analyses to discover the underlying pharmacology of this active regimen are ongoing. Funded by NCI Contract No. HHSN261201500003I. Clinical trial information: NCT02379416. Research Sponsor: U.S. National Institutes of Health.

TLD-1, a novel liposomal doxorubicin, in patients (pts) with advanced solid tumors: Dose escalation and expansion part of a multicenter open-label phase I trial (SAKK 65/16). *First Author: Dagmar Hess, Cantonal Hospital St. Gallen, St. Gallen, Switzerland*

Background: TLD-1 is a novel liposomal doxorubicin that compared favorably to conventional liposomal formulations of doxorubicin in preclinical in vivo mouse breast cancer models. This phase I first-in-human trial is aiming to determine the recommended phase II dose (RP2D), toxicity profile, pharmacokinetics and preliminary activity. **Methods:** Patients with a maximum of 3 prior lines of systemic chemotherapy and preferably anthracycline-sensitive disease were eligible. TLD-1 was administered on day 1 iv over 60-90 minutes (depending on individual dose) q 21 days, for up to 6 or 9 cycles (according to prior anthracycline-exposure) with premedication of 8mg dexamethasone. Dose escalation with dose levels (DL) 1-7 of 10, 16, 23, 30, 35, 40 and 45mg/m^2 started with an accelerated titration design, treating one pt at each DL up to DL6 (40mg/m^2) followed by a modified continual reassessment method at DL7 due to observed toxicity. **Results:** 30 pts (F:M = 24:6) have been treated, one each at DLs 1-6, 15 pts at DL7 and an additional 9 pts at DL6. Most frequent tumor types included breast (n = 13), ovarian (n = 6), cervical cancer (n = 2) and cholangiocarcinoma (n = 2). Median age was 67.5 years (range:38-83), 13 pts were exposed to prior anthracyclines. The median number of cycles was 4 (range:1-9). No dose-limiting toxicities (DLT) occurred during cycle 1. At DLs 1 to 5, no treatment-related G3 AEs (TRAE) were observed. At DL6, there was one case of mucositis G3, one of palmar-plantar-erythrodysesthesia (PPE) G3 and one of anemia and neutropenia G3 each. One patient with pre-existing valvular cardiopathy developed symptoms of heart-failure G3 after 8 cycles. Echocardiography showed severe mitral regurgitation with normal LV-EF. In addition one case of urinary-tract infection G3 was seen. Dose-modifications or -delays due to AEs occurred in 7/50 cycles. At DL7, one case of mucositis G3, 3 events of PPE G3 and one case of fatigue G3 were reported. In addition, one case of infection with shingles occurred. Dose-modifications or -delays due to AEs occurred in 12/61 cycles. Shingles and heart failure were reported as SAEs. All toxicities listed above were categorized as TRAE. 29/30 pts were evaluable for response. Three breast cancer pts had a partial response, 2 at DL7 and 1 at DL6, 14 pts had stable disease. **Conclusions:** No DLT was observed up to DL7. RP2D was defined at 40mg/m^2 due to cumulative PPE G3 at DL7. The trial is ongoing with a comparative PK-part evaluating the two iv liposomal formulations of doxorubicin TLD-1 and Caelyx. Clinical trial information: NCT03387917. Research Sponsor: InnoMedica Holding AG.

3028 **Poster Session**

Phase 1 study of OBT076, a first-in-class anti-DEC205 ADC, in patients with advanced/metastatic solid tumors: Safety, efficacy, and PK/PD results. *First Author: Olivier Rixe, Quantum Santa Fe, Santa Fe, NM*

Background: OBT076, an Antibody Drug Conjugate (ADC) consisting of a fully human IgG1 antibody conjugated via a cleavable linker to the derivative microtubule inhibitor DM4. It has specificity for the CD205/Ly75 target antigen which is an endocytic receptor overexpressed on the cell surface and immunosuppressive dendritic cells. This phase 1 study evaluates safety, tolerability, PK/PD and preliminary efficacy of OBT076 in solid tumor patients with high expression of target protein CD205 (CAP-CLIA validated centralized IHC test). **Methods:** Open label, two parts trial in patients with metastatic CD205+ve solid tumors who progressed on standard therapy. Part 1 of the study consisted in dose escalation from 1.6 mg/kg to 3.5 mg/kg. An mTPI design is used to guide to determine the maximum tolerated dose (MTD) Treatment was given on day 1 every 3 weeks followed by GCSF on day 8. Blood samples and flow cytometry were used to assess PK/PD. Tumor response was assessed every three cycles. Part 2 of trial is an expansion basket trial enriched in indications where preliminary efficacy has been shown. **Results:** The study completed Part 1 dose escalation. Part 2 expansion phase is ongoing. Between Dec 2019 and January 2022, 20 patients were enrolled (18 patients in the dose escalation and 2 in the ongoing expansion). The median age 61, 9 patients were males and 9 had ECOG PS 0. All patients had at least one metastatic site and 90% received at least 2 lines of chemotherapy in the metastatic setting. Recommended dose for the expansion phase is 3.0 mg/kg. No other significant side effects have been observed. PK data showed that Cmax of 40.000-90.000 ng/ml was achieved between 2.5 and 3.5mg/kg dose and is comparable to the therapeutic dose in mouse models. In part 1 of the study, 7 patients derived clinical benefit despite being in disease progression at trial entry. One patient with gastric cancer with linitis plastica experienced major improvement with complete disappearance of ascites and metastatic adenopathy after cycle 3. The six other patients had lasting stable disease and received between 5-14+ cycles with median of 5 cycles. Two patients with low PD-L-1 expression received checkpoint inhibitor treatment with pembrolizumab after 2 and 5 cycles of OBT076, both patients experienced near complete response after only one to two cycles. **Conclusions:** OBT076 at 3.0mg/kg has shown favorable safety profile with manageable neutropenia. The preliminary efficacy has shown preliminary antitumoral single agent activity in gastric, ovarian and lung cancer. The two patients who received a sequential administration of pembrolizumab after OBT076 showed major tumor activity. Sequential administration of OBT076 followed by a PD-1 inhibitor was also supported by PD markers and warrants further evaluation. Clinical trial information: NCT04064359. Research Sponsor: Oxford Biotherapeutics.

First-in-human study of OBI-999: A globo H-targeting antibody-drug conjugate in patients with advanced solid tumors. *First Author: Apostolia Maria Tsimberidou, Department of Investigational Cancer Therapeutics, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: OBI-999 is a novel antibody-drug conjugate, composed of a humanized monoclonal IgG1 antibody which targets the tumor-associated carbohydrate antigen Globo H, conjugated with monomethyl auristatin E (MMAE, vedotin). Upon binding to Globo H, OBI-999 is internalized into the tumor cell, and the linker (Thiobridge) connecting MMAE (an ultrapotent antimitotic agent) to the monoclonal antibody is cleaved by cathepsin B to release MMAE, thereby causing cell cycle arrest by inhibiting tubulin polymerization. We conducted a first-in-human, phase 1, dose-escalation study of OBI-999 monotherapy in patients with advanced cancer (NTC04084366). **Methods:** OBI-999 was administered intravenously at doses of 0.4, 0.8, 1.2, and 1.6 mg/kg on Day 1 of a 21-day cycle. Patients received study treatment until disease progression, unacceptable toxicity, or up to 2 years of treatment. **Results:** Overall, 15 adult patients were treated. OBI-999 administered on Day 1 of each 21-day cycle was well tolerated up to 1.2 mg/kg, the maximum tolerated dose (MTD). Treatment-related AEs (TRAEs) were noted in 40% (6/15) of patients. TRAEs ≥Grade 3 were noted in 27% (4/15) of patients; of whom 3 had neutropenia and 2 had anemia. OBI-999 exhibited non-linear pharmacokinetics from 0.4 mg/kg to 1.6 mg/kg, with lower clearance at higher doses. A retrospective validated automated immunohistochemistry assessment indicated 50% of patients with advanced solid tumors had high Globo H staining (H-score cutoff ≥100). Of 3 patients treated at the 1.6 mg/kg dose level; 2 developed Grade 4 neutropenia during Cycle 1 and the third developed Grade 4 neutropenia on Cycle 2 Day 15. One patient (1.6 mg/kg) with Grade 4 neutropenia also developed Grade 4 renal insufficiency and died from progressive disease (direct bilirubin, 3.5 mg/dL). Five (33.3%) patients had stable disease (SD), including 1 patient with adenoid cystic carcinoma of the oropharynx (SD for 13 cycles); 1 patient with gastroesophageal junction adenocarcinoma (SD for 8 cycles), and 3 patients with other tumor types (SD for 4, 2, and 2 cycles). **Conclusions:** We completed the dose-escalation portion of the study. OBI-999 was well tolerated. The recommended phase 2 dose was determined to be 1.2 mg/kg once every 3 weeks. Dose-dependent, non-cumulative neutropenia was dose limiting. We are currently enrolling patients with high Globo H expressing solid tumors (H-score ≥100) in the expansion phase of the study, which includes pancreatic, colorectal, and cancers of other histologic subtypes. Clinical trial information: NTC04084366. Research Sponsor: OBI Pharma Inc.

3030 **Poster Session**

Safety, pharmacokinetics, and clinical activity of OBI-3424, an AKR1C3-activated prodrug, in patients with advanced or metastatic solid tumors: A phase 1 dose-escalation study. *First Author: Apostolia Maria Tsimberidou, Department of Investigational Cancer Therapeutics, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: OBI-3424 is a novel nitrogen mustard prodrug that can be selectively converted in the presence of the AKR1C3 enzyme into the bis-alkylating agent OBI-2660, which forms intra- and inter-strand DNA crosslinks resulting in cell death. This selective mode of activation distinguishes OBI-3424 from traditional alkylating agents, and potentially improves the safety profile and antitumor activity against chemo- and radio-resistant tumors. We conducted a first-in-human, phase 1, dose-escalation study of OBI-3424 monotherapy in patients with advanced solid tumors (NCT03592264). **Methods:** OBI-3424 was administered intravenously at doses of 1, 2, 4, 6, 8, or 12 mg/m^2 (Days 1 and 8 every 21 days, Schedule A) or 8, 10, 12, or 14 mg/m^2 (Day 1 every 21 days, Schedule B). A "3+3" design was used for dose escalation. Patients received study treatment until disease progression, unacceptable toxicity, or up to 2 years of treatment. **Results:** Overall, 39 adult patients were treated. In patients receiving Schedule A, the maximum tolerated dose (MTD) of OBI-3424 was determined to be 8 mg/m^2. Dose limiting toxicities (DLTs) were reported at the 12 mg/m^2 dose level, including thrombocytopenia (Grade 3-4, 5 of 6 patients) and anemia (Grade 3-4, 5 of 6 patients). Platelet count nadirs were noted on Day 15 or Day 22. These cytopenias led to dose modification and resulted in protocol amendment (Schedule B). In Schedule B, the MTD was not reached at the maximum dose tested (14 mg/m^2). Grade 3 or higher anemia was noted in 3 of 6 patients treated at 14 mg/m^2; the recommended phase 2 dose (RP2D) is 12 mg/m^2 (Day 1 every 21 days). Treatment-related AEs (TRAEs) were noted in 82% (32/39) of patients. The most common TRAEs were anemia (64%), thrombocytopenia (51%), nausea (26%), and fatigue (21%). No patient had a fatal TRAE, 49% had ≥Grade 3 TRAEs, including 3 patients who had serious TRAEs. OBI-3424 showed linear pharmacokinetics from 1 to 14 mg/m^2, with minimal accumulation after repeated dosing. A retrospective validated automated immunohistochemistry assessment indicated that 27% of patients had high AKR1C3 staining (H-score ≥135). Best confirmed response was stable disease in 21 patients (54%). **Conclusions:** We completed the dose-escalation portion of the study. The RP2D was determined to be 12 mg/m^2 once every 3 weeks. OBI-3424 was well tolerated. Dose-dependent, non-cumulative thrombocytopenia and anemia were dose limiting. We are currently enrolling patients with pancreatic cancer and other tumor types with overexpression of AKR1C3 (H-score ≥135) in the expansion phase of the study. Clinical trial information: NCT03592264. Research Sponsor: OBI Pharma Inc.

BOLD-100-001 (TRIO039): A phase 1b dose-escalation study of BOLD-100 in combination with FOLFOX chemotherapy in patients with advanced gastrointestinal solid cancers: Interim safety, tolerability, and efficacy. *First Author: Jennifer L. Spratlin, Alberta Health Services, Edmonton, AB, Canada*

Background: BOLD-100 is a first-in-class ruthenium-based anticancer agent in Phase 1b / 2 clinical development for the treatment of advanced gastrointestinal (GI) cancers in combination with FOLFOX. Being developed primarily as a combinational agent, BOLD-100 induces cellular stress through modulation of the unfolded protein response, production of reactive oxygen species and induction of DNA damage. BOLD-100 demonstrates synergy in established preclinical models in combination with various anticancer therapies, particularly in resistant cell lines. **Methods:** This is a prospective, Phase 1b dose-escalation (Part A) and Phase 2 dose-expansion (Part B) study of BOLD-100 in combination with FOLFOX for colorectal (CRC), pancreatic (PDAC), gastric (GC) and biliary tract (BTC) cancers. Patients (pts) receive BOLD-100 with FOLFOX on day 1 of each 14-day cycle. In Part A, pts are enrolled in a 3+3 design to determine the combination recommended Phase 2 dose (RP2D), with BOLD-100 dose-escalation (420, 500 and 625 mg/m2) up to dose level 3. Part B comprises 5 cohorts treated at the RP2D until progressive disease or unacceptable toxicity. In Part A, reported here, the primary endpoints are safety, tolerability and maximum tolerated dose; the Part B endpoints are efficacy (primary), pharmacokinetic (PK) and pharmacodynamic parameters (secondary), and duration of response (exploratory) (NCT04421820). **Results:** As of 07 Feb 2022 (contains Part A preliminary data), 19 pts (mean age 65 years) were treated: 9 (47%) CRC, 5 (26%) BTC, 4 (21%) PDAC, 1 (5%) GC. Patients had a median of 3 prior systemic therapies, and 18 (95%) were enrolled with stage IV disease. Median number of cycles completed was 5 (range 1-15). 18 pts reported ≥1 treatment-emergent adverse events (AEs), most commonly fatigue (n = 12, 63%), nausea (n = 9, 47%) and stomatitis (n = 8, 42%). The majority of AEs were grade (G) 1-2. 7 G4 AEs (all neutropenia), and 1 unrelated G5 AE of pulmonary embolism occurred. There were 8 serious AEs in 6 different pts, with 1 SAE of dyspnea reported as related to BOLD-100. 2 pts experienced infusion-related reactions, related to chemotherapy. 2 dose-limiting toxicities have been observed: G3-4 neutropenia complicated by fever > 38.5°C or infection (n = 1, cohort #2) and inability to receive planned doses due to AEs (n = 1, cohort #3). To date for evaluable pts (n = 16), disease control rate of 75%, 1 partial response (48% target lesion reduction) and 11 stable disease have been observed. **Conclusions:** BOLD-100 plus FOLFOX is well-tolerated with no clinically significant safety findings. Dose-escalation data supports a BOLD-100 RP2D of 625 mg/m2 for the expansion phase. Progression-free survival, overall survival, and PK data are forthcoming. Clinical trial information: NCT04421820. Research Sponsor: Bold therapeutics.

Increased systemic toxicities from antibody-drug conjugates (ADCs) with cleavable versus non-cleavable linkers: A meta-analysis of commercially available ADCs. *First Author: Carrie Wynn, University of Mississippi Medical Center, Jackson, MS*

Background: Though in theory ADCs should deliver high-dose chemotherapy directly to target cells with few systemic effects, in clinical practice numerous side effects have been observed. We hypothesized that ADCs with cleavable linkers would have more systemic toxicities than those with non-cleavable linkers due to the increased free payload released systemically. To compare their side effect profiles, we conducted a meta-analysis of adverse events (AEs) of commercially available ADCs. **Methods:** Systematic review yielded 12 phase II/III clinical trials that led to the FDA approval of commercially available ADCs. Polatuzumab vedotin was not included because it was only studied in combination with other agents. Any grade AEs and grade ≥3 AEs occurring in at least 5% of patients in each study were recorded. The estimated inverse variance weighted absolute average risk and 95% confidence interval (CI) were estimated for each AE. Absolute risk differences and 95% CIs were estimated by linker type. **Results:** Data from 2,417 patients treated with 9 ADCs were pooled. 7 ADCs had cleavable linkers (N = 1,082), and 2 had non-cleavable linkers (N = 1,335). At least half of studies reported thrombocytopenia, neutropenia, anemia, increased AST and ALT, nausea, vomiting, diarrhea, hypokalemia, headache, and fatigue, as well as rates of all grade and grade ≥3 AEs. AEs ≥ grade 3 occurred in 43% of patients overall, 47% in the cleavable linker arms and 34% in the non-cleavable arms. This was significantly different (weighted risk difference -12.9%; 95% CI -17.1% to -8.8%). There was also a significant difference favoring non-cleavable linkers for ≥ grade 3 neutropenia (-9.1%; 95% CI -12% to -6.2%) and ≥ grade 3 anemia (-1.7%; 95% CI -3.3% to -0.1%). Cleavable linkers were significantly associated with increased AST all grade (3.9%; 95% CI 0.3% to 7.5%) and increased ALT all grade (3.7%; 95% CI 0.2% to 7.3%), though notably the CI approached 0 on the low end of difference for each. There was no significant difference in rates of all grade AEs or in rates of discontinuation due to AEs. There was no significant difference in rates of all grade nausea, vomiting, diarrhea, hypokalemia, or headache. Finally, there was no significant difference in rates of grade ≥3 thrombocytopenia, increased AST/ALT, or fatigue. **Conclusions:** Cleavable linkers appear to have significantly higher rates of ≥ grade 3 AEs and neutropenia within the limitations of this non-randomized comparison and treatment of heterogeneous malignancies. The increased payload in the circulation likely accounts for this; however, it may also make them more efficacious, as suggested by the results of the DESTINY-Breast03 trial. In the final analysis, we will compare the efficacy of cleavable vs non-cleavable ADCs indirectly using the standard of care for each tumor and line of therapy, with the exception of breast cancer. Enabling circulating cell-free mRNA theranostics from PD-L1, ALK, ROS1, NTRK to transcriptomic profiling. *First Author: Chen-Hsiung Yeh, Circulogene Theranostics, Birmingham, AL*

Background: Circulating cell-free mRNA (cfmRNA) expression can be considered as a compendium of transcripts collected from all organs. It has the capability of integrating functional and genetic information of tissues, highlighting this analyte's unique potential as a non-invasive biomarker in early detection, therapy selection and patient follow-up of cancer management. Plasma cfmRNA is usually made up of degraded small fragments of smaller than 200 nucleotides, very low concentration, and with different terminal modification, these properties make it difficult to detect. We have developed, validated and automated a cfmRNA clinical testing workflow for simultaneous measurement of PD-L1 expression, ALK, ROS1 and NTRK fusions. This proprietary real-time qPCR-based process is exosome-free, highly sensitive and requires only half milliliter of plasma with 72-hour turnaround. A plasma cfmRNA profiling database covering 750 genes in 9 major cancer pathways was also established with novel cancer type-specific characteristics. **Methods:** Circulating cfRNA was extracted from 400 uL of plasma and reverse transcribed to cDNA. The cDNA pool then served as the universal source for multi-biomarker tests. All target primer and probe sets were selected based on RNA secondary structures. Plasma PD-L1 expression, ALK, ROS1, NTRK fusions and transcriptomic profiling were performed by Circulogene CLIA/CAP-complied testing platform. **Results:** Limit of detection (LOD) for PD-L1, ALK/ROS1 and NTRK were 1.0 copy/uL, 17.5 copies/uL and 28 copies/uL, respectively. For scoring of PD-L1 expression, based on Keynote trials, we used the 30th percentile Ct value as cutoff in qPCR which corresponded to IHC ≥ 50% TPS; while the 66th percentile Ct value corresponded to IHC ≥ 1% TPS. PD-L1 cfmRNA was demonstrated to be an excellent surrogate marker of tissue PD-L1 protein for clinical outcomes with immunotherapy. In a global cfmRNA landscape, a functional transcriptomic databank was also established, including differential gene expression, classification, functional clustering and cancer type-specific signatures. **Conclusions:** Liquid biopsy qPCR tests targeting PD-L1 expression, ALK, ROS1 and NTRK fusions are commercially available and filling the gap of tissue-based assays and NGS. Our groundbreaking cfmRNA work has research, clinical, and diagnostic value, and provides greater dimensionality to the current knowledge of cfmRNA research and makes a significant jump into understanding and devising strategies to tailor cancer Dx and Rx. Multicancer early detection with a spectroscopic liquid biopsy platform. *First Author: Matthew Baker, Dxcover Ltd., Glasgow, United Kingdom*

Background: A rapid, low-cost, sensitive, multi-cancer early detection (MCED) test would be transformational in the diagnostics field. Earlier cancer detection and instigation of treatment can increase survival rates. An effective test must accurately identify the small proportion of patients with typically non-specific symptoms who actually have cancer. Such symptoms don't easily segregate by organ system, necessitating a multi-cancer approach. **Methods:** In this large-scale study (n = 2094 patients) we applied the Dxcover Cancer Liquid Biopsy to differentiate cancer against non-cancer, as well as organ specific tests to identify cancers of the brain, breast, colorectal, kidney, lung, ovary, pancreas, and prostate. The test uses Fourier transform infrared spectroscopy to analyze all macromolecules in a minute volume of patient serum, and machine learning to build a classifier of the resultant spectral profiles for calling the likelihood of cancer. **Results:** For the overall cancer classification, our model achieved 90% sensitivity with 61% specificity when tuned for sensitivity, with detection rates of 93% for stage I, 84% for stage II, 92% for stage III and 95% for stage IV. We also tuned for maximum sensitivity or specificity, whilst the other statistic was fixed above a minimum value of 45%. This resulted in 94% sensitivity with 47% specificity, and 94% specificity with 48% sensitivity, respectively. For organ specific cancer classifiers area under the curve values were calculated for all cancers: brain (0.90), breast (0.74), colorectal (0.91), kidney (0.91), lung (0.90), ovarian (0.85), pancreatic (0.81) and prostate (0.85). **Conclusions:** Cancer treatment is often more effective when given earlier and this low-cost strategy can facilitate the requisite earlier diagnosis. With further development, the Dxcover MCED test could have a significant impact on early detection of cancer, which is vital in the quest for improved survival and quality of life. Research Sponsor: Dxcover Ltd.

Blood-based detection of actionable alterations from NCI-MATCH patients with no tissue results. *First Author: Robin Harrington, Molecular Characterization Laboratory, Frederick National Laboratory for Cancer Research, Frederick, MD*

Background: The National Cancer Institute Molecular Analysis for Therapy Choice (NCI-MATCH) multi-arm phase II clinical trial tested tumor tissue from 5,954 patients with advanced refractory cancer to assign treatment based on the molecular profile. Molecular profiling was successful for 93% of patients. For 267 of the patients who were not enrolled because molecular profiling was not successful, plasma cfDNA was evaluated to provide insight into the potential utility of blood-based testing in a broad spectrum of histologies when tissue is not evaluable. **Methods:** Cell-free DNA was extracted from plasma collected from Streck blood tubes and quantitated. Libraries were constructed using ^{3} 15 ng cfDNA into the Illumina TruSight Oncology 500 ctDNA RUO Assay, including unique molecular identifiers and duplex barcodes for error correction. Libraries were sequenced on the NovaSeq 6000 with S4 XP flow cells. **Results:** Of the 267 samples, 250 samples (94%) were evaluable, representing 72 histologies, including colorectal cancer (N = 36), lung adenocarcinoma (N = 15), pancreatic adenocarcinoma (N = 14), and invasive breast carcinoma (N = 12). Of these, 231 (92%) had ^{3} 1 OncoKB annotated mutation, with 208 patients (83%) having putative somatic mutations detected in genes not commonly associated with clonal hematopoiesis. The most common somatic mutations were in *TP53*, *KRAS*, *APC*, and *PIK3CA*, reported in 51%, 20%, 12%, and 12% of patients respectively. A total of 109 patients (44%) had ^{3} 1 actionable mutation of interest (aMOI) reported that could have been used for treatment assignment in the NCI-MATCH clinical trial. After applying histology and molecular exclusions, 75 patients (30%) had ^{3} 1 aMOI. The most common assignable treatment arms were *Z1B/Z1BX1* (palbociclib with *CCND1/2/3*, N = 13), Z1F (copanlisib with *PIK3CA* Mutations, N = 13), S1/S1X1 (trametinib with *NF1* mutation, N = 12), and Z1C/Z1CX1 (palbociclib with *CDK4/CDK6* Amplification and Rb Expression by IHC, N = 10). Mutations in genes commonly associated with clonal hematopoiesis (CH) were prevalent in this population. Along with the expected high frequency of *DNMT3A* (21% of patients) and *TET2* (11%) mutations, *PPM1D* mutations were the highest amongst CH genes, with 61 patients (24%) having ^{3} 1 *PPM1D* mutation, likely due to the heavily pre-treated nature of these patients. **Conclusions:** Variants observed in the blood are consistent with what is reported in the tissue. Using liquid biopsy when tissue is not evaluable can expand the ability of patients to obtain mutation information that can inform treatment compared to using tumor tissue only. Cell-free DNA provided valuable mutation information for these patients and could have resulted in up to an additional 75 patients being eligible for treatment selection based on their mutation profile. These results indicate that blood-based screening could be a tool for future NCI-sponsored clinical studies. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Test performance and clinical validity of circulating tumor DNA (ctDNA) in predicting relapse in solid tumors treated with curative intent therapy. *First Author: Abhenil Mittal, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Studies have explored the prognostic value of ctDNA in predicting relapse in solid tumors treated with curative intent. These studies have evaluated ctDNA at specific 'landmark' timepoint or over numerous 'surveillance' time points. However, variable results have led to uncertainty about the clinical validity of this tool. Here, we quantify the predictive and discriminatory accuracy of ctDNA and explore sources of heterogeneity at both landmark and surveillance time points across different tumor sites. **Methods:** A search of MEDLINE (host: PubMed) identified studies evaluating ctDNA after curative intent therapy in solid tumors. Odds ratios (OR) for disease recurrence at both landmark and surveillance time points for each study were calculated and pooled in a meta-analysis using the Peto method. Pooled sensitivity and specificity weighted by individual study inverse variance were estimated and meta-regression utilizing linear regression weighted by inverse variance was performed to explore associations between patient and tumor characteristics and the OR for disease recurrence. **Results:** Of 23 studies identified; 16 (750 patients) and 14 studies (853 patients) reported on landmark and surveillance time points respectively. The median time from completion of definitive therapy to landmark testing was 51.5 days (range 3-120). The pooled OR for recurrence at landmark was 22.22 (95% CI 14.82-33.30) and at surveillance was 27.51 (95% CI 19.1-39.63). The pooled sensitivity for ctDNA at landmark and surveillance time points were 59.9% and 73.2%. The corresponding specificities were 90.9% and 86.6%. Subgroup results are shown in the table. There was lower predictive accuracy with the use of tumor site specific panels, in patients receiving adjuvant chemotherapy and in lung cancer. Meta-regression showed that longer time to landmark and higher number of surveillance blood draws were associated with higher prognostic accuracy, as was a history of smoking. **Conclusions:** Although ctDNA at both landmark and surveillance time points shows high prognostic accuracy, it has low sensitivity, suboptimal specificity and therefore weak discriminatory accuracy to predict relapse in patients with solid tumors treated with curative intent. Testing methodology, time points and patient populations need to be optimized before it can be incorporated routinely in clinical practice. Research Sponsor: None.

An ultra-sensitive assay using cell-free DNA fragmentomics for multi-cancer early detection. *First Author: Yang Shao, Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China*

Background: Although most cancer can benefit from early detection by more effective treatments and better prognosis, current screening programs are only limited to tumor-specific tests for a subset of common cancers. To benefit a broader population and outweigh the risks of single-cancer tests, an effective and affordable multi-cancer test should be developed for sensitive early detection of multiple cancers and accurate prediction of cancer tissue of origin simultaneously. **Methods:** In this study, we enrolled 971 cancer patients of the most prevalent and lethal cancer types, including primary liver cancer (PLC, *N*= 381), colorectal adenocarcinoma (CRC, *N*= 298), and lung adenocarcinoma (LUAD, *N*= 292), as well as 243 healthy controls. The participants were randomly divided into a training cohort and a test cohort in a 1:1 ratio. Five fragmentomic features representing cfDNA fragmentation size, motif sequence, and copy number variation were extracted from processed whole-genome sequencing (WGS) data of the participants to build the base models. Each base model implemented five machine learning algorithms for model training, and the optimal base models were used to create the final multi-dimensional model through ensemble stacked machine learning. The integrated multi-cancer model is composed of the first-level binary cancer detection model and the second-level multi-classification cancer origin model. The training cohort was used to train the models with 10-fold cross-validation. The test cohort remained untouched during model construction and was solely used for performance evaluation. **Results:** Our cancer samples are highlighted by mostly early-stage diseases (early-stage PLC: 88.5%; CRC: 100.0%; LUAD: 100.0%). The cancer detection model reached an area under the curve (AUC) of 0.983 for differentiating cancer patients from healthy individuals in the test cohort. At 95.0% specificity, the sensitivity of detecting all cancer is 95.5%, and 100.0%, 94.6%, and 90.4% for PLC, CRC, and LUAD, respectively. Its sensitivity is consistently high for early-stage, small-size tumors. The cancer origin model demonstrated an overall 93.1% accuracy for predicting tissue of origin in the test cohort (97.4%, 94.3%, and 85.6% for PLC, CRC, and LUAD, respectively). Furthermore, the model's cancer detection and origin classification performance remained robust when reducing sequencing depth to 1× (cancer detection: ≥ 91.5% sensitivity at 95.0% specificity; cancer origin: ≥ 91.6% accuracy). **Conclusions:** We utilized multiple plasma cfDNA fragmentomic features to build an ensemble stacked machine learning model. The assay reached ultrasensitivity and accuracy for multi-cancer early detection, shedding light on leveraging cfDNA fragmentomics for early screening in clinical practice. Research Sponsor: None.

Utilization of cell-free DNA fragmentomics in minimal residual disease detection for non-small cell lung cancer. *First Author: Rong Yin, Department of Thoracic Surgery, Jiangsu Key Laboratory of Molecular and Translational Cancer Research, Jiangsu Cancer Hospital & Nanjing Medical University Affiliated Cancer Hospital & Jiangsu Institute of Cancer Research, Nanjing, China*

Background: Non-small-cell lung cancer (NSCLC) is the leading cause of worldwide cancer-related deaths. Currently, ~30-55% of the NSCLC patients develop recurrence due to minimal residual disease (MRD) after receiving surgical resection of the tumor. Therefore, there is an urgent clinical need to accurately predict the MRD risk in post-surgical NSCLC patients. However, the current targeted ctDNA mutation profiling method is limited by the cost of design and synthesis of patient-specific panels and relatively low sensitivity. Cell-free DNA (cfDNA) fragmentomics have recently shown great accuracy and affordability in early cancer detection. This retrospective study aims to develop an ultra-sensitive and affordable fragmentomic assay for MRD detection in NSCLC patients. **Methods:** A total of 116 NSCLC patients (54 stage I, 21 stage II, 40 stage III and 1 stage IV), who received curative surgical resections (32 patients relapsed during follow-up, median relapse time: 315.5 days), enrolled in the Lung Cancer Tempo-spatial Heterogeneity (LuCaTH) cohort. A total of 231 plasma samples, collected at 7 days post-surgery and 3 months thereafter, were used for whole-genome sequencings (~5X). The cfDNA fragment size profile was used to fit a Regularized Cox Regression model. A leave-one-out cross-validation (LOOCV) was used to evaluate the model's predictive performance, and the optimal cutoff for predicting relapse was determined by identifying the Youden index to the predicted relative risk for all samples. **Results:** Our machine learning model showed an excellent performance in detecting patients with a high risk of recurrence. At 7 days post-surgery, the high-risk patients detected by our model showed an increased risk of 3 times compared to the low-risk patients (hazard ratio [HR] = 3.2, $p < 0.001$). Multivariate analysis confirmed that the association between model-determined high-risk status and patient relapses was not affected by the baseline clinical variables (age, sex, smoking, stage, etc.). Furthermore, the longitudinal analysis showed that our model was capable of detecting high-risk patients who were 11 times more likely to develop recurrence, independent from other clinical factors (multivariate HR = 11.8, $p < 0.001$). Overall, our model was able to identify high-risk status in 26 of 32 relapsed patients (81.2% sensitivity), preceding radiographic relapse by a median of 216 days. Furthermore, the sensitivity for MRD detection reached 91% while combining the model prediction with mutation-based ctDNA results. **Conclusions:** We have developed a predictive model for patient recurrence by detecting the fragmentomic profiling of plasma cfDNA contributed by the MRD. Despite being limited by the relatively small cohort size, our model has shown great sensitivity in predicting patient recurrence, therefore exhibiting a great potential to guide adjuvant therapy decisions. Plasma first: Accelerating lung cancer diagnosis through liquid biopsy. *First Author: Miguel Garcia Pardo, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada*

Background: Molecular profiling of tumor tissue is the gold standard for treatment decision making in advanced non-small cell lung cancer. Results may be delayed or unavailable due to insufficient tissue samples or prolonged wait times for biopsy, pathology assessment and testing. We piloted the use of plasma molecular testing as part of the initial diagnostic work-up for patients with suspected advanced lung cancer (NCT04863924). **Methods:** Patients with radiologic evidence of advanced lung cancer referred to the lung rapid diagnostic program underwent plasma circulating tumor DNA (ctDNA) testing using InVisionFirst-Lung, a next-generation sequencing (NGS) assay targeting 37 genes. Standard tissue testing was performed with comprehensive NGS (Oncomine). The primary endpoint was time to treatment in stage IV NSCLC patients compared to an historical pre-COVID-19 cohort (2018-9). Secondary endpoints included actionable targets identified in plasma, % of patients starting targeted therapy based on liquid biopsy and result turnaround time (TAT). **Results:** Between July 1 to December 31, 2021, 60 patients were enrolled. Median age was 70 years (range 33-91), 52% were female, 57% Caucasian, 48% never smokers. Of these, 73% had NSCLC, 12% small cell, 10% non-lung pathology and 5% declined tissue biopsy. Of 44 NSCLC patients, 5 (11%) had early-stage disease and underwent curative therapy. Most stage IV patients (79%) had systemic treatment. Median time to treatment initiation in the study cohort was 34 days (n = 31, range 10-90) versus 62 days (n = 101, range 13-159) in the historical cohort ($p<0.0001$). Two thirds (N = 23) of stage IV NSCLC patients had actionable alterations identified, (30% in current/ex-smokers); 18 started targeted therapy including 10 based on plasma results before tissue results were available. Median TAT was 7 days for plasma from blood draw to reporting (range 4-14) and 26 days for tissue molecular testing (range 11-42), $p<0.0001$. Concordance was high between plasma and tissue testing (70%). Liquid biopsy identified actionable alterations for 3 patients not identified by tissue NGS. In 4 cases, plasma testing failed to identify actionable alterations detected in tissue, due to undetectable plasma ctDNA. **Conclusions:** Liquid biopsy in the initial diagnostic workup of patients with suspected advanced NSCLC leads to faster molecular results and shortens time to treatment compared to tissue testing alone. Supplementing the current standard of tissue molecular testing with a plasma-first approach during the diagnostic work up of patients with suspected advanced lung cancer may increase access to precision medicine and improve patient outcomes. Clinical trial information: NCT04863924. A cell-free RNA-based next-generation sequencing (NGS) assay for the detection of actionable gene fusions in patients with non–small cell lung cancer (NSCLC). *First Author: Yukti Choudhury, Lucence Diagnostics, Singapore, Singapore*

Background: Gene fusions and alternate RNA splice forms represent clinically actionable driver and resistance-conferring alterations in NSCLC and other cancers. Where tissue samples are inadequate for molecular testing, liquid biopsies could address the gap in detection of clinically relevant gene fusions. Targeted cell-free (cf) DNA-based NGS methods are typically used for non-invasive blood-based testing of gene fusions, but have limited sensitivity if fusion breakpoints involve long intronic regions or repetitive sequences (e.g. *NTRKs* and *NRG1*). RNA-based approaches are not affected by introns, can identify expressed fusion genes and can discriminate splicing. We developed an NGS assay optimized for cfRNA analyte for the detection of actionable gene fusions and exon deletion/skipping events in liquid biopsies. **Methods:** A highly multiplexed molecular-barcoded primer panel was designed for cfRNA-based detection of actionable fusion genes in NSCLC (*ALK*, *BRAF*, *FGFR2*, *FGFR3*, *MET* (including exon 14 skipping), *NRG1*, *NTRK1/2/3*, *RET* and *ROS1*) covering > 90% of reported driver and partner gene exons in COSMIC database. The panel also targets housekeeping genes as endogenous sample controls. We developed a custom bioinformatics pipeline to call fusions and exon skipping based on split and spanning reads. **Results:** In initial analytical validation using fragmented RNA from pre-characterized reference material (representing 32 unique fusions at known copy numbers), the assay could detect as low as 10 fusion copies with a sensitivity of 97.6% and a specificity of 100%. For clinical testing, cfRNA co-eluted with cfDNA in nucleic acid extracts from plasma was used. In plasma samples (n = 103) from advanced NSCLC, 76% (15/21) of fusions (5 *ALK*, 3 *RET*, 2 *ROS1*, 5 *MET* ex14 skipping, 1 *FGFR3-TACC3*) detected in a clinically validated cfDNA assay (LiquidHALLMARK) were also detected in corresponding cfRNA. In a subset of samples that were driver-negative untreated or tyrosine kinase-inhibitor treated, the cfRNA assay yielded 9 gene fusions or breakpoints (1 *CD74-NRG1*, 4 *BRAF*, 2 *MET*, 2 *FGFR3-TACC3* fusions) that could not be detected by the cfDNA assay. This represents an increase of 8.7% (9/103) of actionable alterations (driver or resistance) identified using cfRNA. Together cfRNA and cfDNA resulted in 30 fusion events to be detected compared to 21 by the cfDNA assay alone, representing a 42.8% (9/21) increase in fusion-specific detection of the combined assay. **Conclusions:** This novel cfRNA assay can detect actionable gene fusions and exon skipping events in liquid biopsies with high sensitivity. Combining cfRNA with more routine cfDNA testing can increase the total actionable diagnostic information from non-invasive testing in NSCLC patients where tissue samples are lacking, especially for gene fusions not amenable to detection in cfDNA. Early detection of cancer using cell-free DNA (cfDNA) size analysis on a multiplexed amplicon-based next-generation sequencing (NGS) platform. *First Author: Yukti Choudhury, Lucence Diagnostics, Singapore, Singapore*

Background: Tumor-derived cfDNA fragments are observed to be shorter in length than normal cfDNA. This size (length) difference can be analyzed as a tumor-specific signal. Whole genome or probe hybridization-based NGS methods can capture cfDNA fragments of native sizes. However, amplicon-based NGS assays are not directly amenable to cfDNA size analysis due to predetermination of amplicon sizes by design. Here we present a method to extract relative distribution of cfDNA fragment lengths from a targeted amplicon-based assay and show its utility in cancer detection. **Methods:** The LiquidHALLMARK cfDNA assay is an amplicon-based NGS test for the sensitive detection of genomic alterations in 80 genes. Although panel design is optimized for cfDNA with average amplicon length of ~150 bp, the consecutive tiling design of amplicons for genes with contiguously targeted regions, e.g. *BRCA* permits the formation of longer amplicons (> 150 bp) from physically subsequent primer pairs, provided longer template cfDNA molecules are present. Cancer samples (n = 281), clinically tested by LiquidHALLMARK during Sep 2020-Sep 2021, and healthy samples (n = 28) were included for analysis. For each sample, fragment lengths were inferred from sequencing alignment files, and binned into "short" (0-150 bp) and "long" (151-500 bp) groups. A relative "size ratio" of the total number of short vs. long fragments per sample was calculated, and examined with clinical features, plasma cfDNA concentration (cfDNA/ml) and highest mutation allele frequency (AF%), in a model to predict cancer. **Results:** Calculated size ratios (relative abundance of short fragments) were higher in cancer than normal samples (median 47.6 vs. 31.2, $p < 0.001$). Cholangiocarcinoma and colorectal cancer samples had the highest size ratios (medians: 62.9 and 60.9, respectively) in agreement with a genome-wide NGS study that profiled cfDNA sizes. Size ratios were higher in metastatic (n = 143) compared to early stage (n = 30) lung cancers ($p = 0.0039$), indicating a stage-dependent accumulation of shorter cfDNA fragments. Size ratio was correlated with cfDNA/ml ($r = 0.63$, $p < 0.01$) and AF% ($r = 0.42$, $p < 0.01$). In 20-fold cross-validation of a logistic regression model trained to predict cancer, average area under curve (AUC) was 0.82 using size ratio, 0.86 using cfDNA/ml, and increased to 0.95 with the two features combined. **Conclusions:** Our analysis shows that it is feasible to derive meaningful cfDNA fragment size information from amplicon-based NGS data. Importantly, relative fragment size distributions observed in cancer and healthy plasma samples by this method are concordant with alternate target capture methods. Fragment size ratios derived from relatively small, targeted amplicon panels are a novel feature that, combined with other molecular and clinical features, can enhance non-invasive methods of cancer detection. Detection of homologous recombination deficiency (HRD) in cell-free DNA (cfDNA) using an amplicon-based next-generation sequencing (NGS) assay. *First Author: Jonathan Poh, Lucence Diagnostics, Singapore, Singapore*

Background: Homologous recombination (HR) deficiency is characterized by tumor genomic instability, often due to alterations in *BRCA1/2* and other HR-related genes. HRD predicts sensitivity to PARP inhibitors (PARPi) in prostate, ovarian and breast cancers. For the subset of cancers that have genomic instability without detectable alterations in HR genes, profiling biomarkers of HRD such as loss of heterozygosity (LOH) could identify additional HRD positive (HRD+) patients that may benefit from PARPi. Here, we present a novel cfDNA NGS assay that can detect tumor LOH non-invasively to improve assessment of HRD+ status. **Methods:** An amplicon-based HRD NGS assay covering > 1000 SNPs was developed to detect LOH both globally and on the gene level in cfDNA. Analytical validation was done using LOH+ *BRCA*-mutant cell lines in limiting dilution admixtures. Clinical performance was assessed by benchmarking findings from 46 tumor tissue DNA samples against results from an orthogonal NGS-based genomic scarring assay. Clinical utility of the HRD assay was evaluated in 75 cfDNA samples, including 72% (54/75) from *BRCA*-associated cancers (36 breast, 12 prostate, 4 ovarian, 2 pancreatic) and 28% from other cancer types. All cfDNA samples were previously clinically tested by an NGS assay that included *BRCA1/2* (LiquidHALLMARK). A subset of cfDNA samples identified as HRD+ were further assessed for alterations in 26 key HR genes (*ARID1A, ATM, ATR, ATRX, BAP1, BARD1, BRCA1, BRCA2, BRIP1, CDK12, CHEK1, CHEK2, FANCA, FANCC, FANCG, FANCL, MRE11, NBN, PALB2, PTEN, RAD51, RAD51B, RAD51C, RAD51D, RAD54L,* and *XRCC2*). **Results:** In analytical validation, the assay could detect HRD in admixtures with as low as 18% tumor fraction. In tissue samples, overall concordance of HRD status with the orthogonal test was 91.3% (42/46), with a positive percent agreement of 94.4% (34/36) and negative percent agreement of 80.0% (8/10). In cfDNA, 26.7% (20/75) of samples were HRD+, including 29.6% of *BRCA*-associated cancers (16/54; 12 breast, 2 prostate, 1 ovarian, and 1 pancreatic) and 19.1% (4/21) of other cancer types. In the three HRD+ breast cancers with pathogenic *BRCA* mutations, the assay also identified *BRCA*-specific LOH. Nine HRD+ breast cancers (two *BRCA*+ and seven *BRCA*-) were further analyzed for alterations in 26 HR genes. Of the two *BRCA*+ HRD+ breast cancers, one harbored an additional *PTEN* loss-of-function (LOF) mutation. Of the seven *BRCA*- HRD+ breast cancers, one harbored biallelic *PALB2* and *CDK12* LOF mutations, while another harbored a *CDK12* LOF mutation. **Conclusions:** LOH detection in cfDNA provides additional diagnostic yield of HRD+ status in multiple cancer types, even in the absence of pathogenic HR gene alterations. Further clinical studies to evaluate the utility of HRD detection in cfDNA using LOH and to determine concordance with tumor tissue are ongoing. Research Sponsor: Lucence Diagnostics.

Systemic levels of the soluble co-inhibitory immune checkpoints, CTLA-4, LAG-3, PD-1/PD-L1, and TIM-3 are markedly increased in basal cell carcinoma. *First Author: Bernardo Leon Rapoport, Department of Immunology, Faculty of Health Science, University of Pretoria, Pretoria, South Africa*

Background: Although co-inhibitory immune checkpoint proteins are primarily involved in promoting inhibitory cell-cell interactions in adaptive immunity, especially tumor immunity, the soluble cell-free variants of these molecules are also detectable in the circulation of cancer patients where they retain immunosuppressive activity. Nevertheless, little is known about the systemic levels of these soluble co-inhibitory immune checkpoints in patients with various subtypes of basal cell carcinoma (BCC), which is the most invasive and treatment-resistant type of this most commonly occurring malignancy. **Methods:** In the current study, we have measured the systemic concentrations of five prominent co-inhibitory immune checkpoints, namely CTLA-4, LAG-3, PD-1/PD-L1 and TIM-3, as well as those of C-reactive protein (CRP) and vitamin D (VD), in a cohort of patients (n = 40) with BCC, relative to those of a group of control participants (n = 20), using the combination of multiplex bead array, laser nephelometry and ELISA technologies, respectively. **Results:** The median systemic concentrations of CRP and VD were comparable between the two groups; however, those of all five immune checkpoints were significantly elevated ($P = 0.0184$ - $P \leq 0.00001$), with those of CTLA-4 and PD-1 being highly correlated ($r = 0.87$; $P < 0.00001$). **Conclusions:** This seemingly novel finding not only identifies the existence of significant systemic immunosuppression in BCC, but also underscores the therapeutic promise of immune checkpoint targeted therapy, as well as the potential of these proteins to serve as prognostic/predictive biomarkers in BCC. Research Sponsor: University of Pretoria, South Africa.

Dysregulation of immune checkpoint proteins in patients with newly diagnosed early breast cancer. *First Author: Bernardo Leon Rapoport, The Medical Oncology Centre of Rosebank, Johannesburg, South Africa*

Background: Checkpoint proteins regulate the immune system. Breast cancer (BC) cells can up-regulate or down-regulate these proteins to evade anti-tumor immune responses. Soluble forms of immune checkpoint molecules (ICMs) can be measured in human plasma. The study aimed to measure the systemic levels of a series of co-stimulatory and co-inhibitory ICMs at diagnosis, post-neo-adjuvant chemotherapy (NAC) and post-surgery in newly- diagnosed BC patients (pts) relative to those of a healthy control group. **Methods:** Soluble ICMs were measured using multiplex bead array technology in plasma from 72 BC pts and 45 healthy controls. Data was prospectively obtained and levels compared between pre-treatment, post-NAC, and post-surgery using non-parametric tests (Mann-Whitney & Kruskal-Wallis). **Results:** Pre-treatment levels of the soluble stimulatory molecules *viz.* GITR ($p<0.0001$), GITRL ($p< 0.020$), CD27 ($p< 0.024$), CD40 ($p< 0.021$), ICOS ($p< 0.009$), as well as the inhibitory molecules PD-L1 ($p< 0.0001$), CTLA-4 ($p< 0.005$), TIM-3 ($p< 0.0004$), HVEM ($p< 0.0004$) were significantly lower in early BC pts compared to controls. Post-treatment, there were significant increases in most ICM levels (Table), with the exception of CTLA-4, which decreased significantly following treatment. On the other hand, pre-treatment plasma concentrations of CCL5 (RANTES) (84.22 vs. 48.72 pg/mL, $p<0.0001$), M-CSF (84.41 vs 13.34 pg/mL, $p<0.0001$), FGF-21 (24.36 vs. 8.64 pg/mL, $p<0.001$) and GDF-15 (806.82 vs. 430.03 pg/mL, $p<0.0001$) were significantly increased in the breast cancer pts compared to healthy controls. A pathological complete response (pCR) was documented in 65% of pts (mostly TNBC). There were no correlations between pre-treatment ICM levels, CCL5, M-CSF, FGF-21 and GDF-15 and pCR. **Conclusions:** We identified low levels of stimulatory and inhibitory ICMs in newly-diagnosed, non-metastatic BC pts compared to healthy controls. Following treatment, with the exception of CTLA-4, most of these pre-treatment abnormalities of systemic ICM levels corrected. NAC is associated with up-regulation of sPD-L1 and most other ICMs. These results indicate that early BC is associated with down-regulation of soluble stimulatory and inhibitory ICMs. Newly-diagnosed early BC pts appear to have generalized immune-suppression independent of subtype and stage. To our knowledge, this is the first study to describe the effect of treatment on systemic ICMs in early BC pts. Research Sponsor: CANSA, Pharmaceutical/Biotech Company.

Characterization of genomic landscape using comprehensive circulating cell-free tumor DNA next generation sequencing in advanced thyroid carcinoma. *First Author: Valentina Tarasova, Department of Head and Neck-Endocrine Oncology, Moffitt Cancer Center, Tampa, FL*

Background: Availability of targeted therapies in thyroid carcinoma (TC) has challenged the conventional treatment algorithms and established urgency for timely identification of targetable genetic abnormalities. Tissue-based next generation sequencing (NGS) is often limited by tumor insufficiency and slow turn-around time. Plasma-based circulating tumor DNA (ctDNA) NGS overcomes these barriers and has been widely adopted across advanced-stage solid tumors. To date, plasma-based NGS characterization of genomic alterations in TC has not been determined. Herein, we profile potential actionable mutations detected via ctDNA in patients with advanced TC subtypes. **Methods:** A retrospective analysis of Guardant Health, Inc database was performed using the commercially available Guardant360 plasma-NGS test on advanced metastatic TC samples collected between 2016 and 2021. Patients with papillary TC (PTC), follicular TC (FTC), poorly differentiated TC (PDTC), medullary TC (MTC), and anaplastic TC (ATC) were clustered into four groups (G1: ATC, G2: PTC, FTC, and PDTC, G3: MTC, and G4: unspecified TC). The landscape of genetic alterations, frequencies of alterations in clinically relevant genes, and tumor mutation burden (TMB) were analyzed. **Results:** Of the 1,108 patients included, 47.1% were male. The median age was 65 years old (range 13-98), and 0.18% (n = 5) patients were under 18 years old. Alteration frequencies of selected, clinically relevant genes are demonstrated in the table below. TMB analysis was performed on 315 samples, and the mean TMB was higher in G1 compared to G2, G3, and G4 ($p= 0.0029$, 0.0826, and 0.0112, respectively). **Conclusions:** Plasma-based comprehensive NGS by Guardant360 may be utilized in patients with advanced metastatic TC for detecting clinically relevant genetic alterations for the selection of available targeted therapies, immunotherapy, or determination of the clinical trial eligibility. Future validation of the clinical utility by analysis of paired tumor and plasma samples is warranted. Research Sponsor: None.

Identification of markers for tumor- and immune-derived extracellular vesicles (EVs) in preclinical models. *First Author: Dove-Anna Johnson, NIH, Bethesda, MD*

Background: Extracellular Vesicles (EV) are of broad interest as carriers of molecular signatures of tumor progression and cancer treatment response. EVs, which contain nucleic acids, lipids, and proteins, are released from cells for waste excretion and communication. Numerous proteins and markers are expressed within and on the surface of EVs, but classification markers for murine EV subsets are lacking. To identify tumor and dendritic cell- derived EV markers for preclinical models of breast cancer, we investigated surface marker repertoires of EVs produced by the murine breast cancer and dendritic cell lines, 4T1 and DC2.4. **Methods:** Cells were cultured in serum free media for 2 days. EVs were harvested and isolated by ultrafiltration followed by size exclusion chromatography. EV particle size and concentration were estimated by nanoparticle tracking analysis and microBCA. To identify highly expressed EV markers, a mouse EV multiplex flow cytometry assay was performed using detection antibodies, CD9, CD63, and CD81, with sets of >35 barcoded capture beads, representing more than 100 specific capture: detection combinations. EV marker expression was analyzed using the FCM_{PASS}/MPA_{PASS} software (nano.ccr.cancer.gov). > 250 beads were assessed for each capture- and detection- antibody combination for each EV type and dilution tested; mean fluorescent intensity was determined; and pairwise comparisons between test and control sample sets were evaluated by t-tests. **Results:** Breast cancer (4T1)-derived EVs but not dendritic cell (DC2.4)-derived EVs were strongly detected with CD326 (EpCAM) and CD49b (integrin alpha5, VLA-2) capture beads, using each of the three tetraspanin antibodies. Both types of EVs were detected with anti-CD9 and anti-CD81 when captured by anti-CD44 and anti-CD49e (integrin beta1, VLA-5) beads. DC2.4 EVs were distinctively identified by CD11b capture. CD63 capture and detection antibodies robustly recognized EVs from 4T1 but provided minimal recognition of DC2.4 EVs. Mouse serum EVs from non-tumor bearing mice, showed minimal or no detectable CD326 or CD11b. **Conclusions:** Multiparametric MPA_{PASS}-processed EV repertoire analysis of EVs from murine breast cancer and dendritic cell lines identified CD9, CD81, CD44, and CD49e as common epitopes among both types of evaluated EVs. CD326, CD49b, and CD63 distinguished 4T1 from DC2.4 EVs, and CD11b distinctively identified the DC2.4 EVs. The absence of detected CD326+ and CD11b+ in the serum of non-tumor bearing mice indicates the potential of these two markers for detection of specific tumor and antigen presenting cell EV subsets in serum from mice bearing CD326+ tumors such as 4T1. These results establish a foundation for further tests of detection and tracking of tumor-specific CD326+ EVs as "liquid biopsies" in blood samples as correlates to tumor progression and/or response to treatment. Research Sponsor: U.S. National Institutes of Health.

Cell-free RNA in liquid biopsy and biomarkers profiling of hematologic and solid tumors. *First Author: Maher Albitar, Genomic Testing Cooperative, Irvine, CA*

Background: Expressed RNA can capture mutations, changes in expression levels due to methylation, and provide information on cell of origin, growth, and proliferation status. We developed an approach to isolate fragmented RNA from peripheral blood plasma and explored its potential to be used in liquid biopsy. **Methods:** Peripheral blood cfRNA was extracted from patients with neoplasms in B-cell (#105), T-cell (#16), Myeloid (#73), and from solid tumors (#44), Normal individuals (#51), and reactive post-transplant (#137). RNA was sequenced using a 1459-gene panel. Expression profile was generated using Cufflinks. **Results:** cfRNA levels of various solid tumor biomarkers (CA-125, CA-15-3, CEA 8, Keratin19, Keratin6A...) were significantly higher ($P < 0.0001$) in samples from solid tumors as compared with normal control. Similarly, cfRNA lymphoid markers (CD19, CD22, CD79A, and CD79B...) and cfRNA myeloid markers (CD33, CD14, CD117, CD56...) were all higher in B-cell lymphoid neoplasms and myeloid neoplasms, respectively ($P < 0.0001$), as compared with control. In evaluating the host immune system, cfRNA CD4:CD8B and CD3D:CD19 ratios in normal controls were as expected (median: 5.92 and 6.87, respectively) and were significantly lower in solid tumors (median 3.40 and 2.23, respectively, $P < 0.0002$). Solid tumor cfRNA showed CTLA4:CD8B ratio significantly higher in tumors than in normal (median 0.74 vs 0.19, $P = 0.0001$), while there was no difference in cfRNA PD-L1:CD8B ratio (median 1.45 vs 1.77, $P = 0.96$). Similar distinct patterns are noted for various cytokine and chemokines. cfRNA was highly predictive of diagnosis (AUC > 0.98) of solid tumors, B-cell lymphoid neoplasms, T-cell lymphoid neoplasms, and myeloid neoplasms as compared with normal control. When a specific neoplastic disease was considered against all cases including control and other neoplasms, the AUC varied between 0.77 and 0.949. **Conclusions:** This data shows that liquid biopsy using targeted sequencing of cfRNA in patients with various types of cancer provides comprehensive and reliable information on the neoplastic disease as well as the host. Research Sponsor: None.

Combining cell-free RNA (cfRNA) with cell-free total nucleic acid (cfTNA) as a new paradigm for liquid biopsy. *First Author: Maher Albitar, Genomic Testing Cooperative, Irvine, CA*

Background: Expressed RNA can capture mutations, gene fusions, and biomarker profiles. In principle, each abnormal cell has one copy of mutated gene, but numerous copies of mutated RNA. Cell-free RNA (cfRNA) is not used due to the assumption that it is degraded. Next Generation Sequencing (NGS) by design is particularly adaptable for fragmented DNA and RNA. We developed an approach to isolate cell-free total nucleic acid (cfTNA) and cell-free RNA (cfRNA) from peripheral blood. Using targeted sequencing, we explored the potential of this approach to detect mutations, fusion mRNA, and copy number variation (CNV) in solid tumors and hematologic neoplasms. **Methods:** Peripheral blood cfTNA and cfRNA were extracted from B-cell lymphoid neoplasms (#105), T-cell neoplasms (#16), Myeloid neoplasms (#73), solid tumors (#44), and Normal individuals (#51), and sequenced using a targeted panel of 1459 genes. **Results:** Numbers of mutations detected in solid tumors and hematologic neoplasms were significantly ($P > 0.0001$) higher in cfRNA (No. = 1229) than in cfTNA (No. = 1004). Overall variant allele frequency (VAF) was significantly higher in cfRNA than in cfTNA ($P < 0.0001$). However, numerous mutations detected by RNA were not detected by cfTNA and vice versa. In general, nonsense mutations were more likely to be detected by cfTNA than by cfRNA and at higher VAF. Low-level mutations (VAF < 10%) were more likely to be detected by cfRNA than by cfTNA. For example, 136 mutations in TP53 gene were detected using cfRNA and only 70 mutations were detected in cfTNA. KRAS mutations were also higher in cfRNA (#33) as compared with cfTNA (#21). In contrast, when most of the mutations were nonsense, as in ASXL1 gene, more mutations were detected by cfTNA (24 vs 23). When mutations were detected in both cfRNA and cfTNA, mutation load (level of mutant copies) was overall slightly higher in cfTNA ($P = 0.06$), likely due to higher degradation of RNA, but varied significantly dependent on the type of mutated gene and type of mutation. cfRNA was reliable in detecting fusion transcripts in solid tumors and in hematologic neoplasms (SLC34A2-ROS1, DDX5-BCL6, ETV6-RUNX1, RUNX1T1-RUNX1, PML-RARA, RUNX1-ZFPM2, DEK-NUP214, EP300-ZNF384) irrespective of the breakpoint or partner gene. The cfTNA detected various CNVs expected by cytogenetic analysis when tumor fraction was adequate (VAF > 10%). **Conclusions:** This data demonstrates that using cfRNA and cfTNA provides complementary comprehensive information for evaluating mutations, fusion genes, and CNV. This approach increased sensitivity and reliability of liquid biopsy. Furthermore, the cfRNA provides critical information on relative expression of various genes that can be used as biomarkers in characterizing the neoplastic process (see ASCO abstract, Liquid Biopsy Based on Cell-Free RNA and Biomarkers profiling of hematologic and solid tumors). Serum concentrations of oncometabolite, 2-hydroxyglutarate (2HG), as biomarkers for isocitrate dehydrogenase *(IDH1/2)* mutations in cholangiocarcinoma (ICCA). *First Author: Cha Len Lee, Department of Medical Oncology and Haematology, Toronto, ON, Canada*

Background: Mutations in IDH1/2 genes are common in low-grade glioma (GM) and occur in approximately 20% of intrahepatic cholangiocarcinoma (ICCA). Mutant IDHs leads to preferential accumulation of the R-relative (R2HG) to the S-enantiomer (S2HG) of 2HG. We investigated the utility of circulating R2HG, total R2HG+S2HG (tRS) and ratio of R2HG/S2HG (rRS) as biomarkers in GM and ICCA patients (pts). **Methods:** Blood and tumor tissues samples were obtained from pts with IDH1/2-mutant GM and ICCA. IDH mutation was confirmed by either immunohistochemistry (GM pts) or next generation sequencing (ICCA pts). Samples were analyzed for S2HG and R2HG using a validated HPLC tandem mass spectrometry method. Tissue and serum R2HG, tRS and rRS were compared with paired t-tests for GM pts. Serum S2HG, R2HG, tRS and rRS were compared with unpaired t-tests between GM and ICCA pts. A $p<0.05$ was considered statistically significant. **Results:** Blood and tumor samples were collected from 21 pts (GM = 11, ICCA=10). Tumor tissues were insufficient for analysis in 1 GM and 8 ICCA pts. Tissue S2HG, R2HG, tRS, and rRS were 0.72±0.68 ng/g, 48.92±58.92 ng/g, 66.87±80.35 ng/g and 55.77±36.23 for GM pts. There were no differences in R2HG and tRS between tissue and serum samples, while S2HG was significantly higher in serum samples ($p = 0.001$) and rRS was significantly higher in tissue samples for GM pts ($p = 0.01$). rRS were 144.8 and 244.9 respectively in 2 ICCA pts with sufficient tissues. There was no difference in serum S2HG between GM and ICCA pts. However, serum R2HG, tRS and rRS were significantly higher in ICCA pts. **Conclusions:** In *IDH1/2* mutant GM and ICCA pts, R2HG was increased relative to S2HG in tumor tissues. In GM pts, the accumulation of R2HG in tumor tissues was not reflected in blood, likely due to the inability of 2HG to diffuse across the blood-brain barrier. Serum R2HG, tRS and rRS were significantly elevated in ICCA pts. These biomarkers have no clinical utilities in GM pts. However, they can potentially be used to identify IDH mutations in ICCA pts, especially given the inability to obtain tumor tissue in some ICCA pts. Clinical trial information: NCT03991832. Research Sponsor: University Health Network, Toronto.

Comparison of S2HG, R2HG, tRS, and rRS in the serum of IDH1/2-mutant ICCA vs. GM pts. SD = standard deviation.

Biomarkers	IDH-mutant ICCA (n = 10)	IDH-mutant GM (n = 11)	p-value
Serum S2HG (SD) (ng/mL)	81.5 ± 48.9	60.8 ± 39.1	0.29
Serum R2HG (SD) (ng/mL)	461.9 ± 397.4	55.0 ± 20.0	0.003
Serum tRS (SD) (ng/mL	543.4 ± 392.7	115.9 ± 54.7	0.002
Serum rRS	7.70 ± 8.58	1.08 ± 0.48	0.02

A circulating miRNA-based AI prediction system to identify multiple types of cancer. *First Author: Chih-Hsun Wu, Artificial Intelligence and E-Learning Center, National Chengchi University, Taipei City, Taiwan*

Background: Cancer is a major problem for human health. Development of an early diagnostic tool can increase the survival of cancer patients. Liquid biopsies have many advantages over traditional tumor tissue biopsies. Circulating microRNAs (miRNAs) are one type of liquid biopsies in part because they regulate the expression and thus functions of their target genes. Circulating miRNAs are stable, non-invasive and changes in their expression are detectable in the early stage of cancer progression, often before clear evidence of tissue biopsy/image tests. To date, there are few liquid biopsy-based tools for multiple-cancer diagnosis and their performance is unsatisfactory. The development of a non-invasive, effective early detection system for cancers is urgently needed. **Methods:** We integrated and investigated circulating miRNA expression data of 5046 non-cancer samples along with 3856 cancer samples of 6 major cancer types downloaded from publicly available databases. We used these expression data along with gender to establish a multiple cancer type AI prediction system. Furthermore, we built comprehensive interaction networks (miRNA-drug, miRNA-target gene) and performed functional enrichment analysis. **Results:** We constructed high-performance AI prediction model that can detect and differentiate 6 cancer groups from one non-cancer group. A median of sensitivity of 93.84% in test data was achieved for the multiple cancer classification task. A panel of gender and 15 most important circulating miRNAs was further shown to achieve excellent performance (sensitivity = 90.44%), with just a bit of decrease in the sensitivity of using the full set (gender and 2565 miRNAs). The 15 key circulating miRNAs worked well for the early stage (stage 1: sensitivity = 88%), much better than other liquid-biopsy results reported in the literature. This is important because these miRNAs and the AI system can be used to significantly decrease clinical cost and increase efficiency of early diagnosis, not to mention it is non-invasive. Finally, we constructed comprehensive interaction networks (drug/ target gene) for these key miRNAs to explore potential therapeutic strategies and understand the underlying biological mechanisms. **Conclusions:** In the study, we constructed the multiple-cancer prediction AI system to classify groups of normal individuals and cancer patients of multiple types, while finding key circulating miRNAs. As several key circulating miRNAs were shown to be potential drug targets or serve as diagnosis biomarkers to fulfill the aim of cancer precision medicine, this work represents a significant step toward achieving the goal of developing a non-invasive tool for early diagnosis of cancers. Circulating tumor DNA (ctDNA) in HER2 exon 20 insertion mutations and responses in NSCLC HER2 exon 20 insertion treated with poziotinib. *First Author: Arunthi Thiagalingam, Spectrum Pharmaceuticals, Boston, MA*

Background: ctDNA levels in plasma samples permits temporal assessment of tumor mutational status and tumor burden during therapy. Poziotinib is an oral HER2 TKI in development for NSCLC patients harboring HER2 exon 20 insertion mutations. We assessed serial plasma samples for changes in HER2 exon 20 insertion mutations and other driver mutations in first- and second-line patients comparing to clinical response per RECIST1.1. **Methods:** NSCLC patients harboring HER2 exon 20 insertion mutations were enrolled into the poziotinib ZENITH20 using tumor tissue based NGS. Serial plasma samples were collected at baseline, at C3D1, at Day 1 of every other cycle until disease progression. The Guardant360[a] 74-gene liquid biopsy assay was used to assess changes in tumor-associated somatic variants including the target variant HER2 exon20 insertion as well as other emergent driver mutations in ctDNA as expressed as percent variant allele frequency (%VAF). **Results:** 23 first- and second-line NSCLC patients were evaluable with tumor tissue confirmation of HER2 exon 20 insertion mutations. 22 of 23 (96%) had baseline plasma samples with detectable ctDNA. 21 of 22 samples had detectable HER2 exon 20 insertion mutations (mean % VAF 20±5) resulting in a concordance of 95% versus tissue based NGS. 7 patients had serial testing through C7D1 permitting assessment of ctDNA dynamics and comparison to clinical responses. 5 of 7 (71%) serially tested patients treated with poziotinib at 16mg QD had undetectable HER2 exon 20 insertion at C3D1 which was associated with a tumor response PR. Tumor escape (PD) was observed in 2 of the 5 patients which correlated with increases in target HER2 exon 20 insertion VAF in the plasma with the remaining 3 patients ≥PR. Notably, the rise in HER2 exon 20 in ctDNA occurred prior to tumor escape. In one patient treated with poziotinib at 16 mg QD we observed undetectable levels of the HER2 exon 20 insertion in ctDNA at C3D1 which continued through C16. This patient's responses correlated with patient tumor response of SD at C2 which then became PR through C9 and CR through C17. **Conclusions:** Poziotinib treatment resulted in reductions in HER2 exon 20 insertion mutations in ctDNA preceded and correlated with the clinical tumor response. Increases in ctDNA HER2 exon 20 insertion mutations were observed prior to confirmation of tumor escape. Serial monitoring of ctDNA is a potential predictive biomarker for treatment response and disease progression. Future evaluation in a larger population is required to confirm the impact of these findings. Research Sponsor: Spectrum Pharmaceuticals Inc.

PD-L1 is overexpressed on tumorspheres cultured from circulating cancer stem cells in patients with breast cancer. *First Author: Monika Pizon, Transfusion Center Bayreuth, Bayreuth, Germany*

Background: Circulating cancer cells, and in particular their very rare subpopulation, circulating cancer stem cells (cCSCs), are responsible for recurrence and metastasis. The exact role of cCSCs in escape of cancer from immunosurveillance is still unknown, but recent studies revealed that enhanced PDL-1 expression in cancer stem cells is linked to immune evasion and could crucially contribute to the maintenance of CSC self-renewal. Understanding the mechanisms behind this PDL-1 overexpression in cancer stem cells is critical for developing more effective anti-PD-1/PD-L1 therapy. Therefore the aim of the study was to determine the number of tumorspheres and expression of PD-L1 on tumorspheres cultured from cCSC in breast cancer patients. **Methods:** 110 patients with breast cancer in different stages of disease were included in this study. The determination of circulating cancer stem cells was performed using the sphere-forming assay. Additionally anti-PDL-1 antibody staining was applied to examine PDL-1 expression on breast tumorspheres. **Results:** We have developed an innovative *in vitro* platform for detection of cCSCs from peripheral blood of cancer patients. The number of tumorspheres increased significantly with tumor progression and aggressiveness of primary tumor. Patients with metastatic disease had statistically more tumorspheres as compared to patients without metastasis (30 vs 10/100µl blood, $p < 0.05$). Patients with multiple metastasis had more tumorspheres compared to patients with single metastases (60 vs 30/100µl blood, $p < 0.05$). The number of tumorspheres was positively correlated with Ki-67, Her2 status and grade score in primary breast tumors. We observed high PDL-1 expression and their considerable heterogeneity in enriched tumorspheres. **Conclusions:** The number of tumorspheres cultured from peripheral blood directly reflects aggressiveness and proliferation capacity of primary tumor. The presence of tumorspheres with expression of PDL-1 might suggest their immunregulatory potential. Better understanding of the interaction between cCSCs and tumor immunology may help to identify strategies to eradicate the minor subpopulation that escapes conventional therapy attack, thus providing a solution to the problem of drug resistance and metastasis. Prospective characterization of circulating tumor cell kinetics in patients treated with radiation therapy per definitive intent oligometastatic paradigm. *First Author: Shivani Sud, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Definitive intent oligometastatic paradigm describes a state with limited metastatic sites amenable to comprehensive radiation therapy (RT). We characterized circulating tumor cell (CTC) kinetics in response to definitive RT among patients with oligometastatic cancer and identify a CTC kinetic profile associated with progression free survival (PFS). **Methods:** In this single-institution prospective correlative biomarker study, we enrolled patients with any solid malignancy, ≤ 5 metastatic sites in ≤3 anatomic organ systems undergoing definitive intent RT to all disease sites. Blood specimens were collected prior to RT (baseline), during RT and at follow up visits up to 24 months post RT. Additional lines of therapy were administered per standard of care. CTCs were captured and enumerated using a previously reported nanotechnology-based assay functionalized with aEpCAM, aHER-2, and aEGFR to facilitate biomimetic cell rolling and dendrimer-mediated multivalent binding. Disease status was assessed per RECIST 1.1 criteria. On exploratory analysis disease status was correlated with CTCs as a continuous and ordinal variable (cut-point upper bound of the 3rd quartile). A favorable CTC clearance profile was defined as a decrease in CTC count between pre-treatment and end of treatment - an unfavorable CTC clearance profile was defined as the opposite. **Results:** We enrolled 43 patients with median follow up of 14.3 months corresponding to 255 CTC measurements. Median baseline CTC count was 28 CTCs/ml (range 0.17-1085). Thirty four patients (79%) received stereotactic body radiation therapy. On Wilcoxon signed-rank test there was no association between pre-treatment CTC count and number of disease sites (median 1 metastatic site/patient, range 1-5) nor metastases site (bone, brain, visceral), $p > 0.05$. Thirty one patients (72%) experienced local or systemic progression at subsequent time points. For 90% of patients, a CTC count <15/ml < 100 days post-RT corresponded to durable local control of irradiated lesions. Patients with a favorable versus unfavorable clearance profile had significantly longer PFS (median 13 vs 4 months, log rank test, $p = 0.0011$). During the post-RT period 24 patients (56%) went on to receive systemic therapy (cytotoxic chemotherapy, hormone therapy, immunotherapy, kinase inhibitors). On logistic regression, CTC > 15/ml at a given time point was associated with clinical disease progression within the subsequent 6 months (odds ratio 3.31, $p = 0.007$). An increase in CTCs to > 15/ml preceded radiographic or biochemical progression in 8 of 31 (26%) of patients experiencing disease progression. **Conclusions:** Our data suggests CTCs may serve as a biomarker for disease control in oligometastatic disease and may predict disease progression prior to standard assessments for patients receiving diverse therapies. Clinical trial information: NCT03161821. Research Sponsor: None.

Monitoring engorgement of phagocytic circulating stromal cells during chemo-radiotherapy induction predicts survival in unresectable stage 2/3 NSCLC. *First Author: Kirby P Gardner, Creatv MicroTech, Inc., Monmouth Junction, NJ*

Background: Circulating stromal cells, ie Cancer Associated Macrophage-Like cells (CAMLs), are prevalent in the circulation of non-small cell lung carcinoma (NSCLC) patients (pts), appearing as giant phagocytic macrophages that represent an inflammatory pro-tumorigenic microenvironment. Previously it was shown that pts with engorged CAMLs of ≥50µm after treatment are prognostic for poor clinical outcomes. However, analyzing the dynamic changes in CAMLs over time or in response to treatment, ie chemoradiation (CRT) and immunotherapy (IMT) has not been evaluated. We monitored n = 182 unresectable NSCLC stage II/III pts treated with CRT alone (n = 91) or with concurrent IMT (n = 91) to evaluate changes in CAMLs before and after CRT induction at it relates to progression free survival (PFS) or overall survival (OS). **Methods:** We prospectively procured pts from 3 different regimes, treated with CRT alone (n = 91), treated concurrently with CRT & Atezolizumab (n = 40, clinical trial NCT02525757), or treated concurrently with Durvalumab (n = 51). We recruited 182 pts with pathologically confirmed stage II/III unresectable NSCLC. A total of 15 mL blood samples were drawn prior to start of therapy at baseline (BL) and ~5 weeks (T1) after CRT induction. Blood filtration was done using CellSieve filters, then CAMLs were identified and measured to evaluate PFS & OS hazard ratios (HRs) by censored univariate and multivariate analyses at 2 years. **Results:** CAMLs were found in 89% of all samples tested. Increases in CAML size between BL & T1 were significantly correlated with worse clinical outcomes, with higher CAML increases correlated with increasingly worse outcomes, including CAML increases >10μm resulting in PFS HR=1.7 $p = 0.027$ & OS HR=1.9 $p = 0.045$, through increases >40μm resulting in PFS HR=2.1 $p = 0.013$ & OS HR=2.5 $p = 0.020$. Increases of CAMLs >35μm was optimal at stratifying pts PFS HR=2.2 $p = 0.005$ & OS HR=2.8 $p = 0.005$. Specifically, pts treated with only CRT and increasing CAMLs >35μmhad significantly worse PFS HR=2.7 $p = 0.029$ & OS HR=4.1 $p = 0.013$. In parallel, pts treated with CRT+IMT and increasing CAMLs >35μm had near significance for worse PFS (HR=2.1 $p = 0.073$) & OS (HR=2.3, $p = 0.147$), though follow up clinical data is ongoing. **Conclusions:** Our data suggest that in unresectable stage II/III NSCLC, tracking the increase of pro inflammatory immune cells (CAMLs) in circulation during therapy induction can identify pts less responsive to CRT or PD-L1/PD-1 IMTs. Defining resistance mechanisms to CDK4/6 inhibition in hormone receptor-positive HER2-negative metastatic breast cancer (MBC) through a machine learning approach applied to circulating tumor DNA (ctDNA). *First Author: Lorenzo Gerratana, Department of Medical Oncology, Centro di Riferimento Oncologico di Aviano (CRO), IRCCS, Aviano, Italy*

Background: Although cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) are a primary treatment for hormone receptor-positive/HER2 negative MBC, data regarding resistance mechanisms are still an unmet need. The aim of the study was to highlight new resistance pathways using machine learning (ML) to detect multiparametric patterns in complex datasets. **Methods:** The study retrospectively analyzed a cohort of 610 hormone receptor positive HER2 negative MBC patients (pts) at Northwestern University, Massachusetts General Hospital and Washington University in St. Louis between 2015-2020 with baseline ctDNA testing by Guardant360. Pathways were defined based on previous work (Sanchez-Vega F et al, Cell. 2018) (i.e., RTK, RAS, RAF, MEK, NRF2, ER, WNT, MYC, P53, cell cycle, notch, PI3K). Only pathogenic variants according to OncoKB were included in the models. Associations among single nucleotide (SNVs) and copy number (CNVs) variations, pathway classification and previous exposure to CDK4/6i were explored through logistic regression and Gradient boosted machines (GBMs) ML algorithm. **Results:** at baseline, 322 pts (52.8%) were previously treated with CDK4/6i. The most detected pathway alterations were SNVs in PI3K (37.1%), P53 (31.8%), ER (29.2%) and RTK (22.3%). After stepwise logistic regression, RB1, NF1 and ESR1 SNVs were associated with previous exposure to CDK4/6i (respectively OR: 3.55 $P = 0.017$; OR: 3.06 $P = 0.026$ and OR: 1.82 $P < 0.001$), while SNVs in the ER pathway were associated with CDK4/6i (1.56 $P < 0.001$). Two GBMs models were designed based on gene variants (training AUC: 0.695, cross validation AUC: 0.631) and oncogenic pathways (training AUC: 0.713, cross validation AUC: 0.619). The highest relative importance (RI) was observed for ESR1 SNVs (RI: 35.35), TP53 SNVs (RI: 11.33), NF1 SNVs (RI: 3.45), SMAD4 SNVs (RI: 3.39) and RB1 SNVs (RI: 3.33). Alterations at a pathway level with the highest RI were ER SNVs (RI: 33.50), P53 SNVs (RI: 14.98), PI3K SNVs (RI: 14.40), RTK SNVs (RI: 10.55), RTK CNVs (RI: 10.26), cell cycle CNVs (RI: 6.99), cell cycle SNVs (RI: 6.77) and RAS SNVs (RI: 6.54). Of the previously highlighted pathway alterations, a significant impact on PFS after ctDNA collection was observed among *de novo* pts treated with CDK4/6i (165 pts) for ER SNVs ($P < 0.0001$), RTK SNVs ($P = 0.0011$), RTK CNVs ($P = 0.0006$), Cell cycle CNVs ($P = 0.0010$) and Cell cycle SNVs ($P = 0.0143$). No impact was observed on PFS for pts who had not received a CDK4/6i-based regimen. **Conclusions:** The combination of ctDNA-based datasets and machine learning algorithms defined novel resistance pathways for patients treated with CDK4/6i. Although preliminary, these results suggest that alterations of the ER, RTK and Cell cycle pathways might be crucial to optimize treatment strategy and drug development. Research Sponsor: Lynn Sage Breast Cancer Foundation.

Tracking changes in circulating stromal cells and circulating tumor cells predicts responsiveness of new line induction in metastatic breast cancer after 1 cycle of therapy. *First Author: Daniel L Adams, Creatv MicroTech, Inc., Monmouth Junction, NJ*

Background: In metastatic Breast Cancer (mBC), Circulating Tumor Cells (CTCs) are established prognostic indicators of patients (pts) not responding to new lines of therapy and who have poor clinical outcomes. However, CTCs are typically found in < 20% of mBC pts and many pts without CTCs will also progress. Recently an inflammatory pro-tumorigenic macrophage emanating from tumor stroma (i.e. Cancer associated macrophage-like cell [CAML]) was found in > 90% of mBC pts and were also indicative of poor clinical outcomes. As CTCs & CAMLs are isolated in conjunction from a single blood sample, and both are prognostic for therapy response, we evaluated CTCs & CAMLs before and after initiation of new therapies in mBC to determine their combined prognostic/predictive values. **Methods:** An observational prospective 2-year multi-institutional study was undertaken to evaluate CTCs & CAMLs before, and after, induction of any new line of therapy in pts with diagnosed mBC (n = 101). Anonymized and blinded blood samples were taken at baseline (BL), prior to starting a new systemic therapy, and a 2nd sample (T1) taken after therapy initiation (~30 days). Blood was filtered by CellSieve filtration. The quantities and subtypes of CTCs & CAMLs were analyzed based on RECIST v1.1 for progression-free survival (PFS) and overall survival (OS) hazard ratios (HRs) by censored univariate & multivariate analysis at 2 years. **Results:** CTCs were identified in 35% (n = 35/101) of pts at BL & 24% (n = 24/101) at T1, with a single CTC at T1 being highly prognostic for worse PFS HR = 6.2 95%CI 3.0-13.2, p < 0.001 & OS (HR = 5.1 95%CI 2.0-13.4, p = 0.002. In parallel, CAMLs were found in 93% of BL and 86% of T1 samples, and whose decreases were significantly prognostic for improved PFS (HR = 2.7, 95%CI 1.4-5.1, p = 0.006) and OS (HR = 4.4 95%CI 1.5-13.2, p = 0.018) when CTCs were absent. Overall ≥1 CTC at T1 (n = 24) had median PFS = 2.4 & mOS = 4.8 months (mos), however, in pts without CTCs plus an increase in CAMLs (n = 36) had mPFS = 5.9 & mOS = 14.1 mos, while in pts without CTCs plus a decrease in CAMLs (n = 41) had mPFS = 14.8 & mOS = 18.8 mos. **Conclusions:** Our data confirms that pts with persistent CTCs have the worst clinical outcomes. Further, simultaneous CAML quantification provided a new dynamic predictive blood based biomarker in pts without detectable CTCs which may be useful to better individualize therapy and improve outcomes, though future studies are need to validate these findings. Resolution ctDx FIRST plasma assay as a companion diagnostic for adagrasib and its application to longitudinal monitoring. *First Author: Ira Pekker, Resolution Bioscience, Inc., Kirkland, WA*

Background: KRAS is one of the most commonly mutated oncogenes in cancer. There is a significant need for new treatment options for patients with non–small cell lung cancer (NSCLC) harboring the *KRAS* G12C mutation. Adagrasib is an investigational, highly selective, oral small molecule inhibitor of KRAS G12C that has demonstrated clinical benefit in patients with *KRAS G12C*–mutant NSCLC and CRC. Detection of KRAS G12C in cfDNA is minimally invasive and is of benefit to NSCLC patients, many without lesions accessible by tissue biopsy testing. **Methods:** Resolution ctDx FIRST is a 113 gene comprehensive genomic profiling assay that identifies oncogenic alterations including substitutions, insertions, deletions, gene fusions, and homozygous deletions using targeted NGS sequencing of cfDNA. The Resolution ctDx FIRST assay is being developed as a companion diagnostic for adagrasib in NSCLC patients of the Mirati Study 849-001. **Results:** The LOD95 for SNVs and indels in KRAS and EGFR at a cfDNA input level of 15ng ranged from 0.34% to 0.82%. No false positives were detected in any samples from healthy donors (N = 60). A total of 230 NSCLC plasma samples were orthogonally tested using a ddPCR assay for *KRAS* G12C, using 76 plasma samples from Study 849-001 where KRAS G12C positive results had previously been obtained by a tissue assay, and 154 commercially procured NSCLC samples representative of the trial population. The PPA and NPA for Resolution ctDx FIRST plasma testing relative to ddPCR assay (95% CI) were 87.0% (75.1–94.6%) and 97.6% (94.1–99.4%) respectively. Of 112 Study 849-001 patients, 71 (63.4%) were tested for KRAS G12C mutations with Resolution ctDx FIRST in pretreatment plasma samples. Seventy-four commercially procured matched tissue and plasma samples were tested by Resolution ctDx FIRST and tissue assay. The PPA and NPA for Resolution ctDx FIRST plasma testing relative to tissue assay (95% CI) were 66.2% (54.0-77.0%) and 100% (94.7-100%) respectively. The detection of *EGFR* variants in the Resolution ctDx FIRST assay was compared to results from a ddPCR assay for each variant. A total of 165 NSCLC plasma samples generated a total of 317 comparative valid results. PPA was 100% for EGFR L858R, 88.9% for EGFR T790M, and 91.3% for EGFR Exon 19 Deletions. NPA was 97.8% for EGFR L858R, 100% for EGFR T790M, and 100% for EGFR Exon 19 Deletions. Application of the assay in longitudinally collected NSCLC and CRC patient samples will be presented highlighting changes of VAF over time including identification of oncogenes involved in emerging resistance. **Conclusions:** The Resolution ctDx FIRST assay offers highly sensitive, specific, and robust test results, and meets analytical requirements for clinical applications. Research Sponsor: Mirati Therapeutics, Inc.

Variant	LoD95 (%MAF)	95% CI (%MAF)
KRAS G12C	0.50%	0.379%, 0.667%
EGFR exon 19 deletions	0.34%	0.241%, 0.476%
EGFR L858R	0.38%	0.289%, 0.493%
EGFR T790M	0.82%	0.680%, 0.989%

T-cell receptor repertoire analysis based on RNA sequencing data from tumor cells and tumor-infiltrating lymphocytes. *First Author: Cheng Du, Department of oncology, General Hospital of Northern Theater Command, Shenyang, China*

Background: T-cell receptor (TCR) repertoire has been thought to be indicative in cancer progression and treatment response. Previous methods mainly focused on peripheral blood or fresh tumor tissue, which were sometimes logistically limited in clinical settings. Tumor-infiltrating lymphocytes (TILs), which harbored TCR characteristics, were also mingled with tumor cells (TCs), which brought hurdles in extracting TCR signals from bulk RNA sequencing data. Here we employed a set of RNA sequencing data from paired FFPE tumor samples and their micro-dissected TILs, to analyze and compare the TCR features in tumor cells and TILs. **Methods:** RNA sequencing data of 14 tumor cell samples and matched TILs were downloaded from NCBI-SRA (accession: PRJEB36554). Raw data were cleaned up by Trim Galore (v0.6.2). TCR clonotypes were assembled and quantified from clean fastq files by MiXCR (v3.0.4). Diversity and clonality metrics were analyzed using VDJtools (v1.2.1) and in-house Pearl scripts. **Results:** The median mapping rates of sequencing reads to TCR regions were 0.29% and 1.80% for TCs and TILs respectively (p = 0.00051). TCR diversity of TCs and TILs was characterized by Shannon and Simpson index respectively. The median Shannon index was 1.889 and 2.694 in TCs and TILs (p = 0.00034, unpaired Wilcoxon rank-sum test); the median Simpson index was 0.8724 and 0.9420 in TCs and TILs (p = 0.0058). **Conclusions:** RNA isolated from clinical FFPE samples could be used for TCR analysis. Micro-dissection of TILs could enhance TCR signals of unprocessed tumor tissues. Research Sponsor: None.

Imaging of solid tumors using 68Ga-FAP-2286. *First Author: Thomas A. Hope, University of California, San Francisco, San Francisco, CA*

Background: Fibroblast Activation Protein (FAP) is a transmembrane protein overexpressed on cancer associated fibroblasts (CAFs), and is abundantly present in many epithelial cancers, suggesting FAP is an attractive imaging and therapeutic target. FAP-2286 is a cyclic peptide that binds to FAP and is currently being evaluated as a radioligand therapy to treat patients (pts) with FAP-positive solid tumors. The role of 68Ga-FAP-2286 as a diagnostic agent is unknown. We present an interim analysis of the ability of 68Ga-FAP-2286 to detect metastatic disease across multiple cancer types. **Methods:** This is a first in human Phase I/II study of 68Ga-FAP-2286 (NCT04621435) with a planned total enrollment of 65 pts across 3 cohorts: dosimetry cohort (n = 5), cohort with RECIST measurable disease (n = 30) and a cohort at risk for metastases without measurable disease (n = 30). By the cutoff date of February 12, 2022, 27 pts were enrolled (3 in cohort 1, 15 in cohort 2 and 9 in cohort 3). For each pt, the five largest lesions were included for analysis, and for each lesion, the maximum standardized uptake value (SUVmax) of the 68Ga-FAP-2286 and the size (short axis for lymph nodes) were documented. In pts who had an available FDG PET performed within 8 weeks of 68Ga-FAP-2286 PET, uptake on the two scans was compared. **Results:** Of the 27 enrolled pts, 9 had bladder cancer, 5 sarcoma, 4 head and neck squamous cell cancer (HNSCCA), 3 breast cancer (BC), and 3 castration resistant prostate cancer (CRPC). Most pts (89%, 24/27) had tumors positive for uptake on 68Ga-FAP-2286 PET, including 30 lesions < 1.5 cm, and 17 less than 1.0 cm. 16 pts had a paired FDG PET. In these pts, the average SUVmax on 68Ga-FAP-2286 PET was 244% higher than on FDG PET. Only two pts had higher uptake on FDG PET than on 68Ga-FAP-2286 PET (HNSCCA and DSRCT). The highest relative uptake was seen in 2 pts with BC (both 3.4 times higher on 68Ga-FAP-2286 PET); the average SUVmax in BC was 16.6. The lowest uptake on 68Ga-FAP-2286 PET was CRPC with an average SUVmax of 7.0. Sarcoma had variable uptake with one pt having an SUVmax of 4.5 (Ewing's), while two pts had an SUVmax over 30 (both undifferentiated pleomorphic). Although sarcoma had high uptake on 68Ga-FAP-2286 PET, it was similar to FDG PET uptake across the 5 pts (ratio to FDG PET = 1.0). **Conclusions:** 68Ga-FAP-2286 is a promising imaging agent across cancers, although its benefit is not seen equally. BC had the highest absolute uptake and highest relative uptake compared to FDG PET; prostate cancer had the lowest uptake. Further work should be undertaken to define the settings where 68Ga-FAP-2286 PET may inform clinical decision making, and which pts may benefit from FAP-targeted radioligand therapy. Clinical trial information: NCT04621435. Research Sponsor: Clovis Oncology.

Frequency of practice-changing findings identified by comprehensive genomic profiling in non-myeloid hematologic malignancies. *First Author: Katherine I. Zhou, Department of Medicine, Duke University School of Medicine, Durham, NC*

Background: Comprehensive genomic profiling (CGP) is increasingly used to guide management of myeloid and advanced solid malignancies, but its role in non-myeloid hematologic malignancies is less clear. Studies have found a high rate of potentially actionable variants by CGP in this population, but these do not always translate into clinical practice changes. We aimed to determine the rate at which variants found on CGP changed clinical practice. **Methods:** We retrospectively reviewed a cohort of 101 consecutive patients with non-myeloid hematologic malignancies at Duke, comprising a total of 105 samples that were sent for CGP by FoundationOne Heme (104) or HemeComplete (1) in 2014–2021. We identified variants of clinical significance and classified them by evidence level according to the AMP/ASCO/CAP 2017 guidelines (e.g., for therapies, level A: FDA-approved / in guidelines; B: expert consensus; C: clinical trial / FDA-approved in different tumor type; D: preclinical data). We further identified documented changes in clinical practice that occurred in direct response to CGP results. **Results:** Commonly cited reasons for CGP included guiding therapy selection (27), identifying resistance mutations (19), refining prognosis (14), and clarifying diagnosis (11). Of the 105 samples sent for sequencing, 92 (88%) yielded at least one pathogenic or likely pathogenic variant. CGP resulted after death in 12 patients and within 1 month of death in another 11 patients. Seventy-three out of 101 patients (72%) had at least one variant with therapy sensitizing, diagnostic, or prognostic significance (levels A–C) or associated with therapy resistance (levels A/D). While 61 patients (60%) had a therapy sensitizing variant, only 6 patients (10%) were offered a biomarker-directed therapy. In contrast, the presence of a resistance mutation led to discontinuation of current therapy or influenced future therapy selection in 9 of 13 patients (69%). The absence of a resistance mutation influenced choice of therapy in another 4 patients. Sequencing results also helped clarify a previously uncertain diagnosis in 4 patients and led to medical genetics referrals in 3 patients. **Conclusions:** Comprehensive genomic profiling of non-myeloid hematologic malignancies identified variants of clinical significance in 72% of patients and led to changes in practice in 22% of patients. CGP was often sent late in the clinical course. Research Sponsor: U.S. National Institutes of Health.

Molecular typing and clinical characteristics of synchronous multiple primary colorectal cancer. *First Author: Jun Huang, Department of Colorectal Surgery, The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: Synchronous multiple primary colorectal cancer (sMPCC) is clinically rare while its incidence was increasing in the past decade. However, little was known about molecular and clinical features of sMPCC, which might be different from single primary colorectal cancer (CRC). **Methods:** From November 2012 to April 2021, 239 sMPCC from a total of 13276 CRC patients operated in the 6th Affiliated Hospital of Sun Yat-sen University were enrolled in this study. Mismatch repair (MMR) status in each lesion of all 239 patients was examined by immunohistochemistry (IHC). Totally 78 sMPCC patients and 94 single primary CRC patients conducted an 831-gene panel based next-generation sequencing (NGS) (OncoPanscan, Genetronhealth). Somatic mutations and potential pathogenic germline variants were analyzed. Microsatellite instability (MSI) and tumor mutation burden (TMB) were calculated. **Results:** We found that dMMR/MSI-H frequencies in sMPCC were significantly higher than those in single primary CRC, which were confirmed by both IHC (50/239 vs 872/13037, $p < 0.001$) and NGS (17/78 vs 5/94, $p = 0.0022$). According to the MMR/MSI status at different lesion in sMPCC patients, they were further divided into all MSI-H, MSI-H & MSS and all MSS group, with incidences of 16.7%, 4.2% and 79.1%, respectively. With NGS analysis, we found that the most enriched gene mutation type in sMPCC patients was C > T (G > A), and their most frequently mutated genes were *APC* (65%), *KRAS* (46%), *TP53* (31%), *PIK3CA* (25%), *EGFR* (23%), *ARID1A* (18%), *NF1* (18%), *SOX9* (18%), *FAT4* (16%), and *TCF7L2* (15%), whereas those genes in single primary CRC patients were *APC* (71%), *TP53* (64%), *KRAS* (40%), *FBXW7* (20%), *PIK3CA* (13%), *SMAD4* (12%), *ARID1A* (11%), *FAT4* (11%), *CREBBP* (11%), and *NF1* (10%). Moreover, we found that higher TMB was correlated with higher MSI in sMPCC rather than single primary CRC patients. Furthermore, we found that the mutated genes were different among three subgroups. The top 5 mutated genes in MSI-H group were *APC* (68%), *FAT4* (64%), *TCF7L2* (59%), *KMT2B* (55%), *ARID1A* (45%), whereas those in MSI-H & MSS group were *APC* (57%), *KMT2B* (43%), *KMT2C* (43%), *ATM* (43%), *PRKDC* (43%), and those in MSS group were *APC* (66%), *KRAS* (49%), *TP53* (36%), *PIK3CA* (21%), *EGFR* (20%). Finally, we also found that patients with pathogenic/likely pathogenic germline mutations were comparable between sMPCC and single primary CRC, indicating that sMPCC may not be resulted from germline changes. **Conclusions:** Our results revealed that incidences of dMMR/MSI-H in sMPCC were significantly higher than those in single primary CRC. We proposed that MMR/MSI status of each lesion in sMPCC patients should be verified before treatment and these patients could be divided into three subgroups according to their MMR/MSI status. Our findings indicated that sMPCC patients with different MMR/MSI status might be treated with personalized therapies for better management of their disease. Evaluating the utility of fluorine-18 fluorodeoxyglucose (^{18}F-FDG)-positron emission tomography (PET)/ computed tomography (CT) scan in cancer of unknown primary. *First Author: Tharani Sivakumaran, Peter MacCallum Cancer Centre, Melbourne, Australia*

Background: Cancer of unknown primary (CUP) represents a heterogeneous group of metastatic tumours where standardized diagnostic work-up fails to identify the tissue of origin (TOO). Small studies, to date mainly focused on cervical lymph node squamous cell CUP patients, have shown ^{18}F-FDG-PET/CT can change patient management and identify the TOO. We aimed to describe the Peter MacCallum Cancer Centre experience with ^{18}F-FDG PET/CT in CUP with respect to detection of a TOO and its impact on management. A secondary aim was to compare the overall survival (OS) in patients where TOO is detected with those without TOO detection. **Methods**: Retrospective analysis of CUP patients treated between 2014-2020. Patients were identified from medical oncology clinics and PET/CT records. Information regarding demographics, clinicopathological details, CUP subtype as per ESMO guidelines, genomic analysis (If known), suspected TOO as per clinician pre- and post-FDG PET/CT, treatment details pre- and post FDG PET/CT and follow-up were collated from electronic medical records. Clinical details and genomic analysis were used to determine the clinically suspected TOO and compared against independent blinded nuclear medicine specialist FDG-PET/CT reads to determine sensitivity, specificity, accuracy and detection rate of TOO. **Results:** One hundred and forty-seven patients were identified of whom 65% had undergone molecular profiling. The median age at diagnosis was 61 years (range 20-84) and the median follow-up time was 69 months (range, 26–83). The predominant histological subtype was adenocarcinoma (54%). Eighteen percent of patients had a prior cancer history and 29% had a 1st degree relative with a history of cancer. Ninety-three percent were ECOG 0-1, and the dominant metastatic site was lymph nodes (35%). Eighty-one percent were classified as unfavourable CUP subtype as per ESMO guidelines. FDG PET/CT demonstrated a TOO detection rate of 34% with high specificity (98%) and moderate accuracy (78%). FDG PET/CT resulted in a change in management in 22% of patients and identified occult disease sites in 37% of patients. The median OS for all patients was 17.8 months. Median OS was not reached and 12.5 months for favourable and unfavourable CUP subtypes, respectively ($p < 0.0001$). Median OS when a potential TOO was identified on an FDG-PET/CT scan was 25.4 months compared with 9.1 months when a TOO remained elusive. ($p < 0.0001$). Multivariable analysis of survival adjusted for age and sex remained significant for FDG-PET identification of TOO ($p = 0.004$), favourable CUP ($p < 0.001$) and ECOG ≤ 1 ($p < 0.001$). **Conclusions**: ^{18}F-FDG PET/CT plays a complementary role in CUP diagnostic work-up and was able to determine the likely TOO in a third of cases. OS is improved with TOO identification, demonstrating the value of access to a diagnostic PET/CT scan for CUP patients. Research Sponsor: None.

Baseline tumor size as prognostic index in patients with cancer receiving experimental targeted agents. *First Author: Paolo Tarantino, Division of Early Drug Development, European Institute of Oncology IRCCS, University of Milan, Milan, Italy*

Background: Several studies showed that high baseline tumor size (BTS) is associated with worse outcomes in cancer patients treated with immunotherapy (IO). However, the prognostic impact of BTS for patients receiving targeted therapies (TT) remains uncertain. **Methods:** We collected clinical data for patients with solid tumors consecutively treated within early phase trials at our institution from 01/2014 to 04/2021. Treatments were categorized as IO-based (if any IO-agent was included) or TT-based (biomarker-matched or not). BTS was calculated as the sum of RECIST 1.1 baseline target lesions. Progression-free survival (PFS), overall survival (OS) and objective-response rate (ORR) were compared between patients with high BTS (> median) and low BTS (≤median). **Results:** 444 patients were eligible for the analysis (220 IO, 151 TT biomarker-matched, 73 TT biomarker-unmatched). Median age was 56 years (interquartile range, IQR 48-64) and median BTS was 69 mm (IQR 40-100). Most represented tumor types were breast (49%), lung (9%), melanoma (5%) stomach, colorectal, head and neck and ovarian (4% each). Patients with low BTS were more often female ($p < 0.001$), had a better performance status (PS, $p = 0.008$), lower LDH ($p < 0.001$), lower neutrophile/lymphocyte ratio (NLR, $p < 0.001$) and higher albumin ($p = 0.003$). OS was significantly longer for patients with low BTS (16.6 vs 8.2 months, $p < 0.001$), including when restricting at those receiving IO (12 vs 7.5 months, $p = 0.005$). Among patients receiving TT, those with lower BTS experienced longer PFS (4.7 vs 3.1 months, $p = 0.002$) and OS (20.5 vs 9.9 months, $p < 0.001$) as compared with those with high BTS. However, BTS was only prognostic among patients receiving biomarker-matched TT, with improved PFS (6.2 vs 3.3 months, $p < 0.001$) and OS (21.2 vs 6.7 months, $p < 0.001$) in the low-BTS subgroup, despite a similar ORR (28% vs 22%, $p = 0.57$). BTS was instead not prognostic among patients receiving unmatched TT, with similar PFS (3.7 vs 4.4 months, $p = 0.30$), OS (19.3 vs 11.8 months, $p = 0.20$) and ORR (33% vs 28%, $p = 0.78$) in the two BTS groups. Multivariate analysis confirmed that BTS was independently associated with PFS ($p = 0.03$) and OS ($p < 0.001$) but not with ORR ($p = 0.11$), regardless of tumor site, treatment category, PS, NLR, sites of metastases and number of prior lines. **Conclusions:** Patients receiving biomarker-matched TT experience longer PFS and OS if having a lower BTS, whereas response rate is not affected by this variable. This difference may reflect the faster emergence of molecular mechanisms of resistance among patients with higher baseline burden. Lower BTS is also confirmed to be associated with longer survival among patients receiving experimental IO. BTS has instead no prognostic value among patients receiving unmatched TT. Research Sponsor: None.

A large-scale, multi-center molecular characterization of *MET* fusions in a real-world Chinese population. *First Author: Yutao Liu, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China*

Background: *MET* is a driver gene notable in its diversity of clinically relevant aberrations, including exon 14 skipping, copy number gain, point mutations, and gene fusions. Compared with the former two, *MET* fusions are severely under-reported, leaving unanswered a series of fundamental questions. In this study, we addressed this knowledge gap by screening for and characterizing *MET* fusions in a real-world, multi-center population of Chinese cancer patients. **Methods:** We retrospectively included patients with solid tumors and available genome profiles acquired between August 2015 to May 2021. *MET* fusion-positive (*MET*+) patients were subsequently selected for clinical and molecular characterization. **Results:** A total of 79816 patients across 27 tumor types were screened. We detected 155 putative *MET* fusions from 122 patients, resulting in an overall prevalence of 0.15%. Lung cancer comprised the majority of *MET*+ patients (92, 75.4%). Prevalence was markedly higher in liver, biliary tract cancer, and renal cancer (range 0.52%-0.60%) and lower in ovarian cancer (0.06%). A substantial proportion (48/58, 82.8%) of unique partners were reported for the first time. The fusion partners also turned out to be highly heterogeneous, with *ST7, HLA-DRB1,* and *KIF5B* as the three most common partners. Mutational landscape analysis of lung adenocarcinoma patients (n = 32) revealed high prevalence of aberrant *TP53* in *MET*+ patients as well as *EGFR* L858R, L861Q and *MET* amplification as concurrent alterations. **Conclusions:** This study is, to our knowledge, currently the largest in characterizing *MET* fusions. Our findings warrant further clinical validation and mechanistic study that may translate into therapeutic avenues for *MET* fusion-positive cancer patients. Independent validation of a novel noninvasive 4-microRNA diagnostic model for multicancer early detection. *First Author: Andrew Zhang, Del Norte High School, San Diego, CA*

Background: Cancer early detection is critical to reduce mortality as treating early stage cancers is more likely to have better outcomes. We previously developed a diagnostic model based on 4 serum cell-free microRNAs (miRNAs) capable of detecting 12 cancer types with high accuracy (AACR 2022, Poster 2890; Manuscript submitted). In the current study, we aimed to validate this diagnostic model using independent serum microRNA microarray datasets. **Methods:** Four microarray datasets assessing the expression of 2588 serum miRNAs in patients with esophageal squamous cell carcinoma, gastric cancer, prostate cancer and glioma, as well as non-cancer healthy controls with a standardized platform were identified from Gene Expression Omnibus (GEO). The datasets were combined, cases that were redundant among them or with the cases used in our previous study (correlation > 0.99) were excluded. The 4-miRNA model was applied to the final combined dataset to calculate a diagnostic index and make prediction of cancer vs. no-cancer using previously determined algorithm and cut-point. The performance of the diagnostic model was assessed using Receiver Operating Characteristic (ROC) analysis, sensitivity and specificity. **Results:** After excluding redundant cases, the final combined dataset consisted of 3877 subjects, including 447 esophageal, 1267 gastric, 769 prostate and 196 glioma cancer patients, as well as 1198 healthy controls. The 4-miRNA model demonstrated an area under the curve (AUC) of 0.986, 0.995, 0.992 and 0.990 in the ROC analysis, with a sensitivity of 85.0%, 99.6%, 90.6% and 86.7% for esophageal, gastric, prostate and glioma cancers, respectively, while achieving a 99.1% specificity. These performance metrics were highly consistent to those reported in our previous study (Table). **Conclusions:** The study provided an independent validation of the previously developed 4-miRNA model, further demonstrating that the diagnostic model we developed has the potential to be developed into a simple, inexpensive and noninvasive blood test for multi-cancer early detection with high accuracy. Research Sponsor: None.

Comparison of sensitivities of the 4-miRNA diagnostic model in the four cancer types between our previous study vs. the current study.

Comparative analysis of microsatellite instability-high (MSI-H) *BRAF* V600E-mutated versus MSI-H *BRAF* wild type colorectal cancers (CRC), including tumor microenvironment (TME), associated genomic alterations, and immunometabolomic biomarkers. *First Author: Mohamed E. Salem, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: The $BRAF^{V600E}$ mutation is associated with the hypermethylator phenotype CIMP, which can also lead to the MSI-H phenotype. $BRAF^{V600E}$ mutation and MSI-H/dMMR status seem to be biologically intertwined; however, the impact of coexisting $BRAF^{V600E}$ mutations on the TME and immunometabolomic features of MSI-H/dMMR CRC tumors is not well characterized. **Methods:** A retrospective review of deidentified records of patients with MSI-H/dMMR CRC tumors was conducted using next-generation sequencing data (Tempus lxT assay: DNA-seq of 595-648 genes at 500x coverage, and full transcriptome RNA-seq). Several immune markers of tumor immunogenicity in *BRAF* wild-type ($BRAF^{wt}$) vs. V600E-mutated ($BRAF^{V600E}$) tumors were assessed, including tumor mutational burden (TMB), neoantigen tumor burden (NTB, ScanNeo), PD-L1 expression, immune infiltration, and canonical immuno-metabolomic pathways (82 geneset signatures). **Results:** A total of 459 MSI-H/dMMR CRC tumors were analyzed, of which 123 (27%) tumors harbored $BRAF^{V600E}$mutations, and 336 (73%) were $BRAF^{wt}$. MSI-H/dMMR $BRAF^{V600E}$ tumors were more frequently identified in females (69% vs. 55%; P= 0.01), non-Hispanic or non-Latino (100% vs. 73%; P =0.001), and older patients (median age: 76 yrs vs. 62 yrs; P< 0.001). Compared to $BRAF^{WT}$, $BRAF^{V600E}$ tumors exhibited significantly higher TMB (Median: 49 mut/MB vs. 36 mut/MB; P < 0.001) and were more frequently associated with TMB-High status (> 10 mut/MB; 100% vs. 95%; P = 0.008); however, no significant differences were observed with tumor NTB, immune score, or T cell infiltration (CD4 or CD8). NK cell infiltration was higher in the $BRAF^{V600E}$cohort (< 0.001). When compared to $BRAF^{WT}$ tumors, $BRAF^{V600E}$ tumors harbored a greater frequency of mutations in *MSH6*(42% vs. 20%), *B2M* (33% vs. 16%), *BRCA2* (31% vs. 12%), *ATM* (23% vs. 12%), and *TP53* (30% vs. 19%) but a lower frequency of *MSH2* (3.3% vs. 11%), all P< 0.05. Pathway enrichment analysis identified 10 significantly altered signaling pathways, most of which related to stromal/immune cell signaling and metabolism. Five were upregulated among $BRAF^{V600E}$ tumors: glycerophospholipid, galactose, cyclin-dependent cell signaling; Nucleotide, and TH1 inflammation. Five pathways were downregulated (Wnt, Notch, TH17 inflammation, amino sugar, and cancer stem cell signaling). **Conclusions:** MSI-H/dMMR $BRAF^{V600E}$ CRCs undergo broad metabolic reprogramming (e.g., glycerophospholipidgalactose, nucleotide). A rise in lipid metabolism, particularly with NK inflammation, suggests that $BRAF^{V600E}$mutated tumors may be associated with a non-classical immune component. $BRAF^{V600E}$ and $BRAF^{wt}$ CRCs exhibited similar NTB and T cell infiltration, suggesting that both are likely to benefit from immune checkpoint inhibitors. Research Sponsor: None.

3067 **Poster Session**

Impact of *RAS* mutations on immunologic characteristics of the tumor microenvironment (TME) in patients with microsatellite instability-high (MSI-H) or mismatch-repair–deficient (dMMR) colorectal cancer (CRC). *First Author: Mohamed E. Salem, Levine Cancer Institute, Atrium Health, Charlotte, NC*

Background: The KEYNOTE-177 trial demonstrated pembrolizumab's superiority over first-line chemotherapy in patients with MSI-H/dMMR mCRC. However, in a subgroup analysis, patients with *KRAS* or *NRAS* mutations did not show the same favorable PFS benefit with PD-1 blockade therapy (HR 1,19; CI 0.68-2,07). The impact of *RAS* mutations on the immunologic characteristics of the TME of MSI-H/dMMR CRC has not been well characterized. **Methods:** A retrospective review of deidentified records of patients with MSI-H/dMMR CRC tumors was conducted using next-generation sequencing data (Tempus lxT assay, DNA-seq of 595-648 genes at 500x coverage, and full transcriptome RNA-seq). MSI-H determined by assessment of 239 loci by NGS. Several immune markers were assessed, including tumor mutational burden (TMB), neoantigen tumor burden (NTB, ScanNeo), PD-L1 expression, immune infiltration, and canonical immune pathways (82 geneset signatures). **Results:** A total of 463 MSI-H/dMMR CRCs were analyzed, of which 110 (24%) tumors harbored *RAS* mutations (RAS^{mut}) [*KRAS*: 93%, *NRAS* 6% and *HRAS* 1%), while 353 were *RAS*-wild-type (RAS^{WT}). Compared to MSI-H/dMMR RAS^{WT}, MSI-H/dMMR RAS^{mut} tumors were more frequently identified in males (53% vs. 38%; P= 0.005), and younger patients (median age: 57 yrs vs. 71 yrs, P< 0.001). Although there were no significant differences in median TMB (40 mut/MB for both, p = 0.9) or frequency of TMB-high status (≥10 mut/MB) between the two groups, RAS^{mut}tumors tended to have a lower tumor NTB (16 vs. 12 neoAg/Mb, P <0.001) and lower % CD8 T cell but higher % CD4 T cell infiltration (P < 0.05). Significant differences were observed in genomic alterations co-occurring with RAS^{mut} compared to RAS^{WT} (e.g., *MLH1* (23% vs. 8.8%, P < 0.001), *MSH6 (36% vs. 24%, P = 0.017), APC* (60% vs. 20%, P< 0.001), *ARID1A* (54% vs 30%, P< 0.001), *PIK3CA* (36% vs 19%, P< 0.001), *and TP53* (32% vs. 19%, P = 0.014). Pathway enrichment analysis identified 14 differentially expressed pathways among RAS^{mut} tumors. Four pathways showed significant upregulation, including Hedgehog, Wnt, *TGFβ*, and cancer stem cell pathways. Ten pathways of interest showed significant downregulation among RAS^{mut} tumors. The majority (9/10) were immune-related, including cytokine signaling [*JAK-STAT, TGFβ, TH1*], innate immune [*NK cells*], and adaptive immune events *(CD8 T cell, Tregs*)]. **Conclusions:** MSI-H/dMMR CRCs harboring RAS^{mut} exhibited overall upregulated *WNT/SHH* pathway activity, coupled with reduced NTB, cytokine signaling, and innate and adaptive immune events. *TGFβ* is pleiotropic, and different members were associated with variable modulation. These data suggest that MSI-H/dMMR CRCs harboring *RAS* mutations are less immunogenic and appeared to contain a TME that is less sensitive to immune checkpoint blockade than MSI-H/dMMR RAS^{wt} CRCs. Lesion-specific radiomics analysis shows promising results for early-stage efficacy assessment of IOA-244 in uveal melanoma. *First Author: Martin Gueuning, Radiomics, Liege, Belgium*

Background: Radiomics is an image based approach that allows for characterization and quantification of tumor lesions in cancer patients. Radiomics has been proven capable of potentially adding value in the diagnostic and prognostic patient managment. In this study we evaluated the potential of Radiomics to bring additional insight also in early drug development. **Methods:** All the visible malignant lung and liver metastasis lesions of 7 uveal melanoma patients (86% of women, 60±11y) treated with IOA-244 (EudraCT 2019-000686-20) were manually segmented and analyzed in their size and shape *via* a radiomics approach. The CT scans at baseline and first follow-up (8 weeks) were included in the study and compared. Descriptive statistics and linear mixed effect (LME) models were used to quantify volumetric lesion-specific response to treatment. Response has been defined both as continuous variable and in three discrete categories (lesion shrinkage, stable and progressive disease for a volume change of [-100%;-0%];[0%-+25%] and > 25%, respectively). The influence of lesion shape at baseline (e.g. compactness, elongation or surface roughness among others) on the treatment response has been explore through LME models as well. **Results:** We identified and segmented 126 metastatic lesions (70 lung and 56 liver) from baseline scans and 122 lesions (71 lung and 51 liver) from post treatment scans. Of those, 64% could be consistently mapped between visits, resulting in a total of 147 matching lesions on which the radiomics analysis was performed. We found 19% of complete response and 16% of new lesions appearing. 8 weeks after treatment start, we observed non progressive disease in 61% of all lesions, of which 42% was shrinking. LME did not show a significant change in lesion volume between visits, but the mean difference between visits was negative. LME did show that lesion shape is significantly different between progressors and non-progressors at baseline for lung lesions (compact and irregular lesions are more likely to respond), and that there are moderate correlations (0.4-0.7) between tumor shape and volume change for liver lesions (compact lesions have a larger volume drop). **Conclusions:** This work demonstrates both the clinical potential of IOA-244 for treatment of Uveal Melanoma patients with lesions in the lung and in the liver and the potential of radiomics individual lesion analysis for clinical research in the very early stages of drug development. Lesion evolution volumetric assessment has allowed a more accurate and sensitive understanding of IOA-244 efficacy and impact across different lesions, in both lung and liver. Radiomics showed a promising response of selected population to IOA-244 over the first time point (W0-W8). A further radiomics analysis on next follow-up scans would allow a radiological proof of treatment-induced changes and long-term patient outcome prediction. Research Sponsor: None.

The HERPET study: Imaging HER2 expression in breast cancer with the novel PET tracer [^{18}F]GE-226, a first-in-patient study. *First Author: Laura M. Kenny, Imperial College London, London, United Kingdom*

Background: Over-expression the human epidermal growth factor receptor-2 (HER2) is seen in 20% of breast cancers; this is an adverse prognostic factor and used to guide therapy selection. At present HER2 expression can only be determined using biopsy material using immunohistochemistry or fluorescence in situ hybridisation. Heterogeneous expression of HER2 is now being recognised as a cause of treatment resistance but is difficult to characterise. A non-invasive method for determining HER2 expression could have several advantages and help select appropriate therapy for patients. GE-226 is a novel radiolabelled GE-Affibody radioligand which binds to the HER2 receptor with high affinity at a different epitope than trastuzumab. **Methods:** Patients with locally advanced or metastatic breast cancer were recruited and scanned for 65 mins after iv injection of 200MBq of GE-226 (mean activity injected for each patient 202MBq (range 164-223MBq, mean radiochemical purity 94%) of radioligand, over one bed position for dynamic imaging, followed by a half-body scan. Blood sampling was used to measure metabolism of the tracer. Safety was assessed. HER2-extracellular domain (ECD) domain was measured in blood. Tumoural uptake was quantified by semi-quantitative and fquantitative parameters in HER2 positive and HER2 negative tumours. Patients had routine baseline FDG imaging. **Results:** Twenty patients completed the study. GE-226 scans were well tolerated. There were no serious adverse events. GE-226 was slowly metabolised into a single metabolite in the liver; 97% of parent remained at 60 minutes post injection (range 82-100). There was a significant difference in tumoural radioligand uptake between biopsy proven HER2 positive and HER2 negative tumoural patients as measured by SUV_{mean} and SUV_{max} ($p < 0.001$). Comparing HER2 positive to HER2 negative cases, there was also a significant difference between tumour to normal tissue uptake ratios SUV_{mean}. Heterogeneous uptake was observed in three patients, two with interlesional uptake variation and one with intralesional heterogeneity. Tumoural uptake increased over time. Normal physiological uptake in salivary glands and the thyroid gland was noted. GE-226 was able to differentiate between lymphadenopathy due to sarcoidosis and cancer in one patient and was superior to FDG which had shown widespread uptake in the benign and malignant nodes. **Conclusions:** [18F]GE-226 imaging is well tolerated and shows promise for imaging of HER2 positive breast cancer. Further studies with this agent are now planned. Clinical trial information: NCT03827317. Research Sponsor: Medical Research Council (UK), Pharmaceutical/Biotech Company, Medical Research Council.

[^{18}F]Fluorothymidine(FLT)-PET imaging of thymidine kinase 1 pharmacodynamics in non-small cell lung cancer treated with pemetrexed. *First Author: Preetha Aravind, Imperial College London, London, United Kingdom*

Background: Imaging of tumor proliferation has been studied with FLT-PET in various tumor types including NSCLC. Pemetrexed inhibits thymidylate synthase(TS), dihydrofolate reductase (DHFR), and glycinamide ribonucleotide formyltransferase (GARFT). TS inhibition upregulates the thymidine salvage pathway including relocalisation of ENT1 to membrane and TK1 activation as a transient "flare" response. We hypothesise that this can be detected as an increase in FLT tumoral uptake that subsequently decreases with reduced proliferation. This study was conducted to assess FLT uptake as an early pharmacodynamics(PD) marker of pemetrexed response. **Methods:** This was an open-label imaging study in 21 patients with Stage 3/4 NSCLC treated with pemetrexed and platinum-based chemotherapy. Patients underwent FLT PET/CT scan at baseline and 4h after administration of pemetrexed. Platinum component of treatment was administered on the day after second FLT scan for cycle 1. Plasma for TK1 activity expression were collected before each scan time point and analysed by ELISA. Percentage change in standardized uptake value (%ΔSUV) was calculated as [SUV(PET2) – SUV(PET1)]/SUV(PET1)*100. Treatment response calculated by RECIST 1. 1 and survival data were collected. **Results:** 17 patients had evaluable PET/CT scans for pemetrexed response. Median percentage difference for SUVmean and SUVmax in tumour lesions increased by 3% and 10.3% respectively. 5 patients showed homogeneous FLT flare at 4h after pemetrexed, 2 patients had decrease, 10 patients had heterogeneous FLT response (regardless of platinum doublet). There was no significant correlation between plasma TK1 activity and FLT flare. At 9 weeks, 4 patients had partial response, 9 stable disease and 4 progressive disease. Baseline and weighted average ΔSUVmax were not associated with survival. The 5 patients with FLT flare in all lesions showed a median OS of 31 months, unlike the group with heterogenous or decrease uptake(15 months). FLT uptake in bone marrow and small bowel significantly increased at 4h (t test p = 0.004, p = 0.004, respectively) indicating increased thymidine salvage activity. Early FLT uptake was not predictive for tumour RECIST response or OS. In multivariable cox regression analysis, pre-treatment TK1 activity, adjusted for performance status, smoking history and age, independently affected survival in this group (p = 0.011). **Conclusions:** Early FLT flare at 4h was seen in NSCLC post pemetrexed administration indicating activation of thymidine salvage pathway. Median overall survival of patients with an FLT flare response was more than twice longer than patients with mixed or no response. However, the small sample size lacked power to show statistical significance in the OS comparison. Further studies should evaluate this and the relationship to other prognostic variables in a larger cohort of patients. Clinical trial information: NCRI UK badge 9249. Research Sponsor: Medical Research Council, UK.

Differential expression of somatostatin receptor (SSTR) subtypes across a spectrum of neuroendocrine neoplasms (NENs). *First Author: Emil Lou, Masonic Cancer Center/ University of Minnesota School of Medicine, Minneapolis, MN*

Background: Targeted therapy of NENs based on the presence of SSTRs fills a unique niche in tumor biology and clinical treatment of patients with solid tumors. SSTRs have multiple isoforms and are collectively expressed in the majority of NENs. However, subtypes are still not routinely tested and thus not assessed for clinical decision-making, especially for patients meriting consideration of targeted radionucleotide therapy. Clarifying the landscape of SSTR subtypes using molecular techniques more sensitive than immunohistochemistry (IHC)-the standard of testing, and identifying associated genomic biomarkers that differ between them, will pave the way for more sophisticated decision-making in the future. Additionally, leveraging transcriptomics to better assess mitotic markers such as Ki-67 to assess tumor grade, would increase diagnostic accuracy. Here we provide initial validation across a spectrum of NENs. **Methods:**1595 NENs were analyzed using Next Generation Sequencing (592 gene panel, NextSeq), Whole Exome and Transcriptome Sequencing (NovaSeq), and IHC at Caris Life Sciences (Phoenix, AZ). Significance was determined using chi-square, Fisher-Exact or Mann-Whitney U and p-adjusted for multiple comparisons ($q<0.05$) where applicable. **Results:** In a subset of 492 NENs with accompanying tumor grading information, a median *MKI67* (gene encoding Ki-67) TPM value of 2.27 for low-grade (LG-), and 38.7 for high-grade NENs (HG-NENs) was observed ($q<0.05$). Using ROC curve analysis, a threshold of *MKI67* expression (13.4375 TPM) differentiated LG- from HG-NENs, with a true positive rate of 86.84%, a false positive rate of 11.9% and an AUC of 95% and was subsequently applied to the entire cohort to infer HG/LG. Compared to HG-NENs (n = 862), LG-NENs(n = 733) expressed higher levels of SSTR 1(3.5-fold),2 (2.9-fold) and 5 (1.67-fold) and lower levels of SSTR4 (0.28-fold)($q<0.05$). Further, the expression of SSTRs 3 and 4 in HG-NEN (r_s= 0.63) and SSTRs 1 and 2 in LG-NENs (r_s= 0.64) were positively correlated. Overall, the prevalence of altered *TP53*, *RB1*, *PIK3CA*, *APC*, *KRAS* was higher and *MEN1* was lower in HG-vs LG-NENs ($q<0.05$). For each SSTR subtype, we established high and low cohorts based on median expressions. In LG-NENs, increased alterations in *TP53* and *RB1* were associated with increased expression of SSTRs 1 and 2 and reduced expression of SSTRs 3 and 4. In HG-NENs, increased alterations in APC were associated with increased expression of SSTR 1 and 4 and reduced expression of SSTRs 3 and 5. Additional subtype- and grade-specific alterations were also observed. **Conclusions:** This study provides evidence that WTS and NGS can be leveraged to predict grade of NENs and define characteristic differences in the genomic landscape across SSTR subtypes in HG and LG NENs. Incorporating the molecular profiling of NENs can thus aid in advancing the development of more tailored therapeutic strategies. Research Sponsor: Caris LLC.

Image-based detection of *FGFR3*-fusion in urothelial bladder cancer. *First Author: Nir Peled, Oncology Division, Shaare Zedek Medical Center, Jerusalem, Israel*

Background: Fibroblast growth factor receptor-3 (FGFR3) is a transmembrane protein, somatically altered in a large spectrum of cancer types. Chromosomal rearrangement resulting in *FGFR3* gene fusions leads to a constitutively active tyrosine kinase, mediating tumorigenesis. *FGFR3*-fusion is a prognostic and predictive marker as well as a validated therapeutic target in urothelial bladder cancer. Both FISH and RT-PCR assays can be used for the detection of *FGFR3* rearrangements while immunohistochemistry lacks sufficient sensitivity and specificity. In recent years advances in next-generation sequencing improved their ability to detect these alterations in clinical settings. However, systemic screening of these alterations is still expensive, time-consuming, and requires expertise personnel for data analysis and interpretation. In this study, we aimed to develop and validate an alternative machine learning (ML) based method for the detection of *FGFR3*-fusions directly from routine pathology hematoxylin and eosin (H&E) slides. **Methods:** A cohort of 388 H&E whole slide images of bladder urothelial carcinoma samples, obtained from the TCGA Research Network (https://www.cancer.gov/tcga) was used. Cases were randomly divided into training (n = 238) and testing (n = 150) sets. Advanced Convolutional Neural Network (CNN) was used to generate the *FGFR3*-fusion classifier on the training set following validation on the testing set. **Results:** Validation of the *FGFR3*-fusion classifier was performed on a cohort of 150 cases from 19 different centers, including three positive cases of *FGFR3-TACC3* fusions and 147 negative cases. The AI-classifier performance was measured in comparison to the TCGA dataset. The model demonstrated 100% sensitivity and 94% specificity, with an Area Under the Curve (AUC) of 0.96. **Conclusions:** Herein, we demonstrate a real-time ML-based genomic testing solution for *FGFR3*-fusion detection in bladder cancer directly from H&E stained slide images. Utilization of such an alternative method can facilitate fast, accurate, and systemic screening of patients if integrated within the routine pathological pipeline supporting targeted therapy treatment for these patients. Molecular therapy selection in treatment-refractory advanced cancers: A retrospective cohort study determining the utility of TOPOGRAPH knowledge base. *First Author: Frank Po-Yen Lin, NHMRC Clinical Trials Centre, University of Sydney, Sydney, NSW, Australia*

Background: Comprehensive genomic profiling (CGP) is increasingly used to guide therapy selection in advanced cancer patients who have exhausted standard therapy options. Here we assess the utility of Therapy Oriented Precision Oncology Guidelines for Recommending Anticancer Pharmaceuticals (TOPOGRAPH) to guide matching of drug treatments based on CGP in this setting. **Methods:** This study was conducted in an Australia-wide precision oncology program, the Molecular Screening and Therapeutics Study (MoST, ANZCTR registration ACTRN12616000908437). All patients with advanced cancer after exhausting standard treatments underwent CGP in 2016-2021 were stratified into cohort A (no further therapy received) and B (received ≥1 therapy after CGP). The primary outcome was overall survival (OS) estimated by the Kaplan-Meier method, using the log rank test to assess between-group differences. TOPOGRAPH matched the treatment history to the CGP results, stratified into clinically active (Tiers 1-3, T1-3), investigational (T3B/4), inactive (R2) or unmatched groups. **Results:** Over a median follow-up of 21.7 months (mo) for 2852 patients (75% with rare cancers, n = 2150), the median OS (mOS) from the date of CGP result was 7.0 mo (95% CI 6.4-7.6) for cohort A (n = 1562) and 15.8 mo (95% CI 14.5-16.9) for cohort B (n = 1290). In both cohorts, patients with CGP results matching any TOPOGRAPH tier (T1-4) had shorter OS compared to patients without a matching tier (A: 6.4 v 20.5 mo, hazard ratio for death [HR] 2.15, p<0.001; B: 14.7 v 23.6 mo, HR 1.43, p<0.001). Patients in cohort B receiving matched therapy (n=342, 27%) had a longer mOS than 948 patients who received only unmatched therapy (16.9 v 10.4 mo, HR 0.70, p<0.001). For CGP results matched to T1-3, 122 patients who received a T1-3 therapy had a significantly longer mOS than those who received unmatched therapy (22.1 v 9.8 mo, HR 0.51, p<0.001). For CGP results matched only to T3B/4, a trend toward longer mOS was observed in patients receiving matched therapy in T3B/4 (n = 138, 14.5 v unmatched 10.0 mo, HR 0.81, P = 0.07). In tier-matched analysis, the mOS were not significantly different between patients who received genomics matched v unmatched therapy in T3B (matching outside cognate histotypes, n = 48 v 508, 11.9 v 9.7 mo, HR 0.84, p = 0.36) and T4 (n = 32 v 134; therapy with preclinical/early clinical evidence, 17.1 v 12.2 mo, HR 0.69, p = 0.17). **Conclusions:** TOPOGRAPH is prognostic and likely predictive of treatment effect based on CGP, supporting its utility in guiding molecular therapy selection in patients who have exhausted standard treatment options. Research Sponsor: Office for Health and Medical Research, State of New South Wales and Australian Federal Government.

OS from the next therapy after CGP in cohort B (n = 1290).

Therapy received post CGP	Overall Matched N	mOS (mo)	Tier-matched analysis Matched N	Tier-matched analysis Matched mOS (mo)	Unmatched N	mOS (mo)	HR	P

Development and validation of Duoseq as a novel diagnostic and companion assay for lymphoma and other cancers. *First Author: Chrissie Rozzi, Data Driven Bioscience, Durham, NC*

Background: While NGS applications of DNAseq and RNAseq have proven to be powerful tools for genomic discovery, NGS remains underutilized in the clinic. We hypothesized that the clinical translation of NGS would be greatly improved by addressing two critical issues: first, having a single assay for both DNA and RNA sequencing, and second, including all the bioinformatics to enable rapid analysis and reporting of clinically relevant findings within 2 days rather than 2-3 weeks which remains the widespread standard. We developed Duoseq to address these issues. **Methods:** In most cancer biopsies, RNA constitutes nearly 80% of the total nucleic acid and DNA only 20%. Duoseq incorporates interfering factors that make the ligation of sequencing barcodes to RNA much less efficient than that to DNA to, in effect, invert the proportion of DNA and RNA from the sample. This enables the efficient generation of high quality DNA and RNA libraries. The assay targets over 450 recurrently altered genes in hematologic cancers. We developed secure bioinformatics software that connects to an Illumina sequencer to render four major classes of clinical measurements: mutations, gene expression (cell of origin in DLBCL), Epstein Barr virus (EBV) status and and common translocations (BCL2, BCL6, MYC, IRF4, CCND1). **Results:** Technicians at three different CLIA labs were trained to perform Duoseq at the respective sites using a local Illumina sequencer. The assay was performed on 111 FFPE lymphoma cases including diffuse large B cell lymphoma, and other B and T cell lymphomas that were characterized using clinical standard assays. The standards included Sanger sequencing or Foundation One testing (mutations), in situ hybridization (EBV), immunohistochemistry or Nanostring (expression) and fluorescent in situ hybridization (translocation). The included Duoseq software provided the bioinformatics results as well as annotations. With a minimum input of 50ng of nucleic acid/sample, Duoseq generated a mean depth of coverage of 438X. We found that, compared to clinical standards, Duoseq performed accurately for mutations (95.9%), EBV status (96.5%), translocations (94.1%) and expression (100%). In addition, Duoseq provided information on clonality, specific translocation partners and identified novel fusions that were not available from standard assays. **Conclusions:** Duoseq accurately recapitulates the clinical workup of lymphomas replacing the need for single analyte tests such as FISH, while providing a wealth of additional data. The simplicity of the assay and the included bioinformatics software enables its performance at any clinical lab without the need for specialized personnel or computing infrastructure. We anticipate the application of Duoseq as a diagnostic assay, as well as in clinical trial selection and companion diagnostic applications owing to its high accuracy and short turnaround time. Research Sponsor: Data Driven Bioscience.

Real-world utilization of ctDNA in the management of colorectal cancer. *First Author: Kristin M. Zimmerman Savill, Cardinal Health, Dublin, OH*

Background: The utilization of circulating tumor DNA (ctDNA) as a non-invasive biomarker for the detection of minimal residual disease, prediction of recurrence in the post-operative setting, and real-time monitoring of treatment efficacy has the potential to vastly improve the care and outcomes of patients with colorectal cancer (CRC). In August of 2020, ctDNA testing first gained approval for use in solid tumors and its prognostic benefit after curative intent surgery has been demonstrated to exceed that of prior standard of care clinicopathological criteria in CRC patients. The comprehensive integration of validated ctDNA approaches into the routine clinical care of patients with CRC would not only fundamentally change how risk of recurrence is assessed but could also reduce treatment with unneeded/unwarranted toxic therapies and allow for earlier recognition and treatment in cases with a high risk of relapse. This survey-based study aimed to evaluate the utilization of ctDNA testing in the management of CRC among practicing community oncologists in the U.S. **Methods:** Questions related to ctDNA utilization for patients with CRC were presented to community oncologists during a virtual meeting held in July 2021. Descriptive statistics were used to analyze the results. **Results:** Of 55 participating oncologists geographically distributed across the U.S., 49% indicated not using ctDNA to make treatment decisions in CRC. A proportion of physicians reported using ctDNA to detect recurrence (27% of physicians); make decisions around post-resection adjuvant therapy (25%); monitor disease progression/relapse (18%); and track tumor resistance during treatment (9%). The most frequently cited barriers to ordering ctDNA testing for patients with metastatic CRC were reimbursement issues (reported by 56% of oncologists), insufficient clinical evidence (46%), and limited familiarity with ctDNA use (28%). Oncologists reported that the following would increase their utilization of ctDNA testing: more clinical evidence of the utility of ctDNA (reported by 66% of physicians), increased education on methodology (60%), more education on the use of ctDNA (57%), more financial aid and reimbursement support for patients (49%), more decision support tools (47%), and better communication between physicians and vendors (26%). **Conclusions:** These findings demonstrate limited adoption of ctDNA testing by community oncologists in the care of CRC patients. Insufficient demonstration of clinical utility, limited familiarity with methodology, and reimbursement issues were cited as barriers to uptake. Education for community oncology providers about ctDNA testing and its demonstrated clinical utility, and increased financial support for patients may improve its utilization and adoption in CRC to improve patient outcomes and care. Repeat large panel genomic sequencing identifies actionable alterations and characterizes the genomic landscape in patients with metastatic solid tumors. *First Author: Niamh Coleman, The University of Texas MD Anderson Cancer Center, Houston*

Background: The implementation of genomic profiling with next generation sequencing has revolutionized the field of precision oncology. Comprehensive genomic testing of tumors to identify actionable genomic alterations is now commonly performed in the care of patients with advanced/metastatic disease. Although the genomic profile of tumors has been shown to evolve with progression and intervening treatments, the role of repeat genomic testing is not well established. We sought to determine the evolution of actionable genomic alterations in patients undergoing repeat genomic testing on the same comprehensive genomic panel. **Methods:** We retrospectively examined the molecular profiles and medical records of 262 patients with metastatic solid tumors treated in MD Anderson who underwent genomic testing on the same panel (Oncomine, Thermo Fisher) for the detection of somatic mutations in the coding sequence of 143 cancer-related genes, on at least 2 separate occasions. Genomic alterations were reviewed by a central Precision Oncology Decision Support (PODS) team in order to provide annotations at the alteration level on the functional significance. **Results:** 262 patients underwent repeat genomic testing using the same genomic panel on samples collected at different time points from July 2010 to Dec 2021 across tumor types. Changes in alterations (gain or loss) were identified on repeat testing in most patients (66%) We then specifically assessed changes in alterations that were categorized as actionable if annotated by the PODS team at the time of reporting. A gain or loss of an actionable alteration was detected in 38% (100/262) patients. New actionable alterations were frequently identified (73%; 73/100), while 41% had loss of an actionable alteration (41/100). 14% had both loss and gain of actionable alteration on repeat testing; 58% had new actionable alteration identified alone; 27% had loss of actionable alteration only. Actionable alterations identified on repeat testing included alterations in *PI3K/AKT* (27%), *EGFR* (15%), and *MAPK (*16%). On repeat testing, changes in $^{3}2$ actionable alterations were frequently identified in the same test (43%). **Conclusions:** Repeat large panel genomic testing identifies both gain and loss of actionable alterations in patients with advanced metastatic cancers. Actionable aberrations frequently coexist with alterations in a variety of other genes, which highlights the complexities of treating patients with metastatic cancer on progression of disease and suggests that tailored combination strategies may be necessary in these patients. Research Sponsor: None.

Use of clinical RNA-sequencing in the detection of actionable fusions compared to DNA-sequencing alone. *First Author: Jackson Michuda, Tempus, Chicago, IL*

Background: While targeted DNA-seq can detect clinically actionable fusions in tumor tissue samples, technical and analytical challenges may give rise to false negatives. RNA-based, whole-exome sequencing provides a complementary method for fusion detection, and may improve the identification of actionable variants. In this study, we quantify this benefit using a large, real-world clinical dataset to assess actionable fusions detected from RNA in conjunction with DNA profiling. **Methods:** Using the Tempus Research Database, we retrospectively analyzed a de-identified dataset of ~80K samples (77.4K patients) profiled with the Tempus xT assay (both DNA-seq with fusion detection in 21 genes and whole exome capture RNA-seq). Only patients that had successful RNA- and DNA-seq were included. Fusions were detected using the Tempus bioinformatic and clinical workflow. Candidate fusions were filtered based on read support thresholds, fusion annotation (*i.e.,* breakpoints, reading frame, conserved domains), and manual review. OncoKB was used to select fusion alterations in levels 1 and 2 and to identify those indication-matched to targeted therapies. **Results:** We identified 2118 level 1 and 2 fusion events across 1945 patients across 20 different cancer types. Most fusions were observed in non-small cell lung cancer (NSCLC) (25%) and biliary cancer (9%) samples. Of the 2118 fusion events, 29.1% (616) were detected only through RNA-seq while 4.8% (101) of the events were identifiable only through DNA-seq. Notably, 69.4% of fusions in low-grade glioma and 58.2% in sarcomas were detected only by RNA-seq. When evaluating specific gene fusion events, RNA-seq consistently improved the detection of fusions compared to DNA-seq alone (Table) across all cancer types. A total of 1106 fusions were classified as targetable by OncoKB indication-matched therapies with 19% (214) of these identifiable through RNA-seq alone, 5% (54) by DNA-seq alone, and 76% (838) identifiable through RNA- and DNA-seq. Overall, fusions identified through RNA-seq alone led to a 24% increase in the number of patients who were eligible to receive matched therapies (214 / 892). This included imatinib for patients with CML/BLCL (69.8%), crizotinib for NSCLC (40.3%) and entrectinib for *NTRK* and *ROS1* fusions (32.5%). **Conclusions:** The addition of RNA-seq to DNA-seq significantly increased the detection of fusion events and ability to match patients to targeted therapies. Results support consideration of combined RNA-DNA-seq for standard-of-care fusion calling. Research Sponsor: None.

Pathogenic fusion detection in solid malignancies utilizing RNA-DNA based comprehensive genomic profiling (CGP) testing. *First Author: Brian Piening, Earle A. Chiles Research Institute at Robert W. Franz Cancer Center, Providence Cancer Institute, Portland, OR*

Background: Gene fusions caused by chromosomal rearrangements comprise a key category of oncogenic driver mutations. However, given the diverse array of potentially novel loci where each proto-oncogene can translocate, many assays including DNA-based CGP have technical limitations that disallow the detection of all relevant fusion partners potentially leading to false negatives. Hybrid Capture RNA sequencing renders a more comprehensive evaluation of genes and allows detection of novel and known fusion partners. Here we assessed the impact of utilizing in-house CGP testing with a paired RNA-DNA hybrid assay in the identification of pathogenic fusions and their potential clinical actionability for patients with solid tumors across a large US health system. **Methods:** Patients in the Providence health system diagnosed with advanced solid tumor malignancies over a two-year period (2019-2021) received reflex CGP testing at the time of diagnosis utilizing an internally validated workflow. DNA/RNA sequencing results as well as histology and staging information were curated from deidentified electronic medical records and in-house databases, and tumor types were mapped to OncoTree tissue categories. Potential clinical actionability was assessed based on OncoKB therapeutic levels 1-3 and clinical trial eligibility matched to the biomarker inclusion criteria for ASCO TAPUR, NCI-MATCH and MyPathway studies (both without time limits and at time of testing). **Results:** The median patient age at diagnosis was 67 years, 52% of patients were female, and the majority (80%) were white. Across all tested advanced solid tumors, 6.7% (217/3218) were found to harbor a pathogenic fusion. The tumor types most enriched in this set of pathogenic fusions were prostate (30%), lung (27%), CUP (10%) and breast (9%). 29% (n = 64) of the identified pathogenic fusions were identified as actionable based on OncoKB criteria (levels 1-3), and 31% (n = 69) matched to one or more arms in the ASCO TAPUR, NCI-MATCH or MyPathway basket clinical trials. The most frequent actionable fusion driver genes identified were *ALK* (12%), *FGFR 1-3* (12%), *RET* (7%) *NTRK 1-3* (3%), and *ROS1* (2%) and a subset of these key drivers were fused with novel gene pairs. A subset of fusions co-occurred with other targetable biomarkers, with the most common comprising tumor mutational burden high (TMB-H) (13%), *PIK3CA* (7%) and high microsatellite instability (MSI-H) (2%). **Conclusions:** In-house CGP testing utilizing an RNA-DNA based assay identified actionable fusion targets across tumor types, with many novel fusion partners that may be undetectable by prior generation sequencing assays. While many of these actionable targets are rare individually, the expanding totality of actionable gene alterations supports the growing utility of CGP for identifying patients who are candidates for approved targeted therapies and clinical trials. Research Sponsor: Illumina grant.

DNA methylation profiling to determine the primary sites of metastatic cancers using formalin-fixed paraffin-embedded tissues. *First Author: Hongcang Gu, Zhejiang ShengTing Biotech Co. Ltd/Institute of Health and Medical Technology, Hefei Institutes of Physical Science, Chinese Academy of Sciences, Hefei, Anhui, China*

Background: Metastatic cancers with uncertain primary sites account for a significant portion of new cases. Among them, 3-9% are eventually assigned to cancer of unknown primary (CUP) site after a comprehensive diagnostic workup. Accurate identification of the primary site is the starting point for cancer diagnosis worldwide, and it is critical to guide the subsequent treatments of metastatic cancers. Here we presented a new DNA methylation sequencing-based method to predict the tissues of origin for metastatic cancers, including CUP. **Methods:** Cancer diagnosis relies substantially on histological and immunohistochemical analyses of formalin-fixed paraffin-embedded (FFPE) tissues. To take advantage of sample accessibility, we developed an optimized and streamlined method that was particularly used to generate reduced represent bisulfite sequencing (RRBS) libraries for genome-wide DNA methylation profiling with degraded DNA fragments. After confirming that data quality generated using the new FFPE-RRBS method was comparable with regular RRBS, we created an RRBS database using 541 fresh frozen samples across ten most common cancer types and 58 tumor-adjacent normal tissues. By incorporating four distinct methylation summary scores and seven machine learning approaches, 28 models were trained and compared for multi-class classification using our database. Lastly, we selected the best classifier to predict the tissues of origin utilizing 249 FFPE samples across ten metastatic cancer types and 12 FFPE samples from CUP patients. Meanwhile, the classifier was also cross-validated using a DNA methylation microarray data set of 4702 patients diagnosed with corresponding primary cancers in the TCGA project. **Results:** FFPE-RRBS allowed to construct decent libraries with heavily degraded genomic DNA within 20 hours. Comparable DNA methylation metrics were obtained for the RRBS libraries of paired primary cancer tissues (fresh frozen vs. FFPE) and the libraries of paired FFPE samples derived from primary and metastatic tissues. Among the 28 methylation-based classifiers, the mean methylation-based LinearSVC model performed the best, achieving an overall accuracy of 81% with an AUC of 0.95 in determining the primary sites of 10 metastatic cancers. In a cross-validation assay using the TCGA data set of 4702 cancer patients, the overall prediction accuracy and AUC were 92% and 0.99, respectively. Lastly, our model successfully identified the tissues of origin in 10 of 12 CUP patients in a prospective study. **Conclusions:** The FFPE-RRBS is a novel method for efficient profiling of heavily degraded FFPE samples and the mean methylation-based LinearSVC model can predict the tissues of origin for metastatic cancers and CUP with high accuracy. A first-in-human phase I study of CTX-712 in patients with advanced, relapsed or refractory malignant tumors. *First Author: Toshio Shimizu, Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan*

Background: CTX-712 is a first in class, orally available, highly potent and selective small-molecular inhibitor of CDC2-like kinase (CLK), a key regulator of the RNA splicing process that plays a critical role in driving cell growth. CTX-712 demonstrated potent inhibition of proliferation in a variety of human tumor cell lines in vitro and elicited robust antitumor activity in vivo in multiple xenograft models. The objectives of this study are to determine the recommended dose (RD) by evaluating maximum tolerated dose (MTD) and dose limiting toxicity (DLT), safety, pharmacokinetics (PK) and pharmacodynamics (PD) profiles, and preliminary efficacy of CTX-712 in patients with solid tumors (ST) and hematologic malignancies (HM). **Methods:** This study consists of ST and HM dose escalation cohorts to identify MTD and ST dose expansion cohort to identify RD. The ST dose escalation cohort was initiated with accelerated titration and then switched to a 3+3 design (10, 20, 40, 70, 105, 140 and 175 mg/body twice a week in 28-day cycles). The initial dose of HM dose escalation cohort was decided from the safety information of ST dose escalation cohort. A 3+3 design was used in HM dose escalation cohort. **Results:** As of Dec. 31, 2021, 30 patients were enrolled (16 in the ST dose escalation cohort (10/20/40/70 mg [1], 105/175 mg [3], 140 mg [6]), 10 in the ST expansion cohort, and 4 in the HM dose escalation cohort). In the ST dose escalation cohorts, DLTs were observed in 2 patients (140 mg [platelet count decreased, hypokalemia], 175 mg [dehydration]) and MTD was determined to be 140 mg. Based on this safety information, the ST dose expansion cohort and the HM dose escalation cohort were initiated with the dose of 105 mg twice a week. Among all enrolled patients, the common any-grade Adverse Events (AEs) (≥30%) were nausea (97%), vomiting (63%), diarrhoea (63%), decreased appetite (57%), blood creatinine increased (40%), dysgeusia (37%), constipation (33%), pyrexia (33%) and white blood cell count decreased (30%). The most common Grade 3 or higher AEs were hypokalemia (10%), amylase increased and platelet count decreased (7%). In PK analysis, a dose-dependent increase in systemic exposure of CTX-712 was observed. PD response was assessed in RNA extracted from peripheral blood cells. Dose dependent increases of exon skipping in two marker RNAs were detected. Two Partial Responses and two Complete Responses were observed in ST and HM, respectively. **Conclusions:** CTX-712 demonstrated an acceptable safety profile with early signs of clinical antitumor activity, establishing the initial proof of concept of the CLK inhibitor. Observed DLTs included dehydration, platelet count decreased, and hypokalemia. Investigation is ongoing to determine RD. Clinical trial information: JapicCTI-184188. Research Sponsor: Chordia Therapeutics Inc.

First-in-human phase 1/2 dose escalation and expansion study evaluating first-in-class eIF4A inhibitor zotatifin in patients with solid tumors. *First Author: Funda Meric-Bernstam, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Zotatifin (eFT226) is a first in class, potent and sequence selective inhibitor of RNA helicase eIF4A1 that promotes stable mRNA:eIF4A:drug ternary complex at specific polypurine motifs within the 5'-UTR, preventing ribosome docking and thus, efficient translation of select transcripts. In preclinical models zotatifin treatment simultaneously down-regulated translation of numerous oncogenes with complex 5' mRNA structures, including ERBB2, FGFR1/2, EGFR, KRAS, and CCND1. **Methods:** Patients (pts) with select advanced solid tumors harboring mutations/amplification of ERBB2, FGFR1, FGFR2, EGFR, or KRAS or with pancreatic cancer were enrolled into 3+3 dose escalation portion of the protocol (Part 1), and indication specific expansions continue to enroll at recommended phase 2 dose (RP2D; Part 2). The primary endpoints of Part 1 include determination of safety, tolerability, and maximum tolerated dose (MTD)/RP2D; additional endpoints include characterization of pharmacokinetic, pharmacodynamic (including from blood-based assay during escalation and from pre- and on-treatment biopsy at/near MTD with reverse phase protein array (RPPA)), and initial efficacy. **Results:** As of cut-off date Jan 13, 2022, Dose escalation phase (Part 1) included 37 patients treated with zotatifin at dose levels: 0.005, 0.01, 0.02, 0.035 mg/Kg IV weekly, and 0.035, 0.05, 0.07, 0.1 mg/kg IV 2 weeks-on and 1 week-off. DLTs were observed in 3 patients: Gr 2 thrombocytopenia (0.035 mg/kg weekly), Gr 3 anemia (0.1 mg/kg) and Gr 3 gastrointestinal bleed resulting in anemia (0.1 mg/kg). MTD/RP2D is 0.07 mg/Kg IV 2 weeks-on and 1 week-off. The most common treatment emergent adverse events (TEAEs) in Part 1 include: fatigue, anemia, diarrhea and dyspnea. The most common AEs at RP2D (n = 16 pts; Part 1 and Part 2) include: anemia (25% all gr 1 or 2), fatigue (25% all gr 1 or 2) and dyspnea (19%; 13% Gr 3) diarrhea (13%, all Gr 1 or 2). Pharmacokinetics were generally linear and dose proportional and exposures at MTD/RP2D are consistent with target pharmacologic levels in preclinical models. Blood based biomarkers showed dose- and time- dependent evidence of target engagement. Pre- and on-treatment biopsy data in expansion patients showed decreased expression of target proteins. No patient in dose escalation experienced an objective tumor response; initial efficacy data from Part 2 and at RP2D will be presented. **Conclusions:** eIF4A inhibitor zotatifin achieves pharmacologically relevant exposures with on-target AEs that are manageable at the MTD, with evidence of target knockdown from on-treatment biopsies. Part 2 indication-specific expansions (including in ER+ FGFR-amplified MBC as single agent, ER+ MBC in combination with fulvestrant and abemaciclib, and KRAS NSCLC in combination with sotorasib) are on-going. Clinical trial information: NCT04092673. Research Sponsor: eFFECTOR Therapeutics.

Circulating tumor DNA (ctDNA) determinants of improved outcomes in patients (pts) with advanced solid tumors receiving the ataxia telangiectasia and Rad3-related inhibitor (ATRi), RP-3500, in the phase 1/2a TRESR trial (NCT04497116). *First Author: Ezra Rosen, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: RP-3500 is a selective and potent oral ATRi in development for advanced solid tumors harboring loss-of-function (LOF) alterations in genes associated with ATRi sensitivity. We determined whether ctDNA can facilitate enrollment/monitoring of pts treated with RP-3500. **Methods**: Serial plasma samples collected at baseline (BL, 99 pts) and early timepoints on therapy (89 pts, 3-9 weeks [wks]) were profiled for ctDNA (Tempus xF or Guardant360). Targeted next generation sequencing (NGS) (SNiPDx panel) was performed on matched peripheral blood mononuclear cells and tumor samples collected at BL. Molecular ctDNA response (MR) was defined as ≥50% reduction in mean variant allele frequency (VAF) from BL to any timepoint ≤9 wks on-therapy. Clonal hematopoiesis (CH) or germline alterations were excluded from the analysis. Efficacy was assessed in pts treated with > 100 mg RP-3500/day with ≥1 post-BL response assessment. Endpoints included progression-free survival (PFS) and clinical benefit rate (CBR; CR/PR by RECIST1.1 or PSA/CA-125, or > 16 wks on treatment). **Results:** BL ctDNA was detected in 82% (81/99) of pts. Eligibility alterations were evaluable by the ctDNA panel in 61% (60/99) of pts, excluding structural/copy number variants and genes/exons not on the panel. Percent agreement between BL ctDNA and local eligibility NGS test was 93% (56/60). CH variants were identified in 26 pts (1-14 per pt); median VAF was 0.4% (0.1-12.4%). Two pts with pathogenic ataxia-telangiectasia mutated (*ATM*) alterations were determined to be from CH. MRs were observed in 44% (24/55) of pts with median time to MR of 3.3 wks and were across tumors harboring *ATM* (10/20), *BRCA2* (7/10), *BRCA1* (4/15), *CDK12* (1/3), *PALB2* (1/3) and *RAD51C* (1/1) pathogenic alterations. Four pts with BRCA1 mutant tumors had MRs, 2 of whom (breast cancer) had received prior PARPi and had confirmed BRCA1 reversion mutations and clinical benefit (CB). One pt with g*ATM* pancreatic cancer with CB had > 90% reduction in *KRAS* mutant VAF at 3 wks. MR was associated with longer mPFS (29 vs 12 wks, p = 0.0002) and significantly higher CBR (17/22 (77%) vs. 8/28 (29%); p = 0.001) than those without MR. Pts with MRs not achieving CB (N = 5) included 4 with RP-3500 dose interruptions/reductions and 1 who discontinued early (10 wks) due to clinical progression but with decreased target lesions and stable disease. **Conclusions:** ctDNA testing is a reliable method to detect DNA damage repair LOF alterations but is limited to alterations and genes/exons covered by the ctDNA test. CH alterations are frequent, especially for ATM, thus matched normal analysis is preferred. Changes in ctDNA as early as 3 wks were associated with improved outcomes and may be useful for evaluating drug activity in heterogenous tumors outside of traditional efficacy endpoints. Clinical trial information: NCT04497116. Research Sponsor: Repare Therapeutics.

3083 **Poster Session**

Pharmacokinetic and pharmacodynamic activity evaluation of MAK683, a selective oral embryonic ectoderm development (EED) inhibitor, in adults with advanced malignancies in a first-in-human study. *First Author: Vincent Ribrag, Gustave Roussy, Villejuif, France*

Background: Polycomb Repressive Complex 2 (PRC2) regulates transcription via trimethylation of histone H3 at lysine 27 (H3K27me3). Its dysregulation and over-expression are associated with tumorigenesis in several conditions. MAK683 is a potent oral inhibitor of PRC2 activation, allosterically targeting the EED–H3K27me3 binding site. **Methods:** NCT02900651 is an ongoing first-in-human dose-escalation study of MAK683 in adults with advanced malignancies. MAK683 was administered fasted once (QD) or twice daily (BID) on a continuous schedule in 28-day treatment cycles. The pharmacokinetic (PK) profile of MAK683 was assessed in sequential blood samples on Days 1, 8 and/or 15 of Cycles 1–6. MAK683 pharmacodynamic activity in Cycle 1, measured by change in H3K27me3, was evaluated in peripheral blood monocytes on Days 1, 8, and 15 by flow cytometry and in tumor biopsies at baseline and Day 15 by H-score. **Results:** As of Aug 30, 2021, 125 patients had received MAK683 at doses of 10–800 mg QD or 60–450 mg BID. MAK683 was well absorbed with a median T_{max} of ~1-4 hours across cohorts. PK exposure (C_{max}, AUC) increased generally with dose over the entire dose range with no major deviation from dose proportionality, taking into account the sample size and PK variability. Apparent terminal half-life (geometric mean) was 2.5–6.6 hours across cohorts and constant over time. MAK683 accumulation of ~0.9-2.2-fold (QD) or ~1.3-2.0-fold (BID) was seen with repeat dosing. Peripheral monocytes showed substantial on-treatment reductions from baseline in the H3K27me3/H3 ratio across doses. Maximum percentage reduction was proportional to cumulative MAK683 AUC, with a trend towards greater reductions at higher baseline H3K27me3. H3K27me3 H-score reductions from baseline > 40 were observed in 7/10 patients with diffuse large B-cell lymphoma (n = 4) or epithelioid sarcoma (n = 6) and paired baseline–Day 15 biopsies. RNA-seq characterization of biopsy samples is ongoing. **Conclusions:** MAK683 has a PK profile supportive of QD or BID dosing in patients with advanced malignancies. Analysis of H3K27me3 in blood monocytes and tumor biopsy confirm the *in vivo* pharmacodynamic activity of MAK683. Clinical trial information: NCT02900651. Research Sponsor: Novartis.

3084 **Poster Session**

Phase 1 results of a phase 1/2 trial of CYT-0851, a first-in-class inhibitor of RAD51-mediated homologous recombination, in patients with advanced solid and hematologic cancers. *First Author: Ryan C Lynch, University of Washington/Fred Hutchinson Cancer Research Center, Seattle, WA*

Background: Homologous recombination (HR) is an essential, high-fidelity mechanism to repair DNA double strand breaks (DSBs) in cancer cells. CYT-0851 inhibits HR leading to an accumulation of unrepaired DSBs and tumor cell death. We are reporting the completed Phase 1 dose-escalation results and RP2D selection to support ongoing development of CYT-0851. **Methods:** Patients (pts) with advanced hematologic and solid tumors were treated with continuous 28-day cycles of increasing doses of CYT-0851 following a 3+3 design. The primary objective was determining the maximum tolerated dose. Secondary objectives included safety, pharmacokinetics, and anti-tumor activity. **Results:** As of a 15 Nov 2021 data cutoff (DCO), 73 pts with advanced cancers (NHL n = 18; Sarcoma n = 16; Pancreas n = 11; Breast n = 8; HNSCC n = 6; Ovarian n = 4; SCLC n = 4; Other n = 4; Myeloma n = 2) were treated in 12 cohorts (total daily doses: 30 mg to 1200 mg). One pt experienced a dose-limiting toxicity (DLT) of reversible metabolic acidosis at 1200 mg. Two of 3 pts at 800 mg experienced reversible DLT-like events in Cycle 2 of Gr3 dry skin and Gr3 myalgia and polyarthritis, respectively. Three of 10 pts treated at 600 mg experienced DLT-like events in Cycle 1: 1 pt experienced an SAE of Gr3 anorexia with Gr3 stomatitis, vomiting, and dehydration and 2 pts had Gr3 fatigue. No DLTs occurred at 400 mg daily which was selected as the RP2D. 42 pts (57.5%) experienced a CYT-0851-related adverse event (AE), including 12 (16.4%) with a Gr3/4 AE. There were no treatment-related deaths. AE leading to CYT-0851 withdrawal were reported in 2 pts (2.7%) treated with 600 and 800 mg. The most common CYT-0851-related AEs were primarily Gr1/2 and included fatigue (20.5%), hyperuricemia (11%), nausea (11%), alopecia (9.6%), constipation (8.2%) and headache (8.2%). CYT-0851 exposure was approximately dose-proportional across the evaluated doses with an effective half-life of ~3 days. Exposure at 400 mg daily was consistent with efficacy in preclinical models. 46 pts were evaluable for response at the DCO. 12 pts with NHL were evaluable by Lugano and included 1 CR in FL and 1 PR in DLBCL treated for 393+ and 244 days respectively. 34 pts with solid tumors were evaluable by RECIST v1.1 with 1 PR in a pt with myxofibrosarcoma treated for 313 days and 16 pts with stable disease. Fifteen pts were treated for 100+ days and 5 for 180+ days. **Conclusions:** CYT-0851 has demonstrated promising and broad clinical activity in a Ph 1 population of pts with advanced cancers. The safety profile is favorable as characterized by events that were infrequent, primarily Gr1/2, and reversible. Six expansion cohorts (DLBCL, Follicular Lymphoma, Myeloma, Pancreatic, Ovarian and Sarcoma) are enrolling to characterize activity at the RP2D. Ph 1 evaluation of CYT-0851 in combination with 3 chemotherapy backbones is also ongoing. Clinical trial information: NCT03997968. Research Sponsor: Cyteir Therapeutics.

3085 **Poster Session**

Interim phase 1 results for SQ3370 in advanced solid tumors. *First Author: Sant P. Chawla, Sarcoma Oncology Research Center, Santa Monica, CA*

Background: SQ3370, a novel therapy, utilizes Shasqi's proprietary Click Activated Protodrugs Against Cancer (CAPAC) platform where mutually-reactive click chemistry groups release Doxorubicin (Dox) at the tumor site minimizing systemic exposure. In animals, SQ3370 enhanced survival, T-cell infiltration and antitumor responses in injected and non-injected tumors. Minimal to no toxicity, including no cardiotoxicity was seen in up to 9-fold dose increases in animals. Conventional Dox can induce cardiomyopathy at incidences of 1-20% for cumulative doses from 300-500 mg/m^2 in humans and re-treatment with Dox is less effective in heavily pre-treated patients (pts). Here we report interim results of the Phase 1 (NCT04106492). **Methods:** SQ3370 has 2 components: 1) Intratumoral injection of a protodrug-activating biopolymer (SQL70: 10 mL or 20 mL); 2) 5 consecutive daily IV infusions of an attenuated protodrug of Dox (SQP33). Key eligibility includes locally advanced or metastatic solid tumors, ≤300 mg/m^2 prior exposure to Dox, ECOG 0-1 and no limit to prior systemic therapies. Primary objectives include safety and determining Phase 2 dose. Dose escalation was assessed in 2 stages: 1) accelerated titration; 2) 3+3 design. **Results:** As of 31JAN2022 data cut, 26 pts were treated, 21 with 10 mL biopolymer (bp) and 5 with 20 mL bp over 9 dose escalation protodrug cohorts. MTD has not been reached. Median age was 61 years (26-84), 62% were females, and 69% were ECOG 1. Prior procedures included surgery (89%) and radiation (62%). At study entry, 77% of pts had metastases with a median number of metastatic sites being 2 (1-5); most frequently lung (50%). Tumors were sarcoma (73%), breast cancer (7.7%), gyne (7.7%) and other (11.5%). Twenty-four of 26 (92%) pts received prior systemic therapies with 50% receiving prior Dox. Median number of prior systemic therapies was 2 (1-7). Of the 26 pts, 62% received > 500 mg/m^2 cumulative Dox given as SQP33. Median duration of treatment was 2 cycles (1-12). Most frequent AEs, regardless of causality, for the 10 mL bp group included nausea (n = 11), fatigue (n = 9) and anemia (n = 6), and for the 20 mL bp group included anemia (n = 3) and nausea (n = 2). Ejection fraction (LVEF) remained normal during the study period. No AEs that led to discontinuation or death were related to SQ3370 by investigator. At a median follow-up of 9.2 wks (3-37), 21 pts were evaluable. SD was best response in 71%. Median duration of SD was 80-dys (37-186) corresponding to an overall disease control rate (CR+ PR+ SD x 30-dys) of 71% (68% in 10 mL bp; 100% in 20 mL bp). The remainder of pts had PD as best response. Over 38% of pts remain on drug. **Conclusions:** SQ3370 with 10 mL or 20 mL biopolymer was well tolerated in pts with half being re-treated with Dox. Although > 60% of pts received > 500 mg/m^2 cumulative Dox given as SQP33, LVEF remained normal. Preliminary evidence of disease control was observed in pts despite heavy prior pre-treatment and high cancer burden. Dose escalation is ongoing. Clinical trial information: NCT04106492. Research Sponsor: Shasqi, Inc., U.S. National Institutes of Health.

3086 **Poster Session**

Safety, tolerability, pharmacokinetics and preliminary efficacy of MIL93, an anti-Claudin18.2 monoclonal antibody, in patients with advanced solid tumors: A phase 1 clinical study. *First Author: Jing Huang, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Claudin18.2 (CLDN18.2) is specifically expressed in the tight junction of gastric epithelial cells, and has been identified as a promising target in gastric and pancreatic cancer as well as several other malignancies. MIL93 is a humanized IgG1 monoclonal antibody targeting CLDN18.2. From January 2021, we started a multicenter, dose escalation and expansion phase 1 study of MIL93, for the treatment of patients with advanced solid tumors (Protocol number MIL93-CT101, Beijing Mabworks Biotech Co. Ltd.) at 6 clinical study sites in China. Currently the study is still ongoing. **Methods:** We already enrolled 13 pts aged 18 years or older with advanced solid tumors whose disease had progressed after standard systemic treatments. Pts were required to have measurable lesion as per RECIST v1.1; ECOG PS score of 0-1 and adequate organ functions. In the dose escalation phase, 6 dose levels (0.3mg/kg, 1mg/kg, 3mg/kg, 10mg/kg, 20mg/kg and 30mg/kg, Q3W) of MIL93 were planned for assessment. Accelerated titration was adopted for the first 2 dose levels, and the 3+3 design was used afterwards. In the dose expansion phase, pts with CLDN18.2-positive cancers received the selected RP2D. The primary objectives were the safety and tolerability, dose limiting toxicities (DLTs) and maximum tolerated dose (MTD) of MIL93. Secondary objectives included pharmacokinetics, immunogenicity and preliminary efficacy. **Results:** At the data cut-off date (February 14, 2022), 13 pts were enrolled between April 23, 2021 and February 9, 2022. MIL93 was well-tolerated for the dosages tested (0.3mg/kg through 20mg/kg Q3W) as no DLTs were observed, and dose escalation was ongoing at 30mg/kg. In particular, Grade 3 nausea and vomiting occurred in 2 cases in the third dose group, so preventive antiemetic treatment was given from the fourth dose group. 9 pts (69.2%) experienced at least one treatment-emergent adverse event (TEAE) with no Grade 4 or Grade 5 AEs. The most common treatment-related adverse events (TRAEs) occurring in ≥10% of pts were nausea (46.2%), vomiting (46.2%), fatigue (15.4%), anemia (15.4%). Serious adverse events (SAEs) were observed in 3 (23.1%) pts, and MIL93-related SAEs occurred in 1 pt (7.7%, Grade 3 nausea). Among the 10 pts who had at least one post-treatment radiological evaluation, 1 pt with CLDN18.2-positive gastric cancer achieved PR and 3 pts had SD, including 1 case of gastric cancer, 1 case of gastroesophageal junction cancer and 1 case of gallbladder cancer. **Conclusions:** MIL93 had a favorable safety profile with no DLTs observed through 20mg/kg Q3W. Pts with CLDN18.2-positive gastric cancer responded to the treatment. Dose escalation and expansion in selected tumor types is currently underway. Clinical trial information: NCT04671875. Research Sponsor: Mabworks Biotech Co.Ltd.

3087 **Poster Session**

Molecular landscape and actionable alterations in a genomic-guided cancer clinical trial: First analysis of the ROME trial. *First Author: Andrea Botticelli, Department of Radiology, Oncology and Pathology, "Sapienza" University of Rome, Rome, Italy*

Background: The Rome Trial is a randomized, prospective, multicenter, multi-basket, Phase II clinical trial (EudraCT n° 2018-002190-21; NCT04591431). The aim is to evaluate the efficacy of Tailored Therapy (TT) vs Standard of Care (SoC) in patients (pts) with metastatic solid tumors who received at least one and no more than two lines of treatment. Pts with a molecular alteration were discussed in a Molecular Tumor Board (MTB), assigned to one or a combination of the 20 available treatments, and randomized to TT or SoC. **Methods:** Tissue (collected within 6 months) and blood samples from pts with refractory solid tumors were analyzed centrally with next generation sequencing (NGS, FoundationOneCDx and FoundationOneLiquid). MTB discussed all screened pts with any actionable genomic alterations using common mutational database and ESCAT. Genomic data, MTB reports and treatment outcomes were collected. The 3 outcomes of the MTB were: A) assignment of a TT and randomization, B) screening failure (SF) C) SF for the trial but with relevant information from the genomic test. Outcome C was divided into 3 groups: 1) indication to receive a personalized standard treatment different from the planned one, 2) indication to access to another clinical trial/compassionate use/expanded access, 3) indication to perform a germline test (GT). **Results:** From Oct 2020 to Dec 2021, 497 pts were enrolled in 38 Italian accrual sites, 303 (61.0%) had relevant genomic alterations and were discussed to the MTB. Molecular profiling was determined both on tissue and liquid biopsy in 262/303 (86.5%) pts, while in 11 (3.5%) and 30 (10.0%) only on tissue or liquid, respectively. After applying clinical and molecular exclusion criteria and considering multiple actionable or resistance-conferring mutations (detected in 95 and 70 out of 303 patients): 135 pts (45%) were randomized (outcome A), 19 (30%) were SF (outcome B), and 78 (25%) SF but with an additional indication (outcome C). Of them, 14 patients (18%) were group 1 and 42 (54%) had indication to a target therapy outside from the trial (group 2). MTB suggested a GT to 60/303 pts (20%, group 3). To date, 8 out of 9 GT performed confirmed a germline mutation (4 BRCA1/2, 2 PALB2, 1 MUTHY, 1 ATM). Finally, 213 pts, 71% of those discussed to MTB and 43% of the entire screened population, were randomized or received at least one specific indication following the extended molecular assessment with NGS. **Conclusions:** We demonstrated the feasibility of screening a large numbers of pts from numerous accruing sites in a complex trial to test investigational therapies for moderately frequent molecular targets. Co-occurring resistance mutations were common and endorse to investigate combination targeted-therapy regimens. The Rome trial MTB, even when no actionable alterations were detected, provided a therapeutic and diagnostic indication with a potential impact on patient's outcomes. Clinical trial information: NCT04591431. Research Sponsor: Roche, Bristol Myers Squibb, Incyte, Takeda, Pfizer, Novartis.

Characterizing the genomic landscape of *PIK3CA* alterations from 121,221 adult patients with cancer: The next tissue-agnostic target? *First Author: Niamh Coleman, The University of Texas MD Anderson Cancer Center, Houston*

Background: The PI3K–AKT–mTOR signaling pathway is frequently dysregulated in cancer and small molecule inhibitors targeting various nodes in the pathway have been pursued for decades. Activating mutations in *PIK3CA* are recognized potent drivers of oncogenesis, though the landscape of *PIK3CA* fusions and amplifications has yet to be well-defined. The field has been hampered by issues such as resistance and poor tolerance, however several isoform-specific PI3K inhibitors have now received regulatory approval and allosteric pan-mutant and specific mutant selective Inhibitors of PI3Kα are being investigated in early phase clinical trials. Here, we present a comprehensive analysis of *PIK3CA* alterations in pan-cancer adult malignancies. **Methods:** We analyzed 136096 samples from 121221 patients available from AACR Project GENIE v.11 database for the prevalence of PIK3CA mutations, fusions and copy number alterations in a range of cancer types. **Results:** 15712 alterations in *PIK3CA* were detected in profiled tumor samples (12%), in 14774 of patients profiled (12%), most frequently in endometrial (44% of 4135 cases), anal (35% of 286 cases), breast (35% of 14218 cases), cervical (27% of 761 cases) and colorectal cancer (20% of 3743 cases).*PIK3CA* alterations identified included 17740 mutations (11%) (including duplicate mutations in patients with multiple samples). 16685 missense mutations were identified (12%);14953 were identified as missense in driver mutation (likely oncogenic)(90% of missense); 1,732 were missense of variants of uncertain significance (VUS) using OncoKB database (11%). Missense mutations most frequently involved codons 545(3347, 20% of missense), codon 1047 (3644, 22%) and codon 542 (1881, 11%). 237 truncating mutations were identified (0.2%), 442 in-frame deletions, 29 in-frame insertion mutations. PIK3CA fusions were observed in 0.06% of tumor samples and were most identified in breast, colorectal, lung, GBM and ovarian cancer (24%, 17%, 13%, 7% and 6% of identified *PIK3CA* fusions respectively). PIK3CA fusions were most commonly intragenic fusions(36%);common fusion partners included *TBL1XR1*, *FNDC3B* and *NAALADL2*(17%, 7%, 5% of identified *PIK3CA* fusions, respectively). *PIK3CA* fusions were identified as VUS, aside from *KMT2C-PIK3CA* (2%). *PIK3CA* amplification high level gain occurred in 0.5% of samples tested(662), deletion occurred in 0.16%(21). **Conclusions:** Activating *PIK3CA* mutations occur frequently across cancer types and could be considered for tissue-agnostic drug development. *PIK3CA* fusion and amplification events are extremely rare. Most *PIK3CA* missense mutation variants are described as oncogenic, while fusions are described as VUS, which may limit the impact of precision oncology for patients with this alteration. Further functional characterization of *PIK3CA* variants and basket trial enrollment are warranted. Research Sponsor: None.

A phase I/II study of first-in-human trial of JAB-21822 (KRAS G12C inhibitor) in advanced solid tumors. *First Author: Jian Li, Department of Gastrointestinal Oncology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital and Institute, Beijing, China*

Background: KRAS G12C mutation occurs in approximately 4% of non-small cell lung cancer (NSCLC), 1-2% of colorectal cancer (CRC) and other solid tumors in China. JAB-21822 (Jacobio, Beijing, PRC) is a highly selective, covalent oral inhibitor of KRAS G12C. **Methods:** NCT05009329 is an ongoing first-in-human, open label phase I/II study of JAB-21822 in patients with advanced solid tumors. The primary objective is to evaluate the safety and tolerability of JAB-21822. Other objectives include preliminary efficacy, pharmacokinetics, and biomarkers. Here we report the results from the dose escalation phase of the trial. **Results:** As of January 28th, 2022, 53 patients with a median age of 62 years (39-79) were enrolled in 5 different dose levels: 200mg QD, 400mg QD, 800mg QD, 400mg BID and 400mg TID. Most patients (55%) had $\geq$ 2 prior lines of therapy. No dosing-limiting toxicities were observed. Two treatment-related adverse events (TRAEs) were G4 neutropenia (1 in 400mg BID and 1 in 400mg TID). The most common TRAEs ($\geq$ 10%) included anemia (24.5%), total bilirubin increase (20.8%), direct bilirubin increase (15.1%), proteinuria (13.2%) and indirect bilirubin increase (11.3%). Only Grade 1 and 2 TRAEs were observed in the QD cohorts. A total of 33 patients (22 NSCLC, 9 CRC and 2 pancreatic cancer) had at least 1 post-baseline tumor assessment; in the 800mg QD cohort, overall response rate (ORR) and disease control rate (DCR) were 50% (5/10) and 100% (10/10), respectively, including 4 non-confirmed partial response (PR); in the 400mg QD cohort had an ORR and DCR of 80% (4/5) and 100% (5/5) respectively, including 2 non-confirmed PR. Patients with NSCLC (400mg QD and 800mg QD), the ORR and DCR were 70% (7/10) and 100% (10/10), respectively, including 5 non-confirmed PR. With respect to the pharmacokinetics analysis, JAB-21822 was rapidly absorbed with an average T_{max} of 2 hr and reached higher plasma exposures (C_{max} and $AUC_{0\text{-}24h}$) after a single dose and multiple doses at C1D8. **Conclusions:** JAB-21822 was well tolerated with impressive preliminary efficacy in patients with heavily treated solid tumors harboring KRAS G12C mutation. The study is enrolling patients in the expansion phase. Multiple JAB-21822-based combination trials are also ongoing. Clinical trial information: NCT05009329. Research Sponsor: Jacobio Pharmaceuticals Co., Ltd.

3090 **Poster Session**

Dose optimization for MORAb-202, an antibody-drug conjugate (ADC) highly selective for folate receptor-alpha (FRα), using population pharmacokinetic (PPK) and exposure-response (E-R) efficacy and safety analyses. *First Author: Seiichi Hayato, Eisai Co. Ltd., Tokyo, Japan*

Background: MORAb-202 is an ADC consisting of farletuzumab (an antibody that binds to FRα) paired with eribulin mesylate (a microtubule dynamics inhibitor) conjugated via a cathepsin B-cleavable linker. A phase 1 dose-escalation and expansion study in patients with advanced solid tumors evaluated MORAb-202 doses ranging from 0.3 mg/kg to 1.2 mg/kg IV every 3 weeks (Shimizu 2021, *CCR*). The dose-expansion part included starting doses of 0.9 mg/kg and 1.2 mg/kg in an ovarian cancer (OC) cohort. Objective response rates (ORR) by investigator per RECIST v1.1 and rates of all-grade interstitial lung disease (ILD), an adverse event of interest, were lower at the 0.9 mg/kg dose vs the 1.2 mg/kg dose. To support dose optimization for clinical benefit while reducing the risk of ILD, a MORAb-202 PPK model was developed to characterize the pharmacokinetics and to obtain model-predicted exposure measures. **Methods:** Exposure was predicted for different dosing scenarios: flat dosing, bodyweight (BW)-based dosing with or without a dose cap, adjusted ideal BW dosing, and body surface area (BSA)-based dosing. E-R analyses for efficacy (ie, ORR) and safety (ie, ILD by expert review) were conducted using logistic-regression analysis. Simulations (N = 1000) were performed using a BW distribution from a previous phase 3 farletuzumab study in OC (Vergote 2016, *JCO*) to predict the probability of ORR and ILD in patients treated with MORAb-202. **Results:** MORAb-202 exposures were dose proportional, and the pharmacokinetics were described by a 2-compartment model with zero-order IV infusion and first-order elimination. Patients with higher BW had less-than-proportional increases in clearance (allometric exponent [AE] 0.571) and distribution volume (AE 0.524). MORAb-202 demonstrated a positive exposure (based on area under the curve [AUC]) dependence to ORR and ILD. The probability of achieving a tumor response was higher with higher AUC (odds ratio [OR] for an AUC unit change of 1000 $\mu g \bullet h$/mL: 1.73 [95% CI 1.06–3.11]). The probability of an ILD event was higher with higher AUC (OR for an AUC unit change of 1000 $\mu g \bullet h$/mL: 3.50 [95% CI 1.89–7.81]). Simulations across BW ranges (34.2–144 kg) indicated that BSA-based dosing (33 mg/m^2), compared with BW-based dosing (0.9 mg/kg), yielded similar predicted median (90% prediction interval) rates for ORR (33.7% [19.3–62.2] vs 37.9% [20.6–67.5]) and all-grade ILD (46.8% [18.2–88.2] vs 55.1% [20.7–91.9]). However, BSA-based dosing is predicted to reduce ILD in the highest BW quartile (> 80–144 kg) by approximately 35% compared with BW-based dosing. **Conclusions:** Based on this assessment, BSA-based dosing is predicted to lower the exposure-dependent ILD risk in patients with higher BW and is being further evaluated in ongoing clinical studies. Clinical trial information: NCT03386942. Research Sponsor: Eisai Inc., Nutley, NJ, USA.

3091 **Poster Session**

Adaptive response analysis of colorectal cancer cells to low-dose oxaliplatin as a tool to deciphering mechanisms of synergistic drug interaction. *First Author: Diego Tosi, Medical Oncology Department, Institut du Cancer de Montpellier, Montpellier, France*

Background: Using an *in vitro* dose matrix approach, we previously showed in multiple colorectal cancer cell lines a striking cytotoxic synergism between oxaliplatin at very low concentrations and the ATR inhibitor VE-822. We confirmed this finding *in vivo*, and, surprisingly, in this setting the oxaliplatin-induced cell addiction to VE-822 persists over several days after oxaliplatin elimination. We tried to elucidate the molecular mechanism of the latter phenomenon. **Methods:** We evaluated by RNAseq the gene expression changes induced *in vitro* by low-dose oxaliplatin in the colorectal cancer cell line HCT-116 after 24 and 48 hours of treatment. In order to untangle the functional significance of the adaptive response to oxaliplatin, we performed on the RNAseq data an extensive gene set enrichment analysis (GSEA) using gene set from all Molecular Signature Database v7.4 collections with the exception of C7. For ontology-based gene set collections, we clusterized the enriched gene sets using the semantic similarity methodology in order to increase the readability of global functional response. **Results:** Extensive GSEA showed that after 24 hours of oxaliplatin treatment cancer cells upregulate several gene sets involved in aspecific responses to cellular stress or to various type of extracellular stimulations, including other organisms, oxygen-containing compounds, abiotic stimuli and hypoxia. In addition, several gene sets involved in proteolysis and autophagy are upregulated, suggesting a rewiring of cell machinery. After 48 hours of oxaliplatin treatment, we observed the activation of ribosome function, mitochondrial assembly and synthesis of aminoacids and ribonucleosides. Finally, a widespread negative enrichment of gene sets involved in DNA repair-related was detected both at 24 and at 48 hours, with a far greater negative enrichment at 48 hours, which suggest a commitment of cancer cell to a major limitation of DNA repairing capability lasting several days following a DNA damaging insult. Analysis of leading edge genes from the DNA repair gene sets showed a profound repression both at 24 and 48 hours of the transcripts of BRCA1, BRCA2, ATM, CHK1, WEE1, BARD1, BRIP1, NEHJ1, RAD51, XRCC2, CLSPN, GEN1, DNA2, EXO1, TOPBP1, POLE, RMI1. Interestingly, ATR mRNA was minimally repressed both at 24 and at 48 hours, which could explain the long-standing *in vivo* dependence of cancer cell to ATR after a brief oxaliplatin exposure. **Conclusions:** Extensive GSEA was able to elucidate the molecular mechanism underlying synergistic interaction between oxaliplatin and VE-822. The impact of profiling cancer cell adaptive responses by extensive GSEA should be further evaluated in the setting of rational development of drug combinations. Research Sponsor: None.

^{64}Cu-SAR-Bombesin PET-CT imaging in the staging of ER+/PR+/HER2- metastatic breast cancer: Safety, dosimetry, and feasibility in a phase I trial. *First Author: Keith Wong, Department of Theranostics and Nuclear Medicine, St. Vincent's Hospital, Sydney, NSW, Australia*

Background: Breast cancers are most frequently oestrogen receptor (ER) and progesterone receptor (PR) positive and ^{18}F-Fluorodeoxyglucose PET-CT (FDG) used in conventional staging of breast cancer has lower sensitivity for these subtypes. Gastrin releasing peptide receptors (GRPR) are a potential alternative diagnostic and theranostic target for ER+/PR+ breast cancers due to their overexpression of GRPR. This phase 1 study aims to assess the safety and potential of the novel radiotracer ^{64}Cu-Sarcophagine(SAR)-Bombesin (BBN) in the re-staging of recurrent metastatic ER+/PR+/human epidermal growth factor 2 negative (HER2-) breast cancer. **Methods:** Patients with confirmed recurrent or primary metastatic ER+/PR+/HER2- breast cancer undergoing staging prior to a new treatment underwent ^{64}Cu-SAR-BBN PET-CT with imaging at 1, 3 and 24 hours post-injection. Bloods and vital signs were acquired for patients at baseline, 1, 3 and 24 hours post-injection timepoints, and electrocardiogram (ECG) performed 1 hour pre and 1 hour post injection. Blood tracer-clearance and dosimetry was performed. GRPR receptor status was assessed in 4/7 patients from metastatic-site biopsy samples. Staging of the patients was assessed by conventional imaging (FDG, bone scan and diagnostic CT) within 3 weeks of ^{64}Cu-SAR-BBN imaging. All PET scans were assessed visually, and quantitatively using MIM Software. **Results:** 9 patients were enrolled. 7/9 patients underwent all imaging modalities, while 2/9 did not undergo BBN imaging. 1/7 patient who underwent all imaging had de- novo metastatic ER+/PR+/Her 2- breast cancer and 6/7 recurrent metastatic disease. 2/7 had lobular subtype. There were no adverse events reported, and ECG, vitals and haematological, biochemical and coagulation markers remained unchanged. All 7 patients were positive on conventional imaging, while 6/7 were positive on FDG. BBN was positive in 5/7 patients. Both BBN negative patients had disease identified on FDG. Conversely, 1 patient was BBN positive but FDG negative. 4/7 patients were BBN positive and FDG positive. In these 4 patients, mean SUVmax was higher for BBN than FDG (15 vs. 12). In classical lobular subtype (2/7), BBN was highly avid compared to FDG (SUV max 20 vs 11, and 20 vs <3) and with a higher tumor volume compared to FDG (2034 vs 504, and 634 mL vs FDG negative). **Conclusions:** ^{64}Cu-SAR-Bombesin is a novel tracer which appears safe and may have a diagnostic and theranostic role in patients with metastatic ER+/PR+/HER2- breast cancer, particularly lobular subtype. Further evaluation appears warranted. Research Sponsor: Clarity Pharmaceuticals.

Theranostic pairing: ABY-025/251 targeting HER2 with ^{68}Ga and ^{188}Re—Minimized radioligands using Affibody peptide scaffold technology. *First Author: Yongsheng Liu, Uppsala University, Uppsala, Sweden*

Background: HER2 expressing tumors such as subsets of metastatic breast cancer and gastro-esophageal tumors can be targeted using specific antibodies or antibody-drug-conjugates (ADCs). However, some tumors remain refractory to treatment. External radiation therapy is unsuited to advanced metastatic disease. Targeted molecular radiation therapy has proven useful in other tumors such as neuroendocrine tumors or prostate cancer using ^{177}Lu. ^{188}Re is a beta emitting isotope that when chelated to the ABY-251 Affibody molecule has the potential to precisely target HER2 expressing tumors locally. The ABY-251 Affibody molecule is a very small, structured protein scaffold with a molecular weight of only 7 kDa targeting HER2 with high affinity (K_D = 100pM). ABY-251 can be manufactured by chemical synthesis. A diagnostic analog molecule ABY-025 was also developed with chelation to ^{68}Ga ideal for PET visualization. **Methods:** A pre-clinical study in mice was conducted to investigate tumor/tissue uptake, followed by a clinical diagnostic study for visualization in HER+ patients with metastatic breast cancer, to be followed by a theranostic study in humans. **Results:** Pre-clinical Study: A preclinical study in mice has previously demonstrated high contrast uptake in HER2 tumor tissue using the diagnostic analog ABY-025. Off target accumulation was seen in kidney tissue using the diagnostic ABY-025, which in the ABY-251 therapeutic molecule has been reduced by further engineering of the molecule. This molecule has now been proven to increase survival in mice bearing HER2+ tumors. Median survival in the treated animals was 68 days as compared to 29 and 27.5 days in animals treated with vehicle and non-labelled peptide respectively. Clinical diagnostic study ph1/2: ABY-025 was studied in HER2+ patients with metastatic breast cancer. In a study of 16 women with refractory metastatic breast cancer (>2 prior lines of therapy, 12 IHC positive and 4 IHC negative) 9 out of 10 patients showed high HER2 expression levels as measured with ABY-025 PET despite ongoing treatment with HER2 targeted therapy. Persistent high ^{68}Ga-ABY-025 tumor uptake in patients despite treatment with standard HER2-targeted therapies is a sign of therapeutic drug resistance. These patients would be eligible for treatment with the therapeutic analog ABY-251 using ^{188}Re generated beta radiation for tumor eradication. Clinical therapeutic study (planned): ABY-251 is in development to soon enter therapeutic clinical Ph1/2a trials in patients with refractory HER2+ tumors and positive tumor imaging using ABY-025 as a theranostic pair. **Conclusions:** A radiopharmaceutical theranostic approach diagnosing HER2+ patients with metastatic disease using ^{68}Ga-ABY-025 for targetability and subsequent treatment using ^{188}Re-ABY-251 seems feasible and is currently in clinical trials. Clinical trial information: NCT01858116. Research Sponsor: Uppsala University and Affibody AB.

3094 **Poster Session**

Tumor agnostic efficacy of selpercatinib in patients with *RET* fusion+ solid tumors: A global, multicenter, registrational trial update (LIBRETTO-001). *First Author: Vivek Subbiah, Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Selpercatinib, a first-in-class highly selective and potent RET kinase inhibitor, is approved in multiple countries for the treatment of lung and thyroid cancer with *RET* fusions and medullary thyroid cancer with *RET* mutations. We provide an efficacy and safety update with more patients (pts) and longer follow-up (data cut-off: 24Sep2021) in *RET* fusion+ solid tumors with histologies other than lung/thyroid. **Methods:** The phase 1/2 LIBRETTO-001 trial (NCT03157128) enrolled pts with locally advanced/metastatic *RET* fusion+ solid tumors. Following dose escalation, pts received the recommended dose of 160 mg orally twice daily. The efficacy analysis set consisted of pts enrolled ≥6 months (mo) prior to the cut-off date. If a pt achieved response, an additional ≥6 mo follow-up from the initial response was required. There was no additional follow-up required for non-responders. Response was assessed per RECIST 1.1. Primary endpoint was objective response rate (ORR) by independent review committee (IRC). Secondary endpoints included ORR by investigator (INV), duration of response (DoR), progression-free survival (PFS), time to response (TTR), and safety. **Results:** Forty-five pts with 14 unique *RET* fusion+ tumor types received ≥1 dose of selpercatinib: 12 pancreatic, 10 colon, 4 salivary, 3 unknown primary, 3 sarcoma, 2 each of breast, carcinoma of the skin, xanthogranuloma, and cholangiocarcinoma, and 1 each of lung carcinoid, rectal neuroendocrine, small intestine, ovarian, and pulmonary carcinosarcoma. Median age was 53 years (range 21-85). Forty-one pts received prior systemic therapy (median prior lines: 2, range 0-9); 31% received ≥3 lines. In 41 efficacy-evaluable pts, confirmed ORR by IRC was 44% (18/41, 95% CI: 29-60). Clinical benefit was observed in 63% (26/41) of pts: 2 complete responses (breast, small intestine), 16 partial responses, and stable disease ≥16 weeks in 8 pts by IRC. Responses were observed across a variety of fusion partners. Median TTR was 1.9 mo by IRC. Median DoR was 24.5 mo (95% CI: 9.2-NE) with 50% (9/18) of responses ongoing at a median follow-up of 14.9 mo by IRC. Median PFS by IRC was 13.2 mo (95% CI: 7.4-26.2), with 34.1% alive and progression-free at a median follow-up of 16.4 mo. No new safety signals were identified in this cohort compared to broader safety database. Three grade 5 AEs were observed (unrelated to treatment by INV), and 4 pts discontinued treatment due to AEs (1 deemed related to treatment by INV). **Conclusions:** Selpercatinib continued to demonstrate durable antitumor activity in pts with *RET* fusion+ cancers across multiple tumor types. No new safety signals were identified. These results emphasize the importance of comprehensive genomic profiling to identify actionable oncogenic drivers, including *RET* fusions. The LIBRETTO-001 study continues to enroll pts. Clinical trial information: NCT03157128. Research Sponsor: Eli Lilly and Company.

A phase Ia/Ib, dose-escalation/expansion study of BI 907828 in combination with BI 754091 (ezabenlimab) and BI 754111 in patients (pts) with advanced solid tumors. *First Author: Noboru Yamamoto, Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo, Japan*

Background: Preclinical data show that combining a murine double minute 2–tumor protein 53 (MDM2–p53) antagonist with immune checkpoint inhibitors produces anti-tumor effects in multiple tumor types. This Phase Ia/Ib study (NCT03964233) is assessing BI 907828, a MDM2–p53 antagonist, combined with immune checkpoint inhibitors in *TP53* wild-type cancers. **Methods:** In Phase Ia (dose escalation), pts with advanced/metastatic solid tumors received escalating doses of BI 907828 guided by a Bayesian Logistic Regression Model (starting dose 10 mg orally) plus ezabenlimab 240 mg (anti-PD-1 antibody) and BI 754111 600 mg (anti-LAG-3 antibody) every 21 days (q3w). Primary endpoint was the maximum tolerated dose (MTD) of BI 907828 based on the number of pts with dose-limiting toxicities (DLTs) during cycle one. During Phase Ia, other studies indicated a lack of added efficacy when BI 754111 was combined with ezabenlimab; therefore, the study design was updated to switch the dose escalation to the doublet combination of BI 907828 plus ezabenlimab. **Results:** A total of 11 pts received the triplet combination at 10/20/30/45 mg dose levels (DL; n = 3/3/3/2 respectively); all have discontinued treatment. No DLTs were reported in cycle one; MTD was not reached. As of 20th January 2022, 15 pts have received the doublet combination at 30/45 mg DLs (n = 10/5 respectively). One pt (45 mg) had a DLT during cycle one: G2 neutropenia. Four DLTs were reported after cycle one: G3 anemia (30 mg); G2 thrombocytopenia (45 mg); and G3 neutropenia and G4 thrombocytopenia (45 mg). G≥3 adverse events occurred in eight pts; most commonly anemia (n = 6), thrombocytopenia (n = 4) and lymphopenia (n = 3). There were no notable safety findings with BI 907828 45 mg q3w, the recommended dose for expansion (RDE) for BI 907828 monotherapy. Nine of the 15 pts who received doublet therapy were evaluable for response; four had a confirmed partial response (PR; 30 mg, n = 1; 45 mg, n = 3), two biliary tract carcinoma, one urothelial carcinoma, and one myxoid liposarcoma; one had an unconfirmed PR (30 mg) with adenocarcinoma (primary site intrahepatic cholangiocarcinoma). Four pts with liposarcoma and gastric cancer had stable disease. MTD will be reported. In Phase Ib, pts will receive the RDE of BI 907828 plus 240 mg ezabenlimab (q3w). Pts will be recruited to two cohorts: soft tissue sarcomas (liposarcoma, undifferentiated pleomorphic sarcoma, myxofibrosarcoma, synovial sarcoma and leiomyosarcoma) and selected MDM2-amplified tumors (NSCLC, gastric adenocarcinoma, urothelial carcinoma, and biliary tract carcinoma). Primary endpoints are progression-free survival and objective response (RECIST 1.1). **Conclusions:** The doublet combination of BI 907828 plus ezabenlimab showed a manageable safety profile and early signs of anti-tumor activity. Eleven pts remain on treatment; recruitment is ongoing. Clinical trial information: NCT03964233. Research Sponsor: Boehringer Ingelheim.

3096 **Poster Session**

Interim safety and efficacy results from a phase 1 study of NT219 in adults with advanced solid tumors. *First Author: Alberto Bessudo, Pacific Oncology Hematology Associates Inc., Encinitas, CA*

Background: NT219 is a small molecule, effecting IRS1/2 degradation and inhibiting STAT3 phosphorylation. IRS1/2 and STAT3 are major signaling junctions regulated by various oncogenes, altered during epithelial to mesenchymal transition (EMT) and drug resistance, and play an important role in the tumor and its microenvironment. A Phase 1/2 study (NCT04474470) includes a dose escalation of NT219 administered weekly for the treatment of relapsed and/or refractory cancer patients. **Methods:** In the dose escalation part of the study involving a conventional 3+3 design, patients with recurrent and/or metastatic solid tumors were administered intravenously with NT219 at 3, 6, 12 and 24mg/kg. Safety was assessed according to CTCAE v5 and anti-tumor activity was assessed by the investigators according to RECISTv1.1 using CT/MRI. The primary objectives of this part of the study are to evaluate safety, tolerability, PK and determine the recommended Phase 2 dose (RP2D). The study includes evaluation of potential biomarkers including measurements of STAT3, IRS1/2 phosphorylation, and TILs in biopsy specimens. **Results:** As of data cutoff date of February 8, 2022, a total of 13 patients were enrolled to 4 NT219 dose levels (3 - 24mg/kg) in the dose escalation phase, of which 11 were evaluable for dose limiting toxicity (DLT) determination, including 4 with colorectal cancer (CRC), 2 with pancreatic cancer, 2 with breast cancer, and one of each of the following cancers: gastroesophageal junction (GEJ), esophageal, appendiceal, papillary thyroid, and mesothelioma. Median number of prior treatment regimens for metastatic disease was 4 (2-11). Six Grade 3 adverse events (AEs) were observed, including alkaline phosphatase increase, aspartate aminotransferase increase, toxic encephalopathy, worsening back pain, abdominopelvic ascites, closed displaced fracture of right femoral neck, with the first 2 considered as possibly related to NT219. No Grade 4 AEs or treatment related deaths were reported. For the 11 evaluable patients, best overall response included one confirmed PR (GEJ patient, 5.5 months duration of response), and 3 SD (3 of 4 CRC patients; duration of 5.2, 4, and 2 months with ongoing follow up) with two patients awaiting follow up MRI/CT scans. As of the cutoff date, 9/11 patients that completed the DLT period are either on treatment or in follow up (range 1.1 to 14.7 months). **Conclusions**: Interim analysis of safety results obtained in 4 NT219 dose levels found NT219 to be well tolerated without DLTs in advanced cancer patients. The observed durable PR in a GEJ patient and SDs in 3 CRC patients are an encouraging initial signal of efficacy. Combination treatment of cetuximab with escalating NT219 doses in patients with recurrent/metastatic CRC and squamous cell carcinoma of the head and neck (SCCHN) has begun. An expansion cohort in patients with recurrent/metastatic SCCHN will be initiated at the conclusion of this part. Clinical trial information: NCT04474470. Research Sponsor: Purple Biotech Ltd.

3097 **Poster Session**

A phase 1, first-in-human, dose-escalation and biomarker trial of liposomal gemcitabine (FF-10832) in patients with advanced solid tumors. *First Author: Erkut Hasan Borazanci, HonorHealth, Scottsdale, AZ*

Background: FF-10832 is a stable liposomal formulation of gemcitabine (GEM) shown to overcome resistance through increased plasma stability and enhanced tumor drug delivery. Macrophage uptake and immune activation in the tumor microenvironment (TME) play a role in the superior efficacy of FF-10832 compared to GEM, with selective, marrow-sparing biodistribution contributing to an improved safety profile. **Methods:** A 3+3 design determined the safety, maximum tolerated dose (MTD), dose-limiting toxicities (DLT), pharmacokinetics (PK), and recommended Phase 2 dose (RP2D). FF-10832 was administered IV once or twice per cycle on a 28 or 21-day schedule until disease progression or unacceptable toxicity. Circulating immune cell populations were measured over time by flow cytometry. **Results:** Patients (pts) [n = 73, 26M/47F; median age, 64 (range, 26–84); # prior therapies, 3 (1–11); prior GEM, 60%] received FF-10832 on Day 1 and 15 Q28 days (1.2–30 mg/m^2), Day 1 and 8 Q21 days (12–23 mg/m^2), or Day 1 only Q28 or 21 days (30–55 mg/m^2); median # cycles = 2 (1–14) & time on study = 8.3 (4–60) weeks. Common drug-related adverse events were Grade (Gr) ≤2 rash (22%), nausea (22%, 1 Gr 3), and pyrexia (21%, 2 Gr 3). Dose-limiting Gr ≥3 cellulitis/skin ulcers were observed at ≥23 mg/m^2 with twice per cycle dosing and those regimens discontinued. Dose frequency was reduced to Day 1 only, which was well-tolerated without significant skin toxicity. Gr ≥3 thrombocytopenia and pneumonitis were observed at 55 mg/m^2 Q21 days and the MTD confirmed at 40 (Q21) and 48 mg/m^2 (Q28). Median OS = 25.3 (95%CI: 16–27.1) weeks and PFS = 9.6 (95%CI: 7.9–17.6) weeks. Three of 35 evaluable pts achieved a partial response (PR): one pt with gallbladder cancer who previously progressed on GEM achieved a 50%↓ by Cycle 13 at 40 mg/m^2 Q28 days & maintains response on study at 60 weeks; two pts with pancreatic cancer had ≥30%↓: one adenocarcinoma after 2 cycles at 4.8 mg/m^2 Days 1 & 15 Q28 days, and one acinar cell after 7 cycles at 40 mg/m^2 Q28 days who remains on study. Stable disease (SD) was observed in 16 pts; 9 for ≥20 weeks. AUC increased in proportion to dose without accumulation. An extended plasma $t_{1/2}$ (hrs) for released (39) & total GEM (26) with a free fraction < 1% of total GEM concentrations suggests continuous release in the TME. Pts with PR or SD had dose and time-related log decreases in Ki67+ regulatory T cells relative to total CD4+ cells with increases in anti-tumor CD8+ cells, suggesting a shift to a more immunocompetent environment. **Conclusions:** FF-10832 was well-tolerated in heavily pre-treated pts with solid tumors, with evidence of anti-tumor activity in pts who progressed on prior GEM. Prolonged, continuous exposure and enhancement of anti-tumor immunity may contribute to improved efficacy. Expansion is ongoing in biliary tract cancer pts treated at the RP2D/schedule of 40 mg/m^2 Day 1 of a 21-day cycle. Clinical trial information: NCT03440450. Research Sponsor: FUJIFILM Pharmaceuticals U.S.A., Inc.

3098 **Poster Session**

The bi-steric mTORC1-selective inhibitor RMC-5552 in tumors with activation of mTOR signaling: Preclinical activity in combination with RAS(ON) inhibitors in RAS-addicted tumors, and initial clinical findings from a single agent phase 1/1b study. *First Author: Howard A. Burris III, Sarah Cannon Research Institute and Tennessee Oncology, Nashville, TN*

Background: RMC-5552 is a potent bi-steric mTORC1-selective inhibitor that activates the downstream tumor suppressor 4EBP1, thereby inhibiting initiation of protein translation. This novel therapeutic moiety addresses a key limitation of rapalogs, which do not effectively inhibit phosphorylation of 4EBP1. RMC-5552 has previously demonstrated significant anti-tumor activity in preclinical models of human cancers with mTOR pathway activation. Additionally, mTOR signaling plays a key role in therapeutic response and resistance in RAS-addicted cancers, which represent a significant unmet medical need. **Methods:** We examined the combination of bi-steric mTORC1 inhibitors (RMC-5552 and the research tool compound RMC-6272) with direct inhibitors of active RAS (RAS(ON) inhibitors) in mutant KRAS-driven models. To enable the clinical testing of RMC-5552 as a companion inhibitor for RAS(ON) inhibitors, a Phase 1/1b dose-escalation trial of RMC-5552 monotherapy is currently testing a once-a-week IV schedule. **Results:** RMC-5552 and RMC-6272 demonstrated marked combinatorial anti-tumor activity with RAS(ON) inhibitors across a series of preclinical models of KRAS mutated non-small cell lung cancer. The combination enhanced tumor apoptosis and resulted in durable tumor regressions as compared to tumor growth inhibition resulting from single agents alone. As of 13 January 2022, a total of 14 patients with solid tumors have been evaluated in an ongoing Phase 1/1b trial over 5 dose levels ranging from 1.6 to 12 mg IV weekly. Median age was 62 years and the majority received ≥3 prior therapies. The most common (> 25%) drug-related adverse events were mucositis/stomatitis (43%) and decreased appetite (29%). The most common grade 3 drug-related adverse events were mucositis/stomatitis observed in 3 patients in dose levels ≥ 10 mg (21%) and were dose-limiting. The dose of 6 mg IV weekly was well tolerated. Plasma exposures of RMC-5552 were dose-proportionate at lower dose levels up to 6 mg but increased above dose proportionality with higher dose levels. Plasma exposures at 6 mg and above were consistent with those resulting in inhibition of tumor p4EBP1 in preclinical models. Of 5 patients evaluable for efficacy at doses of 6 mg and higher, one confirmed PR was observed in a patient with head and neck cancer with a pathogenic mutation in *PTEN* (ORR 20%) and 3 patients had a best response of SD. Dose-optimization is ongoing. **Conclusions:** RMC-5552 is clinically active in tumors with mTORC1 signaling activation at a tolerable dose and schedule and has the potential to be a companion inhibitor of choice for RAS(ON) inhibitors in RAS-addicted tumors. Clinical trial information: NCT04774952. Research Sponsor: Revolution Medicines.

3099 **Poster Session**

Updated analysis of the efficacy and safety of entrectinib in patients (pts) with locally advanced/metastatic *NTRK* fusion-positive (*NTRK*-fp) solid tumors. *First Author: Maciej Jerzy Krzakowski, Lung and Thoracic Cancer Department, Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland*

Background: *NTRK* gene fusions, coding for chimeric TRK proteins, are oncogenic drivers in many solid tumors. In an integrated analysis of three phase 1/2 trials (ALKA-372-001 [EudraCT 2012-000148-88]; STARTRK-1 [NCT02097810]; STARTRK-2 [NCT02568267]), entrectinib, a potent CNS-active TRK inhibitor, showed durable systemic and intracranial responses in pts with *NTRK*-fp solid tumors. We report updated data from a larger cohort with longer follow-up (clinical cutoff 2 Aug 2021). **Methods:** Pts with locally advanced/metastatic *NTRK*-fp solid tumors and ≥12 months' follow-up from first tumor assessment were efficacy evaluable. The safety cohort also included pts from TAPISTRY (NCT04589845). Tumor responses were assessed by blinded independent central review (BICR) per RECIST v1.1 at Week 4 and every 8 weeks thereafter. Primary endpoints: objective response rate (ORR) and duration of response (DoR). Progression-free survival (PFS), overall survival (OS), intracranial (IC)-ORR and safety were also assessed. **Results:** The efficacy-evaluable cohort comprised 150 adults (vs 121 previously) with 17 different solid tumor types. Median age was 58.5 years; 91% of pts had ECOG PS 0–1 and 37% had received ≥2 prior lines of therapy. Median survival follow-up was 30.6 months. ORR was 61.3% (n = 92/150; 95% CI: 53.1–69.2), including 25 complete responses. Responses were observed in all tumor types with n>1 (Table). Median DoR, PFS and OS were 20.0 months (95% CI 13.2–31.1), 13.8 months (95% CI 10.1–20.0), and 37.1 months (95% CI 27.2–not estimable [NE]), respectively. In pts with and without investigator-assessed baseline CNS metastases (n = 31 / n = 119), ORR was 61.3% (95% CI 42.2–78.2) and 61.3% (95% CI 52.0–70.1) respectively. IC-ORR was 69.2% (n = 9/13) in pts with BICR-assessed measurable CNS metastases; median IC-DoR was 17.2 months (7.4–NE). In the safety population (N = 235: all treated pts), most treatment-related adverse events (TRAEs) were grade 1/2 and not serious; the most frequent were dysgeusia (36.6%), diarrhea (29.8%) and weight increase (28.5%). TRAEs led to dose interruption, reduction and discontinuation in 32.8%, 24.3% and 7.2% of pts, respectively. **Conclusions:** In this updated analysis, entrectinib continued to demonstrate deep and durable responses and was well tolerated in pts with *NTRK*-fp solid tumors with or without baseline CNS metastases. Clinical trial information: STARTRK-2 [NCT02568267]. Research Sponsor: F. Hoffmann-La Roche Ltd.

NTRK-fp tumor type (N ≥ 5)	ORR, n/N (%)
Sarcoma	19/32 (59.4)
Non-small cell lung cancer	20/31 (64.5)
Mammary analogue secretory carcinoma	22/26 (84.6)
Thyroid	10/16 (62.5)
Colorectal	3/11 (27.3)
Breast	6/9 (66.7)
Head and neck	3/5 (60.0)
Neuroendocrine	2/5 (40.0)

Other tumor types included in efficacy-evaluable population: pancreatic (N = 4); carcinoma of unknown primary (N = 3); gynecological (N = 2); adrenal, cholangiocarcinoma, gastrointestinal tract, neuroblastoma, penile and prostate (N = 1 each).

3100 **Poster Session**

Long-term efficacy and safety of larotrectinib in a pooled analysis of patients with tropomyosin receptor kinase (TRK) fusion cancer. *First Author: Alexander E. Drilon, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Neurotrophic tyrosine receptor kinase (*NTRK*) gene fusions are oncogenic drivers in multiple tumors. Larotrectinib is a highly selective, central nervous system (CNS)-active tropomyosin receptor kinase (TRK) inhibitor, approved to treat adult and pediatric patients (pts) with TRK fusion cancer. In an integrated analysis of 206 pts with non-primary CNS TRK fusion cancer, larotrectinib demonstrated an investigator-assessed objective response rate (ORR) of 75%; median progression-free survival (PFS) was 35.4 months (mo; Hong et al, ASCO 2021). We report updated efficacy and safety data based on central review assessments in an expanded dataset. **Methods:** Data were pooled from three clinical trials (NCT02576431, NCT02122913, and NCT02637687) of pts with non-primary CNS TRK fusion cancer treated with larotrectinib. Larotrectinib was administered until disease progression, withdrawal, or unacceptable toxicity. ORR was assessed by independent review committee (IRC) per RECIST v1.1. Data cut-off was July 20, 2021. **Results:** As of data cut-off, 244 of 269 larotrectinib-treated pts were evaluable for efficacy by IRC. There were 25 different tumor types. The most common were soft tissue sarcoma (STS [43%], including infantile fibrosarcoma [18%] and other STS [25%]), thyroid (11%), lung (10%), salivary gland (9%), and colorectal (7% [colon, n = 18; rectal, n = 1]). Ninety-four (35%) pts were aged < 18 years; 175 (65%) were ≥18 years. Pts had gene fusions involving *NTRK1* (46%), *NTRK2* (3%), or *NTRK3* (51%). A total of 27%, 28%, and 45% of pts had 0, 1, and ≥2 prior lines of systemic therapy, respectively. The ORR was 69% (95% confidence interval [CI] 63–75): 64 (26%) complete response (CR), including 13 (5%) pathological CR, 104 (43%) partial response,41 (17%) stable disease, 20 (8%) progressive disease, and 15 (6%) not determined. Median time to response was 1.8 mo (range 0.9–16.2). Median duration of response (DoR) was 32.9 mo (95% CI 27.3–41.7); median follow-up was 28.3 mo. Median PFS was 29.4 mo (95% CI 19.3–34.3); median follow-up was 29.3 mo. At a median follow-up of 32.2 mo, median overall survival (OS) was not reached; the 48-mo OS rate was 64% (95% CI 55–73). Treatment duration ranged from 0.1 to 67.9 months. Treatment-related adverse events (TRAEs) were mainly Grade 1–2; 50 (20%) pts had Grade 3–4 TRAEs. Five (2%) pts discontinued treatment due to TRAEs. To exclude the possible confounding effect of ongoing enrollment on median DoR, we conducted an exploratory analysis in the subset of 164 pts who were analyzed as of July 2019. The ORR was 74% (95% CI 67–81) and median DoR was 34.5 mo (95% CI 27.6–43.3); median follow-up was 34.1 mo. **Conclusions:** With longer follow-up, larotrectinib continued to demonstrate rapid and durable responses, extended survival benefit, and a favorable safety profile. These results highlight the importance of testing for *NTRK* gene fusions in cancer pts. Clinical trial information: NCT02576431, NCT02122913, NCT02637687. Research Sponsor: Bayer HealthCare and Loxo Oncology.

3101 **Poster Session**

A first-in-human phase 1 dose escalation study of FF-10850 (liposomal topotecan) in patients with advanced solid tumors. *First Author: Ursula A. Matulonis, Dana-Farber Cancer Institute, Boston, MA*

Background: FF-10850 (liposomal topotecan) was developed using a unique dihydrosphingomyelin-based carrier to enhance tumor drug delivery and retention, leading to improved efficacy and safety. Preclinical studies demonstrated superior antitumor activity with less myelosuppression compared to topotecan, with a pharmacokinetic (PK) profile supporting a twice-monthly dosing schedule. **Methods:** Accelerated titration followed by a 3+3 dose escalation design was used to determine the safety, maximum tolerated dose (MTD), dose-limiting toxicities (DLT), PK, and recommended Phase 2 dose. FF-10850 was administered IV on Day 1 and 15 of a 28-day cycle until disease progression or unacceptable toxicity. **Results:** Patients (pts) [n = 29; 4M/25F; median age, 64 (range, 37–79) and # prior therapies, 4 (range, 1–8)] received FF-10850 at doses of 1, 2, 2.5, 3, 3.5 and 5 mg/m^2; median # of cycles, 2 (range, 1–11). FF-10850 was well-tolerated at doses up to 2 mg/m^2. Common drug-related adverse events (AEs) included anemia (83%, 51% Gr≥3), thrombocytopenia (62%, 35% Gr≥3), neutropenia (59%, 45% Gr≥3), nausea (38%), fatigue (24%, 7% Gr≥3), alopecia (24%), and hypokalemia (17%, 3% Gr≥3). Dose-limiting Gr≥3 thrombocytopenia, neutropenia, anemia, and fatigue were observed at doses ≥2.5 mg/m^2. Eight pts required dose reductions due to AEs. The median time on study was 8.3 (1.6–45) weeks, with a median PFS of 9.4 weeks and median OS at least 26 weeks. Of 24 pts evaluable for response, two achieved a partial response (PR). One pt with ovarian cancer treated at 3.5 mg/m^2 achieved a complete response in target lesions by Cycle 2 with stable non-target lesions, and maintained response for > 30 weeks (8 cycles) before progressing; dose was reduced in this pt to 2.6 mg/m^2 at Cycle 2 due to Gr 4 thrombocytopenia. Another pt with refractory metastatic Merkel cell carcinoma tolerated therapy well at 2 mg/m^2 and achieved a 48% reduction in target lesions that was maintained for > 30 weeks (8 cycles). Stable disease was observed in an additional 9 pts for ≥10 weeks (5 ovarian, 2 uterine and 2 cervical); five who maintained disease control for ≥24-45 weeks including one (ovarian) who had previously progressed on topotecan. An extended plasma $t_{1/2}$ for topotecan of 25-30 hours was observed with no apparent dose-dependency or accumulation; < 1% of circulating topotecan was in the free (released) form. **Conclusions:** FF-10850 was well-tolerated up to 2 mg/m^2 with antitumor activity demonstrated in heavily pre-treated pts with solid tumors including ovarian cancer, and an improved PK profile allowing less frequent dosing compared to topotecan. Expansion is ongoing in pts with ovarian and Merkel cell carcinoma at the RP2D of 2 mg/m^2 IV on Day 1 & 15 of a 28-day cycle. Clinical trial information: NCT04047251. Research Sponsor: FUJIFILM Pharmaceuticals U.S.A., Inc.

3102 **Poster Session**

A study of senaparib in combination with temozolomide for the treatment of patients with advanced solid tumors and extensive-stage small cell lung cancer. *First Author: Bo Gao, Blacktown Cancer & Haematology Centre, Blacktown Hospital, Sydney, NSW, Australia*

Background: Senaparib (or IMP4297) is a PARP inhibitor with a novel chemical structure. Preliminary data demonstrate senaparib has significant antitumor activity with good tolerability in some patients with advanced solid tumors. DNA damage caused by temozolomide, a non-classic oral alkylating agent, can sensitize tumors to the effects of PARP inhibitors. In a xenograft model, synergistic antitumor effect was observed with the combination of senaparib and temozolomide, supporting this trial (NCT04434482). **Methods:** This is a phase Ib/II dose-escalation and dose-expansion study. Patients with advanced solid tumors were enrolled for dose escalation to evaluate the safety, tolerability using a modified "3+3" design. Low dose temozolomide (20 to 30 mg, once daily, days 1 to 21) in combination with continuous senaparib (40 to 80 mg, once daily, days 1 to 28) of each 28-day cycle was evaluated. Dose expansion will establish anti-tumor activity and safety of the combination in patients with extensive stage small cell lung cancer (ES-SCLC). **Results:** A total of 14 patients were enrolled for dose escalation as follows: Cohort 1 (1 patient; senaparib 40 mg plus temozolomide 20 mg), Cohort 2 (3 patients; senaparib 60 mg plus temozolomide 20 mg), Cohort 3 (7 patients; senaparib 80 mg plus temozolomide 20 mg), Cohort 4 (3 patients; senaparib 80 mg plus temozolomide 30 mg). One DLT (Grade 4 thrombocytopenia) was observed in Cohorts 3 and 4. The MTD and RP2D were determined as: senaparib 80 mg plus temozolomide 20 mg. Anaemia, neutropenia and thrombocytopenia were the only Grade ≥3 TEAEs occurring in > 1 patient. All AEs were manageable, and no treatment related deaths were reported. The ORR was observed in 3 of 12 (25.0%) evaluable patients, including 2 confirmed PR and 1 unconfirmed PR. The DCR was 83.3% (10 of 12 evaluable patients). Two patients remain on treatment for more than 1 year. **Conclusions:** Preliminary results suggest that low dose temozolomide (D1-21 of a 28-day cycle) in combination with continuous senaparib is generally well tolerated with encouraging anti-tumor activity. Recruitment for dose expansion for ES-ECLC patients has commenced (Sep 2021). Clinical trial information: NCT04434482. Research Sponsor: None.

3103 **Poster Session**

A CRUK first-in-human phase I trial of LY3143921, a novel CDC7 inhibitor, in patients with advanced solid tumors. *First Author: Peter F. Gallagher, Queen's University Belfast, Belfast, United Kingdom*

Background: CDC7, a protein with key roles in regulating cell-cycle progression is often over-expressed in malignant cells, particularly those with *TP53* mutations. LY3143921, an orally administered ATP-competitive CDC7 inhibitor, demonstrated favorable pre-clinical anti-cancer activity in colorectal cancer (CRC) and squamous non-small cell lung cancer (sqNSCLC), particularly in *TP53* mutant models. **Methods:** Phase Ia (dose escalation) recruited patients (pts) with advanced solid tumors enriched for malignancies associated with *TP53* mutation. Pts received LY3143921 OD or BD continuously on a 21-day schedule, using an accelerated 3+3 escalation design, starting at 30 mg OD. Phase Ib recruited pts with CRC or sqNSCLC treated continuously at RP2D, or pts with other advanced tumors treated at RP2D on days 1-3 every 7 days. Radiological assessment was performed every 2 cycles initially. Pts in phase Ib could consent to pre- and on-treatment skin +/- tumor biopsies. Primary objectives: assess safety/tolerability and determine MTD and RP2D of LY3143921. Secondary objectives: evaluate preliminary efficacy and pharmacokinetic (PK) profile of LY3143921. Exploratory objective: correlate efficacy to baseline molecular/genetic alterations, including *TP53* mutation and measure markers including pMCM2 in pre- and on- treatment tumor and skin samples. **Results:** 68 pts were recruited and 67 treated (38 phase Ia, 29 phase Ib). Most frequent drug-related CTCAEs (all grades): nausea (75%), orthostatic hypotension (50%), vomiting (47%), fatigue (45%) & diarrhea (44%). Grade 3-4 LY3143921 related AEs occurred in 17 pts. In phase Ia 8 DLTs occurred in 5 pts (G3 nausea, vomiting, fatigue & hyponatraemia and G2 diarrhea, anorexia & lethargy). RP2D was 360 mg BD (continuous non-fasted dosing schedule). 37 pts were evaluable for radiological response with no complete or partial responses seen, and stable disease (SD) was observed in 24 pts (65%). In phase Ia 3 pts achieved long term SD of 1, 2.5 and 3+ years duration. For evaluable pts treated in phase Ib, SD was seen in 8/12 CRC pts, 1/2 sqNSCLC pts and 2/2 pts treated with the intermittent schedule (median duration 15 weeks, range 6-18+). 2 pts remain on-study. Recruitment ceased due to lack of radiological response according to RECIST. Dose-dependent increases in LY3143921 exposure (C_{max} & $AUC_{0\text{-}24}$) were seen. IHC analyses of skin biopsies demonstrated reductions in pMCM2, indicating on-target activity of LY3143921. Pre-clinical testing of combination with standard of care agents is ongoing. Additional PD and PK data will be presented. **Conclusions:** LY3143921 is well tolerated, exhibits dose-dependent increases in plasma exposure and demonstrates evidence of target inhibition. Significant monotherapy clinical activity was not observed; further analyses should investigate potential predictive response biomarkers and rational combination approaches. Clinical trial information: NCT03096054. Research Sponsor: Cancer Research UK.

3104 **Poster Session**

Mechanisms of acquired resistance to TRK inhibitors. *First Author: Guilherme Harada, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: First-generation TRK tyrosine kinase inhibitors (TKIs) are approved in a tumor-agnostic fashion in more than 40 countries for patients with *NTRK* fusion-positive adult and pediatric cancers. While resistance to these agents has previously been described, the exact frequency with which major mechanisms of resistance emerges is not clearly understood. **Methods:** Patients with an *NTRK*-fusion-positive tumor who received a first-generation TRK TKI were eligible. We retrospectively identified those patients that had post-progression tumor tissue analyzed by next-generation sequencing (NGS). The pattern of serial resistance to a second-generation TKI was analyzed when available. **Results:** Eighteen patients were identified. The median age was 46 years (range 2-67). Nine unique fusions were detected in ten different tumor types. *NTRK1*, *NTRK2*, and *NTRK3* fusions were found in eight (44%), one (6%), and nine (50%) patients, respectively. Thirteen patients (72%) were treated with larotrectinib and five patients (28%) received entrectinib. NGS (MSK-IMPACT n = 17, Foundation One n = 1) carried out on post-progression tissue revealed the following profile of acquired resistance: on-target resistance (83%, n = 15/18), off-target resistance (11%, n = 2/18), and no identifiable mechanism (6%, n = 1/18). Among patients with on-target resistance, the most common mutation involved the solvent front (87%, n = 13/15: n = 7 *NTRK3* G623R, n = 4 *NTRK1* G595R, n = 1 *NTRK2* G639L, n = 1 *NTRK3* G623E) followed by the gatekeeper region (13%, n = 2/15: n = 1 *NTRK1* F589L, n = 1 *NTRK3* F617I). Two patients developed off-target alterations. One acquired *BRAF* V600E mutation and the other *MET* amplification. Interestingly, solvent front mutation loss was observed in two patients who transitioned to and progressed on a second-generation TRK TKI. One patient with a baseline *NTRK1* G595R mutation developed polyclonal resistance with acquisition of *KRAS* G12A and *NTRK1* G667A alterations as well as *NTRK1* G595R loss. The other patient with *NTRK3* G623R developed an *NTRK3* F617I gatekeeper mutation with *NTRK3* G623R loss. **Conclusions:** In *NTRK* fusion-positive cancers, on-target resistance preferentially involving the solvent front is more frequent than off-target resistance to first-generation TKI therapy. Furthermore, the sequential use of second-generation therapy appears to alter the evolutionary kinetics of mutation retention and acquisition. Research Sponsor: U.S. National Institutes of Health.

3105 **Poster Session**

A phase 1 dose-escalation study of the ABN401 (c-MET inhibitor) in patients with solid tumors. *First Author: Dae Ho Lee, University of Ulsan College of Medicine, Asan Medical Center, Seoul, South Korea*

Background: *MET* is a proto-oncogene encoding a receptor tyrosine kinase c-MET for hepatocyte growth factor (HGF). Dysregulated MET signaling by *MET* exon14 skipping, *MET* gene amplification and c-MET overexpression in cancer plays a critical role in the development of primary oncogenesis, acquired drug resistance and metastasis. This is a first-in-human trial, phase 1 dose-escalation study of the highly selective MET kinase inhibitor, ABN401. ABN401was evaluated in subjects with advanced solid tumors in South Korea and Australia. **Methods:** Patients with advanced solid tumors were enrolled in escalating dose cohorts using an accelerated titration design. ABN401 was orally administered daily with 21-day cycle. The primary objective was to evaluate safety and tolerability to define dose-limiting toxicity (DLT), maximum tolerated dose (MTD) according to CTCAE v5. Secondary objectives included pharmacokinetic, recommended phase II dose (RP2D), and preliminary efficacy assessments. Tumor assessment was determined using Response Evaluation Criteria in Solid Tumors (RECIST 1.1). **Results:** Out of 28 screened patients, 16 patients with 6 different tumor types were treated with ABN401 at daily dose levels of 50, 100, 200, 400, 800 and 1200 mg, 15 patients were evaluated for DLT and one unevaluable. No DLT was observed in all 6 dose levels and the MTD has not been reached. No drug related grade ≥ 3 AEs were observed: only one drug-related SAE (transient peripheral edema) was reported. For treatment response, 5 patients with stable disease, and 2 with partial response were observed. These two patients with partial response had non-small cell lung cancer (NSCLC) with c-MET overexpression and had been treated with ABN401 for 10 and 18 months, respectively. **Conclusions:** ABN401 dosed up to 1200 mg QD was well tolerated with an acceptable safety profile and promising preliminary antitumor activity in patients with advanced solid tumors. The extension (pilot expansion) for additional efficacy assessment is under way at 800 mg daily dose with c-MET altered NSCLC patients in South Korea and Australia. In addition, a phase 2 expansion study is to start in the United States and South Korea. Clinical trial information: NCT04052971. Research Sponsor: None.

3106 **Poster Session**

Safety, pharmacokinetics (PK), and clinical efficacy of ICP-723, a highly selective next-generation pan-TRK inhibitor, in patients with solid tumor. *First Author: Xiao-Li Wei, Department of Medical Oncology, Sun Yat-sen University Cancer Centre, Guangzhou, China*

Background: NTRK gene fusion resulting from NTRK1/2/3 genetic alterations occurs in various adult and pediatric cancers, which is one of the most defined driving factors of carcinogenesis. Patients with NTRK fusion positive cancers treated by earlier generation TRK inhibitors achieve rapid and durable responses but can develop on-target resistance. ICP-723 is a highly selective next-generation TRK inhibitor. In preclinical studies, ICP-723 not only markedly inhibits the activity of the wild type TRKA/B/C, but also shows robust activity against resistant mutations, e.g., G595R, F589L or G667C/A/S. A first-in-human clinical study is currently ongoing to evaluate the safety, tolerability, pharmacokinetics (PK) characteristics and efficacy of ICP-723. **Methods:** This is a multi-center, open-label phase I/II clinical trial, which includes a phase I dose escalation part and a phase II dose expansion part. In the phase I dose escalation, patients with advanced solid tumor, who failed from clinical standard of care or for whom there is currently no effective therapy, will be enrolled. The modified "3+3" method is followed for dose escalation. **Results:** As of 11Feb2022, a total of 17 patients in phase I dose escalation were treated with ICP-723 at doses of 1 mg QD to 8 mg QD. The median age of the enrolled patients was 54 yrs, (range: 31 to 69 yrs) and ECOG performance status was between 0-1 (58.8% had ECOG PS of 1). Six of 17 patients were confirmed as NTRK gene fusion positive tumors by either prior gene test reports or the central lab gene test. There is no DLT observed in the 6 dose groups. Most AEs were manageable and grade 1-2. The most common TRAEs (> 20%) were asthenia (23.5%), increased ALT (29.7%), increased AST (29.7%) and anemia (29.7%). Gr ≥3 TRAEs were increased ALT (5.9%), increased AST (5.9%), increased CPK (11.8%), neutrophil count decreased (5.9%) and pain (5.9%). The plasma exposure to ICP-723 increased in a dose proportional manner across the observed dosage levels. According to RECIST 1.1 criteria, among the 6 patients with NTRK fusion, the overall response rate (ORR) was 66.7% (4 patients with partial response (PR)), the disease control rate (DCR) was 100%. It is worth noting that one patient with measurable brain metastasis achieved PR with the target brain lesion shrunk from 10 mm to 3 mm. All patients who achieved PR responded to ICP-723 at the first tumor assessment after 4-week treatment and maintained sustained responses to the date of data cutoff. **Conclusions:** ICP-723 is safe and well-tolerated in patients with advanced solid tumors. Encouraging clinical efficacy including intracranial activity was demonstrated in patients with NTRK gene fusion in various tumor types. Enrollment in phase I is ongoing until the final RP2D is determined, then phase II expansion will be conducted in patients with defined gene alterations. Clinical trial information: NCT04685226. Research Sponsor: InnoCare Pharma Limited.

3107 **Poster Session**

First-in-human (FIH) phase I study of the highly selective phosphoinositide 3-kinase inhibitor delta (PI3Kδ) inhibitor IOA-244 in patients with advanced cancer: Safety, activity, pharmacokinetic (PK), and pharmacodynamic (PD) results. *First Author: Anna Maria Di Giacomo, Center for Immuno-Oncology, University Hospital of Siena, Siena, Italy*

Background: T regulatory (Tregs) cells contribute to immune suppression in cancer. The highly selective inhibitor of PI3Kδ, IOA-244, blocks the activity of Tregs among other things, thus reprograms the anti-tumor immune response. **Methods:** IOA-244 was investigated in a two-part FIH study. Part A explored the continuous daily dosing of IOA-244 at 10, 20, 40 and 80 mg. Part B consists of expansion cohorts of specific tumor indications, including pre-treated uveal melanoma patients (pts). Primary objective: safety of the anticipated biologically effective dose (BED), or the recommended phase 2 dose (RP2D). Secondary objectives: PK; PD (e.g., inhibition of CD63 expression on basophils, changes in immune cell subsets in peripheral blood); RECIST 1.1.-based responses; PFS and OS. Exploratory studies: changes in circulating immune cells by Cytometry by Time of Flight (CyTOF); response assessments by radiomics **Results**: Part A Solid Tumor (completed): Sixteen pts were treated in 4 cohorts each with 4 pts. Pts characteristics: uveal melanoma (9/16; 56%), cutaneous melanoma (5/16; 31%) and pleural mesothelioma (2/16; 13%). Four pts had at least one serious TEAE, none considered related to IOA-244. There was no treatment-emergent adverse events (TEAE) leading to study drug discontinuation, immune related toxicity or Dose Limiting Toxicity. CTCAE v5 Grade 1 and 2 were observed, including 2 cases of transient diarrhoea and 2 of AST/ALT elevation. Part A (Completed) – Subgroup Uveal Melanoma Pts (progressed ≥1 line prior therapy): 9 pts treated (3/9 pts ongoing). Mean time on treatment: 7.7 mo (range: 1.8-16.0 mo with 3 pts ongoing). ORR (RECIST 1.1): CR+PR: 0/9 (0%); SD: 6/9 (67%). Median OS: 5.4 mo - not determined (% alive at 1 year: 44% with 3 pts ongoing). CT images from 7/9 patients were assessed for changes in their metastatic lesions by radiomics (baseline and Week 8). Based on 147 matched lesions, 19% had complete responses and 16% had new lesions. In the liver, non-progressive disease was observed in 61% of all lesions, including 42% with either complete response or volume reduction of more than 30%. Using CyTOF, circulating Tregs were reduced while CD8 and NK cells were increased. Part B Uveal Melanoma Expansion Cohort (ongoing): 7 patients (7/7 pts ongoing); mean time on treatment 3.7 mo. ORR (RECIST 1.1): SD in 4/7 pts (57%). Part A Follicular Lymphoma Cohort (ongoing): At 20 mg: 4/4 pts. No DLT. At 80 mg: recruiting. **Conclusions:** In addition to being well tolerated, IOA-244 at the 80 mg dose shows reduction in peripheral blood Tregs and anti-tumor responses based on radiomics. Therefore, RECIST 1.1.-derived SD may underestimate anti-tumor activity of IOA-244 in treatment-resistant uveal melanoma. Additional patients will be treated to further refine this radiomics-based observation. Clinical trial information: NCT04328844. Research Sponsor: iOnctura SA.

3108 **Poster Session**

Phase Ib study of selinexor and eribulin combination in advanced solid tumors and triple-negative breast cancer. *First Author: Blessie Elizabeth Nelson, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Selinexor (KPT-330) is potent inhibitor of Exportin-1. *In vitro*, Selinexor was found to be synergistic with eribulin in triple negative breast cancer (TNBC) cell lines and enhanced antitumor activity of eribulin in TNBC patient-derived xenografts (PMID 28810913). **Methods:** We conducted a phase Ib trial in combination of selinexor and eribulin using 3 + 3 design in dose escalation for patients with advanced solid tumors and in TNBC in dose expansion cohort. Eribulin could be discontinued after combination for 6 cycles at physician discretion. Primary objectives: Safety, Recommended Phase 2 Dose (RP2D). Secondary Objectives: Objective Response Rate (ORR), Duration of Response (DOR), Disease Control Rate (DCR), Overall Survival (OS) and Progression Free Survival (PFS). **Results:** 31 patients, TNBC (n = 19), sarcoma (n = 8), others (n = 4) enrolled in dose escalation (n = 10) and dose expansion phases (n = 21). Median prior therapies:4 (1–6). Study initiated selinexor at 60mg twice weekly and eribulin 1.4mg/m^2 on Day1, Day8 every 3 weeks which led to 1 Dose Limiting Toxicity (DLT) and hence, selinexor 80mg once weekly and eribulin 1mg/m^2 was elected as RP2D due to efficacy and tolerability. As of 01/15/2022, of 29 patients (94%) who have discontinued treatment, 24 (77%) were due to progressive disease, 3 (10%) withdrew consent and 2 (6%) due to toxicities (G1 pneumonitis; G3 neutropenia) while 2 (6%) remain on trial. All 31 patients had at least one treatment emergent adverse event (TEAE) while most prevalent TEAEs (all grades) were leukopenia (77%), nausea (71%), anemia and neutropenia (68%) and fatigue (48%). The most common G3/4 TEAE were leukopenia (26%) and neutropenia (29%). 2 DLTs occurred; 1 in first dose level (DL); 1 in second DL dosed at selinexor 80 mg once weekly due to G3 neutropenia. ORR for all was 10% while DCR (SD+PR+CR) > 6 months seen in 3 (15%) TNBC and 2 (20%) sarcoma patients. The median OS and PFS for all were 12.3 (7.3, 27.3) months and 2.3 (1.6, 4.1) months. In dose escalation cohort, ORR was 10% where one patient (3%) with vaginal SCC had confirmed PR (-44%) for 2.1 months. Five patients (62.5%) with sarcoma had stable disease (SD). One patient with high grade sarcoma has SD for 68 months and remains on selinexor after 4 months of eribulin and selinexor. In TNBC dose expansion (n = 19), ORR was 10.5% with 2 confirmed PRs and median duration of response (DOR) of 10.8 months. One patient who has remained on treatment for 18 months, and after receiving 8 months of eribulin and selinexor, remains on selinexor with 100% target regression and an indeterminate brain lesion. **Conclusions:** Selinexor with eribulin is safe with manageable toxicity profile and modest overall clinical efficacy. Durable responses and disease control were observed with metastatic TNBC. Further study is needed to examine the determinants of response to this combination. Clinical trial information: NCT02419495. Research Sponsor: Karyopharm Therapeutics, , U.S. National Institutes of Health, Clinical and Translational Sciences Award (1UL1TR003167) (NIH/NCATS), and MD Anderson Cancer Support Grant (P30CA016672) (NIH-NCI).

3109 **Poster Session**

Central nervous system (CNS) outcomes and progression patterns in patients with *RET* fusion-positive lung cancers treated with selpercatinib. *First Author: Yonina R. Murciano-Goroff, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Selpercatinib, a potent/selective RET inhibitor, is approved for the treatment of *RET* fusion-positive non-small cell lung cancers. While the drug is known to have substantial intracranial activity (intracranial ORR 82%) in patients with existing brain metastases, (1) central nervous system (CNS) outcomes in patients without brain metastases and (2) CNS progression patterns in patients with brain metastases have not been explored. **Methods:** Patients with advanced *RET* fusion-positive lung cancers were prospectively treated with selpercatinib on the registrational LIBRETTO-001 trial (NCT03157128) or the LIBRETTO-201 multi-center expanded access program (EAP, NCT03906331). Key overall and CNS eligibility criteria were previously presented. Patients with and without pre-selpercatinib brain metastases who underwent serial CNS and extracranial imaging were eligible for analysis. The data cutoff was November 24, 2020. Cumulative incidence rates (CIRs) were calculated using a competing risk model with systemic progression of disease (PD) or death as competing risks; patients with simultaneous CNS and systemic PD were treated as having had CNS PD. **Results:** Sixty-two patients (48 LIBRETTO-001, 14 EAP) were identified. Median age was 64. Thirty-two (52%) were female and 47 (76%) were never smokers. The most common 5' fusion partner was *KIF5B* (68%). The median number of prior therapies was 2 (range 1-11); 34% received prior multikinase inhibitor therapy. The median time on treatment was 21.8 months. Thirty-one (50%) patients had no baseline brain metastases. In these patients, the CIR of CNS metastasis was 0% at 6 months and 12 months; none of these patients developed CNS metastasis during selpercatinib treatment. The 9 patients that progressed did so extracranially. Of the 31 patients with baseline brain metastases, 12 (39%) had prior CNS radiation and 3 (10%) had prior CNS surgery. At the time of data cut-off, 23 patients had some evidence of progression, including 8 in both the CNS and systemically, 6 only in the CNS, and 9 only systemically. Overall, 17 of the 31 patients with baseline brain metastasis did not develop evidence of CNS progression as of the data cut. Among patients with baseline brain metastasis, the CIR for evidence of CNS PD was 6.7% at 6 months and 27.4% at 12 months. **Conclusions:** In patients with *RET* fusion-positive lung cancers without baseline brain metastases, new CNS metastases were not observed during selpercatinib therapy. Among patients with baseline brain metastasis, a substantial number did not experience progression in the CNS on treatment. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Phase I dose-escalation study of IBI351 (GFH925) monotherapy in patients with advanced solid tumors. *First Author: Qing Zhou, Guangdong Lung Cancer Institute, Guangzhou, China*

Background: IBI351(GFH925) is an irreversibly covalent inhibitor of KRAS^{G12C}. In this first-in-human dose-escalation study, we report the preliminary safety and anti-tumor activity of IBI351 (GFH925) in patients (pts) with advanced solid tumors harboring the KRAS p.G12C mutation. **Methods:** Pts with locally advanced, recurrent or metastatic solid tumors with KRAS^{G12C} mutation for whom standard therapy had failed were enrolled. Phase I dose escalation had an accelerated titration design for dose level 250mg QD and a BOIN design with 450/700/900mg QD. The primary end points were safety and tolerabilityThe secondary end points were pharmacokinetics (PK) and anti-tumor activity of IBI351(GFH925) monotherapy per RECIST v1.1. **Results**: As of Feb 07 2022, 15 pts (13 men, 2 women; median age: 62 yrs, range: 48–74 yrs) were enrolled, among whom 12 had non-small cell lung cancer (NSCLC), and 3 had colorectal cancer (CRC). 4 pts had ≥3 prior lines of treatment (tx). Median tx duration was 66.5 ds (range: 21–98 ds). No dose-limiting toxicity (DLT) or any ≥grade 3 treatment-related adverse events were observed in any dose cohorts. A total of 12 patients (80.0%) had treatment-related adverse events (grade 1, n = 6; grade 2, n = 6). By investigator-assessment, tumor response was evaluated in 9 pts (4 with ≥2 assessments); 6 pts had not reached their first assessment. 2 pts had PR (1 NSCLC at wks 12, 450mg, tx ongoing; 1 CRC at wks 6, 700mg, tx ongoing), 4 pts (NSCLC) had SD, and 3 pts had PD (1 NSCLC at wks 12, 2 CRC at wks 6). As data cut-off date, 11 pts were continuing to receive IBI351 (GFH925). **Conclusions**: IBI351(GFH925) was well-tolerated without unanticipated adverse events across all doses explored in pts with advanced solid tumors harboring the KRAS p.G12C mutation. The data also demonstrated the preliminary efficacy signal of IBI351 (GFH925) in previously treated advanced NSCLC and CRC. Clinical trial information: NCT05005234. Research Sponsor: Innovent Biologics, Inc., China.

Baseline predictors of hematological toxicity in patients with advanced cancer treated with ATR inhibitors in phase I/II clinical trials. *First Author: Natalie Ngoi, Department of Investigational Cancer Therapeutics, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Ongoing trials are exploring ATR inhibitors (ATRi) in genomically selected contexts. However, myelosuppression, particularly anemia, has limited the therapeutic window of this class of drugs. We sought to discover clinical biomarkers predicting severe hematological toxicity from ATRi. **Methods:** We retrospectively analyzed clinical parameters and peripheral blood cell indices retrieved from complete blood count (CBC) reports of patients (pts) pre- and during treatment with an oral ATRi on phase I/II trials at our center. Pts received ATRi monotherapy or in combination with a PD1 inhibitor (PD1i) or a PARP inhibitor (ATRi+PARPi) in dose-escalation and expansion cohorts, which included ATRi at potentially toxic doses. **Results:** 37553 indices from 2209 CBC reports of 141 pts treated with an ATRi from 10/2017 to 1/2022 were analyzed. 132 (93.6%) pts received ATRi +/- PD1i; 9 (6.4%) pts received ATRi+PARPi. The incidences of ≥ grade (G) 3 anemia, neutropenia and thrombocytopenia were 47.5%, 31.9% and 11.4%. 73/141 (51.8%) pts received red cell transfusion. Baseline risk factors predicting ≥G3 anemia on univariate analysis included: lower median (med) hematocrit (Hct) (hazard ratio (HR) (95% confidence interval) = 3.05 (1.82, 5.13) ≤med vs > med; p < 0.0001), hemoglobin (Hb) (HR = 2.74 (1.64,4.57) ≤med vs > med; p = 0.0001), mean corpuscular Hb concentration (HR = 1.85 (1.11,3.10) ≤med vs > med; p = 0.019); and higher median immature reticulocyte fraction (HR = 0.43 (0.25,0.71) ≤med vs > med; p = 0.0012), reticulocyte count (ct) (HR = 0.59 (0.35,0.97) ≤med vs > med; p = 0.037) and red cell distribution width (RDW) (HR = 0.54 (0.33,0.88) ≤med vs > med; p = 0.015). On multivariate analysis, lower median Hct (HR = 3.76 (2.15, 6.6) ≤med vs > med; p < 0.0001), higher immature granulocyte ct (HR = 1.71 (1.30, 2.25) per 1 fold increase; p = 0.0001), higher RDW (HR = 7.83 (1.70, 36.03) per 1 fold increase; p = 0.0082) and higher ATRi starting dose (HR = 1.40 (1.05, 1.86) per 1 fold increase; p = 0.022) significantly predicted ≥G3 anemia risk. Baseline risk factors for ≥G3 neutropenia on univariate analysis included: lower median absolute neutrophil ct (ANC) (HR = 2.26 (1.18, 4.33) ≤med vs > med; p = 0.015) or white blood cell ct (WBC) (HR = 2.73 (1.40, 5.33) ≤med vs > med; p = 0.0032). On multivariate analysis, lower median WBC (HR = 2.85 (1.45, 5.59) ≤med vs > med; p = 0.0024) was associated with higher risk of neutropenia, while ATRi+PARPi increased risk of neutropenia (ANC < 0.75) (HR = 4.15 (1.40, 12.3); p = 0.01) and thrombocytopenia (HR = 3.90 (1.47, 10.4); p = 0.0064). **Conclusions:** ≥G3 anemia was frequent in pts receiving ATRi. At baseline, lower median Hct and higher RDW predict severe anemia, while lower WBC predicts neutropenia from ATRi. ATRi+PARPi has increased risk of neutropenia and thrombocytopenia vs ATRi +/- PD1i. These indices may inform patient selection and CBC monitoring for future ATRi trials. Research Sponsor: None.

3112 **Poster Session**

A phase Ib study of the combination of alisertib (Aurora A kinase inhibitor) and MLN0128 (dual TORC1/2 Inhibitor) in patients with advanced solid tumors, final expansion cohort data. *First Author: S. Lindsey Davis, University of Colorado Cancer Center, Aurora, CO*

Background: In prior work, senescence and up-regulation of genes in the PI3K/AKT/mTor pathway were observed in patient-derived xenograft models treated with alisertib to resistance, and tumor growth inhibition was observed when MLN0128 (sapanisertib) was added to alisertib. In a previously reported dose escalation cohort of patients with advanced solid tumors treated with the combination of alisertib and MLN0128, the maximum tolerated dose (MTD) was alisertib 30mg BID days 1-7 of a 21-day cycle and MLN0128 2mg daily on a continuous schedule. Presented here are final results from the dose expansion portion of this clinical trial. **Methods:** Three cohorts of patients were treated with the combination at the MTD. Patients with advanced solid tumors, refractory to standard therapy, were assigned to either single-agent treatment with alisertib (Group 1) or MLN0128 (Group 2) on days 1-7 of Cycle 1. For the remainder of the study, patients received combination treatment. Group 3 enrolled patients with refractory pancreatic adenocarcinoma who were treated with standard dosing of the combination. Biopsies were performed in Groups 1 and 2 prior to treatment initiation and after both the single-agent lead-in and 7 days of combination treatment, with assessment of pharmacodynamic markers. Functional imaging was performed pre-treatment and after Cycle 1. **Results:** A total of 31 patients with refractory cancers were treated. Group 1 included patients with breast (5), colorectal (2), ovarian (2), and pancreatic (1) cancers. Group 2 included patients with breast (4), colorectal (2), pancreatic (2), uterine (1), and kidney (1) cancers. Eleven patients with refractory pancreatic cancer were treated in Group 3. Median time on study was 11.6 weeks in Group 1, 6 weeks in Group 2, and 9 weeks in Group 3. One partial response was documented in Group 1. One patient with pancreatic cancer in Group 1 continued on study for 47 weeks, and another pancreatic cancer patient in Group 3 continued on study for 28 weeks. Toxicity was similar across cohorts, with mucositis, fatigue, hyperglycemia and neutropenia reported as most common. Biopsy results were significant for increased apoptosis and tumor-infiltrating immune cells noted in tissues from 4 patients treated with the MLN0128 lead-in. Decreased F18-FDG uptake on PET/CT, often with increased ADC values in diffusion MRI, was observed in metastatic liver lesions in 4 patients after Cycle 1. **Conclusions:** In an expansion cohort of 31 patients treated with the combination of MLN0128 and alisertib at the previously defined MTD, treatment was tolerable with an expected toxicity profile. Prolonged stable disease was observed in 2 patients with pancreatic cancer. Increased apoptosis and tumor-infiltrating immune cells were noted in tissues from patients treated with a lead-in of MLN0128. Clinical trial information: NCT02719691. Research Sponsor: Investigator Initiated Trial Agreement between Dr. Jennifer Diamond and Takeda Pharmaceutical Company.

3113 **Poster Session**

Pan-cancer analysis of exogenous (microbial) sequences in tumor transcriptome data from the ORIEN consortium and their association with cancer and tumor microenvironment. *First Author: Daniel Spakowicz, Division of Medical Oncology, Department of Internal Medicine & Department of Biomedical Informatics, Ohio State University, Columbus, OH*

Background: The tumor microbiome holds great potential for its ability to characterize various aspects of cancer biology and as a target for rational manipulation. For many cancer types, little is known about the role of microbes and in what contexts they affect clinical outcomes. Non-human (i.e. exogenous) sequences can be observed in low abundance within high throughput sequencing data of tumors. Here, we describe a collaboration among members of The Oncology Research Information Exchange Network (ORIEN) to leverage tumor biopsy RNAseq data collected under a shared protocol and generated at a single site to better understand the tumor microbiome, its association with prognostic features of the tumor microenvironment (TME) such as hypoxia, and how it may be used to improve clinical outcomes. **Methods:** Tumor RNAseq samples from 10 primary source locations including the tissues colon, lung, pancreas, and skin from ORIEN and similar cancers from The Cancer Genome Atlas (TCGA) were processed through the exoTIC (exogenous sequencing in tumors and immune cells) pipeline to identify and count exogenous sequences, filter contaminants, and normalize across datasets. Gene expression signatures of the TME, such as hypoxia, were calculated using 'tmesig'. Microbe relative abundances were modeled with primary tumor location and hypoxia score using a gamma-distributed generalized linear regression via the stats package in R. **Results:** We analyzed RNA-seq data of 2892 and 2720 tumors from ORIEN and TCGA, respectively. Patients' ages were significantly greater in the ORIEN than the TCGA dataset (62 vs 58 yo, t-test p<0.001). The ORIEN data contained more sarcoma samples than TCGA (n = 691 vs 259) with roughly equivalent numbers in other cancer types. Fewer microbes were significantly associated with the hypoxia score than with cancer type (n = 32 vs 210). This trend was observed in both the ORIEN and TCGA datasets. The largest effect sizes were observed between microbes and small cell lung cancer. **Conclusions:** We found microbial sequences in all ORIEN and TCGA tumor RNA-seq samples tested. Cancer type showed more significant associations with microbes than a hypoxia signature. These observations merit further investigation into the interaction between microbes and the TME. Research Sponsor: None.

Cohort summary.

	ORIEN	TCGA	p
n	2892	2720	
Age (mean (SD))	58.49 (14.49)	62.02 (14.36)	<0.001

Temsirolimus (T) in patients (pts) with solid tumors with mTOR mutation: Results from the Targeted Agent and Profiling Utilization Registry (TAPUR) Study. *First Author: Gordan Srkalovic, Sparrow Cancer Center, Michigan Cancer Research Consortium, Ypsilanti, MI*

Background: TAPUR is a phase II basket study evaluating anti-tumor activity of commercially available targeted agents in pts with advanced cancers with genomic alterations. Results in a cohort of solid tumor pts with *mTOR* mutation (mut) treated with T are reported. **Methods:** Eligible pts had solid tumors, no standard treatment (tx) options, measurable disease, ECOG Performance Status (PS) 0-2, and adequate organ function. Genomic testing was performed in CLIA-certified, CAP-accredited site selected labs. Pts matched to T had various solid tumors with *mTOR* mut. After antihistamine pre-treatment, 25 mg T was infused over 30-60 minutes weekly until disease progression. Primary endpoint was disease control (DC), defined as complete (CR) or partial (PR) response, or stable disease at 16+ weeks (wks) (SD 16+) (RECIST v1.1). Low accruing histology-specific cohorts with the same genomic alteration and tx were collapsed into a single histology-pooled cohort for this analysis. For histology-pooled cohorts with sample size ≤28, the results are evaluated based on a one-sided exact binomial test with a null DC rate of 15% vs. 35% ($\alpha = 0.10$ and power=0.86 for N = 26) and one-sided 90% confidence interval (CI). Other efficacy endpoint estimates are presented with two-sided 95% CIs. Secondary endpoints were progression-free survival (PFS), overall survival (OS) and safety. **Results:** 29 pts with solid tumors (11 histologies) with *mTOR* mut were enrolled from June 2016 to June 2020. 3 pts were not evaluable (2 pts, no post-baseline tumor eval; 1 pt, no measurable disease) and excluded from efficacy analyses. The Table shows demographics and outcomes. 2 PR and 10 SD16+ were observed for a DC rate of 46% (one-sided 90% CI: 32% to 100%) and an objective response (OR) rate of 8% (95% CI: 1% to 25%); the null hypothesis of a 15% DC rate is rejected (p<0.001). 5/10 pts with SD16+ had CRC or biliary cancer. Of the 2 pts with PR, one had uterine cancer and T1977R mut and the other had head and neck cancer and I1636V mut. The durations of PR were 12.3 and 23.9 wks, respectively, and median duration of SD was 34.5 wks (range: 18.7, 90.0) for pts with SD16+. 8 pts experienced grade 3 or grade 4 AEs or SAEs at least possibly related to T, including acute kidney injury, epistaxis, hyperglycemia, hypertension, hypertriglyceridemia, mucositis, leukopenia, thrombocytopenia, and pneumonitis. **Conclusions:** Monotherapy T showed evidence of anti-tumor activity in pts with advanced solid tumors with *mTOR* mut. Additional study is warranted to confirm the efficacy of T in pts with *mTOR* mut. Clinical trial information: NCT02693535. Research Sponsor: Pfizer, Pharmaceutical/Biotech Company.

Demographics and baseline characteristics (n = 29) and efficacy outcomes (n = 26).

Genomic and clinical characteristics of *MET* alterations in solid tumors among the 10,475 Chinese patients. *First Author: Yaping Li, AcornMed Biotechnology Co., Beijing, China*

Background: Somatic alterations of the MET oncogene are emerging as an attractive target in human cancers, thus, understanding the molecular epidemiology of MET alterations is essential. While the occurrence of MET exon 14 skipping mutations (MET ex14) in US lung cancer patients is well defined, it is not widely published for Chinese patients. In addition, reports on the occurrence of METex14 outside lung cancer and other clinically relevant MET alterations across all cancers are limited. **Methods:** The *MET* ex14 alterations and amplification data of 10475 Chinese cancer patients from 16 types of cancer were obtained in Acronmed database, including non-small cell lung cancer (NSCLC, n = 5719), Hepatocellular carcinoma (HCC, n = 511), colorectal cancer (CRC, n = 1779), renal cell carcinoma (RCC, n = 1169), Gastric carcinoma (GC, n = 679), etc. Genomic profiling of DNA was performed through a next-generation sequencing. **Results:** Of all pan-cancer patients, 141 cases (1.3%) with *MET* alterations were identified, including *MET* Amp (0.9%) and *MET* ex14 (0.7%). Compared to Western population (~3%), the frequency of *MET* alterations is much lower in Chinese cancer patients (1.3%). *MET* Amp were most commonly found in HCC (1.7%), GC (1.3%), NSCLC (0.7%), RCC (0.7%), CRC (0.2%). *MET* ex14 occurred most in NSCLC (0.5%), HCC (0.3%), CRC (0.2%). HCC were significantly to have *MET* Amp than NSCLC (P = 0.01), while *MET* ex14 mutations were more likely to be observed in NSCLC (p = 0.02). We further analyzed the *MET* mutation characteristics of NSCLC. The most frequently co-mutated genes in *MET* ex14 cohort were *TP53* (48%,15/31), *KMT2B* (23%,7/31) and *EGFR* (16%, 5/31). Except for *TP53* (65%,22/34) and *EGFR* (56%,19/34) mutations. Interestingly,other gene mutations were rare in the patients with *MET* Amp. In addition, *MET* ex14 patients showed significant lower *EGFR* mutation comparing to the *MET* amp patients (P = 0.002). **Conclusions:** Our study demonstrated a landscape of *MET* alterations among the Chinese population. *MET* mutations occurs in a variety of solid tumors, indicating that these patients may benefit from *MET* inhibitors. Variable detection of actionable alterations across racial groups and association with testing patterns. *First Author: Emma Sturgill, Sarah Cannon Research Institute, Nashville, TN*

Background: Molecular landscape studies are critical to biomarker discovery and precision oncology research. However, non-White patients (pts) have historically been under-represented. In this study, we examine clinico-genomic data from a network of community oncology clinics to evaluate real-world mutational frequencies in Black, White, and Asian pts with cancer. **Methods:** We utilize Genospace, a precision medicine software, to harmonize clinical data from the Sarah Cannon research network of U.S. community oncology practices with genomic data from commercial NGS vendors. Pts with known race and NGS test results from September 2015 to November 2021 are assessed. Variants of uncertain significance (called by NGS vendor) are excluded. Asian pts are not evaluable in all instances because of low pt number. Statistical analyses include Chi squared and two sample test of proportions with Benjamini-Hochberg false discovery rate correction. **Results:** A total of 18,399 pts are assessed, with 7% Black (n = 1,319), 92% White (n = 16,903), and 1% Asian (n = 177) pt representation. The most common tumor types include non-small-cell lung (NSCLC; 27% of Black pts, 30% of White pts, 33% of Asian pts), colorectal (15% of Black pts, 12% of White pts, 14% of Asian pts), breast (14% of Black pts, 11% of White pts, 9% of Asian pts), and prostate (6% of Black pts, 5% of White pts, 3% of Asian pts) at roughly equal proportions across racial groups. In NSCLC, EGFR mutations and ALK fusions significantly enrich in Asian pts while KRAS G12C is detected more frequently in Black patients (see table for details; Black: n = 353, White: n = 5,127, Asian: n = 58). In both prostate and breast cancers, plasma-based NGS is less common in Black pts than White pts (plasma-to-tissue ratio = 1.1 (Black prostate: n = 82); 1.5 (White prostate: n = 863); 0.6 (Black breast: n = 178); 0.9 (White breast: n = 1,918)). In prostate, AR mutations are detected less frequently in Black pts. However, when considering plasma-NGS results alone the detection frequency is roughly equal. Similarly, the gap in ESR1 detection frequencies in breast decreases when considering plasma-NGS results alone. **Conclusions:** Actionable alterations are detected across racial groups at variable frequencies with potential biological and technical underpinnings. In scenarios where plasma-NGS is commonly used to monitor for resistance mutations, discrepancies in NGS ordering patterns likely affect detection frequencies. Research Sponsor: None.

Select gene alteration frequencies across racial groups.

	Black	White	Asian
NSCLC EGFR mutation*	9%	9%	43%
NSCLC KRAS G12C	11%	9%	5%
NSCLC ALK fusion*	1%	1%	5%
Prostate AR mutation	13%	17%	-
Prostate AR mutation (plasma)	22%	22%	-
Prostate AR mutation (tissue)*	3%	8%	-
Breast ESR1 mutation	11%	18%	-

Stress keratin 17 as a novel biomarker of response in immune checkpoint blockade–treated head and neck squamous cell carcinoma. *First Author: Taja Lozar, University of Wisconsin-Madison, Madison, WI*

Background: Low response rates in immune checkpoint blockade (ICB) treated head and neck squamous cell carcinoma (HNSCC)drive a critical need for robust clinically validated biomarkers that can predict response to ICB. Stress keratin 17 (K17) is a known prognostic marker in various types of cancer, including HNSCC; however, its predictive value for ICB response has not been investigated. Preclinical studies suggest K17 suppresses macrophage-mediated CXCL9/CXCL10 chemokine signaling involved in attracting activated CD8+ T cells into tumors. Furthermore, knocking out K17 results in restored response to ICB in a HNSCC mouse model. Here, we evaluated if K17 protein expression predicts response to ICB in human HNSCC patients. **Methods:** We conducted a retrospective analysis of 26 HNSCC patients that received at least one cycle of pembrolizumab at the University of Wisconsin-Madison Carbone Cancer Center. Pretreatment, archival, formalin-fixed, paraffin-embeded samples were stained by immunohistochemistry using a K17 monoclonal antibody. Clinical outcomes were investigator-assessed for all patients with at least one post-treatment scan or evidence of clinical progression after treatment initiation. Based on independent pathology review, cases were categorized into K17 high vs K17 low based on a cut-off of > 5% strong cytoplasmic staining intensity of tumor cells in the invasive carcinoma component. Correlation between K17 expression and clinical outcomes was assesed using Fischer's exact test and log rank test. **Results:** The 26 patients included in this study were 85% male, median age 60.5 years, 74% ECOG performance status < 2, with 80% having received prior chemotherapy. Primary site included oral cavity (54%), oropharynx (23%), larynx (4%), or other (19%). Seventeen tumors (65%) showed high K17 expression, and 9 tumors (35%) showed low K17 expression. Eleven patients (42%) had programmed death ligand 1 (PD-L1)+ tumors as determined by combined positive score. Six patients (23%, all K17 low) achieved clinical benefit, while 20 patients (77%, 17 K17 high and 2 K17 low) had progressive disease. High K17 expression was associated with lack of clinical benefit ($p < 0.001$), shorter time to treatment failure ($p < 0.001$), progression-free ($p = 0.004$) and overall survival ($p = 0.02$). PD-L1 expression by immunohistochemistry (clone 22C3) did not correlate with K17 expression or clinical outcome. **Conclusions:** Our findings suggest that K17 expression may predict clinical benefit from ICB in HNSCC patients, thus supporting further validation studies. Research Sponsor: U.S. National Institutes of Health.

Genomic landscape of SMARCA4-deficient lung tumors by clinical RNA sequencing. *First Author: Brian Pham, University of California-Davis, Sacramento, CA*

Background: SMARCA4-deficient lung cancer is an undifferentiated lung cancer subtype associated with poor prognosis and morphological features that make them challenging to distinguish from sarcoma. These tumors are known to be resistant to standard of care surgery, radiation, and chemotherapy. Recent case reports suggest that these tumors might be resistant to immunotherapy. An assessment of the genomic and transcriptomic features of *SMARCA4*-deficient thoracic tumors may identify potential novel targets and treatment strategies for this new WHO lung cancer classification. **Methods:** We retrospectively analyzed de-identified NGS data from 8,484 thoracic formalin-fixed, paraffin-embedded tumor biopsies from lung cancer patients sequenced using the TempuslxT solid tumor assay (DNA-seq of 595-648 genes at 500x coverage; whole-exome capture RNA-seq). Tumor-normal match sequencing was performed for all tumors, enabling the detection of incidental germline alterations across 46 genes. SMARCA4-deficiency was defined as tumors with a pathogenic or likely pathogenic *SMARCA4* single nucleotide variant, insertion/deletion, or copy number alteration. Statistical significance was determined using Fisher's exact test and Wilcoxon rank-sum tests. **Results:** *SMARCA4*-deficiency was detected in 370 (4.4%) tumors, of which over 80% were stage III or IV. *SMARCA4*-deficient tumors included more male patients (63% vs 49%, $p < 0.001$) and younger age at diagnosis (median 64 vs 68 years, $p < 0.001$). There were more patients with high tumor mutational burden (TMB-H, ≥10 mutations per megabase) (34% vs 15%, $p < 0.001$), and fewer patients with positive PD-L1 immunohistochemical staining (44% vs 54%, $p = 0.009$) compared to *SMARCA4* wild-type tumors. Microsatellite instability status occurred at similar low frequencies across SMARCA4-deficient vs wild-type tumors (0.8% vs 0.5%, $p = 0.5$). *SMARCA4*-deficient tumors showed enrichment for somatic mutations in *TP53* (71% vs 47%, $q < 0.001$), *STK11* (22% vs 6.8%, $q < 0.001$), *KEAP1* (15% vs 4.2%, $q < 0.001$), and *CDKN2A* (15% vs 5.9%, $q < 0.001$) compared to wild-type. Tumor normal-match sequencing identified incidental germline mutations in *MUTYH* (2.2%), *ATM* (1.1%), *ATP7B* (0.5%), and *MSH6* (0.5%) for *SMARCA4*-deficient tumors. RNA-sequencing analysis confirmed reduced transcriptional expression of *SMARCA4* ($p < 0.001$), *CD274* (PD-L1; $p < 0.001$), *TNFRSF18* ($p < 0.001$), and *TNFRSF4* ($p = 0.035$) in deficient tumors vs wild-type. Furthermore, *SMARCA4*-deficient tumors revealed reduced infiltration of CD4+ T cells (19% vs 22%, $p < 0.001$). **Conclusions:** This study reveals the unique genomic and transcriptional characteristics of *SMARCA4*-deficient lung tumors. Further studies are needed to assess the impact of immunotherapies and targeted therapies among this patient population. Research Sponsor: Tianhong Li.

Clinical utility of tumor next-generational sequencing (NGS) panel testing to inform treatment decisions for patients with advanced solid tumors. *First Author: Lucia Bogdan, Department of Internal Medicine, University of Toronto, Toronto, ON, Canada*

Background: There is limited information about the clinical utility of targeted NGS panel testing to inform decision-making for patients with advanced solid tumors. The Ontario-wide Cancer Targeted Nucleic Acid Evaluation (OCTANE) is an ongoing prospective study that enrolled over 4,500 solid tumor patients for NGS panel testing. We performed a retrospective survey of 21 medical oncologists enrolling OCTANE patients at a single academic institution to evaluate the impact of NGS testing on treatment decisions. **Methods**: Patients and treating oncologists were identified at the Princess Margaret Cancer Centre between 2016-2021. Tumor-only sequencing was performed using a custom hybridization capture panel of 555 cancer genes (Hi5) or a commercial 161-gene amplicon DNA/RNA panel (Oncomine Comprehensive v3). Oncologists were asked to review testing results for individual patients and complete a survey indicating whether NGS testing impacted treatment decisions. Mutations were defined as actionable based on clinical judgment and compared to classifications provided by OncoKB, an FDA-recognized precision medicine knowledgebase. The primary outcome of this study was rate of treatment change based on mutation results. Patient, test, and physician factors were evaluated for association with treatment changes using univariate analyses and a mixed effects model. **Results:** Two cohorts were surveyed, the first between 2017-2019 and the second in 2021. Of the 582 surveys sent, 394 (67.7%) were completed. Each physician completed a median of 19 surveys (range, 9-48). We found that 188 (47.7%) patients had a mutation classified as actionable by the oncologist, of whom 134 (71.3%) had ≥1 OncoKB-defined actionable mutation(s). 62/394 (15.7%) patients were matched to a treatment, of whom 37 were enrolled in a clinical trial, 13 received an approved drug, 4 were prescribed off-label therapy and 8 avoided ineffective treatment. 127/188 (67.5%) patients with actionable mutations did not receive treatment due to lack of available therapy, stability on current regimen, clinical deterioration or patient decision. Rate of treatment change was highest for bowel (15/37, 40.5%), breast (14/52, 27.5%), biliary tract (6/22, 27.3%) and lung (4/17, 23.5%) cancers. Treatment decisions were not associated with patient age, gender, physician clinical experience, physician gender, testing experience, OncoKB mutation level or time from biopsy to sequencing. There was no difference in overall survival between patients with matched vs. no matched treatment ($p = 0.55$, median survival not reached). **Conclusions:** OCTANE testing led to a change in drug treatment in 15.7% of patients, supporting the clinical utility of NGS panel testing for patients with advanced solid tumors. Patient, test, and physician characteristics were not significantly associated with treatment change. Research Sponsor: This study was conducted with the support of the Ontario Institute for Cancer Research through funding provided by the Government of Ontario and by the Princess Margaret Cancer Foundation.

Pan-cancer association between increased iron utilization and poor prognosis highlights potential of transferrin receptor-targeting therapies in multiple tumor types. *First Author: Asaad Trabolsi, University of Miami/Jackson Memorial Hospital, Miami, FL*

Background: The cell-surface transferrin receptor TFR1 imports iron-bound transferrin into cells via clathrin-mediated endocytosis. Tumors require constitutive iron import to drive proliferation, and several studies establish TFR1 as a target able to facilitate intracellular delivery of cytotoxic therapeutic molecules. Our own work previously revealed association between high expression of *TFRC*, the gene encoding TFR1, and high risk for poor outcome in diffuse large B-cell lymphoma (DLBCL). We showed therapetuic targeting of TFR1 in DLBCL results in significant anti-tumor benefit. Systematic analysis of *TFRC* expression as a prognostic marker across tumor types, however, has not been investigated. **Methods:** Tissue samples underwent comprehensive molecular profiling at Caris Life Sciences. Analyses included next generation sequencing of DNA (592 Gene Panel, NextSeq, or whole exome sequencing, NovaSeq), RNA (NovaSeq, whole transcriptome sequencing, WTS) and immunohistochemistry. Overall survival (OS) was calculated from date of tissue collection to last contact from insurance claims data and employed Kaplan-Meier analysis by Wilcoxon statistics, with $p < 0.05$ defined as significant. **Results:** Amongst 47 cancer types included, colorectal cancer (CRC) displayed the highest level of *TFRC* mRNA, followed by gastric cancer. In an all-tumor cohort (n = 93248), patients with higher *TFRC* expression (cutoff = median) had significantly worse OS (HR = 1.348, 95% CI [1.317-1.38] , $p < 0.00001$). This was statistically significant in 23 individual tumor types. Drilling down further, *TFRC* adverse prognostic value was mainly driven by cohorts with larger number of samples in the database, including non-small cell lung cancer (n = 17309), CRC (n = 12860), breast cancer (n = 8632), ovarian carcinoma (n = 7998), uterine neoplasms (n = 6097), prostate adenocarcinoma (n = 3411), glioblastoma (n = 2821), gastric cancer (n = 1579), and others. Surprisingly, *TFRC* overexpression correlated with improved outcome in vulvar squamous cell carcinoma (VSCC, n = 297). *TFRC* was found to be most prognostic in prostate adenocarcinoma with median OS 1139 days in pts with high vs 3230 days in pts with low *TFRC* (HR = 2.556, 95% CI [2.213-2.951], $p < 0.00001$). **Conclusions:** Our study is the first to combine modern molecular profiling with a large cohort of clinical tissue samples to reveal a prognostic role for *TFRC* expression in a variety of solid tumor types. We found *TFRC* overexpression to be prognostic in a large proportion of histologies, though surprisingly association with improved OS in VSCC. Highest expression occured in CRC and gastric cancer, diseases with needs for new therapies. A number of TFR1-targeting therapeutics are currently at various stages of development, and warrant further investigation in disease cohorts identified from our study. Research Sponsor: None.

Molecular characterization of cancers with *ALK* gene fusions in nonlung tumors. *First Author: Jin Zhang, Department of Thoracic Surgery, China-Japan Friendship Hospital, Beinjing, China*

Background: *ALK* gene rearrangement is known as "diamond mutation". Targeted tyrosine kinase inhibitors have perfect therapeutic effects on *ALK* fusion lung cancer patients (pts), but the molecular characteristics of *ALK* fusions in other cancers have not been systematically elucidated. **Methods:** We retrospectively analyzed the NGS data of *ALK* fusion-positive Chinese tumor pts (n = 1068) to characterize *ALK* fusions in pan-cancer (excluding lung cancer) pts. **Results:** A total of 66 *ALK* fusion-positive pts with 13 types of cancer (excluding lung cancer) were screened, including 0.4% (24/5800) of brain tumor pts, 0.1% (11/7725) of gastrointestinal cancer pts, 0.4% (7/1741) of thyroid cancer pts, 0.5% (8/1732) of sarcoma pts, 0.2% (4/2031) of liver cancer pts, 0.6% (3/540) of melanoma pts, 9% (2/22) of inflammatory myofibroblastic tumor pts, 2.5% (2/79) of embryonal tumor pts, 0.4% (1/282) of lymphoma pts, 3.2% (1/31) of parotid carcinoma pts, 0.1% (1/985) of breast cancer pts, 0.4% (1/241) of prostatic cancer pts and 0.3% (1/320) of ovarian cancer pts. Herein, we reported 28 *ALK* fusion patterns, of which the most common partners were *EML4* (n = 24) and *STRN* (n = 8), and mainly occurred in brain tumors (14/24, 58.8%) and thyroid cancers (6/8, 75%), respectively. In addition, there were 8 *ALK* fusion modes that were never reported before. Of the *ALK* fusion patterns described above, 92.4% (61/66) of fusions were located at the most canonical site of *ALK* (exon20), preserving the intact kinase domain. Meanwhile, rare fusion positions in the *ALK* gene were also found, such as *PPP1CB-ALK*(ex2:ex4), *NUP107-ALK*(ex20:ex3), *COL14A1-ALK*(ex8:ex4), *BRAF-ALK*(ex9:ex4), which preserve the extracellular and transmembrane domains, as well as *RASD2-ALK*(ex2:ex24), of which the breakpoint in *ALK* gene may disrupt the formation of kinase domain. **Conclusions:** We demonstrated the rarity of *ALK* gene fusions in nonlung cancers. Analyzing the *ALK* fusion characteristics of these cancer may help to clarify their pathogenesis and provide ideas for new drug treatment. Research Sponsor: None.

Results of a phase II trial of the PARP inhibitor, niraparib, in BAP1 and other DNA damage response pathway deficient neoplasms. *First Author: Thomas J. George, The University of Florida Health Cancer Center, Gainesville, FL*

Background: BRCA1-Associated Protein 1 (BAP1) acts as a tumor suppressor and critical regulator of the cell cycle and DNA damage response (DDR). PARP inhibitors (PARPi) demonstrate synthetic lethality in BAP1 mutant (mBAP1) preclinical models, independent of underlying germline BRCA status. mBAP1 leads to a loss of functional protein in several solid tumors. This study aimed to explore the clinical activity of niraparib in patients (pts) with advanced tumors likely to harbor mBAP1. **Methods:** Eligible adult pts with measurable metastatic solid tumors having exhausted approved therapies, adequate organ function, and ECOG PS 0-1 were assigned to Cohort A (histology-specific): tumors likely to harbor mBAP1 (i.e., cholangiocarcinoma, uveal melanoma, mesothelioma, or clear cell renal cell carcinoma) with tissue available for mBAP1 confirmation; or Cohort B (histology-agnostic): tumors with other known non-BRCA confirmed DDR mutations. Known BRCA1 or 2 mutations or prior PARPi exposure were excluded. All pts received niraparib 200-300mg daily, depending on weight and/or platelet count. Radiographic response was assessed by RECIST v1.1 measured every 8 weeks while on treatment. The primary endpoint was ORR with secondary endpoints of PFS, OS, clinical benefit (CR+PR+SD), toxicity, and exploratory biomarker determinations. Cohort A employed Simon's optimal two-stage design to assess a 30% ORR increase ($a = 0.05$; power = 90%). Cohort B aimed to assess a 40% ORR increase for this molecularly selected/enriched patient population. **Results:** From 08/13/2018 to 12/21/2021, 37 pts enrolled from two different centers, with 32 evaluable for response (Cohort A n = 18; Cohort B n = 14). In Cohort A, best ORR was 1 PR (6%), 8 SD (44%; median 5.7 mo; range 2 - 9.4 mo), and 9 PD (50%). Cohort A was stopped at the first stage following the pre-specified Simon's design. mBAP1 was confirmed in 7/9 pts (78%) with PR or SD but in only 2/9 (22%) in those with PD. In Cohort B, best ORR was 6 SD (43%; median 7.5 mo; range 3.3 - 8.6 mo) and 8 PD (57%). Mutations in those with SD included ATM, CHEK2, PTEN, RAD50, and ARID1A. Common grade 3/4 AEs observed were anemia (16%), thrombocytopenia (16%), nausea (11%), and vomiting (8%). There were no unexpected nor grade 5 toxicities. **Conclusions:** The use of niraparib was well tolerated in pts with advanced treatment refractory solid tumors but failed to meet pre-specified efficacy threshold of ORR. However, clinical benefit was identified in 78% of patients in cohort A who had a confirmed mBAP1 tumor. Further correlative analyses are ongoing and additional clinical development restricted to mBAP1 tumors may be justified. Clinical trial information: NCT03207347. Research Sponsor: University of Florida Health Cancer Center and GlaxoSmithKlein.

3123 **Poster Session**

Inference of sample-specific genetic interactions to increase accuracy of indication prioritization in oncology clinical trials and facilitate exploration of combined therapy opportunities. *First Author: Sarah Jenna, My Intelligent Machines Inc., Montreal, QC, Canada*

Background: Precision oncology is growing rapidly in parallel with advances in high throughput sequencing. Development of new anti-cancer therapies is, however, still associated with low efficacy issues, leading to phase II and III clinical trial failures. Improved methodologies are required to identify clinical and molecular patient profiles associated with good drug response to inform decisions on indication prioritization. **Methods:** We used a sample-specific Genetic Interaction Graph Inference ($ssGI^2$) algorithm, integrating bulk tumor transcriptomic data as well as data collected from 120 public databases and scientific literature in oncology, to infer genetic interactions (GI). More than 10,000 genes from 17,000 samples, covering 195 oncology ICD10 codes, were used to infer GIs for each individual sample. GIs involving a given drug target are selected from a compendium of 17,000 networks of 2M GIs each, and ranked based on their prevalence in the patient cohort and data-support. The mean Z-scored expression of genes from the top ranked GIs were subsequently used to predict drug response for each patient and to calculate the response rate for each indication. Detailed information on each drug target's genetic interactors was used to characterize the drug's mechanisms of action and explore opportunities for combined therapies. We investigated our method's ability to predict good responders using four FDA approved immune and targeted therapies (pembrolizumab, nivolumab, ipilimumab and sorafenib) across seven clinical studies. Importantly this methodology is suitable for drugs with no clinical studies available. **Results:** Our results show that the prediction of good responders can be achieved with Precision-Recall AUC on average 13% higher than predictions based on drug target expression level solely, in five out of seven studies. Also, for each drug target, between 30 to 140 genetic interactors with good performance (Precision=0.92; Recall=0.61) were identified, suggesting potential synergistic effects of drugs, some of which have already been confirmed by clinical studies on combined therapies. **Conclusions:** Our $ssGI^2$-derived signatures are powerful predictors of good response to a drug even without available clinical data. Applying this methodology at a pre-clinical stage will significantly de-risk clinical trials, particularly for novel therapies, and could also support investigation of new combined therapies. Research Sponsor: My Intelligent Machines Inc.

Comprehensive genomic profiling to identify gene alterations in DNA repair pathway across solid tumors. *First Author: Kevin J. McDonnell, City of Hope, Duarte, CA*

Background: Deleterious events in DNA damage response (DDR) are hallmarks of cancer associated with sensitivity to PARP inhibitors (PARPi) and immune checkpoint inhibitors (CPI). This study investigated DDR pathway alterations across solid tumors. **Methods:** Samples were sequenced with the Oncomap ExTra assay using tumor-normal paired whole-exome DNA sequencing to detect single base substitutions, indels, and copy number alterations that were clinically actionable, defined as associated with FDA approved drugs or clinical trial enrollment. Here, we report the frequency of MSI-high and TMB-high (>10 mutations/Mb), and clinically-actionable alterations for the following 49 DDR genes: *ARID1A, ATM, ATR, ATRX, BAP1, BARD1, BLM, BRCA1/2, BRIP1, CDK12, CHEK1/2, EPCAM, ERCC1/2/3/4/5, FANCA/C/D2/E/F/G/I/L/M, MLH1, MRE11A, MSH2/6, MUTYH, NBN, PALB2, PMS2, PPP2R2A, PTEN, RAD21/50/51/51B/51C/51D/52/54L, XRCC1/2/3*. **Results:** Of the 6055 patient samples profiled, 1633 (27.0%) had clinically actionable alterations in DDR genes; DDR alterations varied from 0-64.3% across tumor types. For the 5657 samples with TMB/MSI data, 429 (7.6%) had high TMB and 193 (3.4%) were MSI-high; MSI-high samples were usually TMB-high (n = 180; 93.2%). The percent of cancers that were TMB-high or MSI-high varied from 0-64.8% and 0-20.8% respectively. Actionable *BRCA1/2* gene alterations were present in 319 patients (5.3%, range 0-15.3%). Three cancers (biliary, brain and liver) had *BRCA1/2* alterations in less than 2% of patients but across the 49 DDR genes alterations were present in more than 20% of patients, representing a greater than 10-fold difference. Across solid tumors, this analysis identifies a group of 1314 patients (21.7%) who harbor a DDR gene alteration other than *BRCA1/2*. **Conclusions:** Defective DNA repair as detected by deleterious alterations in DDR genes along with TMB/MSI status has the potential to guide clinicians to FDA-approved therapy or clinical trial enrollment in a large percentage of patients across solid tumor types. Research Sponsor: Exact Sciences Corporation.

Number (percent) of patients with alterations in DDR, TMB-High and MSI-High.

Tumor Type	Total	All DDR genes	BRCA1/2	TMB-high	MSI-High

Molecular and immune landscape of *FH*-mutated cancers. *First Author: Bayan A Al-Share, Barbara Anna Karmanos Cancer Institute, Livonia, MI*

Background: Fumarate Hydratase (FH) encodes an essential enzyme in the TCA cycle. Inactivating germline mutations in FH lead to hereditary leiomyomatosis and renal cell cancer syndrome with risk of development of certain cancers. Sporadic FH mutations have been described in different cancers but implications of somatic mutations on cancer outcomes and survival are not well described. Here, we characterize the molecular landscape of FH-mutant cancers. **Methods:** Tumors analyzed using NGS (NextSeq, 592 genes; NovaSeq, WES), IHC, and WTS (NovaSeq) (Caris Life Sciences, Phoenix, AZ). PD-L1 tested by 22c3, 28-8 (Agilent) and SP-142 (Spring Biosciences) IHC (>1%). MSI tested by FA, IHC, and NGS. TMB measured by totaling somatic mutations per tumor (TMB-h > 10 mutations/MB). Real-world overall survival was extracted from insurance claims data and calculated from first treatment to last contact using K-M survival curves for molecularly defined cohorts. Statistical significance was determined using chi-square and Wilcoxon rank-sum test, adjusted for multiple comparisons ($q<0.05$). **Results:** 3239 *FH* mutations were seen in 45 tumor types in 3149 FH-mutated tumors. NSCLC, colorectal and endometrial cancers harbored the most mutations. There were 839 pathogenic (P) or likely pathogenic (LP) and 2400 variants of unknown significance (VUS). Some tumors had multiple mutations. The most common mutations: R233H (P; 37), K477dup (LP; 555), and A41V (VUS; 70). VUS had increased TMB-H (40.4% vs 29.8%, q=0.004) and *CREBBP* mutations (5.1% vs 1.6%, q=0.012) compared to P+LP. A41V-mt tumors had significantly lower TMB-H than other VUS (8.8% vs 41.5%, q=0.002) and lower MSI-H (3.13% vs 3.69% vs 29.4%, q=0.003) and *DICER1*, *PRKDC*, *FBXW7* mutations ($q<0.05$) compared to K477dup and R233. The A41V-mt patients had worse survival compared to patients with P+LP (HR: 1.4, 95% CI: 1.0-2.0, p = 0.049) and a trend toward worse survival compared to K477dup and R233H. In patients treated with chemotherapy, A41 was associated with worse survival compared to P+LP (HR: 4.6, 95% CI: 2.0-10.3, $p<0.0001$) and compared to K477dup and R233 ($p<0.01$). There was a trend towards worse survival after IO of A41-mt compared to P+LP (HR: 1.99, 95% CI: 0.88-4.5, p = 0.093). **Conclusions:** FH alterations are found in multiple cancers. A41V was the most common VUS mutation and is associated with a distinct molecular profile compared to K477dup-mt and R233-mt tumors; it was associated with worse survival in all-comers and after chemotherapy compared to P+LP mutations. This highlights the significance of this mutation and the need for further investigation into how this specific and other FH mutations contribute to cancer progression and treatment outcomes. Insights of clinical significance from solid tumor profiles with FoundationOne CDx. *First Author: Andreas M. Heilmann, Foundation Medicine, Inc., Cambridge, MA*

Background: FoundationOne CDx (F1CDx) is a US FDA-approved companion diagnostic test to identify patients who may benefit from treatment in accordance with the approved therapeutic product labeling for 28 drug therapies. Tumor profiling with F1CDx detects genomic findings with evidence of additional clinical significance. This study analyzes the breadth and impact of clinical decision insights from F1CDx clinical reports across solid tumors. **Methods:** F1CDx consecutive reports (n = 109,695) were retrospectively analyzed for the type and frequency of clinically significant predictive, prognostic, and diagnostic genomic alterations and signatures in common cancer types and across solid tumors. Predictive markers were defined as therapeutically relevant markers in drug labels or NCCN guidelines or targets of ESCAT evidence Tier I/II (Mateo et al., 2018; PMID: 30137196). Prognostic and diagnostic markers were determined in accordance with NCCN, ESMO, or WHO guidelines. We also describe the frequency and targets of interventional clinical trials with targeted therapies or immune checkpoint inhibitors that were matched to tumor profiles based on clinical or strong preclinical evidence. **Results:** Predictive genomic findings of clinical significance were identified in more than half of non-small cell lung cancer (NSCLC), colorectal cancer (CRC), breast cancer (BC), and melanoma (MEL) tissue samples; over a third of ovarian cancer (OC), urothelial carcinoma (UC), and head and neck squamous cell carcinoma (HNSCC); approximately a fourth of prostate cancer (PC), gastro-esophageal adenocarcinoma (GEA), cholangiocarcinoma (CA), and glioma (GL) samples; and one in 18 pancreatic adenocarcinoma (PA) samples (Table). Prognostic markers were reported for patients with NSCLC (18%), CRC (10%), BC (16%), PC (25%), CA (8.1%), MEL (24%), GL (74%), or HNSCC (7.1%). Diagnostic markers were frequently detected for patients with GL and noted for patients with BC, GEA, or MEL (Table). Interventional clinical trials were evidence-matched to most F1CDx tumor profiles (89%, range 82% in PC to 99% in PA), with the targets of approved therapies accounting for a small subset of targets in clinical development. **Conclusions:** F1CDx reports support clinical decision making by interpreting predictive, prognostic, and diagnostic markers according to professional guidelines as well as investigational markers for the enrollment in clinical trials. Research Sponsor: Foundation Medicine, Inc.

Frequency of predictive, prognostic, and diagnostic markers of clinical significance by cancer type in F1CDx reports (N total reports, na not applicable).

Cancer Type	N	Predictive	Prognostic	Diagnostic
NSCLC	22152	59.8%	18.4%	na
CRC	13193	64.7%	10.3%	na
BC	11016	54.2%	16.3%	14.4%
OC	6999	36.2%	na	na
PC	6513	27.3%	24.7%	na
PA	6168	5.5%	na	na
GEA	4762	22.8%	na	6.2%

Molecular reflex testing in non-small cell lung cancer: An optimal approach? *First Author: Kari Hooper, AmeriPath, Oklahoma City, OK*

Background: Molecular testing of non-squamous non-small cell lung cancer (NSCLC) tumors can guide appropriate treatment decisions and improve patient outcomes, but guideline complexity and frequent revision may negatively affect adherence. To assist oncologists in making timelier informed treatment decisions, we implemented a pathologist-directed molecular reflex pathway for non-squamous NSCLC at our clinical laboratory. Testing patterns and adherence to NCCN testing guidelines before and after implementation were reviewed. **Methods:** This retrospective cohort analysis included patients with diagnosed NSCLC who had molecular testing performed without a molecular reflex testing pathway in place (April 2016-March 2018, cohort A) and after the pathway was implemented (April 2018-March 2020, cohort B) at our clinical laboratory. TATs were calculated using dates of biopsy specimen submission and of molecular testing completion. Molecular testing methods (e.g., polymerase chain reaction, next-generation sequencing [NGS]), genetic alterations tested for and identified, PD-L1 by immunohistochemistry, and specimen quantity not sufficient (QNS) for testing were obtained from patients' clinical laboratory reports. NSCLC diagnosis and cancer stage were obtained from electronic medical records, and adherence to NCCN guidelines (i.e., under-tested, over-tested genetic alterations) was evaluated according to specimen submission. **Results:** The mean TAT was 35.1 days for cohort A (n = 123) and 15.8 days for cohort B (n = 168), though the median in both was 14 with a range of 6 – 674 days in cohort A and 9 – 44 in cohort B (Table).Targetable genetic alterations were identified in 12.4% of patients in cohort A and 61.3% in cohort B; 46.3% in cohort A and 60.1% in cohort B had ≥1% positive *PD-L1* staining. QNS results declined from 16.7% (n = 20) in cohort A to 12.5% (n = 21) in cohort B. Non-NCCN guideline testing was observed in 86.7% of patients in cohort A and 25.6% in cohort B, with those in cohort A being primarily under-tested (70%) and those in cohort B being over-tested. Only 13.3% of cohort A had alignment with NCCN guidelines for appropriate time of testing. **Conclusions:** Implementation of a pathology-driven molecular reflex pathway for non-squamous NSCLC was associated with increased identification of potentially targetable genetic alterations and improved adherence to NCCN NSCLC testing guidelines, along with reduction in QNS results. Though the TAT mean decreased after pathway implementation, the median did not change, offsetting the often increased lab TAT for NGS methodology vs. PCR and FISH alone. Research Sponsor: Quest Diagnostics.

	TAT (mean)	Targetable mutations identified	Non-NCCN guideline testing
Total N reviewed (data missing)	291 (3)	291 (6)	291 (3)
2016-2018 cohort A	35.1 days (n = 120)	12.4% (n = 120)	86.7% (n = 120)
2018-2020 cohort B (reflex testing panel)	15.8 days (n = 168)	61.3% (n = 165)	25.6% (n = 168)
Change for cohort B vs cohort A	*-55.1%*	*+48.9%*	*-61.1%*

Molecular correlates of *MAEA* expression in colorectal cancer (CRC). *First Author: Shivani Soni, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Macrophage Erythroblast Attacher (MAEA) plays an important role in actin cytoskeleton rearrangement in macrophages and erythroid cells. We previously reported that MAEA suppresses migration, invasion and enhances chemosensitivity in CRC cell lines. Here we aimed to characterize the molecular features associated with *MAEA* gene expression in CRC. **Methods:** 14416 CRC were tested at Caris Life Sciences (Phoenix, AZ) with NextGen Sequencing on DNA (592 genes or WES) and RNA (WTS). Top quartile transcripts per million (TPM) for *MAEA* expression were considered high (Q4) while bottom quartile low (Q1). Consensus molecular subtypes (CMS) were assessed using RNAseq. Cell infiltration (CI) in the tumor microenvironment (TME) was estimated by QuantiSEQ. X^2 and Fisher-Exact tests were used and significance was determined as *P*-value adjusted for multiple comparisons ($Q < 0.05$). **Results:** *MAEA* expression was highest in rectal tumors (13.6 median TPM) followed by transverse and right-sided tumors (13.0 and 12.8, respectively) and lowest in left-sided tumors (12.5). Overall, *MAEA* TPM were associated with higher tumor mutational burden (≥ 10 Mut/Mb) (11.8% vs. 8.2%) and dMMR/MSI-H (8.7% vs. 5.1%) ($Q < 0.0001$); however, the association with TMB was not observed in MSS tumors. In the MSS cohort, *MAEA* expression was the highest in CMS4 (14.9 median TPM) followed by CMS1 (12.5), CMS2 (11.9), and the lowest in CMS3 (10.3, all intergroup $Q < 0.05$). *MAEA* high was associated with lower mutation rates of *APC* and amplification of *FLT1*/*FLT3* while higher mutation rates of *ASXL1*, *KMT2A/C/D*, *SMARCA4*, *FBXW7*, *PTEN*, *RNF43*, *BRCA2*, *HNF1A* in the overall cohort ($Q < 0.05$). In the MSS cohort, *FBXW7* mutation significance with *MAEA* high expression held true ($Q < 0.05$) while *MAEA* high expression trended to associate with higher mutation rates of *KMT2D*, *SMARCA4*, *PTEN*, *BRCA2* mutations, and a lower frequency of *FLT1*/*FLT3* CNA ($P < 0.05$ but $Q > 0.05$). High *MAEA* was associated with higher immune CI in the TME, including B cells, macrophages (M1 and M2), neutrophils, NK cells, Tregs, CD4+ T cells and myeloid dendritic cells both in the overall cohort and in MSS tumors (fold change: 1.11-1.33, all $Q < 0.001$). **Conclusions:** Our data show a strong association between *MAEA* gene expression and distinct molecular features (including CMS and immune biomarkers) and TME cell infiltration in CRC. These findings suggest that targeting MAEA may have relevant clinical applications in selected CRC subgroups and MAEA may be an important player in determining the composition of the TME. Comprehensive profiling of clock genes expression in colorectal cancer (CRC). *First Author: Francesca Battaglin, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Disruption of the circadian clock has been linked to cancer risk, development and progression. Core clock proteins are emerging as novel therapeutic targets in cancer. We previously showed that polymorphisms in clock genes were associated with anti-VEGF treatment outcome in metastatic CRC. Here we further evaluated the molecular landscape of clock pathway alterations in CRC. **Methods:** 7591 CRC tested at Caris Life Sciences (Phoenix, AZ) with WTS (Illumina NovaSeq) and NextGen DNA sequencing (NextSeq, 592 Genes and NovaSEQ, WES) were analyzed. Clock gene Score (CS) was determined using expression of core clock genes Z scores (positives of *CLOCK*, *ARNTL*, *RORA/B/C* and negatives of repressors *CRY1/2*, *PER1/2/3*, *REVERBA/B*) stratified by quartiles. xCell was used to quantify cell infiltration in the tumor microenvironment (TME). Consensus molecular subtypes (CMS) were assessed by RNAseq. Significance was determined as *P*-values adjusted for multiple testing (*q*) of < .05. Real world survival was obtained from insurance claims data and Kaplan-Meier estimates were calculated for comparison. **Results:** CS was higher in primary tumors than metastases and in right- than left-sided CRC ($P < .001$). Liver metastases were associated with lower CS (23% Q1 vs 19% Q4, $P < .001$). CS was positively associated with CMS1 and 3 (21 vs 11% and 23 vs 9%, respectively, Q4 vs Q1) and negatively correlated with CMS2 and 4 (22 vs 32% and 34 vs 48%) (all $P < .001$). These associations were confirmed in mismatch repair proficient (pMMR) tumors. Overall, TMB-H and dMMR/MSI-H were positively associated with CS (11 vs 6% and 8 vs 4%, Q4 vs Q1, $q < .0001$) and PD-L1 showed a similar trend ($P < .01$, $q = .06$); the association with TMB-H was not significant in pMMR. High CS was associated with alterations of genes in WNT signaling, RAS, PI3K, TGF-*β*, and NOTCH pathways, while negatively associated with *TP53* mutations, *HER2* expression and *CDX2* copy numbers, confirmed in pMMR (all $q < .05$). CS negatively correlated with the angiogenesis pathway signature (Q1 vs Q4 Z score: 6.6 vs -4.6, $P < .001$). B cells, M1 and M2 macrophages, neutrophils, NK, Tregs, CD4+ and CD8+ T cells, and myeloid dendritic cells were more abundant in the TME of tumors with high CS while cancer associated fibroblasts were lower, regardless of MMR status (all $q < .001$). Individually, *ARNTL* tumor expression below median was associated with better OS (overall: HR 0.88, 95% CI [0.82-0.94]; pMMR: HR 0.88 [0.81-0.94]) and longer time on treatment of bevacizumab (overall: HR 0.91 [0.83-0.99]; pMMR: HR 0.91 [0.83-0.99]). **Conclusions:** This is the most extensive profiling study to investigate the expression of clock genes in CRC. Our data show that clock genes expression is strongly associated with distinct molecular features, immune cell infiltration, angiogenesis pathway enrichment and patient outcomes. These findings support the clock pathway as a therapeutic target in CRC, with a major role in CRC biology and TME modulation. Research Sponsor: Partly supported by NCI P30CA014089, Gloria Borges WunderGlo Foundation, Dhont Family Foundation, Ming Hsieh research fund, Daniel Butler Research Fund, Victoria and Philip Wilson Research Fund.

Increasing targeted therapy options for patients with relapsed cancer with broader somatic gene panel analysis from the primary tumor: The Profiler02 randomized phase II trial. *First Author: Olivier Tredan, Medical Oncology Department, Centre Léon Bérard, Lyon, France*

Background: PROFILER-02 is a multicenter randomized prospective study comparing the proportion of metastatic cancer patients (pts) with Targeted Agent (TA) recommendation provided by large NGS panel (FOne panel, 324 genes) *vs* home 87-gene NGS panel (CTRL) (PMID 30865223). **Methods:** Adult pts with advanced/metastatic cancer during 1st or 2nd line of therapy without known targetable gene alteration were eligible and randomized (1:1) to FOne *vs* CTRL panel. Both panels were performed for each patient. The randomization arm defined the first panel reviewed by dedicated Molecular Tumor Board (MTB) at disease progression while the 2nd panel remained blinded. The primary objective was the pts rate with at least one TA recommendation by the MTB using either FOne or CTRL panel. The study was designed in order to detect difference in proportions of 10% between the two panels. A sample size of 289 pts with both panels were requested to show this difference with an expected proportion of discordant pairs of 20% using a McNemar's test with 98% power and 5% two-sided significance level. Secondary endpoints included number of pts receiving at least one TA, progression free survival (PFS) and overall survival (OS). **Results**: From June 2017 to June 2019, among the 339 included pts 171 and 168 pts were randomized in FOne or CTRL panels' first use, respectively. Median age was 57 years [19.0 - 85.0]; 54.9% were female. The median time from randomization to first MTB was 7.62 months [range 0.80 - 48.1]. Among the 339 pts, 147 pts (43.4%) had no TA recommendation, 108 pts (31.9%) had at least one TA recommendation according to both panels, 67 pts (19.8%) had one or more TA recommendation according to FOne panel only and 17 pts (5%) according to CTRL panel only (McNemar $p < 0.001$). At the time of the analysis, 51/339 (15%) pts started recommended treatment: 27 pts (8%) with TA recommendation from both panels, 21 pts (6.2%) from FOne only and 3 pts (0.3%) from CTRL only. Main initiated TA were PARP inh. (FOne n = 12; CTRL n = 9), PI3K/AKT/mTOR inh. (FOne n = 10; CTRL n = 9) and immunotherapy (ICI) (FOne n = 7; CTRL n = 0). Median PFS following first MTB were 3.2 months (95% CI 2.5-3.8) and 2.6 months (95% CI 2.0-3.8), median OS were 8.7 months (95% CI 6.6-10.8) and 8.4 months (95% CI 6.4-9.7), in the FOne and CTRL arm, respectively. **Conclusions**: Larger NGS panel including Tumor Mutational Burden increased the number of recommended options (TA and ICI), as well as the number of treatment initiation. Clinical trial information: NCT03163732. Research Sponsor: Roche, Other Foundation, Other Government Agency.

Primary results from JUPITER, a phase 2 basket trial of combination therapy with trastuzumab and pertuzumab in patients with HER2-amplified solid tumors. *First Author: Sadakatsu Ikeda, Tokyo Medical and Dental University, Tokyo, Japan*

Background: Human epidermal growth factor receptor 2 (HER2) gene amplification or mutations have emerged as oncogenic drivers and therapeutic targets not limited to breast and gastric cancers, but also in a variety of cancers. Despite its considerable therapeutic potential, the evidence has not been established. To address this unmet need, we conducted an organ-agnostic basket trial targeting HER2-amplified solid tumors. **Methods:** JUPITER is a multicenter, single-arm, phase 2 basket trial for solid tumor patients (pts) with HER2 amplification determined by next-generation sequencing (NGS). Both tissue and liquid NGS results were allowed. HER2 amplification by ISH or HER2 overexpression by IHC were not used for inclusion. Pts had treatment-refractory metastatic tumors, or rare cancers without established standard of care. Breast, gastric, and colorectal cancers were excluded. Pts were treated with intravenous trastuzumab (8 mg/kg loading dose followed by 6 mg/kg) and pertuzumab (840 mg loading dose followed by 420 mg) every 3 weeks until disease progression or any other reason for discontinuation. Tumor response was assessed using RECIST v1.1. Primary endpoint was ORR by blinded independent central review (BICR), and secondary endpoints were ORR assessed by the investigators, progression-free survival (PFS), overall survival (OS), duration of response (DOR), and safety. We set the ORR threshold 5% and expected ORR was 20%. Estimated sample size was 38 patients with one-sided alpha 2.5% and power 80%. **Results:** Between April 2019 and June 2020, 42 pts were consented, and 40 pts were treated. Median age was 62 (range, 21-86) and 60% were females. The most common diagnosis was biliary tract cancer (20%), followed by salivary ductal carcinoma (12.5%) and endometrial cancer (12.5%). At data cutoff (1 Sep 2021), ORR by BICR was 22.5% (95%CI: 10.8%-38.5%). ORR assessed by the investigator was 25% (95%CI: 12.7%-41.2%). PFS, OS and DOR were not reached at data cutoff; 3 responders remained on treatment. Of 40 pts, 32.5% had grade ≥ 3 adverse events; 10% were treatment-related, including neutropenia, hypertension, peripheral sensory neuropathy and lymphoedema (all grade 3). No treatment-related death was observed. Exploratory biomarker analysis of response and resistance is in progress. **Conclusions:** Combination therapy with trastuzumab and pertuzumab was well tolerated and showed promising efficacy for the patients with HER2-amplified solid tumors determined by NGS. Clinical trial information: jRCT2031180150. Research Sponsor: AMED (Japan Agency for Medical Research and Development).

Reversion mutations in *BRCA1* or *BRCA2* genes: Resistant mechanism(s) in patients treated with platinum-based agents or poly (ADP-ribose) polymerase(PARP) inhibitors. *First Author: Sourat Darabi, Hoag Family Cancer Institute, Newport Beach, CA*

Background: Reversion mutations (RM) in homologous recombination pathway genes including *BRCA1/2* have been identified in patients with ovarian, breast, and prostate cancers whose tumors have become refractory to platinum chemotherapy or PARP inhibition. Utilizing a multi-institutional molecular database, we report the prevalence of *BRCA1/2* RM in a large cohort across various tumor types. **Methods:** Primary and/or metastatic tumor samples underwent DNA (underwent NextSeq, 592 genes; NovaSeq, whole-exome) and RNA (NovaSeq, whole transcriptome) sequencing (Caris Life Sciences, Phoenix, AZ). RM were identified by a board-certified molecular geneticist and called only if the patient had been treated with a PARPi or a platinum agent. Baseline clinical and outcomes data were obtained through linked insurance claims data. **Results:** Among 118,000 solid tumors profiled, RM were observed in 54 tumors samples. RMs were seen most commonly in ovarian cancer (OC), 1.5% (23/1500) of tumors with *BRCA1/2* pathogenic mutations (mut), followed by breast cancer (BC) (2.4%, 17/700), endometrial cancer (1.0%, 4/400), pancreatic cancer (1.0%, 2/210), cholangiocarcinoma (2.5%, 2/80), prostate cancer (1.3%, 3/230), cervical cancer (1.4%, 1/70), cancer of unknown primary (1.0%, 1/100), and a neuroendocrine tumor of prostate (1 RM of 9 *BRCA* mut). Among all RM, we detected 17 in *BRCA1* and 6 in *BRCA2* in OC. In BC, we identified 7 RM in *BRCA1* and 10 in *BRCA2*. Frameshift mut that restored the reading frame in *BRCA1/2* were the most common type of RM. Molecular profiles of 14 high-grade serous ovarian cancers (HGSOC) with RM were compared to 87 control HGSOC with pathogenic *BRCA1/2* mut without RM. Tumors with RM had lower ER expression (25% vs. 64%, $p = 0.024$) and higher *KDM6A* mut rate (15% vs. 0, $p = 0.016$). Additionally, *TP53* mut rates were similar in RM and control (100% vs. 95%), seen in HGSOC. In patients with RM, 7 of the 14 (50%) *TP53* mut were gain-of-function (GOF) while only 19 of 84 (23%) *TP53* mut in the control group were GOF ($p = 0.048$). More detailed clinical data were available for 29 patients with RM (17 *BRCA1* & 12 *BRCA2*). Among these patients, 7 had received prior platinum-based chemotherapy (carboplatin or cisplatin), 7 patients were treated with PARP inhibitors (olaparib or rucaparib), or both ($n = 7$). Notably, 5 patients had been treated with carboplatin ($n = 2$, ovarian), olaparib ($n = 1$, breast), or both agents ($n = 2$, ovarian and prostate) after the detection of RM. **Conclusions**: This dataset is one of the largest reporting on the prevalence of *BRCA1/2* RM across various tumor types. We demonstrate that the rate of RM was low among *BRCA1/2* mutated tumors; this may be because some patients may not have repeat profiling post-treatment. Repeating tumor profiling at times of treatment resistance can help inform therapy selection in the refractory disease setting. Research Sponsor: None.

Pan-cancer landscape of *CD274* (PD-L1) and *PDCD1LG2* (PD-L2) structural variations. *First Author: Emily L. Hoskins, Ohio State University, Columbus, OH*

Background: PD-1 receptor and PD-L1 ligand interactions are the target of immunotherapies across multiple tumor types. Established biomarkers that predict response to immunotherapy are microsatellite instability, tumor mutational burden, and PD-L1 immunohistochemistry. Structural variations in *CD274* (PD-L1) and *PDCD1LG2* (PD-L2) have been observed in cancer, but the comprehensive landscape is unknown. Here we describe the genomic landscape of *CD274* and *PDCD1LG2* structural variations, their potential impact on the tumor microenvironment, and evidence that patients with these alterations can benefit from immunotherapy. **Methods:** We analyzed sequencing data from 514 cancer cases with *CD274* and *PDCD1LG2* structural variations across 25 publications and data sources, including large pan-cancer sources: Foundation Medicine, Inc (FMI), The Cancer Genome Atlas (TCGA), and Oncology Research Information Exchange Network. To evaluate immune signature enrichment, we ran the software ImSig on gene expression data. We curated literature reporting clinical outcomes of patients harboring structural variations in *CD274* and *PDCD1LG2*. **Results:** From 25 studies and datasets, we curated 514 cancer cases with structural variations in *PD-L1* and *PD-L2*, including 158 duplications, 126 deletions, 97 inversions, 178 translocations, and 96 unclassified structural variations, totaling to 655 events. We observed breakpoint 'hotspots' in the 3'-untranslated regions (UTRs) of *PD-L1* and *PD-L2*. Leveraging TCGA data, we observed, in *CD274*-rearranged tumors, significant upregulation in PD-L1 and PD-L2 expression and signatures for interferon signaling, macrophages, monocytes, T cells, and immune cell proliferation (each $p < 0.001$, compared to *CD274* non-rearranged, copy neutral tumors). Furthermore, retrospective review of 12 studies that included patients with structural variations in *CD274* or *PDCD1LG2*, including duplications, inversions and copy number amplifications, revealed a 73% (52/71) response rate to PD-1 immunotherapy with durable responses. **Conclusions:** Our evaluation of *CD274* and *PDCD1LG2* structural variations shows that the 3'-UTR is frequently affected and is associated with increased expression of ligands and immune signatures. Enriched interferon signaling in *CD274*-rearranged tumors is of particular interest, as interferon exposure is known to drive PD-L1 and PD-L2 expression. Retrospective evidence from curated studies suggests that these genomic alterations could identify candidates for PD-1 or PD-L1 immunotherapy. We expect that these findings will better define *CD274* and *PDCD1LG2* structural variations in cancer and support our pan-cancer prospective clinical trial to target these alterations. Research Sponsor: U.S. National Institutes of Health.

Defining transcriptomic profiles of early-stage mucinous breast cancers: A FLEX sub study. *First Author: Abirami Sivapiragasam, SUNY Upstate Medical University, Syracuse, NY*

Background: Mucinous breast cancer (MuBC) is a rare subtype of invasive ductal carcinoma (IDC) that accounts for less than 2% of all breast cancers and is associated with a favorable prognosis. Since MuBCs are rare in clinical trials, current treatment guidelines are extrapolated from IDC-no special type (IDC-NST). To provide better understanding of MuBCs and factors contributing to their clinical behavior, we examined the transcriptomic profiles of MuBCs in our FLEX study. **Methods:** The prospective, observational FLEX Study (NCT03053193) includes stage I-III breast cancer patients who receive MammaPrint (MP)/BluePrint (BP) testing and consent to full transcriptome and clinical data collection. For this study, histologically confirmed MuBCs ($n = 102$) in the FLEX database were included. All patients examined were ER+/HER2- by immunohistochemistry and Luminal by BP. MuBC was compared with IDC matched for Age, MP, and BP index ($n = 97$). Differential gene expression analyses (DGEA) were performed with R package 'limma' and differentially expressed genes (DEGs) were considered significant if they had an adjusted $p < 0.05$ and fold change ≥ 2. **Results:** DGEA comparing MuBC ($n = 102$) with IDC ($n = 97$) revealed 60 DEGs, regardless of the genomic risk, of which 42 genes were upregulated and 18 were downregulated in MuBC relative to IDC. Genes associated with MuBC, such as MUC2, TFF1, CARTPT were among the upregulated genes. Of the 102 MuBC patients, 56 were Luminal A (MP Low Risk-LR) and 46 were Luminal B (MP High Risk-HR) by MammaPrint and BluePrint. Comparison of LR MuBC with LR IDC revealed 111 DEGs. Functional enrichment showed upregulation of pathways involved in estrogen response (early & late) and androgen response and a downregulation of the epithelial to mesenchymal transition (EMT) and E2F pathways in LR MuBC compared to LR IDC. DGEA between HR MuBC and HR IDC revealed only 22 DEGs with immune pathways being downregulated in HR MuBC. DGEA comparing LR MuBC with HR MuBC resulted in 63 DEGs, indicating LR and HR MuBC are biologically distinct types. Interestingly in LR MuBC, the tumor suppressor marker SCUBE2 is upregulated. Over expression of SCUBE2 is associated with better prognosis. **Conclusions:** Although MuBCs are often expected to have low clinical risk, MP revealed that half of the MuBCs examined in this study were MP High Risk (Luminal B). MP low risk MuBC is biologically different from MP low risk IDC, and downregulation of E2F and EMT pathways might lead to favorable prognoses in MP low risk MuBC. MP high risk MuBC showed limited DEGs compared to high-risk IDCs indicating these tumor types are highly genomically similar and likely to benefit from chemotherapy. The downregulation of immune pathways in MP high risk MuBC may lead to immune surveillance escape resulting in metastasis and further investigation is needed. Clinical trial information: NCT03053193. Clinicopathologic characterization of ERK2 E322K mutation in solid tumors: Implications for treatment and drug development. *First Author: Dazhi Liu, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: *MAPK1* encodes ERK2, a kinase component of the mitogen activated signaling (MAPK) pathway. *ERK2 E322K* is a known activating mutation that leads to increased phosphorylation and ERK signaling. In vitro studies found this mutation to be associated with resistance to dabrafenib, trametinib, but potential sensitivity to ERK inhibitors. Despite its potential as a drug target, little is known about the clinicopathologic characteristics of this hotspot mutation across solid tumors. **Methods:** Patients with solid tumors underwent tumor next-generation sequencing at Memorial Sloan Kettering Cancer Center between Jan 2015 and Sep 2020 using the MSK-IMPACT assay. Using the cBioPortal database and clinical charts, we analyzed tumors harboring MAPK1/ERK2 E322K mutations, assessed their clinicopathologic characteristics, co-mutational status and overall survival (OS). OS was measured from time of tumor sequencing to date of death or last follow-up. **Results:** A total of 37 tumor samples from 35 patients were identified in 59,822 tumors sequenced (0.06%) to harbor an ERK2 E322K mutation. The distribution across tumor types was as follows: head and neck squamous cell carcinoma (29%), bladder cancer (20%), lymphomas (9%), colorectal cancers (9%), gastric cancers (9%), cholangiocarcinoma (6%), cervical cancers (6%), lung cancers (6%), germ cell tumor (3%), Merkel cell carcinoma (3%), and breast cancers (3%). The OS in patients with metastatic disease and ERK2 E322K was 22.29 months (95%CI: 7.56-NA) months. Other mutations in RAS pathway frequently co-occurred with ERK2 E322K mutation (17/37, 46%). Concurrent mutations are also involved in pathways of cell cycle (71%), PI3K (71%), TP53 (66%), NOTCH (57%), RTK (51%), HIPPO (29%), TGF-beta (29%), WNT (26%), NRF2 (20%), MYC (14%). The median TMB score of samples from solid malignancies was 12.3 (range:0-101, quartiles: 6.9-33.0) mutation/Mb. Two patients (2/35, 6%) had microsatellite-instability high (MSI-H) tumors. The most frequent concurrent activating mutations include ARID1A (29%), FBXW7 (26%), PI3KCA (22%), PI3KR1/2/3 (20%), CDKN2A (11%), PTEN (8%), BRCA1/2(8%), FGFR3 (8%), BRAF (6%), Only one of these 35 patients received treatment targeting BRAF/MEK/ERK pathway and achieved partial response. One patient with NSCLC harboring a concurrent EGFR L858R mutation did not respond to erlotinib. One patient with PI3KCA mutated head and neck cancer did not respond to PI3K inhibitor. Two patients had TMB score of 100.9 and 12.9 mutation/Mb had partial response to pembrolizumab. **Conclusions:** ERK2 E322K mutation is a rare oncogenic mutation across diverse solid tumor types, associated with a high co-occurrence of other activating mutations and a high TMB. The lack of response to other targeted therapies suggests ERK2 E322K is a potential driver mutation. These findings may inform treatment and further development of ERK inhibitors. Research Sponsor: U.S. National Institutes of Health.

Using CDKN2A loss in the context of wildtype TP53 to predict sensitivity for the MDM2 inhibitor milademetan. *First Author: Vijaya G Tirunagaru, Rain Therapeutics, Newark, CA*

Background: MDM2 is an E3 ubiquitin ligase that plays a critical role in the degradation of the tumor suppressor p53. Milademetan (RAIN-32) is an orally available, small molecule inhibitor of MDM2 that disrupts the MDM2-p53 complex thereby restoring p53 activity. Approximately 50% of tumors harbor wildtype (WT) *TP53* and thus may be susceptible to strategies that reactivate p53. The *CDKN2A* gene is altered in more than 15% of all tumors (TCGA PanCancer Atlas) and encodes two proteins, $p14^{ARF}$ and p16, which are inhibitors of p53 and cyclin dependent kinases, respectively. Given the role of $p14^{ARF}$ in regulating the MDM2-p53 pathway, we investigated the use of *CDKN2A* loss in the context of WT *TP53* as a strategy for selection of patients who might benefit from milademetan. **Methods:** N/A. **Results:** We evaluated the sensitivity of 215 cancer cell lines to milademetan treatment (Ishizawa et al., 2018) by *CDKN2A* and *TP53* status. The median IC_{50} of *CDKN2A* homozygous (HZ) loss vs. non-HZ loss was 8,620 vs. 10,000 nM. However, when we assessed *CDKN2A* HZ loss with WT *TP53* versus mutant *TP53* the median IC_{50} was 79.5 vs. 10,000 nM demonstrating that the use of both *CDKN2A* and *TP53* was better able to discriminate sensitive vs. resistant cell lines. To validate these *in vitro* findings, we tested milademetan in 5 xenograft models with *CDKN2A* HZ loss and WT *TP53*, all of which demonstrated tumor growth inhibition with milademetan. As suppression of p53 activity by *MDM2* amplification (Kato et al. 2017) or *CDKN2A* loss (Adib et al. 2021) has been associated with resistance to immune checkpoint inhibitors (ICI), we also tested the combination of anti-PD1 with milademetan in the colon-26 syngeneic model (*CDKN2A* HZ loss) and observed a significant enhancement in tumor growth inhibition compared to milademetan or anti-PD1 alone. Based on the differential sensitivity to milademetan using both *CDKN2A* loss and WT *TP53* status we evaluated TCGA Pan-Cancer Atlas data to estimate the frequency of these genetic co-alterations. Among solid tumors types the most frequent percentage of these co-alterations included glioblastoma, mesothelioma, melanoma, bladder, sarcoma, pancreatic and NSCLC. Overall, the percentage of all tumors with co-alteration of *CDKN2A* HZ loss and WT *TP53* was 6.2%. Patients with *CDKN2A* HZ loss had a significantly worse overall survival than those without CDKN2A HZ loss (median OS of 29.7 vs. 97.4 months, $p < 0.0001$), and this was maintained when accounting for tumor type in multivariate analysis ($p < 0.0001$). **Conclusions:** Milademetan showed evidence of preclinical anti-tumor activity across multiple tumor types with *CDKN2A loss* and WT *TP53*. In vivo data supported potential synergy of milademetan with an ICI in this genetic subset. A clinical trial evaluating the safety and efficacy of milademetan plus atezolizumab in advanced solid tumors with *CDKN2A HZ* loss and WT *TP53* (MANTRA-4) is planned. Research Sponsor: Rain Therapeutics.

Identification of homologous recombination deficiency (HRD) by RAD51 in a tumor molecular profiling program for precision medicine. *First Author: Alba Llop-Guevara, Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Tumor molecular profiling by panel sequencing helps to identify candidate patients for precision oncology. Mutations in genes of the homologous recombination repair (HRR) pathway confer DNA repair deficiency and sensitivity to DNA damaging agents, such as PARP inhibitors (PARPi) or platinum-based drugs. RAD51 nuclear foci is a biomarker of functional HRR deficiency (HRD). We aimed to incorporate the RAD51 test in an academic molecular profiling program to identify HRD tumors beyond genetic testing. **Methods:** We included patients with metastatic breast cancer (TNBC, ER+ <60y, 3rd line HER2+ BC), newly diagnosed high-grade epithelial ovarian cancer (HGOC) and metastatic and/or castration-resistant prostate adenocarcinoma (PC) undergoing tumor/germline genetic testing. A customized capture-based targeted sequencing of 450 genes was performed in FFPE tumor samples. RAD51 was manually stained by immunofluorescence and functional HRD was defined as RAD51 score ≤10%. **Results:** Between January 2021 and January 2022, tumor panel sequencing was performed in 279 tumors. Panel sequencing was informative in 264/279 (95%) samples and the RAD51 test was evaluable in 81/90 (90%). In total, 77 samples were evaluable for both tumor/germline sequencing and RAD51, namely 42 BC, 16 HGOC and 19 PC (Table 1). Functional HRD by RAD51 was observed in 15/77 (20%) cases. Panel sequencing identified 17/77 (22%) cases carrying HRR gene alterations, of which nine were confirmed as HRD by RAD51. In BC, 2/6 tumors with HRD by RAD51 did not carry a germline or tumor mutation in HRR genes. HRD tumor profiling triggered the germline analysis of one hereditary *BRCA2* BC patient. Four g*BRCA1/2* BC with HRD by RAD51 became HRR proficient (HRP) at PARPi progression. In addition, the RAD51 test identified 2/5 HGOC and 2/4 PC tumors as HRD despite not carrying a tumor HRR gene mutation. **Conclusions:** RAD51 testing is feasible in an established molecular profiling program and complements gene panel sequencing results by providing evidence of functional HRR status. In particular, the RAD51 test extends the identification of HRD tumors beyond those with HRR gene mutations and captures HRR restoration after PARPi treatment. We aim to expand the analysis of RAD51 to other tumor types. Research Sponsor: Asociación Española Contra el Cáncer (AECC), LaCaixa Foundation (CaixaImpulse grant), Generalitat de Catalunya (AGAUR-Producte and PERIS), Instituto de Salud Carlos III (ISCIII), Fondo Europeo de Desarrollo Regional (FEDER).

Number of samples with both functional HRR status by RAD51 and HRR gene mutation status by panel sequencing in breast, high-grade ovarian and prostate cancers.

Number of cases	Tumor/germline sequencing (HRR genes)	HRD by RAD51	HRP by RAD51
BC (n = 42)	mutated	4	6
	non-mutated	2	30
HGOC (n = 16)	mutated	3	1
	non-mutated	2	10
PC (n = 19)	mutated	2	1
	non-mutated	2	14
All tumor types(n = 77)	*mutated*	***9 (12%)***	***8 (10%)***
	non-mutated	***6 (8%)***	***54 (70%)***

Paired tumor/normal sequencing to overcome racial differences in tumor mutational burden (TMB). *First Author: Kenneth Robert Carson, Tempus Labs, Inc., Chicago, IL*

Background: TMB is routinely reported in cancer patients tested with broad-panel next generation sequencing and has become a predictive biomarker associated with response to checkpoint inhibitor (CPI) therapy. Sequencing of paired tumor and normal specimens allows correction of TMB estimates with patient-specific germline variants. When a paired normal specimen is unavailable, TMB estimates are corrected using germline variant annotations derived from population-scale germline variant surveys. Germline variants do not generate neoantigens, which is the putative target of the immune response in CPI treated patients. To evaluate TMB differences in paired sequencing (PS) and tumor-only sequencing (TOS), we compared TMB assessments—stratified by race—in two common malignancies**. Methods:** Using de identified records from the Tempus clinico-genomic database, cohorts of patients with non-small cell lung cancer (NSCLC) and breast cancer sequenced using the Tempus xT NGS platform (DNA-seq of 595-648 genes at 500x coverage, whole exome capture RNA-seq) and noted to not have microsatellite instability, were identified for analyses. The Kruskall-Wallis test was used to compare TMB distributions. **Results:** Among 4,817 NSCLC patients with race information (13% Black (B), 5% Asian (A), 82% White (W), 3,052 had PS, and 1,765 had TOS performed. Median TMB for B, A, and W patients was 5.8, 2.6, and 4.7 (within group $p < 0.0001$), respectively in patients with PS, and 9.5, 6, and 7.4 (within group $p < 0.0001$), in patients with TOS. Comparisons across PS and TOS were highly significant ($p < 0.0001$). The absolute difference in median TMB was 3.7, 3.4, and 2.5, respectively. Among 3,191 patients with breast cancer (17% B, 4% A, 78% W), 2,220 had PS, and 971 had TOS. Median TMB for B, A, and W patients was 2.6, 2.1, and 2.6 (within group $p = 0.11$), respectively, in patients with PS, and 6.3, 5.8, and 4.7 (within group $p < 0.0001$) in patients with TOS. Comparisons across PS and TOS were highly significant ($p < 0.0001$). The absolute difference in median TMB was 3.7, 3.7, and 2.1, respectively. **Conclusions:** PS reduces estimated TMB compared to TOS across all racial groups with a pronounced difference in Black and Asian racial groups. This is expected as population databases of germline variation are based on cohorts predominantly from individuals of European ancestry, leading to artifactually high TMB in minorities tested with TOS. As a result, artifactually elevated TMB estimates from TOS may promote treatment with CPI in patients with a low probability of response which could exacerbate known race-based outcome disparities. PS provides a more accurate estimate of TMB regardless of race and could reduce the use of CPI in patients with a low likelihood of response. Research Sponsor: Tempus Labs, Inc.

Next-generation sequencing (NGS) for identifying actionable molecular alterations in patients with newly diagnosed and recurrent IDHwt-glioblastoma (GBM): A large mono-institutional experience. *First Author: Marta Padovan, Department of Oncology, Oncology 1, Veneto Institute of Oncology IOV-IRCCS, Padua, Italy*

Background: NGS panels allow the identification of alterations within hundreds of cancer-related genes and can guide a personalized strategy in glioma treatment. **Methods:** From Nov 2019 to Jan 2022 at Veneto Institute of Oncology, Padua, Italy, a large cohort of IDHwt-GBM tissues was analyzed by NGS (FoundationOneCDx). We identified all potential actionable molecular alterations at diagnosis and/or at recurrence. High tumor mutational burden (TMB) was defined as ≥10 mutations/megabase. **Results:** We analyzed 429 IDHwt-GBM samples: NGS profile was available for 419 samples (97.7%); sample failures in 10 cases (2.3%). 351 (84%) and 68 (16%) GBM samples derived from surgery at diagnosis and recurrence, respectively. All patients received radiotherapy and/or temozolomide as first line therapy. Among all the analyzed samples, the most frequent actionable molecular alterations were: CDKN2A (57%), CDKN2B (53%), EGFR amplification (39%), EGFR mutation (24%), PTEN loss (27%), RB1 (23%), NF1 (18%), PIK3CA (18%), CDK4 (15%), MDM2 (10%), PDGFRA (8%), BRCA1-2 (7%), FGFR1-3 (7%), Myc (6%), JAK (6%), ROS1 (5%), METmut (2%), METampl (2%), BRAF V600E (2%). No NTRK1/2/3 druggable alterations were observed. High TMB was found in 18 samples. Incidence of actionable molecular alterations in newly diagnosed and relapsed GBM samples is described in the Table. The incidence of alteration of EGFR (ampl/mut), RB1, PIK3CA was statistically different between the two subgroups of samples (Fisher test). To date, 10% of patients received a personalized treatment as compassionate use, off-label use or in clinical trials (9 Dabrafenib/Trametinib, 8 Alpelisib, 3 Erdafitinib, 2 Ipatasertib, 1 Alectinib, 1 Capmatinib, 1 Palbociclib, 1 Entrectinib, 1 Pamiparib). Activity analysis is still ongoing. **Conclusions:** NGS is feasible in GBM samples. Potentially, a high rate of patients could receive a personalized treatment. The activity analysis is ongoing. However, the incidence of actionable molecular alterations may differ between diagnosis and recurrent GBM samples. Research Sponsor: None.

Combining autophagy and immune characterizations to predict prognosis and therapeutic response in lung adenocarcinoma. *First Author: Qiaxuan Li, Department of Thoracic Surgery, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China*

Background: As a key regulator of programmed cell death, autophagy is critical for maintaining the stability of the intracellular environment. Increasing evidences have found that the clinical importance of the interaction between autophagy and immune status in LUAD. Reliable prognostic signatures based on combination of autophagy and immune status have not been well-established. We aimed to explore the potential autophagy-immune-derived biomarkers to predict prognosis and therapeutic response in lung adenocarcinoma. **Methods:** Patients from GSE72094 dataset were randomized 7:3 to a training set or an internal validation set. Three independent cohorts, TCGA, GSE31210 and GSE37745, were used as the external verification. Unsupervised hierarchical clustering was used to identify the autophagy-associated and immune-associated molecular patterns for LUAD based on autophagy-genes and immune-genes. The LASSO analysis, univariate and multivariate cox regression analysis were performed to filtrate significant prognostic autophagy-immune-based genes, followed with model construction and patient stratification. Tumor immune microenvironment and functional pathways were investigated. The potential therapeutic responses were explored by GDSC database, TIDE algorithm, and immunotherapy clinical cohorts. **Results:** We found that autophagy cluster A had the better survival prognosis ($p < 0.001$) and high immune status ($p < 0.001$) was identified as favorable factors for patients' overall survival. We merged autophagy and immune subtype into a two-dimensional index to characterize the combined prognostic classifier 535 genes were defined as autophagy-immune-related DEGs. Four genes (C4BPA, CD300LG, CD96, and S100P) were identified to construct the autophagy-immune-related prognostic risk model. Survival analysis and receiver operating characteristic curve showed significant prognostic efficacy. Through ssGSEA and CIBERSORT analysis, the majority of immune infiltrating cells were shown to be enriched in the low-risk group. What's more, the expression of crucial immune checkpoint molecules, such as PD-1, PD-L1 and CTLA-4, was observed highest in low-risk group ($p < 0.001$). TIDE and immunotherapy clinical cohorts' analysis showed that low-risk group was predicted with more potential responders to immunotherapy. In addition, there are different patterns of autophagy between low- and high- risk patients. GO, KEGG and GSEA function analysis focus on cell cycle, MAPK, apoptosis, MTORC1 and selective autophagy pathway. Docetaxel, rapamycin and sorafenib may be the potential drugs candidate in high-risk group ($p < 0.01$). **Conclusions:** In summary, the autophagy-immune-based gene signature represents a promising tool for risk stratification tool in lung adenocarcinoma, which can regard individualized treatment and follow-up scheduling for patients. The distribution of genetic mutations correlated with resistance to $KRAS^{G12C}$ inhibitors in Chinese patients with lung cancer. *First Author: Shengcheng Lin, Cancer Hospital Chinese Academy of Medical Sciences, Shenzhen, China*

Background: In lung cancer, p.G12C is the most frequent variant in Kirsten rat sarcoma viral oncogene homologue (KRAS) gene. $KRAS^{G12C}$ inhibitors have shown promising efficacy in lung cancer in recent clinical trials, acquired resistance, however, eventually occurred in most patients. Preliminary studies revealed that a number of genetic mutations were correlated with resistance to this type of drugs, including *KRAS* secondary mutations, *KRAS* activating mutations, mutations in RTK-RAS-MAPK signaling pathways members, oncogene rearrangements and copy number gain. To clarify the potential clinical application of $KRAS^{G12C}$ inhibitors, herein we analyzed the distribution of reported resistance gene alterations in a large and natural group of Chinese lung cancer, as well as the gene mutation landscape of the subset of patients with suspected resistant mutations. **Methods:** A total of 32878 Chinese lung cancer including early-stage, late-stage without treatment or late-stage with previously treated were analyzed in this study. Wide NGS panel testing was used to detected single nucleotide variants (SNV), copy number variants (CNV) and oncogenic gene rearrangements. **Results:** *KRAS* mutations were detected in 2767 (8.4%) cases, of which *KRAS* G12C was the most common variant (30.86%). Among 854 patients (2.6%) harbored *KRAS* G12C, 75 (10%) carried the above resistance mutations, such as G12D/R/V (n = 7). Fusions (20%) which previously observed only in coloretal cancer were unexpectedly detected in this corhort, including *EML4-ALK* (n = 1), *FGFR1-MECOM* (n = 1), *EWSR1-CHEK2* (n = 2), *SPEN-KAZN* (n = 2), *MET-KCNB2* (n = 1), *NOTCH2-NOTCH2NLA* (n = 5), *SMARCA4-DNAH8* (n = 1), and *LIPM-FAS* (n = 1). Furthermore, *KRAS* (46.7%), *MYC* (25.3%) and *MET* (10.7%) were amplified. Among this subset of patients with resistant mutations, *TP53* (66%), *LRP1B* (25%), and *STK11* (22%) were the most frequently mutated genes. It is noteworthy that *STK11/KEAP1 /NFE2L2* gene mutation was detected in nearly 30% in this group of patients. **Conclusions:** The results of our analysis suggested that about 10% *KRAS* G12C-mutated Chinese lung cancer patients would be resistant to *KRAS* G12C inhibitors. Moreover, a small number patients have co-mutated genes which were negatively related to immunotherapy in NSCLC, indicating they were also inappropriate for immunotherapy. Research Sponsor: None.

A digital imaging analysis (DIA) platform for identifying tertiary lymphoid structures (TLS) in lung adenocarcinoma (LUAD). *First Author: Vladimir Kushnarev, BostonGene Corporation, Waltham, MA*

Background: Previous studies of non-small cell lung cancer (NSCLC) have shown that TLS can be predictive of therapy response and a positive prognostic factor for survival. Currently, TLS identification is manually performed by pathologists with limited morphological criteria. Standardizing TLS detection with an automated DIA workflow could guide clinical trials in precision medicine by improving patient stratification. Here, we investigate the reproducibility and sensitivity of our DIA platform for evaluating TLS in LUAD using digital histopathology and machine learning. **Methods:** TLS were assessed by 3 pathologists on whole slide images (WSI) in a validation cohort of 22 LUAD samples using current TLS characterization criteria of dense lymphoid structures, the presence/absence of a germinal center, and high endothelial venules (HEVs). The intraclass correlation coefficient (ICC) was used to measure reproducibility between pathologists. The BostonGene DIA platform was used to train models for automated TLS detection. Quantitative measurements of area, lymphocyte number, and density of each TLS were obtained. A prospective cohort of 8 samples was used to compare pathologist and DIA identification of TLS. Normalized numbers of TLS in the tumor area were used for cohort stratification for overall survival (OS) analysis using the Kaplan-Meier method in an independent clinical cohort of 104 TCGA-LUAD patients. **Results:** A panel of 3 pathologists identified 326 unique TLS from 22 samples. Between-pathologist detection of TLS, independent of germinal center or HEV criteria, resulted in good reproducibility with an ICC of 0.77. Our DIA platform exhibited excellent reproducibility with an ICC of 0.94 when compared to validated prospective cohort annotation. In total, 155 and 189 TLS were identified by pathologists and our DIA platform, respectively. The DIA platform demonstrated a markedly improved sensitivity of 0.91 for TLS identification. Furthermore, OS analysis revealed that a TLS density greater than 0.94 TLS per mm^2 of tumor assessed by DIA is a statistically significant independent biomarker of better OS in the LUAD cohort from TCGA. **Conclusions:** These results demonstrate the BostonGene DIA platform detects TLS in LUAD, with improved reproducibility and sensitivity over previous methods. Additionally, the DIA platform showed a TLS density greater than 0.94 TLS per mm^2 of tumor is a positive prognostic marker for OS in LUAD. Standardized TLS DIA identification can be exploited in digital pathology applications for future clinical trials, informing clinicians of predictive and prognostic information during the decision-making process. Research Sponsor: BostonGene Corporation.

Rapid access to biomarker data in a community setting: Integration of next-generation sequencing into routine pathologic workflow. *First Author: Kirstin Perdrizet, University of Toronto, Toronto, ON, Canada*

Background: Biomarker data in the form of next generation sequencing (NGS) are critical to the delivery of precision cancer care. Onsite testing is often limited to large academic centers, requiring smaller community centers to rely on samples send outs. Turnaround time for biomarkers can be lengthy and can adversely affect the delivery of optimal therapy in many tumor types. This study aims to evaluate the feasibility of rapidly delivered comprehensive NGS in a community center using a novel workflow in the laboratory by integrating NGS into the routine immunohistochemistry (IHC) service. **Methods:** An automated NGS workflow utilizing the Genexus integrated sequencer with the Oncomine precision assay GX (OPA, Thermofisher Scientific), was validated for clinical use and integrated into the routine diagnostic IHC service. During the study period (Oct 2020 – Oct 2021), NGS biomarker data was generated and reported alongside IHC biomarkers where applicable. A retrospective chart review was performed to assess the early experience and performance characteristics of this novel approach to biomarker testing. **Results:** A total of 578 solid tumor samples underwent genomic profiling. Median turnaround time for biomarker results was 3 business days (IQR 2-5). The majority (n = 481, 83%) of cases were resulted in fewer than 5 business days. Tumor types included lung cancer (n = 310, 54%), melanoma (n = 97, 17%), and colorectal cancer (n = 68, 12%). Specimen types included surgical resections (n = 104, 18%), core biopsies (n = 411, 71%), and cytology specimens (n = 63, 11%). NGS testing detected key driver alterations at expected prevalence rates in respective tumor types; lung *EGFR* (16%), *ALK* (3%), *RET* (1%), melanoma *BRAF* (43%), colorectal *RAS/RAF*wild-type (33%), among others. **Conclusions:** This is the first study demonstrating the clinical feasibility and turnaround time statistics of automated comprehensive NGS performed and interpreted in parallel with diagnostic histopathology and immunohistochemistry in a community setting. This novel approach of integrating biomarkers, IHC, and morphology offers rapid turnaround by removing the need for outsourcing biomarker data. This model could be adopted by other community centers to improve rapid access to biomarker data and therapeutic decision making. Research Sponsor: Pfizer Canada, Pharmaceutical/Biotech Company.

Impact of clonal hematopoiesis on tumor control following radiation therapy. *First Author: Jacqueline Tao, Department of Medicine, New York-Presbyterian Weill Cornell, New York, NY*

Background: Clonal hematopoiesis (CH) has well established associations with adverse clinical outcomes including all-cause mortality, cardiovascular disease, and progression to hematologic malignancy. The presence of CH has also been demonstrated to adversely impact survival from non-hematologic cancers, however whether CH may modulate response to radiation therapy (RT) in solid tumors is not known. Here we investigate the potential impact of CH mutations on radiation outcomes. **Methods:** We analyzed data from two previously well annotated cohorts of patients with tumors harboring somatic *ATM* mutations (n = 358) and *FAT1* mutations (n = 365) who received RT and underwent prospective tumor and matched WBC sequencing utilizing the MSK-IMPACT assay. CH variants were detected in the blood samples utilizing a well-validated variant detection and filtration pipeline. Given that pathogenic mutations in ATM have been shown to be strongly associated with improved response to RT, these patients were excluded to avoid confounding. Additionally, patients with blood sampling for CH assessment that occurred more than 6 months after RT were excluded to address the possibility of therapy-related CH. We compared outcomes including irradiated tumor progression in patients with and without CH. **Results:** The final analysis consisted of 412 patients who underwent 811 total courses of radiation. A wide spectrum of solid tumor types were represented, most commonly non-small cell lung cancer (32.5%) and breast cancer (11.9%). A total of 161 patients (39.0%) had CH, with the most commonly mutated genes being *DNMT3A* (25.6%), *PPM1D* (6.2%), *TET2* (5.8%), and *TP53* (5.0%), consistent with prior studies of CH. Patients with CH were older at blood sample collection (67.6 vs 60.2 years, $p < 0.001$), reflecting an expected increase in CH burden with age. Fine Gray competing risks analysis, with death treated as a competing event and with clustering around patient identifier, showed no difference in irradiated tumor progression between patients with and without CH (HR 1.03, 95% CI 0.69 – 1.53, $p = 0.896$). Similarly, subanalyses by CH variant allele frequency and putative CH-driver mutations did not reveal an association between CH and response to RT. A hypothesis generating subgroup analysis by common cancer types, however, suggested that CH was associated with increased risk of progression post-radiation in prostate (HR 4.68, 1.14 – 19.1) and thyroid (HR 3.13, 1.55 – 6.34) cancer cohorts, warranting further investigation. **Conclusions:** We found no difference in irradiated tumor progression among patients who did and did not have CH. There may be an association between CH and poor radiation outcomes in certain cancer types, and further studies are needed to clarify the specific clinical and genomic factors that may influence radiation response. Research Sponsor: None.

De novo EGFR T790M mutations in a community-based oncology practice. *First Author: Marilyn E. Holt, Sarah Cannon Research Institute, Nashville, TN*

Background: With the 2018 FDA approval of osimertinib for first-line treatment in EGFR-mutated lung cancers, the prevalence of acquired EGFR T790M mutations is expected to decrease, heightening the significance of de novo T790M mutations. Previous studies have reported a wide range of de novo T790M prevalence, and smaller retrospective studies have indicated that germline T790M may comprise the majority of de novo T790M mutations. Here, we assess the frequency of de novo T790M mutations in a community-based setting and report on germline T790M mutations occurring within this population. **Methods:** Patients with T790M-positive lung cancer were identified using Sarah Cannon's clinicogenomics database containing information for patients treated within the Sarah Cannon research network. All T790M mutations were detected on tissue- and plasma-based NGS tests delivered as part of routine care. De novo and germline EGFR T790M status was determined via manual electronic health record chart review. When available, allele fraction and %cfDNA values were extracted from the structured NGS report and analyzed separately. **Results:** Of T790M-positive lung cancers with available pretreatment testing results, 36% (16/44) were confirmed to be T790M+ prior to EGFR TKI exposure; five of these patients received germline testing, and all five were confirmed to have originated in the germline. Two patients with germline T790M mutations detected on testing ordered by external providers were added to our de novo T790M+ patient analysis after chart review. Co-occurring EGFR mutations, including L858R, were detected in pre-TKI samples for 78% (14/18) of de novo T790M+ patients (Table). Co-occurring mutations in TP53, KRAS, PTEN, or RB1 were detected in pre-TKI samples of all patients without co-occurring EGFR mutations. EGFR C797S was observed after osimertinib treatment in one of four patients with post-TKI testing results. Of confirmed germline T790M+ cases with available allele frequencies, 100% (4/4) had allele fractions >0.5 (tissue) and/or %cfDNA values >50% (plasma). Average allele fraction and %cfDNA values were higher for de novo T790M mutations (allele fraction: 0.5 ± 0.2; %cfDNA: 40% ± 20%) than for acquired T790M mutations (allele fraction: 0.3 ± 0.2; %cfDNA: 2% ± 2%). **Conclusions:** Roughly one-third of T790M mutations detected in real-world settings occur before EGFR TKI exposure and may be associated with germline inheritance. Allele frequency may be a potential indicator of de novo T790M mutations in scenarios where pre-treatment data is not available. Future studies will investigate the impact of de novo T790M mutations on treatment response and evolution of resistance mechanisms in osimertinib-treated patients. Research Sponsor: None.

Construction of a near-term predictive model for irAEs induced by PD-1 inhibitors. *First Author: Ying Zhang, Changzhi People's Hospital Affiliated to Changzhi Medical College, Changzhi, China*

Background: Immune checkpoint inhibitors have opened a new chapter in cancer therapy, but the incidence of irAEs caused by them is high, and severe irAEs can be fatal. The current research on irAEs is almost focused on early predictions, and there is a lack of near-term predictions (the cycle before the occurrence of irAEs). Absolute eosinophil count (EO#) has been reported to be associated with immune-related pneumonia, but its association with other systemic irAEs requires further exploration. The aim of this study was to explore the near-term predictive value of neutrophil/lymphocyte (NLR), platelet/lymphocyte (PLR), and EO# for PD-1 inhibitor-induced irAEs. **Methods:** The data are from tumor patients who received PD-1 inhibitor therapy in our department from July 2019 to May 2021. A total of 146 cases were included, of which 56 had irAEs. The data of NLR, PLR and EO# in the cycle before the occurrence of irAEs (the median number of cycles was the second cycle) were collected, and the data of the second cycle was used as the control for patients without irAEs group. Logistic method was used to analyze the correlation between NLR, PLR and EO# and irAEs, and a predictive model was constructed. The sensitivity and specificity of the model were evaluated by ROC curve. This study was registered on Chinese Clinical Trail Registry (ChiCTR2100049849). **Results:** A total of 146 tumor patients were included, of which 56 developed at least one irAEs. Grade 1-2 irAEs occurred in 39 cases, grade 3-4 in 12 cases (including cardiac, liver, lung and skin toxicity), grade 5 in 2 cases(including cardiac and lung toxicity), and ungraded in 3 cases. The data of the cycle before the occurrence of irAEs were analyzed. Univariate analysis showed that NLR (odds ratio [OR], 1.4, $p< 0.05$) and EO# (OR, 12.6, $p< 0.05$) were associated with irAEs, and multivariate analysis suggested NLR (OR, 1.7, $p< 0.001$) and EO# (OR, 20.4, $p< 0.05$) were independent risk factors for irAEs. The prediction model composed of NLR, PLR and EO# had a correct rate of 76.7% (AUC = 0.752) in predicting the occurrence of irAEs in the near-term cycle, with a sensitivity of 51.8% and a specificity of 92.2%; the correct rate of predicting irAEs of grade 3 and above was as high as 91.9% (AUC = 0.778), the sensitivity was 14.3% and the specificity was 99.2%. **Conclusions:** The model composed of NLR, PLR and EO# may predict the occurrence of irAEs in the near-term cycle, especially the prediction of irAEs above grade 3, which can provide early warning for the occurrence of irAEs. Clinical trial information: ChiCTR2100049849. Research Sponsor: None.

Landscape of endocytosis pathway in colorectal cancer (CRC). *First Author: Hiroyuki Arai, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Recent proteogenomic analyses of CRC revealed that driver gene alterations are enriched in the endocytosis pathway (Vasaikar S, et al. Cell 2019;177:1035-49). Endocytosis is a cellular system involving post-translational modification of plasma membrane proteins through internalization, intracellular trafficking, degradation, and recycling. Clathrin-mediated endocytosis (CME) is the main endocytic portal, and endosomal sorting complexes required for transport (ESCRT) play a critical role in the lysosomal degradation pathway. Besides the well-known function of endocytosis attenuating signaling pathways through receptor clearance from the cell surface, the opposite function contributing to signal maintenance has also been reported. However, the clinical implications of the endocytosis pathway alterations in CRC are largely unclear. **Methods:** We retrospectively reviewed CRC patient samples (n = 15025) submitted to a commercial CLIA-certified laboratory (Caris Life Sciences, Phoenix AZ). Next-generation sequencing of DNA and RNA (whole-transcriptome sequencing) and immunohistochemistry (IHC) were performed. CME-related (47 genes) and ESCRT-related (35 genes) expression signatures were calculated as composite z-scores and compared between subgroups stratified by *RAS*/*BRAF* mutation status, MSS/MSI status, tumor sidedness, and consensus molecular subtype (CMS). *VPS4A*/*VPS4B* expression correlation with major oncogenic pathway signatures (composite z-scores) and *CMTM6*/*CMTM4*/*HIP1R* expression association with PD-L1+ IHC were also assessed. **Results:** Among 17 endocytosis-related genes, no pathogenic/likely pathogenic mutations were identified. The CME-related signature was increased in *RAS*/*BRAF* wild type vs. mutant (0.93 z-score difference, $p= 0.04$) and MSS vs. MSI-high (6.0 z-score difference, $p< 0.01$), while the ESCRT-related signature was higher in MSS compared to MSI-high (2.7 z-score difference; $p< 0.01$). No differences between tumor sidedness were observed in both CME- and ESCRT-related signatures (0.81 and 1.17 z-score differences, respectively). CMS4 had the highest expression of both signatures, while CMS3 had the lowest, of both CME- and ESCRT-related genes (each > 20 z-score difference, $p< 0.01$). *VPS4A* and *VPS4B* expression had a strong positive correlation with WNT, EGFR/MAPK, TGF-beta, and Notch pathway signatures (0.65-0.83 Spearman, all $p< 0.01$). *CMTM6* expression was positively associated with PD-L1+ IHC (1.2-fold increase vs PD-L1-negative, $p< 0.01$), while *CMTM4* and *HIP1R* expression showed a negative association (0.7- and 0.9-fold decrease, respectively, $p< 0.01$). **Conclusions:** This large study indicates endocytosis pathway expression is positively associated with oncogenic pathway signaling in CRC. Further analysis of *RAS*/*BRAF* wild type, MSS, and CMS4 patient subgroups are warranted to determine the efficacy of targeting endocytosis pathways in CRC. BRAF-targeted therapy for locally advanced ameloblastoma of the mandible: A potential neoadjuvant strategy. *First Author: Shirly Grynberg, Ella Lemelbaum Institute for Immuno Oncology and Melanoma, Sheba Medical Center, Ramat-Gan, Israel*

Background: Ameloblastoma is a rare benign but locally aggressive odontogenic neoplasm, with 2% of cases representing ameloblastic carcinoma or metastatic ameloblastoma. It affects young adults with high recurrence rates after surgery. The standard therapy is radical bone resection with subsequent functional, aesthetic & psychological impairments. Therefore, other therapeutic options, including neoadjuvant approach, should be considered. Sixty to 70% of mandible Ameloblastoma carry a BRAF mutation, usually V600E, and previous case reports have shown durable responses to treatment with BRAF inhibitors in these patients. We sought to explore the possibility of neoadjuvant BRAF or BRAF+MEK inhibition as neoadjuvant treatment in mandible Ameloblastoma. Here we present results of 12 patients with locally advanced disease who were treated with BRAF with or without MEK inhibitors. **Methods:** Patients who were unable to undergo jaw preservation surgery for locally advanced Ameloblastoma with a BRAF V600E mutation were treated with Dabrafenib or Dabrafenib-Tratmetinib in an EAP form. Patient records were analyzed for baseline parameters, treatment regimen, toxicity, response to therapy and the ability to convert to a mandible preservation surgery. Data were collected and analyzed in accordance with Sheba Medical Center IRB approval. Statistical analyses were done with STATA v.17. **Results:** Twelve patients were treated with Dabrafenib/ Dabrafenib-Tratmetinib between 2017-2021. Five patients received BRAF-MEK inhibitors and 7 BRAF inhibitor alone. Median age was 21. Ten patients(83%) showed excellent response to therapy and have successfully converted from planned radical bone resection to mandible preservation surgery. The other 2 patients are still on therapy and have also showed deep responses that enable conversion to mandible preservation. Median time to surgery was 10 months. With median follow up of 18 months, no cases of recurrence were documented. Rate of adverse events was as expected with only 1 case of G3-4 (hepatitis). **Conclusions:** Targeted therapy with BRAF with or without MEK inhibition may serve as an important therapeutic tool for locally advanced Ameloblastoma with the potential of organ preservation treatment, and is an important example of oncological therapy assisting in non-cancerous tumors. Research Sponsor: None.

Updated survival follow-up for phase I study of abexinostat with pazopanib in patients with solid tumor malignancies. *First Author: Erica S Tsang, University of California San Francisco, San Francisco, CA*

Background: Histone deacetylase (HDAC) inhibition downregulates HIF-1a, which may be effective in overcoming resistance to VEGF-targeting tyrosine kinase inhibitors. We report the updated survival follow-up for patients treated with abexinostat and pazopanib in a phase Ib trial. **Methods:** Patients with solid tumor malignancies were enrolled in this phase Ib, open-label trial (NCT01543763) of abexinostat in combination with pazopanib (3+3 design), with a dose expansion restricted to renal cell carcinoma (RCC). Patients received a 1-week run-in period with abexinostat alone, and then combination abexinostat with pazopanib during a 28-day treatment cycle until disease progression, unacceptable toxicity or study withdrawal. Plasma samples from 29 patients were sent for metabolomics analysis. **Results:** 51 patients were enrolled: N = 36 patients in dose escalation, N = 15 in dose expansion. At the time of last report in 2017, 5 patients remained on study treatment: N = 4 with RCC, and N = 1 with thymic neuroendocrine carcinoma. 4 of these patients have now had disease progression. Median duration of therapy measured 44.9 months (range 39.8-102.2). One patient with metastatic RCC (patient 1) remains on study treatment, after progression on 5 prior lines of systemic therapy. With updated survival follow-up, median OS measured 12.4 months in the dose escalation arm and 27.65 months in the RCC dose expansion cohort. Overall median duration of therapy in all 51 patients measured 5.6 months (range 1-103 months). Progression-free survival among patients with high PBMC HDAC2 expression (> 0.4) remains longer compared to those with low expression (median 6.3 vs. 3.7 months, p = 0.0041). Metabolomics analysis demonstrated a negative correlation between HDAC2 and N6-acetyllysine, suggesting that baseline HDAC2 may impact efficacy of HDAC inhibition. **Conclusions:** The combination of abexinostat with pazopanib appears promising, with the potential for long-term responses particularly in patients with metastatic RCC. This has led to an ongoing phase III trial examining this combination in RCC. Clinical trial information: NCT01543763. Research Sponsor: GlaxoSmithKline, Pharmacyclics.

Patient	Pazopanib dose (mg/ daily)	Abexinostat Dose (mg/m^2 twice daily)	Histology	Age at Study Entry	Number of Prior Systemic Therapies	Duration of Therapy (months)	Best Response
1	400	30	RCC	71.1	5	102.2	Partial response
2	800	45	Thymic neuroendocrine carcinoma	66.5	1	57.7	Stable disease
3	800	45	RCC	52	2	43.4	Partial response
4	800	45	RCC	60	None	39.8	Partial response
5	800	45	RCC	73	None	44.9	Partial Response

Combination treatment of radiofrequency ablation and peptide neoantigen vaccination: Promising modality for future cancer immunotherapy. *First Author: Yong Fang, Internal Medicine-Oncology, Sir Run Run Shaw Hospital ZheJiang University School Of Medicine, Hangzhou, China*

Background: We previously reported the safety and immunogenicity of a personalized neoantigen-based peptide vaccine, iNeo-Vac-P01, in patients with a variety of cancer types. The current study investigated the synergistic effects between radiofrequency ablation (RFA) and neoantigen vaccination in cancer patients and tumor-bearing mice. **Methods:** 28 cancer patients were enrolled in this study, including 10 patients who had received RFA treatment within 6 months before scheduled for vaccination, and 18 patients who had not. Individualized neoantigen peptide vaccines were designed, manufactured, and delivered for all patients, followed by subcutaneous administration of GM-CSF as an adjuvant. Mouse models were used to validate the synergistic efficacy of combination treatment of RFA and neoantigen vaccination. **Results:** Longer median progression free survival (mPFS) and median overall survival (mOS) were observed in patients receiving RFA prior to vaccines compared to patients only receiving vaccines (4.42 and 20.18 months vs. 2.82 and 10.94 months). *Ex vivo* ELISpot assay showed that patients who received both had stronger IFN-γ responses against patient-specific neoantigens at baseline and post vaccination. Mice receiving RFA together with vaccine displayed higher antitumor immune responses than mice receiving single modality; addition of anti-PD-1 further enhanced the antitumor response. **Conclusions:** Neoantigen vaccination after RFA treatment led to an overall increase in clinical response and immune response among patients of different cancer types. Combination treatment of both modalities in mice further validated their synergistic antitumor potentials, which could be further enhanced by the addition of anti-PD-1. The mechanisms of their synergies require further investigation. Clinical trial information: NCT03662815. Research Sponsor: National Natural Science Foundation of China; Medical Science and Technology Project of Zhejiang Province; National Natural Science Foundation of China; Natural Science Foundation of Zhejiang Province; Health Commission of Zhejiang Province.

3152 **Poster Session**

Do early phase trials predict clinical efficacy in subsequent phase III biomarker-enriched randomized trials? *First Author: Suji Udayakumar, Sunnybrook Research Institute, Toronto, ON, Canada*

Background: Efficacy endpoints of randomized controlled trials (RCT) are commonly used as the basis of regulatory drug approvals. Recently, promising results in early phase trials have resulted in approval of biomarker-targeted therapies. We examined if early phase trial results were associated with efficacy in subsequent biomarker-enriched RCTs. **Methods:** All cancer drug RCTs conducted between January 2006 and March 2021 were identified through Clinicaltrials.gov. Trials were eligible if a biomarker was used to select a patient population for treatment with a targeted agent. Associated early phase trials were included if they matched the RCT in treatment setting and patient population. Trials pairs were compared using objective response rate (ORR) and progression-free survival (PFS). We assessed difference in endpoints using summary measures (e.g., average, range). We examined whether early phase trials results were associated with RCT results using logistic regression. **Results:** The search yielded 2,157 unique phase III RCTs and 27 RCTs met eligibility criteria pairing with associated early phase trials, where 17 RCTs met their primary endpoint. The most common biomarkers were EGFR+ (n = 8), HER2+ (n = 5) and PD-L1 (n = 5). Based on average difference of trial pairs, ORR was similar between trials (1.59%, 95% CI = -2.5-5.6, p = 0.50) and median PFS was slightly higher in early phase trials (1.95 months, 95% CI = 0.91-2.99, p < 0.05). On an individual pair basis, there was large range of variability in the difference between early phase trials and RCTs for ORR (range = -23.9-20.2%) and median PFS (range = -0.8-7.4 months). The probability of the RCT meeting its primary endpoint is 50% or 95%, when the early phase trial ORR is 41.2% (95% CI = 35.2-47.1%) or 77.7% (95% CI = 71.7-83.6%), respectively. **Conclusions:** Through comparison of early phase trials and subsequent phase III RCT, we found that, overall, ORR has minimal bias in early phase trials, and median PFS appears to be slightly overestimated. Substantial variability in results for trial pairs suggests that, on an individual basis, results in early phase trial can be inconsistent with results in subsequent RCT. Early phase trial results may be associated with RCTs meeting their primary endpoint when ORR is very high; however, caution must be exercised when using early phase trials as representative of RCTs for decision-making as the predictive ability of early phase trials is limited. Research Sponsor: None.

First-in-human study of the B7-H4 antibody-drug conjugate (ADC) AZD8205 in patients with advanced/metastatic solid tumors. *First Author: Funda Meric-Bernstam, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: ADCs are a class of anti-cancer agents that leverage the selectivity of monoclonal antibodies to preferentially target and deliver chemotherapeutic agents to cancer cells. AZD8205 is an ADC, administered by IV infusion, that consists of a human anti-B7-H4 antibody conjugated via a cleavable linker to a topoisomerase I inhibitor (TOP1i) warhead. B7-H4 is a transmembrane protein that binds to an unknown receptor on activated T cells, inhibiting their function. It is highly expressed by a wide variety of tumors including cholangiocarcinoma (CCA) and breast, ovarian and endometrial cancers, and is associated with poor prognosis. AZD8205 specifically binds to B7-H4 expressing tumor cells and is internalized. The TOP1i warhead is released, interfering with TOP1 during DNA replication leading to transcription-mediated DNA damage and cell death. TOP1i ADCs have shown clinical activity in several tumor types including breast cancer. In preclinical studies, AZD8205 has shown promising antitumor activity in various patient-derived xenograft models and an acceptable toxicity profile. This first-in-human study (NCT05123482) is evaluating AZD8205 for the treatment of selected advanced/metastatic tumors. **Methods:** This phase I/IIa, open-label, dose-escalation and dose-expansion study is currently investigating AZD8205 monotherapy in patients ≥18 years old (≥20 years for Japan) with CCA, breast, ovarian or endometrial cancers. Eligibility criteria include relapsed/metastatic disease following standard of care treatment, measurable disease per RECIST v1.1, and ECOG PS 0–1. Key exclusion criteria include spinal cord compression or leptomeningeal carcinomatosis, symptomatic brain metastases, and history of interstitial lung disease/pneumonitis. Expression of B7-H4 will be evaluated using a validated central laboratory immunohistochemistry assay on tumor samples collected before, during, and when feasible, after AZD8205 treatment. In the escalation phase, patients will receive AZD8205 followed by 21 days of observation for dose-limiting toxicities. Patients will be enrolled in escalating dose cohorts using the modified toxicity probability interval-2 model with at least 3 evaluable patients per dose level. Patients will continue on study treatment until disease progression, initiation of alternate anticancer therapy, unacceptable toxicity, or withdrawal of consent. Primary objectives are to determine the safety and tolerability of AZD8205 and identify the maximum tolerated dose and/or recommended phase 2 dose. Secondary objectives include assessing initial activity (objective response and progression-free survival by RECIST v1.1, and overall survival), pharmacodynamics, pharmacokinetics, and immunogenicity. The trial is currently recruiting and will enroll patients globally. Clinical trial information: NCT05123482. Research Sponsor: AstraZeneca.

TPS3154 **Poster Session**

Phase 1 study of SGN-PDL1V, a novel, investigational vedotin antibody–drug conjugate directed to PD-L1, in patients with advanced solid tumors (SGNPDL1V-001, trial in progress). *First Author: Amita Patnaik, START San Antonio, San Antonio, TX*

Background: Programmed cell death ligand 1 (PD-L1) is a cell-surface protein involved in the programmed cell death protein 1 (PD-1)/PD-L1 immune checkpoint, which inhibits T-cell activation. Elevated PD-L1 expression is observed across a broad spectrum of solid tumor types. Expression of PD-L1 in tumors can signal through PD-1 on T cells to inhibit T-cell effector function. Blockade of the PD-1/PD-L1 signaling axis may restore antitumor immunity by reactivating T-cell effector function in the tumor microenvironment. SGN-PDL1V is a novel, investigational vedotin antibody–drug conjugate directed to PD-L1 with multiple proposed mechanisms of action including monomethyl auristatin E (MMAE)-directed cytotoxicity, bystander effect, and immunogenic cell death (ICD). Even in xenograft models with low, heterogeneous PD-L1 expression, SGN-PDL1V demonstrated antitumor activity via direct cytotoxicity and the bystander effect. Cytotoxicity mediated by SGN-PDL1V also led to immune activation due to MMAE-induced ICD (Kwan et al 2021). These preclinical findings provide a rationale for evaluating SGN-PDL1V in patients (pts) with advanced solid tumors. **Methods:** SGNPDL1V-001 (NCT05208762) is a phase 1, first-in-human, multicenter, open-label trial designed to evaluate the safety, tolerability, pharmacokinetics (PK), and antitumor activity of SGN-PDL1V in pts with advanced solid tumors. This study includes 3 parts: dose escalation (Part A), dose and schedule optimization cohorts (Part B), and dose expansion in disease-specific cohorts and a biology cohort (Part C). Adult pts (≥18 years) with histologically/cytologically confirmed metastatic/unresectable solid tumors, including non-small cell lung cancer, head and neck squamous cell carcinoma, esophageal squamous cell carcinoma, melanoma, or ovarian cancer, will be eligible. Pts must have ECOG PS 0–1 and have failed or are unable to tolerate standard therapies. Pts must have PD-L1 expression ≥1 by tumor proportion score or combined positive score based on historical testing. Prior treatment with an MMAE-containing agent or an anti–PD-L1 agent (within 6 months) is not permitted. Primary endpoints include adverse events, laboratory abnormalities, dose-limiting toxicities, and cumulative dose-level safety. Secondary endpoints include rate and duration of objective response, progression-free survival, overall survival, PK, and incidence of antidrug antibodies. Exploratory endpoints include pharmacodynamics (PD), PK/PD relationships, and patient-reported outcomes. Safety and antitumor activity endpoints will be assessed using descriptive statistics. Objective response rate will be analyzed by tumor type, dose levels, and schedules. Enrollment for Part A is ongoing at sites in North America and is planned in Europe. Clinical trial information: NCT05208762. Research Sponsor: Seagen Inc.

TPS3155 **Poster Session**

Phase 1 study of SGN-B7H4V, a novel, investigational vedotin antibody–drug conjugate directed to B7-H4, in patients with advanced solid tumors (SGNB7H4V-001, trial in progress). *First Author: Amita Patnaik, START San Antonio, San Antonio, TX*

Background: B7-H4, a B7 immune checkpoint ligand, is expressed at low levels in normal tissue and negatively regulates T-cell function by inhibiting T-cell proliferation and cytokine production. B7-H4 expression is elevated in solid tumors, including breast, ovarian, and endometrial cancers. Targeting B7-H4–expressing tumor cells may relieve B7-H4–mediated T-cell inhibition. SGN-B7H4V is a novel, investigational vedotin antibody–drug conjugate directed to B7-H4 with proposed mechanisms of action including monomethyl auristatin E (MMAE)-directed cytotoxicity, bystander effect, antibody-dependent cellular cytotoxicity, and antibody-dependent cellular phagocytosis. SGN-B7H4V elicited antitumor activity in cell line-derived xenograft models of triple-negative breast cancer (TNBC) and patient-derived xenograft models of TNBC and ovarian cancer (Gray et al 2021), providing a rationale to evaluate SGN-B7H4V in patients (pts) with advanced solid tumors. **Methods:** SGNB7H4V-001 (NCT05194072) is a phase 1, first-in-human, multicenter, open-label trial evaluating the safety, tolerability, pharmacokinetics (PK), and antitumor activity of SGN-B7H4V in pts with advanced solid tumors. This study includes 3 parts: dose escalation (Part A), dose and schedule optimization (Part B), and dose expansion in disease-specific cohorts and a biology cohort (Part C). Adult pts (≥18 years) with histologically/cytologically confirmed locally advanced unresectable or metastatic solid tumors including high-grade serous epithelial ovarian cancer, primary peritoneal cancer, fallopian tube cancer, human epidermal growth factor receptor 2-negative and hormone receptor-positive breast cancer, TNBC, endometrial carcinoma, squamous non-small cell lung cancer, cholangiocarcinoma, or gallbladder carcinoma, are eligible. Pts must have ECOG PS 0–1 and relapsed/refractory disease or be intolerant to standard-of-care therapies. Prior treatment with an MMAE-containing agent or a B7-H4–targeted agent is not permitted. Primary endpoints include the rate of adverse events, laboratory abnormalities, dose-limiting toxicities, and cumulative dose-level safety. Secondary endpoints are objective response rate (ORR), complete response rate, duration of objective response (DOR), progression-free survival (PFS), overall survival (OS), PK, and incidence of antidrug antibodies. Exploratory endpoints include pharmacodynamic (PD) analyses, PD and PK exposure measurements, B7-H4 characterization on malignant cells, and biomarker analyses. Safety and antitumor activity endpoints will be assessed using descriptive statistics. ORR will be analyzed by tumor type and dose. DOR, PFS, and OS will be estimated using the Kaplan–Meier method. Enrollment for Part A is ongoing in North America and is planned in Europe. Clinical trial information: NCT05194072. Research Sponsor: Seagen Inc.

TPS3156 **Poster Session**

TIP: A phase I/II study of MGTA-117, an anti-CD117 antibody-drug conjugate, in patients with adult acute myeloid leukemia (AML) and myelodysplasia with excess blasts (MDS-EB). *First Author: Andrew S. Artz, City of Hope, Duarte, CA*

Background: Hematopoietic stem cell transplantation (HSCT) is used with curative intent for AML and MDS-EB. MGTA-117 is a novel Ab-drug conjugate (ADC) in development for conditioning prior to HSCT. MGTA-117 selectively targets CD117 (c-Kit) with a human monoclonal Ab to CD117 conjugated to an amanitin payload that depletes CD117-expressing cells by inhibiting RNA polymerase II. Human hematopoietic stem cells and AML tumor cells express high levels of CD117, and MGTA-117 potently depletes these target cells, with an IC50 of <10pM in vitro. MGTA-117 has demonstrated in vitro and in vivo stability, confirming its characterization as a highly potent and selective agent. In a primate GLP toxicology study, MGTA-117 maximally depleted bone marrow stem cells at a dose not associated with evidence of toxicity in other tissues. Dose-dependent reduction of peripheral reticulocytes, produced from CD117+ erythroid precursors in the bone marrow, was an early and time sensitive biomarker of bone marrow CD117+ cell depletion. Higher doses were associated with the elevation of transaminases and histopathology that were asymptomatic and transient. Highest Non- Severely Toxic Dose (HNSTD) was used to establish the starting dose in this First-in-Human study. Based upon dose exposure and allometric scaling, it is expected that the clinical exposures after a 0.02 mg/kg dose in the first human cohort will provide an optimal > 100-fold safety margin over exposures observed after the 0.3 mg/kg dose that was the HNSTD in the primate GLP toxicology study. **Methods:** This phase I/II, multicenter, open-label, dose-escalation study will investigate the safety, tolerability, PK profile, PD activity, and blast depletion activity of MGTA 117 given intravenously as a single dose in adults with R/R AML or MDS-EB. Patients must be 18-75 yrs, have a WHO-defined diagnosis of CD117+ R/R AML or MDS-EB with ≥5% marrow myeloblasts. Patients must have ECOG PS ≤2, and adequate hepatic, renal, and cardiac function. The primary objective is to establish a minimum safe and biologically effective (MSBE) dose of MGTA-117 in R/R AML and MDS-EB patients based on safety and CD117 receptor occupancy (RO) in circulating leukemic blasts after dosing. The observation period for dose limiting toxicities is 21 days. Patients will be followed for changes in reticulocyte, neutrophil, and platelet counts in PB and percent change from baseline in leukemic blasts or stem/progenitor cells in PB and/or BM. CD117 receptor occupancy by MGTA-117 will be measured and MSBE dose will be based on safety and receptor occupancy. The study is designed with the possibility that subjects would proceed to HSCT >28 days after MGTA-117 administration, if eligible per the local transplant practices. Clinical trial information: NCT05223699. Research Sponsor: Magenta Therapeutics.

TPS3157 **Poster Session**

First-in-human, phase 1, open-label, dose-escalation, dose-expansion study of ADCT-901 as monotherapy in patients with select advanced solid tumors. *First Author: R. Donald Donald Harvey, Winship Cancer Institute, Atlanta, GA*

Background: Kidney associated antigen 1 (KAAG1) is highly and selectively expressed on tumor cell surface, such as ovarian, prostate, and triple negative breast cancers (TNBC), and is rapidly internalized and co-localized with a lysosomal marker, making an ideal candidate for an antibody-drug conjugate (ADC) target. ADCT-901 is an ADC composed of a humanized monoclonal antibody IgG1 against KAAG1, conjugated through a cathepsin-cleavable linker to SG3199, a pyrrolobenzodiazepine (PBD) dimer cytotoxin. In mouse xenograft models of human-derived TNBC, ovarian, and renal cancers significant tumor reduction was observed after a single dose of ADCT-901, providing the rationale for clinical development of a PBD-based ADC to treat KAAG1 expressing tumors (Zammarchi et al, AACR 2019). This study aims to identify the recommended dose and schedule for expansion and to characterize safety and tolerability of ADCT-901 in patients (pts) with selected advanced solid tumors that generally express KAAG1. **Methods:** ADCT-901-101 is a phase 1, multicenter, 2-part, open-label study that will enroll ~70 pts (NCT04972981). Part 1: pts will receive escalating doses of ADCT-901 guided by a 3+3 design (1st dose: 15 μg/kg every 3 weeks [Q3W]; highest dose: 290 μg/kg Q3W). Dose escalation will be evaluated by administering the lowest dose to first 3 pts, then increasing/decreasing the dose based on dose-limiting toxicity (DLT) experienced by pts. The dose and schedule of ADCT-901 identified in part 1 will be tested in part 2 to characterize safety, tolerability, and preliminary efficacy of ADCT-901. Primary endpoints include incidence of DLTs (part 1 only), frequency/severity of adverse events (AE) and serious AE, clinically significant changes in vitals, laboratory values, overall tolerability, and frequency of dose interruptions and reductions. Secondary endpoints include overall response rate, duration of response, progression-free and overall survival, pharmacokinetic parameters of ADCT-901 total antibody, PBD-conjugated antibody, unconjugated SG3199 in serum, and frequency of confirmed positive antidrug antibody responses. Exploratory endpoints include tumor modulation and potential pharmacodynamic changes. Key inclusion criteria: pathologic diagnosis of selected solid tumor (cholangiocarcinoma, renal cell carcinoma, ovarian/fallopian tube and prostate cancers, TNBC) locally advanced or metastatic at time of screening, pts refractory or intolerant to existing therapy, tissue biopsy or available tissue sample, ECOG of 0-2, and adequate organ function based on predefined laboratory parameters. Pts with symptomatic CNS metastases and clinically significant third space fluid accumulation will be excluded. The study opened for recruitment in September 2021; enrollment is ongoing. Funding: ADC Therapeutics; medical writing: CiTRUS Health Group. Clinical trial information: NCT04972981. Research Sponsor: ADC Therapeutics.

TPS3158 **Poster Session**

ELU-FRα-1: A study to evaluate ELU001 in patients with solid tumors that overexpress folate receptor alpha (FRα). *First Author: Wen Wee Ma, Division of Medical Oncology, Mayo Clinic, Rochester, MN*

Background: ELU001 is a novel, first-in-class, new molecular entity described as a C'Dot Drug Conjugate (CDC). ELU001 consists of ~12 folic acid targeting moieties and ~22 exatecan topoisomerase-1 inhibitor payloads on Cathepsin-B cleavable linkers covalently bound to the surface of each silicon core/polyethylene glycol C'Dot nanoparticle. CDCs are small in size (~6 nm) , have a greater ability to penetrate into and through tumors as compared to ADCs, and are rapidly eliminated by the kidneys. The rapid systemic elimination is expected to lead to less toxicity than is observed with targeting platforms like ADCs that have a longer half-life in circulation. ELU001's high avidity is believed to promote internalization into FRα overexpressing cancer cells, selectively delivering it's ~22 molecules of payload. The first-in-human clinical trial, ELU-FRα-1, is currently recruiting patients that have advanced, recurrent or refractory FRα overexpressing tumors considered to be topoisomerase 1 inhibitor-sensitive based on the literature, and, in the opinion of the Investigator, have no satisfactory therapeutic options available. **Methods:** This is a Phase 1 / 2 multicenter, open label clinical trial with two parts: Part 1 Dose Escalation and Part 2 Tumor Group Expansion Cohort(s). In Part 1, patients with cancer types with a high likelihood of having FRα overexpressing tumors based on historical data, (specifically, ovarian, endometrial, colorectal, gastric, gastroesophageal junction, triple negative breast, or non-small cell lung cancers, or cholangiocarcinoma), will be enrolled to the study. Patients will receive ELU001 on a weekly dose regimen (QW) (once a week for 3 weeks, 1 week rest) or every other week dose regimen (Q2W, with no rest between cycles). Retrospective analysis of FRα expression will be determined. Part 2 uses a Simon's Two-Stage design to evaluate 4-6 tumor group expansion cohorts, each consisting of patients with specific tumor types (to be identified based on emerging data) that overexpress FRα (prospectively determined prior to enrollment). The primary objective for Part 1 is to identify the MTD/RP2D and for Part 2 is ORR. Dose Escalation will recruit about 25 patients per dose regimen (QW or Q2W). Dose Expansion will recruit about 15 patients per tumor group expansion cohort. Secondary objectives are anti-tumor activity (DOR, PFS, TFST, PFS2, OS), frequency, severity and tolerability of adverse events, PK, ADA, and FRα expression assessments. The study is actively enrolling in the US – Cohorts 1-2 have been completed without DLT. Enrollment to Cohort 3 began in December 2021. Clinical trial information: NCT05001282. Research Sponsor: Elucida Oncology.

TPS3159 **Poster Session**

Phase 1 study of SGN-ALPV, a novel, investigational vedotin antibody–drug conjugate directed to ALPP/ALPPL2 in advanced solid tumors (SGNALPV-001, trial in progress). *First Author: Nehal Lakhani, START Midwest, Grand Rapids, MI*

Background: Alkaline phosphatase placental (ALPP) and ALPP-like 2 (ALPPL2) are proteins with 98% sequence similarity that are highly expressed in ovarian, endometrial, gastric, and testicular cancers. Restricted normal tissue expression and efficient lysosomal trafficking of ALPP and ALPPL2 highlight their potential as anticancer targets. SGN-ALPV is a novel investigational vedotin antibody–drug conjugate composed of a humanized anti-ALPP/ALPPL2 monoclonal antibody, a protease-cleavable linker, and the microtubule disrupting agent monomethyl auristatin E (MMAE). The proposed mechanism of action of SGN-ALPV is binding to ALPP/ALPPL2 on the cell surface, where it is internalized and trafficked to the lysosome. Lysosomal proteases cleave the linker to release MMAE into the cytoplasm, where it binds and disrupts the microtubule network, causing cell cycle arrest and apoptosis. Additional mechanisms of action of SGN-ALPV include immunogenic cell death and apoptosis of neighboring cells via the bystander effect. Promising preclinical data support the evaluation of SGN-ALPV in a clinical trial. **Methods:** SGNALPV-001 (NCT05229900) is a phase 1, open-label, multicenter study designed to evaluate the safety, tolerability, pharmacokinetics (PK), and antitumor activity of SGN-ALPV in patients (pts) with select advanced solid tumors. This study consists of 3 parts: dose escalation (Part A), dose and schedule optimization (Part B), and dose-expansion in disease-specific cohorts and a biology cohort (Part C). Adult pts (≥18 years) with confirmed ovarian, endometrial, non-small cell lung, gastric, cervical cancer, or testicular germ-cell tumors, relapsed or refractory to approved therapies, with measurable disease per RECIST v1.1 and an ECOG PS 0–1 are eligible. Primary endpoints include incidence of adverse events, laboratory abnormalities, dose-limiting toxicities, and cumulative safety. Secondary endpoints include estimates of antidrug antibodies, PK parameters, objective response rate, duration of response, progression-free survival, and overall survival. Exploratory endpoints are pharmacodynamic and biomarker measurements. Safety and antitumor activity endpoints will be summarized using descriptive statistics. Enrollment for Part A is ongoing in sites in North America and Europe. Enrollment for Parts B and C will be opened upon completion of Part A. Clinical trial information: NCT05229900. Research Sponsor: Seagen.

TPS3161 **Poster Session**

Phase 1 study of patritumab deruxtecan (HER3-DXd; U3-1402) in combination with osimertinib in patients with advanced *EGFR*-mutated NSCLC. *First Author: Pasi A. Janne, Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston, MA*

Background: Although first-line treatment with the epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor osimertinib improved survival in patients (pts) with advanced/metastatic *EGFR*-mutated (*EGFRm*) non-small cell lung cancer (NSCLC), therapy after acquired resistance to osimertinib remains an unmet need. HER3 is expressed in the majority of *EGFRm* NSCLCs. HER3-DXd is a novel, investigational, HER3-directed antibody-drug conjugate that demonstrated preliminary single-agent clinical activity in *EGFRm* NSCLC. In preclinical models of *EGFRm* NSCLC, osimertinib increased membrane HER3 expression, improved the internalization rate of HER3-DXd, and enhanced tumor growth inhibition by HER3-DXd. Therefore, HER3-DXd with osimertinib might improve outcomes in pts with disease that progressed with osimertinib therapy. This phase 1 study (NCT04676477; U31402-A-U103) evaluates HER3-DXd in combination with osimertinib in pts with advanced *EGFRm* NSCLC that has progressed with first-line osimertinib therapy. **Methods:** This is an open-label, 2-part study of HER3-DXd in combination with osimertinib. Pts are enrolling in North America, Europe, and Asia. Dose escalation enrolls pts with locally advanced/metastatic NSCLC with an *EGFR*-activating mutation (exon 19 del or L858R) and progression during or after osimertinib therapy. Pts receive HER3-DXd 1.6, 3.2, 4.8, or 5.6 mg/kg intravenously (IV) every 3 weeks (Q3W) in combination with osimertinib 40 or 80 mg orally (PO) once daily (QD). Pts are enrolled in each cohort guided by safety (dose-limiting toxicities) using a Bayesian logistic regression model. Primary objectives of dose escalation are to assess safety and tolerability of the combination and identify a recommended combination dose (RCD). In dose expansion, pts will be randomized 1:1 to receive either HER3-DXd and osimertinib at the RCD (arm 1, [≈60 pts]) or HER3-DXd 5.6 mg/kg IV Q3W (arm 2, [≈60 pts]). A third arm (arm 1b, [≈60 pts]) may be added to evaluate 2 provisional RCDs of HER3-DXd + osimertinib. The primary objective of dose expansion (arms 1, 2, and 1b) is to evaluate efficacy of the combination vs that of monotherapy. The primary endpoint is objective response rate (ORR) as assessed by blinded independent central review. Other efficacy endpoints include ORR by investigator and duration of response, disease control rate, time to response, progression-free survival, and overall survival. If the RCD includes an osimertinib dose of 80 mg PO QD, ≈30 pts with advanced *EGFRm* NSCLC without prior treatment will be enrolled and treated at the RCD in a separate cohort; the primary objective is to assess safety and tolerability. A tumor sample after progression with osimertinib (or prior to entry) is required for pts enrolled in dose expansion for retrospective evaluation of HER3 and biomarker analyses. Clinical trial information: NCT04676477. Research Sponsor: Daiichi Sankyo Inc.

TPS3162 **Poster Session**

Datopotamab deruxtecan (Dato-DXd) plus pembrolizumab in treatment-naive advanced/metastatic (adv/met) non–small cell lung cancer (NSCLC) with PD-L1 ≥ 50% and without actionable genomic alterations. *First Author: Benjamin Philip Levy, Johns Hopkins Sidney Kimmel Cancer Center, Washington, DC*

Background: First-line treatment with immunotherapy has significantly improved survival in patients with adv/met NSCLC. Pembrolizumab (pembro) as monotherapy has shown superior efficacy compared with chemotherapy in treatment-naive patients with advanced NSCLC and PD-L1 expression ≥50%, but most patients will ultimately experience progression. Dato-DXd is an antibody-drug conjugate (ADC) consisting of a humanized anti-TROP2 IgG1 monoclonal antibody attached to a topoisomerase I inhibitor payload via a stable tetrapeptide-based cleavable linker. In the ongoing phase 1 TROPION-PanTumor01 study (NCT03401385; DS1062-A-J101), Dato-DXd 6 mg/kg monotherapy demonstrated an objective response rate (ORR) of 28% and a manageable safety profile in pretreated patients with NSCLC. In addition, preclinical studies showed that DXd ADCs combined with an anti–PD-1 antibody was more effective than monotherapy with either agent alone. The tolerability of Dato-DXd 6 mg/kg in combination with pembrolizumab was confirmed in the phase 1b TROPION-Lung02 trial (NCT04526691; DS1062-A-U102). Here we describe the phase 3 TROPION-Lung08 trial evaluating Dato-DXd combined with pembro in treatment-naive patients with adv/met NSCLC. **Methods:** TROPION-Lung08 (NCT05215340; DS1062-A-U304) is a global, randomized, open-label, phase 3 trial of Dato-DXd plus pembro vs pembro alone in treatment-naive patients with adv/met non-actionable oncogenic driven NSCLC with PD-L1 ≥50% (as determined by PD-L1 IHC 22C3 pharmDx assay). Approximately 740 patients will be randomized to receive pembro 200 mg plus Dato-DXd 6 mg/kg or pembro 200 mg alone every 21 days until discontinuation or 35 cycles of pembro. Randomization will be stratified by Eastern Cooperative Oncology Group performance status (0 vs 1), histology (squamous vs nonsquamous), geographic region (East Asia vs rest of world), and smoking status (former/current vs never). Patients must have stage IIIB/IIIC NSCLC ineligible for curative treatment or stage IV disease. Patients must not have received prior systemic therapy; if patients received neoadjuvant/adjuvant systemic therapy without immune checkpoint inhibitors, it must have been given ≥6 months before the diagnosis of adv/met disease. The primary endpoints are progression-free survival (assessed by blinded independent central review per Response Evaluation Criteria in Solid Tumors [RECIST] version 1.1) and overall survival, with target hazard ratios of 0.65 and 0.75, respectively. Secondary endpoints include ORR, duration of response, time to response, disease control rate, safety, and antidrug antibody prevalence. Pharmacokinetic parameters, biomarkers, and patient-reported outcomes will also be explored. Clinical trial information: NCT05215340. Research Sponsor: Daiichi Sankyo Inc.

TPS3163 **Poster Session**

TARGET National: A U.K.-wide liquid-based molecular profiling program to enhance recruitment to early-phase trials. *First Author: Ana Ortega-Franco, The Christie NHS Foundation Trust, Manchester, United Kingdom*

Background: Precision medicine programs have largely focused on tissue-based assays to screen patients for genomic variants amenable to experimental targeted therapies. Challenges faced in such studies include time taken to acquire archival biopsies and limitation in capturing tumor heterogeneity and clonal evolution. The TARGET study (Rothwell, Nature Medicine 2019) previously demonstrated feasibility of using ctDNA to match patients to early phase trials with the benefit of rapid turnaround of results. With an ever-increasing number of novel therapies in development targeting rare genomic alterations across different tumor types, ctDNA holds great promise in enhancing recruitment to studies with rapid and efficient comprehensive genomic profiling assays covering a broad range of variants. There is need to perform profiling at scale to identify rare alterations and to utilise networks for identification of suitable clinical trials across the country. ctDNA is not detectable in all patients (owing to differences across disease types/ burden), thus tissue analysis still plays an important role. **Methods:** TARGET National is an investigator-initiated multi-centre molecular profiling study. The primary endpoints are to establish a national framework to offer profiling from blood samples (or tissue if appropriate) for patients being considered for early phase clinical trials across the UK Experimental Cancer Medicine Centre (ECMC) Network, and to measure the number of patients receiving matched therapy (MT). Secondary endpoints include curating the genomic landscape of the early phase population in the UK, and outcomes for patients receiving MT versus unmatched. Enrolment began in July 2021 and >250 patients have been recruited across 9 ECMCs with plans to expand to 20 centres by Q3 2022. Planned enrolment is 6000 patients over 5 years. Patients must be ≥ 16 years old, provide written consent, have histologically confirmed advanced solid cancer, progressing disease and be considered fit enough to receive an experimental therapy. ctDNA is analysed with Foundation Medicine Liquid CDx with option for other providers. A multi-disciplinary national Molecular Tumor Board enables interpretation of genomic reports and identifies suitable clinical trials, supported by eTARGET; a bespoke clinical-genomic data capture solution including trial finding software. The study provides broad access to genomic profiling throughout the UK, increasing experience with ctDNA assays, and will improve opportunities for patients to participate in early phase research. The UK database will provide means for identification of rare genomic patient groups for new first-in-human studies, and the program provides a national infrastructure to collect additional samples for translational research and pre-clinical models to progress understanding of biological predictors of response and resistance. Clinical trial information: NCT04723316. Research Sponsor: The Christie Charity, Other Foundation, Pharmaceutical/Biotech Company.

TPS3164 **Poster Session**

DELFI-L101: Development of a blood-based assay that evaluates cell-free DNA fragmentation patterns to detect lung cancer. *First Author: Peter J. Mazzone, Cleveland Clinic, Cleveland, OH*

Background: Despite longstanding national recommendations, uptake of lung cancer screening in the US remains low. Barriers include access to lung cancer screening, costs, and concerns over potential harms like false-positives and radiation exposure. The DELFI technology evaluates fragmentation patterns of cfDNA using supervised machine learning to distinguish cancer from non-cancer [PMID30943338; 34417454; 31142840]. **Methods:** The DELFI-L101 is a case-control observational study (NCT04825834) prospectively enrolling at academic and community sites. Eligible participants (≥50 years of age) are individuals who currently smoke or previously smoked, with smoking histories of ≥20 pack-years. Individuals are ineligible if they had cancer treatment in the prior year or a history of hematologic malignancies or myelodysplasia. Cases are individuals with pathologically confirmed cancers (group A – lung, group C – non-lung). Controls are those without cancer (group B) as determined by low-dose computed tomography screening completed within 6 weeks of enrollment. Cases and controls are identified among enrollees from all participating sites. Total enrollment is estimated to be ~2500 participants across all groups. Blood samples are collected at enrollment for DELFI analyses, which involves cfDNA isolation from plasma, low-coverage, whole-genome, next-generation sequencing, and machine learning methods. Clinical data (medical history, demographics, and diagnostic, surgery, imaging, and pathology reports, and/or other diagnostic information) are collected at enrollment and at 12 months post-enrollment. The primary objective is to train and test a classifier for the detection of lung cancer using the DELFI technology with other biomarkers and clinical features. Secondary objectives include the evaluation of classifiers to distinguish lung cancer from other cancers, modeling benefits and harms using performance estimates of these classifiers, and description of the analytical performance (eg, repeatability and reproducibility) of the DELFI technology and classifiers. The primary endpoint is the accuracy of lung cancer detection as measured by sensitivity, specificity, and the area under the receiver operating characteristic curve. Secondary endpoints include accuracy of tissue of origin classification, and adverse events associated with blood sample collection. The training and performance characterization of a DELFI classifier will further the development of an affordable, accessible, blood-based cancer detection tool with potential to overcome barriers to lung cancer screening. Clinical trial information: NCT04825834. Research Sponsor: Delfi Diagnostics, Inc.

TPS3165 **Poster Session**

A phase 2 study of the MDM2 inhibitor milademetan in patients with *TP53*-wild type and *MDM2*-amplified advanced or metastatic solid tumors (MANTRA-2). *First Author: Ecaterina Elena Dumbrava, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Murine double minute 2 (MDM2) is a potent negative regulator of the tumor suppressor p53. MDM2 induces degradation of p53 and promotes tumorigenesis in solid tumors, and preclinical models have shown that inhibition of MDM2 can restore p53 tumor suppressor activity in *TP53*-wild type (WT), *MDM2*-amplified tumors. We performed a mutual exclusivity analysis of patients with solid tumors (n = 42,125; AACR Project GENIE) and found that the frequency of co-occurring *TP53* mutations decreased with increasing *MDM2* copy number. An *MDM2* copy number of 12 was chosen as the threshold. An estimated 1.1% of solid tumors meet this molecular criteria, excluding glioblastomas, dedifferentiated liposarcomas, and intimal sarcomas where this signature is enriched. Milademetan (RAIN-32), an oral, selective MDM2 inhibitor, inhibits growth of *TP53*-WT/*MDM2*-amplified cell lines and patient-derived xenograft models from varying tumor types. Furthermore, tumor regression was observed in 3/3 non-liposarcoma patients with *MDM2* copy number > 12 in a phase 1 trial of milademetan. MANTRA-2 (RAIN-3202) is a phase 2, multicenter, single-arm, open-label, basket trial designed to evaluate the efficacy or clinical benefit of milademetan in *TP53*-WT solid tumors with *MDM2* amplification (copy number ≥ 12). **Methods:** Eligible patients must be ≥ 18 years of age with histologically and/or cytologically confirmed locally advanced, incurable or metastatic solid tumors refractory to standard therapy. Local testing demonstrating *TP53* WT and *MDM2* amplification is required, defined as a *MDM2* copy number ≥ 12 or 6-fold increase. Patients with well-differentiated/de-differentiated liposarcomas, intimal sarcomas, or primary central nervous system tumors are excluded. Prior treatment with an MDM2 inhibitor is not permitted. Patients receive milademetan 260 mg orally once daily on Days 1–3 and 15–17 of a 28-day cycle. Tumor response is evaluated by RECIST v1.1 at Weeks 8, 16, 24, and 32, and then every 12 weeks. Primary endpoint: objective response rate. Secondary endpoints include: duration of response; progression-free survival; growth modulation index; disease control rate; overall survival; safety; health-related quality of life scores. Exploratory endpoints include: biomarkers in blood and/or tumor tissue; pharmacodynamics; pharmacokinetics. Enrollment of 65 patients is planned to ensure that 57 patients have centrally confirmed *TP53* WT and *MDM2* copy number ≥ 12. The trial opened in November 2021 and is actively enrolling patients. Clinical trial information: NCT05012397. Research Sponsor: Rain Therapeutics, Inc.

TPS3166 **Poster Session**

Rationale and design of phase 1 FTIH study of FOXP3 antisense oligonucleotide AZD8701 in patients with selected advanced solid tumors. *First Author: Michele Petruzzelli, AstraZeneca, Cambridge, MD, United Kingdom*

Background: The forkhead box family transcription factor FOXP3 is essential for T regulatory cells (Tregs) development and immune suppressive function. Tregs are an integral component of the adaptive immune system and contribute to maintaining tolerance to self-antigens and preventing autoimmune diseases. In the context of cancer, however, Tregs contribute to tumor progression by suppressing antitumor immunity. To date inhibition of Treg-mediated immunosuppression tested in the clinic has lacked specificity. Targeting FOXP3 provides a selective approach to impair the immunosuppressive function of Tregs but targeting transcription factors has been a challenge using conventional drug modalities. AZD8701 employs next-generation antisense oligonucleotide (ASO) technology (Ionis Pharmaceuticals) to bind mRNA with high affinity and selectively reduce human Foxp3 mRNA expression levels. Foxp3-specific ASOs promote potent dose-dependent reductions in Foxp3 mRNA and protein in vitro. In preclinical models, AZD8701 induced Foxp3 knockdown results in Tregs with a reduced immunosuppressive capacity, loss of immunosuppressive markers, and increased markers of activation on $CD8^+$ T-cells. AZD8701 reduces tumor growth as monotherapy in preclinical models and increased tumor inhibition is obtained by combining AZD8701 with a PD-L1 inhibitor. **Methods:** This is a Phase I multicenter study of AZD8701 alone or in combination with durvalumab in participants with selected advanced solid tumors. Eligible patients must have ECOG performance status 0 or 1, measurable target lesion per RECIST v1.1 and be diagnosed with selected tumor types as described below. Monotherapy and combination dose escalation phase is open for participants with head and neck squamous cell carcinoma (HNSCC), triple-negative breast cancer (TNBC), non-small-cell lung cancer (NSCLC), clear cell renal cell carcinoma (ccRCC), gastroesophageal cancer, melanoma, cervical cancer, small-cell lung cancer (SCLC), and/or solid tumors that have demonstrated a response to prior programmed death-ligand-1 (PD-[L]1) treatment (as defined by duration of response > 18 weeks). Participants with NSCLC, HNSCC, TNBC, and ccRCC will be included in the pharmacodynamic cohort at the selected monotherapy dose and/or disease expansion cohorts. The primary objectives are to assess safety and tolerability and to determine the preliminary antitumor activity of AZD8701 (objective response rate) when administered as monotherapy or in combination with durvalumab. Secondary endpoints include, disease control rate, duration of response, progression free survival and overall survival, pharmacokinetics and pharmacodynamics (including changes in Foxp3 mRNA in paired tumor samples). The trial is currently recruiting. Clinical trial information: NCT04504669. Research Sponsor: AstraZeneca.

TPS3167 **Poster Session**

Design and rationale of a phase 1 dose-escalation study of AMG 193, a methylthioadenosine (MTA)-cooperative PRMT5 inhibitor, in patients with advanced methylthioadenosine phosphorylase (MTAP)-null solid tumors. *First Author: Miguel Angel Villalona-Calero, City of Hope National Medical Center, Duarte, CA*

Background: Protein arginine methyltransferase 5 (PRMT5) is an emerging target for cancer treatment. MTAP homozygous deletion occurs in 15% of cancers and often coincides with deletion of the tumor suppressor gene CDKN2A, leading to buildup of its substrate MTA. MTA shares close structural similarity to S-adenosyl methionine (SAM), the substrate methyl donor for PRMT5. By competing with SAM, MTA partially inhibits PRMT5. Thus, MTAP-null cancers are susceptible to further PRMT5 inhibition (Kryukov *Science* 2016). Current direct/indirect PRMT5 inhibitors (PRMT5i) showed preliminary anticancer activity, albeit with considerable toxicities due to their indiscriminate activities. AMG 193 is an MTA-cooperative PRMT5i that preferentially targets the MTA-bound state of PRMT5 that is enriched in MTAP-null tumors and represents a novel strategy to increase the therapeutic margin of this class of inhibitors. AMG 193 potently inhibits MTAP-null cancer cell lines and patient-derived xenografts. **Methods:** NCT05094336 is a first-in-human (FIH), multicenter, open-label, phase 1/1b/2 trial evaluating the safety, tolerability, pharmacokinetics (PK), pharmacodynamics, and efficacy of AMG 193 in patients with advanced MTAP-null solid tumors. Eligible patients (≥ 18 years) with histologically confirmed locally advanced/metastatic solid tumors not amenable to curative treatment with surgery and/or radiation, homozygous MTAP and/or CDKN2A deletion (by local next generation sequencing), or MTAP protein loss in tumors (by central immunohistochemistry), measurable disease, ECOG PS 0–1, adequate hematopoietic, renal, liver, pulmonary, cardiac, coagulation function and glucose control will be included. The study will be conducted in 3 parts, each with subparts. Here, we describe Part 1a/b (dose exploration). Five dose levels are planned. Treatment continues until progression or withdrawal. The primary objectives are to evaluate the safety and tolerability of AMG 193 monotherapy; endpoints include dose-limiting toxicities, treatment-emergent adverse events, serious adverse events, electrocardiograms, laboratory abnormalities, and vital signs. Secondary objectives include the characterization of the PK parameters of AMG 193 including C_{max}, T_{max}, and AUC after single or multiple doses. This study is expected to enroll approximately 30 patients in Part 1a/b. This is the first FIH trial open for enrollment for this new class of PRMT5i and enrollment is ongoing. Clinical trial information: NCT05094336. Research Sponsor: Amgen Inc.

TPS3168 **Poster Session**

A phase 1, first-in-human study of IK-930, an oral TEAD inhibitor targeting the Hippo pathway in subjects with advanced solid tumors. *First Author: Anthony W. Tolcher, NEXT Oncology and Texas Oncology, San Antonio, TX*

Background: The transcriptional enhanced associate domain (TEAD) family of proteins are key transcription factors in the Hippo signaling pathway and play a critical role in cell proliferation, migration, angiogenesis, and apoptosis. Published literature demonstrates that approximately 10% of all solid tumors present with a dysregulated Hippo pathway and subsequent constitutive activation of TEAD, which drives gene expression involved in cell growth and pro-survival signaling. Deficiencies in neurofibromin 2 (NF2), a key regulator of the Hippo pathway, can be found in over 40% of cases of malignant pleural mesothelioma (MPM). *NF2* deficiency also occurs at high incidence in meningiomas, cholangiocarcinomas, thymoma, and schwannoma. Gene fusions in in Yes1 associated transcriptional regulator (YAP1) or WW domain containing transcription regulator 1 (TAZ/WWTR1) are also indicative of high TEAD activation and can be seen in solid tumors including epithelioid hemangioendothelioma (EHE) where >90% of cases are associated with TAZ-CAMTA1 gene fusion and the other 10% of cases have YAP1/TFE3 gene fusion. IK-930 is a novel, selective, small molecule inhibitor of TEAD that prevents palmitate binding and thereby disrupts aberrant TEAD-dependent transcription. In preclinical models, IK-930 demonstrates antitumor activity in mouse xenograft models with Hippo pathway genetic alterations. IK-930 is under clinical investigation as an oral agent in patients with advanced solid tumors. **Methods:** This is a phase 1, first-in-human, open-label, multicenter dose escalation and dose expansion study to evaluate the safety and tolerability of IK-930 as monotherapy, and to determine the recommended phase 2 dose (RP2D) and/or maximum tolerated dose (MTD) using the Bayesian Optimal Interval Design (BOIN). Eligible participants in dose escalation include adult patients with advanced or metastatic solid tumors for whom there is no available therapy known to confer clinical benefit. Patients will receive escalating doses of IK-930 starting at 25mg daily. IK-930 will be administered initially in a 28-day cycle and will progress to a 21-day cycle when evaluated as safe and well-tolerated. A dose expansion phase will follow with four genetically defined cohorts of solid tumors, including: *NF2*-deficient MPM (Cohort 1), other *NF2*-deficient solid tumors agnostic to tumor type (Cohort 2), EHE with *TAZ-CAMTA1* or *YAP1-TFE3* gene fusions (Cohort3), and solid tumors with *YAP1/TAZ* gene fusions agnostic to tumor type (Cohort 4). Primary endpoints include evaluation of dose-limiting toxicities and treatment-emergent adverse events and determination of RP2D and/or MTD. Secondary objectives include evaluation of preliminary antitumor activity by RECIST 1.1 and pharmacokinetic (PK) parameters. The study began in January 2022 and is currently enrolling. Clinical trial information: NCT05228015. Research Sponsor: Ikena Oncology.

TPS3169 **Poster Session**

Phase 1a/b open-label study of IK-175, an oral AHR inhibitor, alone and in combination with nivolumab in patients with locally advanced or metastatic solid tumors and urothelial carcinoma. *First Author: Meredith McKean, Sarah Cannon Research Institute, Tennessee Oncology, PLLC, Nashville, TN*

Background: Aryl Hydrocarbon Receptor (AHR) is a ligand-activated transcription factor that regulates the activity of multiple innate and adaptive immune cells. Kynurenine, generated from tryptophan by IDO1 and TDO2, is a ligand that binds AHR and leads to a net immunosuppressive tumor microenvironment, making AHR an attractive therapeutic target in multiple cancer types. IK-175 is a selective, small molecule inhibitor of AHR being developed as an oral agent. In preclinical mouse tumor models, IK-175 demonstrates antitumor activity as a single agent or in combination with checkpoint inhibitors. AHR immunohistochemistry (IHC) tumor microarray analysis across 15 different tumor types revealed that bladder cancer has the highest level of AHR protein expression and nuclear localization indicative of ligand-bound and active AHR signaling. Therefore, nuclear AHR in urothelial carcinoma tumors is being investigated for potential predictive clinical benefit with IK-175. **Methods:** This is a first-in-human, phase 1a/b, open-label, multicenter, dose-escalation and expansion study of IK-175 as a single agent and in combination with nivolumab. The primary objectives are to determine the maximum tolerated dose (MTD) and/or maximum administered dose (MAD), identify the recommended phase 2 dose (RP2D), and evaluate the safety and tolerability of IK-175 alone and in combination with nivolumab. Secondary objectives are to evaluate the pharmacokinetics (PK) of IK-175, evaluate pharmacodynamic (PD) immune effects, and assess preliminary antitumor activity. Key exploratory objectives are to evaluate the PD effects on peripheral immune cells and target gene expression, to assess candidate baseline biomarkers, and correlative analyses of tumor AHR nuclear localization with clinical response. The study is exploring tumor AHR nuclear localization by IHC as a predictive biomarker in patients with urothelial carcinoma. A minimum of 10 patients with a positive AHR nuclear localization test (cutoff for positive AHR is 65% tumor cells positive for 2+/3+ nuclear AHR by a validated IHC assay) will be enrolled in the combination arm. IK-175 is administered daily in 21 or 28 day-cycles as a single agent, and in combination with nivolumab (480 mg q4w on Day 1 of every cycle), in adult patients with advanced solid tumors (dose escalation) and urothelial carcinoma (dose expansion). Key eligibility criteria include patients with histologically confirmed solid tumors (including urothelial carcinoma) who have locally recurrent or metastatic disease that have progressed on or following all standard of care therapies deemed appropriate by the treating physician including prior checkpoint inhibitors. Estimated enrollment is 93 patients; the study began in January 2020 and is ongoing. Clinical trial information: NCT04200963. Research Sponsor: Ikena Oncology.

TPS3170 **Poster Session**

Phase 1 study of KT-413, a targeted protein degrader, in adult patients with relapsed or refractory B-cell non-Hodgkin lymphoma. *First Author: Don A. Stevens, Louisville Onc, Louisville, KY*

Background: Oncogenic mutations in myeloid differentiation primary response 88 (MYD88) occur in approximately 25% of diffuse large B-cell lymphoma (DLBCL) cases, including approximately 30% of activated B-cell DLBCL and up to 70% of primary extranodal DLBCL, and are associated with poor survival following 1st line therapy. MYD88 mutations result in activation of the NF-κB pathway which drive a range of protumor activities including upregulation of proinflammatory cytokines and genes involved in tumor cell proliferation and survival. Activation of this pathway results in upregulation of IRF4 through the transcription factors Ikaros and Aiolos, which in turn further augments NF-kB activation while simultaneously downregulating Type I IFN signaling, thereby preventing oncogene-induced cell death. Constitutive NF-kB pathway activation resulting from MYD88 mutations is dependent on the interleukin-1 receptor associated kinase 4 (IRAK4), a key component of the myddosome complex which normally stimulates NF-kB signaling following TLR or IL-1R engagement and MYD88 activation. KT-413 is a potent and selective heterobifunctional small molecule protein degrader mediating the degradation of both IRAK4 and the IMiD substrates Ikaros and Aiolos via the ubiquitin-proteasome system. The therapeutic hypothesis is that degradation of IRAK4 and IMiD substrates will maximize NF-κB inhibition while simultaneously upregulating the Type I Interferon response, thus restoring the apoptotic response and enabling oncogene-mediated cell death, resulting in robust antitumor response in MYD88-mutant DLBCL. KT-413 induced strong antitumor activity, including complete or partial regressions, in cell line- and patient-derived xenograft models of $MYD88^{MT}$ DLBCL (Mayo 2021). **Methods:** KT-413 is being evaluated in an open label, dose escalation (Phase 1a) study in patients with relapsed/refractory (R/R) B-cell non-Hodgkin lymphoma (NHL), followed by dose expansion (Phase 1b) in patients with R/R DLBCL with documented tumor MYD88 mutation status. All patients must be ineligible or refused auto-SCT or CAR-T therapy. The Phase 1a (n = 40) utilizes an accelerated titration followed by a 3+3 design in ascending doses of IV administered KT-413 in once every 21-day cycles to identify the maximum tolerated dose (MTD)/recommended Phase 2 dose (RP2D) (primary endpoint). Secondary endpoints include pharmacokinetics (PK) and preliminary pharmacodynamic effects (PD) using blood and tumor tissue. Once MTD/RP2D is determined in 3-6 patients, it will be confirmed by enrolling additional patients with B-cell NHL, for a total of nine. In Phase 1b, up to 40 R/R DLBCL patients will be enrolled into one of two cohorts (n = 20): $MYD88^{MT}$ or $MYD88^{WT}$ to further characterize tolerability, PK, PD and evaluate the clinical activity of KT-413. KT413-DL-101 began enrollment in February 2022. Clinical trial information: NCT05233033. Research Sponsor: Kymera Therapeutics.

TPS3171 **Poster Session**

Phase 1 study of KT-333, a targeted protein degrader, in patients with relapsed or refractory lymphomas, large granular lymphocytic leukemia, and solid tumors. *First Author: Alexander Starodub, The Christ Hospital, Cincinnati, OH*

Background: The signal transducer and activator of transcription 3 (STAT3) protein is activated by cytokines and growth factors resulting in tumor growth and promotion and hindering antitumor immunity. Approximately 70% of human cancers including both hematological malignancies and solid tumors exhibit increased levels of phosphorylated STAT3 (pSTAT3). There is evidence of constitutive activation of STAT3 through genetic mutations or aberrant cellular signaling pathways in tumors such as large granular lymphocytic leukemia (LGL-L), peripheral T-cell lymphoma (PTCL), and cutaneous T-cell lymphomas (CTCL). Hyperactivation of STAT3 has been reported in a variety of solid tumors. In several of these cancers, the levels of pSTAT3 and/or activated STAT3 have been shown to correlate with poor clinical prognosis. As with other transcription factors, selective inhibition of STAT3 has been proven to be difficult with conventional therapeutic approaches. KT-333 is a potent highly selective, heterobifunctional small molecule degrader of STAT3. In preclinical studies, durable tumor regressions were seen with weekly KT-333 administration in STAT3-dependent T cell lymphomas, and antitumor activity was seen in solid tumors in combination with anti-PD1 (ASH 2021, SITC 2021). **Methods**: KT-333 is being evaluated in an open-label, dose escalation (Phase 1a, n = 40) study in patients with lymphomas relapsed or refractory (R/R) to at least two prior systemic treatments or for whom standard therapies are unavailable. Dose escalation will be conducted by accelerated titration followed by a 3+3 design in ascending doses of intravenous KT-333 administered once weekly in 28-day cycles to evaluate safety and define the maximum tolerated dose (MTD)/recommended Phase 2 dose (RP2D) (primary endpoint). Secondary endpoints include pharmacokinetics (PK) in plasma and urine and preliminary pharmacodynamic effects (PD) of KT-333 using blood (peripheral blood mononuclear cells [PBMCs], plasma/serum) and tumor tissue. After confirming the MTD/RP2D in patients with lymphoma, patients with advanced solid tumors will be enrolled in a separate Phase 1a cohort at the MTD/RP2D. In Phase 1b (n = 80), patients with PTCL, CTCL, LGL-L (T-cell LGL-L or chronic lymphoproliferative disorder of natural killer-cells), or solid tumors R/R to at least one prior systemic standard of care treatment or for whom standard therapies are not available, will be enrolled in separate 20 patient cohorts. This will further characterize safety, PK, PD and evaluate the clinical activity of KT-333. Treatment with KT-333 will continue until disease progression, unacceptable toxicity, or patient refusal. KT333-TL-101 began enrolling in January 2022. Clinical trial information: NCT05225584. Research Sponsor: Kymera Therapeutics.

TPS3172 **Poster Session**

A two-part, phase II, multi-center study of the ERK inhibitor ulixertinib (BVD-523) for patients with advanced malignancies harboring MEK or atypical BRAF alterations (BVD-523-ABC). *First Author: Mark E. Burkard, University of Wisconsin Carbone Cancer Center, Madison, WI*

Background: Ulixertinib (BVD-523) is a small molecule inhibitor of extracellular signal-regulated kinases 1/2 (ERK1/2) in development as a novel anti-cancer drug. Early clinical data demonstrated anti-tumor activity, especially for patients with tumors harboring atypical BRAF or MEK1/2 alterations (Sullivan et al., Cancer Discov. 2018;8(2):184-195). Atypical BRAF (non-V600) alterations can be categorized according to characteristics of molecular signaling (Class II or III), are seen in approximately 3% of all human cancers, and there are currently no approved therapies for this indication. Similar to atypical BRAF alterations, the incidence of MEK1/2 alterations are rare in human tumors (< 1 %). Preclinical data have demonstrated activity of ulixertinib in MEK mutant models. Ulixertinib has FDA fast-track designation for patients with solid tumors, other than CRC, with specific BRAF mutations (G469A, L485W, or L597Q). Designed with intent to register, the BVD-523-ABC clinical trial will continue evaluation of ulixertinib in patients with tumors harboring any atypical BRAF or MEK1/2 alteration (NCT04488003). **Methods:** This multi-center, phase II study, will be conducted in two parts and assess the clinical benefit, safety, pharmacokinetics, and pharmacodynamics of ulixertinib in patients with advanced malignancies. Ulixertinib will be administered at the RP2D of 600 mg BID for 28-day treatment cycles. Eligible patients will have locally advanced or metastatic cancer which progressed following standard systemic therapies, or for which the patient is not a candidate or refused systemic therapy. Planned correlative analyses include reverse phase protein array and transcriptomics of tumor tissue. Part A is open-label and tumor agnostic, except for group 4 and 6 (CRC patients only). Patients will enroll into one of six groups based on BRAF (groups 1-4) or MEK1/2 (groups 5-6) tumor alteration (38 patients per group). Overall response rate (ORR) is the primary endpoint for Part A, with secondary endpoints including duration of response (DOR), progression-free survival (PFS), and overall survival (OS). Part B is tumor histology specific. Patients will be randomized to receive either ulixertinib or physician's choice of treatment in a 2:1 ratio. Up to three specified tumor histologies will be defined, guided by available Part A data (n = 80-100 per histology). The primary endpoint of Part B is PFS, and secondary endpoints include OS, ORR, and DOR. This study has enrolled 43 patients of the planned 228 in Part A at the time of abstract submission. Clinical trial information: NCT04488003. Research Sponsor: BioMed Valley Discoveries.

TPS3173 **Poster Session**

Phase 1/2 dose escalation study of NUV-422, a potent inhibitor of cyclin-dependent kinases 2, 4, and 6, in recurrent or refractory (r/r) high-grade gliomas (HGG) and solid tumors. *First Author: Patrick Y. Wen, Dana-Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA*

Background: CDKs that govern the G1-S transition of the cell cycle (CDK2, CDK4 and CDK6) are deregulated in many cancers. CDK2 expression, in particular, is associated with worse overall survival in glioblastoma (GB), disease-free recurrence in prostate cancer, and resistance to approved CDK4/6 inhibitors (CDK4/6i) in breast cancer. These provide rationale for inhibition of CDK2/4/6 as a potential novel therapeutic strategy in these cancers. NUV-422 is a potent (low nM) small molecule CDK2/4/6i with limited activity against CDK1, a target potentially associated with toxicities in other CDKi. Preclinical studies have shown that NUV-422 has favorable blood-brain barrier penetration, inhibited growth of multiple glioma cell lines in vitro, and exhibited antitumor activity in GB xenograft models. NUV-422 also exhibited antitumor activity in multiple patient-derived xenograft (PDX) models of HR+ HER2- mBC resistant to CDK4/6i, and PDX models of prostate cancer resistant to anti-androgens. **Methods:** NUV-422-02 (NCT04541225) is a phase 1/2, first in human, open label, multicenter study to evaluate single-agent NUV-422 (given orally) in patients with advanced solid tumors (r/r HGG, r/r HR+ HER2- mBC, or r/r mCRPC). The Ph 1 dose escalation will use a 3+3 design to evaluate safety, tolerability, and PK of NUV-422 and establish the recommended phase 2 dose (RP2D). Ph 1 also includes a randomized surgical substudy to characterize PK and pharmacodynamics (PD) of preoperative NUV-422 in resected GB tumor tissue. After the RP2D is identified, parallel enrollment into phase 2 expansion cohorts will begin. Cohort 1 will evaluate isocitrate dehydrogenase wild type (IDH-WT) GB. Cohort 2 will evaluate HR+ HER2- mBC (without active brain metastases); Cohort 3 will evaluate mCRPC; and Cohort 4 will evaluate HR+ HER2- mBC with active brain metastases. The Ph 2 primary endpoint is objective response rate. Secondary efficacy endpoints include clinical benefit rate, duration of response, progression-free survival, and overall survival. Response assessments will be based on response criteria appropriate to the tumor type (HGG [RANO]; HR+HER2- mBC [RECIST 1.1 or RANO-Brain Metastases]; mCRPC [RECIST 1.1, PCWG3, prostate-specific antigen decrease]). Blood, urine, or tumor tissue will be obtained to assess safety, PK, PD, and for additional exploratory analyses to characterize NUV-422 mechanism of action. Enrollment was initiated in December 2020, and dose escalation is ongoing. The NUV-422 program will also be expanded in 2022 to include additional studies in mBC and mCRPC in combination with standard of care treatments. Clinical trial information: NCT04541225. Research Sponsor: Nuvation Bio.

TPS3174 **Poster Session**

A phase I trial of elimusertib in combination with cisplatin or with cisplatin plus gemcitabine in advanced solid tumors with an emphasis on urothelial carcinoma. *First Author: Ryan Leibrandt, UC Davis Comprehensive Cancer Center, Sacramento, CA*

Background: Cisplatin, a well-established backbone of combination therapy of various advanced solid tumors, inhibits DNA synthesis by forming DNA cross-links and adducts. Despite the activity of cisplatin, tumor cells can either be refractory or develop resistance to treatment. Cisplatin has been demonstrated to cause cell cycle G2/M arrest, which may allow for DNA damage response (DDR) and repair. Ataxia telangiectasia mutated (ATM) and ataxia telangiectasia and Rad 3-related (ATR) protein kinases are key regulators of DDR, and contribute to maintaining genomic integrity in response to various exogenous and endogenous genotoxic insults like cytotoxic chemotherapy. In fact, cisplatin has been shown to transiently increase ATR expression. Inhibitors of ATR have been studied in combination with cisplatin both *in vitro* and *in vivo*, demonstrating enhanced activity. The oral small molecule ATR inhibitor elimusertib, which has been studied as a single agent in a Phase I study, has also demonstrated enhanced activity with cisplatin *in vitro* in lung cancer and bladder cancer cell lines. We sought to conduct a Phase I study evaluating the combination of elimusertib with cisplatin or with cisplatin and gemcitabine. **Methods:** In the first cohort, patients with histologically confirmed advanced solid tumors for which cisplatin-based therapy would be considered appropriate, who exhibit adequate organ function, and have received < 300 mg/m^2 of cisplatin previously are treated with cisplatin on Day (D) 1 and with elimusertib on D2 & 9 of each 21-day cycle. The study follows a phase I queue (IQ) 3+3 dose escalation design, following standard practices for dose-limiting toxicity (DLT) impact on escalation, and when the maximum tolerated dose (MTD) is established with cisplatin alone, this will inform the first dose level of the next cohort, in which patients will be treated with cisplatin on D1, gemcitabine on D1 & 8, and elimusertib on D2 & 9 of each 21-day cycle. An expansion cohort will enroll urothelial carcinoma patients when the second MTD is established. The primary objective of the study is to evaluate the safety and MTD of elimusertib in combination with cisplatin, as well as in combination with cisplatin and gemcitabine. Secondary study objectives include evaluation of pharmacokinetics of elimusertib in these combinations, preliminary efficacy, and evaluating the association between ATM expression and responses to therapy. Currently, 6 patients have been enrolled to the first cohort of the study. Clinical trial information: NCT04491942. Research Sponsor: U.S. National Institutes of Health.

TPS3175 **Poster Session**

A first-in-human phase I dose-escalation trial of the B7-H6/CD3 T-cell engager BI 765049 ± ezabenlimab (BI 754091) in patients with advanced solid tumors expressing B7-H6. *First Author: Gerald Steven Falchook, Sarah Cannon Research Institute at HealthONE, Denver, CO*

Background: B7-H6 is a member of the B7 family of immune receptors, which is expressed in several solid tumors, but with little to no expression detected in normal tissues[Brandt et al. J Exp Med 2009;206.1495–503; Boehringer Ingelheim. Data on file]. BI 765049 is a novel IgG-like bispecific T-cell engager (TcE) designed to bind simultaneously to B7-H6 on tumor cells and CD3 on T cells, resulting in cytolytic synapse formation and tumor lysis. Preclinical studies have demonstrated that BI 765049 monotherapy induced dose-dependent antitumor activity in humanized *in vivo* CRC tumor models. Consistent with the mode of action, treatment with BI 765049 led to profound infiltration of T cells into the tumor tissue, which correlated with apoptosis and tumor shrinkage. The inflammatory tumor microenvironment created by treatment with the B7-H6/CD3 TcE also led to an increase of PD-1 on T cells and PD-L1 on the tumor cells [Hipp et al. AACR Annual Meeting 2021]. This upregulation of PD-(L)1 provides the rationale for combining BI 765049 with a PD1 inhibitor. **Methods:** NCT04752215 is a first-in-human, open-label, dose-escalation trial of BI 765049 ± the PD-1 inhibitor, ezabenlimab. Adults with advanced, unresectable and/or metastatic CRC, NSCLC, HNSCC, hepatocellular, gastric or pancreatic carcinoma are eligible. Patients must have progressed on, or be ineligible for, standard therapies. B7-H6 positivity must be confirmed at screening by central review (immunohistochemistry assay) in archived tissues/fresh biopsies (except CRC). Patients must have ≥1 evaluable lesion (modified RECIST 1.1) outside of the central nervous system and adequate organ function. The primary objective is to determine the maximum tolerated dose (MTD) or recommended dose for expansion of BI 765049 ± ezabenlimab, based on dose-limiting toxicities during the MTD evaluation period. Further objectives are to evaluate safety, tolerability, PK/PD, and preliminary efficacy of BI 765049 ± ezabenlimab. The trial will assess up to four intravenous dosing regimens: A (BI 765049 once every 3 weeks [q3w]); B1 (BI 765049 qw); B2 (BI 765049 qw with step-in dosing); C (BI 765049 + ezabenlimab q3w). Dose escalation will be guided by a Bayesian Logistic Regression Model with overdose control that will be fitted to binary toxicity outcomes using a hierarchical modelling approach to jointly model all dosing regimens. Treatment will be allowed to continue until confirmed progressive disease, unacceptable toxicity, other withdrawal criteria, or for a maximum duration of 36 months, whichever occurs first. Approximately 150–175 patients will be screened and ~120 patients enrolled. As of January 2022, eight patients have been recruited in early dose-escalation cohorts. Clinical trial information: NCT04752215. Research Sponsor: Boehringer Ingelheim.

TPS3176 **Poster Session**

A phase 1 dose-escalation and expansion-cohort study of the oral CDK7 inhibitor XL102 as a single-agent and in combination therapy in patients (pts) with advanced solid tumors. *First Author: Geoffrey Shapiro, Dana-Farber Cancer Institute, Boston, MA*

Background: XL102 is an orally bioavailable, selective, and covalent small-molecule inhibitor of cyclin-dependent kinase 7 (CDK7). CDK7 is a serine/threonine kinase that is overexpressed in multiple tumor types. CDK7 controls cell cycle progression via the phosphorylation of CDKs (1, 2, 4, and 6) and regulates transcription through phosphorylation of RNA polymerase II. XL102 induced cell death in various cancer cell lines and caused tumor regression in multiple human tumor cell line to mouse xenograft tumor models. Here, we present the study design of an ongoing phase 1 trial in pts with advanced solid tumors, including hormone receptor-positive breast cancer (HR+BC), triple-negative breast cancer (TNBC), epithelial ovarian cancer (EOC), and metastatic castration-resistant prostate cancer (mCRPC). **Methods:** This first-in-human, open-label, phase 1 trial (NCT04726332) consists of a dose-escalation stage and a disease-specific cohort expansion stage. In the dose-escalation stage (modified interval 3+3 design), a maximum tolerated dose and/or recommended dose (MTD/RD) of XL102 will be established (primary endpoint) for use alone (solid tumors) and then for use in combination with standard dose fulvestrant (HR+BC) or abiraterone/prednisone (mCRPC); dose escalation will require ~36 pts for the single-agent cohort and ~15 pts for each combination cohort. Pts enrolled in the dose-escalation stage must have an unresectable or metastatic tumor for which available therapies are intolerable, ineffective, or do not exist. Upon determining the MTD/RD for each regimen, the cohort-expansion stage will enroll according to Simon's Two-Stage Minimax design, assuming a power of 80% and one-sided α of 15%, for single-agent XL102 (HR+BC, TNBC, EOC, and mCRPC) and XL102 in combination therapy (HR+BC and mCRPC); the expansions will enroll ~36 pts for each single-agent cohort and ~44 pts for each combination cohort. Pts enrolled in the expansion stage must have measurable disease per Response Evaluation Criteria in Solid Tumors version 1.1 (RECIST v1.1), adequate organ function, and exposure to prior therapy, with specific therapy requirements based on the disease cohort. The primary endpoint of the expansion stage is objective response rate (ORR) of XL102 alone and in combination therapy as assessed by investigator per RECIST v1.1. Secondary endpoints are safety, tolerability, and pharmacokinetics. Exploratory endpoints include duration of response (DOR) and progression-free survival (PFS) as assessed by the investigator per RECIST v1.1, overall survival, and correlation of tumor and blood biomarkers with response. ORR, DOR, and PFS may also be assessed by blinded independent radiology committee in selected expansion cohorts. The study began enrolling pts in February 2021 and is ongoing. Total enrollment is estimated to be up to 298 pts. Clinical trial information: NCT04726332. Research Sponsor: Exelixis, Inc.

TPS3177 **Poster Session**

Phase 1 study of C019199, an oral CSF-1R/DDRs/VEGFR2 multiple kinase inhibitor, to assess the safety, tolerability, pharmacokinetics, and pharmacodynamics in patients with advanced solid tumors, including tenosynovial giant cell tumor. *First Author: Lin Shen, Department of Gastrointestinal Oncology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital & Institute, Beijing, China*

Background: C019199 was designed to be a tumor immune microenvironment (TME) modulator in order to improve the efficacy against tumor growth when combined with immune checkpoint inhibitors, like anti-PD1 or anti-PD-L1. It was shown to have a specific inhibition profile against CSF-1R, DDR1 and VEGFR2 with IC_{50} of 14nM, 40nM and 79nM, respectively. CSF-1R's inhibition may deplete Tumor-associated macrophages (TAMs) in TME, help the infiltration of T cells and enhance T cell responses. But a single modulating mechanism may not be strong enough or may be vulnerable and easily overcome by tumors. C019199 can reshape the TME by additionally inhibiting DDRs and VEGFR2, which may remove the "physical barrier" of tumor extracellular matrix and further increase T cell infiltration on top of inducing tumor blood vessels normalization. As a single agent with the appropriate combination of multiple modulation effects, it will potentially turn "cold" tumors into "hot" tumors. Preclinical studies have shown that C019199 inhibits tumor growth in multiple animal tumor models and has better antitumor efficacy when combined with immune checkpoint blockades. **Methods:** A first-in-human, open label, multicenter, dose-escalation/expansion study of C019199 is currently enrolling. Eligible subjects (age ≥ 18 years and <76 years) with histologically or cytologically confirmed relapsed, refractory, or progressive metastatic solid tumors will be enrolled in. In Part A, the safety and tolerability of C019199 will be assessed in about 25 subjects to identify the maximum tolerated dose and recommended phase II dose (PR2D). In Part B, the safety and antitumor activity of the RP2D will be assessed in about 60 subjects in disease-specific expansion cohorts. Primary endpoints are adverse events, laboratory abnormalities, dose-limiting toxicities. Secondary endpoints will include pharmacokinetics, objective response rate, progression-free survival, and disease control rate. Exploratory biomarker analyses include CSF-1 and VEGF. Clinical trial information: CTR20202045. Research Sponsor: Fujian Haixi Pharmaceuticals Co., Ltd.

TPS3178 **Poster Session**

A phase 1/2 study of DCC-3116 as a single agent and in combination with trametinib in patients with advanced or metastatic solid tumors with RAS or RAF mutations. *First Author: Anthony W. Tolcher, Texas Oncology-San Antonio Babcock NEXT Oncology, San Antonio, TX*

Background: Autophagy, a catabolic process to resupply nutrients and recycle damaged organelles, is activated by cancer cells to survive hypoxia, limited nutrients, or chemotherapy. The RAS family of oncoproteins are the most commonly mutated oncoproteins in human cancer and require autophagy for tumor growth and survival. RAS activates signaling through the mitogen-activated protein kinase (MAPK) pathway that is responsible for regulating cell survival. ULK1/2 are kinases that receive and process input from nutrient and stress sensors to initiate autophagy. Inhibition of the MAPK pathway releases tonic inhibition of ULK1/2 and triggers autophagy as a survival mechanism, suggesting that ULK1/2 may provide a promising therapeutic target. DCC-3116 is a potent and selective ULK inhibitor that showed preclinical antitumor activity in combination with the MAPK kinase inhibitor trametinib (Smith et al. 2019 AACR-NCI-EORTC Poster). Here, we describe the Phase 1 study of DCC-3116 monotherapy and combination therapy with trametinib in patients with RAS or RAF mutant advanced or metastatic solid tumors. **Methods:** This is a Phase 1/2, multicenter, open-label, first-in-human study evaluating safety, tolerability, clinical activity, pharmacokinetics, and pharmacodynamics of DCC-3116 as a single agent and in combination with trametinib (NCT04892017). The study consists of single agent and combination dose escalation cohorts and expansion of combinations with demonstrated safety. Single-agent oral DCC-3116 will be administered twice daily (BID) in escalating cohorts in 28-day cycles until the recommended Phase 2 dose (RP2D) is determined. Subsequently, the single-agent RP2D or one level below the maximum tolerated dose (MTD) will be administered in combination with trametinib. Participants in the dose escalation phase must be ≥18 years with a histologically confirmed diagnosis of advanced or metastatic solid tumor with a documented RAS or RAF mutation, have progressed despite standard therapies, and have received ≥1 prior anticancer therapy. In the dose expansion phase, DCC-3116 will be given BID with trametinib in 28-day cycles to participants with pancreatic ductal adenocarcinoma, non-small cell lung cancer, colorectal cancer, or melanoma (Cohorts 1–4, respectively). Primary outcomes are incidence of adverse events, identification of MTD, and objective response rate per RECIST v1.1. Secondary outcomes include duration of response, clinical benefit rate, time to response, progression-free survival, and pharmacokinetic/pharmacodynamic attributes. Participants in dose expansion cohorts must be ≥18 years and meet cohort-specific criteria including histologically confirmed diagnoses, documented mutation status, and number of prior lines of systemic therapy. This study is recruiting and plans to enroll up to 130 participants. Clinical trial information: NCT04892017. Research Sponsor: Deciphera Pharmaceuticals, LLC.

TPS3179 **Poster Session**

A multicenter, open-label, phase 1a/b study of HC-7366, a modulator of integrated stress response (ISR) kinase GCN2 in subjects with advanced solid tumors. *First Author: Meredith Pelster, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: To survive harsh tumor microenvironments, cancer cells actively utilize ISR as an adaptive stress response and survival mechanism. General control nonderepressible 2 (GCN2), a serine-threonine kinase is essential for maintaining cellular homeostasis in amino acid stress conditions. HC-7366 is a novel, highly selective, and potent GCN2 kinase modulator. Single agent HC-7366 has demonstrated potent anti-tumor activity resulting in regression and complete responses in several pre-clinical tumor models. **Methods:** This is a first in human, multicenter, open label, Phase 1a/b dose escalation and expansion study to establish the maximum tolerated dose, evaluate safety and tolerability, and determine the recommended Phase 2 dose of daily oral dosing of HC-7366 in patients (pts) with advanced solid tumors. Up to 36 pts with squamous cell carcinoma of the head and neck (SCCHN), colorectal cancer (CRC), non-small cell lung cancer (NSCLC), or transitional cell carcinoma of the bladder (TCC) will be enrolled into Phase 1a; other solid tumors are eligible if selection criteria are met (capped at 50%). A 3+3 design will be employed and dose escalation determined by occurrence of dose limiting toxicities (DLT) within Cycle 1 (21 days). A Safety Monitoring Committee will review each cohort when the planned number of pts complete the DLT period. Six dose levels (10, 20, 40, 75, 125, 150 mg) of HC-7366 will be evaluated. Phase 1b will be an expansion of up to two Phase 1a dose levels and enroll 15 pts per cohort. Secondary endpoints include ORR, DOR, TTF, PFS, and OS. Pharmacokinetic data will be profiled. Exploratory objectives include evaluation of pharmacodynamic markers in tumor biopsies and immunophenotyping in blood samples. Main inclusion criteria include: SCCHN, CRC, NSCLC, TCC or other solid tumors; >1 radiologically measurable lesion per RECISTv1.1; >1 biopsiable lesion at baseline; no immune checkpoint inhibitor within 4 weeks (wks) of 1st dose; ECOG 0 or 1; <10% body weight loss in 4 wks before 1st dose & serum albumin >3 g/dL; and normal/adequately controlled pan-endocrine function. Main exclusion criteria include: autoimmune disease, organ transplant, retinitis or photosensitive skin disorders; history of interstitial lung disease or pneumonitis within 1yr; and overt or latent disorders of the exocrine pancreas. Formal hypothesis testing will not be performed. Descriptive statistics of parameters of interest will be presented by dose level and safety parameters will be summarized. The trial is sponsored by HiberCell, Inc. Approximately 9 US sites will participate. Clinical trial information: NCT05121948. Research Sponsor: HiberCell, Inc.

TPS3180 **Poster Session**

Efficacy of afatinib in patients with advanced/metastatic solid tumors harboring *NRG1* gene fusions: A novel, prospective real-world outcomes study based on single-patient protocol data. *First Author: Stephen V. Liu, Georgetown University Medical Center, Washington, DC*

Background: Oncogenic neuregulin 1 (*NRG1)* gene fusions occur in ~0.2% of solid tumors overall and in up to 31% of cases of invasive mucinous lung adenocarcinoma [Laskin et al. *Ann Oncol.* 2020;31(12):1693–1703; Cadranel et al. *Oncologist.* 2021;26(1):7–16]. NRG1 fusion proteins provide an extracellular anchor for the epidermal growth factor (EGF) domain of NRG1 to bind to ErbB3 (HER3), leading to HER3 heterodimerization and activation of downstream signaling pathways, resulting in oncogenesis. Afatinib, an irreversible pan-ErbB tyrosine kinase inhibitor, represents a potential treatment for *NRG1*-fusion positive (*NRG1+*) tumors. This study aims to examine the safety and efficacy of afatinib in patients with *NRG1+* solid tumors, for which no authorized targeted therapy exists. **Methods:** This prospective, decentralized, US study (NCT05107193) will include 40 evaluable patients aged ≥18 years. Participating molecular test providers across the USA will identify eligible fusions in the course of routine diagnostic assays. When a patient with an *NRG1* fusion is identified, participating test providers will notify the treating physician of the study as a treatment option for the patient. Patients' primary oncologists will then contact the trial sponsor to confirm patient eligibility. Once approved by the central Institutional Review Board, patients will receive afatinib on a single-patient protocol basis, until disease progression or treatment is no longer tolerated. The recommended dosage per SmPC is 40 mg orally QD. Patients will be screened and enrolled into the study at their existing point-of-care setting. Inclusion criteria include a histologically or cytologically confirmed diagnosis of an advanced, unresectable/metastatic, non-hematologic malignancy with an *NRG1* fusion, evaluable per RECIST 1.1. Any coding gene as the *NRG1* fusion partner is permitted. Fusion status will be confirmed prospectively by a contracted molecular test provider. Exclusion criteria include prior systemic anti-cancer therapy or investigational drug within 14 days or 5 half-lives (whichever is shorter) of the start of afatinib treatment; an actionable driver mutation other than *NRG1* fusion for which FDA-approved targeted therapy is available; and prior treatment with an ErbB-targeted therapy. The primary endpoint of the study is confirmed objective response (OR) by independent central review per RECIST 1.1, defined as best overall response of either complete response or partial response and analysed as the proportion of patients with an OR. The key secondary endpoint is duration of response, defined as the time from the first documented OR to progression or death. Secondary endpoints include time to OR and disease control per investigator assessment. Safety will also be assessed. The study is open for recruitment. Clinical trial information: NCT05107193. Research Sponsor: Boehringer Ingelheim.

3500 **Oral Abstract Session**

Perioperative chemotherapy with mFOLFOX6 or CAPOX for patients with locally advanced colon cancer (OPTICAL): A multicenter, randomized, phase 3 trial. *First Author: Huabin Hu, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*

Background: Adjuvant chemotherapy is the recommended standard treatment for resected stage III and high-risk stage II colon cancer, but disease recurrence remain common. Perioperative chemotherapy has proved effective in several tumors, but not in colon cancer. We aimed to assess whether perioperative chemotherapy could improve outcomes in patients with locally advanced colon cancer. **Methods:** In this multicenter, randomized, phase 3 trial, participants were recruited from 28 hospitals in China. Eligible patients were aged 18-75 years, had a colon adenocarcinoma, with radiologically staged locally advanced (T3 with ≥5 mm invasion beyond the muscularis propria or T4 assessed by CT). Patients were randomly assigned (1:1) to either the experimental group or standard of care group, stratified by center, cT stage, and cN stage. The experimental group received 3 months of neoadjuvant chemotherapy with mFOLFOX6 or CAPOX, then surgery, then 3 months of adjuvant chemotherapy. The standard of care group received immediate surgery, and optional adjuvant chemotherapy (per physician's discretion according to pathological stage). The primary endpoint was disease-free survival assessed in the intention-to-treat population at 3 years. **Results:** Between January 6, 2016, and April 3, 2021, 752 patients were enrolled and randomly assigned to a treatment, of whom 744 were eligible (371 in the experimental group; 373 in the standard of care group). At a median follow-up of 32.5 months (IQR 19.2-45.7), 3-year disease-free survival rates were 78.7% (95%CI 73.8-83.5) in the experimental group and 76.6% (95%CI 71.8-81.4) in the standard of care group (stratified HR 0.83, 95%CI 0.60-1.15; p = 0.138). A pathological complete response was achieved in 26 (7%) of 371 patients in the experimental group. 69 (19%) patients in the experimental group had low pathological disease stage (pT0-2N0) compared with 16 (4%) of 373 in the standard of care group (p < 0.0001). 3-year overall survival rates were 94.9% (95%CI 92.1-97.7) in the experimental group and 88.6% (95%CI 84.6-92.5) in the standard of care group (stratified HR 0.47, 95%CI 0.25-0.87; p = 0.012). The post hoc subgroup analyses revealed perioperative chemotherapy induced an increase in disease-free survival in female patients (HR 0.54, 95%CI 0.31-0.83; p = 0.025). **Conclusions:** In patients with locally advanced colon cancer, perioperative chemotherapy with mFOLFOX6/CAPOX increased chance of pathological downstaging, but did not improve disease-free survival compared with standard of care. Clinical trial information: NCT02572141. Research Sponsor: Sun Yat-sen University Clinical Research 5010 Program.

3501 **Oral Abstract Session**

Noninferiority multicenter prospective randomized controlled study of rectal cancer T2–T3s (superficial) N0, M0 (T2T3sN0M0) undergoing neoadjuvant treatment and local excision (TEM) versus total mesorectal excision (TME): Preoperative, surgical, and pathological outcomes—The TAUTEM-study. *First Author: Xavier Serra-Aracil, Corporacion Sanitaria Parc Tauli, Sabadell, Spain*

Background: The standard surgical treatment of rectal adenocarcinoma above T1 is total mesorectal excision (TME), but it is associated with high morbidity and quality of life disorders. Transanal endoscopic microsurgery (TEM) achieves minimal postoperative morbidity rates. The treatment of T2, T3 superficial, N0, M0 rectal cancers is TME due to local excision achieving high recurrence rates. Initial reports of preoperative chemoradiotherapy (CRT) in association with TEM shows reduction in local recurrence. The TAU-TEM study aims to demonstrate the non-inferiority of the oncological outcomes and the improvement in morbidity and quality of life achieved with CRT-TEM compared with TME. **Methods:** Prospective, multicenter, randomized controlled non-inferiority trial including patients with rectal adenocarcinoma less than 10 cm from the anal verge and up to 4 cm in size, staged as T2T3sN0M0. Patients were randomized to: CRT-TEM (Arm A) or TME (Arm B). Postoperative morbidity and mortality were recorded and patients in both arms completed quality of life questionnaires when starting treatment and 6 months after surgery. Patients attended follow-up controls for local and systemic relapse. Trial registration: ClinicalTrials.gov Identifier: NCT01308190. **Results:** From July/2010 to October/2021, 173 patients from 17 Spanish hospitals were included (Arm A: 86, Arm B: 87). Ten were excluded after randomization (Arm A: 4, [3 re-staged > T2T3sN0M0, 1 refused follow-up study]; Arm B: 6 [4 refused the arm, 2 re-staged > T2T3sN0M0]). Therefore, the patients with modified intention to treat analysis were: TME, 81 and CRT-TEM, 82. There was no mortality after CRT. In this group, 2 patients abandoned neoadjuvant therapy; thus 80/82 (97.6%) completed CRT. The CRT-morbidity was low (25/82, 30%) and of low grade (95% G1-2). In the CRT-TEM group, MRI showed disease progression in 3 patients who were treated with TME. Finally, 77 patients underwent TEM surgery. One patient died in each arm (1.2%). Postoperative morbidity was 41/81 (50.6%) (Arm B) and 17/82 (20.7%) (Arm A) (p < 0.001, 95 CI% 43.9 to 15.9). Median Comprehensive Complication Index was 8.7 (IQR 20.9) Arm B and 0 (IQR 0) Arm A (p < 0.001). Median hospital stay was 7 days (IQR 7) Arm B and 2 days (IQR 2) Arm A (p < 0.001). Complete response in Arm A was 45.3% (34/75 patients) with 5.3% ypT3 (4/75 patients) and in Arm B: pT1 (12.3%; 10/81patients), deep-pT3 (4.95; 4/81patients), pN1 (21%; 17/81). **Conclusions:** CRT-TEM treatment obtains high pathological complete response rates (45.3%), with a high CRT compliance rate (97.6%) and low morbidity. Postoperative complications and hospitalization are significantly lower in the CRT-TEM group. We await the results of the follow-up. Clinical trial information: NCT01308190. Research Sponsor: Olga Torres Foundation Grant, Other Foundation.

3502 **Oral Abstract Session**

STAR-TREC phase II: Can we save the rectum by watchful waiting or transanal surgery following (chemo)radiotherapy versus total mesorectal excision for early rectal cancer? *First Author: Simon Parkinson Bach, University of Birmingham, Birmingham, United Kingdom*

Background: No randomised trials have compared non-operative organ preservation (OP) therapy for early-stage rectal cancer versus standard of care (SoC) using total mesorectal excision (TME) alone. STAR-TREC evaluated the feasibility of recruiting to a study comparing contrasting OP therapies, optimised for treatment of early tumours, versus SoC. **Methods:** STAR-TREC was a prospective, randomised, open-label, feasibility study in the UK, Netherlands and Denmark. Patients with biopsy proven adenocarcinoma of the rectum, staged ≤mrT3b N0 M0, ≤40mm diameter, ECOG 0-1 were randomised in a 1:1:1 ratio to TME, OP via mesorectal short-course radiotherapy (5x5 Gy), or OP via mesorectal chemo-radiotherapy (25x2 Gy + capecitabine) (Peters FP et al. Mesorectal radiotherapy for early stage rectal cancer: A novel target volume. *Clin Transl Radiat Oncol* 2020; 21: 104-11). Standardised response assessment classified OP cases as complete response for no further treatment, partial response for transanal endoscopic microsurgery or poor response for TME by 20 weeks. Surveillance following OP consisted of 3-monthly endoscopy/MRI. All cases had CT thorax/abdomen/pelvis at 24 months (m). The primary outcome was recruitment rate over 2 years, with randomisation of 120 international cases calculated as sufficient to support a phase III trial. Secondary outcomes included acute toxicity, stoma and OP rates at 12m, disease free survival (DFS) and non-regrowth DFS (NRDFS) at 24m and EORTC QLQ-C30 summary score at 12 and 24m. Phase II analysis was pre-specified, approved by the data monitoring committee conditional upon grouping of OP arms to inform phase III design, without prejudicing the outcome (STAR-TREC Phase III protocol. *Colorectal Disease* 2022). **Results:** Recruitment endpoints were met on 28 Oct 2019. Key secondary outcomes are tabulated by intention to treat. No 6-month mortality occurred. **Conclusions:** OP pathways optimised for early tumours reduce acute surgical morbidity without introducing substantial radiation toxicity to achieve OP in 60% with no increase in NRDFS at 24m compared to SoC. Overall quality of life was evenly matched. STAR-TREC phase III will determine the optimal strategy for achieving OP (STAR-TREC Phase III protocol. *Colorectal Disease* 2022). Clinical trial information: NCT02945566. Research Sponsor: Cancer Research UK, Dutch Cancer Society, Danish Cancer Society.

Randomized intermittent or continuous panitumumab plus FOLFIRI (FOLFIRI/PANI) for first-line treatment of patients (pts) with RAS/BRAF wild-type (wt) metastatic colorectal cancer (mCRC): The IMPROVE study. *First Author: Antonio Avallone, Istituto Nazionale Tumori Fondazione G. Pascale, Naples, Italy*

Background: Continuous anti-EGFR-based FOLFIRI is a first-line standard of care in pts with RAS/BRAF wt mCRC. The emergence of resistance and treatment-related toxicity limit the efficacy of continuous treatment. Thus, an intermittent strategy could reduce both toxicity and resistance. **Methods:** This is a prospective, randomized, non-comparative, open-label, multicenter phase II study. Unresectable, previously untreated RAS/BRAF wt mCRC pts, were randomized to a control arm (A) receiving FOLFIRI/PANI continuously until progression or to the experimental arm (B), receiving 8 cycles of the same regimen followed by a treatment free interval. This lasted until progressive disease, when another treatment period of up to 8 cycles was restarted. This intermittent strategy was continued until progression occurred on treatment. Tumor assessment was always done every 8 weeks in both arms. Pts were stratified for center, ECOG PS (0-1 vs 2), previous adjuvant therapy (yes or no), sidedness (right vs left) and metastatic sites (1 vs ≥ 2). The primary endpoint was the progression-free survival on treatment (PFSOT) at 1 year. Assuming p1=43% PFSOT at 1 year, corresponding to an expected median PFSOT time ≥ 10 months in the experimental arm, and a 5% drop-out rate, a sample size of 68 pts in each arm granted the study a power of 80%, with a type I error of 10% (binomial test) for rejecting the null hypothesis, p0=30%, corresponding to a median PFSOT time of ≤ 7 months. Secondary endpoints were safety, quality of life, OS and response rate (ORR); ctDNA samples were also collected. No formal comparison between the two arms was planned. **Results:** From May 2018 to June 2021, 137 pts were randomized (69 arm A/68 arm B). Main pts' characteristics were (arm A/B): males 59/61%; median age 62/66yrs; PS 0 84/72%; right colon 17/15%; previous adjuvant therapy 22/29%; single metastatic site 33/26%. At a median follow-up of 18 months (IQR: 10-26), median PFS OT was 12.6 months (95% CI: 9.0-16.1) in arm A and 17.6 months (95% CI: 7.5-27.8) in arm B with a 1 year PFSOT rate of 51.7% and 61.3%, respectively. ORR (arm A/B) was 64/56%. Median number of FOLFIRI/PANI cycles administered per patient were (arm A/B) 13/12. Main grade 3-4 toxicities were (arm A/B): skin 27/13%, neutropenia 23/22%; diarrhea 13/15%. **Conclusions:** The primary endpoint of the study was met with the intermittent FOLFIRI-PANI strategy producing a long PFS with a reduced skin toxicity. These data deserve further investigations in a phase III trial. Clinical trial information: NCT04425239. Research Sponsor: AMGEN (partially funded).

3504 **Oral Abstract Session**

STRATEGIC-1: Multi-line therapy trial in unresectable wild-type KRAS/NRAS/BRAF metastatic colorectal cancer—A GERCOR-PRODIGE randomized open-label phase III study. *First Author: Benoist Chibaudel, Department of Medical Oncology, Franco-British Institute, Levallois-Perret, France*

Background: The management of unresectable metastatic colorectal cancer (mCRC) is a comprehensive treatment strategy involving several lines of therapy, maintenance, salvage surgery, and treatment-free intervals. Besides chemotherapy (fluoropyrimidine, oxaliplatin, irinotecan), anti-angiogenic and anti-epidermal growth factor receptor (EGFR) agents have become available. Ultimately, strategy trials are needed to define the optimal use and the best sequencing of these agents. **Methods:** Patients with previously untreated RAS/BRAF wild-type unresectable mCRC were randomly assigned (1:1 ratio) to receive either FOLFIRI-cetuximab followed by mFOLFOX6-bevacizumab (arm A) or OPTIMOX-bevacizumab followed by FOLFIRI-bevacizumab followed by EGFR mab +/- irinotecan (arm B). This trial was designed as a superiority study (hypothesis arm B > arm A) with Duration of Disease Control (DDC) as primary endpoint, defined as the sum of PFS of each active sequence of treatment (Chibaudel B, J Clin Oncol, 2011). Secondary endpoints were overall survival (OS), Time to Failure of Strategy (TFS), Progression-free survival (PFS) and response rate (RECIST version 1.1) per sequence, salvage surgery rate, safety, and Quality of life (QoL). **Results:** Between October 2013 and May 2019, 263 eligible patients were randomized (arm A, n = 131; arm B, N = 132). After a median follow-up of 51.2 months (95% CI 43.3-57.4), 188 events for DDC were observed. Efficacy outcomes are presented in table. Median DDC was similar in both arms (HR 0.97, 95% CI 0.72-1.29; P = 0.805). Salvage surgery for metastasis (+/- radiofrequency ablation) was done in 36 (27.5%) patients in arm A and 28 (21.2%) in arm B. Median time until definitive deterioration of QoL (global health status) were 18.3 and 18.0 months (P = 0.628). The safety profiles were consistent with the established safety profiles of each treatment regimen. **Conclusions:** STRATEGIC-1 is the first randomized phase III study comparing multi-line standard treatment strategies in patients with KRAS/NRAS/BRAF wild-type mCRC. This study did not meet its primary endpoint of DDC. The treatment strategy starting with FOLFIRI-cetuximab followed by mFOLFOX6-bevacizumab led to higher response rates and to a trend for better median OS exceeding 3 years. These findings may add to our understanding of treatment sequencing in mCRC. Clinical trial information: NCT01910610. Research Sponsor: ROCHE, GERCOR.

Atezolizumab plus modified DCF (docetaxel, cisplatin, and 5-fluorouracil) as first-line treatment for metastatic or locally advanced squamous cell anal carcinoma: A SCARCE-PRODIGE 60 randomized phase II study.

First Author: Stefano Kim, Bourgogne-Franche Comté University, Department of Medical Oncology, Besançon University Hospital, Besançon, France

Background: Modified docetaxel, cisplatin, and 5-fluorouracil (mDCF) regimen is one of the first-line standard regimens for the treatment of metastatic or unresectable locally advanced recurrent squamous cell carcinoma of the anus (SCCA) after demonstrating an improved efficacy (12-month PFS of 47%) in the Epitopes-HPV02 trial. Antibodies targeting the checkpoint inhibitor (CKI) programmed cell death protein-1 have been shown to be effective as monotherapy in advanced SCCA, refractory to chemotherapy. The aim of this study was to evaluate the combination of atezolizumab and mDCF as first-line treatment. **Methods:** This is a 2:1 randomized, non-comparative, multicenter, phase II study (NCT03519295) with an experimental arm (Arm A, mDCF plus atezolizumab) and standard arm (Arm B, mDCF). Patients with chemo-naive SCCA, metastatic or unresectable locally advanced recurrence were eligible. In Arm A, survival probabilities for null and alternative hypotheses for the primary endpoint 12-months PFS rate were 35 and 50%, respectively. Using one-arm non-parametric survival with unilateral alpha type I error of 5% and a statistical power of 81%, 64 patients in 2 years with 1 year of follow-up need to be randomized in Arm A. The lowest expected critical value would be a PFS rate of 46% to reject H0. In both arms, 8 cycles of mDCF were administered. In Arm A, patients received a fixed dose of atezolizumab (800 mg every 2 weeks) before each mDCF cycle and were followed up to 1 year. **Results:** Ninety-sevenevaluable patients were enrolled, 64 in Arm A and 33 in Arm B. The median age was 64.1 years, 73.2% were women, and 78,3% had a metastatic disease. More patients in Arm A had an ECOG-PS 1 (42.2% vs 27.3%), liver involvement (56.9% vs 48%), and an extensive local recurrence (23.5% vs 8%). The median follow-up was 22.3 months (95% CI 20.8-24.8).The 12-month PFS rate was 44.2% (90% CI 33.7-54.2) and 43.2% (90% CI 28.5-57.0) in Arm A and Arm B, respectively, and the 12-month OS rate was 77.7% (95% CI 68.1-88.7) and 80.8% (95% CI 68.1-95.9).The objective response rate was 74.6% and 78.1% in Arm A and Arm B, respectively. A high dose-intensity and a good safety profile were observed in both arms. Grade ≥3 toxicities were observed in 59.0% and 36.4% of patients in Arm A and Arm B, respectively, with no toxic death. **Conclusions:** The results of SCARCE trial are consistent with previous results of mDCF, with high efficacy and safety at first-line in patients with advanced SCCA. However, the concomitant addition of CKI did not make a significant clinical impact at 12 months. Updated results will be presented. Clinical trial information: NCT03519295. Research Sponsor: ROCHE, GERCOR.

Phase II study of nivolumab in combination with FOLFOXIRI/bevacizumab as first-line treatment in patients with advanced colorectal cancer RAS/BRAF mutated (mut): NIVACOR trial (GOIRC-03-2018).

First Author: Angela Damato, Medical Oncology Unit, Azienda USL-IRCCS Reggio Emilia, Reggio Emilia, Italy

Background: FOLFOXIRI plus bevacizumab (BEV) represents standard chemotherapy in first-line treatment of patients (pts) with metastatic colorectal cancer (mCRC). The NIVACOR study evaluates the addition of nivolumab (NIV) to FOLFOXIRI/BEV as first-line therapy in mCRC RAS/BRAF mut pts regardless of MSS/MSI status. **Methods:** This is a single-arm, multicenter, open-label, phase II trial in first-line treatment of pts with mCRC RAS/BRAF mut. Pts received NIV at a flat dose of 240 mg q14 days, FOLFOXIRI (irinotecan 165 mg/m^2, oxaliplatin 85 mg/m^2, leucovorin 200 mg/m^2, and 5-fluorouracil CI 3,200 mg/m^2 for 48 hours) in combination with BEV at the dose of 5 mg/kg IV q14 days for eight cycles and then, the maintenance with BEV/NIV until PD or unacceptable toxicities. The primary endpoint was the ORR according to RECIST 1.1 Criteria. All images are reviewed by Independent Data Monitoring Committee. According to Fleming's design with alpha and beta levels of 0.05 and 0.2 respectively, in a sample size of 73 pts (comprehensive of a 10% drop-out rate), at least 56 responses were necessary to not reject the alternative hypothesis of an ORR=0.80. **Results:** From October 2019 to March 2021, 73 pts were enrolled in 9 Italian centers. The median age was 60 (51-65) years and 50.7% were male; the main primary tumor side was right (50.7%). The molecular characterization was: 87.7% RAS mut, 16.2% BRAF mut, and 4.5% both RAS and BRAF mut; 10/62 were MSI (16.1%), 52/62 (83.9%) MSS, and 11 pts not assessed. Liver metastases were present in 56.2% pts. The median follow-up was 14.3 (IQR 11.5-16.5) months on December 31, 2021. The median (m) duration of treatment was 12 (8-17) cycles. The ORR was 76.7%, with 7(9.6%) CR and 49(67.1%) PR. SD were 15(20.6%) with a DCR of 97.3%; 2(2.7%) pts were not evaluable. The mDOR was 8.4 (95%CI, 7-NE) months. The mPFS was 10.1 months (95%CI, 9.4-NE) and 12-months PFS was 53.4%. At data cut-off, 65 (89.1%) pts are still alive. In subgroups analysis of MSS pts the ORR was 78.9% with a mDOR of 7.59 (95% CI 6.21 -11.43) months, DCR of 96.2%, and mPFS of 9.8 (95%CI 8.18-15.24) months. The surgery of the primary tumor, metastases, or both was performed in 6(8.2%), 9(9.6%), and 5(6.9%) of pts, respectively. The main grade (G) 3 -4 toxicities were: neutropenia (G3 21.9%, G4 15.1%), diarrhea (G3 17.8%, G4 1.4%), hypertension G3 (6.8%), fatigue G3 (6.8%), and febrile neutropenia G4 (4.1%). **Conclusions:** The primary endpoint ORR was met. These results show the preliminary efficacy and safety of NIV in combination with FOLOXIRI/BEV as first-line therapy in pts with mCRC RAS/BRAF mut. Also, promising activity was observed in MSS subgroup pts. These data support the conduction of phase III randomized-controlled study. Research Sponsor: Bayer, Bristol Myers-Squibb. Clinical trial information: NCT04072198.

Nivolumab (NIVO) ± ipilimumab (IPI) in patients (pts) with microsatellite instability-high/mismatch repair-deficient (MSI-H/dMMR) metastatic colorectal cancer (mCRC): Five-year follow-up from CheckMate 142.

First Author: Michael J. Overman, University of Texas MD Anderson Cancer Center and SWOG, Houston, TX

Background: NIVO ± IPI is approved in previously treated pts with MSI-H/dMMR mCRC in the US, EU, and Japan, based on findings from the phase 2 CheckMate 142 study (NCT02060188). NCCN guidelines include NIVO + IPI as an initial therapy option for pts with MSI-H/dMMR mCRC. Results from a ~ 5-year follow-up from CheckMate 142 cohorts 1–3 (C1–3) are reported here. **Methods:** In this non-randomized, multicohort study, pts with MSI-H/dMMR mCRC were treated as follows: C1 (2L+; NIVO 3 mg/kg Q2W), C2 (2L+; NIVO 3 mg/kg + IPI 1 mg/kg Q3W [4 doses], followed by NIVO 3 mg/kg Q2W) and C3 (1L; NIVO 3 mg/kg Q2W + IPI 1 mg/kg Q6W), until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) by investigator assessment (INV) per RECIST v1.1. Other key endpoints were disease control rate (DCR), duration of response (DOR), progression-free survival (PFS), all by INV and blinded independent central review; overall survival (OS), and safety. **Results:** In C1 (N = 74), C2 (N = 119), and C3 (N = 45), median (range) follow-up (time from first dose to data cutoff) was 70.0 (66.2–88.7), 64.0 (60.0–75.8), and 52.4 (47.6–57.1) months (mo), respectively. ORR (95% CI) by INV was 39% (28–51), 65% (55–73), and 71% (56–84; Table) and progressive disease (PD) rates were 26%, 12%, and 16% in C1, C2, and C3, respectively. Median DOR was not reached in the 3 cohorts. The 48-mo PFS rates were 36%, 54%, and 51% and 48-mo OS rates were 49%, 71%, and 72% in C1, C2, and C3, respectively (Table). PFS and OS rates with up to 60 mo of follow-up will be presented. Safety data are shown in the table. **Conclusions:** With extended follow-up of ~ 5 years, NIVO ± IPI continued to demonstrate durable OS and PFS benefit, with no new safety signals. These updated data further support current treatment recommendations for 2L+ NIVO ± IPI and 1L NIVO + IPI for pts with MSI-H/dMMR mCRC. Clinical trial information: NCT02060188. Research Sponsor: Bristol Myers Squibb.

Neoadjuvant nivolumab, ipilimumab, and celecoxib in MMR-proficient and MMR-deficient colon cancers: Final clinical analysis of the NICHE study.

First Author: Yara L. Verschoor, Netherlands Cancer Institute, Amsterdam, Netherlands

Background: The combination of PD-1 and CTLA4 blockade has changed the treatment landscape for several cancer types. Although this treatment is highly effective in metastatic mismatch-repair deficient (dMMR) colorectal cancers, metastatic MMR-proficient (pMMR) tumors do not respond. The NICHE study was the first neoadjuvant immunotherapy study in colon cancer (CC) to show impressive responses in 100% of dMMR (n= 20) and 27% of pMMR (n= 15) CC. In contrast, pathologic response to neoadjuvant chemotherapy using standard of care folfox is approximately 5% in dMMR tumors. Here we present the final efficacy data for the original NICHE study cohorts. **Methods:** Patients with non-metastatic, resectable dMMR or pMMR CC were treated with a single dose of ipilimumab 1mg/kg and two doses of nivolumab 3mg/kg and underwent surgery within 6 weeks. In addition, patients with pMMR tumors were randomized to receive celecoxib. The primary endpoints were safety and feasibility, and secondary endpoints included pathologic response rate and disease-free survival in 30 patients with dMMR and 30 with pMMR tumors. Pathologic response was defined as 50% or less viable tumor rest (VTR), and major pathologic response (MPR) as <10% VTR. **Results:** Thirty patients with pMMR and 32 with dMMR tumors were evaluable for the efficacy analyses. In the pMMR cohort, pathologic response was observed in 9/30 (30%, 95% CI 14-46%) patients, consisting of 7 MPR (including 3 pathologic complete responses {pCR}) and 2 partial responses. Four out of 9 pMMR responders had received celecoxib. Five patients received adjuvant chemotherapy. At a median follow-up of 25 months (IQR 12-35 months), 3 patients (all non-responders) in the pMMR group had disease recurrence. In the 32 patients with dMMR tumors, pathologic response was observed in 100% of patients, with 31/32 MPR (97%, 95% CI 91-100%) and one partial response. Pathologic complete response was observed in 22/32 (69%, 95% CI 53-85%) patients. None of the patients in the dMMR cohort had disease recurrence. Surgery was delayed in one patient with a pMMR tumor due to myositis. Grade 3 immune-related adverse events were observed in 12% of patients, consistent with our previous report on the primary endpoint. There were no grade 4 immune-related AEs nor unexpected surgical complications. **Conclusions:** These data confirm our previously published results of the NICHE study, with responses to neoadjuvant nivolumab plus ipilimumab in 30% of pMMR and 100% of dMMR CC in the completed original cohorts. Validation of the dMMR responses in a large group of dMMR patients is ongoing and has the potential to change current practice. Clinical trial information: NCT03026140. Research Sponsor: BMS.

Contact x-ray brachytherapy (Papillon) in addition to chemoradiotherapy to improve organ preservation in early cT2-T3 rectal adenocarcinoma: The 3-year results of OPERA randomized trial (NCT02505750). *First Author: Jean-Pierre Gerard, Department of Radiation Oncology, Centre Antoine Lacassagne, Côte d'Azur University, Nice, France*

Background: The OPERA trial was testing the hypothesis that Contact x-ray brachytherapy (CXB) 50 kV boost will increase the rectal preservation rate in early T2-T3ab rectal adenocarcinoma. We present the 3 years clinical results. **Methods:** Inclusion criteria were: Age > 18 years, PS: 0-1, adenocarcinoma, distal - middle rectum, cT2-T3ab cN0-N1 < 8mm staged using MRI, M0. Stratification: T < vs ≥ 3 cm diameter. Control arm (A) was chemoradiotherapy (CRT) 45Gy/ 5 weeks with concurrent chemotherapy (Capecitabine 825 mg / m^2) and external beam radiotherapy boost (9Gy/ 5 fr/ 1 week). Experimental arm used the same CRT (Cape 45) but the boost used CXB (90 Gy/ 3 fr/ 4 weeks). CXB was given first (B1) for tumor < 3 cm and after cap 45 (B2) for tumor ≥ 3 cm. Response assessment was made at week 14 after treatment start using palpation, endoscopy and MRI. A new assessment could be made at week 20 and 24 with a second MRI.TME was recommended in case of Partial response, Watch& Wait in case of clinical complete response (cCR). Bowel function measurement used LARS score. Main end- point was: Rate of organ preservation at 3 years. The hypothesis (in 2014) was 20% arm A vs 40% arm B (HR:0.53). **Results:** Between 5-2015 and 6-2020, 144 patients were included (France 96, UK 44, Switzerland 4). The analysis was made in 01-2022 with a median Follow-up time of 34 months. Treatment compliance was good in ≥ 90% of patients. Table gives main patients characteristics and clinical outcome. At three years the OP rate (Kaplan Meier estimate) was respectively arm A vs B: 60% vs 81% (HR 0.34 [95% CI 0.19 – 0.73]; *p*= 0.005). At three years OP for group A1 and B1 were: 65% vs 97% (HR 0.081 [95% CI 0.01-0.64]; *p*= 0.02). **Conclusions:** A CXB boost, when combined with chemoradiotherapy, increases the rate of organ preservation in early rectal adenocarcinoma. Starting with CXB in T < 3 cm appears as an attractive option. A B A1*(T < 3cm)* B1 *(T < 3cm)* N° patient 71 73 30 32 Median age 68 69 69 70 Gender M/F 45/26 43/30 18/12 18/14 T2/T3 45/26 47/26 25/5 29/3 Distal/middle 53/18 53/20 21/9 27/5 cCR (W 14-24) 61% 90% p < 0.001 70% 94% p = 0.027 TME 26 12 8 1 Death 2 2 1 0 LARS < 30 80% 83% 87% 86%. Primary surgery followed by selective radiochemotherapy versus conventional preoperative radiochemotherapy for patients with locally advanced rectal cancer with MRI-negative circumferential margin (PSSR): A multicenter, randomized, open-label, noninferiority, phase 3 trial. *First Author: Ke-Feng Ding, Department of Colorectal Surgery and Oncology, Key Laboratory of Cancer Prevention and Intervention, Ministry of Education, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: Neoadjuvant radiochemotherapy is the standard treatment for locally advanced rectal cancer. However, radiation therapy can lead to bowel, urinary and sexual dysfunction. The study aims to clarify whether locally advanced rectal cancer with a distance of 6 to 12 cm from the anus with negative circumferential margins (CRM) predicted by MRI can be exempted from preoperative radiotherapy. **Methods:** PSSR (NCT02121405), a multicentre, randomized, open-label, non-inferiority, phase 3 trial, was done across 10 hospitals in China. Patients aged from 18 to 75 years with locally advanced rectal cancer (including all cT3/4 and/or Nany) with negative MRI-predicted CRM and tumor distance of 6 to 12 cm from anus were randomly assigned (1:1), by central randomization, to intervention group (surgery directly, in which positive CRM was supplemented with chemoradiotherapy, negative CRM received adjuvant chemotherapy according to surgical pathologic staging), or control group (neoadjuvant chemoradiotherapy then underwent surgery and adjuvant chemotherapy). The primary endpoint is the rate of 3-year disease-free survival (DFS). A sample size of 350 was set according to the original non-inferiority margin of 15% for the difference of rates for 3-year DFS, which was changed to 5% under the Data Safety Monitoring Board (DSMB) suggestion after an interim analysis. The efficacy analysis followed the per-protocol (PP) principle. **Results:** From December 2015 to February 2021, 299 patients were recruited. DSMB stopped this trial due to the difference of 3-year DFS's rate between two groups more than 5% at the interim analysis in July 2021. A total of 275 were included for the final analysis. Based on the PP dataset, 238 patients followed the original protocol (135 patients in the intervention group and 103 patients in the control group). Patients who had positive CRM were 2(1.5%) and 1(1.0%) in two groups, respectively (*P*= 1.00). After a median follow-up of 34.6 (IQR: 18.2-45.7) months, a total of 42 patients had positive events (30 patients in the intervention group and 12 patients in the control group). There were 5 (3.7%) patients with local recurrence in the intervention group (*P*= 0.062). Patients with pathological complete response (pCR) and near pCR were 19 (18.4%) and 21 (20.4%) in the control group. The rate of 3-year DFS was 81.1% (77.3%-84.9%) (HR = 2.02, 95%CI: 1.01-4.06, *P*= 0.048) in the intervention group and 86.6% (82.7%-90.5%) in the control group, with difference of 5.4% (5.3%-5.6%), which did not meet the criteria for non-inferiority. **Conclusions:** In terms of DFS, initial surgery was inferior to conventional preoperative radiochemotherapy for locally advanced middle rectal cancer with MRI negative circumferential margin. Clinical trial information: NCT02121405. Research Sponsor: Grant Number: RCT-2019-005A.

3516 **Poster Discussion Session**

Short-term outcomes of laparoscopy-assisted versus open surgery for low rectal cancer (LASRE): A multicenter, randomized, controlled trial. *First Author: Pan Chi, Fujian Medical University Union Hospital, Fuzhou, China*

Background: The efficacy of laparoscopic versus open surgery for low rectal cancer has not yet been established. We aimed to evaluate whether laparoscopic surgery is non-inferior to open surgery for low rectal cancer in terms of oncologic outcomes. **Methods:** LASRE trial (NCT01899547) is a multicenter, noninferiority, randomized controlled trial being conducted in 22 tertiary hospitals across China. Patients with low rectal cancer and without evidence of pelvic lateral lymph nodes or distant metastasis were randomly assigned (2:1) to laparoscopic or open surgery. The primary outcome was 3-year disease-free survival (DFS). Secondary outcomes included pathological outcomes, 30-day postoperative complications, 30-day mortality, overall survival (OS), and quality of life. The target sample size was 1065 patients. The short-term pathological, surgical, and postoperative recovery outcomes, analyzed in a modified intention-to-treat population (mITT). **Results:** Between November 12, 2013, and June 6, 2018, 1070 patients were randomized into laparoscopic (n = 712) or open surgery (n = 358) groups; 1039 were included in the mITT analysis (685 in laparoscopic and 354 in open group). Seventeen patients (2.5%) in the laparoscopic group required conversion to open surgery. There were no significant between-group differences in the rates of complete mesorectal excision (85.3% vs. 85.8%; p = 0.777), negative circumferential resection margins (98.2% vs. 99.7%; p = 0.085), negative distal resection margins (99.4% vs. 100%; p = 0.362), and numbers of retrieved lymph nodes (13.0 vs. 12.0; p = 0.394). The laparoscopic surgery group exhibited a shorter time to first flatus (40.4 vs. 44.8 hours; p = 0.006), time to first defecation (61.2 vs. 66.3 hours; p = 0.031), duration of analgesic use (45.0 vs. 48.0 hours; p = 0.001), and duration of hospitalization (8.0 vs. 9.0 days; p = 0.008) compared to the open surgery group. The postoperative complication rates were 13.0% and 17.2% in the laparoscopic and open surgery groups, respectively (p = 0.065). There was no incidence of 30-day mortality. **Conclusions:** In patients with low rectal cancer, laparoscopic surgery performed by experienced surgeons can provide pathological outcomes comparable with those of open surgery in terms of complete mesorectal excision and negative resection margins, rapid postoperative recovery, and fewer postoperative complications. Clinical trial information: NCT01899547. 3517 **Poster Discussion Session**

International validation of the Immunoscore-biopsy (IS_B) to guide selection and monitoring of patients treated with watch-and-wait (WW) strategy for rectal cancer. *First Author: Franck Pages, Department of Immunology, Hôpital Européen Georges Pompidou, University of Paris, Paris, France*

Background: The WW strategy for patients with rectal cancer who achieved a clinical complete response (cCR) after neoadjuvant therapy (nT) allows to avoid major resection and the associated morbidity and mortality. Standardized criteria to select and monitor WW patients, including biomarkers predicting recurrence after nT, are lacking. The prognostic impact of the immune infiltrate in colorectal cancers is now demonstrated and has been implemented into clinics through the Immunoscore, the first standardized digital-pathology-based assay, recommended by academic institutions. We evidenced that an Immunoscore adapted to biopsies (IS_B) performed at diagnosis, predicts the response to nT and the risk of recurrence after nT. Its clinical utility was suggested in a test cohort of WW patients (El Sissy et al., Clin Cancer Res 2020). The aim of this study was to confirm the ability of the IS_B to predict clinical outcomes, improve patients' eligibility for the WW strategy, and optimize a follow-up schedule. **Methods:** A total of 304 WW patients from 10 centers across 7 countries were included. Tumor biopsies before treatment were immunostained for CD3+ and CD8+ T-cells and converted to IS_B using the predefined cut-off. The primary endpoint was time-to-recurrence (TTR). Secondary endpoint was disease-free-survival (DFS). As immune response originates in draining lymph nodes, signs of immune activation were carried out in lymph nodes of additional patients managed by radical surgery with complete pathological response (pCR; n = 12) or non-pCR (n = 12) by 3' RNA-Seq and immunofluorescence technologies. **Results:** High-IS_B patients presented with the lowest risk of recurrence after WW. 5-year recurrence-free rates were 97% (92%-100%), 61% (49%-76%), and 56% (44%-73%) with IS_B High, Intermediate, and Low, respectively (HR [Low-vs-High] = 14.3, 95% CI 1.8-100). In patients with cCR after nT (n = 209), High-IS_B showed a significant association with prolonged TTR and DFS (Logrank P = 0.005 and P = 0.006, respectively). When IS_B was evaluated as a continuous variable, the risk of recurrence was increasing along with decreasing IS_B (Wald tests, all P < 0.005). In multivariate analyses, IS_B was independent of age, sex, location, and cTNM stage and was the single parameter correlated with TTR (HR [IS_B High-vs-Low] = 0.08, 95% CI 0.01-0.6; P = 0.015) and DFS (P = 0.013). Unlike for patients with cCR, no difference according to IS_B was observed for those with incomplete response (n = 41) or treated with brachytherapy (n = 34). Finally, intranodal signs of T-cell and B-cell activation were only evidenced in patients with pCR. **Conclusions:** IS_B provides a reliable biomarker to predict clinical outcomes, improve eligibility, and optimize patients' follow-up. Intranodal T-cell and B-cell activation further supports the immune benefit of both organ and lymph node preservation. Research Sponsor: None.

3518 **Poster Discussion Session**

Plasma *RAS* dynamics and anti-EGFR rechallenge efficacy in patients with *RAS*/*BRAF* wild-type metastatic colorectal cancer: REMARRY and PURSUIT trials. *First Author: Yoshinori Kagawa, Department of Gastroenterological Surgery, Osaka General Medical Center, Osaka, Japan*

Background: Rechallenge with anti-EGFR monoclonal antibody (EGFR mAb) showed certain activities in patients (pts) with *RAS*/*BRAF* V600E wild-type (wt) metastatic colorectal cancer (mCRC), particularly in pts with negative plasma *RAS* (p*RAS*) mutation by circulating-tumor DNA (ctDNA) assay at 'just before' the rechallenge therapy. However, the efficacy is unknown in pts with *RAS*/*BRAF* wt mCRC whose p*RAS* was converted to positive once during or after EGFR mAb. Therefore, we conducted REMARRY, a prospective longitudinal study to investigate the p*RAS* dynamics, and PURSUIT trials, a phase II trial to investigate the efficacy of EGFR mAb rechallenge in pts with p*RAS* wt just before rechallenge therapy. **Methods:** The eligibility criteria of REMARRY trial included *RAS*/*BRAF* V600E wt mCRC; ECOG PS 0-1; CR or PR during EGFR mAb; and a refractory ≤ 2 months from the last administration of EGFR mAb. p*RAS* status by the BEAMing method was prospectively monitored at timepoints of progression on EGFR mAb and each subsequent therapy. The eligibility criteria of PURSUIT trial included enrollment in the REMARRY trial with confirmed p*RAS* wt prior to enrollment in PURSUIT trial; being refractory or intolerant to fluoropyrimidine, oxaliplatin, and irinotecan; and ≥ 4 months of EGFR mAb-free interval. Study treatment was rechallenge with panitumumab + irinotecan (6 mg/kg + 150 mg/m^2 q2wks). Primary endpoint was a confirmed objective response rate (ORR) according to RECIST v1.1. The required number of pts was 45, with a null ORR of 10%, an expected ORR of 25%, power of 85%, and one-sided α of 0.05. **Results:** Between May 2019 and May 2021, 183 pts with 343 timepoints (median, 2) were enrolled in REMARRY trial from 27 institutions, and 50 pts were enrolled in PURSUIT trial; median age, 68 years; left-sided primary, 44 pts; prior EGFR mAb, 1st/2nd/≥3rd lines was 28/6/16 pts; and p*RAS* status at progression on prior EGFR mAb, wt/mutant (mt)/unknown in 31/7/12 pts. Confirmed ORR and disease control rate were 14% (90% CI, 7.8%–23.9%) and 80% (95% CI, 67.0%–88.8%), respectively. In addition, 4 pts showed an unconfirmed PR. With a median follow-up time of 8.7 months, median progression-free survival was 3.6 months (95% CI, 3.0 – 4.7 months). The subgroup analysis showed a significantly higher confirmed ORR in pts with a longer EGFR mAb-free interval than a shorter one (> vs. < 365 days, 44.4% vs. 7.3%, p = 0.0037). Without any unexpected safety signals, 58.5% of pts had ≥ grade 3 adverse events. Of 31 patients with wt p*RAS* at progression on prior EGFR mAb, 5 had a confirmed response (ORR, 16%), whereas no response was observed in patients with 7 p*RAS* mt (ORR, 0%) (p = 0.25). **Conclusions:** The primary endpoint of confirmed ORR was not met; however, pts with p*RAS* wt at progression on prior EGFR mAb may benefit from rechallenge with, implying a lack of or worse response if p*RAS* becomes positive even once during or after EGFR mAb. Randomized study to investigate a switch maintenance concept with 5-FU plus bevacizumab after FOLFIRI plus cetuximab induction treatment versus continued treatment with FOLFIRI plus cetuximab: Report of a secondary endpoint of the phase-III FIRE-4 study (AIO KRK-0114). *First Author: Sebastian Stintzing, Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Hematology, Oncology, and Cancer Immunology (CCM), Berlin, Germany*

Background: FIRE-4 (AIO KRK-0114) is performed in RAS-wild-type (wt) mCRC patients. This randomized study tests the efficacy of early switch maintenance during 1st-line therapy (part 1) and re-challenge with cetuximab (part 2) in later-line treatment. In part 1, all patients received first-line induction treatment with FOLFIRI plus cetuximab (FOLFIRI/Cet). In arm A, patients were randomized to continue FOLFIRI/Cet until progression or intolerable toxicity. In arm B, patients received FOLFIRI/Cet for 8-12 cycles, after which maintenance therapy with Fluoropyrimidin plus bevacizumab was applied. The first randomization evaluates the question if an early switch from cetuximab to bevacizumab during maintenance therapy may prolong PFS. **Methods:** Within this randomized, controlled, open-label phase-III study, patients received FOLFIRI (irinotecan plus 5-FU/FA) plus cetuximab every two weeks at the standard dosing schedule. In arm A, FOLFIRI plus cetuximab was continued every 2 weeks until progression or intolerable toxicity. De- and re-escalation was allowed according to the local standard of care. In arm B, patients received 8 cycles of FOLFIRI plus cetuximab (in case of tumor response) or 12 cycles (in case of stable disease) followed by maintenance with Fluoropyrimidin plus bevacizumab (5mg/kg) every two weeks until disease progression or intolerable toxicity. Overall survival after second randomization (part 2) is evaluated as a primary endpoint. Here, we report PFS in first-line (part 1) as a secondary study endpoint of the study. Other secondary endpoints included ORR, OS, safety, and tolerability. **Results:** From August 2015 to January 2021, 672 patients were randomized and 656 patients were assigned to treatment in 120 German and 10 Austrian centers (327 arm A and 329 in arm B). PFS was comparable between both treatment arms (10.7 vs 11.3 months, HR 0.92 (95% CI: 0.76-1.10), p = 0.36). ORR in evaluable patients was not different and reached 75.7% and 72.3% with a DCR of 94.6% vs. 92.5% in the respective arms. Preliminary OS (≤40% of OS events recorded) was also similar between both arms (HR 1.030; p = 0.81) . Updated results will be presented at the meeting. No new or unexpected toxicities were observed. **Conclusion:** Switch from FOLFIRI cetuximab to maintenance therapy with 5-FU plus bevacizumab did not induce superior efficacy (PFS, ORR, OS) compared to continued application of cetuximab. The results suggest that early switch maintenance from cetuximab to bevacizumab is not effective to postpone disease progression during targeted therapy. FIRE-4 confirms the efficacy of FOLFIRI plus cetuximab as first-line treatment of patients with RAS wild-type mCRC. Clinical trial information: NCT02934529. Research Sponsor: MERCK.

3520 **Poster Discussion Session**

Phase 2 study of anti-EGFR rechallenge therapy with panitumumab with or without trametinib in advanced colorectal cancer. *First Author: Christine Megerdichian Parseghian, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: In *RAS/RAF* WT colorectal cancer (CRC), rechallenge with anti-EGFR therapy (EGFRi) in patients (pts) with prior response leads to clinical benefit, with response rates up to 30% in prior trials. However, secondary MTs in the MAPK signaling pathway have been implicated in resistance to EGFRi. We designed a phase 2 trial to evaluate the efficacy of EGFRi rechallenge +/- a MEK inhibitor (trametinib) based on pre-treatment ctDNA MTs. **Methods:** This trial evaluated the efficacy and safety of EGFRi rechallenge +/- trametinib in pts with *RAS/BRAF* WT, MSS, treatment refractory mCRC who achieved clinical benefit with prior EGFRi based therapy for ≥16 weeks with subsequent progression. Pre study ctDNA was used to enroll in one of 3 arms: Arm A: Pts with an acquired *EGFR* ECD MT but absence of *RAS/BRAF/MAP2K1* or with absence of any acquired resistance MT (Arm C) at time of study initiation received panitumumab 6 mg/kg IV Q2 wks. Arm B: Pts with an acquired *RAS/BRAF/MAP2K1* MT received panitumumab 4.8 mg/kg plus trametinib 1.5 mg PO daily. Pts in Arms A and C were allowed to cross over on progression. The primary endpoint was ORR by RECIST v1.1. **Results:** 54 pts were enrolled, with 52 evaluable for efficacy. Median age is 59 yrs (range, 37-78), and 23 (46%) are female. Median number of prior therapies was 3. Three, 20, and 31 pts were enrolled in Arms A, B, C, respectively. Grade 3 TREAs occurred in 29 (54%) pts (all receiving the doublet regimen) and included acneiform rash in 17 (31%) and others occurring in < 5% of pts. There were no grade 4 TRAEs. In pts with no acquired MTs (Arm C), ORR was 20% (6/30) (95% CI, 0.07-0.37), DCR 67% (20/30) (95% CI, 0.45- 0.81), and median PFS and OS 4.1 mo and 11.2 mo, respectively. The median DOR was 5.5 mo. 22 patients crossed over to add trametinib at time of progression, without any responses. In contrast, in pts with acquired *RAS/RAF/MAP2K1* MTs (Arm B), there were no responses, with DCR of 63% (12/19) (95% CI, 0.36-0.81), and median PFS and OS 2.1 mo and 5.9 mo, respectively. Only 3 pts were identified with *EGFR* ECD MTs (Arm A), and ORR is 0% (0/3) in this cohort, with DCR 67% (2/3) (95% CI, 0.09-0.99). Pts with PR had a longer median interval from prior EGFRi and longer time on prior EGFRi than those with SD+PD (5.5 vs 3.6 mo; p = 0.03, and 9.5 vs. 8.8 mo; p = 0.03, respectively). **Conclusions:** CtDNA guided rechallenge leads to responses in 20% of pts without acquired resistance MTs, with DCR of 67%. This exceeds current third line standard options. While panitumumab has the potential to block EGFR ECD mutations arising from cetuximab, these mutations in isolation were uncommon and there were no signals of efficacy. Although the acneiform rash induced by the combination of MEK and EGFR inhibition was manageable with close dermatologic management, the combination failed to improve outcomes for pts with acquired resistance. Alternative approaches to downstream MAPK blockade should be explored to improve outcomes. Clinical trial information: NCT03087071. Research Sponsor: Amgen and Novartis, U.S. National Institutes of Health.

Pembrolizumab (pembro) plus mFOLFOX7 or FOLFIRI for metastatic colorectal cancer (CRC) in KEYNOTE-651: Long-term follow-up of cohorts B and D. *First Author: Richard D. Kim, Moffitt Cancer Center, Tampa, FL*

Background: Response to antiPD-1 monotherapy is poor in patients (pts) with advanced microsatellite stable (MSS)/mismatch-repair proficient (pMMR) CRC. Combination of chemotherapy with antiPD-1 pembro may potentiate the antitumor immune response and provide greater antitumor activity than either agent alone. Combination of pembro and mFOLFOX7 or FOLFIRI in the ongoing phase 1b multicohort KEYNOTE-651 (NCT03374254) study in metastatic MSS/pMMR CRC showed antitumor activity. We present results with approximately 20 mo of additional follow-up. **Methods:** Pts had metastatic MSS/pMMR CRC and were previously untreated (cohort B) or received 1 prior line including a fluoropyrimidine + oxaliplatin (cohort D). Pts received pembro 200 mg Q3W + mFOLFOX7 Q2W (cohort B) or pembro 200 mg Q3W + FOLFIRI Q2W (cohort D). Primary end points were safety (DLT) and RP2D. Secondary end point was ORR per RECIST v1.1 by investigator review. DOR, DCR, and PFS per RECIST v1.1, and OS were exploratory end points. **Results:** Median study follow-up (range) at data cutoff (Oct 15, 2021) was 30.2 mo (25.0-43.6) for cohort B (n = 31) and 33.5 mo (25.2-43.2) for cohort D (n = 32). Treatment was discontinued in 29 pts (94%) in cohort B and 28 pts (88%) in cohort D, mostly because of PD (61% and 66%, respectively). At prior analysis (Feb 10, 2020), RP2D was confirmed as the starting dose in both cohorts; no new DLT had occurred. In cohort B, gr 3/4 TRAEs occurred in 18 pts (58%), most commonly neutropenia and decreased neutrophil count (both n = 5; 16%); 19 pts (61%) discontinued drug because of a TRAE. In cohort D, gr 3/4 TRAEs occurred in 17 pts (53%), most commonly, neutropenia (n = 7; 22%), diarrhea and fatigue (both n = 4; 13%); 3 pts (9%) discontinued drug because of a TRAE. There were no gr 5 TRAEs in either cohort. Efficacy by cohort and *KRAS* mutation status are below (Table). PD-L1 data and DNA/RNA-based biomarker data including GEP, consensus signatures, TMB, and LoF mutations will be included in the presentation. **Conclusions:** After 2.5 y of follow-up, the combination of pembro with either mFOLFOX7 or FOLFIRI continued to demonstrate a manageable safety profile with no new safety signals. Efficacy data from these single-arm cohorts appear comparable to historical data for current SOC. Clinical trial information: NCT03374254. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Mucinous adenocarcinoma of the anal canal: Clinical characteristics and outcomes of 767 patients from National Cancer Database. *First Author: Sam Melamed, The Lundquist Research Institute, Torrance, CA*

Background: Mucinous adenocarcinoma of the anal canal (MAAC) is a relatively rare disease, constituting less than 10% of anal cancers. It carries a relatively poor 5-year survival rate of between 50-60%. MAAC rarity and proximity to rectal mucosa can present a diagnostic challenge as it can be misidentified as adenocarcinoma of the lower rectum. Because of its rarity, the bulk of knowledge of the disease is derived from individual case studies or small institutional reviews. Thus, there remains no clear standard of treatment for AAC. While abdominal perineal resection is the main management approach, the role of systemic therapy and radiation on clinical outcomes remains ill-defined. The lack of national guidelines, variability in institutional approaches and in access to tertiary cancer centers may contribute to differences in patient outcomes and raise the question of healthcare disparities. In this study, we analyzed the data from 767 patients with MAAC from the National Cancer Database (NCDB). **Methods:** We obtained clinicopathological demographic, socioeconomic data and survival outcomes from 767 patients with MAAC that were registered in the NCDB from 2004 to 2017. The treatment patterns and prognostic factors were analyzed. **Results:** The majority of patients, 85%, were older than 50. White patients comprised 75.6%, Black 18.8% and Asians 3.3%. Only 3.9% were Hispanics. Among 647 patients who had survival data, the majority received the following therapies: 311 received surgery and chemoradiation, 131 only surgery and 131 only chemoradiation. White and Black patients had similar survival odds, whereas Asian patients had significantly higher overall survival (OS) (HR 0.42). Patients treated at academic facilities had significantly better OS than patients treated at non-academic facilities (HR 1.41-1.57), and patients with private insurance (HR 0.37) had significantly better survival when compared to patients with other insurance types. Patients with only Stage II exhibited significant survival differences when given both surgery and chemoradiation, compared being given either treatment modality alone (HR 0.56); interestingly, male patients in this group did not benefit from adding chemoradiation to surgery while female patients did (p = 0.1, p = 0.011). **Conclusions:** Surgical resection seems to be the most important treatment modality in MACC, while for patients with stage II addition of chemoradiation statistically significantly improves survival. Access to tertiary cancer centers and therapy costs contribute to differences in survival outcomes, which brings the question of healthcare disparities and the need for national guidelines for MACC management. ***DEFB1* gene expression and the molecular landscape of colorectal cancer (CRC).** *First Author: Jae Ho Lo, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Defensins are antimicrobial peptides that play important roles in innate immune response. Deregulation of beta-defensin-1 (*DEFB1*) gene expression has been implicated in several cancers and we previously showed that single nucleotide polymorphisms in *DEFB1* are associated with clinical outcomes in patients with metastatic CRC. Hence, we aimed to further characterize the molecular features associated with *DEFB1* gene expression in CRC. **Methods:** 14416 CRC tumors tested at Caris Life Sciences (Phoenix, AZ) with NextGen Sequencing on DNA (592 genes or WES), RNA (WTS) and IHC were analyzed. Top quartile transcripts per million (TPM) for *DEFB1* expression were considered high (Q4) while bottom quartile low (Q1). Consensus molecular subtypes (CMS) were assessed using RNAseq. Cell infiltration in the tumor microenvironment (TME) was estimated by QuantiSEQ. X^2/Fisher-Exact were used and significance was determined as *P*-value adjusted for multiple comparison ($Q < .05$). Real-world overall survival information was obtained from insurance claims data and Kaplan-Meier estimates were calculated for molecularly defined patients. **Results:** *DEFB1* expression was highest in left-sided and rectal tumors (median TPM 2.27) and lowest in right-sided tumors (median TPM 1.62). Overall, when compared to low expression, high *DEFB1* was negatively associated with high TMB (≥ 10 Mut/Mb) (4.8% vs 17%), dMMR/MSI-H (2.2% vs 13.1%), and PD-L1 expression (3.1% vs 5.2%) (all $Q < .05$). Additionally, *DEFB1* high was associated with higher expression of immune checkpoint genes *CD274*, *CD80*, *CD86*, *HAVCR2*, *LAG3*, *PDCD1* and *PDCD1LG2* (Fold Change/FC: 1.27-1.56) but lower *IDO1* (FC: 0.89) (all $Q < .05$). Similar results were confirmed in MSS tumors only, but IDO1 was now positively associated with *DEFB1* high (FC: 1.23). In the MSS cohort, *DEFB1* expression was highest in CMS2 and lowest in CMS3 (2.84 vs 1.67 median TPM, $Q < .05$). In the MSS cohort, *APC* mutations were more frequent in *DEFB1* high tumors (79% vs 72%) while *BRAF* (5.8% vs 9.4%), *GNAS* (1.1% vs 4.4%), *FBXW7* (7.8% vs 10.5%), *SMAD4* (12.3% vs 17%), *RNF43* (2.2% vs 3.5%) and *POLE* (0.2% vs 0.7%) mutations as well as *MYC* (1.2% vs 2.6%) and *MYB* amplifications (0.1% vs 0.9%) were less frequent in *DEFB1* high (all $Q < .05$). Higher neutrophils, NK cells, M2 macrophages, CD4+ T cells and myeloid dendritic cells but lower M1 macrophages, Tregs and CD8+ T cells in the TME were significantly associated with high *DEFB1*; both in the overall and MSS cohorts ($Q < .001$). CRC patients with *DEFB1* expression level above the median had worse OS compared to those below the median both in the overall cohort (HR: 1.18, 95% CI: 1.10-1.27) and in MSS tumors (HR: 1.18, 95% CI: 1.10-1.27). **Conclusions:** Our data show a distinct molecular landscape, including mutational profiles, CMS, immune biomarkers, and TME cell infiltration associated with *DEF1B* gene expression in CRC. These findings suggest a key role for DEF1B in modulating anti-tumor immunity and TME. Prognostic role of systemic inflammatory markers in patients with metastatic MSI-h/dMMR colorectal cancer receiving immunotherapy. *First Author: Deepak Bhamidipati, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Markers of systemic inflammation including neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), and monocyte-to-lymphocyte ratio (LMR) are prognostic in patients with metastatic colorectal cancer receiving systemic chemotherapy. The presence of liver metastases has also been hypothesized to modulate response to immunotherapy. In this study, we assess the prognostic role of these markers in patients with microsatellite high (MSI-H)/deficient mismatch repair (dMMR) tumors receiving immunotherapy for metastatic or unresectable colorectal cancer (CRC). **Methods:** This was a single-institution retrospective analysis of patients with dMMR/MSI-H CRC who received anti-PD-(L)1 and/or anti-CTLA-4 therapy for metastatic or unresectable disease at between 2015 and 2021 (n = 59). NLR, PLR, and LMR were calculated based on the complete blood count obtained within 1 week prior to treatment. Patient and tumor characteristics were obtained from the clinical record. Patient characteristics were compared using Fisher's exact test and Mann-Whitney U where appropriate. Progression free survival (PFS) and overall survival (OS) were the primary endpoints and log-rank test was used for comparison of survival distribution among groups. **Results:** 59 patients with metastatic dMMR/MSI-H CRC were identified. Median age was 60, 53% (n = 31) had right-sided tumors, 35% (n = 35) of patients with testing available had RAS-mutated tumors, and 37% (n = 22) received prior chemotherapy. Most common sites of metastatic disease were peritoneum (n = 23, 39%) and liver (n = 17, 29%). Patients were divided into NLR-High (NLR ≥ 3, n = 20) and NLR-Low (NLR < 3, n = 39), and both groups had similar baseline characteristics. The rate of progressive disease as best response was not different in NLR-Low versus NLR-High (15% vs 30%, p = 0.3). At a median follow-up of 32 months, neither median PFS nor median OS were reached. 74% (n = 29) remained progression free at 1 year in the NLR-Low group versus 60% (n = 12) in NLR-High group which was not statistically significant (p = 0.37); 90% (n = 35) remained alive at 2 years in the NLR-low versus 80% (n = 16) in the NLR-High group (p = 0.4). Similarly, using a cut-off of 150 and 3 for PLR and LMR respectively, there was no significant difference between PFS at 1 year in the PLR-Low (n = 32) vs PLR-High (n = 27) (66% vs 74%, p = 0.58) and LMR-Low (n = 35) vs LMR-High (n = 24) (60% vs 83%, p = 0.084) groups. The presence of liver metastasis or the presence of a RAS mutation did not influence PFS at 1 year (p = 0.35 and p = 1.00, respectively). **Conclusions:** Markers of systemic inflammation may have a limited prognostic role for patients with dMMR/MSI-H CRC receiving immunotherapy. Research Sponsor: None.

3525 **Poster Session**

Effect of primary tumor sidedness on the association of tumor-infiltrating lymphocytes with survival of patients with stage III colon cancer (NCCTG N0147) [alliance]. *First Author: Bahar Saberzadeh Ardestani, Mayo Clinic, Rochester, MN*

Background: Tumor-infiltrating lymphocytes (TILs) are significantly associated with clinical outcomes in patients with colon cancer. However, the potential for a differential effect of TILs on prognosis based on primary tumor sidedness has not been studied. We determined the interaction between TILs and tumor sidedness in relationship to disease-free survival (DFS). **Methods:** We analyzed data on TIL densities by primary tumor sidedness in 1532 stage III colon carcinomas from participants in a phase III trial of FOLFOX-based adjuvant chemotherapy (NCCTG N0147). TIL densities were dichotomized as low or high (≤3 /HPF) based on an optimized cut-off previously identified for DFS in this cohort. Right-sided tumors were defined as proximal to the splenic flexure. Analysis of TILs and sidedness with DFS were examined using Kaplan-Meier methodology and multivariable Cox regression. **Results:** Overall, tumors with high vs low TILs had the best DFS [HR_{adj}: 0.58 (95%CI: 0.45-0.74); P_{adj} <0.0001]. The association of TIL densities with 5-yr DFS differed significantly by primary tumor sidedness ($P_{interaction\ (adj)}$ = 0.045). Among right-sided tumors, high vs low TILs were significantly associated with improved DFS (P_{adj} <0.0001)[Table]. Among left-sided tumors, however, DFS did not differ significantly for high vs low TILs (P_{adj} =0.173)[Table]. Similar results for TILs and DFS by sidedness were found for pMMR cancers. We then analyzed our data in low risk (T_{1-3}, N_1) and high risk (T_4 and/or N_2) tumors. Among low risk tumors, high vs low TILs was significantly associated with improved 5-yr DFS only in right-sided tumors (P_{adj} =0.006) [Table]. Among high risk tumors, high vs low TILs were significantly associated with better DFS in both right-sided (P_{adj}<0.001) and left-sided (P_{adj} =0.024) tumors. **Conclusions:** Overall, tumors with high TIL densities had significantly better DFS in right-sided but not left-sided cancers. Among low risk patients, the association of high TILs with better DFS was limited to right-sided tumors. These findings suggest that TILs should be interpreted by sidedness for prognostication. ClinicalTrials.gov Identifier: NCT00079274. Disease-free survival for patients with colon cancer stratified by TILs and sidedness among overall population, high-risk patients, and low-risk cases.

Population	Tumor sidedness	5-year Free	Disease Survival	HR (95%CI)	P-value
		High TILs	Low TILs		
Overall	Right	77%	57%	0.50 (0.36-0.69)	<0.0001
	Left	76%	69%	0.77 (0.52-1.13)	0.173
Low risk	Right	84%	70%	0.48 (0.28-0.83)	0.006
	Left	79%	78%	0.97 (0.57-1.66)	0.914
High risk	Right	68%	44%	0.49 (0.32-0.75)	0.0004
	Left	71%	60%	0.54 (0.30-0.96)	0.024

Estimating the impact of reducing the age of colorectal cancer screening on cancer incidence, mortality, and costs in Canada using OncoSim. *First Author: Anastasia Kalyta, University of British Columbia Faculty of Medicine, Vancouver, BC, Canada*

Background: Organized colorectal cancer (CRC) screening programs currently cover Canadians aged ≥50 at average-risk of developing CRC and have contributed to declining CRC incidence. Rising incidence of early-onset CRC in individuals < 50 has led to lowering of the recommended screening start age to 45 rather than 50 in some jurisdictions. We used OncoSim, a publicly-available simulation tool, to model the effects of earlier screening initiation on Canadian CRC incidence, mortality and healthcare costs. **Methods:** OncoSim uses Canadian population and cancer registry data to simulate a representative sample of individuals from birth to death. We modeled four scenarios: no screening in average-risk individuals, screening initiation at age 50, initiation age lowered to 45 in 2022, and initiation age lowered to 40 in 2022. Each includes 32 million simulated participants. In the model, average-risk screening involves biennial FIT, available to all simulated participants regardless of family history with participation of 60% at the first recruitment attempt and 80% for repeat screening. Participants with a family history in all 4 scenarios were eligible for additional screening by colonoscopy every 5 years. **Results:** In our model, earlier screening yields reduced CRC incidence and mortality with increasing benefit over time. By 2051, screening initiation at age 45 or 40 reduces age-standardized incidence by 3.4% and 4.8% respectively, and age-standardized mortality by 3.3% and 4.6% respectively, compared to initiation at age 50. Screening initiation at age 45 yields 3,848 additional quality-adjusted life-years (QALYs) in 2051 at a cost of $9,350 per QALY gained and a 5% increase in colonoscopies performed. Initiation at age 40 yields 6,255 additional QALYs at $16,350 per QALY gained and a 9% increase in colonoscopies. The difference in screening costs compared to screening from age 50 is consistent year-to-year after 2024. In 2051 screening costs increase by $75mil and $155mil per year with initiation at ages 45 and 40 respectively, while costs of cancer management (including diagnosis, treatment, recurrence, palliative and end of life care) decrease by $42mil and $57mil respectively. **Conclusions:** Our model predicts that lowering the CRC screening initiation age for average-risk Canadians to 45 or 40 could reduce CRC incidence and mortality. Costs per QALY gained are high in the first few decades but decrease over time. Costs are modest after 30 years of screening compared to other life-preserving interventions such as dialysis. Our results suggest that lowering the screening age in Canada may be warranted, but further investigation is needed to assess capacity for increased colonoscopy demand. Research Sponsor: None.

Race, age, and sex differences on the influence of obesity on colorectal cancer (CRC) sidedness and mortality: A national cross-sectional study. *First Author: Mark Bilinyi Ulanja, CHRISTUS Ochsner St. Patrick Hospital, Lake Charles, LA*

Background: CRC sidedness has recently been recognized as a significant prognostic factor for survival; left-sided colorectal cancer (LCRC) is associated with superior outcomes as compared to right-sided colon cancer (rCC). Although obesity has long been recognized as a risk factor for CRC, the influence of obesity on CRC sidedness remains to be elucidated. To evaluate the effect of obesity on CRC sidedness and determine how race, age, and sex affect mortality among individuals with obesity and CRC. **Methods:** A survey-weighted analysis was conducted using data obtained from the National Inpatient Sample (NIS) between 2016 and 2019. **Results:** Of the 24,549 patient discharges included in the cohort with a diagnosis of CRC and a reported body mass index (BMI), 52.6% were LCRC and 47.5% were rCC. The race distribution was 67.7% White, 17.6% Black, 10.0% Hispanic, and 4.8% Other (American Indian, Asian, Pacific Islander, or Alaskan Native). Overweight and obese individuals were more likely to have rCC as compared to normal weight patient discharges [adjusted OR (aOR) = 1.28; 95% CI:1.17 – 1.39 and aOR = 1.45; 95% CI:1.37 –1.54, respectively). In addition, among the obese population, Blacks were more likely to have rCC as compared to Whites (aOR = 1.23; 95% CI: 1.09 – 1.38). Normal weight, overweight, and obese individuals in the "Other" race category had increased odds of death as compared to all other races (aOR=1.18; 95% CI:1.13-1.22; aOR=1.09 95% CI: 0.99-1.19; and aOR=1.19; 95% CI: 1.13-1.25, respectively). Overweight and obese patient discharges over the age of 65 years were more likely than their younger counterparts to present with rCC. As compared to males, females had a higher likelihood of presenting with rCC irrespective of weight, but lower mortality across all weight categories (Table). **Conclusions:** Obesity is associated with an increased risk of rCC. Racial disparities in CC sidedness and outcomes are particularly pronounced among the overweight and obese population. Investigation into causes of these disparities may help improve outcomes among all individuals with CRC. Research Sponsor: None.

Race, age, and sex effect on obesity and sidedness of colon cancer (right vs. left).

Clinical impact of DNA methylation status on first-line antiepidermal growth factor receptor treatment in patients with metastatic colorectal cancer. *First Author: Hiroki Osumi, Department of Gastroenterology, The Cancer Institute Hospital of the Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: The CpG island methylator phenotype (CIMP), important for carcinogenesis, is a predictor of prognosis and chemotherapy sensitivity in colorectal cancer. However, there is a lack of consensus of CIMP markers, and thus, more comprehensive methylation markers are required to reliably predict the clinical outcomes. Previously, we reported that genome-wide DNAmethylation statuscould predict the effect of epidermal growth factor receptor (EGFR) inhibitors more accurately than previously reported methylation classifications (Ouchi et al. Cancer Sci 2015). Moreover, we had developed a DNA methylation assay based on MethyLight to reflect genome-wide DNA methylation status and reported its usefulness in predicting prognosis in patients with metastatic colorectal cancer (mCRC) treated with EGFR inhibitors as a third-line chemotherapy (Ouchi et al. Cancer Sci 2022). This study aimed to clarify the effects of genome-wide DNA methylation status on clinical outcomes in patients with mCRC treated with first-line EGFR inhibitors. **Methods:** We enrolled 241 patients with mCRC, who received chemotherapy plus EGFR inhibitors as a first-line treatment, and analyzed the associations between genome-wide DNA methylation status using a novel comprehensive methylation marker panel and clinical outcomes and evaluated the predictive power and value of the methylation status. **Results:** Total 169 patients were included in the final analyses. The frequency of highly methylated CRC (HMCC) was 8.9% (15/169). The characteristics of patients with HMCC included right-sided primary tumor location (P = 0.042), undifferentiated histology (P = 0.047), and *BRAF*V600E mutation (P < 0.001). Patients with HMCC showed worse clinical outcomes than those with low methylated CRC in terms of response rate (P = 0.017), progression-free survival (PFS; P = 0.004), and overall survival (P = 0.019). In the multivariate analysis, peritoneal metastasis (Hazard ratio (HR): 2.24, P = 0.017), methylation status (HR: 3.04, P = 0.037), and *BRAF*V600E mutations (HR: 5.83, P = 0.0001) were independent factors for shorter PFS. **Conclusions:** Genome-wide DNA methylation status may be an independent predictor of first-line EGFR inhibitors in patients with mCRC. A secondary data analysis of colorectal cancer screening among males assigned at birth: Differences by sexual orientation and race/ethnicity. *First Author: Hui Xie, Zilber School of Public Health, University of Wisconsin-Milwaukee, Milwaukee, WI*

Background: We have limited information on CRC screening disparities in people of color (POC) with sexual minority identity. **Methods:** We analyzed the Behavioral Risk Factor Surveillance Survey (BRFSS) data of males assigned at birth age 50-75 years for up-to-date CRC screening. Descriptive analyses in demographics, socioeconomics, healthy behaviors, and CRC screening were conducted by race/ethnicity, followed by multivariable regressions to identify predictors of CRC screening stratified by race/ethnicity. **Results:** About 67.70% of eligible males reported having an up-to-date CRC screening that met the USPSTF guideline, with the highest rate among gay men (74.92%) and the lowest among bisexual men (65.35%; p = 0.0024). Non-Hispanic Whites had the higher rates of receiving CRC screening across all groups (p < 0.010). In the adjusted multivariable logistic models for NH-White males, gay men (1.52, 95% CI: 1.20-1.91), non-current smokers (1.56, 95% CI: 1.44-1.69), being overweight/obese (1.15, 95%CI: 1.07-1.23), and being physically active (1.08, 95%CI: 1.00-1.16) had greater odds of having CRC screening. Similar patterns were not found in Hispanic and non-Hispanic Black males. Gay men (3.88, 95% CI: 1.51-9.98) had greater odds of CRC screening in Hispanics, whereas being a non-current smoker (1.42, 95%CI: 1.13-1.79) was a significant factor in NH-Blacks. Health insurance coverage was a significant factor across all racial/ethnic groups. **Conclusions:** CRC screening disparities were most pronounced among racial/ethnic minority males. Future work on developing tailored CRC screening programs for racial/ethnic subgroups using an intersectional framework is warranted to elucidate observed heterogeneity across race/ethnicity and sexual orientation. Analysis of plasma angiogenesis factors on the efficacy of first-line (1L) chemotherapy (chemo) combined with biologics in *RAS* wild-type metastatic colorectal cancer (mCRC): Results from GI-SCREEN CRC Ukit study. *First Author: Satoshi Yuki, Department of Gastroenterology and Hepatology, Hokkaido University Hospital, Sapporo, Japan*

Background: Angiogenesis factors have been reported as prognostic and predictive biomarkers of angiogenesis inhibitors for mCRC (Weickhardt AJ. Br J Cancer 2015. Tabernero J. Ann Oncol 2018). We investigated whether plasma angiogenesis factors could predict the efficacy of biologics combined with chemo in 1L treatment in patients (pts) with *RAS* wild-type mCRC. **Methods:** Serial plasma samples were prospectively collected at the time points of pre- and post-treatments in mCRC pts receiving biologics in either 1L or 2nd-line (2L) chemo. From Sep 2017 to Dec 2020, 497 pts were enrolled [1L chemo plus bevacizumab (1L BEV, n=102), 1L chemo plus anti-EGFR antibody (1L aEGFR, n=100), 2L chemo plus bevacizumab (n=100), 2L FOLFIRI plus RAM (n=99), 2L FOLFIRI plus aflibercept (n=85) and other treatment (n=11)]. Total of 17 plasma angiogenesis factors (HGF, PlGF, VEGF-A, VEGF-D, Angiopoietin-2, IFN-γ, IL-6, IL-8, sNeuropilin-1, TSP-2, OPN, sVEGFR1, sVEGFR2, sVEGFR3, sICAM-1, sVCAM-1, and TIMP-1) were analyzed by the multiplex assay with Luminex® technology. Interactions of their pre-treatment measurements with treatment groups on PFS and OS were assessed via Cox proportional hazards model. The strength of interactions was estimated using a propensity score weighting analysis, and the continuous plasma angiogenesis variables were categorized according to the median. The significance level in the interaction was defined as p≤0.1. **Results:** 133 pts were included in adjusted *RAS* wild-type 1L cohort (1L BEV: n=33, 1L aEGFR [reference]: n=100). Baseline characteristics of adjusted *RAS* wild-type 1L cohort were as follows; median age 64 years; male 62.4%; left-sided tumor 88.7%; triplet chemo 15.0%. Propensity-score weighted Cox model for OS showed significant interactions in IL-8 (median 8.03 pg/mL, high: HR 1.738, p=0.0838, Low: HR 0.479, p=0.2624, interaction p=0.0283), sVEGFR-1 (median 1,350 pg/mL, high: HR 0.333, p=0.1770, Low: HR 1.311, p=0.3004, interaction p=0.0777), and sVCAM-1 (median 1,020,000 pg/mL, high: HR 0.100, p=0.0558, Low: HR 1.616, p=0.1765, interaction p=0.0011). In terms of PFS, there were significant interactions in IL-8 (high: HR 1.322, p=0.0418, Low: HR 0.517, p=0.0528, interaction p=0.0752) and sVCAM-1 (high: HR 0.285, p=0.0414, Low: HR 1.200, p=0.7725, interaction p=0.0156). **Conclusions:** Pre-treatment plasma IL-8 and sVCAM-1 could be predictive biomarkers for efficacy of biologics combined with chemo in 1L treatment of *RAS* wild-type mCRC. Clinical trial information: UMIN000028616. Research Sponsor: Japan Agency for Medical Research and Development.

Microbial translocation, toll-like and vitamin D receptor polymorphisms in blood and risk of recurrence in stage III colorectal cancer. *First Author: Ippokratis Messaritakis, Laboratory of Translational Oncology, School of Medicine, University of Crete, Heraklion, Greece*

Background: Microbial translocation from the intestinal lumen into the blood circulation is significantly linked to intestinal dysbiosis; thus, leading to colorectal cancer (CRC), disease progression and decreased survival. Toll-like (TLRs) and vitamin D receptors (VDRs) play essential role in immunity and gut microbiome determination. Polymorphisms in such receptors have been associated with increased CRC incidence risk and mortality. The aim was to evaluate the microbial translocation in the blood of stage III CRC patients and correlate the presence of TLR and VDR genetic variants with microbial DNA fragments at risk of CRC development and progression. **Methods:** A total of 132 stage III CRC patients and 100 healthy donors were enrolled in the study. Peripheral blood DNA was analyzed using PCR for the amplification of microbial DNA encoding 16S rRNA, β-galactosidase gene of *Escherichia coli*, glutamine synthase of *Bacteroides fragilis*, and *5*.8S rRNA of *Candida albicans*. Moreover, DNA from patients and controls was analyzed using PCR and PCR-RFLP for genotyping functional polymorphisms of both *TLR* (TLR2, TLR4, TLR9) and *VDR* (*Taq*I, *Apa*I, *Fok*I and *Bsm*I) genes. **Results:** Median age of patients was 62 years, 59.8% were males, 92.7% had a colon/sigmoid tumor, 24.4% had a right colon tumor and 99.2% had a good performance status. Microbial DNA fragments from 16S rRNA, *E. coli*, *B. fragilis,* and *C. albicans* were detected in 43.2%, 20.5%, 31.8% and 36.4% of patients, respectively. Significantly higher rates of all microbial fragments, but *E. coli*, were detected in the group of patients in comparison to healthy donors ($p < 0.001$). Similarly, higher rates of both TLR and VDR genetic variants were detected in CRC patients compared to healthy donors ($p < 0.001$). Moreover, individuals with homozygous mutant alleles of either TLR or VDR polymorphisms had significantly higher detection rates of microbial DNA fragments. *KRAS*, *BRAF* and MSI status were significantly correlated with TLR9 genetic variants ($p= 0.001$, $p= 0.013$ and $p= 0.011$, respectively) and MSI status was significantly correlated with all four VDR polymorphisms (*Taq*I, $p= 0.044$; *Apa*I, $p= 0.037$; *Fok*I, $p= 0.002$ and *Bsm*I, $p< 0.001$). Cox regression analysis revealed that *BRAF* mutations, histology type and *Apa*I genetic variants are significantly associated with shorter disease-free survival (DFS). *C. albicans* detection is significantly associated with shorter overall survival, and *B. fragilis* is an independent poor prognostic factor for decreased DFS (HR = 33.85; $p = 0.018$). **Conclusions:** The detection of higher frequencies of the *TLR*/*VDR* genetic variants was correlated with significantly higher detection rates of microbial DNA fragments. The detection of these TLR/VDR polymorphisms and microbial DNA fragments in CRC patients highlighted their role in cancer development, progression, and patients' survival. Research Sponsor: None.

Metagenomic analysis of the fecal microbiome in patients with colorectal cancer compared to healthy controls as a function of age. *First Author: Jordan Kharofa, University of Cincinnati Cancer Center, Cincinnati, OH*

Background: Colorectal cancer (CRC) incidence is increasing in young patients (< 50 years old) without a clear etiology. Emerging data has implicated the fecal microbiome in CRC carcinogenesis. However, its impact on young onset CRC (YO-CRC) is poorly defined. Colibactin producing *E. Coli* and fadA producing *Fusobacterium nucleatum* can drive CRC carcinogenesis, however their effects across the age spectrum are unknown. **Methods:** We performed a meta-analysis of fecal metagenomics sequencing from n = 692 patients with CRC and n = 602 healthy controls from eleven studies to evaluate species and known microbial derived factors (colibactin and FadA) associated with CRC as a function of age. Generalized linear mixed effects regression was used to model the predicted prevalence of gene families and taxa as a non-linear function of age. Two-stage individual patient data meta-analysis (IPDMA) with adjustment for gender, CRC status, and body mass index was also used to estimate summary odds ratios for colibactin, *F. nucleatum,* and *E. Coli*. Interaction ORs were obtained to assess the difference in the effect of each gene or taxa on CRC case status in YO-CRC. Shannon Diversity index and metabolic pathway differences in the fecal metagenome for YO-CRC patients were assessed using phyloseq and MetaCyc respectively using an IPDMA approach. **Results:** Summary odds ratios (OR) for CRC were increased relative to controls with the presence of colibactin (OR 1.92 95%CI 1.08-3.38), fadA (OR 4.57 95%CI 1.63-12.85), and *F. nucleatum* (OR 6.93 95%CI 3.01-15.96) in models of all patients adjusted for age, gender, and body mass index. The OR for CRC for the presence of *E.coli* was 2.02 (0.92-4.45). An increase in the prevalence of *F. nucleatum* (OR = 1.40 [1.18; 1.65] and *Escherichia coli* (OR = 1.14 [1.02; 1.28]) per 10-year increase *in age* was observed in models including samples from both CRC and healthy controls. No difference was observed for Shannon Diversity (OR 1.36 95%CI 0.68-2.72) or MetaCyc pathways in YO-CRC patients. Species relative abundance was differentially enriched in YO-CRC relative to old CRC patients and controls for five species-*Intestinimonas butyriciproducens, Holdemania filiformis, Firimicutues bacterium CAG 83, Bilophilia wadsworthia, and Alistipes putredinis.* **Conclusions:** Strong associations with CRC status were observed for colibactin, fadA, and *F. nucleatum* with *increased F. nucleatum* in older patients. Several species were enriched in YO-CRC patients including *B. wadsworthia* which can produce carcinogenic sulfur metabolites and is increased with adherence to a sulfur microbial diet-low in vegetables and legumes. A sulfur microbial diet has also been associated with higher incidence of YO-CRC in population studies (Nguyen *Gastroenterology* 2021). Additional study is warranted to understand causal mechanisms of enriched species observed in YO-CRC patients. Research Sponsor: None.

Clinical and genomic distinction of class 1/2/3 *BRAF*-mutant colorectal cancer and differential prognosis. *First Author: Yungchang Chen, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China*

Background: Mutations occurring at the V600 amino acid of *BRAF* is the most common *BRAF* mutations in colorectal cancer (CRC), which lead to RAS-independent active monomers (Class 1) and are the targets of BRAF inhibitors. *BRAF* non-V600 mutants can be further classified as RAS-independent active dimers (Class 2) and RAS-dependent impaired kinase (Class 3). The clinical and genetic distinction of CRC patients carrying different subtypes of *BRAF* mutations remain to be revealed. **Methods:** A multicenter retrospective study investigated the mutational profiles of 2,118 CRC patients whose baseline tumor samples were analyzed between June 2015 and June 2020 using capture-based hybrid NGS targeting 400+ cancer-related genes. Clinical characteristics including age, sex, stage, and tumor location were analyzed. A public cBioPortal cohort of 471 metastatic CRC patients was used for survival analysis. **Results:** A total of 473 patients were identified to contain *BRAF* mutations and can be sub-grouped into Class 1 (N = 246), Class 2 (N = 29), Class 3 (N = 53), and others (N = 145). All Class 1 *BRAF* mutations were V600E, while the Class 2 and Class 3 mutations were predominantly G469 (52%) and D594 (56%), respectively. No difference in patient's age, sex, and stage was observed among *BRAF* Class 1-3 subgroups, but the anatomical location of the tumor differed among subgroups, particularly between Class 1 and Class 3 *BRAF*-mutant patients significantly (p = 0.027). Specifically, 39% of tumors carrying Class 1 mutations occurred at the right colon, while the most frequent location of tumors with Class 3 mutations was rectum (58%). Mutational profiling revealed that *KRAS* and *APC* mutations were enriched in Class 2/3 compared to Class 1 *BRAF*-mutant patients, while *RNF43* and *SMAD4* mutations were more frequently observed in Class 1 patients. Mutations causing the activation of the Wnt or RTK/RAS signaling pathways were also more common in Class 2/3 subgroups comparing to Class 1 patients. Furthermore, based on the analysis of mutation allele frequency, Class 1 *BRAF* mutations tended to be drivers while Class 2/3 *BRAF* mutations were more likely to be passengers. In addition, mutational signature profiling showed that the NER signature was enriched in Class 1 *BRAF*-mutant patients but the APOBEC signature in Class2/3 classes. The tumor mutational burden of Class 2 *BRAF* tumors was higher than the other two subgroups (median: 10.4 vs 7.6 and 8.4), and microsatellite instability-high tumors were more common in Class 1 (11% vs 7% and 4%). In the cBioPortal cohort, Class 1 *BRAF*-mutant patients had the worst overall survival whereas Class 3 patients demonstrated the best prognosis. **Conclusions:** The clinical and genetic features of CRC patients harboring Class 2 and 3 *BRAF* mutations were different from those carrying Class 1 *BRAF* mutations in aspects including tumor location, concurrent mutations, mutational signatures, as well as survival outcomes. Research Sponsor: None.

Clinical outcomes of immune checkpoint inhibitor (ICI) therapy among Veterans Affairs patients with colorectal cancer and discordant dMMR/MSI-H status. *First Author: James Isaacs, Duke University, Durham, NC*

Background: Clinical trials have demonstrated improvements in survival with immune checkpoint inhibitors (ICIs) for advanced colorectal cancer patients with MSI-H/dMMR detected using PCR-based assays (PCR) or immunohistochemistry (IHC), respectively. MSI-H can also be assessed by next-generation sequencing (NGS). Evaluation of real-world outcomes among MSI-H patients by NGS treated with ICIs are warranted, particularly when results are discordant between these tests. **Methods:** The VA National Precision Oncology Program Database was accessed to select veterans with colorectal cancer and an MSI-H biomarker by NGS. Baseline patient variables, disease characteristics, and duration of ICI treatment were obtained from the VA's Corporate Data Warehouse. Concordance between NGS and IHC or PCR testing was computed, and the response rate and duration of ICI treatment in patients with discordant test results were recorded from chart review. **Results:** Among 1,276 colorectal cancer patients, 71 (5.6%) were found to have MSI-H by NGS. Of these, 22 (30.1%) received ICI. Among 49 patients who did not receive ICI, 36 had stage I-III disease, 5 had limited performance status, 5 were actively being treated with chemotherapy and 3 had completely resected stage IV disease. Of the 71 patients, 29 had dMMR IHC testing, 8 had MSI-H PCR testing, 1 had both IHC and PCR testing, and 34 patients had only NGS testing. No PCR tests were discordant with NGS but 8 of 29 IHC tests were discordant. Among these 8 patients with discordant IHC MMR and MSI-H by NGS, 5 received pembrolizumab. There were 3 partial responses, 1 stable disease and 1 progressive disease. Durable responses were seen with 3 of 5 patients remaining on therapy without progression at the time of this analysis at a median follow up of 8.5 months. **Conclusions:** In a cohort of NGS MSI-H colorectal cancer patients, there was a high rate of discordant IHC results. Clinical benefit is seen in patients treated with ICI with discordant testing results, suggesting that NGS testing identifies patients with false negative dMMR IHC testing in the real-world clinical setting. Research Sponsor: U.S. National Institutes of Health.

Molecular characteristics of advanced colorectal cancer and multi-hit *PIK3CA* mutations. *First Author: Michael Cecchini, Yale Cancer Center, New Haven, CT*

Background: Approximately 20% of colorectal cancer (CRC) has an activating mutation in the *PIK3CA* oncogene. *PIK3CA* codes for the catalytic subunit of phosphoinositide 3-kinase alpha (PI3Kα), which ultimately activates the AKT and mammalian target of rapamycin (mTOR) pathway. The PI3Kα inhibitor alpelisib has been approved for breast cancer where a single *PIK3CA* activating mutation is sufficient for response. However, two activating mutations (multi-hit) in the *PIK3CA* allele substantially increases PI3Kα signaling compared to single hot spot mutations and results in exceptional response to PI3Kα inhibition. We aimed to identify the prevalence of *PIK3CA* multi-hit mutations in CRC to identify patients potentially susceptible to PI3K inhibitors. **Methods:** Tissue-based comprehensive genomic profiling (CGP) was performed in a Clinical Laboratory Improvement Amendments (CLIA)-certified, CAP (College of American Pathologists)-accredited laboratory (Foundation Medicine Inc., Cambridge, MA, USA) on all-comers during the course of routine clinical care from 2013-2021. Approval was obtained from the Western Institutional Review Board (Protocol No. 20152817). Hybrid capture was carried out for at least 324 cancer-related genes, including *PIK3CA*. **Results:** We identified 48,836 patients with advanced CRC who underwent Foundation Medicine testing and 846 (1.7%) patients with multi-hit *PIK3CA* mutations. Additional clinical and molecular data was available for 41,154 of these patients of which 710 (1.7%) had multi-hit *PIK3CA* and 7627 (19%) had any deleterious *PIK3CA* mutation. The local colon tumor was used for sequencing in 70% of cases and a separate site in 30% of cases. Patients with *PIK3CA* multi-hit mutations were 53% male with a median age of 60 (interquartile range 50-70). The microsatellite status was available for 697 of 710 patients with multi-hit *PIK3CA* and 123/697 (18%) were microsatellite instability-high. The Table outlines the genes with cooccurring mutations of >10% prevalence for multi-hit *PIK3CA* CRC, including the clinically relevant mutations in KRAS (65%) and BRAF (13%). The four most common *PIK3CA* variants were H1047R (9.8%), E545K (9.2%), E542K (9.0%) and R88Q (7.1%). The most common variant pair was E542K with E545K in 4.7% of multi-hit cases. **Conclusions:** Double-hit mutations in *PIK3CA* are seen in 1.7% of advanced CRC patients and may represent a subset of patients that may have enhanced sensitivity to PI3K inhibitors. Given the high prevalence of CRC in the United States and worldwide this represents a clinically meaningful prevalence of multi-hit *PIK3CA*. Future investigation on the clinical utility of PI3K inhibitors may be warranted in multi-hit *PIK3CA* CRC. Research Sponsor: Foundation Medicine.

Negative hyperselection for mutations associated with anti-EGFR antibody resistance in *RAS* wildtype metastatic colorectal cancer (mCRC): Evaluation of the PANAMA trial (AIO-KRK-0212, maintenance therapy with 5-FU, folinic acid (FU/FA) with or without panitumumab). *First Author: Andreas Kind, Department of Hematology, Oncology and Cancer Immunology (CCM), Charité-Universitätsmedizin Berlin, Freie Universität Berlin, Humboldt-Universität zu Berlin and Berlin Institute of Health, Berlin, Germany*

Background: We evaluated the prognostic and predictive impact of DNA mutations related to anti-EGFR antibody resistance in patients of the PANAMA trial, which compared Panitumumab (Pmab) and FU/FA versus FU/FA maintenance therapy after Pmab-FOLFOX induction therapy in *RAS* wild-type (wt) mCRC. **Methods:** Next generation panel sequencing was conducted on 201 of 248 tumors obtained prior to study inclusion from the full analysis set using the Cancer Hotspot Panel v2 on an Illumina MiSeq system. Hyperselection covered mutations of the following genes: *KRAS, NRAS, BRAF, HER2, PTEN, AKT1, PIK3CA.* Median progression-free (PFS) and overall survival (OS) since start of maintenance were estimated by Kaplan-Meier and Cox-regression (log rank test). Objective response rates (ORR) of maintenance therapy were compared by Chi-square-test. **Results:** From 201 tumors, 41 (20.4 %) carried at least one mutation: *KRAS:* 7 (3.5%), *BRAF:* 23 (11.4%), *PTEN:* 4 (2.0%), *AKT1:* 2 (1.0%), *PIK3CA:* 12 (6.0%), with 6 tumors harboring co-occuring mutations. No mutations were found in NRAS and HER2. Negative hyperselection (wt for all genes) was associated with (numerically) favourable prognosis in terms of PFS (HR 0.79 (95% CI 0.55 – 1.12), p=0.184), OS (HR 0.61 (95% CI 0.40 – 0.95), p=0.028) and ORR (39.4% vs. 29.3%, p=0.279). The benefit of adding Pmab to FU/FA during maintenance was limited to the hyperselection wt subgroup, with significantly longer PFS (9.9 vs. 6.0 months, 0.64 (95% CI 0,46 – 0.90), p = 0.011), numerically longer OS and significantly higher ORR (49.4% vs 26.6%, p=0.009) compared to FU/FA (Table). **Conclusions:** Mutations related to resistance concerning anti-EGFR antibodies were detected in 41 of 201 (20.4%) of analysed tumors and associated with a worse prognosis compared to hyperselected wt tumors. Negative hyperselection may aid in the identification of patients with relevant benefit from maintenance therapy including Pmab. Consensus molecular subtypes (CMS) as prognostic and predictive biomarkers of panitumumab (Pmab), fluorouracil and folinic acid (FU/FA) or FU/FA maintenance therapy following Pmab-FOLFOX induction in *RAS* wildtype metastatic colorectal cancer (mCRC): PANAMA trial (AIO-KRK-0212). *First Author: Beeke Hoppe, Charité - Universitaetsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Hematology, Oncology and Tumor Immunology, Berlin, Germany*

Background: Consensus molecular subtypes (CMS1-4) of colorectal cancer were evaluated as prognostic and predictive biomarkers in the PANAMA trial. PANAMA compared maintenance therapy with panitumumab (Pmab) and fluorouracil/folinic acid (FU/FA) vs. FU/FA alone after Pmab-FOLFOX induction therapy in RAS wildtype mCRC. **Methods:** Gene expression was measured after mRNA isolation in 179 of 248 patients of the full analysis set. The analysis was conducted using a customized Nanostring PanCancer Progression Panel. The original CMS classifier was re-derived for Nanostring data using a multinomial regression analysis.Median progression-free (PFS) and overall survival (OS) since start of maintenance were estimated by Kaplan-Meier-method and Cox-regression, using the log rank test. Objective response rates (ORR) of maintenance therapy were compared by Chi-square-test. **Results:** Prevalence of CMS was: CMS1, n = 15 (8.4 %); CMS2, n = 82 (45.8 %); CMS3, n = 20 (11.2 %) and CMS4, n = 62 (34.6 %). A prognostic impact of CMS regardless of treatment was not evident for PFS (p = 0.245) and OS (p = 0.169), but for ORR (p = 0.022), with CMS1 and CMS3 being associated with unfavourable efficacy during maintenance therapy. Potential predictive effects of CMS were observed in patients with CMS2 and CMS4 tumours. In CMS2 and CMS4 tumours, ORR was significantly higher when treated with Pmab-FU/FA in maintenance therapy (CMS2: 56.5% vs 30.6%, p = 0.026; CMS4: 55.6% vs. 28.6%, p = 0.040). In patients with CMS2 mCRC, this translated into a significant effect on PFS (Hazard ratio: 0.61 (95% CI 0.38 – 0.99) p = 0.046 (Table). **Conclusions:** CMS have limited prognostic impact for pmab-based maintenance therapy. However, CMS2 and CMS4 are positively associated with Pmab efficacy during maintenance therapy in the PANAMA trial. Further trials are necessary to confirm these results. Comprehensive characterization of *PTPRT* expression in colorectal cancer (CRC). *First Author: Francesca Battaglin, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: *PTPRT* is a protein coding gene involved in signal transduction and cellular adhesion. It acts as a tumor suppressor gene and mutated *PTPRT* has been implicated in the early metastasis of CRC. *PTPRT* mutations have been reported as independent potential biomarkers for bevacizumab resistance in metastatic CRC and linked to improved response and survival of patients treated with checkpoint inhibitors in several tumors. Here we characterized the molecular features and clinical outcomes associated with *PTPRT* gene expression in CRC. **Methods:** 15025 CRC tested with NextGen Sequencing on DNA (592 genes or WES) and RNA (WTS) by Caris Life Sciences (Phoenix, AZ) were analyzed. Top quartile transcripts per million for *PTPRT* expression were considered high (H) and bottom quartile low (L). Cell infiltration in the tumor microenvironment (TME) was estimated by QuantiSEQ. X^2, Fisher-Exact, Mann-Whitney tests were used and significance determined as *P*-value adjusted for multiple comparisons ($Q < .05$). Real world survival was obtained from insurance claims data and Kaplan-Meier estimates were calculated for molecularly defined patients. **Results:** *PTPRT* expression was higher in left- than right-sided CRC and in metastases than primary/local tumors; it was highest in CMS4 and lowest in CMS1 (all $Q < .05$). *PTPRT* mutants had lower expression than wild type (0.037 vs 0.064, Q < .05). Overall, *PTPRT*-H had a lower rate of TMB-H (5% vs 17%), deficient mismatch repair (dMMR) (3% vs 13%) and PD-L1 (2% vs 6%) (H vs L, all $Q < .05$). In the proficient MMR (pMMR) cohort, *PTPRT*-H remained inversely correlated with TMB and PD-L1, was negatively associated with rates of mutated *KRAS*, *PIK3CA*, *SMAD4*, *FBXW7*, and positively associated with mutated *TP53* and *CDX2* amplification (all $Q < .05$). Expression of immune related genes was higher in *PTPRT*-H CRC, including *CD274*, *CD80*, *CD86*, *CTLA4*, *HAVCR2*, *IDO1*, *IFNG*, *LAG3*, *PDCD1*, and *PDCD1LG2*, regardless of MMR status (all $Q < .05$). *PTPRT*-H was associated with higher immune cell infiltration in the TME including B cells, M2 macrophages, neutrophils, NK, Tregs, CD4+ and CD8+ T cells, and myeloid dendritic cells (fold change/FC: 1.21-7.1), but lower M1 macrophages (FC: 0.76), regardless of MMR status (all $Q < .05$) with the only exception of CD8+ T cells in dMMR. *PTPRT* expression above median was associated with better OS (overall: HR 0.69, 95% CI [0.64-0.74]; pMMR: HR 0.67 [0.63-0.73]), longer time on treatment of bevacizumab (overall: HR 0.80 [0.74-0.87], pMMR: HR 0.80 [0.74-0.87]), and shorter time on immunotherapy treatment in the dMMR cohort (HR 2.13 [1.33-3.45]). **Conclusions:** Our data show a strong association between *PTPRT* expression and distinct molecular features (including CMS and immune biomarkers), TME cell infiltration and targeted treatment outcomes in CRC. These findings support *PTPRT* as a candidate prognostic and predictive biomarker for bevacizumab and immunotherapy treatment, and as a potential target in CRC. Discovering colorectal cancer biomarkers with individual fragments analysis of cell-free DNA using attention-based deep multi-instance learning. *First Author: Eunsaem Lee, Amsquare, Pohang-si, Gyeongsangbuk-do, South Korea*

Background: Cell-free DNA(cfDNA) are DNA fragments circulating in blood stream. Among these fragments, there are tumor-derived DNA(ctDNA) fragments which can be a significant biomarker for cancer diagnostics. Recently, there are evidences that reveals methylation patterns of ctDNAs facilitate statistical models to diagnose cancers with plausible accuracy than mutation patterns. Despite of such promising facts, an early detection of cancers with methylation patterns of ctDNAs is still statistically difficult since proportion of ctDNAs to cfDNAs is marginal. As a result, it is difficult to set differential threshold on ctDNA proportion to successfully classify early cancer patients. For such a reason, we develop a high-throughput classifier whose classification resolution is per-fragment unlike per-batch approach in existing models. **Methods:** Targeted methylation sequencing was performed with DNA extracted from plasma cfDNA of 141 colon adenocarcinoma (COAD) patients and 200 healthy individuals. To extract DNA fragment-level methylation status, we profiled the methylation status using Bismark software and home-built python scripts were used to recover methylation status of DNA fragments. We implement an attention based multi-instance learning model which is permutation-invariant with fragments to analyze the impact of individual fragments on COAD prediction. Our models were trained using k-fold cross-validation and to assess generalization performance. **Results:** We first trained on local differentially methylated regions (DMRs) that contain 80 to 200 CpG sites using our deep learning model. With a single local region, we achieved a mean sensitivity of 87.2% (mean 95% CI 75.8–93.2%) at 97.7% (mean 95% CI 88.3–99.1%) specificity. By analyzing attention weights, we scored on each fragment according to the model contribution to predicting cancers. To find biomarkers, we added up scores according to methylation of each CpG site. Top 10 high scored CpG sites were validated with tissue sample DNA and almost all of them are overlapped with the 10 CpG sites with the highest statistical differences between cancer and normal tissue in the region. For the global region analysis, we combined local DMRs to confirm collaboration between distant regions and other chromosomes in the colorectal cancer prediction. We achieved a mean sensitivity of 93.4% (95% CI 80.1–98.1%) at 98.3% (95% CI 90.4–99.3%) specificity for the global region prediction. **Conclusions:** Our study shows a potential of targeted sequencing cell-free DNA as a cancer biomarker. An attention based deep learning model allowed for the analysis of individual fragments and showed the potential for biomarker discovery. The model uses only cell-free DNA and excludes tissue sample DNA, which makes our model less sensitive to the tumor heterogeneity. Research Sponsor: AMSquare, Pharmaceutical/Biotech Company.

The clinical relevance of tumor RAS/TP53 dual mutation in early and metastatic colorectal cancer (CRC). *First Author: Jenny F. Seligmann, University of Leeds, Leeds, United Kingdom*

Background: The relevance of individual RAS (KRAS and NRAS) and TP53 mutations in CRC is well described, but the impact of the combination of both mutations together is less understood. RAS/TP53-mutant (mut) patients (pts) were selected in FOCUS 4-C for treatment with Adavosertib (Wee1 inhibitor) due to hypothesised sensitivity due to replication stress and loss of cell cycle checkpoint control. Initial analyses in CRC suggest that RAS/TP53-mut pts may be prognostically distinct from either mutation alone. Here we examine the impact of RAS/TP53-mut status in both early stage and metastatic CRC (mCRC). **Methods:** RAS and TP53 mutational status were assessed by whole gene targeted NGS or PCR in hotspot regions. Pts with RAS/TP53 status in the following studies were included after exclusion of BRAF-V600E mutants and MSI-H cases: for early-stage, QUASAR2 trial (N = 408) and an Australian community cohort (N = 654); for mCRC, FOCUS (N = 373) and FOCUS4 (N = 721). Biomarker prevalence, clinical characteristics and outcome data in the RAS/TP53-mut group were compared to pts not showing dual RAS/TP53-mut. **Results:** The prevalence of RAS/TP53-mut was greater in mCRC compared to early CRC (43.9% vs 25.4% respectively, $p < 0.001$). In early-stage (II & III) cohorts combined, RAS/TP53-mut pts were more likely to be female, have a right-sided primary tumour, and involved lymph nodes. In early CRC RAS/TP53-mut pts had worse outcome: DFS HR = 1.49[1.19-1.88], p = 0.001, and OS HR = 1.48[1.16-1.89], p = 0.001. In FOCUS, RAS/TP53-mut mCRC pts had inferior PFS with 1st line chemotherapy than not dual RAS/TP53-mut: 6.9 vs 8.6 months (HR = 1.44[1.17-1.79], p = 0.001), and also shorter post-progression survival (HR = 1.49, p = 0.001), and overall survival (14.9 vs 18.9 mths [HR = 1.60, $p < 0.0005$]). Consistently, during 16 weeks of induction chemotherapy for mCRC pts in FOCUS4, 27.4% of RAS/TP53-mut pts had progressive disease, compared with 18.4% in not dual RAS/TP53-mut; PFS from study registration was reduced in RAS/TP53-mut (5.3 vs 6.1 mths;HR = 1.53[1.22-1.94],$p < 0.001$), but no statistically significant difference in OS (13.6 vs 17.6 mths;HR = 1.27,p = 0.23). Outcomes by each of the four biomarker groups (RAS/TP53 dual mut; RASwt/TP53mut; RASmut/TP53 wt; RAS/TP53 dual wt) will be presented but in all cases the dual mut subgroup had the worst outcomes compared to the other three groups, marginally better than BRAF-V600E CRC. **Conclusions:** RAS/TP53 dual mutation status provides useful and readily available prognostic information in both early and mCRC, independent of MSI and BRAF status. It is associated with increased risk of recurrence in early CRC, and a higher risk of chemotherapy resistance and inferior outcomes in mCRC. Evaluation of treatment strategies in this sizeable patient group and further understanding of the underlying mechanism of poor outcomes are urgently required. Research Sponsor: None.

Cell-free DNA (cfDNA) fragmentomes predict tumor burden in metastatic colorectal cancer (mCRC). *First Author: Alessandro Leal, Delfi Diagnostics, Inc., Baltimore, MD*

Background: Measurement of plasma mutant allele fraction (MAF) in patients with cancer provides prognostic information, but this approach typically relies on prior tumor tissue analyses or knowledge of specific mutations. There is a clinical need to develop rapid and accurate noninvasive plasma-only approaches to estimate disease burden dynamics. Comprehensive genome-wide analyses of cfDNA fragmentomes has become a useful tool for noninvasive cancer characterization. Here we present a novel application to predict MAF from genome-wide fragmentation-related profiles (fMAF) as a prognostic marker in mCRC patients with initially unresectable liver-only metastases enrolled in the phase III CAIRO5 study (NCT02162563). **Methods:** 693 longitudinal plasma cfDNA samples were obtained from patients with RAS/BRAF-mutant mCRC (training arm, N = 78) and patients with RAS/BRAF wild-type mCRC (validation arm, N = 75) treated with first-line fluoropyrimidine-based chemotherapy were collected. MAFs as measured by digital droplet PCR (ddPCR) were obtained for patients in the training arm. We trained an initial regression model to predict MAFs with genome-wide fragmentation features using subject-level random intercepts. Out of sample predictions for participants in the RAS/BRAF-mutant mCRC arm were obtained through cross-validation. Cox proportional hazards models were used to evaluate the association between fMAF and PFS and overall survival (OS) at pre- and first post-treatment blood draws. Standardized hazard ratios (sHR) and 95% confidence intervals (CI) are reported. **Results:** There were 68 and 61 evaluable participants with median (range) age of 62 y (41-79 y) and 58 y (27-76 y), and 38% and 36% female in the training and testing arms, respectively. Median time between pre- and post-treatment blood draw was 8 weeks. In the training cohort, median fMAFs dropped from pre- to post-treatment initiation (17.8% to 1.8%). Median PFS was 9 months. For both fMAFs and RAS/BRAF MAFs, the association with PFS was stronger for the pre-treatment than the post-treatment timepoint (Table). Post-treatment fMAFs were not associated with PFS in the training cohort and similar trends were observed for OS. **Conclusions:** Initial modeling demonstrates the ability of cfDNA fragmentomes to estimate cell-free DNA tumor burden with performance comparable to standard approaches. Ongoing modeling efforts will result in evaluation of a final model in the testing arm. The development of a noninvasive tissue-independent diagnostic approach that does not rely on mutation detection in the circulation has the potential to expand the use of liquid biopsies for advanced disease monitoring. Clinical trial information: NCT02162563. Research Sponsor: Roche.

		fMAF (Training Arm)	MAF (Training Arm)
		sHR (95% CI)	sHR (95% CI)
Pre-treatment	PFS	1.23 (0.96 to 1.58)	1.51 (1.16 to 1.97)

Development of a highly sensitive multicancer, targeted, cell-free DNA epigenomic assay for integrated screening of lung and colorectal cancer. *First Author: Anton Valouev, Guardant Health, Palo Alto, CA*

Background: Cancer screening in asymptomatic individuals who meet guideline criteria has yielded reductions in cancer death rates. However, adherence to screening guidelines remains below targets set forth by leading health-care organizations. A blood-based multi-cancer screening assay with clinically meaningful sensitivity and specificity, in cancer types where early detection and intervention can save lives, that is integrated with existing clinical pathways may increase access to and adherence with guideline recommendations, ensuring more individuals benefit from these proven interventions. We evaluated the performance of a blood-based multi-cancer screening assay that interrogates cell-free DNA (cfDNA) methylation signatures for cancer detection and tissue of origin prediction in a set of tumor types where cancer screening can save lives. **Methods:** Whole blood from 1,607 individuals with and 3,298 individuals without cancer was obtained from multiple unique cohorts. Plasma-derived cfDNA was profiled using a custom assay that enriches fragments with dense CpG methylation and further depletes uninformative background molecules containing unmethylated CpGs. We utilized a broad genomic panel (16 Mb) targeting regions with low rates of methylation in individuals without cancer. The panel captures tumor-associated molecules and allows for high sensitivity of detection at low sequencing costs. A cross-validated analysis was used to estimate the performance of the predictive model upon the sample set. Classification thresholds corresponding to 90%, 95%, and 98% specificities were established using samples from individuals without a cancer diagnosis. **Results:** At 90% specificity, overall sensitivity for lung cancer detection was 92.1% (95% CI: 80-100%; 90.2% in Stage I/II disease (N = 82) and 93.1% in Stage III/IV disease (N = 159)) and 93.1% (CI: 88-98%) for CRC detection (92% in Stage I/II disease (N = 743) and 94.5% in Stage III/IV disease (N = 623)). Tissue of origin prediction evaluated at 98% specificity yielded accurate identification in 99% of CRC and 98% of lung cancers. Lung cancer histology was known for approximately 74% of the cohort. Across Stage I – IV cancers, at 90% specificity, sensitivity was 97.3% in lung squamous cancer (N = 73) and 86.8% in lung adenocarcinoma (N = 106). At 95% and 98% specificity thresholds, overall sensitivity was 86.3% (CI: 75-98%) and 66.4% (CI: 56-77%) for lung cancer and 85.7% (CI:81-91%) and 71.6% (CI: 67-76%) for CRC, respectively. **Conclusions:** This blood-based multi-cancer screening assay yields clinically meaningful sensitivity and specificity for early-stage cancers. This assay is undergoing further development to expand detection capabilities to additional cancer types where screening can save lives. Clinical evaluation in registrational screening trials is ongoing (SHIELD; NCT05117840). Research Sponsor: Guardant Health.

A tumor immune microenvironment-related lncRNA signature for the prognosis and immunotherapeutic sensitivity prediction in colorectal cancer. *First Author: Chuling Hu, Department of Colorectal Surgery, The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China*

Background: As important molecules in the CRC tumor microenvironment (TME), long non-coding RNAs (lncRNAs) regulate the functions of tumor infiltrating immune cells and sculpt the tumor immune microenvironment (TIME), resulting in difference in survival and response to immunotherapy among CRC patients. However, challenges remain in selecting TIME related lncRNAs (TIME-lncRNAs) of prognosis value and stratifying CRC patients for immunotherapy. Here, the aim of our study was to develop a CRC TIME-lncRNAs signature to provide survival and immunotherapy response predictions. **Methods:** Gene expression profiles and clinical information of CRC cases (n = 1807) were collected from 7 datasets and divided into training cohort (n = 519) and two testing cohorts (n = 595 and 693, respectively). Utilizing gene expression data of 97 immune cell lines and 61 CRC cell lines, differential expression analysis was used to identify TIME-lncRNAs. Univariate Cox regression and LASSO regression analysis were used to establish a TIME-lncRNAs signature to predict the prognosis of CRC patients. To further investigate the model, multivariate Cox regression, lncRNA-mRNA regulation analysis, gene enrichment analysis and immune infiltration analysis were carried out. The immunotherapy response predicting ability of the model was verified with an independent immunotherapy dataset. **Results:** Integrating the expression profiles of 10 TIME-lncRNAs, the model stratified CRC patients into low and high-score groups. Patients of the low score group had significantly prolonged survival in both training (hazard ratio (HR) = 2.63, 95% confidence interval (CI) = 1.9-3.63, $P < 0.001$) and testing cohorts (testing cohort 1: HR = 1.6, 95% CI = 1.19-2.16, $P = 0.002$; testing cohort 2: HR = 1.64, 95% CI = 1.19-2.26, $P = 0.002$), while higher tumor purity and less pro-tumor immune cells infiltration were also observed in the low score group. Further investigation showed that both genes differentially expressed between different groups and mRNAs regulated by 10 lncRNAs of the signature were enriched in immune-related and immunotherapy-related pathways. Multivariate Cox regression indicated that the TIME-lncRNAs signature was an independent prognosis factor. Validated with external immunotherapy dataset, the signature provided distinct predictions for patients' responses to PD-L1 inhibitor therapy, suggesting cases of high score group could benefit more from immunotherapy. **Conclusions:** Based on the expression of 10 lncRNAs in the TIME, the signature makes predictions for patients' survival and immunotherapy responses, which could help in stratifying CRC patients for immunotherapy at the bedside. Survival outcomes following colorectal cancer surgery in low- and middle-income countries: A systematic review. *First Author: Tom M. Diehl, University of Wisconsin Hospitals and Clinics, Madison, WI*

Background: Colorectal cancer (CRC) is a surgical disease that ranks among leading causes of global deaths, but little is known about survival outcomes following CRC surgery in low- and middle-income countries (LMICs). In this study, we sought to review all published literature on long-term outcomes following CRC resections in LMICs. **Methods:** We completed a systematic review of original research articles presenting survival outcomes after CRC resection with curative intent in LMICs. Databases searched included PubMed, Web of Science, Embase, and Global Index Medicus. Country income groupings were determined by 2020 World Bank data. We excluded articles involving pediatric populations (<18 years), non-primary colorectal cancers, benign disease, and endoscopic/transanal resection only. Articles published before 2005 or without English full text were also excluded. Abstracts and full texts were assessed for eligibility by two independent reviewers; conflicts were resolved by a third reviewer. Data from China dominated the published literature and were excluded from final analysis. Survival data were extracted for 5-year disease free survival (DFS) and overall survival (OS). **Results:** Our search returned 29,134 articles. After automated and manual deduplication, 18,849 abstracts were assessed for eligibility. Following abstract and full-text review, 583 articles met the inclusion criteria for the study. Table 1 shows the most-represented countries and their associated income levels. In total, 1/27 low-income countries, 11/55 lower-middle income countries, and 16/55 upper-middle income countries were represented, which accounted for 0.3%, 12.9% and 86.8% of all included articles, respectively. The majority of articles were from China (379/583; 65%). Excluding data from China, 5-year disease DFS and OS varied significantly across included studies: Stage I = 64-100% DFS and 70-100% OS; Stage II = 75-94% DFS and 50-94% OS; Stage III = 34-87% DFS and 20-93% OS; Stages I-III combined = 53-86% DFS and 29-97% OS. **Conclusions:** There is a dearth of data on long-term outcomes following CRC operations in LMICs, especially among low-income countries. OS ranges markedly by country income group highlighting global disparities in cancer care. Our review emphasizes a dire need for cancer research capacity building in LMICs. Research Sponsor: U.S. National Institutes of Health, Fogarty International Center.

Trends in ethnic-specific colorectal cancer mortality in patients with and without diabetes in the United States: A CDC database population-based study 2011-2019. *First Author: Abdul Rahman Al Armashi, St. Vincent Charity Medical Center, Cleveland, OH*

Background: Colorectal cancer (CRC) is the third most frequent type of cancer and the second most lethal in both sexes combined. CRC is strongly associated with both environmental and genetic risk factors. Previous studies reported an increased mortality in CRC patients with diabetes mellitus, however, the interplay between ethnicity and diabetes mellitus was not explored. This study analyzes trends in mortality across ethnic groups and assess the impact of diabetes mellitus. **Methods:** We queried the Multiple Cause of Death database (International Classification of Diseases, 10th revision) between 2011 and 2019, we identified all patients (Hispanic and non-Hispanic origin) who died of a malignant neoplasm of the colon, rectosigmoid junction, and rectum {Codes C18.x to C20.x reported as the underlying cause of death (UCD)}. Then we identified the same group (UCD) among individuals with diabetes (Insulin-dependent diabetes mellitus and non-insulin-dependent diabetes mellitus) (Codes E10.x to E11.x reported as multiple causes of death). Age-adjusted mortality rates per million persons (PMP) were estimated, standardized to US census data from 2000, and stratified by Hispanic origin. **Results:** In the general population, a total of 464,058 deaths from CRC were identified, with an overall age- adjusted mortality rate of 137.9 PMP (Hispanic: 109.3, Non-Hispanic: 141.1). Overall, age-adjusted mortality declined by 13% among Hispanic, from 118.1 PMP in 2011 to 102.9 PMP in 2019, and by 8% among non-Hispanic, from 153.3 PMP in 2011 to 141.1 PMP in 2019. In the diabetic population, a total of 8679 CRC death were identified, with an overall age-adjusted mortality rate of 2.6 PMP (Hispanic: 3.6, Non-Hispanic: 2.5). Age-adjusted mortality increased by 32% in Hispanic from 3.1 PMP in 2011 to 4.1 PMP in 2019 and by 13% in non-Hispanic from 2.4 PMP in 2011 to 2.7 PMP in 2019. **Conclusions:** This study concludes that between 2011 and 2019, the CRC mortality was reduced in both Hispanic and non-Hispanic in the general population. Notably, this tendency was not observed in the diabetic population, where mortality increased, particularly among Hispanic. Additional studies are warranted to determine the causes of the rise among diabetics and strategies for minimizing the disparity between Hispanic and non-Hispanic. Research Sponsor: None.

Colorectal cancer mortality rates between 2011 and 2019.

Population Type	Ethnicity	Deaths	Population	Crude Rate Per 1,000,000	Age-Adjusted Rate Per 1,000,000
General	Hispanic or Latino	33,779	507,985,686	66.5	109.3
	Non-Hispanic or Latino	430,279	2,378,178,634	180.9	141.1
	Total	464,058	2,886,164,320	160.8	137.9
Diabetic	Hispanic or Latino	1,030	507,985,686	2	3.6
	Non-Hispanic or Latino	7,649	2,378,178,634	3.2	2.5
	Total	8,679	2,886,164,320	3	2.6

CXCR4 overexpression: An indicator of poor survival and predictor of response to immunotherapy in patients with metastatic colorectal cancer. *First Author: Sepideh Gholami, University of California Davis Comprehensive Cancer Center, Sacramento, CA*

Background: CXC-chemokine receptor 4 (CXCR4) is a ubiquitous chemokine receptor activated by the CXCL12 ligand and is implicated in tumor invasion, metastasis, and immune cell (IC) trafficking. High CXCR4 expression is associated with poor prognosis in colorectal cancer (CRC). < 10% of metastatic CRC cases harbor microsatellite instability (MSI-H) and demonstrate lower tumor mutation burden (TMB), decreased IC infiltration, and lack of response to current immunotherapy regimens. This study aims to interrogate the role of CXCR4 mRNA expression on the the tumor microenvironment (TME) and its prognostic and predictive value to tailor immunotherapeutic treatment strategies in CRC. **Methods:** A total of 15,026 CRC samples were analyzed using whole-exome sequencing, whole-transcriptome sequencing, and immunohistochemistry (Caris Life Sciences, Phoenix, AZ). Study cohort was stratified by CXCR4 mRNA expression levels in quartiles (Q1 (low) vs Q4 (high)). IC fraction was calculated by QuantiSeq, and real-world overall survival information was obtained from insurance claims data and calculated from tissue collection time to last day of contact. Statistical significance was determined using chi-square/Fisher-Exact and adjusted for multiple comparisons ($q < 0.05$). **Results:** Samples obtained from metastatic sites showed higher CXCR4 mRNA expression than those from primary tumors (22.7 vs 18.6 median transcripts per million (TPM), $p < 0.001$). CXCR4 mRNA expression was significantly lower in liver metastases than in non-liver metastases (21.2 vs 24.8 TPM, $p < 0.001$). Median CXCR4 mRNA expression was highest in the consensus molecular subtypes 4 (33.3 TPM) and lowest in 3 (13.0 TPM, $p < 0.05$). CXCR4 mRNA expression was positively associated with TMB-H, MSI-H/dMMR, and positive PD-L1 IHC status. In the TME, high CXCR4 mRNA expression was observed in tumors with a higher IC infiltration including B cells, M1/M2 macrophages, NK cells, $CD8^+$ T cells and T-regs, regardless of MSI status. High CXCR4 mRNA expression in the primary tumor was associated with poor prognosis (HR 0.77, 95% CI 0.70-0.85; $p < 0.001$), regardless of MSI-status. In metastatic tumors, low mRNA expression was correlated with improved survival (HR 0.89, 95% CI 0.80-0.99; $p = 0.34$); however, this did not reach statistical significance in the MSS cohort (HR 0.90, 95% CI 0.80-1.0; $p = 0.06$). Of note, high CXCR4 mRNA expression was associated with improved survival in all patients with CRC who received pembrolizumab (HR 2.12, 95% CI 1.16-3.91; $p = 0.013$). **Conclusions:** This is the largest clinical dataset to date demonstrating high CXCR4 expression as a predictor for poor survival in CRC. Furthermore, high CXCR4 expression was associated with improved outcome after checkpoint inhibition immunotherapy, indicating its strong potential as a predictive biomarker that could inform immunotherapeutic strategies in CRC. Characterization of TIM3 and its ligands in colorectal cancer. *First Author: Sandra Algaze, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: TIM-3 is an inhibitory checkpoint glycoprotein found on innate and adaptive immune cells and is highly expressed on tumor infiltrating lymphocytes. TIM-3 and its ligands, Galectin 9 (Gal9), HMGB1 and CEACAM1 play a critical role in immune regulation and preclinical data suggest a role in the pathogenesis of colorectal cancer (CRC). We aimed to characterize the molecular features and prognostic value of TIM3 and its ligands in CRC. **Methods:** Tumor molecular profiling was performed from 15,026 FFPE samples by NextGen Sequencing on DNA (592 genes or WES) and RNA (WTS) and immunohistochemistry (IHC) at Caris Life Sciences (Phoenix, AZ). Top quartile transcripts per million (TPMs) for *TIM-3, Gal9, HMGB1 and CEACAM1* were considered high (Q4) while bottom quartile low (Q1) expression (exp). X^2/Fisher-exact tests were used for comparison and significance was determined as *P*-value adjusted for multiple comparison and this was found for the results reported here ($Q < 0.05$). Cell infiltration in the tumor microenvironment (TME) was estimated by quanTIseq. Real-world overall survival (OS) information was obtained from insurance claims data and Kaplan-Meier estimates were calculated for molecularly defined pts. **Results:** Gal 9/TIM3-high tumors had higher prevalence (prev) of high tumor mutational burden (TMB ≥ 10 Mut/Mb) (12% vs. 8%; 14% vs. 6%), deficiency in mismatch repair (dMMR) (9% vs. 5%; 10% vs. 4%), PD-L1 exp (5% vs. 3%; 7% vs. 2%), and was highest in transverse (Fold Change; FC: 1.05, 1.12) and right sided tumors (1.04, 1.10) compared to left sided tumors, and CMS4. In contrast, HMGB1 and CEACAM1-high tumors had lower prev of dMMR (5% vs. 8%, 3% vs. 12%), PD-L1 exp (3% vs. 5%, 3% vs. 6%) and TMB-H (8% vs. 11%, 6% vs. 16%), and was highest in CMS2. In MSS tumors, Gal9/TIM3-high tumors were associated (assoc) with lower frequency of *TP53*, amplifications (amp) of FLT1/3, CDX2, FOXO1, and CDK8 while CEACAM1 and HMGB1-high were assoc with higher mutation (mut) rates of *TP53*, *APC*, *NRAS*, amp of FLT1/3, CDX2, CDX8, and lower mut in *GNAS*, *FBXW7* and *RNF43*. High Gal9 and TIM3 exp was assoc with higher infiltration of B cells, M1 and M2 macrophages, NK cells, CD4+ and C8+ T cells, and Tregs, while high HMGB1 and CEACAM1 exp was negatively assoc with Tregs, M1 macrophages, monocytes and CD8+ T cells. High exp of Gal9, TIM3, HMGB1, and CEACAM1 was assoc with worse OS in the entire cohort (HR 0.90, 95%CI, 0.84-0.97, $P = 0.005$, HR 0.81, 95% CI, 0.75-0.87, $P < 0.00001$; HR 0.88, 95% CI, 0.82-0.95, $P < 0.001$; HR 0.80; 95%CI, 0.74-0.86, $P < 0.00003$, respectively). **Conclusions:** Strong assoc were identified between Gal9/TIM3, HMGB1 and CEACAM1 gene exp and IO biomarkers, distinct molecular features, CMS, TME cell infiltration, and patient outcomes in CRC. Significantly different mut frequencies may signify unique subsets of CRC. These findings provide rationale for further evaluation of TIM3 and its ligands in CRC as prognostic biomarkers and potential therapeutic targets modifying the TME. Research Sponsor: None.

Association between environmental quality index and young onset colorectal cancer. *First Author: Suleyman Yasin Goksu, University of Texas Southwestern Medical Center, Dallas, TX*

Background: The factors associated with the rise of young-onset colorectal cancer (YOCRC) remain unclear. However, environmental exposures are believed to be associated with YOCRC in addition to hereditary factors. Therefore, we evaluated the association between the national level Environmental Quality Index (EQI) and YOCRC in the US. **Methods:** We queried the SEER database to identify adult colorectal cancer patients diagnosed between 2010-2016. YOCRC was defined as age at diagnosis < 50 years. EQI (2005-2010) is a measure of county-level cumulative environmental exposures that includes 5 domains: sociodemographic, built, air, land, and water. A higher value represents a lower environmental quality. We distributed the total EQI and each EQI domain into five quintiles. Multivariable logistic regression analysis was used to assess the relationship between YOCRC and quintiles (upper-most vs. lowest) of EQI after adjusting by race (White, Black, and Others), gender, and stage at diagnosis. The age-adjusted incidence rate was also calculated using the SEER*Stat, and correlation efficiency was estimated between EQI domains and incidence rate. **Results:** A total of 261,417 CRC patients were included; 11% were YOCRC. In the adjusted multivariable analysis, poor built EQI (OR 1.15 [1.11-1.20]) and water EQI (OR 1.08 [1.03-1.12]) were more likely to be associated with YOCRC. Poor built EQI was more strongly associated with Black YOCRC (OR 1.21 [1.09-1.35]) as compared to White YOCRC (OR 1.14 [1.09-1.19]). Poor sociodemographic EQI was more strongly associated with Others (OR 1.47 [1.25-1.72]) compared to Black YOCRC (OR 1.14 [1.03-1.25]). In addition, poor built EQI (OR 1.19 [1.12-1.27]) and water EQI (OR 1.12 [1.05-1.19]) were more strongly associated with the metastatic disease among YOCRC patients. However, the total poor EQI was not associated with YOCRC (OR 0.99 [0.95-1.03]). On incidence analysis, there was a positive correlation between the incidence rate of YOCRC and sociodemographic EQI (rho = 0.49, $p < 0.001$), air EQI (rho = 0.30, $p < 0.001$), and land EQI (rho = 0.18, $p < 0.001$). **Conclusions:** This study evaluated a population-based ecological approach and showed that YOCRC was associated with lower environmental quality, including built and water domains. EQI domains were also associated with different racial groups among YOCRC. Instead of studying single environmental exposures, the impact of the cumulative environmental index should be recognized and studied further to understand the mechanism of cancer development. Dietary quality in early-onset gastrointestinal malignancies: NHANES 2005-2018. *First Author: Mir Lim, UT Southwestern Medical Center, Dallas, TX*

Background: The incidence of early-onset colorectal, stomach, esophageal, and pancreatic cancer, which occur in individuals <50 years of age, is rising worldwide. However, little is known about why rates have been up trending. Previous studies have linked poor diet and nutrition to an increased risk of typical-onset gastrointestinal (GI) malignancies. In this study, we aimed to describe dietary quality in individuals with early-onset GI malignancies and compare it to typical-onset GI malignancies. **Methods:** We queried the 2005-2018 National Health and Nutrition Examination Survey (NHANES) database for all survey participants diagnosed with GI malignancies, including colorectal, esophageal, gallbladder, liver, pancreas, rectal, and stomach cancer. We classified early and typical-onset GI cancer based on age of diagnosis of <50 and ≥50 years, respectively. Participants <50 without a history of cancer were classified as controls. We assessed the dietary quality by calculating the healthy eating index score (HEI-2015) from NHANES database for all participants. The primary outcome was mean HEI-2015 score for early onset GI malignancies. We performed propensity score weighted analysis to balance gender, race, income, education level, and BMI between the groups. We used logistic regression analysis to assess the relationship between early-onset GI malignancies and HEI-2015 quintiles. **Results:** Out of 32,235 participants in NHANES database, 330 individuals (1%) reported a diagnosis of GI malignancy. Sixty-eight (20.5%) individuals had early-onset GI malignancies. We identified 17,420 controls who were <50 years old with no reported history of malignancy. Fifty-three percent of early-onset GI cancers were female vs 47% of typical-onset GI cancers; 59% vs 59% were non-Hispanic White; 66% vs 40% had a college degree; 13% vs 7% had high income and 40% vs 36% were obese. The mean HEI-2015 score in early-onset GI cancer was 52.9 (SD 14.7) compared to 53.6 (SD 13.0) in typical-onset GI cancers, which was not significantly different (p=0.72). There was no significant association between poor HEI-2015 scores in individuals with early-onset vs typical-onset GI malignancies on logistic regression analysis (OR 0.84 [0.35-2.03]). In addition, HEI-2015 quintiles were not significantly associated with those with early-onset GI malignancies compared to controls <50 years old (OR 2.06 [0.72-5.9]). **Conclusions:** The diet quality of early-onset GI malignancies does not align with the national Dietary Guidelines. However, in this analysis of the NHANES database, we did not find a significant difference in HEI-2015 scores between early-onset versus typical-onset GI malignancies. Research Sponsor: None.

Early detection of colorectal adenocarcinoma by decoding epigenetic and DNA fragmentation fingerprints of plasma cell-free DNA. *First Author: Li Suxing, Genecast Biotechnology Co., Ltd., Wuxi, China*

Background: Cell-free DNA (cfDNA) methylation, fragmentation patterns, chromosome instability, and chromatin accessiblity have been previously shown to be valid plasma biomarkers for non-invasive cancer detection. However, conventional whole-genome bisulfite sequencing (WGBS) is unable to simultaneously profile all these biomarkers due to bisulfite-induced DNA damages. Here we developed a machine learning approach to comprehensively integrate multiple types of cancer genomic markers from enzyme-conversion-based low-pass whole-methylome sequencing (WMS) of plasma cfDNA to non-invasively detect colorectal adenocarcinoma. **Methods:** Plasma cfDNA sampels from 215 colorectal adenocarcinoma patients and 568 healthy individuals were collected and were split into the discovery and independent testing cohort. The discovery cohort includes 150 cancer patients and 398 healthy individuals and the independent testing cohort includes 65 cancer patients and 170 healthy individuals. Whole methylome sequencing (WMS) libraries were generated from enzymatically converted cfDNA and were subsequently paired-end sequenced at ~2X coverage. The genome-wide methylation density, fragmentation fingerprints, chromosome instability, and chromatin accessibility were extracted from the WMS data and individually modelled via machine learning methods such as SVM, LR, GBDT, random forest. The final predictive model is an ensemble model integrating all uni-modal models. All models were trained and fitted on the discovery cohort. **Results:** Data of different modalities provide complementary information in separating the cancer patients from the healthy individuals. Unsupervised clustering of the individuals showed clear separation between cancer patients and healthy individuals. The final predictive model achieved AUC =0.982 in the discovery cohort and AUC =0.9664 in the independent testing cohort. Under a specificity of 94.71% (CI: 90% - 98.82%), sensitivity was 78.46% (CI: 60% - 92.31%) in the independent testing cohort. Separating the cancer patients into different stages, we found that the detection power is usuaul lower for early-stage cancer patients. **Conclusions:** These results demonstrate the first proof of principle on the feasibility of integrating multiple genomic cancer markers to non-invasively detect colorectal adenocarcinoma from WMS plasma cell-free DNA. A large prospective cohort study is planned to further validate its clinical performance. Research Sponsor: None.

Impact of consensus molecular subtyping (CMS) on survival in the CO.26 trial of durvalumab plus tremelimumab versus best supportive care (BSC) in metastatic colorectal cancer (mCRC). *First Author: Jonathan M. Loree, BC Cancer, Vancouver, BC, Canada*

Background: CO.26 was a phase 2 trial (2-sided α=0.1 and 80% power) that randomized 180 patients with refractory mCRC 2:1 to durvalumab + tremelimumab vs BSC with improved overall survival (OS) (HR 0.73, 90%CI 0.55-0.97, P=0.07). A Nanostring assay validated for use with FFPE was used to determine CMS for correlation with outcome. **Methods:** Archival FFPE from 163/180 (91%) of patients (pts) underwent RNA extraction and CMS subtyping. Cox proportional hazard models evaluated the prognostic and predictive impact of CMS on overall survival. **Results:** CMS distribution was skewed towards CMS4 (76%), with lower prevalence of CMS1 (2%), CMS2 (16%) and CMS3 (2%). There were 7/163 cases of indeterminate CMS (4%). Subgroup analysis was restricted to CMS2 and CMS4 based on sample size. With BSC alone, CMS2 showed trends to worse OS compared to all other patients pooled (HR 1.93, 90% CI 1.03-3.61, P=0.085), while CMS4 did not (HR 0.86, 90% CI 0.50-1.48, P=0.64). OS but not progression free survival (PFS) was improved with durvalumab + tremelimumab in the overall population. OS was improved with durvalumab + tremelimumab among patients with CMS2 tumors (HR 0.39, 90% CI 0.19-0.82, P=0.035) but not in patients with CMS4 tumors (HR 0.73, 90% CI 0.52-1.02, P=0.12) compared to BSC. Neither CMS2 (P-interaction=0.37) nor CMS4 (P-interaction=0.91) were predictive of OS benefit from durvalumab + tremelimumab compared to BSC. Disease control rate (DCR) trended to being better among CMS4 (24/85) than CMS2 cancers (1/15, OR 5.51, 90% CI 1.10-29.88, P=0.11) or CMS4 vs all non CMS4 cancers (1/21, OR 7.87, 90% CI 1.65-41.98, P=0.023) for patients on durvalumab + tremelimumab. PFS was not improved with durvalumab + tremelimumab in CMS2 (P=0.19) or CMS4 (P=0.29) cancers relative to BSC. **Conclusions:** In this trial of refractory colorectal cancer, we saw a shift in CMS subtype with more CMS4 than expected. Compared to CMS4, CMS2 showed stronger signals towards improved OS with durvalumab + tremelimumab but had a lower disease control rate. Differences in immune signaling by CMS may be important determinants of which component of immune regulation needs to be targeted in mCRC to improve outcomes. Clinical trial information: NCT02870920. Research Sponsor: Canadian Cancer Society, AstraZeneca (trial costs).

Comparison of activity of durvalumab plus tremelimumab vs. best supportive care in treatment refractory metastatic colorectal cancer.

Group	OS HR (90% CI, P)	PFS HR (90% CI, P)	Disease control rate (DCR) (%) Odds Ratio (OR), (90% CI, P)
All Pts	0.73 (0.55-0.97, P=0.07)	1.01 (0.76-1.34, P=0.97)	23 vs 6.6%, OR 4.18 (90% CI 1.39-12.60, P=0.01)
CMS2	0.39 (0.19-0.82, P=0.035)	1.79 (0.86-3.72, P=0.19)	7 vs 0%, OR n/a, (P=0.99)
CMS4	0.73 (0.52-1.02, P=0.12)	0.81 (0.58-1.13, P=0.29)	28 vs 8%, OR 4.46 (90% CI 1.49-10.85, P=0.017)

Real-world outcomes of biosimilar bevacizumab-awwb versus reference bevacizumab in patients with metastatic colorectal cancer. *First Author: Catherine Pham, Kaiser Permanente, Downey, CA*

Background: Bevacizumab-awwb was the first biosimilar approved by the U.S. Food and Drug Administration (FDA) for treatment of cancer and became available for use in July 2019. Clinical comparative efficacy and safety of bevacizumab-awwb to bevacizumab was established in a single study of adult patients with advanced non-squamous non-small cell lung cancer. Approval based on extrapolation was granted by the FDA for all other indications, including metastatic colorectal cancer (mCRC). The objective of this study was to evaluate the real-world effectiveness and safety outcomes of patients with mCRC initiated on bevacizumab-awwb versus bevacizumab in an integrated healthcare delivery system. **Methods:** This was an observational cohort study of patients with mCRC in Kaiser Permanente California, Colorado, and Mid-Atlantic States who were initiated on bevacizumab-awwb between July 2019 and March 2020 or reference bevacizumab between July 2015 and June 2018. Patients with history of bevacizumab use in the 6 months prior to the index treatment date were excluded. Patients were followed until 12 months after treatment initiation, end of plan membership, or death, whichever occurred first. The primary outcome of overall survival (OS) was analyzed using a non-inferiority test with lower margin of 10% and Cox proportional-hazards modeling. Secondary outcomes included count of doses received, treatment duration, all-cause hospitalizations, and incidence of serious adverse events. **Results:** A total of 1,445 patients initiated on either bevacizumab-awwb (n=239) or bevacizumab (n=1,206) were included in the analysis. The mean overall age was 60 ± 13 years and 54% of patients were male. The OS rate was 72.8% and 73.1% for patients receiving bevacizumab-awwb and bevacizumab, respectively ($p<0.01$ for non-inferiority). The adjusted hazard ratio for mortality was 1.01 (0.77-1.33, $p=0.93$). There were no statistically significant differences in secondary outcomes between the 2 study groups (Table). **Conclusions:** Bevacizumab-awwb is a safe and effective option when compared to the reference bevacizumab in the treatment of mCRC. Future studies should evaluate outcomes after longer follow-up time and in different cancer types. Research Sponsor: None.

Unadjusted secondary outcomes of patients with mCRC by treatment group (n=1,445).

OUTCOME	BEVACIZUMAB-AWWB (n = 239)	BEVACIZUMAB (n = 1,206)	*p*-value
Count of doses received, *mean ± SD*	11.2 ± 6.7	10.5 ± 6.6	0.14
Treatment duration (months), *mean ± SD*	6.7 ± 4.1	6.5 ± 4.2	0.67
All-cause hospitalizations, *n (%)*	105 (43.9%)	503 (41.7%)	0.52
Serious adverse events, *n (%)*			
Hemorrhage	11 (4.6%)	52 (4.3%)	0.84
GI perforation	5 (2.1%)	26 (2.2%)	0.95
Severe thromboembolism	12 (5.0%)	34 (2.8%)	0.08

Gene expression of vitamin D (VitD) pathway markers and survival in patients (Pts) with metastatic colorectal cancer (mCRC): CALGB/SWOG 80405 (Alliance). *First Author: Christine G Kohn, Beth Israel Deaconess Medical Center, Boston, MA*

Background: Higher levels of plasma 25-hydroxyvitamin D [25(OH)D)] are associated with better outcomes in mCRC, but underlying biologic mechanisms are unknown. Key components of the VitD metabolic pathway include CYP27B1 (encodes 1-α-hydroxylase, converts 25(OH)D to active calcitriol), VitD receptor (VDR), and CYP24A1 (encodes 24-hydroxylase, degrades calcitriol and 25(OH)D into excreted metabolites). Since these factors may affect 25(OH)D levels and potentially mediate VitD activity in mCRC, we examined the relationship between tumoral gene expression (GEx) of CYP27B1, VDR, and CYP24A and pt outcome in a study nested in a randomized phase III trial of first-line chemotherapy plus biologics in mCRC pts, CALGB/SWOG 80405. **Methods:** We determined GEx of CYP27B1, VDR, and CYP24A1 by RNA sequencing (RNA-Seq) of archival tumor samples using the Illumina TruSeq platform. Primary endpoints were overall (OS) and progression-free survival (PFS). Cox proportional hazard models were used to calculate hazard ratios (HRs) and 95% confidence intervals (CIs), adjusting for prognostic and molecular characteristics. **Results:** 562 pts with RNA-Seq data were included. Pts with higher CYP27B1 expression (>median) were less likely to have BRAF wild type (WT) (79% vs 90%) compared to pts with lower expression (p=0.0007). Pts with higher VDR expression (>quartile 1 [Q1]) were younger (median age 59 vs 62 years; p=0.03), more likely to have left-sided (63% vs 46%; p=0.0005) and BRAF WT tumors (89% vs 70%; p<0.0001), and less likely to have RAS WT tumors (70% vs 80%; p=0.02) compared to pts with lower VDR. Pts with higher CYP24A1 expression (>median) were more likely to have left-sided tumors compared to pts with lower expression (63% vs 54%; p=0.03). On multivariable analysis, pts with higher CYP27B1 expression had significantly improved OS (HR 0.84; 95% CI, 0.75-0.93; p=0.002) and PFS (HR 0.89; 95% CI, 0.80-0.99; p=0.04). Higher VDR expression (up to Q1) was associated with significantly improved PFS (HR 0.69; 95% CI, 0.53-0.91; p=0.007) but not OS (HR 0.85; 95% CI, 0.66-1.09; p=0.20). Above Q1, this improvement attenuated. Higher CYP24A1 GEx was not associated with improved OS (HR 0.98; 95% CI, 0.88-1.08; p=0.66) or PFS (HR 0.98; 95% CI, 0.89-1.08; p=0.68). We found no significant interactions between GEx of CYP27B1, VDR, or CYP24A with baseline plasma 25(OH)D levels (p for interaction ≥0.10 for all). **Conclusions:** Our findings suggest an association between GEx of VitD pathway markers, particularly CYP27B1 and VDR, and survival in pts with mCRC, lending biologic plausibility to a role of VitD in CRC pathogenesis. Future studies are needed to confirm these findings and elucidate underlying mechanisms of action. Clinical trial information: NCT00265850. Resistance mechanisms to anti-EGFR therapy in *RAS*/*RAF* wildtype colorectal cancer varies by regimen and line of therapy. *First Author: Christine Megerdichian Parseghian, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The conventional theory for the development of treatment resistance to anti-EGFR for metastatic colorectal cancer (mCRC) is the selective growth advantage of pre-existing therapy-resistant subclones with genomic mechanisms such as *RAS* mutations, leading to treatment resistance and disease progression. However, the impact of cytotoxic chemotherapy in combination with anti-EGFR on the mechanisms of resistance has not been assessed. **Methods:** We analyzed paired plasma samples from *RAS/BRAF/EGFR* wild-type mCRC patients enrolled in three large randomized phase 3 trials of anti-EGFR rechallenge in whom paired baseline and time of progression plasma samples had been collected for sequencing of ctDNA on a platform optimized for very low allele frequencies. 569 patients had paired baseline and progression ctDNA samples analyzed, including 147 in the first line study of FOLFOX +/- panitumumab, 91 patients in third line with panitumumab vs best supportive care, and 331 patients in the third line study of cetuximab vs. panitumumab. The mutational signature of the alterations acquired with therapy was evaluated. We also established colon cancer cell lines with resistance to cetuximab, FOLFOX, and SN38, and profiled transcriptional changes. **Results:** Using serial plasma samples, we demonstrate that patients whose tumors were treated with and responded to anti-EGFR alone were approximately 5-times more likely to develop acquired mutations at progression compared to those treated with an EGFR inhibitor in combination with cytotoxic chemotherapy (46% vs. 9%, respectively; $p < 0.001$). Consistent with this clinical finding, cell lines with non-genomic acquired resistance to cetuximab were cross-resistant to cytotoxic chemotherapy and vice-versa, with transcriptomic profiles consistent with epithelial to mesenchymal transition. In contrast, common acquired genomic alterations in the MAPK pathway that drive resistance to EGFR monoclonal antibodies do not impact sensitivity to cytotoxic chemotherapy. Further, contrary to the generally accepted hypothesis of clonal expansion of acquired resistance, in our work we demonstrate that baseline resistant subclonal mutations rarely expanded to become clonal at the time of progression (8%), and most remained subclonal (44%) or disappeared (49%). **Conclusions:** Collectively, this work outlines a model of resistance where non-genomic mechanisms of resistance common to both EGFR inhibitors and cytotoxic chemotherapy predominate in patients treated with EGFR and chemotherapy combinations. With EGFR inhibitor monotherapy, genomic acquired resistance mechanisms predominate, although only rarely through expansion of pre-existing subclones. These findings have important implications for strategies of EGFR-inhibitor rechallenge studies. Research Sponsor: Andrew Sabin Family Fellowship, NIH/NCI GI SPORE, Pharmaceutical/Biotech Company.

Aflibercept-LV5FU2 as first-line treatment of non-resectable metastatic colorectal cancers: Results of the FOLFA randomized phase II trial. *First Author: Jean-Louis Legoux, Centre Hospitalier Régional, Orléans, France*

Background: Previous trials have demonstrated that bevacizumab and fluoropyrimidine combination is effective and well-tolerated in older patients (pts) with non-aggressive unresectable metastatic colorectal cancer. We evaluated in this trial safety and efficacy of aflibercept and infusional 5-fluorouracil/folinic acid (LV5FU2 regimen) combination versus LV5FU2 alone in older pts, asymptomatic and/or frail, deemed unsuitable for doublet cytotoxic chemotherapy. **Methods:** The main eligibility criteria for this randomized phase II trial were age ≥ 65 and WHO performance status < 2. Randomization was stratified according to thymidylate synthase (TS)-*5'UTR* germline polymorphism. Common (also called simplified) LV5FU2 regimen was preceded or not by aflibercept (4mg/kg). The primary endpoint was the 6-month progression-free survival (PFS) rate, achieved if > 40% in the experimental arm. Secondary objectives were safety, quality of life, overall survival (OS), and the prognostic impact of TS-*5'UTR* polymorphism. **Results:** 117 patients (pts) were included, 59 in arm A (5FU-aflibercept), 58 in arm B (5FU alone), of median age 81 years (range 67-91; > 75 years: 81%). *RAS*/*BRAF* status (available in 112 pts [96%]) was mutated in 49% and 7%, respectively. The 6-month PFS was 54% in both arms (same 90% CI 42-65). The disease control rate was 83% in arm A and 87% in arm B. The median OS was 21.8 months in arm A and 25.1 months in arm B. The toxicities were more common in arm A: at least 1 grade 3-4 toxicity > 2 in 82% versus (vs) 58.2% pts, hypertension grade > 3 in 42% vs 18% pts, proteinuria (any grade) in 51% vs 11% pts, dysphonia (grade < 3) in 19% vs 2%, 1 colic perforation in arm A. Treatment delays for toxicities were required for 4% of the 753 courses in arm A vs 2% of the 780 courses in arm B, 5FU bolus suppression was decided for 29.8% pts vs 20% (arm A vs arm B), median 29 days vs 73 days after the first course (arm A vs B), without difference in the doses of infusional 5FU. A second and third line of treatment were received in 41% and 14% of pts in arm A vs 67% and 29% of pts in arm B, respectively. The TS *5'UTR* polymorphism (3R3R vs 2R2R or 2R3R) had no impact on PFS or OS. Regarding the quality of life (QLQ C30 score), the difference of overall health score was on average -6.39 (SD = 26.68) in arm A vs -4.91 (SD = 27.15) in arm B, and was very similar in all components. The median time to definitive deterioration in quality of life was 15 months (95% CI: 9-22.8) in arm A vs 9.6 (95% CI: 5.1-19.4) in arm B. **Conclusions:** FOLFA trial meets is primary endpoint with 53.6% of 6-month PFS with LV5FU2-aflibercept. Nevertheless, as compared with LV5FU2 alone we observed no increase in PFS or OS and more toxicities. These results do not argue for an evaluation of LV5FU2-aflibercept combination in a randomized phase III trial. Clinical trial information: EudraCT 2014-001837-10. Has the COVID-19 pandemic lead to an upshift in emergency presentation and stage migration of colorectal cancer in Uruguay? *First Author: Santiago Fontes, Servicios Oncológicos de la Asociación Española Primera de Socorros Mutuos, Montevideo, Uruguay*

Background: Effective Cancer screening is critical in reducing cancer related mortality in CRC by increasing the detection in earlier stages. Worldwide, practically all cancer pathways have been negatively affected by the implications of the COVID-19 pandemic. Oncological care has not escaped the effects of reprioritization of health care services to handle the surge of COVID-19 patients adequately. Cancer screening programs are no exception as many were temporarily halted to alleviate the pressure on overwhelmed health care systems. In Uruguay, the first covid patients were detected in March 2020, and since then, the country's Public Health policies have been marked by the covid-19 public health emergency. The aim of this study is to assess the impact of the COVID-19 pandemic on CRC diagnosis. We further aimed to analyze the effect on the clinical presentation and stage at diagnosis during 2020-2021 compared with previous years. **Methods:** This was a retrospective cohort study performed at a single tertiary center. Patients diagnosed and managed with colorectal adenocarcinoma during the years 2020-2021 were compared with patients from 2018-2019. Those enrolled in 2018-2019 were classified as the "pre-pandemic group", and those enrolled in 2020-2021 were classified as the "pandemic group". The primary outcome was the rate of stage IV disease at the time of diagnosis. Mann-Whitney test was used in the comparison of quantitative variables and Fisher's exact test was used for qualitative variables. **Results:** A total of 370 patients were included in this study. From March 2018 to 2019 (pre-pandemic), 217 patients were considered, and from March 2020 to 2021 (pandemic), 153 patients. Median age of pre-pandemic and pandemic group was 64.4 and 65.6 years, respectively. There was no statistically significant difference in cancer obstruction or perforation at diagnosis. Patient demographics and tumor clinicopathological features were comparable. The percentage of surgical candidates was lower during the pandemic (69% vs 62%). There was a significant difference in TNM tumor distribution between pre-pandemic and pandemic subgroups with a higher incidence of advanced (cT4 or cN+ or M1) tumors. T4 tumors and node positive disease were equivalent in both groups but the incidence of disseminated disease (cM1) was significantly higher in the pandemic group ($P < 0.001$) **Conclusions:** Our study demonstrates how cancer diagnostic variables, mainly stage at diagnosis, have been affected by the impact of the COVID-19 pandemic on cancer screening programs. Therefore, it is of utmost importance that cancer diagnosis and treatment pathways be reinstalled in full to return to and build on pre-pandemic priority to ensure the benefits from earlier diagnosis and treatment. Future studies are needed to verify the tendency in stage migration and to optimize CRC care in the pandemic scenario. Research Sponsor: None.

Bcl-xL and association with apoptosis following KRASG12C inhibition in KRASG12C mutant colorectal cancer. *First Author: Hajrah Khawaja, Queen's University Belfast, Belfast, United Kingdom*

Background: Novel covalent inhibitors of $KRAS^{G12C}$ have shown modest response rates in $KRAS^{G12C}$ mutant (MT) colorectal cancer (CRC) patients. Thus, novel $KRAS^{G12C}$ inhibitor combination strategies that can achieve deep and durable responses are needed. **Methods:** The small molecule $KRAS^{G12C}$ inhibitors AZ'1569 and AZ'8037 were employed. To identify novel candidate combination strategies for AZ'1569, we performed RNA sequencing, siRNA and high-throughput drug screening. Top hits were validated in a panel of $KRAS^{G12C}$MT CRC cells and *in vivo* xenograft models. AZ'1569 acquired resistant CRC models were generated and characterised. **Results:** Response to AZ'1569 was heterogeneous across the $KRAS^{G12C}$MT models. AZ'1569 was ineffective at inducing apoptosis when used as a single agent or combined with chemotherapy or agents targeting the EGFR/KRAS/AKT axis. Using a systems biology approach, we identified the anti-apoptotic BH3-family member *BCL2L1*/Bcl-xL as top hit mediating resistance to AZ'1569. Further analyses identified acute increases in the pro-apoptotic protein BIM following AZ'1569 treatment. ABT-263 (Navitoclax), a pharmacological Bcl-2 family-inhibitor that blocks the ability of Bcl-xL to bind and inhibit BIM, led to dramatic and universal apoptosis when combined with AZ'1569 in a panel of $KRAS^{G12C}$ MT CRC cells. Furthermore, this combination also resulted in dramatically attenuated tumour growth in $KRAS^{G12C}$ MT CRC xenografts. Finally, AZ'1569 acquired resistant $KRAS^{G12C}$ MT CRC cells showed amplification of $KRAS^{G12C}$, EphA2/c-MET activation, increased pro-inflammatory chemokine profile and cross-resistance to standard-of-care chemotherapy and several targeted agents. Importantly, the KRAS amplification and AZ'1569-resistance were reversible upon drug withdrawal, arguing strongly for the use of drug holidays in the case of KRAS amplification. **Conclusions:** Combinatorial targeting of Bcl-xL and $KRAS^{G12C}$ is highly effective, suggesting a novel therapeutic strategy for $KRAS^{G12C}$MT CRC patients. The cross-resistance to other targeted therapies and importantly conventional chemotherapy in the AZ'1569 acquired resistant cells poses a challenge, with implications for the optimal use of $KRAS^{G12C}$ inhibitors as a second or third line option. Patient-reported outcomes from the GARNET trial in patients with advanced or recurrent mismatch repair deficient (dMMR) colorectal cancer (CRC): A post hoc subgroup analysis. *First Author: Jennifer Hanlon, GlaxoSmithKline, Waltham, MA*

Background: Dostarlimab is a programmed death 1 (PD-1) inhibitor approved in the US as a monotherapy in patients (pts) with dMMR advanced/recurrent endometrial cancer that has progressed on or after prior treatment with a platinum-containing regimen or in pts with dMMR solid tumors that have progressed on or after prior treatment, with no satisfactory alternative treatment options. Here we report on patient-reported outcomes (PROs) in pts with dMMR CRC, a post hoc subgroup analysis. **Methods**: GARNET is a multicenter, open-label, single-arm phase 1 study. Cohort F enrolled pts with dMMR/microsatellite instabilityhigh or $POL\varepsilon$-mutated non-endometrial solid tumors. Pts with CRC must have received prior fluoropyrimidine, oxaliplatin, and irinotecan. Pts received 500 mg of IV dostarlimab Q3W for 4 cycles, then 1000 mg Q6W until discontinuation. PRO assessment, an exploratory endpoint, was measured using the EORTC-QLQ-C30. PROs were collected at baseline, at each dose cycle, and after discontinuation. Multi-item and item-level analyses were collected and scored; improvement was defined as mean change from baseline (directional change dependent on item). A 10-pt change in mean from baseline was considered clinically significant for the analysis. **Results**: PRO data at baseline were available for 96 pts with CRC who received ≥1 dose of dostarlimab. Improvements from baseline for quality of life (QOL) and most gastrointestinal symptom scales were observed and maintained from cycle 2 through 7 (Table). Stability in diarrhea was seen from cycles 2 through 7. **Conclusions**: PROs from the GARNET trial in pts with dMMR CRC show that QOL and disease-related gastrointestinal symptoms were improved or maintained while on dostarlimab treatment. These data, with the previously reported efficacy and safety profile, support the use of dostarlimab in pts with dMMR CRC. Clinical trial information: NCT02715284. Research Sponsor: GlaxoSmithKline.

	Cycle					
	2	3	4	5	6	7
Patients ongoing in trial, n (%)	91 (94.8)	83 (86.5)	81 (84.4)	76 (79.2)	69 (71.9)	67 (69.8)
Mean change from baseline (95% CI)[a]						
QOL	3.5 (–0.0 to 6.9)	9.0 (5.0 to 13.0)	9.7 (5.3 to 14.2)	11.3 (6.9 to 15.8)	13.9 (9.1 to 18.8)	15.3 (10.0 to 20.7)
Nausea/vomiting	–1.6 (–7.5 to 4.2)	–4.1 (–9.6 to 1.4)	–6.3 (–12.2 to –0.4)	–6.4 (–13.4 to 0.5)	–8.1 (–13.9 to –2.2)	–8.9 (–15.9 to –1.8)
Appetite loss	–1.2 (–7.7 to 5.3)	–11.2 (–17.5 to –4.8)	–14.9 (–23.1 to –6.7)	–18.6 (–26.6 to –10.6)	–20.7 (–30.2 to –11.1)	–23.7 (–33.7 to –13.8)

Alternative biweekly dosing schedule of trifluridine-tipiracil (TAS-102) reduces rates of myelosuppression while maintaining therapeutic efficacy in patients (pts) with previously treated metastatic colorectal cancer (mCRC). *First Author: Christopher G Cann, Vanderbilt University Medical Center, Nashville, TN*

Background: Colorectal cancer remains a significant source of morbidity and mortality within the United States, causing nearly 53,000 deaths in 2021. For unresectable pts, the estimated 5-year survival rate is 14%. Given recent advances in treatment, 50% of pts with mCRC will receive third-line therapy or greater, making optimization of therapy in these settings pivotal. Trifluridine-tipiracil (TAS-102) is FDA approved for third-line or greater in mCRC per the RECOURSE Trial. Standard dosing is 35 mg/m^2 twice daily (maximum = 80 mg/day) on Days 1-5 and Days 8-12 of 28-day cycles. This dosing schedule is associated with Grade 3-4 neutropenia (38%), requiring treatment delays (53%), dose reductions (14%) and G-CSF support (9%). To reduce this toxicity while maintaining efficacy, we studied an alternative biweekly dosing (Days 1-5 and Days 15-19 of 28-day cycles). **Methods:** A retrospective analysis was completed (2019-2021) at Vanderbilt-Ingram Cancer Center in pts with refractory mCRC and appendiceal cancer (CA) who completed > 12 days of TAS-102 therapy. Diagnostic imaging was completed every 8-12 weeks. Patient data was evaluated for lines of prior therapy, ECOG performance status (PS), the addition of bevacizumab, and CTCAE grade of treatment-related myelotoxicity. Evaluation of progression-free survival (PFS) was performed only in mCRC pts. **Results:** 24 pts met the criteria, with a mCRC:appendiceal CA ratio of 20:4 and Male:Female 13:11. Median age 61.5 yrs (range 31-80); median number of prior therapies 3; median ECOG PS of 1; and median duration of therapy 73.5 days. Hematologic toxicities: Neutropenia 30% [Grade 3 (13%), Grade 4 (0%)]; anemia 17.4% [Grade 3 (8.7%), Grade 4 (0%)]; thrombocytopenia 4.3% [Grade 3/4 (0%)]. No pts required G-CSF. One patient required a treatment-related dose delay (neutropenia), and 2 pts required dose reductions (fatigue). In mCRC pts, the median PFS was 2.3 months. To date, 7 mCRC pts remain on treatment (range: 38-385). **Conclusions:** In our retrospective cohort analysis, TAS-102 biweekly dosing schedule (35 mg/m^2 twice daily; Days 1-5 and Days 15-19 of 28-day cycles) for pts with refractory mCRC and appendiceal CA reduced Grade 3 myelotoxicity without Grade 4 toxicities, while preserving PFS in pts with mCRC. With an improved toxicity profile, this alternative TAS -102 dosing schedule may be a more favorable option for future combination studies. Additional prospective data are needed to validate these findings. To our knowledge, this is the first analysis of biweekly TAS-102 in a US patient population. Research Sponsor: None.

3560 **Poster Session**

Impact of circulating tumor DNA (ctDNA) mutant allele fraction in response to anti-angiogenic therapy in *RAS*-mutant metastatic colorectal cancer (mCRC): Clinical data in the first-line setting and correlation in patient-derived xenograft (PDX) models. *First Author: Nadia Saoudi Gonzalez, Medical Oncology Department, Vall dHebron University Hospital, Barcelona, Spain*

Background: Currently, there are no well-established biomarkers available to select mCRC patients (pts) who will benefit most from antiangiogenic therapy. *RAS* mutant (mt) allele fraction in plasma (plMAF) is an independent prognostic factor in mCRC. Preliminary data from our group suggests the possible predictive role of plMAF in *RAS* mt pts treated with 1st line chemotherapy (ct) +/- bevacizumab (bev). **Methods:** Data prospectively/retrospectively collected from *RAS*mt mCRC pts who received 1st line ct+/-bev treatment in our center, selecting the subset of pts with plMAF sample evaluable with digital PCR (BEAMing) at baseline. Pts were stratified as high (≥ 5.8%) or low (< 5.8%) plMAF, based on a previously established prognostic cutoff (Elez et al, Mol Onc 2019). We investigated the associations between clinic-pathological variables, overall survival (OS), and progression-free survival (PFS) stratified by plMAF *RAS* levels using Cox regression models. OS and PFS were calculated by Kaplan-Meier method. Murine PDX were developed from mCRC pts including models from patients with *KRASG12/G13* mutations to explore recapitulation of the clinical findings. **Results:** From October '17 to December '21, 102 basal plasma samples were analyzed by BEAMing. 47 pts (46%) were classified as high, 39 pts (38%) as low, and 16 (16%) as no-mt detected by BEAMing (non-shedding). OS was significant longer in low plMAF pts than in high plMAF pts (median OS 15.9 vs 37.1 months (mo); HR 0.43; p = 0.001). In high plMAF pts, a trend towards a better PFS was observed in those pts treated with ct+bev compared to ct alone (median 9.4 vs 6.1 mo; HR 0.6; p = 0.18). No differences were observed in low plMAF pts treated with ct +/- bev (median 14.5 vs 14.9 mo; HR 1.2; p = 0.58). Results were not modified when adjusted by the presence of liver metastases. The multivariate PFS model showed no association between *RAS* plMAF and clinicopathological variables, except for treatment benefit with ct+bev and better outcomes in pts with resectable liver metastases. Interestingly, human ctDNA in one murine PDX model from non-shedding pt was not detectable, whereas human ctDNA was present in another PDX model with a plMAF of 36.2%. **Conclusions:** This study suggests that plMAF could be a promising predictive biomarker of response to bev in 1st line *RAS*mt mCRC, but more pts need to be analyzed to confirm this effect. Our results confirm the prognostic role of *RAS*mt plMAF in mCRC. plMAF could partially depend on tumor cell shedding degree and characteristics on the tumor vasculature architecture, this is being investigated in ongoing imaging studies and PDX models. These models will also help to understand the biology behind tumor response to bev and its connection with ctDNA shedding. Research Sponsor: None.

3561 **Poster Session**

Regorafenib (REGO) plus FOLFIRINOX as frontline treatment in patients (pts) with RAS-mutated metastatic colorectal cancer (mCRC): A phase I/II, dose-escalation and dose-expansion study. *First Author: Antoine Adenis, Institut du Cancer de Montpellier, Montpellier, France*

Background: Standard treatment options for RAS-mutated mCRC pts include the combination of bevacizumab with FOLFIRINOX, a three-drug chemotherapy regimen. Unlike bevacizumab, REGO – an oral multi-tyrosine kinase agent - exhibits not only antiangiogenic properties with cytostatic effects but also true cytotoxic effects. We report the preliminary results of the FOLFIRINOX-R trial (NCT03828799), in which we evaluated the safety and the efficacy of REGO in combination with FOLFIRINOX in pts with RAS-mutated mCRC. **Methods:** FOLFIRINOX-R trial is a prospective, dose-finding, phase I/II study whose dose-escalation part has been completed. Dose escalation was implemented following a 3 + 3 design and included three dose levels (DL). FOLFIRINOX regimen includes oxaliplatin (85 mg/m^2), folinic acid (400 mg/m^2), irinotecan (150–180 mg/m^2), 5-fluorouracil (400 mg/m^2 in bolus then 2400 mg/m^2 over 46h), and was administered every 14 days. REGO (80 to 160 mg per day, as per DL) was administered on days 4 to 10 of each cycle. Treatment was continued up to 12 cycles or until progression or unacceptable toxicity. The primary objectives of the dose-finding part of the study were to determine the maximum tolerated dose (MTD) using as endpoint the incidence of DLTs during the three first cycles of treatment, and to select the recommended phase 2 dose (RP2D). Key eligibility criteria include ECOG PS ≤1 and RAS-mutated mCRC not amenable to surgery with curative intent and not previously treated for metastatic disease. Patients with the 7/7 variant of the UGT1A1*28 polymorphism were not eligible. Prophylactic G-CSF was administered from Day-7 to Day-12. **Results:** Thirteen pts were enrolled across the 3 DL (DL 1: 3 pts, DL 2: 6 pts, DL 3: 4 pts); 46% of pts were female, the median age was 65 yo [range: 40 ; 76]. One pt (at DL 3) was not evaluable for DLT because of poor observance during the first 2 cycles. At data cut-off, median treatment duration and median follow-up were 4.6 mo. (range: 2.3; 10) and 13.4 mo. (range: 3.8; 18.0), respectively. One DLT (a grade 3 hypokalaemia related to grade 2 diarrhoea) occurred at DL 2. MTD was not reached at DL 3 (REGO 160 mg/day). The most common grade ≥3 TRAE per patient were grade 3 neutropenia (n = 1), grade 4 neutropenia (n = 1), grade 3 neuropathy (n = 2) and grade 3 diarrhoea (n = 7). Dose reductions/discontinuations due to grade ≥3 TRAE were necessary in 12/13 (92%) pts. The ORR was 62% (95% CI 32%-86%) and median PFS was 9.1 mo (range: 3.1; 15.4). **Conclusions:** Full-dose FOLFIRINOX plus full-dose REGO (160mg/day, days 4 to 10) can be administered safely. Due to the manageable toxicity profile and the promising efficacy observed in the dose-escalation stage, this regimen deserves to be evaluated in the dose-expansion stage. Clinical trial information: NCT03828799. Research Sponsor: Bayer Pharma.

3562 **Poster Session**

Molecular characterization and subsequent treatments after encorafenib-cetuximab +/- binimetinib in BRAF V600E-mutated colorectal cancer. *First Author: Javier Ros Montañá, Vall d'Hebron Institute of Oncology (VHIO), Medical Oncology, Vall d'Hebron University Hospital (HUVH), Barcelona, Spain*

Background: The *BRAF-V600E* mutation confers poor prognosis in patients with mCRC. E-C+/-B improve clinical outcomes compared with standard of care. Data about subsequent treatment lines and the impact of NGS in the treatment choice after the BRAF targeted treatment are still limited. We have analyzed the global overall survival (OS) and the impact of NGS to guide subsequent treatments (approved targeted therapies (TT) or clinical trials (CT)) after E-C+/-B. **Methods:** Patients who had received E-C+/-B were included. Clinical data was collected prospectively. Tissue NGS was performed prospectively and retrospectively using an in-house NGS panel (VHIO-300). Subsequent treatments' clinical outcomes were described. Percentage of patients who received TT or CT based on NGS results is reported. Clinical outcomes were calculated using survival Kaplan-Meier curves. **Results:** From 2017 to 2021, 59 patients with refractory mCRC received E-C+/-B at our institution. 50 patients have already progressed to the BRAF inhibitor combination and 9 patients remain on BRAF inhibitor treatment. Tumor tissue for NGS testing before BRAF inhibitor treatment was available in 70% of patients (41/59). *BRAF-V600E* mutation was confirmed in tissue using ddPCR in all patients. The most frequent alterations were: *BRAF-V600E* 93%, *TP53* 64%, *RNF43* 30%, *APC* 20%, *PIK3CA* 14%, *NOTCH1/2* 9%, *RANBP2* 8%, *PTEN* 8%, *MET* amplification 5%. MSI incidence was 10%, 2 out of 6 (33%) received subsequent immunotherapy. After the BRAF inhibitor combination, 23 patients (38%) did not receive subsequent treatment (clinical deterioration or death). The 27 remaining patients (62%) received 41 subsequent treatments (37% of them were TT or CT). Median subsequent lines after the BRAF inhibitor combination were 1 (0-3). NGS led to targeted therapy in 20% of the patients: BRAF inhibitors combos (20%), microtubule inhibitors (13%), antiPD1 (13%), NOTCH inhibitors (6%), and MET inhibitor (6%). ORR among patients who received matched TT or CT was 6% and DCR (CR+PR+SD) was 47%. The median OS after the BRAF inhibitor was 3.8 months; 10.1 months vs 3.0 months (HR 0.43 (95%CI 0.2-0.95), p = 0.04) for those patients who received TT or CT vs patients who did not receive TT or CT. When MSI patients were excluded mOS was 5.2 vs 3.0 months (HR 0.61 (95%CI 0.27-1.37), p = 0.23) respectively. There were no differences in terms of OS regarding the number of previous lines (0-1 vs 2-3, HR 0.75 (95%CI 0.4-1.42), p = 0.37) or with the BRAF inhibitor regimen used (E-C vs E-C-B) (HR 0.84, (95%CI 0.44-1.6), p = 0.61) **Conclusions:** This study suggests that patients with *BRAF-V600E* mutant mCRC could have benefit when treated with TT and/or in CT after a BRAF inhibitor-based therapy, including immunotherapy. Genomic analysis might help to guide subsequent treatments. Because of molecular heterogeneity, these patients should be discussed in Molecular Tumor Boards. Research Sponsor: None.

A phase 2 trial of sintilimab (IBI 308) in combination with CAPEOX and bevacizumab (BBCAPX) as first-line treatment in patients with RAS-mutant, microsatellite stable, unresectable metastatic colorectal cancer. *First Author: Xuefeng Fang, Department of Medical Oncology, Key Laboratory of Cancer Prevention and Intervention, Ministry of Education, The Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: The prognosis of metastatic colorectal cancer (mCRC) patients with RAS gene mutation and microsatellite stable (MSS) is poor. MSS patients account for 95% of CRC and have a low response rate to immunotherapy. Previous studies have reported that chemotherapy and anti-angiogenesis therapy can promote immunotherapy response. This study aims to assess the safety and antitumor activity of sintilimab (IBI308) combined with CapeOx and bevacizumab in the first-line treatment of patients with RAS-mutant and MSS mCRC. **Methods:** This is an open-label, single-arm, phase II trial. Eligible patients were aged 18 to 75 years with histologically confirmed unresectable metastatic colorectal adenocarcinoma by multidisciplinary team, and had RAS gene mutation and confirmed MSS status. All patients received treatment with sintilimab (200 mg, day 1) plus bevacizumab (7.5mg/kg, day 1) and oxaliplatin (135 mg/m^2, day 1) and capecitabine (1g/m^2, bid, day 1-14) of each 21-day cycle. The primary endpoint included objective response rate (ORR) evaluated via RECIST 1.1 criteria and adverse events according to CTCAE 5.0. Secondary endpoint was progression-free survival (PFS). **Results:** 25 patients were enrolled and received at least two cycle treatment. At baseline, median age was 60 years (range 45-74), 72% of patients were male, ECOG PS 0/1 was 100%, 60% had liver metastases (mets), and the primary tumor site was right-sided colon in 36.0% and left-side colorectum in 64.0%. 25 patients completed at least one efficacy evaluation. 2 (8.0%) patients showed complete response (CR), 19 (76.0%) patients had a partial response (PR) and 4 (16.0%) had stable disease (SD). Patients with liver or lung mets had a higher ORR (93.3% and 100%, respectively) compared to the overall ORR (84.0%). Disease control rate (DCR) reached 100%. Median PFS has not yet reached. No grade 5 adverse events occurred. The most common treatment-related adverse events (TRAEs) in all grades were anemia (19/25, 76.0%), peripheral neurotoxicity (6/25, 24.0%) and neutropenia (17/25, 68.0%). The most frequent grade 3/4 TRAEs were neutropenia (3/25, 12.0%), elevated aspartate transaminase (1/25, 4.0%), elevated alanine transaminase (1/25, 4.0%) and elevated bilirubin (1/25, 4.0%). **Conclusions:** Combination treatment with sintilimab (IBI308) plus CapeOx and bevacizumab demonstrated a high ORR (84.0%; 93.3% in patients with liver mets, and 100% in patients with lung mets) and a manageable safety profile in RAS-mutant and MSS mCRC. Clinical trial information: NCT05171660. Research Sponsor: Innovent Biologics, Inc.

	Liver mets(N = 15)	Lung mets(N = 4)	Other mets(N = 6)	All patients(N = 25)

NSABP FC-11: A phase II study of neratinib (N) plus trastuzumab (T) or N plus cetuximab (C) in patients (pts) with "quadruple wild-type" metastatic colorectal cancer (mCRC) based on HER2 status. *First Author: Samuel A. Jacobs, NSABP Foundation, Inc., Pittsburgh, PA*

Background: Patients (pts) with KRAS wild-type (WT) mCRC treated with single agent anti-EGFR therapy (tx) have improved OS compared to BSC but only a 10-15% response rate. Prior EGFR tx may upregulate HER amplification. For pts with quadruple WT mCRC (KRAS, NRAS, BRAF, PIC3KA), data suggest that dual targeting of the MAPK pathway, specifically EGFR and HER2, may be more effective. The purpose of this study was to evaluate the activity of dual MAPK pathway inhibition based on HER2 status: amplified (amp), non-amplified (non-amp), or mutated (mt). **Methods:** This 2-arm phase II trial enrolled pts with quad WT mCRC with ECOG PS 0-2, adequate organ function, prior oxaliplatin- and irinotecan-based regimens, and known HER2 status. Arm 1: HER2 amp (confirmed as >2.14 copy number by Guardant 360) and prior anti-EGFR tx or HER2 mt (with qualifying mt) with or without prior anti-EGFR tx; Arm 2: HER2 non-amp or HER2 amp without prior anti-EGFR tx. Tx included T 4 mg/kg IV loading dose → 2 mg/kg/wk and N 240 mg po daily (Arm 1) or C 400 mg/m^2 IV loading dose → 250 mg/m^2/wk and N 240 mg po daily (Arm 2). Imaging was performed every 8 wks with response per RECIST 1.1. Primary end point (EP) of each arm was 6 mo PFS (PFS_6). Secondary EPs: Response rate (ORR), clinical benefit rate (CBR), toxicity and exploratory assessments of N pharmacokinetics, genetic and molecular analyses, and evaluation of multiple drug combinations in PDX/PDXO models. We tested H_0: PFS_6 <0.13 *v* H_A: PFS_6 >0.47 (α=0.05; power=0.90 to reject H_A). Treating 15 pts in each arm, if ≥5 pts are alive and progression free (PFS_6 0.33), the arm is worth further testing. **Results:** From Jul 2018 - Mar 2021, 25 pts enrolled from 9 different centers. Arm 1 closed due to poor accrual (n=4). Those pts have been excluded from further analysis. Arm 2 enrolled 21 pts. with 15 evaluable for response by imaging. Early discontinuation occurred in 6 of 21 pts: 2 withdrew consent, 3 due to toxicity, and 1 physician withdrawal. Of the 15 evaluable pts, there were 6 PR, 5 of 13 HER2 non-amp, 1 of 2 HER2 amp, (duration 120-171 days; mean 140) and 5 SD (duration 59-231 days; mean 124). The ORR (CR/PR) in all pts who received at least one dose of tx is 33% (6/20). 8 of 15 evaluable pts (53%) were progression free at cycle 6. Common grade 3+ AEs (>5%) included diarrhea (24%), rash (8%), and abdominal pain/distension (8%), without any grade 5 AEs. **Conclusions:** The combination of C+N was reasonably well tolerated with expected toxicities of diarrhea and rash. The ORR, CBR, and PFS compare favorably to pts previously relapsed following oxaliplatin and irinotecan and treated with single-agent anti-EGFR tx. Upon entry, biopsies for PDX implantation had an engraftment success rate of ~80%. We anticipate using these grafts to establish PDXO models for molecular analyses and further drug testing. Support: NSABP Foundation, Puma Biotechnology. Clinical trial information: NCT03457896. Research Sponsor: Puma Biotechnology, Other Foundation.

Phase II study of pembrolizumab plus capecitabine and bevacizumab in microsatellite stable (MSS) metastatic colorectal cancer (mCRC). *First Author: Andrea Grace Bocobo, University of California San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco, CA*

Background: MSS mCRC rarely responds to pembrolizumab monotherapy, but capecitabine and bevacizumab may induce immune-stimulatory effects. This study evaluates the safety, tolerability and preliminary efficacy of pembrolizumab in combination with capecitabine and bevacizumab in MSS mCRC. **Methods:** Single-center, phase 2 trial with safety lead-in to confirm the recommended phase 2 dose (RP2D) for capecitabine and expansion cohorts (NCT03396926). Key eligibility: MSS mCRC with stable disease (SD) or progressive disease (PD) on prior fluoropyrimidine-based therapy. Treatment: Capecitabine 1000 mg/m2 PO BID D1-14 Q21 days (confirmed RP2D) plus pembrolizumab 200 mg IV D1 Q21 days and bevacizumab 7.5 mg/kg IV D1 Q21 days. Endpoints: Primary: Objective response rate (ORR) by RECIST 1.1. Key secondary: Safety, duration of response (DOR), progression-free survival (PFS), overall survival (OS). **Results:** From 04/2018-10/2021, 44 patients (pts) were enrolled. Overall: Median age 53 years (range 28-79); female 50%; Caucasian 61%. Liver metastases at enrollment 80%. Prior therapies: median prior lines of therapy 2 (range 1-5); PD on fluoropyrimidine-containing regimens 91%; prior exposure to bevacizumab 86%. Complete toxicity data are available for 36 off-treatment pts. Grade ≥ 3 treatment-related (tr)AEs occurred in 10 (28%) pts, including grade 3 immune-related AEs in 4 (11%) pts. All-cause serious (s)AEs occurred in 13 (36%) pts and trSAEs in 5 (14%) pts. (tr)AEs leading to dose interruptions, reductions, or delays occurred in 21 (58%) pts, most commonly palmar-plantar erythrodysesthesia syndrome in 17 (47%) pts. Disposition: of 44 pts enrolled, 35 were removed for PD and 1 was removed for treatment noncompliance; 8 treatment ongoing. ORR in 40 evaluable pts was 5% (95% CI: 0.6,16.9). Best response by RECIST 1.1: partial response (PR) in 2 (5%); SD in 26 (65%); PD in 12 (30%). 2 responders: DOR 12 and 15 months, both with liver metastases. Median follow up was 7 months (range 1-45), with median PFS 4.3 months (95% CI: 3.9, 6.1), PFS at 6 months 31.1% (95% CI: 19.2%, 50.4%), and median OS 9.6 months (95% CI: 6.2, 13). Median time on treatment was 5 months (range 1-26). Single cell RNA sequencing on a subset of paired pre- and on-treatment biopsies demonstrated changes in the frequency of dendritic cells. **Conclusions:** The combination of pembrolizumab with capecitabine and bevacizumab was found to be tolerable with an expected toxicity profile in MSS mCRC pts. The ORR of 5% did not meet the prespecified target of ≥ 15%, however nearly a third of pts had PFS > 6 months. Immune profiling of tumor biopsies and peripheral blood is ongoing. Clinical trial information: NCT03396926. Research Sponsor: Merck.

3566 **Poster Session**

Efficacy and safety of tislelizumab plus cetuximab and irinotecan in patients with previously treated RAS wild-type advanced colorectal cancer: Preliminary findings of a phase II, single-arm study. *First Author: Xiaojing Xu, Department of Oncology, Cancer center, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: For adequately treated patients (pts) with advanced colorectal cancer, the current third-line treatment standard of TKIs or TAS-102 administration has a low clinical objective response rate and its effectiveness seems to be limited. Preclinical studies have suggested that EGFR pathway blockage and immune checkpoint inhibition have synergistic therapeutic effects in these pts. The purpose of this study was to examine the efficacy and safety of tislelizumab (anti-PD-1 antibody) plus cetuximab and irinotecan in pts with previously treated RAS wild-type advanced colorectal cancer. **Methods:** This is an open-label, single-arm, phase II study. RAS wild-type advanced colorectal cancer pts with at least two previous lines of therapy were included in this study and administered with tislelizumab plus cetuximab and irinotecan until disease progression or intolerable toxicity. The primary endpoint was objective response rate (ORR) (RESCIT 1.1). Secondary endpoints included DCR, PFS, OS and safety. **Results:** In total, 35 eligible RAS wild-type advanced colorectal cancer pts were enrolled from March 2021 to September 2021. The median age was 58 years. All 35 pts were identified as BRAF/RAS wild-type, and 33 (94%) had left-sided colon cancer. The percentages of pts with second-line, third-line and ≥fourth-line previous treatments were 37%, 49%, and 14%, respectively. Thirty-four pts (97%) had received targeted therapies previously, including 29 (83%) with anti-EGFR therapy. By December 31, 2021, 2 pts had withdrawn from the study for personal reasons, and the remaining 33 were evaluated for efficacy. Twelve of the 33 (36.4%) pts achieved clinical partial remission and 14 (42.4%) achieved stable disease; disease progression occurred in 6 pts and 1 patient died. The ORR was 36.4% and the DCR was 78.8%. Until December 31, 2021, 23 pts continued treatments, and the median PFS was not reached. Among the 33 treated pts, 32 (97.0%) had treatment-related adverse events (AEs). Common AEs included rash (n = 32), fatigue (n = 29), decreased appetite (n = 24), nausea (n = 24), diarrhea (n = 13), liver dysfunction (n = 10), vomiting (n = 7), leukopenia (n = 7), anemia (n = 6), paronychia (n = 5), oral mucositis (n = 4), and neutropenia (n = 4). Four (12%) of the 33 pts reported grade ≥3 AEs, including rash (n = 1), neutropenia (n = 2) and vomiting (n = 1). **Conclusions:** Tislelizumab plus cetuximab and irinotecan shows an encouraging clinical efficacy and tolerable safety in previously treated pts with RAS wide-type advanced colorectal cancer. Clinical trial information: NCT05143099. Research Sponsor: Special fund for clinical research of Zhongshan Hospital.

3567 **Poster Session**

Impact of age and gender on the efficacy and safety of panitumumab plus fluorouracil and folinic acid versus fluorouracil and folinic acid alone as maintenance therapy in RAS WT metastatic colorectal cancer (mCRC): Subgroup analysis of the PANAMA-study (AIO-KRK-0212). *First Author: Kathrin Heinrich, Department of Medicine III and Comprehensive Cancer Center (CCC Munich LMU), University Hospital, LMU Munich, München, Germany, Munich, Germany*

Background: Clinical trials in mCRC are usually conducted irrespective of gender and mostly also irrespective of age. However, gender- and age-associated differences relating to safety and efficacy in the treatment of mCRC are of presently moving into the focus of interest. We investigated the effect of gender and age on efficacy and safety in the PANAMA trial. **Methods:** PANAMA investigated the efficacy of panitumumab (Pmab) plus fluorouracil and folinic acid (FU/FA) versus FU/FA alone after first-line induction therapy with six cycles of FU/FA and oxaliplatin plus Pmab in patients with *RAS* wild-type metastatic colorectal cancer. In this post-hoc analysis, the study population was stratified for age (≤ 65 years versus > 65 years) and gender (male versus female). Evaluated efficacy endpoints were progression-free survival (PFS), overall survival (OS) of maintenance therapy and objective response rate (ORR) during maintenance therapy. Safety endpoints were rates of any grade and grade 3/4 adverse events (AEs). **Results:** In total, 165 male and 83 female patients were randomized and treated. Male patients had a significant benefit from the addition of Pmab to maintenance treatment with regard to PFS (HR 0.63; 95% CI 0.45-0.88; p = 0.006) and demonstrated a strong trend towards better ORR during maintenance therapy (Odds ratio 1.92; 95%CI 1.02-3.70, p = 0.053). In female patients, no difference regarding PFS was seen between treatment arms (HR 0.85; 95% CI 0.53-1.35, p = 0.491), while a trend towards better ORR with Pmab (Odds ratio 2.50; 95% CI 0.99-6.25; p = 0.063) was observed. Gender had no significant impact on OS, nor did age categories affect survival endpoints. Adverse events grade ≥ 3 occurring during maintenance therapy were comparable between male and female patients (12.9% vs 13.5%; p = 0.791) and in different age categories (p = 0.393). **Conclusions:** In the Panama trial, addition of Pmab to maintenance treatment with FU/FA improved outcome in *RAS* wild-type mCRC. This effect is irrespective of age and is pronounced in male patients. Our results support the relevance of gender in mCRC. Clinical trial information: NCT01991873. Research Sponsor: None.

3568 **Poster Session**

Trifluridine/tipiracil plus bevacizumab (FTD/TPI + BEV) and trifluridine/tipiracil (FTD/TPI) monotherapy in metastatic colorectal cancer (mCRC): Results of a meta-analysis. *First Author: Takayuki Yoshino, Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: FTD/TPI is approved for patients (pts) with refractory mCRC. FTD/TPI + BEV has been evaluated in refractory mCRC in phase 1 and 2 trials and shown efficacy and tolerability, but few head-to-head studies compare FTD/TPI + BEV with FTD/TPI. We therefore conducted this meta-analysis to evaluate outcomes with FTD/TPI + BEV and FTD/TPI monotherapy in mCRC. **Methods:** We searched MEDLINE, Embase, and Cochrane Library databases; ASCO, ESMO, and AACR proceedings (past 3 years); Clinicaltrials.gov and UMIN registries; systematic review bibliographies; gray literature; and guidelines through June 2021 for studies involving pts with mCRC treated with FTD/TPI + BEV or FTD/TPI. Only randomized controlled trials (RCTs), non-RCTs, and prospective observational studies of previously treated pts with mCRC were evaluated. Outcomes included objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), adverse event (AE) rates, and AE-related discontinuation rates. Fixed and random effects models based on inverse-variance weighting were used to estimate relative effects and pooled absolute outcomes for ORR, DCR, AE rates, and AE-related discontinuation rates. PFS and OS were estimated from pooled Kaplan–Meier curves using Guyot's algorithm. **Results:** Twenty-nine of 875 screened publications were selected, which included a total of 10,285 pts and reported on 5 RCTs, 11 non-RCTs, and 10 prospective observational studies. In an RCT (n = 93; Pfeiffer et al. *Lancet Oncol.* 2020), FTD/TPI + BEV was associated with significant reductions in risks for progression and death versus FTD/TPI. Pooled efficacy outcomes were higher with FTD/TPI + BEV than FTD/TPI (Table). Pooled rates for grade ≥3 febrile neutropenia, asthenia/fatigue, diarrhea, nausea, and vomiting were similar with FTD/TPI + BEV and FTD/TPI, although grade ≥3 neutropenia occurred more frequently with FTD/TPI + BEV than FTD/TPI (43% vs 29%). AE-related discontinuation rates were similar (Table). **Conclusions:** This meta-analysis suggests that FTD/TPI + BEV provides benefits over FTD/TPI in pts with refractory mCRC and has a similar safety profile, but it is associated with a higher rate of grade ≥3 neutropenia. Limitations of the analysis include study design heterogeneity. Data from RCTs (eg, phase 3 SUNLIGHT trial [NCT04737187]) are required to confirm these findings. Research Sponsor: Taiho Oncology, Inc.

NSABP FC-10: A phase Ib study of pembrolizumab (pembro) in combination with pemetrexed (pem) and oxaliplatin (oxali) in patients with chemo-refractory metastatic colorectal cancer (mCRC). *First Author: John C. Krauss, University of Michigan, Ann Arbor, MI*

Background: Most pts with mCRC have microsatellite stable (MSS) disease (95%) which is unresponsive to checkpoint inhibition. Chemotherapy activity is mediated through both cytotoxicity as well as immunological effects including reduced T-regulatory cell activity, enhanced tumor antigen presentation, and induced PD-L1 tumor cell expression. Chemotherapy with checkpoint inhibitors can potentially activate T cells and alter the microenvironment to improve outcomes. Our purpose was to evaluate pembro plus pem in a safety run-in (cohort 1) and the same with dose-escalated oxali (cohort 2). **Methods:** Eligible pts with MSS mCRC had ECOG PS of 0-1, measurable metastatic disease, adequate organ function, and prior treatment with fluoropyrimidine-, oxali-, and irinotecan-based therapies (plus an anti-EGFR agent, if apropos). Cohort 1 treatment was pem 500 mg/m^2 IV plus pembro 200 mg IV every 3 wks. Cohort 2 treatment was the same, plus oxali at an escalating dose of 85-120 mg/m^2 utilizing a 3+3 design with expansion of 6 additional pts at the RP2D. Imaging was performed every 3 cycles; response was determined by RECIST 1.1. Primary endpoint (EP) of each cohort: safety and best ORR with cohort 2 also to establish the RP2D. Secondary EPs: Clinical benefit rate (CBR), PFS, OS at 1 year, and exploratory assessments of circulating immunologic profiles and molecular predictors of response. Descriptive statistics were planned as a signal-seeking study. **Results:** From Jul 2019-Apr 2021, 34 pts enrolled from 4 different centers. In cohort 1 (n=15), one pt was taken off study due to LFT elevation and orchitis attributed to pembro with reduced lymphadenopathy upon withdrawal. There was 1 PR (duration 686 days) and 4 SDs (61, 66, 124, 128 days) among 11 evaluable for response. There were no unexpected nor grade 5 toxicities. In cohort 2 (n=19), 2 pts achieved a PR (127 and 185 days), with SDs in 5 (59, 63, 69, 115, 437), among 13 evaluable for response. At oxali dose of 85 mg/m^2, 1/6 pts had DLT (grade 4 neutropenia ≥7 days); another 1/6 pts had DLT at 120 mg/m^2 (grade 3 AST/ALT). The RP2D was 120 mg/m^2. Common grade 3/4 AEs included: neutropenia (24%), anemia (9%), fatigue (9%), abdominal pain (6%), nausea (6%), and ALT/AST (6%). There was no febrile neutropenia nor any grade 5 events. Combined cohort rates of PR/CBR were 3/24 (12.5%) and 12/24 (50%), respectively. **Conclusions:** In this study of heavily pretreated pts with MSS mCRC, combining pembro plus pem or pem+oxali was well tolerated. Overall CBR was 50%, with objective responses (PRs) in 3/24 (12.5%) evaluable pts. This compares favorably with KEYNOTE 016, in which pembro in MSS mCRC pts had 0/18 objective responses and CBR=11% (2/18). Further studies testing these agents in earlier lines of treatment with robust correlative analyses is supported. Support: NSABP Foundation; Merck; Lilly. Clinical trial information: NCT03626922. Research Sponsor: Merck; Lilly, Other Foundation.

Optimal cytoreductive LIVER surgery for unresectable colorectal liver metastases: A prospective observational study. *First Author: Rene Adam, AP-HP, Hôpital Paul Brousse, Univ Paris-Saclay, Villejuif, France*

Background: Patients with multiple colorectal liver metastases (CLM) involving all the hepatic segments are currently not eligible for potentially curative liver surgery. Transplantation is a promising alternative but graft shortage and stringent selection criteria limit its accessibility. Owing to the improving efficacy of chemotherapy, the impossibility to resect all the initial metastatic sites could lead to revisit the role of optimal cytoreductive liver surgery (CLS) aiming to treat by resection ± radiofrequency, all the macroscopic residual tumors after a good response to chemotherapy. Although validated for ovarian cancer and peritoneal carcinomatosis, this strategy remains unexplored in CLM. Our objective was to evaluate the outcome of this strategy in patients with definitively unresectable CLM. **Methods:** Within a prospective monocentric study, we enrolled for debulking surgery, between 2017 and 2021, all consecutive patients with multinodular unresectable CLM involving all segments on initial imaging and consequently ineligible for a curative surgery either after a one or two-stage hepatectomy. These patients should have a strong response to chemotherapy (> 50 % on RECIST criteria) for at least a 3-month period and no or limited extrahepatic disease, to be included. End-points of the analysis were overall and disease-free survival at 3 years. **Results:** Among 26 patients considered for this strategy, optimal CLS could be achieved in 21 patients after a median interval of 10 months from CLM diagnosis. The median number of lesions was 11 (7 - 26) on initial imaging. Four patients (19%) had synchronous lung metastases. Liver-first strategy was undertaken in 19 patients (90%). Postoperative complications (Grade ≥ III) occured in 5 patients (24%). One patient died within 90-day after operation from intra-abdominal hemorrage while on anticoagulation therapy. After a median follow-up of 25 months from hepatectomy, the 3-year OS rates was 85%. Median survival was not reached at the time of the analysis. Of the 4 (19%) patients with complete pathological response on the liver specimen, 3 developed recurrence. A total of 17 patients (81%) developed recurrence after a median time of 10,5 months from hepatectomy. Among them, repeat hepatectomy could be undertaken in four patients. The survival time to surgical failure (recurrence untreatable with curative intent) was 32% and 16% at 2 and 3 years. At last follow-up, seven patients (33%) are alive and recurrence-free. **Conclusions:** The promising results of this prospective series suggest that CLS may be worthy in patients with diffuse CLM non curatively treatable by surgery but responding well to chemotherapy. This strategy should however be reserved to hyperselected patients, super responders, eligible for an optimal resection of all the macroscopic residual tumors, and confimed by other expert centers, to be definitively validated. Research Sponsor: None.

Identification of an optimal circulating tumor DNA (ctDNA) shedding threshold to detect actionable driver mutations in colorectal and pancreatic adenocarcinoma. *First Author: Bennett Adam Caughey, Division of Medical Oncology, Duke University School of Medicine, Durham, NC*

Background: In colorectal cancer (CRC), mutations in *KRAS*, *NRAS*, and *BRAF* predict resistance to anti-EGFR therapies. In pancreatic ductal adenocarcinoma (PDAC), ~90% of patients harbor *KRAS* mutations, while *KRAS* wild-type tumors often have clinically actionable fusion alterations. Thus, in both cancers, the accurate ascertainment of *RAS* and *BRAF* driver status is essential. Sequencing of cell-free DNA (cfDNA) from plasma allows convenient assessment of a tumor's molecular profile, but sensitivity can be limited by low ctDNA shedding. We sought to establish a ctDNA shedding threshold at which actionable driver mutations can be reliably detected. **Methods:** Molecular reports and matched clinical data were obtained from the Duke Molecular Registry of Tumors and the SCRUM-Japan GOZILA and GI-SCREEN. CRC or PDAC patients with a pathogenic *KRAS*, *NRAS*, or *BRAF* activating point mutation ("driver") present on tissue next-generation sequencing (NGS) assays and who also had cfDNA assay available were included. Tissue NGS included Foundation One CDx and Oncomine Comprehensive Assay. Guardant 360 (G360) was the sole plasma cfDNA assay. 131 CRC and 24 PDAC cases with 189 total G360 assays met criteria and were included. Samples were analyzed according to detection of the driver mutation and the maximum mutant allele frequency (MAF) of non-driver mutations on G360. An optimal cut-point for max MAF was explored among the CRC and PDAC patients using a maximally selected Wilcoxon rank statistic method. **Results:** 76.8% of driver mutations were in *KRAS*, 22.6% in *BRAF*, and 1.9% in *NRAS* with an overlap of 1 *BRAF* and 1 *NRAS* mutation with a *KRAS* mutation. Overall sensitivity of G360 for drivers was 83.0% for CRC and 54.2% for PDAC. No variants were detected on G360 in 9.1% of CRC and 37.5% of PDAC. Sensitivity for driver mutations increased with higher maximum non-driver MAF, with MAF > 1% predicting sensitivity > 98% (Table). Optimal cut-point analysis identified MAF of > 0.34% ($p < 0.0001$), above which the driver was identified in 97% of patients and below which only 27%. **Conclusions:** In our study, non-driver MAF > 1% on cfDNA NGS predicts high sensitivity for *RAS* and *BRAF* mutations and thus is adequate to guide clinical decisions such as anti-EGFR therapy in CRC, evaluation for fusions in PDAC, and validity in clinical trials. MAF ≤0.34% is a clear threshold to consider an assay inadequate and thus seek alternative testing. Sensitivity rises for MAF between 0.35 and 1% but will require greater patient numbers to establish clinically relevant sensitivity thresholds. These results will be updated with additional data for final presentation. Research Sponsor: Duke University, SCRUM-Japan Funds.

Non-driver max MAF range	Driver detection sensitivity (95% CI)	N
0% (no variants)	7.7% (0.95-25.1)	26
> 0 to ≤0.5%	64.5% (45.4-80.77)	31
> 0.5 to ≤1%	85.7% (57.2-98.2)	14
> 1 to ≤5%	100% (86.8-100)	26
> 5 to ≤10%	95.8% (78.9-99.9)	24
> 10%	98.5% (92.1-99.96)	68

Response to epithelial growth factor receptor inhibitor (EGFRi) treatment in patients with early-onset, treatment-naïve metastatic colorectal cancer (mCRC): An ARCAD database analysis. *First Author: Zhaohui Jin, University of Iowa, Iowa City, IA*

Background: Early onset colorectal cancer (eoCRC: disease diagnosed < 50) has been increasing over the past 2 decades. Currently, standard treatment recommendations for eoCRC patients (pts) with metastatic disease does not differ from late-onset CRC (loCRC) pts although outcomes data in eoCRC pts is limited. **Methods:** Individual patient data on 5,761 treatment-naive metastatic eoCRC pts was pooled from 8 phase II and III randomized EGFRi studies (2000 - 2012) from the ARCAD mCRC database. The distribution of demographics, clinicopathological features, and biomarkers were summarized by age groups. Progression-free survival (PFS) was compared between age groups by stratified Cox models, adjusting for potential confounders. Predictive value of age group was evaluated by testing interaction effect between treatment and age variables based on a subset of trials with concurrent randomizations between regimens with and without EGFRi **Results:** eoCRC (n=756) were more evenly distributed between gender, had improved performance status (PS), increased likelihood of metastatic resection, and distant lymph node metastasis, but were less likely to have lung metastasis or KRAS mutation compared to loCRC (n=5,005, table 1). eoCRC and loCRC patients had similar distribution of primary tumor sidedness, primary resection, liver and/or peritoneal involvement, number of metastatic sites involved, and BRAF mutations (MT). No difference in PFS for eoCRC versus loCRC pts was noted (7.8 vs. 7.9 months [M], adjusted hazard ratio [HR_{adj}], 1.02, 95% confidence interval [CI], 0.93-1.11). Among pts with KRAS wild type (WT) and left sided primary tumors, univariable analysis of EGFRi demonstrated improved mPFS in loCRC (9.9 vs 8.5M, HR = 0.74, p<0.001), but this benefit was not seen in eoCRC (8.3 vs 8.9 months, HR 1.20, p=0.36). The same pattern was observed upon multivariable analysis (Table). **Conclusions:** In our pooled analysis,EGFRi + chemotherapy significantly improved PFS in treatment-naïve loCRC patients but not in left sided, KRAS WT, eoCRC patients. Further validation in an independent cohort is warranted. Research Sponsor: None.

Pembrolizumab (pembro) plus binimetinib (bini) with or without chemotherapy (chemo) for metastatic colorectal cancer (mCRC): Results from KEYNOTE-651 cohorts A, C, and E. *First Author: Eric Xueyu Chen, Princess Margaret Hospital, Toronto, ON, Canada*

Background: Response to antiPD-1 monotherapy is poor in microsatellite stable (MSS)/mismatch-repair proficient (pMMR) mCRC; the combination of antiPD-1 pembro + anti-MEK bini, with or without chemo, may improve upon this limited response. KEYNOTE-651 (NCT03374254) is an open-label phase 1b multicenter trial of pembro + bini (cohort A) or pembro + bini + chemo (mFOLFOX7 in cohort C, FOLFIRI in cohort E) in MSS/pMMR mCRC. Preliminary results from the dose-finding phase at 2 dose levels (DL) of bini are presented. **Methods:** Patients (pts) had MSS/pMMR mCRC and must have been previously treated with fluoropyrimidine, irinotecan, and oxaliplatin in cohort A, or with fluoropyrimidine + oxaliplatin-based regimen in cohort E; pts were previously untreated in cohort C. Pts received pembro 200 mg Q3W + bini 30 mg BID (cohort A, DL1), pembro 200 mg Q3W+ bini 30 mg BID + mFOLFOX7 Q2W (cohort C, DL1) or pembro 200 mg Q3W + bini 30 mg BID + FOLFIRI Q2W (cohort E, DL1). Bini dose escalation to 45 mg BID (DL2) was planned in cohorts A, C, and E, with a target dose-limiting toxicity (DLT) of 30%. Primary end point was safety (DLT). Secondary end point was ORR. DCR, PFS, and OS were exploratory. ORR, DCR, and PFS were assessed by investigator per RECIST v1.1. **Results:** Median study follow-up at data cutoff (Oct 15, 2021) was 36 mo (range, 32-43) for cohort A, 17 mo (2-24) for cohort C, and 11 mo (2-25) for cohort E. In cohort A, 1/6 pts (17%) had DLT at DL1; no DLT occurred in 14 pts (0%) at DL2. In cohort A, gr 3/4 TRAEs occurred in 3/6 pts (50%) at DL1 and 8/14 pts (57%) at DL2. In cohort C, 3/9 evaluable pts (33%) had DLT at DL1; thus, bini dose was not escalated to DL2. In cohort C, gr 3/4 TRAEs occurred in 9/11 total pts (82%). In cohort E, 1/5 evaluable pts (20%) had DLT at DL1 and 5/10 evaluable pts (50%) had DLT at DL2. Enrollment was stopped in cohort E, DL2 and bini dose was de-escalated to DL1; 2/4 additional pts (50%) had DLT at DL1 (total 3/9 pts [33%] had DLT in cohort E, DL1). In cohort E, gr 3/4 TRAEs occurred in 5/9 pts (56%) at DL1 and 10/11 total pts (91%) at DL2. No gr 5 TRAEs occurred in any cohort. ORR was 0% in cohort A; limited efficacy was seen in cohorts C and E (Table). **Conclusions:** Bini could be safely combined with pembro in cohort A. However, with bini + pembro + chemo, the 45-mg dose of bini was not well tolerated and required dose reduction to 30 mg. Addition of bini to pembro + chemo did not improve efficacy; therefore, enrollment was prematurely closed in cohorts C and E. Efficacy by *KRAS* mutation status will be shown. Clinical trial information: NCT03374254. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

CPGJ602 plus mFOLFOX6 as first-line treatment for patients with KRAS/NRAS/BRAF wild-type metastatic colorectal cancer: A randomized phase II study. *First Author: Jianming Xu, Department of Gastrointestinal Oncology, The Fifth Medical Center, General Hospital of People's Liberation Army, Beijing, China*

Background: CPGJ602 is a recombinant anti-EGFR human-mouse chimeric monoclonal antibody. CPGJ602 plus modified fluorouracil, leucovorin, and oxaliplatin (mFOLFOX6) may have efficacy in KRAS/NRAS/BRAF wild-type metastatic colorectal cancer. **Methods:** In this open-label, randomized trial, patients who had received no previous treatment were randomly assigned (2:2:1) to receive CPGJ60 （325mg/m^2, q2w) plus mFOLFOX6 (biweekly group), CPGJ602 (400 mg/m ^{2} initial dose followed by 250 mg/m^2 /week thereafter) plus mFOLFOX6 (weekly group) or cetuximab (400 mg/m^2 initial dose followed by 250 mg/m^2 /week thereafter) plus mFOLFOX6 (cetuximab group). All subjects received treatment up to 16 weeks. The primary endpoint was the best overall response (BOR) at 16 weeks. The second endpoints were DCR, DOR, PFS, safety. **Results:** As of Dec 30, 2021, 76 patients were enrolled (30 in biweekly group, 32 in weekly group and 14 in control group). The best overall response achieved at 16 weeks was 76.7% (23/30, 95% CI 60.3% - 92.0%),78.1% (25/32, 95% CI 62.5% - 92.5%) and 78.6% (11/14, 95% CI 49.2% - 95.3%) in the biweekly group, weekly group and cetuximab group, respectively. The confirmed overall response rate at 16 weeks was 60%(18/30), 71.9%(23/32) and 57.1%(8/14) in the biweekly group, weekly group and cetuximab group, respectively. The PFS rates at 16 weeks were 81.5% (95% CI 57.7% -92.6%), 96.8% (95% CI 79.2%-99.5%), 81.3% (95% CI 41.5%- 95.2%) in the biweekly group, weekly group and cetuximab group, respectively. The most common adverse events were a decreased neutrophil count (60%， 78.1% and 71.4% in the biweekly group, weekly group and cetuximab group respectively), decreased white-cell count (53.3%, 78.1% and 71.4% respectively), decreased platelet count (40.0%, 40.6% and 42.9% respectively), and elevated serum aspartate aminotransferase (43.3%, 37.5% and 35.7% respectively). **Conclusions:** CPGJ602 plus mFOLFOX6 could be an option for KRAS/NRAS/BRAF wild-type metastatic colorectal cancer. Clinical trial information: NCT04466254. Research Sponsor: Sunshine Guojian Pharmaceutical (Shanghai) Co., Ltd.

Post-treatment detection of circulating methylated *BCAT1* and *IKZF1* as prognostic indicators for recurrence in patients with colorectal cancer. *First Author: Graeme P. Young, Flinders University, Adelaide, SA, Australia*

Background: Patient risk for recurrence after completion of initial treatment of colorectal cancer (CRC) is difficult to predict. Post-treatment circulating tumor DNA (ctDNA) analysis is a promising approach for stratifying such patients but the value of using tumor-uninformed biomarkers, such as methylated *BCAT1* and *IKZF1*, is unknown. This study aimed to determine whether detection of circulating methylated *BCAT1* and *IKZF1* DNA following completed initial treatment with curative intent, identified patients at elevated risk of CRC recurrence. **Methods:** CRC stage I-III cases were eligible for study inclusion if a *BCAT1/IKZF1* methylation test result was available at least 2 weeks after, but within 12mo, of completing initial treatment, and had had at least 2y follow-up unless recurrence was evident sooner (n = 142). Surveillance included regular clinical assessments and radiographic imaging. Level of methylation was reported as the total methylated *BCAT1/IKZF1* expressed as percent of cell-free DNA; levels ≥0.07% were considered positive. Primary outcome measure was recurrence-free survival. Mantel-Cox (log-rank) method was used to assess the association between *BCAT1/IKZF1* results and recurrence-free survival. Multivariable survival analysis by Cox proportional hazards modelling assessed the impact of covariates, including: *BCAT1/IKZF1* result, age, gender, T-stage (T1-2 vs T3-4), N-stage (N0 vs N1-2), extra- and/or intra-mural vascular invasion (EMVI/IMVI) and nature of treatment. Time to recurrence was measured from the date of treatment completion to first evidence of recurrence and data were censored to last date of follow-up. **Results:** 33/142 (23.2%) cases had recurrence detected at a median 1.6y (IQR: 0.8-2.4). Follow-up time for those who remained recurrence free was 5.3y (IQR: 3.7-6.9). The time between completing treatment and *BCAT1/IKZF1* testing was not different between these groups (median 2.4 vs 3.1mo, p = 0.530). 13 (9.2%) cases were positive for methylated *BCAT1/IKZF1* after completing treatment and a positive result was associated with a significant risk of recurrence (hazard ratio [HR], 10.0 (95%CI 2.6-39.3), p < 0.001). In the multivariable survival analysis, only a positive *BCAT1/IKZF1* methylation result following treatment (HR 2.6, 95%CI: 1.0-6.0, p = 0.041) and evidence of EMVI or IMVI (HR 2.3, 95%CI: 1.0-5.1, p = 0.044) were significant predictors of survival. **Conclusions:** This study shows that post-treatment *BCAT1/IKZF1* methylation testing, which does not need personalization using tumor genotyping, is a promising independent prognostic indicator for CRC recurrence. Such cases are at high risk of recurrence compared to those who had no detectable ctDNA post treatment. These patients warrant enhanced and/or extended surveillance for recurrence. Clinical trial information: 12611000318987. Research Sponsor: Clinical Genomics Inc., Other Foundation.

BRAF-mutant metastatic colorectal cancer: Prognostic and predictive value of primary tumor location—A pooled analysis of the AIO studies FIRE-1, CIOX, XELAVIRI, FIRE-3, and VOLFI. *First Author: Annabel Helga Sophie Alig, Charité- Universitaetsmedizin Berlin, corporate member of Freie Universitaet Berlin and Humboldt-Universitaet zu Berlin, Department of Hematology, Oncology, and Cancer Immunology (CCM), Berlin, Germany*

Background: Primary tumor location (PTL: left vs. right) is an established prognostic marker in metastatic colorectal cancer (mCRC) and has predictive impact for anti-EGFR antibody (mAb) efficacy in patients with *RAS* (*KRAS* and *NRAS*) wild-type (WT) mCRC. This analysis of five pooled studies evaluates PTL as a prognostic and - concerning anti-EGFR mAb efficacy - predictive marker in *BRAF* V600E-mutant/*RAS* WT and mCRC. **Methods:** The analysis is based on individual patient data of five pooled 1st-line studies with varying treatment strategies: the pooled population comprises of *BRAF* V600E-mutant/*RAS* WT (*BRAF*mt) mCRC with known PTL. For analysis, treatment was stratified into two groups: treated with or without anti-EGFR mAb. Dichotomous variables (overall response rate, ORR; characteristics) were compared by Chi-Square or Fisher's exact test and time-to event endpoints (progressive-free survival, PFS; overall survival, OS) by Kaplan-Meier method, log rank test and Cox regression. **Results:** Of 102 patients (pts) with *BRAF*mt mCRC, 55 pts (54%) presented with right-sided primary tumors (RPT), 47 (46%) presented with left-sided primary tumors (LPT). Pts with RPT were more likely to be female (p= 0.04). ORR was inferior in RPT compared to LPT (35% vs. 55%; p= 0.04). No difference was seen in PFS (HR 0.8 (95% CI 0.6-1.3; p= 0.32) or OS (HR 0.8; 95% CI 0.8-1.3; p= 0.46). In male pts PTL trended to be associated with longer OS (HR 0.6; 95% CI 0.3-1.0; p= 0.06). 25 pts with RPT (45%) and 21 with LPT (45%) received anti-EGFR mAb. In pts with LPT anti-EGFR mAb based treatment was associated with higher ORR (81% vs. 35%; p< 0.01). No effect was seen in RPT (ORR 35% vs. 36%; p= 0.82). Anti-EGFR mAb treatment resulted in inferior PFS in RPT (HR 2.0; 95% CI 1.1-3.5; p= 0.02) and showed a trend towards improved PFS in LPT (HR 0.6; 95% CI 0.3-1.1; p= 0.11). Pts with RPT had a worse OS when treated with anti-EGFR mAb (HR 1.8; 95% CI 1.0-3.1; p= 0.05), whereas pts with LPT appeared to have a favorable outcome when treated with an anti-EGFR mAb containing regimen (HR 0.4; 95% CI 0.2-0.7; p< 0.01). **Conclusions:** This exploratory analysis of five studies suggests that PTL has limited prognostic impact in *BRAF*mt mCRC but might carry predictive information regarding anti-EGFR mAb efficacy in a 1st-line treatment setting. Further prospective studies are needed to validate these results and to grasp the differences in the heterogeneous group of *BRAF*mt pts. Clinical trial information: FIRE-1 was before mandatory registration, NCT00254137, NCT00433927, NCT01249638, NCT01328171. Research Sponsor: None.

Camrelizumab plus famitinib in patients with metastatic colorectal cancer: Results from an open-label, multicenter phase II basket study. *First Author: Tianshu Liu, Department of Medical Oncology, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Dual blockade of immune checkpoint and angiogenesis is an effective strategy for multiple cancers. We initiated an open-label, multicenter phase II basket study to evaluate the antitumor activity and safety of camrelizumab (an anti-PD-1 antibody) plus famitinib (a receptor tyrosine kinase inhibitor) in patients (pts) with advanced solid tumors. Herein, we report the results from the metastatic colorectal cancer (mCRC) cohort. **Methods:** Pts with histologically confirmed mCRC, who had received previous irinotecan, oxaliplatin, and fluoropyrimidine combination chemotherapy, and progressed after ≥ 2 lines of systemic treatment were enrolled to receive camrelizumab (200 mg i.v. every 3 weeks) and famitinib (20 mg orally once daily). Primary endpoint was objective response rate (ORR) per RECIST version 1.1. **Results:** Between Jul 10, 2020, and Jul 12, 2021, of all the 44 mCRC pts enrolled, 14 (31.8%) pts had colon cancer (CC) and 30 (68.2%) pts had rectal cancer (RC). As of Nov 30, 2021, the median time from enrollment to data cutoff was 10.6 months (range, 4.7-16.7). The ORR was 13.6% (95% CI, 5.2-27.4) and the DCR was 45.5% (95% CI, 30.4-61.2) in all mCRC pts. Of them, no pts with CC achieved response; six pts with RC achieved PR, with the ORR of 20.0% (95% CI, 7.7-38.6) and the DCR of 46.7% (95% CI, 28.3-65.7). Pts with RC showed a median duration of response (DoR) of 7.1 months (95% CI, 2.3-not reached [NR]). The median overall survival (OS) was 15.2 months (95% CI, 7.2-NR) in pts with RC. Of all 44 mCRC pts, 28 (63.6%) had grade 3 or higher treatment related adverse events (TRAEs), mainly hypertension (25.0%), proteinuria (18.2%), decreased platelet count (11.4%), decreased neutrophil count (11.4%) and palmar-plantar erythrodysaesthesia syndrome (11.4%). Three (6.8%) pts discontinued any study treatment due to TRAEs. No grade 5 TRAE was reported. **Conclusions:** Camrelizumab plus famitinib appeared to show encouraging antitumor activity in pts with mCRC, especially in those with RC, and the safety profile of this combination regimen seemed to be manageable and consistent with single agent alone. Clinical trial information: NCT04346381. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Summary of efficacy outcomes in mCRC cohort.

Variables	Colon cancer (n=14)	Rectal cancer (n=30)	All mCRC patients (n=44)
Best overall response, n (%)			
PR	0	6 (20.0)	6 (13.6)
SD	6 (42.9)	8 (26.7)	14 (31.8)
PD	6 (42.9)	12 (40.0)	18 (40.9)
NE	2 (14.3)	4 (13.3)	6 (13.6)
ORR, % (95% CI)	—	20.0 (7.7-38.6)	13.6 (5.2-27.4)
DCR, % (95% CI)	42.9 (17.7-71.1)	46.7 (28.3-65.7)	45.5 (30.4-61.2)
OS, months, median (95% CI)	8.9 (4.8-11.5)	15.2 (7.2-NR)	10.9 (8.0-NR)
DoR, months, median (95% CI)	—	7.1 (2.3-NR)	7.1 (2.3-NR)

First-line (L1) therapy targeting EGFR in lung metastases (mets) of colorectal cancer (mCRC): An ARCAD pooled analysis. *First Author: Einat Shacham Shmueli, Cancer center, The Chaim Sheba Medical Center, Ramat Gan, Affiliated with the Sackler School of Medicine, Tel Aviv University, Ramat Gan, Israel*

Background: Monoclonal antibodies (mab) targeting EGFR are recommended in L1 treatment (trt) for mCRC in patients (pts) with RAS wild-type (WT) tumor and primary left CRC. ARCAD database contains individual data of randomized trials that evaluated anti-EGFR mab plus chemotherapy (CT). In this analysis we aimed to evaluate anti-EGFR benefit in mCRC with lung mets, either as single site or multiple sites. **Methods:** Individual pts data from four trials (PRIME, CRYSTAL, COIN, OPUS) comparing CT +/- anti-EGFR were pooled. KRAS status was not required at inclusion to these studies. The primary endpoint, overall survival (OS), was estimated using Kaplan-Meier method, prognostic value of lung mets was evaluated by stratified Cox models in pts groups defined by KRAS status. The predictive value was evaluated by interaction test (Int) between trt and lung mets status in pts group defined by KRAS status and considered as significant with a $P < 0.1$. **Results:** 3681 pts with known KRAS status were included, 2171 WT and 1510 mutant (MT). Pts characteristics were well balanced. Significant median OS benefit of anti-EGFR was observed in the whole KRAS WT population and in the left colon and rectum subgroup but not in the right colon subgroup. In pts with KRAS WT single site mets, a non-significant benefit of anti-EGFR was observed only among pts without lung mets (N = 642). In pts with lung single site mets (N = 129), a significant benefit (P= 0.018) in the KRAS MT population (N = 55) was observed, but Int was non-significant (P =0.157). In pts with KRAS WT and multiple without lung mets sites (N = 673), no benefit of anti-EGFR was observed and Int was significant (P= 0.054). Pts with KRAS MT multiple sites with (N = 656) or without (N = 397) lung mets, had no benefit of anti-EGFR. The same findings were found in the left primary pts and in the two fluoropyrimidine backbone. PFS analyses confirm the OS results. **Conclusions:** In this ARCAD analysis pts with lung mets as a single site appear to benefit from anti-EGFR L1 therapy in case of KRAS MT. This unexpected result based on a limited sample size cannot be explained on the knowledge of anti-EGFR therapy. Furthermore, pts with multiple mets sites have a benefit of anti-EGFR therapy only in the presence of lung mets even in KRAS WT left primary tumor. These findings need further confirmation and may initiate the search for a specific molecular phenotype associated with lung mets in CRC pts. Research Sponsor: A.R.CA.D Foundation.

Phase 1b study of RGX-202-01, a first-in-class oral inhibitor of the SLC6A8/ CKB pathway, in combination with FOLFIRI and bevacizumab (BEV) in second-line advanced colorectal cancer (CRC). *First Author: Andrew Eugene Hendifar, Samuel Oschin Cancer Center, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: A proprietary *in vivo* target discovery screen identified creatine kinase-B (CKB) as a cancer driver in KRAS mutant (KRAS-mut) CRC. CKB promotes tumor growth and survival under hypoxia. CKB generates the energetic metabolite phospho-creatine (PCr), which is imported into cells through the creatine transporter, SLC6A8. PCr generates intracellular ATP that enables tumoral survival. RGX-202-01 is a small molecule inhibitor of SLC6A8 that depletes intracellular PCr and ATP, resulting in apoptosis. In a completed Phase 1a study, RGX-202-01 monotherapy demonstrated objective anti-tumor activity in the relapsed/refractory KRAS-mut CRC setting without dose-limiting toxicity. The objectives of this ongoing Phase 1b study are to evaluate safety, PK/PD, and efficacy of RGX-202-01 in combination with standard-of-care (SOC) FOLFIRI + BEV in second-line CRC, a setting where SOC therapy results in an ORR and mPFS of approximately 15% and 6 months, respectively. **Methods:** Subjects with advanced CRC who had disease progression after receiving a first line oxaliplatin-containing regimen were eligible. The dose expansion phase of the study was restricted to CKB-expressing CRC tumors. As of 01-14-2022, 16 patients (pts) have been enrolled. 8 pts were enrolled in 2 dose escalation cohorts of RGX-202-01: 2400mg BID (4 pts) and 3000mg BID (4 pts) combined with FOLFIRI and BEV. 8 pts were enrolled in the dose expansion phase of the study and received RGX-202-01 3000mg BID combined with FOLFIRI and BEV **Results:** No DLTs were observed and the MTD was not reached in the dose escalation phase. Grade 3 TRAEs were observed in 25% of pts. Most common TRAEs were GI in nature. There were no Grade 4-5 TRAEs. PK analysis showed sustained RGX-202-01 drug exposures in both escalation cohorts above target levels (IC_{50}). Serum and urine creatine measurements indicated robust SLC6A8 target inhibition. 9 pts had KRAS-mut CRC, and all were evaluable for RECIST 1.1 response. 4 of these pts had cPR ,1 patient had uPR and 4 pts had SD as best response (ORR 56%, DCR 100%). 5 of these pts remain on therapy ranging from 11-54 weeks and a patient with a cPR at 16 weeks followed by surgery with curative intent remains with NED at 24 weeks after surgery. Seven pts had KRAS WT CRC, of which 3 were evaluable (2 pts are pending 1st scan assessment; 2 pts are off study and did not receive 1 full cycle of treatment). Of the 3 KRAS WT evaluable pts, all had SD as best response. 2 were on study for 38 and 24 weeks respectively and 1 is ongoing at 16 weeks. **Conclusions:** RGX-202-01 combined with FOLFIRI and BEV was well tolerated with no DLTs at the dose levels evaluated which induced potent inhibition of SLC6A8. Antitumor activity was noted in KRAS mutated colorectal cancer, consistent with preferential pre-clinical activity in RAS mutated tumors. Enrollment in the expansion phase continues. Clinical trial information: NCT03597581. Research Sponsor: Inspirna Inc.

Predictive value of *MAOB* gene expression for targeted therapy in patients (pts) with metastatic colorectal cancer (mCRC) enrolled in CALGB (Alliance)/SWOG 80405. *First Author: Wu Zhang, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: Monoamine oxidases (MAOs), including MAOA and MAOB, are mitochondrial enzymes responsible for catalyzing monoamine oxidation. Increased expression of MAOs were found in several cancer types and high MAOB was associated with worse disease stage and poorer survival in CRC. Positive and negative correlations of *MAOB* expression with mesenchymal type and epithelial type gene expressions, respectively, have been reported. Hence, we investigated whether *MAOB* expression is predictive for targeted therapies in mCRC. **Methods:** 430 mCRC pts treated with either bevacizumab (BEV, n = 224) or cetuximab (CET, n = 206) in combination with first-line chemotherapy within the CALGB/SWOG 80405 trial were included in the analysis. *MAOB* RNA was isolated from FFPE tumor samples and sequenced on the HiSeq 2500 (Illumina). Overall survival (OS) and progression-free survival (PFS) were compared between groups of pts categorized by tertiles of *MAOB* expression into high (H), medium (M) and low (L). Hazard ratios (HR) and 95% confidence intervals (CI) were computed from multivariable Cox proportional hazards model, adjusting for age, sex, location, number of metastases, *KRAS*, MSI status, and treatment with FOLFOX or FOLFIRI. Sensitivity analyses were conducted after stratifying by sex. Logrank *P*-values describe differences without adjustment for patient characteristics. **Results:** In CET-treated pts, *MAOB*-L showed significantly longer OS (median 39.2 vs 30.9 vs 15.9 months, logrank $P = 4.7E-05$, L vs H (as reference) adjusted HR 0.42, 95% CI [0.27, 0.65]) and PFS (median 13.2 vs 11.8 vs 7.6 months, logrank $P = 0.006$, L vs H adjusted HR 0.59 [0.40, 0.88]) compared to *MAOB*-M and *MAOB*-H, respectively. Similar results were observed when evaluating *MAOB* expression as a continuous variable. In BEV-treated pts, no significant differences were observed when comparing *MAOB* expression tertiles; however, pts with lower *MAOB* expression had significantly better OS, but not PFS, when evaluating *MAOB* as a continuous variable (Cox LRT $P = 0.015$, covariate adjusted). In CET-treated pts, the effect of *MAOB* expression was observed in male but not female pts (OS: median 40.3 vs 30.9 vs 16.1 months by *MAOB*-L, M, H, respectively, logrank $P = 6.8E-05$, L vs H adjusted HR 0.33 [0.19, 0.59]; PFS: median 13.8 vs 12.6 vs 7.9 months, logrank $P = 0.001$, L vs H adjusted HR 0.46 [0.28, 0.79]). A significant interaction was observed between *MAOB* expression and treatment for OS ($P = 0.010$) in males and females combined, but only in males ($P = 0.018$) when stratified by sex. **Conclusions:** Our results suggest that pts with *MAOB*-L tumors may have greater benefit from CET-based treatment and that targeting *MAOB* may be a promising strategy to improve patient outcomes. Further validation studies are warranted to develop a novel personalized approach based on *MAOB* expression in mCRC pts. Clinical trial information: NCT00265850. An immune-related gene expression profile to predict the efficacy of adding atezolizumab to first-line FOLFOXIRI plus bevacizumab in metastatic colorectal cancer: A translational analysis of the phase II randomized AtezoTRIBE study. *First Author: Alessandra Boccaccino, Department of Translational Research and New Technologies in Medicine and Surgery-Unit of Medical Oncology 2, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy*

Background: The phase II randomized AtezoTRIBE study demonstrated that the addition of atezolizumab (atezo) to first-line FOLFOXIRI plus bevacizumab (bev) prolongs PFS of mCRC patients, but benefit is limited among patients with proficient mismatch repair (pMMR) tumours. Among these patients, identifying a subgroup able to achieve benefit from immune-checkpoint inhibitors is a crucial challenge of translational research. To this end, we investigated the potential predictive role of an immunomodulatory gene expression signature (IO score), measuring the presence of infiltrating inflammatory cells and differentiated stromal microenvironment. **Methods:** AtezoTRIBE was a phase II comparative trial in which mCRC patients, unselected for MMR status, were randomized 1:2 to receive first-line FOLFOXIRI/bev (control arm) or FOLFOXIRI/bev/atezo (experimental arm). RNA was obtained from FFPE blocks of tumour specimens collected at baseline from 142 (65%) out of 218 enrolled patients. RT-qPCR was performed using DetermaIO™, to assess mRNA expression of a targeted panel of 27 genes. The established pan-cancer IO score and threshold were applied to dichotomize tumours as IO-positive (IO^+) or IO-negative (IO^-). **Results:** IO score was successfully determined in 122 (86%) cases, and 33 tumours were defined as IO^+ (27%). No differences in terms of baseline clinical and molecular features were observed between IO^+ and IO^- tumours. Patients with IO^+ and IO^- tumours showed similar PFS (median PFS: 14.4 vs 13.6; HR 0.84 [95%CI: 0.53-1.33], p = 0.468). An interaction between IO status and treatment effect was reported (p for interaction = 0.066), with higher PFS benefit in favour of the experimental arm among patients with IO^+ tumours (HR 0.39 [95% CI:0.15-1.02]) than among those with IO^- tumours (HR 0.83 [95% CI 0.50-1.35]). A similar trend was observed in the pMMR subgroup (n = 110) (IO^+ tumours: HR for PFS 0.47 [95% CI 0.18-1.25]; IO^- tumours: HR for PFS 0.93 [95% CI 0.56-1.55]) (p for interaction = 0.139). No differences in terms of ORR were reported between arms according to the IO status. **Conclusions:** The investigated immunomodulatory signature (IO score) may be helpful to predict benefit from the addition of atezolizumab to first-line FOLFOXIRI/bev in metastatic colorectal cancer, also in the cohort of pMMR tumours. Our results support the hypothesis that a deeper characterization of tumour immune microenvironment may help identifying mCRC patients more likely to benefit from ICI-based therapeutic strategies. These findings are worthy of further investigation in independent cohorts. Research Sponsor: None.

A phase 1 dose-escalation study of GCC19 CART a novel coupled CAR therapy for subjects with metastatic colorectal cancer. *First Author: Jiuwei Cui, Cancer Center, First Hospital of Jilin University, Changchun, China*

Background: Chimeric antigen receptor (CAR) T-cell therapy has shown remarkable clinical efficacy in hematologic malignancies but limited success in solid tumors. GCC19CART, the first clinical candidate from the CoupledCAR solid tumor platform, is designed to overcome the limitations of conventional CAR T-cells in solid tumor malignancies by pairing solid tumor CAR T-cells with CD19 targeting CAR T-cells to amplify proliferation and activation of the solid tumor CAR T component. GCC19CART targets guanylate cyclase-C (GCC) which is expressed in the metastatic lesions of 70%-80% of subjects with colorectal cancers. A Phase 1 investigator-initiated clinical trial is underway in China for patients with relapsed or refractory metastatic colorectal cancer who have received at least 2 prior lines of therapy. Based on a data cutoff on December 13, 2021, 21 subjects have been enrolled in 2 dose escalation groups at 5 hospitals in China. **Methods:** Subjects are screened for GCC expression by immunohistochemistry. Eligible subjects undergo leukapheresis, a single dose of lymphodepleting chemotherapy (fludarabine 30mg/m2 and cyclophosphamide 300mg/m2) 3 days prior to infusion, and then administration of a single infusion of GCC19CART at one of two preassigned doses: $1x10^6$ or $2x10^6$ CAR T-cells/kg. Endpoints are safety and preliminary evidence of efficacy as determined by CT or PET/CT per RECIST 1.1 or PERCIST 1.0. All responses were confirmed by an independent third-party imaging contract research organization (CRO). **Results:** 13 subjects have been enrolled to dose level 1 ($1x10^6$ cells/kg) and 8 subjects have been enrolled to dose level 2 ($2x10^6$ cells/kg). The most common adverse events were cytokine release syndrome (CRS) in 21/21 subjects (Grade 1 19/21 (90.48%) or Grade 2 2/21 (9.52%)) and diarrhea in 21/21 subjects (Grade 1 6/21 (28.57%) Grade 2 5/21 (23.81%) Grade 3 9/21 (42.86%) or Grade 4 1/21 (4.76%)). Neurotoxicity was observed in 2/21 (9.52%) subjects at Grade 3 or 4 and resolved with corticosteroids. The combined overall response rate (ORR) for both dose levels was 28.6% (6/21). For dose level 1, the overall response rate (ORR) per RECIST 1.1 was 15.4% (2/13). Two subjects demonstrated a partial response (PR) while 3 additional subjects had partial metabolic response (PMR) on PET/CT with stable disease (SD) or progressive disease (PD) per RECIST 1.1. For dose level 2, The ORR per RECIST 1.1 was 50% (4/8). 4 subjects demonstrated a PR (3 at month 1, 1 at month 3 after being SD at month 1) and 2 additional subjects had PMR on PET/CT with SD per RECIST 1.1. **Conclusions:** GCC19CART demonstrated meaningful dose dependent clinical activity and an acceptable safety profile in relapsed or refractory metastatic colorectal cancer. This trial is ongoing and updated data will be presented. A United States based Phase 1 trial of GCC19CART is anticipated for mid-2022. Clinical trial information: ChiCTR2100053828. FORECAST-1: Feasibility of organoid response assessment to define effective treatments for patients with colorectal cancer after failure of standard therapy. *First Author: Margaret Lee, Eastern Health, Western Health, Walter and Eliza Hall Institute of Medical Research, Melbourne, VIC, Australia*

Background: There are limited treatment options for patients with metastatic colorectal cancer (mCRC) who have progressed on standard therapies. A personalised approach to guide treatment selection would maximise efficacy whilst minimising unnecessary toxicity. Patient derived tumour organoids (PDTO) are self-organizing three-dimensional in vitro models cultured from a fresh tumour biopsy. Drug sensitivity testing on PDTO models have the potential to guide personalised treatment in this clinical setting. **Methods:** FORECAST-1 is a feasibility study, sponsored by the Australian Gastro-Intestinal Trials Group, of PDTO-based drug sensitivity testing for 30 patients with mCRC that have failed ≥two lines of therapy. Established PDTOs underwent drug sensitivity screening including regorafenib, TAS102, oxaliplatin, irinotecan, 5FU, gemcitabine, pemetrexed and temozolomide. Patients underwent treatment at clinician's discretion, with clinical response correlated with PDTO response. **Results:** Between September 2020 and December 2021, 30 patients were enrolled in the study with a median age of 59 years (range 36-71). All patients were ECOG 0-1 and eight patients had received prior TAS102 treatment. Fresh tumour biopsies were obtained from liver (N = 17), soft tissue/peritoneal metastases (N = 5), lung (N = 3), lymph node (N = 2), primary colon (N = 1), brain (N = 1) and bone (N = 1). 20/30 (67%) of patients had successful drug sensitivity screening performed at a median PDTO age of 62 days (range 42-128), nine PDTO cultures failed, and one is still undergoing culture. 15/17 (88%) of PDTO cultures obtained from a fresh liver biopsy were successfully cultured to drug sensitivity testing. 14/20 (70%) of PDTOs that underwent drug sensitivity testing identified therapies with intermediate to high likelihood of clinical response, including regorafenib (N = 7), TAS102 (N = 5), gemcitabine (N = 4), oxaliplatin (N = 3), irinotecan (N = 1), 5FU (N = 1) and temozolomide (N = 1). Subsequent anti-cancer treatment received by patients after study enrolment included TAS102 (N = 7), FOLFOX (N = 3), FOLFIRI+EGFR-inhibitor (N = 2), FOLFIRI (N = 2), regorafenib (N = 1), capecitabine (N = 1) and an immunotherapy based clinical trial (N = 2). As of February 2022, 11 patients remain on active anti-cancer therapy and 17 patients have died. **Conclusions:** Improving therapeutic selection in refractory mCRC patients remains an area of high clinical need. Two-thirds of patients achieved PDTO establishment to allow drug sensitivity testing in a timely manner. Of these further potentially efficacious treatments were able to be successfully identified. Methods to accelerate PDTO culture and drug testing are being pursued to increase the feasibility of a planned prospective study of PDTO sensitivity informing patient management. Clinical trial information: ACTRN12620001353987. Research Sponsor: Australiasian Gastro-Intestinal Trials Group (AGITG) Innovation Grant.

Real-world experience on the efficacy and tolerability of biweekly trifluridine/tipiracil with or without bevacizumab in metastatic colorectal cancer. *First Author: Choon Seong Ang, Department of Haematology-Oncology, National Cancer Institute Singapore, Singapore, Singapore*

Background: Trifluridine/tipiracil (TAS-102) is currently approved as third-line treatment in metastatic colorectal cancer (mCRC). However, there is paucity of real-world data on the tolerability and efficacy with biweekly dosing as monotherapy or in combination with bevacizumab. In this study, we present our center's experience with biweekly TAS-102 with or without bevacizumab in mCRC patients (pts). **Methods:** We performed a single center retrospective observational study of pts receiving TAS-102 between 2018 and 2021. **Results:** A total of 83 pts were included (53 men, 30 women), with a median age of 64 years. Majority of pts were treated with TAS-102 in the 3rd-line (48.2%) and 4th-line (28.9%) setting. Almost all (94.0%) were of ECOG ≤ 1 at the initiation of treatment. The mean number of cycles administered was 3.8 and bevacizumab (5mg/kg on Day 1, every 2 weeks) was used in combination with TAS-102 in 18 pts (21.7%). Majority of pts (84.3%) were given TAS-102 using the biweekly regimen (35mg/m2 BD, on Day 1-5 and 15-19, q28 days) rather than standard regimen (35mg/m2 BD, on Day 1-5 and 8-12, q28 days) following a change in institutional practice. Fifteen pts (18.1%) had their initial dose reduced to 30mg/m2 BD at prescriber's discretion. Median PFS and OS were 2.37 and 10.15 months, respectively. In terms of tolerability, fatigue (any grade, 42.2%) and neutropenia (any grade, 44.6%) were the two most common adverse events reported. Grade 3 or higher neutropenia and febrile neutropenia were 16.9% and 3.6%, respectively. Dose reduction during treatment was required in 15 pts (18.1%), dose delay in 31 pts (37.3%) and six pts (7.2%) discontinued treatment due to toxicity. More than half (54.2%) had at least an additional line of therapy (regorafenib, clinical trials or re-challenge previous chemotherapy agents) following disease progression with TAS-102. **Conclusions:** We report the largest real-world experience with biweekly TAS-102. Our pts treated with TAS-102 had comparable median PFS to the RECOURSE cohort but with significantly better OS as more than half continued to receive treatment. Biweekly dosing of TAS-102 with or without bevacizumab is well tolerated with significantly lower rates of Grade 3 neutropenia compared to the published data in the literature. Research Sponsor: None.

Clinical outcomes following termination of immunotherapy due to long-term benefit in MSI-H colorectal cancer. *First Author: Kristen Simmons, Baylor College of Medicine, Houston, TX*

Background: Immune checkpoint blockade therapy improves survival in patients (pts) with microsatellite instability-high (MSI-H) advanced colorectal cancer (CRC). Oncologists often discontinue immunotherapy after 2 years of disease control based on prior trial data. Recurrence outcomes following discontinuation of immunotherapy and clinicopathologic features associated with recurrence remain underreported given the recent advent of these agents for pts with MSI-H advanced CRC. **Methods:** Records from pts with MSI-H CRC from MD Anderson Cancer Center who received immunotherapy between 2015-2022 and stopped after clinical benefit were reviewed. Median survival was estimated according to the Kaplan-Meier method. Associations between the event of recurrence and coexisting mutations (*KRAS, NRAS, BRAF^{V600E}, PIK3CA, APC, TP53, POLE/POLD*), metastatic site (lung, liver, lymph nodes, or peritoneum), primary tumor sidedness (right vs. left colon), and prior immunotherapy (anti-PD-(L)1 alone or with anti-CTLA-4 antibodies) were measured by Fisher's exact tests. **Results:** Thirty-six pts with MSI-H CRC without progression on immunotherapy were reviewed. Of these 29 and 7 received anti-PDL1 antibody alone or in combination with anti-CTLA-4 antibody, respectively. Median exposure to prior immunotherapy was 24 months (range, 5-43). After a median follow-up of 19 months (95% CI, 14-26) after stopping immunotherapy, 30 of 36 pts (83%) remained without disease progression. For the 6 patients with progression after stopping, median time to relapse was 13 months (range, 5-31). Median disease-free survival (DFS) was not reached. The estimated 1-year, 2-year, and 3-year DFS probabilities were 90% (95% CI, 79-100), 79.1% (95% CI, 64-98), and 68% (95% CI, 47-98), respectively. Median overall survival from the time that immunotherapy was stopped was 54 months (95% CI, 47-NA). Only 1 pt died due to unrelated illness. There were no observed associations between disease recurrence and co-existing mutations, metastatic organ involvement, primary tumor sidedness, or immunotherapy used. **Conclusions:** Most pts with MSI-H advanced CRC who achieve initial clinical benefit and do not progress on immunotherapy do not recur after treatment is stopped. Our data suggest that favorable outcomes do occur following cessation of immunotherapy in this setting even with concomitant prognostically unfavorable clinical features (RAS, BRAFV600E mutations; liver, peritoneal metastases). Predictive value of *CDC37* gene expression for targeted therapy in metastatic colorectal cancer (mCRC). *First Author: Hiroyuki Arai, Division of Medical Oncology, USC Norris Comprehensive Cancer Center, Keck School of Medicine, Los Angeles, CA*

Background: HSP90 mediated chaperoning is a well-conserved biological mechanism for stabilization and activation of kinases. More than 60% of human kinases including VEGFR, CRAF, CSF1R, and FGFR are target of HSP90 (client kinases), whereas EGFR is non-client. CDC37 is a specific co-chaperone determining selectivity of client kinases recognized by HSP90. We hypothesized that gene expression levels of *CDC37* have predictive values for anti-angiogenic therapies in mCRC. **Methods:** The subjects of this study were mCRC patients treated with regorafenib (REGO, Japanese retrospective cohort) and those treated with bevacizumab (BEV) or cetuximab (CET) in combination with first-line chemotherapy (CALGB/SWOG 80405 trial cohort). *CDC37* expression levels were measured using RNA isolated from FFPE samples by nCounter gene expression profiling (Nanostring) and HiSeq 2500 (Illumina) in the Japanese and CALGB/SWOG 80405 cohorts, respectively. Overall survival (OS) and progression-free survival (PFS) were compared between patients with high *CDC37* expression (*CDC37*-H) and those with low expression (*CDC37*-L), grouped by median cutoff value in each cohort. **Results:** In total, 484 patients were included (50 treated with REGO, 227 treated with BEV, and 207 treated with CET). In REGO-treated patients, *CDC37*-H showed significantly better OS (median 11.3 vs 6.0 months, adjusted hazard ratio [HR] 0.24, 95% confidence interval [CI] 0.11-0.54, p <0.01) and PFS (median 3.5 vs 1.9 months, adjusted HR 0.51, 95% CI 0.28-0.94, p = 0.03) compared to *CDC37*-L. Similarly, in BEV-treated patients, *CDC37*-H showed significantly better PFS (median 13.5 vs 9.6 months, adjusted HR 0.59, 95% CI 0.43-0.79, p <0.01) and numerically better OS (median 34.1 vs 29.4 months, adjusted HR 0.81, 95% CI 0.60-1.11, p = 0.20) compared to *CDC37*-L. However, in CET-treated patients, *CDC37*-H and *CDC37*-L patients showed similar OS (median 33.7 vs 26.1 months, adjusted HR 1.00, 95% CI 0.73-1.38, p = 0.98) and PFS (median 11.3 vs 11.0 months, adjusted HR 1.08, 95% CI 0.81-1.45, p = 0.60). Significant interaction was observed between *CDC37* expression and treatment in terms of PFS in the CALGB/SWOG 80405 cohort (p = 0.01). **Conclusions:** Our results suggest patients with CDC37-dependent (*CDC37*-H) tumors may derive more benefit from REGO and BEV both of which target HSP90 client kinases or signaling pathways, but not from CET which target HSP90 non-client kinase. Further validation studies are warranted to develop a novel personalized approach for targeted therapies based on *CDC37* expression in mCRC patients. Support: U10CA180821, U10CA180888; Pfizer, Genentech; https://acknowledgments.alliancefound.org. ClinicalTrials.gov Identifier: NCT00265850. Research Sponsor: U.S. National Institutes of Health.

Predictive and prognostic value of carcinoembryonic antigen (CEA) on maintenance therapy with 5-fluoruracil/leucovorin plus panitumumab or 5-fluoruracil/leucovorin alone in RAS wildtype metastatic colorectal cancer: Evaluation of the phase II PanaMa trial (AIO KRK 0212). *First Author: Annika Kurreck, Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Hematology, Oncology, and Cancer Immunology (CVK), Berlin, Germany*

Background: Carcinoembryonic antigen (CEA) may reflect response to antitumor treatment in metastatic colorectal cancer (mCRC). The predictive value of CEA has not yet been proven for subsequent maintenance therapy. This analysis aims to evaluate the predictive and prognostic value of pre- and post-induction treatment CEA on maintenance with 5-fluoruracil/leucovorin (FU/FA) plus panitumumab (pmab) [arm A] or FU/FA alone [arm B] in RAS wildtype mCRC patients treated within the PanaMa trial. **Methods:** Patients with CEA measurements (pre- and post-induction therapy) were grouped as normal (both measurements ≤5 ug/l), stable (between +25% and -25%), decreasing (<-25%), and increasing (>+25%) CEA. Survival parameters (overall survival (OS), progression-free survival (PFS) from initiation of maintenance therapy) were expressed by the Kaplan-Meier method and compared by log-rank testing, and Cox regression. The objective response (OR) to maintenance therapy was analyzed by chi-square testing. **Results:** Out of 248 patients in the in the full analysis set, 245 patients were eligible for CEA analysis. Normal CEA occurred in 58 (23.7%), stable CEA in 16 (6.5%), decreasing CEA in 161 (65.7%), and increasing CEA in 10 (4.1%) patients. In the subgroup of decreasing CEA, there was a significant difference in the prediction of OR between both treatment arms with a better positive predictive value for the pmab-containing maintenance (44.0% vs. 27.5%, p=0.032). Increasing compared to decreasing CEA was associated with unfavourable survival outcome of maintenance irrespective of treatment arm (Table). **Conclusions:** CEA kinetics during induction therapy appears to have a predictive value for subsequent maintenance, notably pmab-based. Besides that, CEA levels had a significant impact on survival parameters of maintenance irrespective of the addition of pmab to FU/FA. This analysis is limited by the small number of patients in the subgroup of increasing CEA. Clinical trial information: NCT01991873. Research Sponsor: AIO Studien gGmbH, Pharmaceutical/Biotech Company.

HER3 expression in metastatic colorectal cancer: Defining the clinicomolecular profile of an emerging target. *First Author: Alisha Heather Bent, MD Anderson Hematology/Oncology Fellowship, Houston, TX*

Background: The success of tailored systemic therapies in treating distinct molecular subsets of patients (e.g., deficient mismatch repair, BRAF mutant, HER2 amplified) has spurred further exploration of novel targetable subsets within the heterogeneous landscape of metastatic colorectal cancer (mCRC). Human epidermal growth factor receptor 3 [HER3 (ErbB3)], a member of the HER (ErbB) receptor tyrosine kinase family, plays an important role in tumorigenesis and metastases and has emerged as a promising therapeutic target in a diverse array of cancers. For example, patritumab deruxtecan (U3-1402; HER3-DXd) is a HER3-directed antibody drug conjugate that has demonstrated clinically meaningful antitumor activity and acceptable safety profiles in metastatic breast cancer and EGFR-mutated non-small cell lung cancer. There is limited data, however, on the clinicopathological characterization of HER3 expression in mCRC. **Methods:** Tissue samples (surgical-metastatectomy) (N = 115) were obtained from a clinical cohort of patients (N = 99) with histologically proven mCRC and liver metastases who underwent liver resection with/without perioperative systemic chemotherapy. HER3 expression was analyzed on whole-mount preparations by immunohistochemistry (IHC). Staining was performed and visualized using the HER3 (D22C5) XP Rabbit-mAb (Cell Signaling Technology). Patients were categorized based on membranous intensity score as follows: Low with IHC 0 (absence of staining or staining in < 10% of tumor cells), 1+ (faint/barely perceptible staining in ≥10% of tumor cells) or 2+ (weak to moderate staining in ≥10% of tumor cells), or High with IHC 3+ (strong staining in ≥10% of tumor cells). Clinicomolecular and treatment data, including gender, tumor sidedness, mutational status (RAS or BRAF), and prior chemotherapy were collected by review of patient electronic medical records. Chi-squared (or Fisher's exact) test were used to determine associations between groups. Overall survival (OS) was calculated using Kaplan-Meier method and compared using log-rank tests. **Results:** Among 99 analyzed patients, 98 were evaluable for HER3 expression. Of these 25.5%, 26.5%, 40.8% and 7.2% showed HER3 IHC scores of 3+, 2+, 1+ and 0, respectively. No significant association was seen with HER3 expression and clinicopathological variables, mutational status, or prior treatment. Among patients with 2 samples analyzed from the same liver surgery, there was a moderate level of heterogeneity with concordance of 78.5% (kappa 0.43). Patients with high HER3 expression had poorer OS (5-year OS: 52%; median: 90.2 months) compared to low HER3 expression (5-year OS: 85%; median: not reached). **Conclusions**: In this large cohort of mCRC, HER3 expression was observed in 92.8% of patients and across diverse clinical and molecular features, supporting HER3 as a promising targetable biomarker in a large subset of mCRC. The prognostic significance of *TP53* mutations in patients with right-sided and left-sided colorectal cancer. *First Author: Moh'd M. Khushman, Department of Hematology-Oncology, University of Alabama at Birmingham/O'Neal Comprehensive Cancer Center, Birmingham, AL*

Background: In patients with colorectal cancers (CRCs), prior studies have reported that various *TP53* mutations have prognostic significance. The anatomic location of the primary CRC and the *TP53* mutation subtype influence patient survival. In this study, we explored the prognostic significance of *TP53* mutations *(mTP53)* classified as gain-of-function (GOF) or non-GOF in patients with right-sided (RCC) and left-sided CRCs (LCC). **Methods:** CRC specimens (6,248 RCCs and 14,215 LCCs) were tested at Caris Life Sciences (Phoenix, AZ) with NextGen Sequencing (NGS) of DNA (592-gene panel or whole- exome sequencing). *R175H*, *R248W*, *R248Q*, *R249S*, *R273H*, *R273L*, and *R282W* were defined as GOF *mTP53* and all other *mTP53* were defined as non-GOF *mTP53*. MSI-H/dMMR status was determined by immunohistochemistry (IHC) of MMR proteins and/or NGS. Real-world median overall survival (mOS) was obtained from insurance claims data and calculated from tissue collection to last contact using Kaplan-Meier estimates. **Results:** GOF *mTP53* and non-GOF *mTP53* were identified in 15% and 39% respectively, in RCC and 17% and 46% respectively, in LCC. In RCC, the mOS for patients with wild-type *TP53* (*wtTP53*) vs. GOF *mTP53* was 34 months (m) vs. 23m ($p < 0.00001$), and the mOS for patients with *wtTP53* vs. non-GOF *mTP53* was 34m vs. 27m ($p < 0.001$). In LCC, the mOS for patients with *wtTP53* vs. GOF *mTP53* was 35m vs. 33m ($p = 0.056$), and the mOS for patients with *wtTP53* vs. non-GOF *mTP53* was 35m vs. 35m ($p = 0.32$). The mOS for patients with non-GOF *mTP53* vs. GOF *mTP53* in RCC and LCC was 28m vs. 24m ($p = 0.096$), and 35m vs. 34m ($p = 0.175$), respectively. The prognostic value of GOF *mTP53* and non-GOF *mTP53* was further explored in relation to MSI-H/dMMR, *RAS*, *BRAF*, and *PIK3CA* mutation status. The worse prognosis associated with *mTP53* in RCC was seen in all comparisons, except in GOF *mTP53*/MSI-H/dMMR, and non-GOF *mTP53*/*wtKRAS* subgroups. In patients with LCC, worse prognosis associated with GOF *mTP53* and non-GOF *mTP53* was only noticeable in *KRAS* and *PIK3CA* mutant subgroups. **Conclusions:** This is the largest study to explore *TP53* mutations and their prognostic significance in patients with RCC and LCC. The prevalence of GOF *mTP53* and non-GOF *mTP53* was higher in LCC compared to RCC. However, both GOF *mTP53* and non-GOF *mTP53* were associated with worse mOS for patients with RCC, but not LCC. Our study validates the sidedness-dependent prognostic significance of *TP53* mutations. It also shows that the worse prognosis of *mTP53* is independent of the approach of collectively classifying *TP53* mutations into GOF vs non-GOF. Given the sheer extent and diversity of *TP53* mutations, a more nuanced approach towards re-classification of GOF *mTP53* is warranted. Detailed information on p53 mutations will be crucial for the interpretation of future clinical trials and for the design of novel therapeutic strategies. Research Sponsor: None.

Co-occurring alterations across molecular pathways in metastatic colorectal cancer (mCRC). *First Author: Alex John Liu, Mayo Clinic Arizona, Phoenix, AZ*

Background: Co-occurring alterations (COAs) in the *HER2* and MAPK pathway are rare in mCRC. *RAS, HER2* and *BRAF* alterations have been associated with resistance to EGFR inhibitor therapy (EGFR-mab). Typical co-occurring mutually exclusive gene mutations such as in *KRAS* and *BRAF* have been reported. This study aims to evaluate the prevalence of co-occurring alterations in the MAPK pathway or across MAPK/*HER2* and correlate to outcomes in patients with mCRC treated with EGFR-mab. **Methods:** This is a retrospective study of patients with mCRC within the Mayo Clinic database who have available blood-based NGS Guardant 360 data (September 2017-November 2021) and contained co-alterations in the MAPK pathway or across MAPK/*HER2*. MSI-high cases were excluded. Typical-RAS was defined as alterations in codons 12, 13, 59, 61, 117, and 146 of *KRAS*, *HRAS*, and *NRAS*. Atypical-RAS alterations were considered mutations at other codons of these genes. Patient characteristics, specific mutations, and outcome data were assessed. **Results:** 692 patients (pts) with mCRC were identified and 66 (9.5%) of those had COAs detected. 59/66 pts had clinical data available. Median age was 52 years, 55.9% were male, and 61.0% had left-sided tumors. The frequency of detected alterations was: *BRAF*-V600E (7.3%), *BRAF*-non-V600E (7%), *BRAF*-amplification (3.04%), *RAS*-typical (39.5%), *RAS*-atypical (2.1%), *HER2* amp (0.5%), *HER2*-mutation (1.2%) and PIK3CA (13%). COAs are described in the table. Twenty-three pts received EGFR-mab; COAs developed in 19 of them after progression on EGFR-mab. Four pts received EGFR-mab with documented COAs at baseline with none of them responding to treatment. **Conclusions:** COAs in MAPK and MAPK/*HER2* pathway are not uncommon in pts with mCRC emphasizing on the importance and feasibility of blood based NGS vs. selected gene testing. In pts with prior EGFR-mab treatment, COAs were detected after progression on treatment in the majority of pts, suggesting a mechanism of secondary treatment resistance. Further data including prospective validation is warranted. Research Sponsor: None.

Total pts 692	BRAF-V600E	BRAF-non-V600E	BRAF amp
RAS Typical	12 (1.7%)	26 (3.7%)	24 (3.5%)
RAS atypical	0	1 (0.1%)	1 (0.1%)
HER2 amp	0	2 (0.3%)	4 (0.6%)
HER2 mutation	1 (0.1%)	4 (0.6%)	2 (0.3%)

Preliminary results of raltitrexed in Chinese patients with metastatic colorectal cancer: A prospective, multicenter, real-world study. *First Author: Jin Li, Department of Oncology, Shanghai East Hospital, Shanghai, China*

Background: Raltitrexed-based chemotherapy regimen is one of the common regimens for the treatment of metastatic colorectal cancer (mCRC). This prospective observational real-world study aimed to evaluate the safety and effectiveness of raltitrexed administered to Chinese patients with mCRC in real life setting. **Methods:** This is a prospective, multicenter, real-world study . Prospectively registered Patients received second-line treatment of raltitrexed plus irinotecan combined with or without target therapy until progression disease or unacceptable toxicity. The primary endpoint was progression-free survival (PFS), and the secondary endpoints were objective response rate (ORR), disease control rate (DCR), overall survival (OS), quality of life (QOL) and safety. Totally,1000 patients were required for primary point testing. **Results:** Between May 2018 and December 2021,a total of 1039 patients from 57 centers were screened for enrollment,among which 271 patients were treated with raltitrexed plus irinotecan, 753 patients accepted target therapy (bevacizumab or cetuximab) additionally, and 15 patients combined with other drugs. Overall mPFS was 6.8 months (95%CI: 6.5-7.1) ,ORR was 20.2%, and DCR was 85.7%; The ORR of combined with or without target therapy were 21.6% and 16.2% ($p = 0.038$) ,respectively, the DCR were 88.2% and 79.0% ($p < 0.001$). The mPFS of combined without or with target therapy were 5.2 months (95% CI: 4.7 to 5.7) and 7.3 months respectively (95% CI: 7.0-7.7) [HR = 0.67, 95% CI 0.56~0.80, $p < 0.001$], The mPFS of combined with bevacizumab or cetuximab were 7.4 months (95% CI: 7.0 -7.8) and 6.8 months (95% CI: 5.9-7.7) [HR = 1.15, 95% CI 0.88~1.51, $p = 0.3$]. mOS has not yet reached. Majority of treatment-related adverse events (TEAEs) were grade I or II. The most common grade III or IV TRAEs reported by 116 patients (11.2%) were aspartate aminotransferase increased (4.0%), alanine aminotransferase increased (3.7%), neutrocytopenia (2.7%), glutamyltransferase increased (2.5%), leukocytopenia (1.1%). **Conclusions:** The real-world study confirmd that raltitrexed was an effective and safe regimen for the second-line treatment in Chinese patients with mCRC, especially combined with target therapy additionally, which was aligned with previous trials. Clinical trial information: ChiCTR1800016185. Research Sponsor: None.

***RAS* co-mutation and early onset disease represent an aggressive phenotype of atypical (non-V600) *BRAF* mutant metastatic colorectal cancer.** *First Author: Benny Johnson, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: While *BRAF*^{V600E} accounts for the majority of *BRAF* mutations in mCRC, non-V600 *BRAF* variants *(aBRAF)* have emerged in recent years as a distinct molecular subtype. There are no consensus recommendations regarding management. This study provides a comprehensive profile of a*BRAF*, their clonalities and co-mutations in mCRC using a large genomic database as well as a prospective treatment cohort of patients with a*BRAF* and mCRC managed at a single center. **Methods:** A systematic analysis was performed of patients with mCRC who underwent ctDNA testing (Guardant360 platform, Guardant Health) from September 2014 to May 2021. A variant was defined as clonal if the mutant allele frequency (MAF) was greater than 50% of the highest somatic MAF in the sample; otherwise it was defined as subclonal. Co-mutation analysis was conducted with *BRAF*, *KRAS*, *NRAS*, *NF1*, *ERBB2*, *PIK3CA* and *SMAD4*. Treatment history and overall survival (OS) for patients with a*BRAF* mCRC from MD Anderson Cancer Center were included. **Results:** 1,733 out of 14,742 mCRC patients had at least one *BRAF* variant, including 6.5% of patients with *BRAF*^{V600E} variants and 6.2% with a*BRAF* variants (1.1% with class II, 1.9% with class III, and 3.2% with unclassified variants). 431 unique BRAF variants were identified in a total of 1,905 BRAF variants. *BRAF* class II and III variants showed a higher rate of co-occurring *KRAS* mutations (25.6% and 21.5%) and co-occurring *NRAS* mutations (5.8% and 2.7%) compared with *BRAF*^{V600E} variants (2.4% for *KRAS* and 0.1% for *NRAS*); however, co-occurring *KRAS* G12C was only noted in one patient. In our MDACC cohort, 38 patients were included in the analysis. The median age was 55, 81% were Caucasian, and 74 % had left sided primary tumors (45% rectal, 24% sigmoid) with 37% being exposed to at least 2 lines of therapy. The most common mutations in clinical practice were class III, D594G (39%), followed by class II G469A (10%), & class III G466E (7%). The median follow-up time was 23.8 months (mo). While there were no survival differences between a*BRAF* classes II and III, there was a significant difference in OS in patients with *RAS* co-mutation (28.3 mo vs not reached [NR], p = 0.05) or liver involvement (28.8 mo vs NR, p = 0.02). Patients < 50 years of age had extremely poor survival with OS of 16.3 mo (vs. NR) and HR 7.51 (95% CI 1.82-31.0, p = 0.005). Treatment with anti-EGFR or use of metastasectomy was not associated with improved survival. **Conclusions:** a*BRAF* mutations have historically been considered a favorable prognostic marker in mCRC. Co-mutation with *RAS* is frequent for both classes and portends poor survival in our real-world cohort. Furthermore, early onset a*BRAF* mCRC is associated with more aggressive disease. These factors highlight the need for dedicated clinical trials for this unique subset of mCRC and may represent an opportunity to improve management in early onset colorectal cancer. Research Sponsor: U.S. National Institutes of Health.

Codon-specific KRAS mutations predict overall survival benefit of trifluridine/tipiracil in metastatic colorectal cancer. *First Author: Joris van de Haar, Netherlands Cancer Institute (Netherlands), Amsterdam, Netherlands*

Background: Genomics-based precision medicine has greatly improved how patients with cancer are being treated with targeted agents, but clinical-grade genomic biomarkers for chemotherapies are currently lacking. The chemotherapeutic trifluridine/tipiracil (FTD/TPI) is approved for the treatment of late-stage metastatic colorectal cancer (mCRC). We aimed to find genomic biomarkers to improve patient selection for FTD/TPI treatment in mCRC. **Methods:** In a discovery cohort of FTD/TPI-treated mCRC patients (n = 37), genome-wide somatic variants were tested for association with treatment duration and overall survival (OS). *In vitro* drug testing on isogenic cell lines and patient-derived mCRC organoids, as well as a re-analysis of the double-blind, placebo-controlled, phase 3 RECOURSE trial (n = 800) were performed to support our findings. **Results:** In the discovery cohort, KRAS codon G12 (KRAS^{G12}) mutation status was the only significant genomic determinant of poor outcome of FTD/TPI treatment, which could be replicated *in vitro* by drug testing on isogenic cell lines and PDOs. In these models, KRAS^{G12} mutations were associated with increased resistance to FTD-induced (geno)toxicity *in vitro*. KRAS^{G12}-based resistance was absent for the closely related chemotherapeutic 5-FU. In the RECOURSE study, KRAS^{G12} mutations were predictive biomarkers for reduced OS benefit of FTD/TPI vs placebo (unadjusted interaction P= 0.0017, adjusted interaction P= 0.017). For patients with KRAS^{G12} mutations, OS was not significantly prolonged with FTD/TPI vs placebo (n = 279; HR, 0.97; 95% CI, 0.73–1.20; P= 0.85). An exploratory analysis showed that the KRAS^{G13} mutant subgroup demonstrated clearly prolonged OS with FTD/TPI vs placebo (n = 60; unadjusted HR, 0.29; 95% CI, 0.15–0.55; P< 0.001; adjusted HR, 0.20; 95% CI, 0.092–0.45; P< 0.001), which was significantly more pronounced as compared to the KRAS^{G12} mutant and KRAS^{WT} populations (adjusted interaction P< 0.001 and P= 0.036, respectively). **Conclusions:** Together, KRAS^{G12} mutations were associated with reduced OS benefit of FTD/TPI treatment, with potential implications for ~28% of patients with metastatic colorectal cancer now considered for treatment with FTD/TPI. Furthermore, our data show that genomics-based precision medicine may be possible for a subset of chemotherapies. Research Sponsor: Oncode Institute.

Biweekly mXELIRI versus FOLFIRI in combination with bevacizumab as the first-line treatment for metastatic colorectal cancer (EXIST): A multicenter, randomized, open-label, phase 2 study. *First Author: Zhichao Jiang, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Irinotecan and fluorouracil are the most effective drugs in the treatment of metastatic colorectal cancer (mCRC). But XELIRI (irinotecan plus capecitabine) has not been recommended in the 1st-L setting due to the toxicity in the Western countries. While, modified 3-weekly XELIRI has been proved to be effective and safe in the 2nd-L therapy in Asian mCRC patients. Therefore, this study aimed to assess the efficacy and safety of biweekly mXELIRI with reduced dose of irinotecan in the 1st-L treatment of mCRC. **Methods:** This was a randomized, open-label, non-inferiority study undertaken at 11 hospitals in China. Eligible patients were aged ≥18 years with unresectable metastatic histologically diagnosed colorectal adenocarcinoma; had an ECOG of 0 or 1 and at least one measurable disease according to the RECIST v 1.1 without any systemic chemotherapy for metastatic disease. Patients were randomly assigned (1:1) stratified by the location of primary tumor (left or right site) to receive 9 cycles of mXELIRI + bevacizumab (Bev) (irinotecan 150mg/m^2 D1, capecitabine 1000mg/m^2 bid D1-10, Bev 5mg/kg D1, Q2W) or FOLFIRI + Bev (irinotecan 180mg/m^2 D1, CF 400mg/m^2 D1, 5-Fu 400mg/m^2 bolus D1, 5-Fu 2400mg/m^2 civ 46h D1, Bev 5mg/kg D1, Q2W) followed by maintenance treatments with capecitabine + Bev or 5-FU + CF + Bev. The primary endpoint was 12-month progression-free survival (PFS) rate. The secondary endpoints included objective response rate (ORR), PFS, overall survival (OS) and safety. **Results:** From May, 2018 to Apr, 2021, 264 pts were randomized (mXELIRI + Bev 132; FOLFIRI + Bev 132). The median age was 61 (29-80) years old. 62.5% of the patients were men. With a median follow-up of 17.1 months, the 12-month PFS rates were 43.9% vs. 28.8% in the mXELIRI + Bev and FOLFIRI + Bev groups, respectively. The HR was 0.72 (95%CI 0.51 -1.02) which didn't cross the predefined non-inferiority margin of 1.18 (upper bound < 1.18). The median PFS were 10.5 months vs. 9.6 months (p = 0.056, HR 0.74, 95%CI 0.55-1.01). The median OS was still not mature. The ORR were 51.5% vs. 47.0% (p = 0.460), respectively. The incidence of treatment related adverse events (TRAEs) between these two groups were similar. The most common TRAEs were neutropenia (mXELIRI + Bev vs. FOLFIRI + Bev: 51.8% vs. 57.0%), leukopenia (43.9% vs. 55.3%), anemia (54.4% vs. 45.6%), nausea (31.6% vs. 40.4%), ALT/AST increased (22.8% vs. 23.7%), diarrhea (21.1% vs. 16.7%), fatigue (20.2% vs. 23.7%), vomiting (17.5% vs. 20.2%) and hyperbilirubinemia (14.9% vs. 17.5%). No treatment- related deaths were reported. **Conclusions:** Biweekly mXELIRI with reduced dose of irinotecan plus bevacizumab was noninferior to the standard dose of FOLFIRI + Bev in PFS, with similar safety profile in the patients with untreated mCRC. Clinical trial number: NCT04247984. Research Sponsor: No Clinical trial information: NCT04247984. Research Sponsor: None.

Interim analysis of the phase II AVETUXIRI trial: Avelumab combined with cetuximab and irinotecan for treatment of refractory microsatellite stable (MSS) metastatic colorectal cancer (mCRC). *First Author: Nicolas Huyghe, Institut Roi Albert II, Cliniques Universitaires Saint-Luc, Université Catholique de Louvain, Brussels, Belgium*

Background: Immune checkpoint inhibitors demonstrated poor efficacy in MSS mCRC. Cetuximab (anti-EGFR inhibitor) could initiate, independently from RAS mutation, an immunogenic tumor cell death and mediate antitumor immune response. In this trial, we aim to explore the clinical efficacy and safety of avelumab (anti-PDL1) combined with cetuximab and irinotecan for treatment refractory MSS mCRC and to understand its mechanisms of action through associated translational research. **Methods**: AVETUXIRI trial (NCT03608046) enrols MSS, chemorefractory (fluoropyrimidine, oxaliplatin, irinotecan and anti-EGFR treatment if RAS wt tumor) mCRC patients in 2 cohorts (A: RAS-wt, n = 10 – B: RAS-mut, n = 13). Primary endpoints are safety and tumor response rate ((i)RECIST1.1). Secondary endpoints include disease control rate (DCR), progression-free survival (PFS) and overall survival (OS). According to a Simon 2-stage design, 23 patients have been included in the first stage of the trial. Multiplex immunofluorescence and RNA sequencing were realized on metastasis biopsies performed before, during and after the treatment. Densities of CD3+ (T cells) and CD8+ (cytotoxic) were quantified and analyzed with to generate an immunoscore (IS). RNA-seq data was used to perform differential expression analysis (DESeq2), gene set enrichment analysis (GSEA), deconvolution analysis (Consensus^{TME}) and gene ontology analysis (GO). **Results**:: No unexpected safety signals were observed. 3/10 tumor responses were observed in cohort A, 0/13 in cohort B. DCR was 60.0% and 61.5% in cohort A and B, respectively. 6-months PFS and 12-months OS rates were respectively 40.0% and 50.0% (cohort A) and 38.5% and 46.2% (cohort B). Independently of RAS mutation, patients with a high IS (metastasis biopsy, baseline) had significantly higher tumor shrinkage (OR = 18.67 p = 0.019), median PFS (6.9 vs 3.4 months; HR = 0.16, p = 0.002) and median OS (13.7 vs 7.9 months, HR = 0.26, p = 0.009). Similarly, tumor shrinkage and survival outcome (PFS > 6 months, OS > 12 months) were associated with upregulation of an adaptive immune response signature (including Th1, chemokine, adhesion molecules, immune checkpoints and T-cell activation genes, p. adj = 0.009) and the GSEA hallmark of epithelial to mesenchymal transition (p. adj = 0.045). Few modifications of IS and gene expression profiles were observed on the different metastasis biopsies performed overtime in the included patients. **Conclusions:** AVETUXIRI met its preliminary primary efficacy endpoint for RAS-wt mCRC pts, justifying its current continuation. Encouraging survival data observed in RAS-mut cohort allow the opening of a new cohort (PFS as primary endpoint). IS and adaptive immune response signature evaluated on metastases biopsies were associated with treatment efficacy and survival. Clinical trial information: NCT03608046. Research Sponsor: Merck restricted grant (investigator initiated sponosorized trial), N.A.

Homogeneity of pathological response (PR) and histopathological growth pattern (HGP) in resected colorectal liver metastases (CRLM) are associated with favorable survival outcome after surgery.

First Author: Pamela Baldin, Cliniques Universitaires Saint-Luc, Brussels, Belgium

Background: Surgical resection of CRLM aims to maximize patient survival. However, recurrence rates remain high post-surgery. We previously reported the prognostic relevance of tumor regression grading (TRG) and HGP of resected CRLM. Several studies reported the association of tumoral heterogeneity with anti-cancer drug resistance and prognosis. This study aims to explore tumoral heterogeneity for TRG and HGP in patients resected for CRLM and its prognostic implication. **Methods:** Tumor homogeneity for PR and HGP was evaluated in 2 independent cohorts. Cohort 1 included 57 patients (159 CRLMs) resected after chemotherapy/bevacizumab (prospective BEV-ONCO trial). Cohort 2 included 221 patients (582 CRLMs) operated after preoperative treatment or not. TRG (1 to 5 according complete to no response), HGP (desmoplastic, pushing, replacement or mixed) were evaluated for each CRLM. Max-TRG (higher TRG among all the CRLM) was used to define PR. Homogenous TRG (TRG-h) and HGP (HGP-h) was defined when all CRLMs had the same TRG or HGP pattern. HGP homogeneous desmoplastic (HGP-hd) was defined when all CRLM had a desmoplastic HGP. TRG-h, HGP-h and HGP-hd were combined into a homogeneity score (H-score: 0 to 3, 1 point given for each parameter and summed-up). Overall survival (OS for both cohorts), progression-free survival (PFS for cohort 1) and time to relapse (TTR for cohort 2) were estimated using the Kaplan–Meier method and compared by log-rank tests. Cox proportional hazard models were used for univariate and multivariate analyses. **Results:** Patient and disease characteristics were comparable in both cohorts excepted for preoperative treatment. In cohort 1, TRG-h and HGP-h were significantly associated with a longer PFS (HR = 0.21; 95CI:0.10-0.43, p < 0.001; HR = 0.27; 95CI = 0.14-0.54, p < 0.001) and better OS (HR = 0.23; 95CI = 0.07-0.70, p = 0.010; HR = 0.32; 95CI = 0.10-0.93, p = 0.037). Interestingly, the same significant results were observed in cohort 2 for TTR (TRG-h: HR = 0.60; 95CI = 0.43-0.85, p = 0.004; HGP-h: HR = 0.68; 95CI = 0.49-0.94, p = 0.017) and OS (TRG-h: HR = 0.51;95CI = 0.33-0.80, p = 0.003; HGP-h: HR = 0.63; 95CI = 0.41-0.97, p = 0.034). HGP-h reported a significant association with TRG-h, a Max-TRG < = 3, the absence of HGP replacement and mixed, a desmoplastic pattern, and the absence of sinusoidal obstruction syndrome in both cohorts. H-score was significantly associated with TTR (score 1-2: HR = 0.57; 95CI = 0.38-0.85, p = 0.004; score 3: HR = 0.4; 95CI = 0.24-0.64, p < 0.001) and OS (score 3: HR = 0.31; 95CI = 0.15-0.64, p < 0.001) in univariate analysis and with OS (HR = 0.74; 95CI = 0.59-0.94, p = 0.011) in multivariate analysis (cohort 2). **Conclusions:** TRG-h and HGP-h are strongly associated with patient's survival. H-score could be an easy morphological and prognostic score to assess. Validation studies are needed. Research Sponsor: None.

Metastasis patterns and racial disparities in gastrointestinal cancers: A SEER database population study 2010–2018.

First Author: Abdul Rahman Al Armashi, St. Vincent Charity Medical Center, Cleveland, OH

Background: Metastatic disease at the time of diagnosis of gastrointestinal (GI) malignancies is a strong predictor of poor outcomes. Differences in metastatic patterns among Caucasians (C) and African-Americans (AA) needs further elucidation. In this study, we analyzed the patterns of metastasis in C and AA in colorectal cancer (CRC), pancreatic cancer (PC), gastric cancer (GC), and liver cancer (LC). **Methods:** We identified patients with CRC, PC, GC, and LC from the Surveillance, Epidemiology, and End Results Program (SEER) database from 2010-2018. We obtained metastasis data to lungs, liver, bone, and brain at the time of diagnosis. We calculated the relative risk (RR), confidence interval (CI), and standard error with the use of SPSS software, 28.0 (IBM). **Results:** The most common metastasis site was the liver being highest at 39% in AA with PC. Brain metastasis was the least common. Significant racial disparities were noted. In CRC, AA had a 35-37% increased risk of metastasis to the liver, lung, or bone. AA had a higher risk of liver metastasis in PC and GC, whereas C had a higher risk of lung metastasis. Table 1 summarizes the data findings. **Conclusions:** This study illustrates the disparities of metastasis from GI cancers among AA and C. While a delay in screening, earlier onset of CRC in AA and socioeconomic factors may explain the disparities witnessed in CRC. However, these factors will fail to explain the difference in metastasis pattern in PC and GC in that AA had a higher risk of liver metastasis, and C had a higher risk of lung metastasis. Moreover, In GC, the brain metastasis rate in C was double that of AA. Further studies of possible biological and other risk factors are needed. Research Sponsor: None.

Cancer	Total number of patients by race	AA compared to C. Metastasis site prevalence (%). RR, 95% CI, and *p*-value
Colorectal	AA: 30,365	Liver: AA 7,453 (24.5%) C 36.184 (19.7%) - RR 1.37 - CI [1.33 to 1.41] P < 0.001 Lung: AA 2,571 (8.5%) C 12,233 (6.6%) - RR 1.35 - CI [1.29 to 1.41] P < 0.001

Phase I/II trial of encorafenib, cetuximab, and nivolumab in patients with microsatellite stable (MSS), *BRAF*^{V600E} metastatic colorectal cancer.

First Author: Van K. Morris, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Treatment with encorafenib (E) and cetuximab (C) offers response and survival benefit for patients (pts) with MSS, *BRAF*^{V600E} metastatic colorectal cancer (CRC). BRAF + EGFR inhibition induced a transient MSI-H phenotype in preclinical models of MSS, *BRAF*^{V600E} CRC and may prime these tumors for response to immunotherapy with anti-PD-1 antibodies like nivolumab (N). **Methods:** In this single-arm, single-institution, phase I/II clinical trial, pts with treatment-refractory MSS, *BRAF*^{V600E} metastatic CRC were eligible. No prior BRAF, MEK, or ERK inhibitors, anti-EGFR antibody, or immunotherapy was permitted. Pts received E (300 mg PO daily), C (500 mg/m^2 IV q14 days), and N (480 mg IV q28 days). The primary endpoints were best overall response (RECIST 1.1) and safety/tolerability (CTCAE v5). A Simon two-stage design (H_0: p≤ .22; H_a: p≥ .45, where p = percentage of pts with radiographic response) was employed using a one-sided α = .05 and β = .20. Median progression-free survival (PFS) and overall survival (OS) were estimated via Kaplan-Meier. To measure ex vivo treatment responses with an E-slice assay (EMPIRI), 300 μm fresh tissue slices from core biopsies were generated and cultured in serum-free media with E, C, and N. Longitudinal changes in viability were measured at days 4, 8, and 12 and compared to baseline viability in each tissue. Ex vivo "response" was defined if < 1X baseline tumor cell viability. **Results:** With a data cutoff of 2/8/2022, all pts are enrolled: 26 evaluable for toxicity and 23 for response. Median age is 60 years (range, 32-85), and 16 (62%) are female. Grade 3-4 treatment-related adverse events (AE) have occurred in 5/26 (19%) patients: colitis, maculopapular rash, leukocytosis, and myositis/myocarditis (all N = 1); asymptomatic elevated amylase/lipase (N = 2). Overall response rate is 48% (95% CI, 27-69), and disease control rate is 96% (95% CI, 78-100). Median PFS is 7.4 months (95% CI, 5.6-NA). For the 11 pts with responses, median duration of response is 7.7 months (95% CI, 4.5-NA). Median OS is 15.1 months (95% CI, 7.7-NA). E-slices showed concordance between pts with radiographic responses and reduction in cell viability, and between non-responders and increase in cell viability. Final results will be presented. **Conclusions:** E + C + N appears to be effective and well-tolerated for pts with MSS, *BRAF*^{V600E} metastatic CRC. Ex vivo analysis of pretreatment tissue predicted eventual clinical response in matched patients. A follow-up randomized phase II trial (SWOG 2107) to evaluate encorafenib/cetuximab with or without nivolumab in pts with MSS, *BRAF*^{V600E} metastatic CRC will activate in 2022. Clinical trial information: NCT04017650. Research Sponsor: Bristol Myers Squibb, Pfizer, Pharmaceutical/Biotech Company.

First experience with ^{224}Radium-labelled microparticles (radspherin) after CRS-HIPEC for peritoneal metastasis in colorectal cancer (a phase 1 study).

First Author: Stein G Larsen, Section for Surgical Oncology, Norwegian Radium Hospital; Department of Gastroenterological Surgery, Oslo University Hospital, Oslo, Norway

Background: Peritoneal metastasis (PM) from colorectal cancer carries a dismal prognosis. Improved survival can be achieved by combining extensive cytoreductive surgery and hyperthermic intraperitoneal chemotherapy (CRS-HIPEC). However, median time to recurrence is short (11-12 months) and there is a need for novel therapies to prevent subsequent PM. Radspherin consists of the α-emitting radionuclide radium-224 (^{224}Ra), half-life 3.6 days, adsorbed to a suspension of biodegradable calcium carbonate microparticles, designed to give short-range radiation to the serosal peritoneal surface, aiming to kill remaining free cancer cells and small tumor cell clusters. **Methods:** A first-in-man phase 1 study (EudraCT 2018-002803-33) was conducted at two specialized CRS-HIPEC centers. Radspherin was injected in the abdominal cavity through a catheter 2 days after CRS-HIPEC. Dose escalation at increasing dose levels of 1-2-4-7-MBq, repeated injection and expansion cohorts evaluated the safety and tolerability of Radspherin, explored maximal tolerated dose and biodistribution by using single photon-emission computed tomography/computed tomography (SPECT/CT) imaging. Results from the planned safety interim analysis after completion of the dose-limiting toxicity (DLT) period are presented. **Results:** Twenty-three patients were enrolled, dose escalation cohort (14), repeated cohort (3) and expansion cohort (6). Nineteen patients were treated in Oslo/ 4 in Uppsala. Twelve patients had synchronous PM Stage IV and 11 metachronous PM (Stage II (6), Stage III (5). Disease-free interval 15 months (3-39); males (7), females (16); median age 64 years (28-78). Peritoneal cancer index was median 7 (3-19), operation time 395 minutes (194-515) and hospital stay 12 days (7-37). Accordion ≥3 grade events (6); including anastomotic leaks (2); abscess (1); drains (2) and missed lesion (1), all reported as serious adverse events (SAEs). The 7MBq dose was selected as recommended dose as no DLT was observed. A total of 185 treatment emergent adverse effects (TEAE) were recorded, most were of low grade and considered related to CRS and/or HIPEC. Few patients (7) had TEAEs considered related to a combined impact of Radspherin and CRS-HIPEC. The biodistribution of Radspherin showed a relatively even peritoneal distribution, and no patients had compartments of the abdominal cavity without radioactivity (cold spots), and low number had hot spots. Long-term safety, dosimetry and first efficacy results of Radspherin will be reported after 12 months follow up period. **Conclusions:** All dose levels of Radspherin were well tolerated with DLT not reached. No deaths occurred and no SAEs were considered related to Radspherin. The biodistribution of Radspherin showed good peritoneal distribution of the radiolabeled microparticles. Clinical trial information: 2018-002803-33. Research Sponsor: Oncoinvent A/S, N-0484 Oslo, Norway., Innovation Norway, Pb. 448, N-0104 Oslo, Norway.

Effects of liver metastases on efficacy of immune checkpoint blockade in treatment refractory, metastatic colorectal cancer (CRC): CCTG CO.26. *First Author: Eric Xueyu Chen, Department of Medical Oncology and Haematology, Toronto, ON, Canada*

Background: Immune checkpoint blockade has limited activity in microsatellite-stable (MSS) or mis-match repair proficient (pMMR) CRC. Recent findings suggest that immunotherapy efficacy may be modulated by the presence of liver metastases. We conducted a retrospective analysis of the Canadian Cancer Trials Group (CCTG) CO.26 study to investigate the relationship between the presence of liver metastases and activity of immune checkpoint blockade. **Methods:** The CCTG CO.26 study was a randomized phase II study (NCT02870920). Pts with treatment refractory CRC were randomized to durvalumab, tremelimumab and best supportive care (BSC) or BSC alone in a 2:1 fashion. Treatment consisted of durvalumab (1500 mg) q 28 days and tremelimumab (75 mg) q 28 days for the first 4 cycles. The primary endpoint was overall survival (OS) and a two-sided p-value <0.10 was considered significant. **Results:** Between 08/20106-06/2017, 180 pts were enrolled and 179 treated as randomized. Pt baseline characteristics were balanced between groups. With a median follow-up of 15.2 months, the median OS was 6.6 months for durvalumab and tremelimumab and 4.1 months for BSC (p = 0.07; Hazard ratio (HR): 0.72, 90% confidence interval (CI): 0.54 – 0.97). Progression free survival (PFS) was 1.8 months and 1.9 months respectively (HR 1.01, 90% CI: 0.76 – 1.34). Disease control rate (DCR) was 22.6% for durvalumab and tremelimumab and 6.6% for BSC (p = 0.006). At study entry, liver metastases were absent in 29.4% pts. Pts without liver metastases had improved OS compared to those with liver metastases, irrespective of treatments. PFS was significantly longer in those without liver metastases on durvalumab and tremelimumab (HR: 0.55, 90% CI: 0.31 – 0.97, p = 0.08, interaction p = 0.02). DCR was 49% in patients without liver metastases with durvalumab and tremelimumab, compared to 10% in those with liver metastases (Odds Ratio: 0.12, 90% CI: 0.05 – 0.26). **Conclusions:** Pts without liver metastases had improved OS and PFS, and higher DCR. Absence of liver metastases may be an indicator for improved efficacy of immune checkpoint blockade and should be investigated in future studies. Research Sponsor: AstraZeneca.

	D + T	BSC	Hazard (Odds) Ratio
OS, months (90% confidence interval)			
Liver metastases: present	5.49 (3.98–6.44)	3.79 (3.25–5.22)	0.79 (0.58–1.08)
Absent	9.43 (7.39–12.3)	7.66 (3.02–11.2)	0.65 (0.37–1.16)
PFS, months (90% confidence interval)			
Liver metastases: present	1.82 (1.71–1.84)	1.84 (1.77–1.91)	1.36 (1.00–1.86)
Absent	2.04 (1.87–3.71)	1.87 (1.71–2.10)	0.55 (0.31–0.97)

Using cell-free circulating tumor DNA (cfDNA) to identify guideline-relevant biomarkers for therapy selection in 14,000 patients (pts) with metastatic colorectal cancer (mCRC). *First Author: Pashtoon Murtaza Kasi, Weill Cornell Medicine, New York City, NY*

Background: Two cfDNA assays are FDA-approved for use in advanced cancer pts across solid tumors. While several NCCN guidelines recommend cfDNA as a valid and useful method for molecular testing, the utility varies by cancer type. Despite the growing number of molecular alterations pertinent to first-line treatment in mCRC, current guidelines offer little guidance on the use of cfDNA in mCRC. Here we assess the ability of cfDNA to detect guideline-relevant actionable biomarkers informative for first-line therapy selection and beyond in patients with mCRC. **Methods:** We queried consecutive samples from advanced cancer pts with a diagnosis of CRC who underwent testing via a commercially available cfDNA assay (Guardant360) from September 2018 to January 2022. Validation and content of this assay has been previously described. To enrich for less heavily treated pts, we limited analysis to those whose first cfDNA test was done during the study period and only included the pt's first test. The maximum variant allele fraction (maxVAF) for each test was used as a proxy for tumor shed and was compared between cancers with a Mann-Whitney test. The frequency of suspected germline alterations was assessed only in pts who received testing via a panel version with expanded mismatch repair (MMR) gene coverage. Tissue frequencies for select biomarkers were obtained from the MSK-IMPACT Clinical Sequencing Cohort in cBioPortal. **Results:** In total, 14,345 pts with mCRC received their first cfDNA test during the study period, with 92% of pts (13,190) having >1 cfDNA alteration detected. Median age was 62 and 44% of pts were female. The frequencies of key biomarkers are listed in Table 1. The median maxVAF was 5.6%, compared to 2.5% and 1.8% for pts with advanced gastric and NSCLC, respectively (p = < 0.0001 for both). The average turnaround time (TAT) for tests was 7 calendar days. **Conclusions:** cfDNA results from pts with mCRC demonstrated detection of biomarkers essential to first-line treatment decisions at a frequency comparable to what has been reported via tissue genotyping. mCRC pts had significantly higher tumor shed compared to other cancer types with guidelines that recommend cfDNA as an option for molecular testing, suggesting a potential gap in coverage. Tissue availability in mCRC does not guarantee comprehensive testing is completed quickly (compared to the 7-day TAT seen for cfDNA here), making it an attractive alternative strategy for first-line therapy selection in mCRC. Research Sponsor: None.

Effectiveness of nationwide insurance coverage for next-generation sequencing in advanced colorectal cancer: A real-world data study. *First Author: Sun-Kyeong Park, The Catholic University of Korea, Bucheon, South Korea*

Background: Next-generation sequencing (NGS) has been covered by Korean national health insurance since March 2017 for patients with advanced colorectal cancer (CRC). We explored the clinical and socioeconomic impact of NGS compared with that of a single gene test (SGT) alone. **Methods:** From the nationwide database, we identified patients who 1) are diagnosed with advanced CRC classified as a distant disease using Summary Stage between March 1, 2017, and December 31, 2018; 2) had NGS or SGT within 2 months after diagnosis of advanced CRC. Multivariate logistic regression with covariates including age, sex, Charlson comorbidity index, insurance type, year of diagnosis, and region and type of hospital with the initial diagnosis was conducted to identify factors affecting the performance of NGS. We conducted 1:3 propensity score matching to minimize the impact of confounding factors. The median overall survival and the adjusted hazard ratio (aHR) were estimated using the Kaplan-Meier method and the Cox proportional hazard model, respectively. We calculated the total medical cost, and per patient per year (PPPY) cost adjusted for the survival period. **Results:** Among 5,029 patients with advanced CRC, 655 patients were identified as NGS group and 1,995 as SGT group after matching. Old age, low household income, rural location, and non-tertiary hospital were all characteristics that reduced the likelihood of obtaining an NGS test. The NGS group showed significantly favorable survival compared to the SGT group (median survival 29.2 vs. 24.9 months, P = .031; adjusted hazard ratio [HR] 0.86, P = .034). The total medical cost was lower in the NGS group ($55,445) than the SGT group ($57,989), and the PPPY cost was also lower in the NGS group ($44,879 and $49,734, respectively). **Conclusions:** We found that some socioeconomic factors such as age, insurance type, region, and hospital type may hamper the implementation of NGS. Also, lowering the barrier of NGS tests by reimbursing NGS in a specific clinical setting may have survival and cost-benefit in patients with advanced CRC. Research Sponsor: Ministry of Health & Welfare (HI19C0481, HC19C0238).

Phase 1b/ 2 study of a radio-enhancer, PEP503 (NBTXR3), in combination with concurrent chemo-radiation in locally advanced or unresectable rectal cancer. *First Author: Ching-Wen Huang, Division of Colorectal Surgery, Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung, Taiwan*

Background: PEP503 (aka NBTXR3) is a novel radio-enhancer composed of functionalized hafnium oxide nanoparticles that increases the energy deposition of radiotherapy. A phase 3 study in soft tissue sarcoma patients has significantly increased pCR and R0 when PEP503 was added to preop radiotherapy. This phase 1b/2 study was conducted with the aim to identify a recommended phase 2 dose (RP2D), and evaluate the efficacy of PEP503 intratumoral injection in combination with concurrent chemoradiation (CCRT) in patients with locally advanced rectal cancer (LARC). **Methods**: Patients with stage T3-T4 LARC (or with unresectable disease) suitable for neoadjuvant CCRT were enrolled. An intratumoral single administration of PEP503 (multiple punctures) was done 24 to 72 hours prior to IMRT of 50 Gy in 25 fractions of 2 Gy per fraction over 5-6 weeks with concurrent capecitabine or 5-FU. Traditional 3 + 3 design with 4 levels, 5%, 10%, 15%, and 22%, of the baseline GTV as measured by MRI, of PEP503 were assessed in Phase Ib. PEP503 nanoparticles intratumoral dispersion was analyzed by CT-scan. Surgery was performed 8 to 12 weeks after the completion of CCRT for patients with resectable tumors. Body kinetics was evaluated in Phase Ib. (ClinicalTrials.gov, NCT02465593) **Results**: Thirty-two (32) patients (male/female: 20/12; median age 62 years, range 38 to 76) were enrolled (1 dropped out before starting CCRT). In Phase 1b, 20 patients were treated and dose was escalated to 22%. RP2D was then determined as 22% with 6 patients treated at this dose level without DLT. Twelve (12) patients were included in the Phase 2. One (1) (3.2%) and 19 (61.3%) of evaluable patients (n = 31) had CR and PR, respectively, as the best tumor response across dose levels. No patient progressed as all evaluable patients (n = 31) achieved disease control for a DCR of 100%. Furthermore, twenty-five patients underwent surgery, of which 24 (96%) had microscopically clear resection margins and 5 of them (20%) had pathological complete response (pCR). The G3 AEs were diarrhea, ileus, thrombocytopenia, urosepsis, procedural haemorrhage, wound complication, hypokalaemia, and myalgia (all in 3.1%). No G4 AE were observed. The results of CT scans for nanoparticles dispersion demonstrated PEP503 remained within the tumor without leakage to the surrounding healthy tissues, before and after CCRT. In most patients, hafnium was not detected or below the Lower Limit of Quantification (LLOQ) in the circulation 60 minutes after PEP503 injection and was not found in urine. **Conclusions**: A single intratumoral injection of PEP503 in locally advanced or unresectable rectal adenocarcinoma undergoing capecitabine or 5-FU based CCRT is feasible and safe. The preliminary observed efficacy results may warrant further examination in larger clinical studies. Clinical trial information: NCT02465593. Research Sponsor: PharmaEngine, Inc.

Effect of more versus less frequent abdominopelvic computed tomography follow-up testing on overall survival in patients with stage II or III colon cancer. *First Author: Jeon Jeongseok, Yonsei University, College of Medicine, Seoul, South Korea*

Background: Patients with colon cancer undergo an abdominopelvic computed tomography (AP-CT) scan surveillance every 6-12 months for five years after surgery. However, evidence of survival benefit from more intensive AP-CT patients in stage II and III colon cancer is still elusive. **Methods:** A total of 2,137 patients with stage II-III colon cancer who received curative aim surgery were analyzed in the Yonsei Cancer Registry Database between Jan 1, 2005, to Dec 31, 2015. The surveillance start date was defined as 90 days after curative resection or one day after adjuvant chemotherapy. All patients had at least one AP-CT for two years after the surveillance period. The average interval of AP-CT per patient was calculated as the postoperative surveillance duration divided by the number of AP-CT examinations. Patients who underwent AP-CT with an average interval of 6 months and 12 months were assigned to the high-frequent and low-frequent surveillance groups. Association of AP-CT frequency and demographic factors with overall survival (OS) were evaluated. Univariate and multivariate analyses were conducted. **Results:** Among 2,137 patients who underwent curative aim surgery, the median intervals of AP-CT scan were 6.1 months in high-frequent surveillance and 10.8 months in the less-frequent surveillance group, respectively. The 5-year overall survival (OS) was not significantly different in both groups; however, OS was significantly longer in the high-frequent surveillance group of patients who harvested lymph nodes less than 12 in curative resection ($P = 0.015$) or measured postoperative serum carcinoembryonic antigen (CEA) level higher than 5 ng/ml ($P = 0.023$). Of note, high-frequent surveillance group detected liver metastasis earlier (6.7 months) than the low-frequent group, leading to more curative aim metastasectomy (28.0% vs 4.3%, $P = 0.020$), and significantly longer 5-year OS (62.2% vs 34.8%, $P = 0.017$). Multivariate analysis showed that harvesting lymph nodes less than 12 (HR = 4.37, P = 0.004) and postoperative CEA level higher than 5 ng/ml (HR = 7.39, P < 0.001) were prognostic factors for overall survival. **Conclusions:** The average interval of AP-CT in patients with stage II-III colon cancer is not associated with improved OS. However, a high-frequent AP-CT enabled early detection of liver metastases, leading to the improved OS in high-risk patients, including the number of harvested lymph nodes less than 12 or postoperative CEA level is higher than 5 ng/ml. The risk-stratified approach is warranted to guide postoperative colon cancer surveillance. Research Sponsor: None.

Preoperative chemoradiotherapy with capecitabine with or without temozolomide in patients with locally advanced rectal cancer: A prospective, randomized phase 2 study stratified by MGMT (O^6-methylguanine DNA methyltransferase) status: KCSG-CO17-02. *First Author: Chung Ryul Oh, Department of Internal Medicine, Chung-Ang University Hospital, Chung-Ang University College of Medicine, Seoul, South Korea*

Background: We aimed to evaluate the clinical efficacy of adding temozolomide (TMZ) to preoperative capecitabine (CAP)-based chemoradiotherapy (CRT) in patients with locally advanced rectal cancer (LARC) and validate O^6-methylguanine DNA methyltransferase (MGMT) methylation status as a predictive marker for TMZ combined regimens. **Methods:** : LARC patients with clinical stage II (cT3-4N0) or III ($cT_{any}N+$) disease were enrolled. They were stratified into MGMT unmethylated (uMGMT) and MGMT methylated (mMGMT) groups by methylation-specific PCR before randomization, and then were randomly assigned (1:1) to one of four treatment arms: uMGMT/CAP (arm A), uMGMT/TMZ+CAP (arm B), mMGMT/CAP (arm C), and mMGMT/TMZ+CAP (arm D). The primary endpoint was the pathologic complete response (pCR) rate. **Results:** Between November 2017 and July 2020, 64 patients were randomized. Slow accrual caused early study termination. After excluding 4 ineligible patients, 60 were included in the full analysis set. The pCR rate was 15.0% (9/60), 0%, 14.3%, 18.8%, and 26.7% for arms A, B, C, and D, respectively ($p = 0.0498$ between arms A and D). The pCR rate was 9.7% in the CAP group (arms A+C), 20.7% in the TMZ+CAP group (arms B+D), 6.9% in the uMGMT group (arms A+B), and 22.6% in the mMGMT group (arms C+D). Grade 1–2 nausea or vomiting was significantly more frequent in the TMZ+CAP treatment groups (arms B+D) than in the CAP treatment groups (arms A+C, $p < 0.001$) with no difference in grade 3 adverse events (AEs). There were no grade 4 or 5 AEs. **Conclusions:** The addition of TMZ to CAP-based CRT tended to improve pCR rates, particularly in those with mMGMT LARC. MGMT status may warrant further investigation as a predictive biomarker for chemotherapeutic agents and radiotherapy. Clinical trial information: NCT03156036. Research Sponsor: This study was supported by a grant 2017-0274 from the Asan Institute for Life Sciences, Asan Medical Center, Korean Cancer Study Group, and a grant from the National R&D Program for Cancer Control, Ministry of Health and Welfare, Republic of Korea (17201.

Using T stage to predict outcomes of adjuvant oxaliplatin (OX)-based chemotherapy (CT) in stage III colon cancer (CC): An ACCENT pooled analysis. *First Author: Romain Cohen, Sorbonne University, Department of Medical Oncology, Saint-Antoine Hospital, AP-HP, Paris, France*

Background: Standard adjuvant CT for stage III CC are FOLFOX and CAPOX. Recently, IDEA study separated stage III patients (pts) into low risk (T1 to 3, N1) and high risk (T4 or N2). We recently confirmed benefit of OX in both risk groups. However, we observed a difference in the two high-risk subgroups, with benefit in N2 but not in T4 (Margalit O et al; Clin Colorectal Cancer 2021). This prompted us to compare outcomes (OS/TTR) between treatment with OX vs. without OX within sub-stage III CC groups defined by T and N. **Methods:** We pooled 4941 stage III CC pts from the three studies evaluating 6 months of CT with fluoropyrimidine (FP) ± OX: MOSAIC, C-07 and XELOXA. Baseline characteristics were compared using χ^2 and *t*-test. OS was compared between OX and no OX in T and N subgroups. Kaplan-Meier analyses, adjusted and unadjusted Cox models stratified by study were used. Sub-groups classification was done according to OX benefit and verified by interaction test (Int) considered as significant with a $P<0.1$. We considered for recommendation of using OX-based adjuvant CT, 1) significant benefit in OS, 2) significant Int between substage and adjuvant therapy, and 3) the three individual trials showing similar results (benefit or non-benefit of OX). **Results:** In stage III population, T3 pts were 74.9%, T1-2 12.4%, T4 13.1%, while N stage was N1 64.7% and N2 35.3%. Population was well balanced according to treatment allocation in most subgroups. A significant benefit of OX was only observed in T3N1 and T3N2 (OS HR 0.76). Whatever N stage, there was no significant benefit of OX in the T1-2 and T4 subgroups. The effect of OX+FP vs FP alone in OS of the three studies differed between T3 and T1-2 subgroups (P = 0.047). Interaction was borderline between T3 and T4 subgroups (P = 0.10) but there was no interaction between T1-2 and T4 subgroups (P = 0.429). A benefit of OX in TTR remained in the T4 population. Discrepancy between advantage in time to relapse (TTR) and no advantage in OS was not explained by survival post relapse. **Conclusions:** Our analysis suggested that pts with T1-2N1-2 and T4N1-2 disease had no OS benefit of addition of OX to FP. The good survival achieved with FP alone in T1-2N1-2 pts (5-yr OS 89%) question the addition of OX. In the T4 population our results suggested that benefit of OX was limited and that further studies should assess this issue or at least stratify pts on T stage in the future adjuvant trials in CC. Research Sponsor: None.

The effect of OX use on OS according to T & N stage combinations.

Testing of a machine learning (ML) model for ability to predict oxaliplatin and bevacizumab (bev) benefit in NRG Oncology/NSABP C-07 and C-08. *First Author: Xinghua Lu, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Through mining The Cancer Genome Atlas (TCGA) data and a large set of transcriptomes of CRC in GEO, we constructed 15 metagenes reflecting the transcriptomic impact of major driver genes of CRC. Independent of any clinical information, we used metagenes as features to further develop an ML model, then tested it using gene expression (GE) data from C-07 and C-08. **Methods:** We carried out a prospectively designed and double-blind study to evaluate the clinical utility of the ML model in the adjuvant setting. Samples were classified as Sig+ or Sig-. Association of signatures with recurrence free interval were tested using log-rank test, and significance was set at P<0.05. Cox regression models were used to estimate hazard ratios in univariate and multivariate models and for significance testing in multivariate models. Clinical variables included in multivariate models were nodal status, age, sex, and T stage. **Results:** We tested the ML model for its ability to predict oxaliplatin benefit in all C-07 pts with available GE data (n=846). Sig+ pts received significant benefit from oxaliplatin (HR=0.68, 95% CI=0.48-0.95, p=0.025) but Sig- did not (Sig- HR=1.05, 95% CI=0.72-1.53, p=0.79), however, the int p value showed only a trend for significance (int p=0.091). Sig+ remained significant for oxaliplatin benefit in multivariate analysis (HR=0.67, 95% CI=0.48-0.95, p=0.024). When we combined all C-07 pts (C-07 FULV-trtd n=298, FLOX n=304) with C-08 FOLFOX-treated pts (n=226) the Sig+ was significantly associated with oxaliplatin benefit (HR=0.65, 95% CI=0.48-0.89, p=0.0065) with a significant int p=0.03. We also tested the signature for association with bev benefit in C-08 (n=438), using a different cut off. Sig+ showed only a trend for an association with bev benefit (HR=0.63, 95% CI=0.35-1.12, p=0.11). To increase the power to detect bev benefit, we also tested the signature for association with bev benefit in all C-08 patients and C-07 pts treated with FLOX. The Sig+ group received significant benefit from bev (HR=0.58, 95% CI=0.36-0.94, p=0.025) but the Sig- group did not (HR=1.02, 95% CI=0.64-1.63, p=0.94), however, the int p was not significant (p=0.101). The model also showed an association with prognosis within the FULV treatment arm in C-07 (HR=1.51, 95% CI=1.07-2.14, p=0.018) and the FOLFOX+bev arm in C-08 (HR=0.55, 95% CI=0.30-1.01, p=0.049). **Conclusions:** Although our study is not optimally powered, our analyses indicate that the ML model was predictive for oxaliplatin benefit in stage II and III CC and may be useful for detecting bev benefit. Importantly, the Sig- population is candidate for omitting oxaliplatin (de-escalation) in adjuvant setting but will require further validation. Computerized features of tumor diversity on pre-chemoradiation MRI are associated with pathologic complete response in rectal cancers: A multi-institutional study. *First Author: Sneha Singh, Case Western Reserve University, Cleveland, OH*

Background: Neoadjuvant chemoradiotherapy (nCRT) prior to total mesorectal excision (TME) reduces the risk of local recurrence and is a standard-of-care treatment for patients with locally advanced rectal cancer. Previous studies have indicated up to 30% of patients who undergo TME demonstrate a pathologic complete response (pCR) to nCRT [2], but current serum markers and clinical evaluation have limited utility in predicting benefit from nCRT. In this study, we evaluated if tumor diversity features on baseline pre-treatment MRI were predictive of pCR in rectal cancers. **Methods:** Pre-nCRT T2-weighted MRIs from 126 patients who later underwent nCRT and TME (without neoadjuvant chemotherapy) were retrospectively collected from 2 institutions. 69 patients (14 pCR, Institution 1) formed the training cohort D1, while 57 patients (10 pCR, Institution 2) formed the independent holdout validation cohort D2. Response groupings were based on AJCC tumor regression grade (TRG) evaluation where pCR corresponded to no residual tumor cells in excised histopathologic specimens after nCRT (i.e. TRG0) and non/partial response otherwise (TRG1-3). Computerized tumor diversity algorithms extracted measurements of fractal dimensions, surface topology, and persistent homology from annotated tumor regions on MRI to quantify visual patterns, spatial geometry, and prolonged structural similarity. Top tumor diversity features identified via Wilcoxon rank-sum testing were used to train a random forest (RF) machine learning classifier to predict the likelihood of pCR using D1 and then independently evaluated for predicting pCR in D2. **Results:** Machine learning analysis identified 5 tumor diversity measurements associated with pCR on pre-nCRT MRI. The associated RF classifier for pCR achieved an AUC of 0.98 (95% CI, 0.9808-0.9949) in D1 and an AUC of 0.9117 in hold-out validation on D2. This corresponded to predicting 100% of non/partial response prior to nCRT as well as 80% of pCR patients via tumor diversity features on pre-nCRT MRI. **Conclusions:** Computerized tumor diversity features on pre-nCRT MRI can predict pathologic complete response to nCRT in rectal cancers. These findings need to be validated in larger multi-institutional cohorts to establish independent predictive utility of MRI-based biomarkers, which could aid in the selection of patients who will see maximal response from neoadjuvant therapy and avoid unnecessary surgery. PKUCH 04 trial: Total neoadjuvant chemoradiation combined with neoadjuvant PD-1 blockade for pMMR/MSS locally advanced middle to low rectal cancer. *First Author: Aiwen WU, Peking University Cancer Hospital and Institute, Beijing Cancer Hospital, Beijing, China*

Background: Total neoadjuvant therapy (TNT) with induction chemotherapy and chemoradiation is the standard of care for locally advanced rectal cancers. Incorporation of PD-1 blockade in the neoadjuvant setting is promising for mismatch repair deficient (dMMR) patients, yet the efficacy of TNT combined with PD-1 blockage for pMMR/MSS patients is little unknown. The purpose of this study is to evaluate the clinical benefit of neoadjuvant PD-1 blockade combined with TNT in pMMR/MSS locally advanced rectal cancer. **Methods:** We designed a prospective, single-arm, phase II study on locally advanced dMMR/MSS rectal cancer (PKUCH 04 trial). Patients will receiving neoadjuvant regimen (PD-1 inhibitor, camrelizumab, also called SHR01210, 200mg d1, oxaliplatin 130mg/m2 d1, capecitabine 1250mg/m2 bid1-14, for three cycles, then long course chemoradiation (IMRT, 1.8Gy/f*25f), then another two cycles of CapeOx (oxaliplatin 130mg/m2 d1, capecitabine 1250mg/m2 bid1-14, q3wks) if no disease progression occurs. The primary endpoint was pathologic complete response (pCR) rate, and the secondary outcome include adverse event and surgical complication. Tumor assessment was carried out after induction, chemoradiation, and before the decision of either surgery or watch and wait. **Results:** A total of 27 patients were screened and finally 25 patients were eligible for further analysis, with median age 58 years (range 31-70). The median distance from the anal verge was 5.3 cm (1.2-10). 76% were male, 76% had N2 disease, 56% positive MRF, 80% positive EMVI. All patients have completed the induction and chemoradiation phases. 21 patients underwent TME surgery, of which 7 had pathological complete response (33.3%). Four achieved clinical complete or near complete response and chose watch and wait. 7 had major pathological remission (over 90% remission). Another 7 had partial pathological remission. No progressive disease was found. 14 had LAR, 7 APR, and . The surgical complication rate was 14.3%, and the mortality rate was 0. The common adverse events included nausea (80%), lymphopenia (80%), paresthesia (76%), reactive cutaneous capillary endothelial proliferation (72%), neutropenia (68%). Grade 3 adverse events include lymphopenia (24%), diarrhea (8%), and thrombocytopenia (4%) and no grade 4 or 5 events were observed. Till January 2022, no recurrence or regrowth was found. **Conclusions:** Total neoadjuvant chemoradiation combined with neoadjuvant PD-1 blockade is safe and effective which can achieve good regression and sphincter preservation for pMMR/MSS rectal cancer. This suggests a potential new paradigm for treatment of pMMR/MSS locally advanced rectal cancer and necessitates further investigation. Clinical trial information: NCT04340401. Research Sponsor: Jiangsu Hengrui Medicine Co.

Effect of adjuvant chemotherapy in patients with stage III colon cancer based on the Multi-Institutional Registry of Large Bowel Cancer in Japan. *First Author: Yasuhide Yamada, National Center for Global Health and Medicine, Tokyo, Japan*

Background: A fluoropyrimidine plus oxaliplatin is the standard of care for stage III colon cancer but a fluoropyrimidine alone is also recommended for stage III patients in Japanese and other practice guidelines. We assessed efficacy of adjuvant fluoropyrimidine with or without oxaliplatin across a population of stage III colon patients in the Multi-Institutional Registry of Large Bowel Cancer in Japan. **Methods:** 7,024 of stage III colorectal cancer patients in this registry were analyzed. Endpoints were relapse-free survival (RFS) and overall survival (OS). **Results:** All patients received adjuvant chemotherapy between 2008 and 2011.Patient characteristics except lymph node metastases were well balanced across groups. The RFS of fluoropyrimidine with or without oxaliplatin show comparable efficacy for stage III, even for stage IIIc patients, less than 70 years old, and T4 or N2b. Median follow-up was 74.9 months in oxaliplatin combined therapy and 74.7 months in fluoropyrimidine monotherapy. The additive efficacy of oxaliplatin was not shown for RFS and OS. **Conclusions:** Adjuvant fluoropyrimidine monotherapy and fluoropyrimidine plus oxaliplatin show comparable efficacy benefits for the treatment of stage III of Japanese colon cancer patients; supporting fluoropyrimidine alone as standard options for the adjuvant therapy of stage III in Japan. Research Sponsor: Funding for Nationwide Colorectal Cancer Registry by Japanese Society for Cancer of the Colon and Rectum.

Total neoadjuvant chemoradiation combined with neoadjuvant PD-1 blockade for patients with pMMR, high-risk, and locally advanced middle to low rectal cancer. *First Author: Aiwen Wu, Peking University Cancer Hospital and Institute, Beijing Cancer Hospital, Beijing, China*

Background: Total neoadjuvant therapy (TNT) with chemotherapy and chemoradiotherapy (CRT) is the standard treatment for locally advanced rectal cancer patients, especially for those with high risk factors. And the effects of immune checkpoint inhibitors (ICIs) on rectal cancer with defect mismatch repair (dMMR) have been demonstrated. However, the efficacy of TNT combined with PD-1 blockage for rectal cancer patients with proficient mismatch repair (pMMR) is unknown. The purpose of this study is to evaluate the clinical safety and efficacy of neoadjuvant PD-1 blockade combined with TNT in locally advanced rectal cancer with pMMR. **Methods:** We designed a prospective, single-arm, phase II study on stage II and III dMMR rectal cancer with high risk factors. Patients received neoadjuvant POC regimen (PD-1 inhibitor, camrelizumab, also called SHR01210, 200mg d1, Oxaliplatin 130mg/m2 d1 and Capecitabine 1250mg/m2 bid1-14, q3wks) for three cycles, then with long course chemoradiation (IMRT, 1.8Gy/f*25f). If there were no disease progression occurs, patients would be treated with another two cycles of CapeOx. The primary endpoint was pathological complete response rate (pCR rate), and the secondary outcome include adverse events and surgical complication. Biopsies and plasma pre-neoadjuvant therapy were collected and performed with whole-exome sequencing (WES), and ctDNA sequencing, respectively. **Results:** 27 patients were screened, of whom 25 patients were enrolled. All patients have completed the TNT. After neoadjuvant treatment, 21 patients underwent TME surgery. 7 (33.3%) patients were pCR, 3 (14.3%) achieved clinical complete or near complete response and 7 (33.3%) had a major pathological response. No progressive disease was found. WES and ctDNA sequencing analysis showed that tumor mutation burden (TMB) and level of ctDNA did not differ significantly between responders and non-responders. However, 3 responders with TMB high were found to be defective in other DNA damage repair pathways. **Conclusions:** Total neoadjuvant chemoradiation combined with neoadjuvant PD-1 blockade can achieve high pathological response rate, demonstrating its antitumor efficacy in pMMR locally advanced rectal cancer patients with high risk factors. Research Sponsor: None.

Phase II, multicenter, open-label, non-randomized study of neoadjuvant chemotherapy NALIRINOX (5-FU/LV + oxaliplatin + nal-IRI) followed by chemoradiotherapy in patients with rectal cancer in a watch-and-wait program.

First Author: Cesar Gregorio Muñoz, HM-CIOCC, Madrid, Spain

Background: Despite optimal treatment sequence are still challenging, Neoadjuvant chemotherapy (NAC) followed by chemoradiotherapy (CRT) in patients with local rectal cancer (LRC), known as total neoadjuvant therapy (TNT), offers early treatment of micrometastases, with optimal exposure to systemic chemotherapy (CT) and rapid relief of local symptoms. In one hand, Nal-IRI has demonstrated efficacy and safety in the treatment of GI tumors. On the other hand, Watch and Wait (W&W) protocol is currently being imposed as an alternative to surgery in selected patients with LCR who achieve complete clinical response (cCR), offering the possibility of a rectum preservation strategy without the need to surgical intervention. Accordingly, TNT with NAC Nal-IRI, 5-FU, Oxaliplatin (NALIRINOX) could help to increase cCR rates in LRC treatment, allowing to enter W&W protocol. **Methods:** We performed a national, single arm, multicenter phase II study of patients with LRC treated with biweekly NAC NALIRINOX for 8 cycles followed by CRT. Main inclusion criteria were patients with confirmed histopathological diagnosis of LRC, good performance status and candidates for W&W protocol. Primary objective was the % of cCR rate obtained. Secondary objective was safety profile of NAC NALIRINOX combination. The first reassessment was carried out at 10 +/- 2 weeks after finish CRT, with digital rectal examination (DRE), pelvic MRI, CT body scan and rectoscopy. The results were evaluated and discussed by the multidisciplinary gastrointestinal Tumors Board (including Radiological Oncology, Medical Oncology, Surgery, Gastroenterology, Nuclear Medicine, Radiology and Pathology Departments) If patient achieved cCR, was included in W&W protocol with close follow-up with the same tests. **Results:** 30 subjects with LRC were recruited between March 2019 and July 2020 (22 men and 8 women); 26 (86.7%) subjects received 8 NAC NALIRINOX cycles. 1 subject received only 1 cycle, 2 subjects received 3 cycles and 1 received 7 cycles. A total of 25 (83.3%) subjects were evaluated for either W&W or surgery after CRT. 10 of them (45.5%) underwent surgery: 5 (50%) Low anterior resection (LAR) and 4 (40%) Abdominoperineal resection (APR). Therefore, 12 (54.5%) obtained cCR after first reassessment and underwent W&W protocol surveillance. Regarding safety endpoint, 6 (20%) subjects reported at least one grade 3 CTCAE toxicity related to any of the NALIRINOX medications. Diarrhea was the most frequent (13.3%), followed by asthenia (3.3%) and decreased appetite (3.3%). All of them had been resolved. **Conclusions:** TNT with NAC NALIRINOX is a safe and effective therapeutic approach to increase cCR rates and enable to select patients with LRC for W&W protocols Clinical trial information: NCT04009876. Functional impact of somatic mutations in early-onset (EO) versus average onset (AO) microsatellite stable (MSS) stage III colorectal cancer (CRC).

First Author: Emily Harrold, Memorial Sloan Kettering Cancer Centre, Dublin, Ireland

Background: Analysis of the IDEA database demonstrates significantly worse disease-free survival in high-risk stage III EO CRC vs AO CRC, regardless of adjuvant therapy intensity or duration. Critically this analysis omits somatic mutational data and germline status. Enrichment of TP53 in EO metastatic CRC (mCRC) is well described and functionality of individual TP53 mutations has been proposed as a potential mechanism of chemotherapy resistance. The prognostic and functional impact of somatic mutations merits analysis in the EO high-risk Stage III cohort. **Methods:** The Memorial Sloan Kettering MSKCC IMPACT database was queried for MSS Stage III AO CRC (≥50 yrs) and EO CRC (< 50 yrs) patients(pts); clinico-pathological characteristics, systemic therapies received, and survival outcomes were reviewed. MSI, POLE mutated or hereditary syndrome associated tumors were excluded. We further classified TP53 mutations as GOF (gain of function) versus non GOF/ LOF (loss of function) (Pan M, JCO. 2022, Muller PA, Cancer cell. 2014). **Results:** 272 pts were included in the analysis (EO = 184, AO = 88). 50% of the EO and 62.5 % of the AO cohorts were male. Tumors were predominantly adenocarcinoma (EO 89% vs AO 91%), moderately differentiated (EO 78% vs AO 74%) and left sided (EO 77% vs AO 48.8%). 87% of the EO and 63.6 % of the AO cohort were TP53mut (p value 0.0003); TP53mut was enriched in the EO cohort regardless of sidedness but there was no significant difference in TP53 mutations between EO high vs low risk. Classifying by 7 putative GOF mutations (R175H, R248Q/W, R249S, R273H/L and R282W) 28.7% of the EO cohort harbored a GOF mutation vs 19.6% of the AO cohort. There was no statistically significant survival difference between pts with TP53mut tumors vs TP53 wild type (TP53wt) in the entire cohort (AO+EO) (p 0.041) or EO or AO cohorts (p 0.049). There was no significant difference in survival outcomes across all cohorts of TP53mut groups, both high and low risk, both GOF and non GOF, treated with 3 vs 6 months of chemotherapy (p 0.67). The EO TP53wt group was enriched relative to the EO TP53mut group for KRAS (60% vs 32%), BRAF (11% vs 4%), and PI3K driver alterations (PIK3CA, 20% vs 13%) and PTEN: (8% vs 3%) In the multivariate survival analysis of EO Stage III CRC BRAFmut status is highly statistically significant (p < 0.001). **Conclusions:** EO Stage III CRC is enriched for TP53 mutations regardless of sidedness and GOF mutations are identified in a higher proportion of EO CRC than AO CRC. We found no statistically significant difference in survival by TP53mut status across the entire MSS Stage III CRC cohort. There was no interaction between TP53mut status, duration of chemotherapy and overall survival. The functional impact of additional molecular features is being explored and the novel prognostic significance of BRAF demonstrated in this EO Stage III cohort requires further validation. Adiposity in resectable colorectal cancer.

First Author: Jessica Hopkins, Department of Surgery, University of Calgary, Calgary, AB, Canada

Background: Sarcopenia and myosteatosis affect survival in colorectal cancer (CRC). The role of adiposity is not yet fully elucidated. This study explores visceral and subcutaneous adipose tissue (VAT/SAT) distributions, and how they affect overall (OS), disease-free (DFS) and cancer specific survival (CSS). **Methods:** This retrospective cohort study, included resected stage I-III CRC in Alberta from January 2007 to December 2009. We excluded recurrent/metastatic disease or no CT scan. This study was approved by the Health Research Ethics Board at the University of Alberta. Body composition parameters were measured from CT scans. Sarcopenia and myosteatosis were defined by cohort-specific cut-off values. Total and visceral fat areas were indexed by height, and cohort-specific cut-offs defined total and visceral obesity (VO). SAT (SC:TFR) and VAT (V:TFR) to total adipose ratios were compared by gender, as described by Fleming. SAT and VAT fat radiodensity (Hounsfield units, HU) was measured and divided into quartiles. Differences between groups were compared with student's t-test and Fisher Exact test. Cox proportional hazard models were created, adjusting for important covariates, to assess adiposity effects on OS, DFS and CSS. **Results:** Our cohort included 968 patients with a median follow up of 63.5 months. The majority were stage II (38.6%) and III (51.0%). In total, 67.9% had total obesity and 51.0% had visceral obesity. In males, there was no difference in the incidence of myosteatosis or sarcopenia, regardless of V:TFR or SC:TFR. In women, those with a high V:TFR or SC:TFR had significantly higher incidence of myosteatosis, but not sarcopenia. Men and women with elevated V:TFR had significantly lower VAT and SAT HU (p<0.001, p=0.0113). Those with elevated SC:TFR had significantly higher VAT and SAT HU (p<0.001). VAT and SAT HU was lowest in those with myosteatosis alone (p<0.001; p=0.005). In survival analysis, VO and VAT HU quartiles predicted worse OS in uni-, but not multivariate analysis. SAT HU quartiles predicted worse survival in uni- and multivariate analysis, with the highest quartile of SAT HU predicting increased risk of death (HR 1.35, p=0.037). Adiposity was not predictive of CSS or DFS in uni- or multivariate analysis. **Conclusions:** This study demonstrated changes in VAT/SAT in relation to well described body composition parameters. SAT HU may have a more important role in OS than visceral adipose characteristics, despite known metabolic characteristics of VAT. True roles of adipose tissue in CRC outcomes remains unclear. VAT/SAT measurements using cross-sectional imaging allows for a detailed analysis and understanding of how adiposity may affect survival. Research Sponsor: Alberta Health Services.

Trend of sphincter-preserving surgeries for resectable low rectal cancer: A 20-year experience in China.

First Author: Qingqing Hu, Johnson & Johnson Epidemiology, Shanghai, China

Background: Over the last decades, patients with low rectal cancer have realized better functional, morbidity, and quality-of-life outcomes from improvements in surgical techniques in sphincter preservation. We aimed to quantify the trend in sphincter-preserving surgeries for low rectal cancer over 20 years in China. **Methods:** Between November 1999 and October 2021, a cohort of patients with pathologically confirmed primary malignant rectal tumor ≤5cm from the anal verge and who received selective surgery at Changhai Hospital, was identified. Demographic and clinical data were extracted from electronic medical records. Survival data were collected from outpatient medical records and follow-up phone interviews. A Joinpoint Regression Model was used to analyze trends in surgical procedures by average annual percentage change (AAPC). A Cox proportional hazards regression model adjusting for demographic and clinicopathological confounders was used to assess the overall survival for patients with sphincter-preserving surgery vs. abdominoperineal resection (APR). **Results:** Among 19,276 patients with colorectal cancer, 4,072 (21.1%) had a tumor in the low rectum during the study period; 3,025 (74.2%) underwent a sphincter-preserving surgery and 1,047 (25.7%) received APR. Sphincter-preserving surgery increased 3.6% per year (AAPC 3.6, p=.006). Anterior resection was the most performed procedure (86.3%) and maintained a steady trend (AAPC 0.13, p=.49), while intersphincteric resection (including conformal sphincter preservation operation) increased 49.4% annually (AAPC 49.4, p=.003). Laparoscopic techniques increased 15.1% per year (AAPC 15.1, p=.035). Sphincter-preserving surgery increased annually for tumors ≤2cm, 2-3cm and 3-4cm from the anal verge (AAPC 7.08, p=.001; 4.69, p=.001; 2.66, p=.001, respectively). A total of 2,854 patients had sufficient vital status data for inclusion in the survival analysis. The characteristics of those with and without a follow-up encounter were comparable. Patients with sphincter-preserving surgery had a lower risk of death compared to APR (adjusted HR 0.78, 95% CI, 0.65-0.93, p=.01). **Conclusions**: Utilization of sphincter-preserving surgeries increased significantly over the last 20 years. Patients with low rectal cancer who underwent sphincter preservation had better survival than similar patients who underwent APR. Research Sponsor: None.

Hazard ratios (HRs) for all-cause mortality among patients with low rectal cancer.

Characteristics		HR (95% CI)	P
Sphincter-preserving surgery (vs. APR)		0.78[a] (0.65-0.93)	0.01
Tumor location (vs. 4-≤5cm from the anal verge)	≤2cm	1.19 (0.95-1.48)	0.13
	2-≤3cm	0.92 (0.76-1.12)	0.40
	3-≤4cm	0.99 (0.83-1.20)	0.96
Pathological stage (vs. I)[b]	II	0.97 (0.80-1.18)	0.79
	III	2.01 (1.70-2.38)	<0.005

Label-free and automated approach to rapidly classify microsatellite instability (MSI) in early colon cancer (CC) analyzing the AIO ColoPredictPlus 2.0 (CPP) registry trial. *First Author: Stephanie Schörner, Center for Protein Diagnostics (PRODI), Dept. of Biophysics, Ruhr-Universität Bochum, Bochum, Germany*

Background: MSI due to mismatch repair defects accounts for 15-20% of all CC, has high prognostic and predictive value and is broadly utilized in treatment decisions. Artificial intelligence (AI) integrated, label-free quantum cascade laser (QCL) based infrared (IR) imaging resolves spatial and molecular alterations such as MSI in unstained cancer tissue sections. We aimed to evaluate the method for microsatellite instability/stability (MSI/MSS) classification in samples from the prospective multicenter AIO CPP registry trial. **Methods:** Paraffin-embedded unstained cancer tissue slides from patients (pts.) participating in CPP were measured (avg. 30 min/slide) and analyzed. The cohort was split into training (train), test (test), and validation (vali) sets. Cancer regions were first preselected based on a self-developed convolutional neural network (CNN) CompSegNet (Schuhmacher, medrxiv 2021). A VGG-16 CNN then classified MSI/MSS in these regions. Endpoints were area under receiver operating characteristic (AUROC) and area under precision recall curve (AUPRC). **Results:** 547 pts. (train n=331, test n=69, vali n=147) were analyzed. The baseline characteristics for the sub-cohorts are illustrated in the table. Mutation (MT) status: RAS MT: train 30% / test 30% / vali 37%; BRAF MT: train 27% / test 23% / vali 14%. The preselection of cancer regions reached a validation AUROC of 1.0. The subsequent MSI/MSS classifier reached a validation AUROC of 0.9 and AUPRC of 0.74 (sensitivity 85%, specificity 84%). **Conclusions:** Our multicenter approach using AI integrated label-free IR imaging provides an automated, fast, and reliable classification for MSI/MSS with an AUROC of 0.9 (sensitivity 85%, specificity 84%) almost comparable to the present gold standard immunohistochemistry. The method described here requires less samples for training when compared to other AI approaches which could facilitate the development of prognostic/predictive classifiers in the setting of randomized controlled trials. This novel technique may support further understanding of the increasingly important MSI CC cohort and support treatment decisions e.g. in specific subgroups such as targetable fusions. We expect our approach to be a broadly applicable diagnostic tool in the future. Research Sponsor: Ministry of Culture and Science (MKW) of the State of North-Rhine Westphalia, Germany, Pharmaceutical/Biotech Company.

A phase II trial of TGFβ type I receptor inhibitor, galunisertib, plus neoadjuvant chemoradiation in patients with locally advanced rectal cancer. *First Author: Kristina Hoot Young, Earle A. Chile Research Institute, Providence Cancer Institute, Portland, OR*

Background: Transforming growth factor beta (TGFβ) is an immunosuppressive cytokine upregulated in colorectal cancer. Preclinical data demonstrated improved response to chemoradiation with TGFβ blockade in colorectal adenocarcinoma. Here we report the results of our single arm Phase II study combining the TGFβ type I receptor kinase inhibitor, galunisertib, with neoadjuvant chemoradiation in patients with locally advanced rectal adenocarcinoma. **Methods:** Eligible patients had T3+ or N+ rectal adenocarcinoma planned for surgical resection. Enrolled patients completed a 14-day course of galunisertib, followed by chemoradiation with continuous infusion 5-fluorouracil or capecitabine with radiation to 50.4-54Gy in 28-30 fractions. On day 30, patients underwent another 14-day course of galunisertib concurrent with ongoing chemoradiation. Five to nine weeks after completing neoadjuvant therapy, patients underwent response assessment. Those with complete response by physical exam, proctoscopy, and MRI, could opt for non-operative management and proceed to mFOLFOX6. Those with less than a complete response underwent surgical resection. The primary endpoint was complete response rate (CR), which was a composite of pathologic complete responses in those patients who proceeded to surgery, and clinical complete responses maintained at 1 year after completion of therapy for those who chose non-operative management. Using a Simon Two-Stage approach with 90% power and $\alpha = 0.05$, to detect a 20% improvement in complete response rate compared to historical control (15% vs 35%); we reject the null hypothesis if ≥10/38 patients have a CR. 38 patients were enrolled with 35 patients evaluable. **Results:** Median age was 51y, 68% of patients were male, 87% of patients were Stage III, 97% of patients were node-positive, and 97% were proficient in mismatch repair. 95% of patients completed study therapy. Toxicity attributed to galunisertib was Grade 1-2. 28 patients went to surgery, with a mean neoadjuvant rectal (NAR) score (NAR = 5pN-3(cT-pT)+12]^2/9.61) of 11.29, and pCR in 7 patients. 7 patients underwent non-operative management, with 5 achieving cCR at 1 year. Therefore, complete responses were observed in 12 patients. Peripheral immune monitoring revealed percent change in CD3+CD4-CXCR3+ T cells and activated $CD8_{EM}$ T cells correlated with response to therapy. 2y PFS and OS were 81.5% and 97%. **Conclusions:** The addition of TGFβ inhibition to neoadjuvant chemoradiation in locally advanced rectal cancer markedly improved response to therapy, was well tolerated, and warrants further investigation. Clinical trial information: NCT02688712. Research Sponsor: None.

Clinical and radiological predictors of organ preservation in patients with rectal cancer treated with total neoadjuvant therapy. *First Author: Jonathan B Yuval, Colorectal Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Baseline rectal MRI is routinely used for tumor staging, selecting the initial treatment and prognostication of patients with rectal adenocarcinoma. However, associations of baseline clinical and MRI variables with organ preservation (OP) in a prospective randomized trial have not been reported. **Methods:** Patients with MRI staged clinical stage II or III rectal adenocarcinoma treated in a prospective phase II clinical trial were randomized to either induction chemotherapy (FOLFOX or CAPEOX) followed by chemoradiation or chemoradiation followed by consolidation chemotherapy (FOLFOX or CAPEOX) and recommended total mesorectal excision (TME) or watch-and-wait (WW) based on clinical response. The primary outcome was OP, defined as the time from randomization to the clinical decision of TME or last follow-up, whichever occurred first. Clinical variables included: age, sex, race, tumor grade, radiation dose and treatment arm. Radiological variables (evaluated by baseline MRI prior to randomization) included: distance from the anal verge, tumor length, clinical T stage, clinical N stage, relationship to the mesorectal fascia, presence of extramural vascular invasion (EMVI) and mucinous radiographic findings (>50%). Associations of OP with clinical and radiological variables were assessed utilizing the Cox regression model in univariate and multivariate settings. The final multivariate model was chosen using backward selection. Results were analyzed by intention to treat. **Results:** Case report forms (CRFs) from baseline MRI were available for 289 of 324 randomized patients (89%). Patients with CRFs differed from those without CRFs in race, distance of the tumor from the anal verge and clinical T stage. Median follow-up was 3.4 years. A total of 156 of 324 patients were recommended TME during the study period. The 3-year OP rate was 47%. Independent predictors of OP in the multivariate analysis can be seen in the table. **Conclusions:** Although the patients included in this analysis may not be fully representative of the entire cohort, our data shows that several radiological variables associated with unfavorable tumor biology – tumor involvement of the mesorectal fascia, presence of EMVI and involved mesorectal nodes – were negatively associated with organ preservation. This information will be useful in selecting rectal cancer patients for WW and should be used for patient stratification in future clinical trials. Clinical trial information: NCT02008656. Research Sponsor: U.S. National Institutes of Health.

Genetic ancestry differences in tumor mutation in early and average-onset colorectal cancer. *First Author: Brooke Rhead, Tempus Labs, Inc., Chicago, IL*

Background: The incidence and mortality of early onset colorectal cancer (EOCRC), defined as CRC diagnosed prior to age 50, are rising, in contrast to declining rates of average onset CRC (AOCRC). Epidemiologic trends for CRC appear to differ by race/ethnicity, which could be related in part to underlying differences in tumor mutation and gene expression. Previous research has used self-reported race/ethnicity categories, which has been shown to be missing or inaccurate, particularly in highly admixed groups such as Black and Hispanic patients. Hence, we examined tumor profiles of EOCRC and AOCRC using genetic ancestry. **Methods:** Genetic ancestry was inferred from de-identified data of 1,443 and 3,315 patients with EOCRC and AOCRC, respectively, who underwent tumor profiling with the Tempus xT NGS 648-gene panel and targeted RNAseq. Ancestry informative markers were used to estimate likelihoods for the five continental groups defined in the 1000 Genomes Project: Africa (AFR), Americas (AMR), East Asia (EAS), Europe (EUR), and South Asia (SAS). We assessed the association of genetic ancestry proportions (per 10% increase in each ancestry proportion) with presence of protein altering somatic mutations in key driver genes in CRC. We also assessed interactions between onset age (EOCRC vs. AOCRC) and genetic ancestry in somatic mutations. **Results:** Across all ages, African ancestry was associated with higher odds of mutations in APC and KRAS and lower odds of BRAF mutations (Table). East Asian ancestry was associated with higher odds of mutations in NTRK3 and TP53. For EOCRC, the association between KRAS and African ancestry remained significant (OR 1.07, p=0.04). Furthermore, there was an interaction (p=0.031) between onset age and race/ethnicity such that the association between African ancestry and APC mutation was significant in AOCRC (OR=1.09) but not EOCRC (OR=1.00). **Conclusions:** The use of genetic ancestry instead of categorical race/ethnicity provides a more quantitative and precise profile of shared genetic background that can underlie biological race differences in CRC cancer etiology and outcomes. Research Sponsor: Philanthropic funding (Dedman Family Scholar in Clinical Care).

Gene	Odds Ratio	p-value AFR	p-value AMR	p-value EAS	p-value SAS
APC	1.05 (AFR)	<0.001	1.00	1.00	1.00
BRAF	0.91 (AFR)	<0.001	0.51	1.00	1.00
KRAS	1.08 (AFR)	<0.001	1.00	1.00	1.00
NTRK3	1.11 (EAS)	1.00	1.00	0.036	1.00
TP53	1.06 (EAS)	1.00	1.00	0.036	1.00

The impact of African ancestry on colorectal cancer disparity. *First Author: Yoo Jin Joung, Morehouse School of Medicine, Atlanta, GA*

Background: Colorectal cancer is the second leading cause of cancer deaths in the world to affect both men and women. Racial disparities have been known to affect the disease diagnosis and progression, and proliferative genomic studies have been undertaken to elucidate their relationship. In this study, we investigate the tumor mutation profile in colorectal adenocarcinoma (COAD) based on genetic ancestry using The Cancer Genetic Ancestry Atlas (TCGAA). **Methods:** 59 AA (African American) individuals in TCGAA COAD dataset were identified. To account for and eliminate the biases introduced by self-identification of races, we utilized TCGAA genomic analysis to accurately estimate the ancestral genomic composition of each individual. For each individual, percentages of European (EA), West African (WA), East Asian (EAA), and Native American (NA) ancestry were identified based on Local Ancestry in adMixed Populations (LAMP). Individuals were screened for dominant WA ancestry (≥50% based on LAMP) and assigned to three groups, ≥90%, 80-89%, and 50-79%. Differences in gene mutation frequency and overall survival were compared among the three subgroups of individuals with WA ancestry. **Results:** Based on genomic ancestry analysis, 58 individuals with dominant WA ancestry (Range 53%-100%) were identified. We classified them into three groups based on percentage of WA ancestry: ≥90% (n = 17), 80-89% (n = 26), and 50-79% (n = 15). *APC* was the most frequently mutated gene in all groups except ≥90% WA ancestry, which had the most mutation frequency in *TP53*. ≥90% WA ancestry showed the highest rate of mutation of 81.3% in *TP53* compared to 70.8% (80-90% WA ancestry) and 40.0% (50-79% WA ancestry). Interestingly, ≥90% WA ancestry had the highest average rate of mutation (33%) for 7 tumor suppressor genes (*AMER1, APC, ARID1, FBXW7, TCF7L2, TGFBR2,* and *TP53*), compared to 29% and 22% in 80-89% WA ancestry and 50-79% WA ancestry, respectively. In addition, ≥90% WA ancestry had a lower rate (19%) of mutation in 6 oncogenes (*BRAF, NRAS, KRAS, PIK3CA, SMAD4,* and *SOX9*) compared to 24% in both 80-89% and 50-79% WA ancestry. Although not statistically significant, a higher percentage of WA ancestry in an individual was correlated with a downward trend in the overall survival rate (median survival 56.3 months in ≥90% WA ancestry vs 61.8 months in 80-89% WA ancestry). **Conclusions:** In this study, we analyzed different gene mutations correlated with African ancestry and their potential relationship to the etiology, progression, and prognosis of COAD. The mutation profile of these genes will allow us to investigate altered pathways associated with African ancestry and draw insight into colon cancer pathogenesis in various ancestry groups. Further studies are warranted to elucidate the role of genetic ancestry in tumorigenesis and disease progression and to identify potential therapeutic targets specific to groups disproportionately affected by cancer. Research Sponsor: None.

Radical versus local surgical excision for early rectal cancer: A systematic review and meta-analysis. *First Author: Sarah El-Nakeep, Ain Shams University, Department of General Internal Medicine MD, Cairo, Egypt*

Background: Colorectal cancer is the third common cancer worldwide. Radical excision (RE) as total mesorectal excision for rectal cancer carries a higher risk of mortality and morbidity, while local excision (LE) could decrease these postoperative risks. However, the long-term oncologic outcomes of LE are still debatable. We aim to study the effect of LE versus RE in T1 and T2 rectal cancer. **Methods:** We conducted a systematic review and meta-analysis. We searched PubMed and CENTRAL databases, using an optimized search-strategy from inception until 15 June 2021, without restriction on publication date or status. We included only cohort and randomized controlled trials (RCTs). Two authors independently screened the title, abstracts, and full-text manuscripts for inclusion and data extraction. All included trials contained at least one of the primary outcomes. We used RevMan 5.4 tool for data analysis. We calculated both hazards ratio (HR) and risk ratio (RR) for the 5-years survival analyses, with their 95% confidence intervals (CI). We assessed both clinical and statistical heterogeneity of the studies; I^2 >75% was considered highly heterogeneous. We used random effect model (REM). We used standardized mean difference (SMD) for hospitalization days. We conducted a subgroup analysis of patients with T1-only without adjuvant chemo/radiotherapy (CRT). **Results:** We retrieved from the search a total of 1243 reports. A total of 18 studies were included for final meta-analysis (4 RCTs and 14 retrospective cohorts). Nine studies were multi-central while ten were unicentral studies. We did not find any difference in risk ratio (RR) between overall survival (OVS) and disease-free survival (DFS). But there were higher HRs in OVS and DFS with LE as compared to RE. A higher recurrence rate was also seen with LE. Six studies showed absent 30-days postoperative mortality in both groups so we used peto-odds ratio. Postoperative mortality and morbidity were lower with LE rather than RE. **Conclusions:** LE for early stage rectal cancer has a higher risk of decreased 5-year OVS and DFS than RE, with higher local recurrence rate. However, LE is associated with lower early postoperative mortality, morbidity, and hospitalization days, as compared to RE. Patient selection is key to balance these risks for the optimal outcome. Research Sponsor: None.

LE vs. RE meta-analysis results.

Outcome or Subgroup	Number of Studies	Number of Participants	Statistical methods	Estimate effect, 95% CI
1- OVS in 5-years	14	23717	HR	1.41 [1.14, 1.74]
2- OVS in 5-years %	15	27037	RR	0.95 [0.91, 0.99]
3- DFS in 5-years	10	2568	HR	1.95 [1.36, 2.78]
4- DFS in 5-years %	10	3541	RR	0.93 [0.87, 1.01]
5- Local recurrence rate %	13	6952	RR	2.85 [1.86, 4.36]
6- Mortality in 30-days	10	8800	Peto Odds Ratio	0.36 [0.22, 0.59]
7- Total post-operative morbidity	7	671	RR	0.38 [0.18, 0.80]

Circulating tumor DNA (ctDNA) as a minimal residual disease (MRD) assessment and recurrence risk in patients undergoing curative intent resection with or without adjuvant chemotherapy in colorectal cancer: A systematic review and meta-analysis. *First Author: Anusha Chidharla, University of Illinois at Peoria, Peoria, IL*

Background: Minimal residual disease (MRD) assessment may effectively detect cure in patients with colorectal cancer (CRC). Emerging data have suggested that circulating tumor DNA (ctDNA) can be a reliable biomarker for MRD in patients. Recent studies have shown the ability to detect MRD using ctDNA assay to assess recurrence risk and patient selection for adjuvant chemotherapy. We performed a systematic review and metanalysis of post operative ctDNA in Stage I-IV (oligometastatic) CRC patients after curative intent resection with or without adjuvant chemotherapy. **Methods:** We searched PubMed/Medline, EMBASE, Web of Science, Cochrane Library, and Google from inception to February 3, 2022 using keywords related to colorectal cancer, ctDNA, and MRD. The search also includes paper and conference presentations. The search resulted in 427 studies after removing the duplicates. Data were extracted to perform a meta-analysis using RevMan 5.4. software. Subsequent subgroup analysis was performed for stages I-III and oligometastatic stage IV CRC patients. **Results:** After the initial abstract screening, 48 studies were identified. The final review led to the inclusion of 27 studies representing 3459 patients with evaluable ctDNA, with 623 having +ve post-surgery ctDNA levels. Seven studies had analyses of patients specifically with oligometastatic disease, the rest 20 studies subdivided within stages I-III. The pooled HR for RFS in post-surgical ctDNA +ve vs -ve patients in all stages was 7.16 (95% CI 6.12-8.36) p <0.00001. Subgroup analysis revealed pooled HR = 8.27 (95% CI 6.16-11.09) and 6.07 (95% CI 4.54-8.13) for stage I-III and IV CRC, respectively. Only 11 studies did analysis for post adjuvant chemotherapy patients based on ctDNA status. The pooled HR for RFS in post-adjuvant chemotherapy ctDNA +ve versus -ve patients in all stages was 12.40 (95% CI 9.24-16.64) p <0.00001. Subgroup analysis revealed pooled HR = 13.95 (95% CI 9.08-21.43) and 11.39 (95% CI 5.99-21.66) for stage I-III and IV CRC, respectively. **Conclusions:** This is the largest and most current meta-analysis done on ctDNA levels as MRD assessment in CRC. Our analysis emphasizes that post operative ctDNA is a strong prognostic marker of RFS. Based on our results ctDNA can be a significant and independent predictor of RFS. Several ctDNA-based randomized adjuvant trials are ongoing internationally to confirm the clinical utility of ctDNA in colorectal cancer. Research Sponsor: None.

RFS by ctDNA status.

	HR (95%CI)	P value
RFS by Post-surgery ctDNA status		
All Stages	7.16 (6.12-8.36)	<0.00001
Stage I-III	8.27 (6.16-11.09)	<0.00001

Total cost of care differences in National Comprehensive Cancer Center (NCCN) concordant and non-concordant patients with colon cancer. *First Author: Ujwal Sapkota, CVS Health, Lincoln, RI*

Background: National Comprehensive Cancer Network (NCCN) colon cancer treatment guidelines have been developed to standardize and improve quality of care. While studies have shown that concordance to these guidelines improves survival, little information exists regarding the impact of concordance and total cost of care (TCOC). This study aimed to evaluate the economic impact of NCCN concordance in patients with colon cancer versus those receiving non-concordant therapies. **Methods:** This is a retrospective study of patients throughout the United States with colon cancer at a large national Medicaid, Medicare, and commercial insurer from January 1, 2019 - December 31, 2020. NCCN regimen concordance was identified from pharmacy and medical claims and defined as concordant if the entire prescribed treatment regimen matched an NCCN regimen (Level 1 and 2a); patients not receiving an NCCN recommended regimen were deemed to be non-concordant. TCOC and its cost components were contrasted on a matched population of concordant and non-concordant patients with a ratio of 2:1. To eliminate possible selection bias and differences in baseline characteristics that could affect cost, propensity scores were developed using logistic regression and used to match patients on age, comorbidity, socioeconomic status (SES) index and treatment type (chemotherapy and radiation). **Results:** A total of 937 patients with colon cancer were included (Medicare n = 588; commercial fully insured n = 149; commercial self-insured n = 200). Beginning with and including the first treatment and for up to 180 days after, the TCOC in the concordant group was significantly less among Medicare patients; a reduction of 33% (a difference of $2,986, p < 0.001) in TCOC per member per month (PMPM) was observed. This cost difference was driven primarily by medical chemotherapy spend as concordant patients spent 26% less (a difference of $1,160, p < 0.001). Concordant patients spent 29% less PMPM than non-concordant patients (a difference of $35, p < 0.001) on Evaluation and Management compared to non-concordant patients. There were no significant differences in Inpatient, Emergency Room and Radiation Oncology costs among all patients (p > 0.05). No significant differences were seen in TCOC among commercial fully insured (a difference of $69, p = 0.99) and commercial self-insured (a difference of $5,413, p = 0.07) patients, likely due to smaller sample sizes. **Conclusions:** In this study, Medicare patients who received NCCN concordant colon cancer regimens spent significantly less in TCOC than patients receiving non-concordant regimens. These savings highlight the importance of evidence-based guidelines in treatment determinations to optimize the value of cancer care. More extensive studies are needed to assess if these findings translate to commercially insured patients and the long-term economic impact of concordance. Research Sponsor: None.

The differential response to immune checkpoint inhibitors in colorectal and endometrial cancer patients according to different mismatch repair alterations. *First Author: Moh'd M. Khushman, Department of Hematology-Oncology, University of Alabama at Birmingham/O'Neal Comprehensive Cancer Center, Birmingham, AL*

Background: In colorectal cancer (CRC) and endometrial cancer (EC) patients (pts), preliminary data suggest a differential response to immune checkpoint inhibitors (ICIs) according to different MMR alterations. The drivers of this difference remain unknown and no reliable predictive biomarker has been found. We explored the genomic alterations, tumor mutation burden (TMB), immune-related gene expressions and signatures, tumor microenvironment (TME), neoantigen load and median overall survival (mOS) inCRC and EC pts treated with ICIs with different MMR alterations. **Methods:** 13,701 CRC and 3,315 EC specimens were tested at Caris Life Sciences (Phoenix, AZ) with Next Gen Sequencing (NGS) of DNA (592-gene or whole exome) and RNA (whole transcriptome). MMR/MSI status was determined by IHC of MMR protein and/or NGS. Immune cell abundance was quantified using quanTIseq. Gene expression profiles were analyzed for T cell-inflamed signature (TIS) and IFN-gamma scores. Immune epitope prediction was performed using the NetMHCpan v4.0 method in the Immune Epitope Database. Real-world mOS was obtained from insurance claims data and calculated from tissue collection or ICIs start to last contact. Statistical significance was determined using chi-square/Fisher-Exact and adjusted for multiple comparisons (adjusted $p < 0.05$). **Results:** In CRC, 84 (0.6%) pts had intact expression of MLH1 and PMS2 and co-loss of MSH2 and MSH6 (MutS) and 648 (4.7%) had co-loss of MLH1 and PMS2 and intact MSH2 and MSH6 (MutL). 117 (0.9%) had other MMR IHC loss. APC, KRAS, ERBB2, ERBB3 and MSH2 mutations rates were higher in MutS while BRAF mutation rate was higher in MutL. B cell, NK cell content and neoantigen load (high affinity epitopes: $p < 0.05$, intermediate: $p < 0.01$, low: $p < 0.001$) were higher in MutS. The mOS in MutS (N = 149) vs. MutL (N = 980) was 56 months (m) vs. 36 m ($p = 0.003$). In ICI-treated pts, the mOS in MutS (N = 28) vs. MutL (N = 149) was not reached (NR) vs. 32 m ($p = 0.005$). BRAF mutation didn't impact survival in MutL. In EC, 48 (1.4%) pts had MutS and 915 (27.6%) had MutL. 81 (2.4%) had other MMR IHC loss. IHC-PD-L1, TMB, neoantigen load (high affinity epitopes: $p < 0.01$, intermediate: $p < 0.0001$, low: $p < 0.0001$), TIS, IFN-gamma scores, immune related gene expressions, TME (Macrophage M1, CD8+) were higher in MutS. The mOS in MutS (N = 94) vs. MutL (N = 1804) was NR vs. 47 m ($p < 0.001$). In ICI-treated pts, the mOS in MutS (N = 11) vs. MutL (N = 273) was NR vs. NR ($p = 0.559$). **Conclusions:** This is the largest study to explore differential response to ICIs in CRC and EC pts with different MMR alterations. In pts with CRC and EC, the mOS was longer in MutS compared to MutL. In ICI-treated pts, the mOS was longer in MutS compared to MutL in CRC but not in EC. Among the explored biomarkers, neoantigen load was higher in MutS compared to MutL in both CRC and EC and maybe the driving factor for differential response to ICIs. Research Sponsor: None.

Impact of the COVID-19 pandemic on colorectal cancer (CRC) care: Data from 22 German cancer centers (CC) and the Institute of Pathology, Ruhr-University Bochum - the AIO (Working Group for Internal Oncology of the German Cancer Society) CancerCOVID Consortium - AIO-YMO/KRK 520/ass. *First Author: Celine Lugnier, Department of Hematology, Oncology and Palliative Care, St. Josef-Hospital, Ruhr-University Bochum, Bochum, Germany*

Background: CRC still is one of the leading causes of cancer related death though prognosis has improved through guideline based management. The COVID-19 pandemic lead to re-allocation of resources subordinating all sections of care for CRC patients. We present data on changes of CRC care during the pandemic from 22 German AIO CC and our high volume Institute of Pathology (pathology). **Methods:** Data was collected retrospectively comparing the months (mo) of the first wave (fw) (4-6/2020) and second wave (sw) (11-12/2020) of the pandemic with corresponding periods (cp) in 2019 focusing on the number of precancerous (ICD-O/0+2) and malignant (ICD-O/3+6) colorectal lesions (CRL) diagnosed by our pathology, the number/stage of primary diagnoses (PD) and the number of surgeries (surg) at AIO CC. There, quality criteria of CRC care were also assessed (number of PD discussed within a multidisciplinary tumor board (tb), received social service (soc)/ psychological (psy) counseling or recruited into a clinical trial). Statistical analysis was performed using students t-test for paired data. **Results:** Numbers of CRL detected upon histology (row 1-3), number of cases, surg and quality criteria from AIO CC (row 4-9) are displayed in the table. We saw a dip in diagnosed CRL and number of surg ($p=0.007$) only during fw, whereas PD dipped significantly in both waves. A significant reduction in diagnosis of stage III CRC was detected for 2019 vs. 2020 ($p=0.001$), not for other stages. Quality criteria showed a significant reduction in clinical trial inclusion, a small dip in soc/psy counseling and persistently high tb presentation. **Conclusions:** We detected a significant decrease of premalignant lesions and primary cancers during the first year of the pandemic which may impact cancer mortality in the future. Certified German CC provided CRC care with significant reduction in clinical trial inclusion only, suggesting high stability of established certified cancer care infrastructure. Research Sponsor: Bundesministerium fuer Bildung und Forschung.

Validation of a multi-modal blood-based test for the detection of colorectal cancer with sub single molecule sensitivity. *First Author: Kevin D'Auria, Guardant Health, Redwood City, CA*

Background: Blood-based colorectal cancer (CRC) screening tests can improve adherence to screening guidelines. Yet, current commercially available options have poor sensitivity and specificity inhibiting incorporation into routine clinical care. Here we report the validation of a blood-based test for the detection of colorectal cancer and advanced neoplasia. **Methods:** This blood-based test aims to detect colorectal neoplasia by identifying tumor-associated biomarkers including genomic or epigenomic (methylation and fragmentomics) signatures in cell-free DNA (cfDNA). cfDNA is partitioned based on methylation level, enriched for informative genomic regions, and sequenced. This novel workflow enables high-fidelity analysis of multimodal information in majority of extracted cfDNA molecules. Results are integrated into a binary "detected" versus "not-detected" result using a proprietary bioinformatic pipeline (Guardant Health, USA). The assay was trained on samples obtained from >6,000 unique individuals (2,685 cancer-free and 1,698 with advanced colorectal neoplasia (ACN) for training, 1,072 cancer-free and 551 with ACN for threshold setting). The thresholds were frozen prior to validation targeting a specificity of > 91.5%. Each aspect of the validation study followed Nex-StoCT CLIA working group and CLSI guidelines. **Results:** Limit of detection (LoD) was established across six dilutions. Even for low cfDNA mass inputs of less than 4ng, the 95% LoD was determined to be less than 1 tumor-derived genomic equivalent (0.5), indicating over at least 10-fold increase in assay sensitivity compared to best-in-class assays for somatic mutation detection. Precision studies in 60 positive and negative replicates from clinical samples yielded >90% average positive and negative percent agreement both within and between batches. Endogenous interference studies yielded > 90% positive and negative percent agreement between reference control and common endogenous substances, including albumin, bilirubin, hemoglobin, triglycerides, and genomic DNA, in clinical positive and negative samples and minimally manipulated samples. The clinical validation of the test was conducted in > 300 cases (biobanked pre-operative cohort for CRC cases and screening cohort for advanced adenoma and negative cases). **Conclusions:** Here we present the validation of a multi-modal blood-based test for the detection of colorectal cancer. This test is currently being evaluated in a registrational study (ECLIPSE: NCT04136002). Research Sponsor: Guardant Health.

Disproportionate morbidity and mortality in African American and Asian patients from colorectal cancer: A nationwide analysis. *First Author: Jorge Franco, Universidad Latina, San José, Costa Rica*

Background: Published literature points towards the disproportionate prevalence of colorectal cancer (CRC) in ethnic groups. Racial minorities are also prone to higher mortality due to inequalities in access to healthcare. Therefore, we examined the disparities in hospital-related outcomes among racial groups from CRC. **Methods:** We investigated the National Inpatient Sample 2019 employing International Classification of Diseases-10 (ICD-10) codes to include adult patients with CRC. We compared various outcomes stratified by racial groups with White as the reference group. Analyses were performed using STATA (v 14.2), considering 2 sided *P*< 0.05 as statistically significant. Proportions were compared using Fisher exact test and continuous variables using Student's t-test. Confounding variables were adjusted using multivariate logistic and linear regression analyses and included: gender, Charlson Comorbidity Index, median household income for patients' zip codes, hospital location/region/bedside, and insurance status. **Results:** Out of 732,492 included patients, 72.77% White, 13.66% African American (AA), 9.91% Hispanics, and 3.65% Asians were in the cohort. AA and Asians had higher mortality odds than White, while Hispanics had mortality similar to White. AA had a lower mean length of stay by 0.74 days than White. All racial groups incurred higher mean total charges compared to White. AA and Hispanics had lower odds of undergoing colectomy. Overall, all racial groups had high morbidity compared to White. Among subgroups, the odds of morbidity markers (sepsis, lower GI bleed, and acute renal failure) were higher in AA and Asians than Hispanics. Post-op adhesions and DVT/PE were not significantly different among racial groups. **Conclusions:** AA and Asians disproportionately suffer from higher mortality from colorectal cancer than Hispanics and White. Lower colectomy rates (a definitive CRC treatment) in AA and higher in-hospital complication burden in Asians are possible explanations; however, further research needs to establish if race-specific genomics are also responsible for disparities. Outcomes of appendiceal cancer treated at a state peritonectomy service.

First Author: Madeleine Cornelia Strach, Department of Medical Oncology, Chris O'Brien Lifehouse, Sydney, Australia

Background: Appendiceal cancers (AC) are rare with varied prognosis. Nomenclature refined by the WHO 2019 classification is: appendiceal mucinous neoplasms (AMNs), adenocarcinomas (AA) including mucinous (MAC), not otherwise specified (ANOS), signet ring (SRC) and goblet cell (GCA), and neuroendocrine tumours (NET). Cytoreductive surgery and heated intraperitoneal chemotherapy (CRS+HIPEC) is the definitive treatment. The role of chemotherapy remains unclear with conflicting outcomes and there is need to delineate the optimal regimen in different disease settings. The aim of this study was to evaluate AC treatment and clinical outcomes by the WHO 2019 classification and analyse the impact of perioperative chemotherapy. **Methods:** We reviewed prospective data from the database at an Australian state peritonectomy service, Apr 2017-Dec 2021. Variables included demographics, tumour characteristics, treatment details and survival outcomes. Analysis was by the Kaplan-Meier method using the log-rank test for statistical comparison (SPSSv27). **Results:** 115 patients (of 207 referred) with confirmed AC proceeded to CRS. Histopathology comprised 49 AMNs (43%), 62 (63%) AA, 3 SRCs and 1 NET. The mean age was 56y (21-78), 53% female. 94% had CRS+HIPEC (Mitomycin 85%). 70% had cytoreductive score 0. The median peritoneal cancer index was 23 (0-39). 20 (17%) had localised (M0) disease, 10 acellular mucin (M1a) and 85 (74%) metastases (M1b/c). 71% were lymph node negative (N0). 40% had chemotherapy (oxaliplatin/5-fluorouracil 57%). 8 of 15 who had molecular testing had a KRAS mutation. Median follow-up was 26m (1.9-167). The table shows univariate survival analysis. **Conclusions:** This is the first study evaluating outcomes of perioperative chemotherapy for AC in a cohort of patients since the WHO 2019 classification. MAC have worse survival compared to ANOS, but similar to GCAs. Peritoneal acellular mucin has a similarly improved prognosis to patients with no peritoneal disease compared to those with cellular disease. Chemotherapy demonstrated worse survival compared to no chemotherapy, also seen in the literature and likely influenced by selection of more aggressive disease. There is a need to develop biomarkers and better treatments to improve the survival of these patients. Further multivariate analysis for prognostic and predictive factors is planned. Research Sponsor: None.

CoRInTH: A phase Ib/II trial of checkpoint inhibitor, pembrolizumab (PD-1 antibody [Ab]) plus standard intensity modulated chemoradiotherapy (IMCRT) in HPV-induced stage III squamous cell carcinoma (SCC) of the anus.

First Author: Marcia Hall, Mount Vernon Cancer Centre, Northwood, United Kingdom

Background: SCC of anus (SCCA) are considered rare tumours, but the incidence is increasing. Only 65% patients with later stage T3/T4 +/-N1 SCCA remain disease free at 3 years (Gunderson 2013, James 2013). The cytotoxicity of IMCRT enhances tumour antigen presentation and promotes cytokine release as well as enhancing the MHC (Demaria 2004, Reits 2006). Immune therapy, against PD-1, have been approved for patients with SCC arising from other primary sites eg. head and neck, lung cancer. The addition of such checkpoint inhibitors might also result in improved PFS and OS for higher risk SCCA patients. **Methods:** A multicentre, single arm, open-label, non-randomised study to evaluate the safety and tolerability of different schedules of exposure to pembrolizumab (P) with standard IMCRT in 50 patients with locally advanced T3/4 anal cancer. The first cohort of 6 patients commenced standard IMCRT and received P 200mg every 21d beginning at Week 5 day 1 of the IMCRT schedule. If this is considered safe and tolerable with not more than 3/6 SAEs within first 6 weeks after completion IMCRT, a second cohort of 6 patients will be recruited where P is introduced on Week 1 Day 1 with standard IMCRT. Pembrolizumab monotherapy will be continued for a total of 6 months. Primary endpoint is safety and tolerability by assessing AEs and protocol adherence. Secondary endpoints include feasibility, clinical response assessment by RECIST (MRI) for ORR at 3, 6 and 12 months, imaging response assessments by TRG MRI using changes in Apparent Diffusion Coefficient (ADC) on diffusion weighted sequences and patient reported outcomes, using EORTC quality of life questionnaires. Patients are being asked to contribute to translational endpoints with the donation of tissue and blood samples. Eligible patients will have Stage IIIA/B (T3/4, any N, M0) SCCA, performance status 0 or 1 and be suitable for IMCRT. Patents with anal tumours of non-epithelial origin, metastatic disease or a diagnosis of immunodeficiency are excluded. Single phase IMRT with a simultaneous integrated boost to achieve 53.2Gy in 28 fractions over 5.5 weeks to PTV_A, according to the UK consensus is mandated. Concomitant chemotherapy can either be cisplatin 60mg/m2/ or mitomycin 12mg/m2 with either 5FU 1000mg/m2 or capecitabine 825mg/m2 at investigator discretion. The first cohort has completed recruitment with Safety Review Committee / IDMC review planned for April 2022. Patients will then be sought to start P on Week 1 Day 1 with IMCRT. Further safety review will be undertaken following the first 6 patients entered into the second cohort but recruitment will continue in an expansion phase to a maximum of 44 patients. Clinical trial information: NCT04046133. Research Sponsor: Merck Shard & Dohme (UK) Limited.

TPS3631 **Poster Session**

Five- or 10-year colonoscopy for 1-2 non-advanced adenomatous polyps (FORTE) NRG-CC005 study: A randomized phase III non-inferiority trial comparing colorectal cancer incidence in participants with 1-2 non-advanced adenomas randomized to a 5- and 10-year surveillance colonoscopy exam schedule versus a 10-year surveillance colonoscopy exam schedule.

First Author: Robert E Schoen, University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Adenomatous polyps are the acknowledged precursors of colorectal cancer (CRC). Identification and removal of adenomas is the mechanism by which screening is effective in reducing CRC incidence and mortality. Patients with 1-2 non-advanced adenomas (< 1 cm with neither villous components nor high grade dysplasia) are recommended to return at a timing ranging from 5-10 yrs. However, evidence for the benefit, optimal timing, and recommended frequency of surveillance colonoscopy is not available. A randomized, clinical trial to demonstrate the difference in results between 5- or 10-yr surveillance for participants with non-advanced adenoma can guide clinical practice. **Methods:** NRG-CC005/FORTE is a prospective, randomized, non-blinded, Phase III, non-inferiority clinical trial comparing CRC incidence in participants randomized to recommendation for a 5- and 10-yr vs. a 10-yr only surveillance colonoscopy exam schedule. Other pre-defined exploratory endpoints include incidence of advanced adenomas, CRC mortality, and incidence of stage III-IV CRCs. Stratification factors include age, gender, and time from qualifying colonoscopy to randomization. Participants ≥50 and < 70 yrs of age at the time of randomization with a first-time diagnosis of 1-2 non-advanced tubular adenomas from the qualifying colonoscopy within 4 yrs prior to randomization will be eligible. Participants with a clinical diagnosis of a significant genetic risk for CRC or with a family history of CRC diagnosed at ≤60 yrs in a first degree relative or in two first degree relatives diagnosed at any age are ineligible. Other ineligibility criteria include prior history of CRC or colorectal adenomas, a hyperplastic polyp measuring ≥1 cm or traditional serrated adenomas, or life expectancy < 10 yrs due to comorbid conditions. Collection of blood, stool, and tissue samples is planned. Statistics: The primary endpoint for the trial is CRC incidence. The trial is focused on CRCs diagnosed between year 5 and year 10. By incorporating a window of +/- 1 yr to allow for somewhat earlier and later procedures, as typically occurs in clinical medicine, the primary endpoint will include incident cancers identified in years 4 through 11. A crude 4- to 11-yr incidence rate of 0.387% is assumed for the 5- and 10-yr schedule arm. The study is powered at 90% to detect a non-inferiority margin difference of 0.387% at alpha 5% in CRC incidence rate between two schedules. 9,500 participants are to be enrolled. Support: U10CA180868, -180822, UG1CA189867, U24CA196067 Clinical trial information: NCT05080673. Research Sponsor: U.S. National Institutes of Health.

NSAB C-14: CORRECT-MRD II—Second colorectal cancer clinical validation study to predict recurrence using a circulating tumor DNA assay to detect minimal residual disease.

First Author: Mohamed E. Salem, Levine Cancer Institute, Atrium Health, Charlotte, NC

Background: Patients (pts) with stage II and III colon cancer (CC) have unique post-operative decisions regarding adjuvant chemotherapy (ACT). There is a subset of stage II pts with defined clinicopathologic features associated with poor prognosis who may benefit from ACT, although more discriminating and objective predictors of benefit are needed. In addition, there may be a subset of Stage III CC pts who could tolerate a de-escalation of ACT or who may require intensification of ACT to improve clinical outcome. Detectable ctDNA after resection of early-stage solid tumors has been associated with very high risk of recurrence, suggesting ctDNA is evidence of minimal residual disease (MRD). Several studies are ongoing to investigate the role of ctDNA in the optimal management of pts with CC using different assay technologies. **Methods:** This is a prospective, observational, multicenter study in the United States and Canada of 750 pts who have undergone complete surgical resection for stage II or III CC, have FFPE tissue available from the primary resection sufficient for a novel bespoke MRD assay, and are willing to provide serial whole blood specimens for ctDNA analysis. Subjects are asked to provide study specimens at baseline, pre-recurrence follow-up, and clinical recurrence (if applicable) study visits. ctDNA will be analyzed with an NGS-based MRD assay that identifies somatic genetic alterations from DNA derived from the pt's tumor tissue, subtracts germline variants, and detects a subset of these tumor-specific (bespoke) ctDNA in the pt's blood. The primary objective is to validate the association of post-definitive therapy and pre-recurrence follow-up ctDNA positivity with recurrence-free interval (RFI). Further objectives are to assess the: sensitivity and specificity of ctDNA positivity for subsequent clinical recurrence; contribution of post-surgery baseline, post-adjuvant therapy, and pre-recurrence follow-up ctDNA results on RFI; time from positive ctDNA to clinical recurrence in subjects who had a positive ctDNA result; and compare the Oncotype Colon Recurrence Score estimate of 3 yr recurrence risk with the observed 3 yr recurrence rate. The primary analysis will use a Cox proportional hazards regression applied to the RFI with ctDNA result (positive or negative) measured at post-surgical baseline (or end of ACT if ACT was used) and serially after that as a single, time-dependent covariate. Protocol: 16-002/NSABP C-14. Support: NSABP Foundation. Clinical trial information: 05210283. Research Sponsor: Exact Sciences, Other Foundation.

TPS3633 **Poster Session**

A biomarker enrichment trial of anti-EGFR agents in right primary tumor location (rPTL), *RAS* wild-type (*RAS*-wt) advanced colorectal cancer (aCRC): ARIEL (ISRCTN11061442). *First Author: Christopher Williams, Leeds Cancer Centre, Leeds, United Kingdom*

Background: Meta-analysis of 6 RCTs indicates that anti-EGFR agents are ineffective in rPTL *RAS*-wt aCRC (Arnold D, et al. *Ann Oncol.* 2017;28:1713-1729). However, data from the phase III PICCOLO and COIN trials suggest high tumor expression of the EGFR ligands, EREG and AREG, confers sensitivity to anti-EGFR agents in a subset of this population (Adams RA, et al. *J Clin Oncol.* 2012;30(30_suppl):32-32; Seligmann JF, et al. *Ann Oncol.* 2020;31:1021-1029). More data is needed before ligand assessment can be integrated into routine care: to date, *EREG/AREG* mRNA has only been assessed retrospectively, and feasibility of timely delivery of results must be demonstrated. The ARIEL trial aims to determine whether first-line chemotherapy plus cetuximab or panitumumab is more effective than chemotherapy alone in achieving early tumor shrinkage (ETS) after 8 weeks of treatment in patients (pts) with *EREG/AREG*-high rPTL *RAS*-wt aCRC. **Methods:** ARIEL is a multicentre, phase IV, open label, biomarker enrichment RCT. Pts with previously untreated rPTL *RAS*-wt (or *RAS*-unknown) aCRC are eligible for registration and *EREG/AREG* assessment using archival FFPE tumor tissue. Those confirmed as *RAS*-wt *EREG/AREG*-high (expression above 30th centile based on PICCOLO)[3] are eligible for randomization to chemotherapy alone (fluoropyrimidine backbone plus irinotecan or oxaliplatin) *vs* chemotherapy (FOLFOX or FOLFIRI) plus anti-EGFR therapy (panitumumab or cetuximab) (options at physician's discretion). Pts with *EREG/AREG*-low tumors are not eligible for randomization but may consent to translational research and follow-up. The primary endpoint is ETS at 8 weeks (≥30%, yes *vs* no). Secondary endpoints are depth of response at 16 weeks, overall survival, overall treatment utility, pt-reported quality of life, cost per QALY, pt acceptability of trial procedures, and safety. Pre-trial work-up included cross-validation of the *EREG/AREG* RT-qPCR assay at trial laboratories in Leeds and Birmingham, UK demonstrating reproducibility of biomarker results. Recruitment to an internal pilot phase is currently ongoing to demonstrate feasibility of timely delivery of biomarker results to sites (lower limit of 90% CI of mean result delivery time for first 20 pts must include 3 weeks). Mean monthly recruitment rate will be assessed at 18 months to determine likelihood of completion of the trial within the 3 year recruitment period. ARIEL is funded by the UK National Institute for Health Research (NIHR) and opened the first of 40 sites in February 2022. 440 pts will be registered for biomarker assessment in order to randomize 162 pts. All pts will be followed-up to 1 year post-randomisation, with a final assessment in all pts when the last pt has completed a year of follow-up (median 3.5 years). ARIEL is participating in the NIHR Associate PI scheme. Clinical trial information: 11061442. Research Sponsor: National Institute for Health Research, United Kingdom.

TPS3634 **Poster Session**

SEAMARK: Randomized phase 2 study of pembrolizumab + encorafenib + cetuximab versus pembrolizumab alone for first-line treatment of *BRAF* V600E-mutant and microsatellite instability-high (MSI-H)/mismatch repair deficient (dMMR) metastatic colorectal cancer (CRC). *First Author: Scott Kopetz, MD Anderson Cancer Center, Houston, TX*

Background: Among patients with MSI-H/dMMR CRC, *BRAF* mutations occur in approximately 30%. MSI-H/dMMR and *BRAF* mutations are both associated with poor prognosis; in patients who have both biomarkers, poor prognosis is thought to be driven by the *BRAF* mutation. Pembrolizumab is indicated for the treatment of patients with MSI-H/dMMR unresectable or metastatic CRC (mCRC). The BRAF inhibitor encorafenib, in combination with cetuximab, is indicated for previously treated patients with *BRAF* V600E-mutant mCRC. Currently, there are no first-line treatment options indicated specifically for patients with both MSI-H/dMMR and *BRAF* V600E-mutant mCRC. To assess the safety and efficacy of combining pembrolizumab with encorafenib + cetuximab, the SEAMARK study (NCT05217446) will evaluate this combination vs pembrolizumab alone in patients with previously untreated *BRAF* V600E-mutant MSI-H/dMMR mCRC. **Methods:** SEAMARK is an open-label, multicenter, randomized, phase 2 study. Approximately 104 patients (randomized 1:1; stratified by Eastern Cooperative Oncology Group Performance Status [ECOG PS] 0 vs 1) will receive either pembrolizumab + encorafenib + cetuximab or pembrolizumab. Enrolled patients must be aged ≥16 or ≥18 years (per country-specific regulations) and have previously untreated *BRAF* V600E-mutant MSI-H/dMMR mCRC; measurable disease (Response Evaluation Criteria in Solid Tumors v1.1); ECOG PS 0 or 1; and adequate bone marrow, hepatic, and renal function. Patients who received prior treatment with BRAF/EGFR inhibitors or immune checkpoint inhibitors, or who have brain metastases (unless radiologically stable) or *RAS* mutation (or unknown *RAS* status), will be excluded. The primary endpoint is investigator-assessed progression-free survival. Secondary endpoints include safety and tolerability, overall survival, objective response rate, duration of response, and quality of life. Enrollment will begin in April 2022. Clinical trial information: NCT05217446. Research Sponsor: Pfizer.

TPS3635 **Poster Session**

Phase 2/3, randomized, open-label study of an individualized neoantigen vaccine (self-amplifying mRNA and adenoviral vectors) plus immune checkpoint blockade as maintenance for patients with newly diagnosed metastatic colorectal cancer (GRANITE). *First Author: J. Randolph Hecht, David Geffen School of Medicine at UCLA, Santa Monica, Los Angeles, CA*

Background: Treatment options for most patients with metastatic colorectal cancer (mCRC) are largely limited to cytotoxic chemotherapy, with little advancement in the last decade. Encouragingly, a small subset of patients deficient in mismatch repair (dMMR/MSI-hi) benefit from checkpoint inhibitors (CPI) whereas those proficient in mismatch repair (pMMR/MSS) do not. The absence of clinical benefit in patients with pMMR/MSS mCRC may relate to a lack of neoantigen-specific T cells and immune infiltration. An individualized neoantigen vaccine that induces CD8 T cells capable of tumor lysis has the potential to expand the number of patients with mCRC who may benefit from immunotherapy. Data from a Phase 1/2 study evaluating neoantigen vaccines in combination with CPIs in patients with previously treated mCRC demonstrated a 44% molecular response (MR) rate (≥50% decrease in ctDNA relative to baseline) in 4/9 patients; this correlated with improvement in OS relative to those without a MR. To further investigate neoantigen vaccines in earlier lines of treatment, a Phase 2/3 study in the1L maintenance setting in mCRC was initiated. **Methods:** GO-010 is a Phase 2/3, randomized, open-label, multi-center study evaluating the efficacy and safety of 2 neoantigen-containing vectors (GRT-C901-adenoviral vector plus GRT-R902-self-amplifying mRNA vector) as prime/boost in combination with CPIs as an add-on to fluoropyrimidine/bevacizumab (bev) following 1L therapy with FOLFOX/bev in patients with mCRC. During Phase 2, up to 90 patients will be randomized 1:1 to the vaccine or control arm with a primary objective of assessing efficacy by MR. During Phase 3, up to 226 patients will be randomized with a primary objective of assessing PFS per iRECIST in a blinded, independent manner. There are two stages to the study. In the vaccine production stage, while patients receive FOLFOX/bev 1L therapy, neoantigen prediction is performed using a tumor biopsy and Gritstone's EDGE™ neoantigen prediction model. For patients in the vaccine arm the top 20 predicted neoantigens are included in the vaccine vectors. After completing oxaliplatin, patients will enter the study treatment stage. Patients in the control arm will continue with maintenance therapy whereas patients in the vaccine arm will add the vaccine regimen to maintenance therapy. The vaccine regimen consists of GRT-C901/GRT-R902 as well as SC ipilimumab (30 mg) and IV atezolizumab (1680 mg). Over the first year of treatment, 6 vaccinations will occur. Ipilimumab will be administered SC with the first doses of GRT-C901 and GRT-R902. Atezolizumab will be administered every 4 weeks for up to 2 years. Study assessments include imaging, ctDNA, safety, immunogenicity and exploratory biomarker analysis. Clinical trial information: NCT05141721. Research Sponsor: Gritstone bio.

TPS3636 **Poster Session**

Phase III study to compare bevacizumab or cetuximab plus FOLFIRI in patients with advanced colorectal cancer RAS/BRAF wild type (wt) on tumor tissue and RAS mutated (mut) in liquid biopsy: LIBImAb Study. *First Author: Angela Damato, Medical Oncology Unit, Azienda USL-IRCCS Reggio Emilia, Reggio Emilia, Italy*

Background: KRAS, NRAS, and BRAF mutations are well-established negative predictive biomarkers of response to anti-EGFR monoclonal antibodies (MoAbs) in metastatic colorectal cancer (mCRC) patients (pts). In clinical practice, RAS/BRAF wild-type (wt) patients receive first-line therapy regimens containing anti-EGFR agents. However, tumor heterogeneity might drive primary and acquired resistance to anti-EGFR MoAbs. In fact, circulating tumor DNA (ctDNA) testing reveals RAS/BRAF mutations in approximately 10% of pts who resulted in wt at tumor tissue. In addition, 30% to 50% RAS wt pts develop, during the treatment with anti-EGFR MoAbs, RAS mut can be detected in the ctDNA several weeks before clinical progression. As today, it is not known whether revealing RAS mut in liquid biopsy (LB) earlier than the appearance of a clinical/radiological disease progression, could impact pts' outcomes. Similarly, there are no data suggesting the best therapeutic approach in patients with RAS/BRAF wt tissue and mutated ctDNA. **Methods:** This is a phase III, randomized, open-label, comparative, multicenter study to assess the superiority of Bevacizumab (BEV) compared to Cetuximab (CET) plus FOLFIRI in treatment naïve mCRC RAS/BRAF wt on tumor tissue (TT) and mutated in plasma samples. RAS/BRAF wt pts on TT will undergo the first LB, and RAS mut pts will be randomized 1:1 to receive FOLFIRI/CET (control arm) or FOLFIRI/BEV (experimental arm). Instead, RAS wt pts at first LB will be treated with FOLFIRI/CET up to 8 cycles. Pts who have not progressed after 8 cycles of treatment will undergo a second LB. If RAS mut was detected, pts will be randomized 1:1 to continue FOLFIRI/CET or switch to FOLFIRI/BEV. If not, pts will continue FOLFIRI/CET outside the clinical trial. Pts will be treated until disease progression, unacceptable toxicity, or withdrawal of consent. Among 26 pts screened at the first LB, actually 1 KRAS mut and 1 BRAF mut pts were detected. The primary endpoint is the PFS Plasma samples will be analyzed for KRAS, NRAS, and BRAF mutations by Idylla ctKRAS and Idylla ctNRAS-BRAF-EGFGR. All samples will be also analyzed by NGS, in order to better evaluate the correlation of tumor heterogeneity with pts' outcomes. Clinical trial information: EudraCT Number: 2020-005078-82, NCT04776655. Research Sponsor: Agenzia Italiana del Farmaco/Italian Drug Agency (AIFA) Independent Research Fund 2018.

TPS3637 **Poster Session**

A multi-arm, phase 2, open-label study to assess the efficacy of RXC004 as monotherapy and in combination with nivolumab in patients with ring finger protein 43 (RNF43) or R-spondin (RSPO) aberrated, metastatic, microsatellite stable colorectal cancer following standard treatments. *First Author: Scott Kopetz, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: The Wnt pathway is a critical driver of cancer. RXC004 is a potent, selective, orally active inhibitor of the key Wnt pathway regulator, Porcupine. Inhibition of Porcupine blocks the release of all Wnt ligands from cells, preventing both tumour growth and tumour immune evasion. Wnt pathway alterations, including loss-of-function (LoF) RNF43 mutations and RSPO gene fusions, increase expression of the Wnt receptor Frizzled (Fzd) on the tumour cell surface, driving Wnt-ligand signalling. These alterations are present in ~8% (Gao, 2013; Cerami, 2012; Shesagiri, 2012; Shinmura, 2014; Kleeman, 2019) of colorectal cancers (CRC). LoF RNF43 mutations are associated with poor prognosis in MSS CRC (Yaeger, 2018*)*. Preclinical genetically selected CRC models showed disease stabilisation, differentiation towards a normal colonic phenotype with increased mucin secretion, and reduced metabolic activity on FDG-PET. In a Phase 1 study in patients with advanced solid tumours (NCT03447470), RXC004 was safe and tolerated at doses up to 2mg QD, the recommended phase 2 dose (RP2D), and showed a differentiated efficacy signal in Wnt-ligand dependent tumours (Cook, 2021*)*. **Methods:** The PORCUPINE (NCT04907539) trial is a 2-arm Phase 2 trial of RXC004 monotherapy (Arm A) and RXC004 in combination with nivolumab (Arm B). 20 evaluable patients will be enrolled into each Arm. The study initially opened with Arm A; Arm B will be opened once the RP2D for RXC004 in combination with nivolumab is established in a separate phase 1 study. Once Arm B is opened, patients in Arm A may be treated with RXC004 + nivolumab if they have progressive disease on the first RECIST assessment scan. To be eligible for this study, patients must have metastatic microsatellite stable (MSS) CRC that has progressed following standard therapies. Tumours must have a LoF RNF43 mutation, or an RSPO2/3 fusion. As Wnt inhibition can affect bone metabolism, patients undergo a screening DEXA scan and receive prophylactic denosumab throughout the treatment period. The primary endpoint for Arm A is the disease control rate (DCR= CR+PR+SD at 16 wks), and for Arm B is objective response rate (ORR). Secondary endpoints are Safety and PK. Exploratory endpoints include FDG-PET changes and on-treatment changes in protein and gene expression in tumour biopsies. For Arm A, a target value (TV) of 60% DCR is considered a clinically significant improvement over standard of care against a lower reference value (LRV) of 40% DCR (Grothey, 2013; Mayer, 2015*)*. For Arm B, a TV of 30% ORR is considered clinically significant against a LRV of 10% ORR (Eng, 201*9)*. RXC004 is also being investigated in a second Phase 2 trial, PORCUPINE 2 (NCT04907851), in Biliary Tract Cancers and RNF-43 mutated Pancreatic Cancers. Clinical trial information: NCT04907539. Research Sponsor: Redx Pharma.

TPS3638 **Poster Session**

STOPTRAFFIC-1: A phase I/II trial of SX-682 in combination with nivolumab for refractory *RAS*-mutated microsatellite stable (MSS) metastatic colorectal cancer (mCRC). *First Author: Benny Johnson, Department of Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Refractory RAS mutated MSS mCRC represents a critical unmet need with minimal response to immune checkpoint blockade (ICB). Preclinical CRC models reveal that *KRAS* mutations activate the CXCR2 axis promoting an immunosuppressive tumor microenvironment (TME). This occurs via KRAS repression of interferon regulatory factor 2 (IRF2) resulting in upregulation of CXCL3 chemokines, which bind CXCR2 and recruit myeloid-derived suppressor cells (MDSC; Liao et al, Cancer Cell 2019; Grover et al, Cancer Discovery, 2022). SX-682 is a novel oral small-molecule inhibitor of the CXCR1/2 chemokine receptors involved in MDSC-recruitment to the TME. This proof-of-concept study investigates whether de novo immunotherapy resistance in MSS *RAS* mutated mCRC can be overcome by treatment with a small molecule CXCR1/2 antagonist in combination with anti-PD-1 therapy. **Methods:** STOPTRAFFIC-1 (NCT04599140, enrolling) is a phase I/II, open-label, dose-escalation/dose expansion study of SX-682 in combination with nivolumab to evaluate safety and clinical activity for patients (pts) with refractory *RAS* (*KRAS* and *NRAS*) mutated MSS mCRC. Key eligibility criteria: patients (pts) with MSS mCRC with measurable disease, progression or intolerance to at least 2 prior lines of standard therapy, and ECOG 0 or 1. Pts will receive SX-682 (5 dose levels: 25 mg, 50 mg, 100mg, 200mg, or 400 mg by mouth twice daily) administered in an 8-week cycle with intravenous nivolumab (480 mg) on days 1 and 29 of each cycle. Adverse events are assessed according to CTCAE v5.0. Response assessments (per RECIST) occur every 8 weeks. In dose escalation, pts enter a 3-week monotherapy safety run-in of SX-682 followed by 3-week combination with nivolumab for a six-week dose-limiting toxicity (DLT) period. Cohorts 1-4 have been completed without DLT. Enrollment to cohort 5 began in January 2022. Following determination of maximum tolerated dose (MTD), dose expansion design is a Simon's optimal two-stage design. Efficacy will be assessed in the first 15 pts with a requirement of at least 2 responses in order to enroll 14 additional pts (N=29) in the second stage. Pre- and on-treatment tissue biopsies will be collected in the expansion phase. The primary objectives are to determine the safety profile of SX-682 alone and in combination with nivolumab, including the MTD, recommended phase 2 dose, and the DLT. The secondary objectives include overall response rate, progression-free survival, overall survival, and pharmacokinetic profiles of SX-682. Translational analyses include correlations of clinical outcomes with genomic and immune biomarkers from paired tissue and plasma samples. Clinical trial information: NCT04599140. Research Sponsor: Bristol Myers Squibb; Syntrix.

TPS3639 **Poster Session**

Phase 2 study of pembrolizumab-based combination therapy in patients with microsatellite instability-high (MSI-H) or mismatch repair-deficient (dMMR) stage IV colorectal cancer (CRC). *First Author: Thierry Andre, Hôpital Saint-Antoine, Paris, France*

Background: Robust clinical activity has been observed with anti–PD-1 pembrolizumab (pembro) in patients (pts) with dMMR/MSI-H metastatic CRC tumors. However, given the response rate of 45% with first-line pembro demonstrated in KEYNOTE-177, there is room for improvement. Adding a second checkpoint inhibitor targeting a different pathway such as CTLA-4, LAG-3, TIGIT, or ILT4 may improve the efficacy of PD-1 inhibition. This ongoing, open-label, multicenter, multiarm, randomized, phase 2 trial (NCT04895722) will evaluate efficacy and safety of coformulated pembro and anti–CTLA-4 quavonlimab compared with pembro monotherapy in chemotherapy-refractory stage IV dMMR/MSI-H CRC in cohort A; the study will also evaluate the efficacy and safety of 4 pembro-based combinations (coformulation of pembro with either quavonlimab, anti–LAG-3 favezelimab, or anti-TIGIT vibostolimab; anti-ILT4 MK-4830 given sequentially with pembro) compared with pembro monotherapy in previously untreated stage IV dMMR/MSI-H CRC in cohort B. **Methods:** Pts aged ≥18 y with histologically confirmed stage IV dMMR/MSI-H CRC who have measurable disease per RECIST v1.1 by investigator and confirmed by blinded independent central review (BICR), will be enrolled. Pts in cohort A must have experienced PD after fluoropyrimidine, irinotecan, and oxaliplatin, with or without anti-VEGF antibody, and anti-EGFR antibody for pts with left-sided tumors that are *RAS* WT. Pts in cohort B will not have been previously treated for metastatic disease. Additional eligibility criteria include ECOG PS 0 or 1, adequate organ function, and availability of archival or newly obtained tissue sample. Pts with autoimmune disease, active CNS metastases, and those who received systemic therapy within 4 wks or radiotherapy within 2 wks before intervention will be excluded. Pts in cohort A will be randomly assigned 1:1 to receive either coformulated quavonlimab 25 mg/pembro 400 mg IV Q6W or pembro 400 mg IV Q6W. Pts in cohort B will be randomly assigned 1:1:1:1:1 to receive coformulated quavonlimab 25 mg/pembro 400 mg IV Q6W, favezelimab 800 mg/pembro 200 mg IV Q3W, vibostolimab 200 mg/pembro 200 mg IV Q3W, MK-4830 800 mg + pembro 200 mg IV Q3W (given sequentially), or pembro 400 mg IV Q6W. Pts will be stratified by *RAS* mutation (mutant vs WT). Treatment will continue for ≤2 y or until unacceptable toxicity, disease progression, confirmed CR (after ≥6 mo of study treatment and pts have received ≥6 wk of treatment after initial CR), or withdrawal from study. Disease assessment by CT or MRI will be performed Q9W. For both cohorts, primary end point is ORR by BICR per RECIST v1.1; secondary end points are ORR assessed by investigator, DOR and PFS assessed by BICR and by investigator per RECIST v1.1, OS, and safety and tolerability graded per NCI CTCAE v5.0. Enrollment in this trial is ongoing. Clinical trial information: NCT04895722. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS3640 **Poster Session**

Myopenia and mechanisms of toxicity in older adults with colorectal cancer (CRC): The M&M study (WF-1806). *First Author: Grant Richard Williams, Institute for Cancer Outcomes and Survivorship, University of Alabama at Birmingham, Birmingham, AL*

Background: CRC is the 2nd most common cause of cancer death in the US, and nearly 60% of CRC cases occur among older adults. There is a critical unmet need to understand the underlying cause(s) of observed variability in chemotherapy toxicity (chemotoxicity) outcomes to minimize adverse outcomes and appropriately personalize therapy for older adults. Low muscle mass, known as myopenia, is prevalent in older adults with CRC (~60%) and is associated with chemotoxicity and decreased overall survival (OS). However, little is known about trajectories of myopenia and underlying mechanisms of increased toxicities and decreased survival in myopenic patients. We address these gaps in a prospective cohort study, with the central goal of examining the role of myopenia in chemotoxicity in older adults with metastatic CRC undergoing 5-Fluouracil (5FU) based chemotherapy, and to explore the mediating influence of germline genetic variants and pharmacokinetics (PKs) in the association between myopenia and chemotherapy toxicity. **Methods:** This prospective cohort study is accruing through the Wake Forest NCI Community Oncology Research Program Research Base (WF NCORP) and funded by the NCI grants 2UG1CA189824 and K08CA234225. The study examines the impact of myopenia on chemotoxicity and OS in older adults with newly diagnosed metastatic CRC planning to receive systemic 5FU-based chemotherapy (either as monotherapy or in combination with oxaliplatin and/or irinotecan +/- biologics) (NCT03998202). All patients undergo the Cancer & Aging Resilience Evaluation and Life-Space Evaluation at baseline, 3 and 6 months. Standard of care Computed Tomography (CT) images will be obtained to assess muscle measures (skeletal muscle area/density) at the L3 cross-section. The primary outcome is grades 3 to 5 chemotoxicity measured up to 6 months after initiation of chemotherapy using the National Cancer Institute Common Terminology Criteria for Adverse Events (NCI CTCAE) version 5.0. We will assess the association of baseline myopenia and trajectories of myopenia with severe chemotherapy toxicities. Secondary outcome measures include OS at 1 year and chemotoxicities using the Patient Reported Outcomes (PRO) version of the CTCAE. The study also explores the mediating/moderating influence of genetic variation and altered PKs (n = 60) in the association between myopenia and chemotherapy toxicity. To date, the study has accrued 73 of the 300 targeted patients from 110 NCORP practices. Clinical trial information: NCT03998202. Research Sponsor: U.S. National Institutes of Health.

TPS3641 **Poster Session**

A phase 2 multicenter, open-label, randomized, controlled trial in patients with stage II/III colorectal cancer who are ctDNA positive following resection to compare efficacy of autogene cevumeran versus watchful waiting. *First Author: Scott Kopetz, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Colorectal cancer (CRC) is one of the most commonly occurring cancers with high recurrence and mortality rate. Circulating tumor DNA (ctDNA) can be used as a marker of minimal residual disease after completion of surgical resection of stage II/III CRC, where detectable ctDNA levels (positive) post-AdCTx are associated with an increased risk of disease recurrence and novel therapies are needed. Autogene cevumeran is an investigational individualized neoantigen-specific immunotherapy that is designed to harness an immune response against patient-specific, tumor neoantigens. This clinical trial is in progress in patients with Stage II (high risk) / Stage III colorectal cancer who are ctDNA positive following resection. **Methods**: Autogene cevumeran is being evaluated in an open-label, Phase 2, randomized, controlled trial in patients with Stage II / III CRC patients who are ctDNA positive following resection. Patients are randomized to adjuvant therapy followed by autogene cevumeran compared to adjuvant therapy followed by watchful waiting. The primary endpoint is disease-free survival (DFS). The trial has a Biomarker Cohort of 15 patients who will receive autogene cevumeran irrespective of the ctDNA status to pursue exploratory objectives. The main study of the phase 2 trial consists of a randomized (1:1) design comparing the experimental arm (autogene cevumeran) with the observational arm (watchful waiting) in ctDNA positive CRC patients. A third Exploratory Cohort explores the efficacy and safety of autogene cevumeran in ctDNA positive CRC patients with early recurrence/relapse during or after completion of AdCTx. Patients enrolled onto the experimental group, the biomarker and exploratory cohorts will receive autogene cevumeran 6x q1w, followed by 2x q2w, followed by 7 "booster" doses q6w, to receive a total of 15 doses (dosed at 25μg). AEs are assessed according to CTCAE v5. DFS will be determined by an independent central radiology assessment. Key eligibility criteria include 1) Patients must have stage II/III rectal cancer or stage II (high risk)/III colon cancer that has been surgically resected (R0 confirmed by pathology report); 2) patients must be ctDNA positive following resection; and 3) at least 5 tumor neoantigens must be identified in the provided tumor sample for autogene cevumeran manufacturing (RNA lipoplex, RNA-LPX). ClinicalTrials.gov identifier: NCT04486378. Research Sponsor: Pharmaceutical/Biotech Company.

TPS3642 **Poster Session**

NSABP FC-12: A single-arm, phase II study to evaluate treatment with gevokizumab in patients with stage II/III colon cancer who remain ctDNA+ after curative surgery and adjuvant chemotherapy. *First Author: Thomas J. George, The University of Florida Health Cancer Center, Gainesville, FL*

Background: Detection of circulating tumor DNA (ctDNA) in patients (pts) following surgery is indicative of presence of minimal/molecular residual disease (MRD) and confers a near-certain risk of disease recurrence. Therapeutic strategies to treat MRD following standard curative therapies are needed because the risk of recurrence is high and therapeutic intervention may provide clinical benefit to patients. Gevokizumab is a recombinant humanized monoclonal antibody targeting interleukin-1β (IL-1β), which is involved in all phases of the malignant process (tumorigenesis, invasion, metastasis, angiogenesis, progression, and the modulation of anti-tumor immunity). Gevokizumab has been validated in pre-clinical colon cancer (CC) models and safety established in the advanced-stage clinical setting. In this trial in progress, we aim to test the efficacy of gevokizumab in pts with early-stage CC with MRD (ctDNA-positivity) following definitive treatment. **Methods:** NSABP FC-12 is a single-arm, multi-centered phase II study that will include pts with stage II/III CC who test MRD+ within 6 wks following completion of curative surgery and ≥3 mos of adjuvant chemotherapy. MRD will be assessed using a personalized and tumor-informed ctDNA assay (Signatera bespoke assay). Gevokizumab will be given at a flat dose of 120 mg IV every 28 days for 13 cycles. The primary endpoint is relapse-free survival (RFS) following initiation of study therapy through one year of follow-up. Secondary endpoints are rate of ctDNA clearance at 8 wks from start of study therapy, as well as safety, toxicity, pharmacokinetics, and immunogenicity of gevokizumab. Exploratory and correlative endpoints will include outcomes associated with ctDNA clearance kinetics, tumor mutations, tumor mutational burden, circulating methylated DNA, tumor immune microenvironment profile, peripheral blood immune profile, and stool microbiome analyses. The enrollment period will be ~12 mos. Pts will be followed for 18 mos following enrollment with ctDNA analysis at prespecified timepoints until imaging is positive for recurrence of disease or death. CT scans will be at 6-mo intervals. RFS will be determined in pts who clear ctDNA at 8 wks compared to those who do not. A single-stage design to test the null hypothesis that the 12-mo RFS is P≥0.20 versus the alternative (HA) that P≥0.35 has a sample size of 31 (alpha=0.151; power 0.811). If ≥9 of 31 pts (29%) are alive and recurrence-free at 12 mos, then gevokizumab will be considered promising for further study. Enrollment continues towards the primary endpoint. Clinical trial information: 05178576. Research Sponsor: Novartis, Natera, Other Foundation.

TPS3643 **Poster Session**

Colon adjuvant chemotherapy based on evaluation of residual disease (CIRCULATE-US): NRG-GI008. *First Author: Arvind Dasari, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Currently, there are no biomarkers validated prospectively in randomized studies for resected colon cancer (CC) to determine need for adjuvant chemotherapy (AC). However, circulating tumor DNA (ctDNA) represents a highly specific and sensitive approach (especially with serial monitoring) for identifying minimal/molecular residual disease (MRD) post-surgery in CC patients (pts), and may outperform traditional clinical and pathological features in prognosticating risk for recurrence. CC pts who do not have detectable ctDNA (ctDNA-) are at a much lower risk of recurrence and may be spared the toxicities associated with AC. Furthermore, for CC pts with detectable ctDNA (ctDNA+) who are at a very high risk of recurrence, the optimal AC regimen has not been established. We hypothesize that for pts whose CC has been resected, ctDNA status may be used to risk stratify for making decisions about AC. **Methods:** In this prospective phase II/III trial, up to 1,912 pts with resected stage III A, B (all pts) and stage II, IIIC (ctDNA+ only) CC will be enrolled. Based on the post-operative ctDNA status using personalized and tumor informed assay (SignateraTM, bespoke assay) , those who are ctDNA- (Cohort A) will be randomized to immediate AC with fluoropyrimidine (FP) + oxaliplatin (Ox) for 3-6 mos per established guidelines *vs.* serial ctDNA monitoring. Patients who are ctDNA+ post-operatively or with serial monitoring (Cohort B) will be randomized to FP+Ox *vs.* more intensive AC with addition of irinotecan (I) for 6 mos. The primary endpoints for Cohort A are time to ctDNA+ status (phase II) and disease-free survival (DFS) in phase III in the immediate *vs.* delayed AC arms. The primary endpoint for Cohort B is DFS in the FP+Ox *vs* FP+Ox+I arms for both phase II and phase III portions of the trial. Secondary endpoints include prevalence of detectable ctDNA post-operatively, time-to-event outcomes (overall survival and time to recurrence) by ctDNA status, and the assessment of compliance to adjuvant therapy. Biospecimens including archival tumor tissue, post-operative and serial matched/normal blood samples will be collected for exploratory correlative research. Active enrollment across the NCTN started in early 2022. Support: U10-CA-180868, -180822; UG1CA-189867; Clinical trial information: NCT05174169. Research Sponsor: Natera, U.S. National Institutes of Health.

EA2201: An ECOG-ACRIN phase II study of neoadjuvant nivolumab plus ipilimumab and short course radiation in MSI-H/dMMR rectal tumors. *First Author: Kristen Keon Ciombor, Vanderbilt University Medical Center, Nashville, TN*

Background: Trimodality therapy including chemoradiation, chemotherapy and surgical resection is standard for patients with T3-4 and/or node-positive (N+) rectal adenocarcinomas. Pathologic complete response (pCR) rates after neoadjuvant chemoradiation approach 15% in all-comers and 27% in patients with microsatellite instability-high (MSI-H) or deficient mismatch repair (dMMR) rectal cancer. Additionally, preclinical data suggest that hypofractionated radiation (large dose per fraction) may enhance immunogenicity. Given high response rates to immunotherapy in MSI-H/dMMR early stage and metastatic colorectal cancer (CRC), we hypothesized that neoadjuvant nivolumab plus ipilimumab and short course radiation in locally advanced MSI-H/dMMR rectal cancer (LARC) would result in increased pCR rates. **Methods:** EA2201 (NCT04751370) is an NCTN phase II clinical trial for patients with treatment-naïve locally advanced (T3-4Nx or TxN+) rectal adenocarcinoma that is dMMR or MSI-H. Patients receive nivolumab (480 mg) and ipilimumab (1 mg/kg) every 28 days for 2 cycles, followed by short course radiation (5 Gy x 5 fractions; total 25 Gy) and an additional 2 cycles of nivolumab and ipilimumab prior to disease reassessment and TME. The primary endpoint is pCR at TME. Secondary endpoints include 5-year disease-free survival, overall survival, treatment-related toxicities, and sphincter preservation rate for low-lying tumors. This study has a single-arm, two-stage design; a pCR rate of 50% or more will be taken as evidence of promising activity in this patient population. We plan to enroll 31 patients, with accrual currently ongoing. Clinical trial information: NCT04751370. Research Sponsor: U.S. National Institutes of Health.

TPS3645 **Poster Session**

NEOPRISM-CRC: Neoadjuvant pembrolizumab stratified to tumor mutation burden for high-risk stage 2 or stage 3 deficient-MMR/MSI-high colorectal cancer. *First Author: Kai-Keen Shiu, University College Hospital, NHS Foundation Trust, London, United Kingdom*

Background: The prognostic advantage of early stage deficient-MMR/MSI-High CRC is lost after relapse, so there is a pressing clinical need to maximize the chance of cure in the early stages where prevalence of dMMR is higher comprising approximately 12% of Stage 3 and 20% of Stage 2 CRC. The efficacy of adjuvant checkpoint inhibition in this patient group has yet to be demonstrated in the context of micrometastatic disease without a supporting immune-competent microenvironment. Longitudinal studies especially in the neoadjuvant setting would optimally interrogate post-immunotherapy changes both in time and space. The NEOPRISM-CRC (NEOadjuvant PembRolizumab In Stratified Medicine – ColoReCtal) study is a Phase II Trial to determine whether neoadjuvant Pembrolizumab stratified to tumour mutation burden (TMB) is efficacious and safe. It will also be a platform to explore the relationships between possible predictive novel biomarkers and response to Pembrolizumab in blood, tumour tissue and microbiome. **Methods:** The study population consists of subjects with newly diagnosed operable dMMR/MSI-H CRC. Patients must be fit and eligible for planned curative surgery based on a) radiological node positive T1-4 CRC or b) high risk T3 defined as EITHER ≥ 5mm of extramural depth of invasion or unequivocal EMVI on imaging (regardless of depth), or T4 disease. They will receive one of two pre-operative regimens depending upon their TMB based on the FoundationOne®CDx test (FM1CDx). All patients will have one 21 day cycle of Pembrolizumab 200 mg IV. Prior to cycle 2 and with the result of the FM1CDx test, patients will continue their treatment as follows: A) TMB-high (defined as ≥20 mutations per Mb) or TMB-medium (defined as 6-19 mutations per Mb), or MSI-H on PCR if FM1CDx test is not evaluable: A further 2 cycles of Pembrolizumab 200 mg IV every 21 days. B) TMB-low (defined as ≤5 mutations per Mb), or if FM1CDx and PCR tests are not evaluable: No further Pembrolizumab given. Surgery to remove the CRC will be performed 4-6 weeks after the last dose of Pembrolizumab in both arms. Following resection patients may receive adjuvant chemotherapy in accordance with local institutional guidelines. The primary end point is pathological complete response rate (pCR). Secondary endpoints include 3 year RFS, OS, safety and health-related quality of life. Up to 32 patients will be registered over a 18-24 month period assuming that the pCR with 3 cycles of Pembrolizumab will be ≥ 33% for patients with high or medium TMB based on the FM1CDx profile, and intend to rule out a percentage ≤10%. To reach 80% power with 5% statistical significance, 19 patients are required in the high/medium TMB arm. The trial will be considered a success if at least 5/19 patients have a pCR after 3 cycles of Pembrolizumab. Enrolment will commence in March 2022. Clinical trial information: NCT05197322. Research Sponsor: Merck Sharpe and Dohme, To be confirmed. Other sources of funding will be obtained for any additional translational exploratory work using research funds at UCL/UCLH and scientific collaborators.

TPS3646 **Poster Session**

SPAR: A randomized placebo-controlled phase 2 trial of simvastatin in addition to standard chemotherapy and radiation in preoperative treatment for rectal cancer: An AGITG clinical trial. *First Author: Michael B. Jameson, Waikato Clinical Campus, Hamilton, New Zealand*

Background: In retrospective studies statin use during preoperative chemo-radiation (pCRT) for rectal cancer is associated with improved overall survival, pathological tumor response and treatment toxicity. In vivo preclinical studies show that statins radiosensitize cancer cells, with improved tumor control and reduced radiation-induced gastrointestinal (GI) and skin toxicities. A prospective randomized trial is justified to confirm these clinically important benefits. Tumor regression following pCRT has strong prognostic significance, as assessed radiologically (MRI-based tumor regression grading [mrTRG]) prior to, or pathologically (pathTRG) following, surgery. Using mrTRG after each treatment phase in total neoadjuvant therapy (TNT) programs could assess incremental tumor regression and optimize patient management including surgery. **Methods:** Design: This double-blind phase 2 trial is recruiting 222 patients planned to receive long-course fluoropyrimidine-based pCRT for rectal adenocarcinoma at 17 sites in New Zealand and Australia. Patients are randomized to simvastatin 40mg or placebo daily for 90 days, starting 1 week prior to pCRT, with minimization for major prognostic variables. Pelvic MRI at baseline and 6-8 weeks after pCRT will assess mrTRG. A protocol amendment allows TNT using consolidation chemotherapy after pCRT; MRI timing is unchanged. Primary objective: comparison of rates of grades 1-2 mrTRG following pCRT with simvastatin or placebo, considering mrTRG in 4 ordered categories (1, 2, 3, 4-5). Secondary objectives: comparison of rates of grades 1-2 pathTRG in resected tumors; incidence of > grade 2 acute GI and non-GI adverse events (AE); incidence of late GI AE; compliance with intended pCRT and trial medication; proportion of patients undergoing surgical resection post-pCRT; 3-year local recurrence rate, disease-free and cancer-specific survival; and pathological scores for radiation colitis. Tertiary and correlative objectives: association between mrTRG and pathTRG grouping; inter-observer scoring agreement on mrTRG and pathTRG; comparison of the association between tumor CD3+ and/or CD8+ T-cell infiltrates in diagnostic biopsies and pathTRG; intensity and distribution of subsets of infiltrating T-cells in irradiated resected normal and malignant tissue; and the effect of simvastatin on markers of systemic inflammation (modified Glasgow prognostic score and the neutrophil-lymphocyte ratio). Eligibility criteria exclude statin use within 6 weeks prior to trial entry, patients intolerant of statins, and planned use of oxaliplatin or biological agents during pCRT. Trial recruitment commenced April 2018 and 95 of 222 patients have been recruited as at 21 January 2022. Clinical trial information: ACTRN12617001087347. Research Sponsor: Health Research Council of New Zealand, Other Foundation.

TPS3647 **Poster Session**

Colorectal cancer metastatic dMMR immuno-therapy (COMMIT) study: A randomized phase III study of atezolizumab (atezo) monotherapy versus mFOLFOX6/bevacizumab/atezo in the first-line treatment of patients (pts) with deficient DNA mismatch repair (dMMR) or microsatellite instability high (MSI-H) metastatic colorectal cancer (mCRC)—NRG-GI004/SWOG-S1610. *First Author: Caio Max Sao Pedro Rocha Lima, Wake Forest University Baptist Medical Center, Winston-Salem, NC*

Background: Despite the superiority in progression-free survival (PFS) of inhibition of programmed cell death-1 (PD-1) pathway in dMMR/MSI-H as compared to chemotherapy with either anti-vascular endothelial growth factor receptor (VEGFr) or anti-epithelial growth factor receptor (EGFr) antibodies in mCRC, more pts had progressive disease as the best response in the anti-PD1 monotherapy arm (29.4% *v* 12.3%) with mean PFS of 13.7 mos, with ~45% of pts in the IO arm progressed at 12 mos (*N Engl J Med* 2020; 383:2207). We hypothesize that the dMMR/MSI-H mCRC pts may be more effectively treated with the combination of PD-1 pathway blockade and mFOLFOX6/bevacizumab (bev) rather than with anti-PD-1 therapy (atezo) alone. Preclinical work demonstrated synergistic effects between anti-PD-1/anti-VEGF and between oxaliplatin/anti-PD-1 in murine CRC models and phase II data, which showed activity of anti-PD-1/anti-VEGF in chemotherapy refractory colon cancer. A recent randomized trial subgroup analyses of 8 pts with dMMR metastatic colon cancer treated with FOLFOXIRI+bev+atezo, with the first patient having progression ~16 mos (*ESMO 2021, Abstt LBA20*). Additionally, in other solid tumor malignancies, anti-PD1 plus anti-VEGFr (i.e., HCC and RCC) as well as anti-PD1 plus chemotherapy (i.e., gastric and esophageal cancers) combinations are standard first-line treatments. **Methods:** The redesigned COMMIT study was reactivated on 1/29/2021 as a two-arm prospective phase III open-label trial randomizing (1:1) mCRC dMMR/MSI-H to atezo monotherapy *v* mFOLFOX6/bev+atezo combination. Assuming our control arm, atezo monotherapy (48% PFS at 24 mos as assessed by site investigator), we have 80% power to detect a hazard ratio of 0.6 (equivalent to 64.4% PFS at 24 mos) with alpha 0.025 one-sided. Stratification factors include BRAFV600E status, metastatic site, and prior adjuvant CRC therapy. Secondary endpoints include OS, objective response rate, safety profile, disease control rate, and duration of response. Health-related quality of life is an exploratory objective. Archived tumor tissue and blood samples will be collected for correlative studies. Key inclusion criteria are: mCRC without prior chemotherapy for advanced disease; dMMR tumor determined by local CLIA-certified IHC assay (MLH1/MSH2/MSH6/PMS2) or MSI-H by local CLIA-certified PCR or NGS panel; and measurable disease per RECIST. Enrollment actively continues to the target accrual of 211 patients randomized between the two immunotherapy arms. Support: U10CA180868, -180822, -180888, UG1CA189867, U24CA196067. Clinical trial information: NCT02997228. Research Sponsor: Genentech, Inc, U.S. National Institutes of Health.

4001 **Oral Abstract Session**

The first report of K-Umbrella Gastric Cancer Study: An open label, multicenter, randomized, biomarker-integrated trial for second-line treatment of advanced gastric cancer (AGC). *First Author: Sun Young Rha, Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: To explore proper agents for AGC patients as 2nd-line treatment based on optimal biomarker, we conducted K-Umbrella GC study with standard of care (SOC) controlled umbrella trial design. **Methods:** HER2-negative AGC patients from 6 Korean cancer centers were centrally screened for druggable targets by IHC and *in situ* hybridization. Patients were randomized to the biomarker *vs.* control group with SOC as 4:1 ratio. In the biomarker group, patients were treated with specific targeted agents in combination with weekly paclitaxel; 1) EGFR 2+/3+ patients for pan-ERBB inhibitor (afatinib; EGFR cohort), 2) PTEN loss/null (H-score <100) patients for PIK3Cβ inhibitor (GSK2636771; PTEN cohort), and 3) PD-L1+, dMMR/MSI-high, or EBV-related cases for anti-PD-1 inhibitor (nivolumab; NIVO cohort). Control group and NONE cohort in biomarker group without predefined biomarkers were treated with SOC (weekly Paclitaxel±Ramucirumab). Primary endpoint was PFS between control and biomarker groups. Secondary endpoints included efficacy and safety of each cohort. **Results:** Between Feb 2016 and Feb 2021, total 722 patients were centrally screened. 329 patients were enrolled and randomized to control group (n=63) or biomarker group (n=266; EGFR cohort n=67; PTEN cohort n=42; NIVO cohort n=54; NONE cohort n=103). With a median follow-up of 35 months (95%CI 26.1-55.3), median PFS and OS were 3.8 (95%CI 3.2-4.3) and 8.9 (95%CI 7.8-10.1) months for biomarker group and 4.1 (95%CI 3.0-4.8) and 8.7 months (95%CI 7.2-10.2) for control group. In control group, PTEN loss/null was poor prognostic marker; patients with PTEN loss/null (n=12) showed worse survival compared to PTEN intact patients (n=51) (mPFS, 2.8 vs 4.3 months, *P*=0.03; mOS, 8.7 vs 9.1 months), where other biomarkers showed similar prognosis. Afatinib for EGFR cohort or GSK2636771 for PTEN cohort did not show significant survival benefit compared to control group (Table). Among patients with immune-related biomarkers, addition of nivolumab showed durable survival benefit (mOS 12.0 vs 7.6 months, *P*=0.08) compared to SOC. **Conclusions:** Considering the characteristics of umbrella design with multiple biomarkers having different biological roles, biomarker group did not show the improved survival over control arm with these 3 drugs. For optimal biomarker-driven targeted agent applications, NGS-based biomarker driven K-Umbrella GC-2 study is ongoing. Clinical trial information: NCT02951091. Research Sponsor: National R&D Program for Cancer Control, Ministry of Health and Welfare, Republic of Korea (1520190), and the National R&D Program for Cancer Control, Ministry of Health and Welfare, Republic of Korea (HA16C0018).

Group	Cohort	Regimen	N	mPFS (95%CI)	mOS (95%CI)
Control	Control	Paclitaxel±Ramucirumab	63	4.1 (3.0–4.8)	8.7 (7.1–10.2)

4003 **Oral Abstract Session**

Surgical and pathological outcome, and pathological regression, in patients receiving perioperative atezolizumab in combination with FLOT chemotherapy versus FLOT alone for resectable esophagogastric adenocarcinoma: Interim results from DANTE, a randomized, multicenter, phase IIb trial of the FLOT-AIO German Gastric Cancer Group and Swiss SAKK. *First Author: Salah-Eddin Al-Batran, Institut für Klinische Krebsforschung IKF am Krankenhaus Nordwest, Frankfurt Am Main, Germany and Krankenhaus Nordwest, University Cancer Center Frankfurt, Frankfurt Am Main, Germany*

Background: DANTE evaluates atezolizumab in the perioperative treatment of resectable gastric or gastroesophageal junction (GEJ) adenocarcinoma in combination with FLOT. Here, we report interim results. **Methods:** DANTE is a multicenter, investigator-initiated, phase IIb trial. Patients (pts) with resectable adenocarcinoma of the stomach and GEJ (≥cT2 and/or N+) were randomized to receive 4+4 cycles of periop. FLOT chemotherapy (arm B) or the same regime with additional atezolizumab at 840 mg, q2w, followed by atezolizumab monotherapy for 8 cycles at 1200 mg, q3w (arm A). The primary endpoint is progression-free survival. The secondary endpoints surgical outcome (pTNM, R0 resection rate and periop. morbidity/mortality), path. regression and safety are reported here. TNM stage was evaluated by local pathologists and path. regression (Becker-Classification) by local and central pathologists. PD-L1 and MSI status were centrally evaluated. **Results:** In total, 295 pts were randomized (A, 146; B, 149) with baseline characteristics as follows: median age 61y, male 74%, intestinal type 42%, GEJ 61%, cT3/4 77%, N+ 78%. Twenty-five pts (8.5%) were MSI; 50% had PD-L1 CPS ≥1, 23% PD-L1 CPS ≥5 and 15% PD-L1 CPS ≥10. Pre-op FLOT cycles were completed in 93% of pts and post-op cycles in 43% of pts, with no difference between arms. Surgical morbidity (A, 45%; B, 43%) and mortality (overall 2.5%) were comparable between arms, as were R0-resection rates (arm A, 92% vs. arm B, 91%). Downsizing favored arm A vs B (pT0, 23% vs 15%; pN0, 68% vs 54%). Increases in path. regression rates were seen, particularly with higher PD-L1 expression (Table). **Conclusions:** The analysis shows beneficial effects of atezolizumab combined with FLOT vs FLOT alone on path. stage and path. regression that seem to be more pronounced with higher PD-L1 expression. Sponsor: Institut für Klinische Krebsforschung IKF am Krankenhaus Nordwest. EudraCT: 2017-001979-23. Clinical trial information: NCT03421288. Research Sponsor: Roche.

4004 **Oral Abstract Session**

A randomized study of temozolomide or temozolomide and capecitabine in patients with advanced pancreatic neuroendocrine tumors: Final analysis of efficacy and evaluation of MGMT as a predictive biomarker (ECOG-ACRIN E2211). *First Author: Pamela L. Kunz, Yale Cancer Center, Yale School of Medicine, New Haven, CT*

Background: Patients with advanced pancreatic neuroendocrine tumors (NETs) have few treatment options that yield objective tumor response. Retrospective and small, prospective studies suggest that the combination of capecitabine and temozolomide is associated with high response rates (RR) and relative long progression-free survival (PFS). This trial was conducted to establish a role for the combination of capecitabine and temozolomide. **Methods:** E2211 was a multicenter, randomized, phase II trial comparing temozolomide (200 mg/m2 PO QD days 1-5) vs. capecitabine/temozolomide (capecitabine 750 mg/m2 PO BID days 1-14; temozolomide 200 mg/m2 PO QD days 10-14) in patients with advanced pancreatic NETs. Eligibility criteria included: metastatic or unresectable, low or intermediate grade pancreatic NETs, progression within preceding 12 months, and no prior temozolomide, DTIC, capecitabine or 5-fluorouracil. The primary endpoint was PFS; secondary endpoints were Overall Survival (OS), RR, safety, and MGMT as evaluated by immunohistochemistry (IHC) and promoter methylation. Allowing for 5% ineligibility, 145 randomized patients were required to obtain 138 eligible patients to detect a difference in median PFS of 9 versus 14 months (hazard ratio of 0.64) using a two-sided log-rank test at the overall 0.20 significance level with 81% power. **Results:** 144 patients were enrolled between 4/2013 to 3/2016 to temozolomide (n = 72) or capecitabine/temozolomide (n = 72); the efficacy analysis population included 133 eligible patients. At the scheduled interim analysis in January 2018, median PFS was 14.4 months for temozolomide vs. 22.7 months for capecitabine/temozolomide (HR = 0.58), which was sufficient to reject the null hypothesis for this final primary endpoint (stratified log rank p = 0.022. In the final analysis (5/2021), median OS was 53.8 months for temozolomide and 58.7 months for capecitabine/temozolomide (HR = 0.82, p = 0.42) and RR was 34% for temozolomide and 40% for capecitabine/temozolomide (p = 0.59). Capecitabine/temozolomide was associated with higher rates of grade 3-4 AEs (45% vs. 22%, p = 0.005). MGMT deficiency, defined as either low IHC or positive promoter methylation, was associated with greater odds of response (OR [95% CI] = 6.38 [2.19, 18.60] and 9.79 [1.09, 87.71], respectively). **Conclusions:** E2211 is the first prospective randomized trial of capecitabine/temozolomide and shows the longest PFS and highest RR reported for patients with pancreatic NETs in a prospective randomized study. MGMT deficiency was associated with greater odds of objective response. Clinical trial information: NCT01824875. Research Sponsor: U.S. National Institutes of Health.

4005 **Oral Abstract Session**

NET-02: A multicenter, randomized, phase II trial of liposomal irinotecan (nal-IRI) and 5-fluorouracil (5-FU)/folinic acid or docetaxel as second-line therapy in patients (pts) with progressive poorly differentiated extrapulmonary neuroendocrine carcinoma (PD-EP-NEC). *First Author: Mairead Geraldine McNamara, University of Manchester, Manchester, United Kingdom*

Background: The prognosis for pts with PD-EP-NEC is poor. A recognised first-line (1L) treatment for advanced disease is etoposide/platinum-based chemotherapy; there is no standard second-line (2L) treatment (area of unmet need). **Methods:** This was a multi-centre, randomised (1:1), phase II trial of IV nal-IRI (70mg/m^2 free base)/5-FU (2400 mg/m^2)/folinic acid, Q14 days (ARM A), or IV docetaxel (75mg/m^2), Q21 days (ARM B), as 2L therapy in a planned 102 pts with progressive PD-EP-NEC, aimed at selecting a treatment for continuation to a phase III trial. Pts with histologically-confirmed PD-EP-NEC (Ki-67>20%; Grade 3, WHO 2019), who had prior 1L platinum-based chemotherapy and radiological disease progression or discontinuation of 1L therapy due to intolerance, with an ECOG performance status ≤2 were eligible. Randomisation was stratified by Ki-67, ECOG PS, presence of liver metastases, and response to previous platinum-based therapy. Primary endpoint was 6 month (mo) progression-free survival (PFS) rate; 80% power to demonstrate the one-sided 95% confidence interval (CI) of the 6 mo PFS rate excluded 15%, if the true rate was at least 30%, where 30% was the required level of efficacy; a rate of <15% would give grounds for rejection. Intention was to show that the regimens were sufficiently active, but not to assess superiority of one regimen over the other. Secondary endpoints included objective response rate (ORR), PFS, overall survival (OS), and toxicity. Based on futility analysis, the DSMB recommended closure of recruitment in Dec 21. **Results:** Of 58 patients in 15 UK centres (Nov 18-Dec 21), 29 in ARM A, 29 in ARM B, 57% were male, median age (range): 63.5 years (22-85), 90% ECOG PS 0/1, 10% PS 2, 90% Ki-67≥55%, 33%/38%/29% small/large cell/unknown morphology, primary site: 69% gastrointestinal, 12% unknown, 9% genitourinary, 5% head & neck, 3% gynae, 2% breast, 60% had liver mets, 91%/7%/2% were resistant/sensitive/intolerant to 1L platinum-based treatment. At a median follow up of 6.6 mo, the primary end-point of 6-mo PFS rate was met in ARM A; ORR, median PFS and OS are also presented (Table). Adverse events ≥ grade 3 occurred in 51.7% and 55.2% in ARM A and B and there were 1 and 6 discontinuations due to toxicity in ARM A and B, respectively. Data cleaning is on-going. **Conclusions:** nal-IRI/5-FU, but not docetaxel, met the primary endpoint (exceeding the threshold for efficacy), with manageable toxicity, and warrants evaluation in a phase III trial. Clinical trial information: 03837977. Research Sponsor: Servier.

	ARM A (N=29) nal-IRI/5-FU	ARM B (N=29) Docetaxel

Median PFS (mo)	3 (95% CI 2-6)	2 (95% CI 2-2)
Median OS (mo)	9 (95% CI 3-15)	5 (95% CI 3-11)

*N=28, **N=27 (6 mo PFS rate awaited for 3 pts).

4006 **Oral Abstract Session**

Trastuzumab deruxtecan (T-DXd; DS-8201) in patients (pts) with HER2-expressing unresectable or recurrent biliary tract cancer (BTC): An investigator-initiated multicenter phase 2 study (HERB trial).

First Author: Akihiro Ohba, National Cancer Center Hospital, Tokyo, Japan

Background: BTCs have an aggressive tumor biology with limited treatment options. With a HER2-positivity rate of 5–20% in BTCs, case series and small clinical trials have shown signs of activity for HER2 blockade in these pts. T-DXd is an antibody-drug conjugate composed of a humanized monoclonal anti-HER2 antibody, a cleavable linker, and a topoisomerase I inhibitor. The HERB trial is an investigator-initiated, multicenter, single-arm phase 2 trial of T-DXd in pts with HER2-expressing BTCs. **Methods:** Centrally confirmed HER2-expressing (HER2-positive: IHC3+ or IHC2+/ISH+, and HER2-low-expressing [HER2-low]: IHC/ISH status of 0/+, 1+/-, 1+/+, or 2+/-) pts with BTCs who were refractory or intolerant to gemcitabine containing regimen received 5.4 mg/kg of T-DXd every 3 weeks. The primary endpoint was the confirmed objective response rate (ORR) in HER2-positive pts by independent central review. The sample size of 22 had 80% power with one-sided alpha error of 5%; threshold ORR, 15%; and expected ORR, 40%. The ORR, disease control rate (DCR), progression-free survival (PFS), overall survival (OS) in HER2-positive/-low pts, and incidence of treatment-emergent adverse events (TEAEs) were assessed as secondary endpoints. **Results:** A total of 32 pts, 24 with HER2-positive and 8 with HER2-low BTCs, received T-DXd. Twenty-two pts with HER2-positive, excluding 2 ineligible pts, were identified for primary efficacy analysis. Among the 22 pts, IHC3+ and IHC2+/ISH+ were 45.5% and 54.5%, primary sites: gallbladder/extrahepatic/intrahepatic/Vater were 11/6/3/2, median number of prior regimens was 2 (range, 1–4). The confirmed ORR in HER2-positive pts was 36.4% (8/22; 2 CR and 6 PR; 90% CI, 19.6–56.1), indicating statistically significant improvement in ORR (P = 0.01). The DCR, median (m) PFS, mOS were 81.8% (95% CI, 59.7–94.8), 4.4 months (mo) (95% CI, 2.8–8.3), 7.1 mo (95% CI, 4.7–14.6), respectively. In addition, encouraging efficacy were seen even in HER2-low pts; ORR, DCR, mPFS, and mOS were 12.5% (1/8; 1 PR; 95% CI, 0.3–52.7), 75.0% (95% CI, 34.9–96.8), 4.2 mo (95% CI, 1.3–6.2), and 8.9 mo (95% CI, 3.0–12.8), respectively. In the safety analysis set (n = 32), TEAEs of > = grade (G) 3 occurred in 81.3% (26/32); the common TEAEs were anemia (53.1%), neutropenia (31.3%), and leukopenia (31.3%). TEAEs leading to drug discontinuation occurred in 8 pts (25.0%). Eight pts (25.0%) had interstitial lung disease (ILD; G1/G2/G3/G5 were 3/1/2/2) not adjudicated by an independent committee. **Conclusions:** T-DXd showed promising activity in pts with HER2-expressing BTCs. Although the safety profile was generally consistent with other T-DXd studies, ILD, an important identified risk of T-DXd, requires more careful monitoring and intervention. These results support further exploration of T-DXd in this patient population. Clinical trial information: JMA-IIA00423. Research Sponsor: Japan Agency for Medical Research and Development, Pharmaceutical/Biotech Company.

Adapted physical activity in patients (Pts) with advanced pancreatic cancer (APACaP): Results from a prospective national randomized GERCOR trial.

First Author: Cindy Neuzillet, Department of Medical Oncology, Institut Curie-Site Saint Cloud, Versailles Saint-Quentin University, Paris Saclay University, Saint Cloud, France

Background: The benefit of adapted physical activity (APA) on health-related quality of life (HRQoL) in Pts with advanced pancreatic ductal adenocarcinoma (aPDAC) treated by chemotherapy (CTx) has never been prospectively assessed. **Methods:** Pts with aPDAC and ECOG performance status (PS) 0–2 were randomized 1:1 to receive usual care (UC) including first-line CTx at the investigator's choice (standard arm), or UC plus a home-based 16-week APA program (APA arm). The APA program consisted of personalized aerobic and resistance exercises, with a weekly remote supervision by an APA professional trainer, and unsupervised sessions with a family member or friend (APA partner). The primary objective was the effect on HRQoL at week 16 (W16) measured by 3 dimensions of the EORTC QLQ-C30, global health status (GHS), physical functioning (PF), and fatigue (FA), with a one-sided type I error of 0.016 for each dimension. The primary HRQoL analysis was performed in Pts with available baseline and W16 scores for the 3 targeted dimensions (mITT1). Secondary analyses of HRQoL changes by the mixed model for repeated measures (MMRM) and time until definitive deterioration (TUDD) methods included Pts with baseline and ≥1 follow-up score (mITT2). Differences > 5 points in scores were considered clinically significant. **Results:** A total of 313 Pts (median age: 64 years; men: 55%, ECOG PS 0-1: 93%; metastatic: 77%; FOLFIRINOX: 78%, gemcitabine-based: 13%) were included from 11/2014 to 10/2020 (standard arm: n = 157, APA arm: n = 156). In the mITT1 population (n = 172), mean differences in HRQoL at W16 adjusted from baseline were -0.98 (SD 23.87; p = 0.39), -2.08 (SD 21.34; p = 0.26), and 4.16 (SD 29.18; p = 0.18) for GHS, PF, and FA, respectively. In the mITT2 population (n = 259), APA was associated with significant improvements in 5 (GHS, PF, cognitive functioning [CF], social functioning [SF], appetite loss) and 8 (GHS, CF, emotional functioning [EF], SF, insomnia, constipation, pain, financial difficulties) dimensions of HRQoL by MMRM and TUDD, respectively (Table). Secondary endpoints, including overall survival, progression-free survival, and chemotherapy toxicity will be presented. **Conclusions:** APA in combination with usual care improved several dimensions of HRQoL in Pts with aPDAC receiving first-line CTx. Clinical trial information: NCT02184663. Research Sponsor: GERCOR, A.R.CA.D Foundation.

Scores	MMRM mean difference with 95%CI*	TUDD Hazard Ratio with 95%CI**

Randomized phase III trial of induction chemotherapy followed by chemoradiotherapy or chemotherapy alone for nonresectable locally advanced pancreatic cancer: First results of the CONKO-007 trial.

First Author: Rainer Fietkau, Department of Radiation Oncology, Universitatsklinikum Erlangen, Friedrich-Alexander-Universitat Erlangen-Nürnberg, Erlangen, Germany

Background: Chemotherapy (CT) is the standard of care in nonresectable locally advanced pancreatic cancer. The CONKO-007 trial studied the role of sequential CT and chemoradiotherapy (CRT). **Methods:** In this randomized multicenter phase III trial resectability was judged by an independent surgical board. Patients (pts) received induction chemotherapy (IC) for 3 months (3 cycles gemcitabine (Gem, 1000 mg/m^2 d1, 8, 15, q4w) or FOLFIRINOX (6 cycles, q2w)). After IC pts without progression were randomized to either continuing CT for another 3 months or receiving CRT (cumulative dose of 50.4Gy, single dose 1.8Gy + Gem 300 mg/m^2 weekly, followed by 1 cycle of Gem 1000 mg/m^2 at d1, 8, 15). The primary endpoint of the study was overall survival (OS) since the begin of IC. Determination of sample size calculated 590 pts to be randomized. Due to the exclusion of pts with progressive disease after IC a total of 830 pts should be enrolled. Due to delayed patient accrual the primary endpoint was changed to R0 resection rate resulting in an estimated sample size of 525 pts. **Results:** Between 04/2013 and 02/2021 a total of 525 pts were enrolled in 47 sites. 402 pts received IC with FOLFIRINOX and 93 pts with Gem. After IC 190 pts were excluded due to progression or toxicity, 335 were randomized, their median FU was 16 months. Hematological toxicities were significantly increased in the CRT arm, non-hematological toxicities were comparable. R0 CRM- resection rate and pCR rate was significantly higher in the CRT arm. R1-resections occurred significantly more often in the CT arm. Median progression-free survival (PFS) (HR 0.919, 95% CI 0.702-1.203, p=0.540) and OS (HR 0.964, 95% CI 0.760-1.225, p=0.766) did not differ significantly in both arms, whereas the PFS rate tended to be higher in the CRT arm after 2 years. OS rates for CRM- R0 surgery with 87.5. ± 0.05% (1y) and 67.2 ± 0.05% (2y) were significantly higher (p<0.01) than for CRM+ R0 surgery with 66.7 ± 0.15% (1y) and 41.2 ± 0.1% (2y) as well as for patients without or incomplete surgery with 68.5 ± 0.03% (1y) and 26.4 ± 0.03% (2y). **Conclusions:** The addition of radiotherapy after IC improves the R0 CRM - resection and pCR rate without significant change in R0 resection rate (primary endpoint). Pts with R0 CRM - resections had a better prognosis compared to patients with either R0 CRM+ or incomplete or without surgery. However, this effect on resectability did not translate into a statistically significant PFS or OS benefit in the whole cohort. Clinical trial information: NCT01827553. Research Sponsor: Deutsche Krebshilfe.

Updated results of the FOENIX-CCA2 trial: Efficacy and safety of futibatinib in intrahepatic cholangiocarcinoma (iCCA) harboring *FGFR2* fusions/rearrangements.

First Author: Lipika Goyal, Mass General Cancer Center, Harvard Medical School, Boston, MA

Background: Survival outcomes are historically poor in patients (pts) with advanced/metastatic iCCA, with median overall survival (mOS) times of approximately 1 year with first-line gemcitabine plus cisplatin and approximately 6 months with second-line chemotherapy. Futibatinib, a highly selective, irreversible FGFR1–4 inhibitor, demonstrated efficacy with durable responses in pts with iCCA harboring *FGFR2* fusion/rearrangements in the pivotal FOENIX-CCA2 phase 2 study (NCT02052778). At the primary analysis of this trial (data cutoff: October 1, 2020), an objective response rate (ORR) of 41.7% was observed, with a median duration of response (mDOR) of 9.7 mo. Here, we report updated efficacy (including mature OS data) and safety data from the final analysis with an additional 8 mo of follow-up. **Methods:** FOENIX-CCA2 was a single-arm phase 2 study that enrolled pts with advanced/metastatic iCCA with *FGFR2* fusion/rearrangement and progressive disease (PD) after ≥1 prior treatment (tx; including gemcitabine plus platinum-based chemotherapy). Pts received futibatinib 20 mg once daily until PD/intolerability. The primary endpoint was ORR per RECIST v1.1 by independent central review. Secondary endpoints were DOR, disease control rate (DCR), progression-free survival (PFS), OS, safety, and patient-reported outcomes. **Results:** At the time of the final data cutoff (May 29, 2021), median follow-up was 25.0 mo, and 96/103 pts (93%) had discontinued tx. The median number of tx cycles was 13.0 for a median tx duration of 9.1 mo. The confirmed ORR was 41.7% (43/103) and thereby the same as of the primary analysis, as was the DCR (at 82.5%). The ORR was consistent across pt subgroups. The mDOR was 9.5 mo, and 74% of responses lasted ≥6 mo. mPFS was 8.9 mo, with a 12-mo PFS rate of 35.4%. Mature mOS was 20.0 mo, with a 12-mo OS rate of 73.1%. No new safety signals were identified. Common tx-related adverse events (TRAEs) included hyperphosphatemia (85%), alopecia (33%), dry mouth (30%), diarrhea (28%), dry skin (27%), and fatigue (25%). TRAEs resulted in tx discontinuation in 4 pts (4%). No tx-related deaths occurred. Quality of life was maintained from baseline to tx cycle 13. **Conclusions:** Findings from the final analysis of FOENIX-CCA2 confirm the results of the primary analysis and reinforce the durable efficacy and continued tolerability of futibatinib in previously treated pts with advanced/metastatic iCCA harboring *FGFR2* fusion/rearrangements. Mature OS data were consistent with data from the primary analysis and far exceed historical data in this patient population. Clinical trial information: NCT02052778. Distinct biosignatures associate with survival after chemoimmunotherapy in a randomized, three-arm phase II study in patients with metastatic pancreatic cancer. *First Author: Lacey J. Padrón, Parker Institute for Cancer Immunotherapy, San Francisco, CA*

Background: Preclinical and small clinical studies of chemoimmunotherapy for metastatic pancreatic ductal adenocarcinoma (mPDAC) point to a yet unrealized potential of clinically significant immune activation. In our phase II study of the CD40 agonist antibody sotigalimab (sotiga) and/or nivolumab (nivo) with gemcitabine and nab-paclitaxel (chemo), we observed promising improvements in overall survival (OS) in 105 patients with newly diagnosed mPDAC (NCT03214250); the primary endpoint of 1-year OS rate was 57.7% (p = 0.006) in the nivo/chemo arm, 48.1% (p = 0.062) in the sotiga/chemo arm and 41.3% (p = 0.233) in the nivo/sotiga/chemo arm (O'Hara, ASCO 2021) as compared to a historical control of 35%. Here, we report results of multi-omic translational analyses designed to identify signatures predictive of OS benefit. **Methods:** Longitudinal blood and tumor tissue samples were collected for immune and tumor biomarker analysis. Tumor samples underwent RNA sequencing and multiplex immunofluorescence (mIF). Peripheral blood was analyzed by mass cytometry time of flight (CyTOF), high parameter flow cytometry, and proteomics. Machine learning (ML) algorithms were applied to the data to identify biosignatures related to OS in each arm. **Results:** Comprehensive multi-omic, multi-parameter immune and tumor biomarker analyses identified distinct pretreatment immune signatures predictive of longer OS specific to nivo/chemo or sotiga/chemo (Table, representative examples). Because patients in each arm received chemotherapy, these and other arm-unique biomarkers suggest a relationship to the immunotherapy rather than chemotherapy in this randomized study. There was evidence of immune exhaustion in the sotiga/nivo/chemo arm that may explain the lack of survival benefit. **Conclusions:** From in-depth translational and ML analyses of randomized phase II trial of first-line chemoimmunotherapy in mPDAC patients, we identified novel biomarkers that associated with OS distinctly in each arm. Clinical trials in first-line mPDAC exploiting these previously unappreciated biomarkers and aiming to enrich patients for response, are warranted to further advance chemoimmunotherapy in this disease. Clinical trial information: NCT03214250. Research Sponsor: Parker Institute for Cancer Immunotherapy, Cancer Research Institute, Pharmaceutical/Biotech Company.

Selected pretreatment immune features associated with overall survival benefit.

Immune Feature	Sample	Nivo/Chemo (p-value, by log rank)	Sotiga/Chemo (p-value, by log rank)
Lower expression of TNF-α signaling via NFκB hallmark gene signature	Tumor	0.001	Not significant (ns)
Lower expression of the E2F targets hallmark gene signature	Tumor	ns	0.021
Higher frequencies of Tfh cells	Blood	< 0.0001	ns
Higher frequencies of PD-1+ CD39+ CD4 Central Memory T cells	Blood	0.037	ns

Nimotuzumab combined with gemcitabine versus gemcitabine in K-RAS wild-type locally advanced or metastatic pancreatic cancer: A prospective, randomized-controlled, double-blinded, multicenter, and phase III clinical trial. *First Author: Shukui Qin, Department of Medical Oncology, Cancer Center of Jinling Hospital, Nanjing, China*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

4012 **Poster Discussion Session**

A randomised phase II clinical trial of low-dose cyclophosphamide and transarterial chemoembolization (TACE) with or without vaccination with dendritic cells (DC) pulsed with HepG2 lysate ex vivo in patients with hepatocellular carcinoma (HCC): The ImmunoTACE trial. *First Author: Yuk Ting Ma, University of Birmingham, Birmingham, United Kingdom*

Background: A previous study by our group using autologous monocyte-derived DC pulsed ex vivo with HepG2 cell lysate showed some clinical benefit with evidence of antigen-specific T-cell responses in patients with advanced HCC. The current trial reports the activity of this vaccine in combination with TACE in patients with HCC. All patients also received low-dose cyclophosphamide to deplete regulatory T cells and thereby enhance vaccination. **Methods:** Patients with intermediate stage HCC (performance status 0-2, Child Pugh A/B7) were randomised 1:1 to TACE plus low-dose cyclophosphamide (Group 1) or TACE plus low-dose cyclophosphamide plus dendritic cell vaccination (Group 2). Cyclophosphamide was administered on Day 1 and 29 followed by TACE on Day 31 (+/- DC infusion), with further cyclophosphamide on Days 60, 90 and 120 (+/- additional DC infusions on Days 62, 92 and 122). The primary endpoint was progression free survival (PFS) by RECIST v1.1. Secondary endpoints included radiological response by RECIST v1.1, PFS and radiological response according to modified (m) RECIST, overall survival (OS), immune response and toxicity. Target recruitment was 48 evaluable patients (24 patients in each arm) to detect a 20% increase in PFS rate at 1 year (30% vs 50%) with a relaxed one-sided statistical significance level of 20% and 80% power using a logrank test. **Results:** Between March 2016 and October 2019, 55 patients from 3 UK centres were randomised of whom 48 were evaluable (24 each arm). Median PFS by RECIST criteria was significantly longer in Group 2 compared to Group 1 (18.6 vs 10.4 months: hazard ratio (HR) 0.43, 80% CI -∞-0.59; one-sided p = 0.02). Median PFS using mRECIST criteria showed a similar magnitude of benefit (18.6 vs 10.8 months: HR 0.48, 95% CI 0.22-1.02). Median OS was 25.7 months in Group 2 vs 21.5 months in Group 1 (HR 0.61, 95% CI 0.27-1.38). Group 2 showed a higher overall response rate (complete and partial response) by RECIST (54% vs 29%) and mRECIST (75% vs 54%) and a higher disease control rate (complete and partial response and stable disease) by RECIST (92% vs 67%) and mRECIST (88% vs 67%). Treatment with DC infusions was well tolerated; the most common adverse events were chills (30%), fatigue (22%) and nausea (22%), all of which were low grade. Immune response analyses are currently ongoing. **Conclusions:** The addition of tumour lysate pulsed DC infusions to treatment with TACE plus low-dose cyclophosphamide significantly increased PFS in patients with HCC. To the best of our knowledge, this is the first randomised study to demonstrate efficacy using DC in HCC. Further investigation of the role of DC infusions in the treatment of HCC are warranted but will need to take into account the current evolving immunotherapy landscape. Clinical trial information: 11889464. Research Sponsor: National Institute for Health Research (UK): The Efficacy and Mechanism Evaluation (EME) Programme.

4013 **Poster Discussion Session**

Postoperative adjuvant hepatic arterial infusion chemotherapy (HAIC) with FOLFOX to improve outcomes of patients with hepatocellular carcinoma with microvascular invasion: A prospective multicenter, phase 3, randomized, controlled clinical trial. *First Author: Shaohua Li, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: To report the efficacy and safety of postoperative adjuvant hepatic arterial infusion chemotherapy (HAIC) with FOLFOX (5- fluorouracil, leucovorin, and oxaliplatin) in hepatocellular carcinoma (HCC) patients with microvascular invasion (MVI). **Methods:** In this randomized, open label, multicenter, phase 3 trial, histologically confirmed HCC patients with MVI were randomized (1:1) to receive either 1 to 2 cycles of adjuvant HAIC-FOLFOX (treatment group) or routine follow-up without any adjuvant treatment (control group). The primary endpoint was disease free survival (DFS), Secondary endpoints included overall survival (OS), recurrence rate and safety. Survival rates were calculated by the Kaplan-Meier plots. Adverse events (AE) were graded according to NCI-CTCAE version 5.0. **Results:** Between June, 2016 and August, 2021, a total of 315 patients in 5 centers were enrolled in to the study and eligible patients were randomly assigned to the treatment group (n = 157) or control group (n = 158) and were included in the intention-to-treat (ITT) population. Among these 14 patients from treatment group and 15 patients from control group were excluded from the per-protocol (PP) population. 148 patients in treatment group underwent at least 1 cycle of HAIC were included in safety analyses. The median DFS of treatment group and control group were 27.0 months (95% CI, 17.0-37.0) and 11.3 months (95% CI, 7.9-14.7), respectively in ITT population, while which was 20.4 months (95% CI, 9.5-31.3) and 9.7 months (95% CI, 6.9-12.4), respectively in PP population. The DFS were significantly better in the treatment group than in the control group in both ITT population and PP population (p = 0.001 and < 0.001, respectively). The DFS rates at 1, 2, and 3-years were 64.3%, 50.4%, and 44.3% in treatment group and 47.3%, 33.3%, and 24.2% in control group, respectively in ITT population, while which were 64.0%, 48.2%, and 42.2% in treatment group and 43.3%, 27.1%, and 18.4% in control group, respectively in PP population. The OS rates at 1, 2, and 3-year for the treatment group were 94.7%, 87.6%, and 80.5%, and were 91.9%, 85.9%, and 77.0% for the control group, respectively in ITT population, while which were 94.9%, 86.7%, and 80.9% in treatment group and 91.8%, 84.9%, and 75.3% in control group, respectively in PP population. Furthermore, in ITT population, there were 63 (40.1%) patients in the treatment group and 88 (55.7%) patients in the control group had recurrence. Majority of the AEs observed were grade 0-1 (n = 124 (83.8%)) and no treatment related death was observed during the study period. **Conclusions:** Postoperative adjuvant HAIC with FOLFOX significantly improved the survival benefits with acceptable toxicities in HCC patients with MVI. Clinical trial information: NCT03192618. Research Sponsor: None.

4015 **Poster Discussion Session**

Preoperative chemoradiation (CRT) with carboplatin (CBP)/paclitaxel (PCL) (CP) or with 5-fluorouracil (FU)/oxaliplatin (OX) (Fx) for esophageal or junctional cancer: A randomized phase 2 trial. *First Author: Antoine Adenis, Department of Medical Oncology, Montpellier Cancer Institute (ICM), Montpellier, France*

Background: Preoperative CRT with a FU/platinum regimen has been used for years for esophageal or junctional cancer before the CP regimen became a standard of care following the results of the CROSS study (van Hagen 2012). We aimed at evaluating the complete resection (R0) rate and severe postoperative morbidity rate associated with these 2 neoadjuvant regimens, each being combined with the radiation (RT) regime used in the CROSS trial. **Methods:** PRODTECT is a multicenter, randomized, non-comparative, phase 2 trial (NCT02359968) in patients (pts) with resectable esophageal or Siewert type I-II junctional cancer, stage II (T1-2N1 or T3N0) or stage III (T3N1 or T4anyN) tumors (UICC-7 classification), and ECOG PS ≤2. Following randomization (balanced by ECOG PS 0 vs 1-2, stage II vs III, squamous-cell (SCC) vs adenocarcinoma (ADK), center), pts received CP (AUC2 CBP plus PCL 50mg/m^2 / week x 5 weeks), or Fx (FU 400 mg/m^2 bolus Day 1, then FU 1600 mg/m^2 continuous infusion over 2 days, plus OX 85 mg/m^2, and Folinic acid 200 mg/m^2, 2-h infusion, Day 1; 3 cycles every 2 weeks). RT technique was similar in both arms: 3D-conformal as published in the CROSS trial or IMRT (n = 35); total dose of 41.4Gy, 5 fractions of 1.8Gy / week, starting at Day 1 of chemotherapy. Surgery was performed 4 to 8 weeks after completion of CRT through a transthoracic or mini-invasive approach with a two field extended lymphadenectomy. Co-primary endpoints were R0 (failure: R1 or disease progression under CRT), and severe postoperative morbidity rate ≤30 days after surgery (Clavien-Dindo grade ≥ III). Based on a Bryant and Day 2-stage design (p0 = 75% and p1 = 90% for resection; p0 = 45% and p1 = 25% for morbidity; α = 10% and β = 15%), 48 evaluable pts were required by arm. **Results:** 100/104 pts recruited from 02/2015 to 08/2020, started the study treatment: 50 CP & 50 Fx. Overall, median age = 64 (range, 33-79); 82/100 males; 62 ADK and 38 SCC; 66 esophageal and 34 junctional site; 31 stage II; 68 stage III, 1 Nx. R0 resection was obtained in 46/50 CP pts (92.0%, 95% CI: 80.8-97.8%), and in 42/48 Fx pts (87.5%, 74.8-95.3%); 2 non evaluable pts because of event unrelated to disease progression. Severe postoperative adverse events (AEs) occurred in 34/91 pts who underwent surgery: 21/48 CP (43.8%, 29.5-58.8%) and 13/43 Fx (30.2%, 17.2-46.1%). Severe AEs were respiratory disorders (CP 26%; Fx 26%), esophageal fistula (CP 18%; Fx 6%), infection (CP 5%; Fx 3%), haemorrhage (CP 5%; Fx 0%) and gastric tube necrosis (CP 6%; Fx 3%). 5 pts died from AEs (3 CP, 2 Fx). A TRG1-2 was observed in 29/48 (60.4%, 95% CI: 44.3-74.2%) CP pts, and in 19/43 (44.2%, 29.1-60.1%) Fx pts. **Conclusions:** When combined to preoperative radiation therapy at 41.4Gy, both regimens (CP and Fx) provided short-term benefit on R0 resection; however, CP is associated with a severe postoperative morbidity rate higher than expected. Clinical trial information: NCT02359968. Research Sponsor: PHRC 2014.

4016 **Poster Discussion Session**

Nimotuzumab plus concurrent chemo-radiotherapy versus chemo-radiotherapy in unresectable locally advanced esophageal squamous cell carcinoma (ESCC): Interim analysis from a prospective, randomized-controlled, double-blinded, multicenter, and phase III clinical trial (NXCEL1311 Study). *First Author: Xue Meng, Department of Radiation Oncology, Shandong Cancer Hospital and Institute, Jinan, China*

Background: 70% of esophageal carcinoma are unresectable at diagnosis. Despite active clinical research on the treatment of esophageal squamous cell carcinoma (ESCC), the long-term survival rate of advanced patients is still very low, with a 5-year survival rate of 30%-40%. A prospective, randomized-controlled, double-blinded, multicenter, and phase III study (NXCEL1311) was designed to investigate the efficacy and safety of nimotuzumab (anti-EGFR humanized monoclonal antibody;abbreviate,Nimo) plus concurrent chemo-radiotherapy compared with placebo plus chemo-radiotherapy in unresectable locally advanced ESCC. **Methods:** Unresectable locally advanced ESCC patients were randomized (1:1) to receive Nimo (400 mg, qw) or placebo in combination with concurrent chemo-radiotherapy (paclitaxel+ cisplatin+3DCRT/IMRT) for seven weeks. Patients were followed for five years.The primary endpoints were OS, and the secondary endpoints included ORR, DCR, PFS. **Results:** 200 patients were assigned to the Nimo group (n = 99) or placebo group (n = 101). An interim analysis was conducted for short term efficacy, i.e secondary endpoints (ORR, DCR) and safety, after completing the 6 months follow-up. The OS events are not enough for analysis. The two groups were comparable on baseline characteristics. Eighty patients in the Nimo group and eighty-two patients in the placebo group were evaluable. The ORR of the Nimo group (75/80, 93.8%) was significantly higher than the placebo group (59/82, 72.0%;Chi-square test, p < 0.001). Twenty-six patients in the Nimo group reached the complete response (CR), and ten placebo group patients were CR. The CR rate in the Nimo group was significantly higher than placebo group (32.5% vs.12.2%, p = 0.002). The DCR of the Nimo group and placebo group were 98.8% (79/80) and 91.5% (75/82), respectively (p = 0.064). Single factor logistic aggression analysis showed that age, sex, target lesion number, and BMI did not affect ORR, CR, and DCR (p > 0.05). Multiple factor correction analysis showed the difference of CR, ORR and DCR between two groups is 20% (95%CI 6.0%~40.2%), 30% (95%CI 10.6%~52.1%) and 10% (95%CI -5.2%~31.1%). The incidence of grade 3-5 drug-related AEs was 11.1%vs.10.9% (p > 0.05). Common drug-related AEs in patients with Nimo plus chemo-radiotherapy treatment were leucopenia, neutrophilic granulocytopenia, thrombocytopenia, hemoglobin, bone marrow inhibition, nutritional anemia, and radioactive inflammation. **Conclusions:** This interim analysis showed that nimotuzumab in combination with chemo-radiotherapy is safe and can increase the CRR and ORR of the treated patients. The OS needs to be followed and finally analyzed. Clinical trial information: 02409186. Research Sponsor: None.

4017 **Poster Discussion Session**

Safety, tolerability, and preliminary efficacy results in patients with advanced gastric/gastroesophageal junction adenocarcinoma from a phase Ib/II study of CLDN18.2 CAR T-cell therapy (CT041). *First Author: Changsong Qi, Department of Gastrointestinal Oncology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital & Institute, Beijing, China*

Background: Claudin18.2 (CLDN18.2) has emerged as a promising therapeutic target, which is normally confined to gastric mucosa tight junctions but is often expressed in gastric/gastroesophageal junction (G/GEJ) cancer. CT041, an CLDN18.2-redirected CAR T-cell therapy, showed promising anti-tumor activity in preclinical studies (Hua J. J Natl Cancer Inst. 2019). Recently reported results of a phase I study (Qi C. Ann. Oncol 2021) showed that CT041 was well tolerated and had encouraging efficacy in previously treated patients with CLDN18.2-positive advanced G/GEJ cancer. Here we report the preliminary safety and efficacy data on patients with G/GEJ cancer in an ongoing phase Ib/II study (CT041-ST-01, NCT04581473). **Methods:** This open-label, 2-part, multicenter, phase Ib/II study was conducted to assess the safety, tolerability and efficacy of CT041 in patients with previously treated, CLDN18.2-positive advanced G/GEJ cancer. The study consisted of a dose escalation/dose-expansion phase (phase Ib) and a safety/efficacy confirmatory phase (phase II). In the dose escalation/de-escalation phase, CT041 dose levels of 2.5×10^8 and 3.75×10^8 were investigated using 3 + 3 design. The primary objective of the phase Ib part was to determine the safety, tolerability and recommended phase 2 dose (RP2D) of CT041. Data are reported as of December 22, 2021. **Results:** From November 2020 to May 2021,14 eligible patients with G/GEJ cancer were enrolled in phase Ib. The median (range) age was 44.5 (23-71); 85.7% had received 2 prior lines of treatment and 14.3% had at least 3 lines; 57.1% had ≥ 3 metastatic organs, with 92.9% had peritoneal dissemination; 64.3% had signet ring cell carcinoma. Among them, 3 received 3.75×10^8 and 11 received 2.5×10^8 dose level with up to 3 doses, respectively. Most commonly reported AEs of grade 3 or higher were hematologic toxicity related with lymphodepletion. There were no dose-limiting toxicities, treatment-related death, neurologic toxicity (ICANS) or gastrointestinal toxicities observed. Most CRS were grade 1 or 2, and only one patient experienced grade 4 CRS and fully recovered. As of the data cut-off, 8 of 14 (57.1%) patients achieved partial response (PR); 2 of 14 (14.3%) patients showed stable disease (SD). With a median follow-up time of 8.9 months (95%CI 5.91, NE), the median progression-free survival (PFS) was 5.6 months (95%CI 1.9, 7.4), and median overall survival (OS) was 10.8 months (95%CI 5.1, NE) with 7 patients still alive at last follow-up. **Conclusions:** These preliminary results suggest that CT041 had manageable safety/tolerability profile and promising efficacy in patients with previously treated advanced G/GEJ cancer. This study is ongoing with further investigation of CT041 in phase II underway. Clinical trial information: NCT04581473. Research Sponsor: CARsgen Therapeutics Ltd., Co.

4018 **Poster Discussion Session**

Comprehensive genomic and transcriptomic characterization of small bowel adenocarcinoma. *First Author: Karan Pandya, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ*

Background: Small bowel adenocarcinoma (SBA) is a rare cancer with rising incidence and worse overall survival (OS) compared to other intestinal cancers. Clinical management of SBA is primarily extrapolated from colorectal cancer (CRC). Comprehensive genomic and transcriptomic profiling of SBA will facilitate development of disease-specific therapeutic strategies. We investigated molecular alterations and association with clinical outcomes in a large cohort of SBA pts. **Methods:** Tumors were analyzed using 592 gene next-generation sequencing of DNA (592 genes or WES), RNA (WTS) and IHC (Caris). Immune infiltration was calculated by QuantiSeq. OS was calculated from treatment start/tissue collection to last contact from insurance claims. **Results:** We analyzed 823 SBA tumors: 448 primary/312 metastases, 586 duodenal (DA)/95 jejunal (JA)/38 ileal (IA). Median age of JA pts was lower (57yo) than DA (67yo) and IA (68yo). Upon subsite comparison, HER2 overexpression (2.5%) and amplification (3.6%) was only seen in DA, while HER2 mutations (mts) were most common in JA (10%) and absent in IA. IA had the lowest rate of KRAS (30%) and APC (11%) mts and highest rate of DDR mts (37%). JAs were enriched in RSPO3 fusion (19%) and BRAF mts (21%). Among BRAF mts in SBA, class 3 comprised 53%, class 2 37% and class 1 10%. MSI/dMMR was seen in 8% SBA and TMB-H in 11% with no difference among subsites. Compared to 14000 CRC tumors, SBA had significantly higher immune infiltrates regardless of MSI status (p<0.001), with highest fold change in myeloid dendritic cells (15.5), Tregs (9.4), neutrophils (3.6) and M2 Macrophages (3.5). When investigating clinical outcome of SBA pts (n=751), favorable prognostic markers included TMB^{3}8 mts/Mb (HR: 0.65, 95%CI: 0.50-0.85), mts in APC (HR: 0.76, 95% CI: 0.62-0.93), MSH6 (HR: 0.45, 95% CI: 0.20-0.99), HNF1A (HR: 0.268, 95% CI: 0.11-0.65), PRKDC (HR: 0.45, 95% CI: 0.20-1.01) and ERBB3 (HR: 0.46, 95% CI: 0.26-0.82), while TP53 (HR: 1.32, 95% CI: 1.10-1.59) and CDKN2A (HR: 1.7, 95% CI: 1.25-2.3) mts and positive PD-L1 (HR: 1.44, 95% CI: 1.09-1.90) predicted worse OS. Among SBA pts treated with chemotherapy (n=258), DA had worse OS than IA/JA (HR: 1.44, 95% CI: 1.05-1.98), which had worse OS than left-sided [LS] (HR: 1.86, 95% CI: 1.39-2.46) and right-sided [RS] CRC pts (HR: 1.35, 95% CI: 1.01-1.79). DA pts had significantly worse OS compared to LS (HR=2.97, 95% CI: 1.73-5.08) and RS (HR=1.88, 95% CI: 1.08-3.24) CRC pts. **Conclusions:** This study represents the largest SBA cohort with comprehensive genomic and transcriptomic profiling. We identified subsite-specific enrichment in targetable alterations, including HER2 overexpression/amplification in DA, BRAF/HER2 mts and RSPO3 fusions in JA, and DDR mts in IA. SBAs harbor higher immune infiltrates than CRC, suggesting active immune modulation. DA is characterized by poor overall outcomes and decreased therapeutic benefit from chemotherapy compared to LS- and RS- CRCs. Research Sponsor: None.

4019 **Poster Discussion Session**

Adjuvant gemcitabine plus cisplatin (GemCis) versus capecitabine (CAP) in patients (pts) with resected lymph node (LN)-positive extrahepatic cholangiocarcinoma (CCA): A multicenter, open-label, randomized, phase 2 study (STAMP). *First Author: Changhoon Yoo, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea*

Background: Adjuvant CAP is the standard of care for resected CCA according to the BILCAP trial. However, the prognosis of patients with resected CCA is still poor. As GemCis is the standard first-line therapy for unresectable/metastatic BTC, we investigated the role of adjuvant GemCis in resected BTC. Because BTC is heterogeneous disease according to the primary tumor site, this study included only pts with resected LN+ extrahepatic CCA. **Methods:** STAMP is a multicenter, open-label, randomized phase 2 study. Pts with ≥ 19 years, ECOG PS 0/1, adenocarcinoma of perihilar or distal bile duct, at least one regional LN metastasis (N1 or greater), complete macroscopic (R0 or R1) resection within 12 weeks before randomization were eligible. Distant metastasis or R2 disease, previous chemotherapy or radiotherapy, or a serum CA 19-9 level ≥ 100 U/mL were ineligible. Pts were randomized 1:1 to GemCis (Gem 1,000 mg/m2 IV, and Cis 25 mg/m2 IV on day 1 and 8, every 3 weeks) or CAP (1,250 mg/m2 orally twice daily on days 1-14, every 3 weeks) for 8 cycles. Tumor response was performed every 12 weeks for the first 2 years, followed by every 24 weeks for the next 3 years. Primary endpoint was disease-free survival (DFS). Secondary endpoints were overall survival (OS) and safety. This study was designed to improved 2-year DFS rates from 22% (CAP) to 40% (GemCis). Considering follow-up loss rates of 10% with a 1-sided type I error of 0.1 and a type II error of 0.2, a total of 100 patients (50 in each arm) were required. **Results:** Between JUL 2017 and NOV 2020, a total of 101 pts (50 for GemCis group and 51 for CAP group) were included in the ITT population. Perihilar and distal bile duct were primary tumor sites in 45 pts (44.6%) and 56 pts (55.4%), respectively and 32 pts (31.7%) had R1 resection. Pts characteristics were well balanced between two arms. With median follow-up duration of 28.7 mo (IQR 17.2-39.4), the 2-year DFS rates were 38.5% (1-sided 90% CI, 29.5-47.4%) in GemCis group and 25.1% (17.4-33.5%) in CAP group. The median DFS were 14.3 mo (10.7-16.5 mo) in GemCis group and 11.1 mo (8.4-12.7 mo) in CAP group (HR=0.96 [0.71-1.30], p=0.86). The median OS were 35.7 mo (29.5 mo-not estimated [NE]) in GemCis group and 35.7 mo (30.9 mo-NE) in CAP group (HR=1.08 [0.72-1.64], p=0.81). Grade 3-4 adverse events (AEs) occurred in 42 pts (84.0%) and 8 (16.0%) in GemCis and CAP groups, respectively. The most common AE of grade 3-4 was neutropenia (n = 36, 72.0%) in GemCis group and hand-foot skin reaction (n = 4, 8.0%) in CAP group. **Conclusions:** In this study including prognostically homogeneous pts population, GemCis was feasible as adjuvant therapy, but failed to improve survival outcomes compared to CAP. CAP should remain standard adjuvant therapy for resected BTC. Clinical trial information: NCT03079427. Research Sponsor: CKD pharmaceuticals and Ildong pharmaceuticals.

4020 **Poster Discussion Session**

Randomized phase II study of platinum and etoposide (EP) versus temozolomide and capecitabine (CAPTEM) in patients (pts) with advanced G3 non-small cell gastroenteropancreatic neuroendocrine neoplasms (GEPNENs): ECOG-ACRIN EA2142. *First Author: Jennifer Rachel Eads, University of Pennsylvania, Abramson Cancer Center, Philadelphia, PA*

Background: High grade (G3) GEPNENs are a rare and heterogeneous disease entity for which there is little prospective treatment data. EP chemotherapy is the treatment standard but this may not be appropriate for all G3 GEPNEN pts. CAPTEM has demonstrated activity in G3 GEPNENs and may be a promising alternative. EA2142 aimed to determine if CAPTEM was superior to EP in pts with G3 GEPNENs. **Methods:** This was a multicenter, randomized (1:1) phase II trial for pts with a locally advanced and unresectable or metastatic well differentiated G3 neuroendocrine tumor (NET) or a poorly differentiated, non-small cell G3 neuroendocrine carcinoma (NEC) of suspected gastrointestinal origin and an ECOG PS of 0-2. Pathology must have demonstrated a Ki-67 of 20-100% or at least 10 mitoses/10 high powered field. Pts were randomized to receive capecitabine 750 mg/m2 orally every 12 hours on days 1-14 and temozolomide 200 mg/m2 orally once daily on days 10-14 of a 28-day treatment cycle (Arm A) or etoposide 100 mg/m2 daily on days 1-3 with either cisplatin 25 mg/m2 daily on days 1-3 or carboplatin AUC 5 on day 1 of a 21-day treatment cycle (Arm B). Restaging scans were performed every 8 weeks and toxicity monitored per CTCAEv4. Final statistical plan was to accrue 80 pts to detect a 67% improvement in progression free survival (PFS) (primary endpoint) with CAPTEM as compared to EP, 80% power and one-sided significance level of 0.10. A planned interim analysis for efficacy and futility was conducted. **Results:** A total of 67 pts were enrolled (Arm A, n=32; Arm B, n=35). Male 58%, African American 4%, Asian 3%. Mean age 61. Among 63 eligible pts, primary tumor site pancreatic 56%, non-pancreatic 43%. Poorly differentiated 57%, well differentiated 33%, unknown 10%. Mean Ki-67 48% (Arm A), 60% (Arm B). The study was closed prior to full accrual due to futility at 57.7% information time. In the interim analysis, among 62 eligible pts, PFS, overall survival and response rate with CAPTEM were 2.43 months (mos) (95% CI 2.04, 7.72), 12.6 mos, 9% respectively vs 5.36 mos (95% CI 2.14, 7.23), 13.6 mos and 10% with EP. Toxicity was evaluable in 57 pts with Grade (G) 3/4 events occurring in 29% of pts on Arm A, 66% of pts on Arm B. G3/4 events occurring in more than 5% of pts on Arm A—febrile neutropenia (n=2); abdominal pain (n=2); diarrhea (n=2); nausea (n=2); neutropenia (n=2); dehydration (n=2) and on Arm B—anemia (n=8); febrile neutropenia (n=2); fatigue (n=2); lymphopenia (n=2); neutropenia (n=12); thrombocytopenia (n=4); leukopenia (n=6). There was one G5 event on Arm A due to sepsis. **Conclusions:** CAPTEM does not appear to be superior to EP chemotherapy as front-line treatment for pts with G3 NENs but does demonstrate a more favorable toxicity profile. Studies assessing G3 NET independently of G3 NEC are needed. Clinical trial information: NCT02595424. Research Sponsor: U.S. National Institutes of Health.

4021 **Poster Discussion Session**

A randomized phase Ib/II study of niraparib (nira) plus nivolumab (nivo) or ipilimumab (ipi) in patients (pts) with platinum-sensitive advanced pancreatic cancer (aPDAC). *First Author: Kim Anna Reiss, University of Pennsylvania Abramson Cancer Center, Philadelphia, PA*

Background: Establishing alternatives to perpetual chemotherapy for pts with aPDAC has been proposed to address inevitable chemotherapy resistance and cumulative toxicity. Poly (ADP ribose) polymerase (PARP) inhibitors have shown clinical efficacy in this setting, and preclinical data suggest that the addition of immune checkpoint blockade (ICB) may offer synergistic tumor control. We performed a randomized, phase Ib/II study of nira plus anti-PD-1 (nivo) or nira plus anti-CTLA-4 (ipi) maintenance for pts with aPDAC who had not progressed after >4 mo of platinum-based therapy. **Methods:** After discontinuation of chemotherapy, pts were randomized 1:1 to nira 200mg PO daily plus either nivo 240mg IV q2 weeks (later amended to 480mg IV q4 weeks) or ipi 3mg/kg IV q3 weeks for four doses. Nira could be escalated to 300mg PO daily if tolerated. Pts were treated until progression or unacceptable toxicity. The primary endpoint was progression free survival at six months (PFS6) in each arm. Secondary endpoints included safety, OS, ORR, and outcomes by DNA damage repair (DDR) deficiencies. Pts were evaluable for safety if they had received > 1 dose of study treatment and for efficacy if they had also received > 1 follow-up imaging study. Based on historical data, the null hypothesis of PFS6 = 44% vs a 2-sided alternative hypothesis of PFS ≠ 44% was tested. 42 pts per arm provided 81% power for testing at a 5% significance level to detect inferior PFS6 < 27% or superior PFS6 > 61%. **Results:** As of Oct 2021, 91 pts were enrolled, of whom 84 were evaluable for efficacy (44 nira/nivo; 40 nira/ipi). The median potential follow-up was 23 mos. Most common treatment-related AEs were nira/nivo: thrombocytopenia (28%), arthralgia (25%), nausea (23%), and fatigue (23%) and nira/ipi: thrombocytopenia (45%), anemia (43%), fatigue (43%), nausea, (41%), AST increase (36%), rash (34%) and ALT increase (29%). 88% of AEs were grade 1-2. Efficacy results were: nira/nivo: PFS6 20.6% (95% CI 8.3-32.9, p = 0.0002), mPFS 1.9 mo and nira/ipi: PFS6 59.6% (95% CI 44.3-74.9, p = 0.045), mPFS 8.1 mo. Fifteen pts (8 nira/nivo; 7 nira/ipi) had pathogenic variants in *BRCA* or *PALB2*. Excluding these: mPFS on nira/nivo was 1.9 mo (95% CI 1.8-1.9) and mPFS on nira/ipi was 7.6 mo (95% CI 4.0 – 11.1). **Conclusions:** In a randomized phase 1B/II study, nira/ipi as maintenance therapy met the primary endpoint of superior PFS6 while nira/nivo yielded inferior PFS6 for pts with aPDAC who had not progressed on first-line platinum-based chemotherapy. The benefit of nira/ipi maintenance persisted in pts without known DDR variants. Clinical trial information: NCT03404960. Research Sponsor: Glaxo-Smith-Kline and Bristol-Myer-Squibb.

4022 **Oral Abstract Session**

Sequential *nab*-paclitaxel/gemcitabine followed by modified FOLFOX for first-line metastatic pancreatic cancer: The SEQUENCE trial. *First Author: Alfredo Carrato, IRYCIS, CIBERONC, Alcalá University, Hospital Universitario Ramón y Cajal, Madrid, Spain*

Background: Sequential treatment with nab-paclitaxel, gemcitabine followed by oxaliplatin, leucovorin and 5-fluorouracil (*nab*-P/Gem-mFOLFOX) have shown a good safety profile and clinical activity in metastatic pancreatic ductal adenocarcinoma (mPDAC) in a previously published phase I SEQUENCE trial. **Methods:** We have compared nab-P/Gem-mFOLFOX to the standard *nab*-P/Gem in first-line treatment, in an open-label multi-institutional prospective randomised phase II trial in patients with untreated mPDAC from 14 Spanish hospitals. Patients were allocated 1:1 to *nab*-paclitaxel (125 mg/m^2) plus gemcitabine (1000 mg/m^2) on days 1, 8 and 15, followed by modified FOLFOX-6 (oxaliplatin [85 mg/m^2], L-leucovorin [200 mg/m^2] or racemic leucovorin [400 mg/m^2], 5-fluorouracil bolus [400 mg/m^2], and 5-fluorouracil 48-hour continuous infusion [2400 mg/m^2]) on day 29 of a 6-week cycle or *nab*-paclitaxel (125 mg/m^2) plus gemcitabine (1000 mg/m^2) on days 1, 8 and 15 of a 4-week cycle. The primary endpoint was the 12-month overall survival rate (OS) in randomised patients. EudraCT number 2014-005350-19; ClinicalTrial.gov identifier NCT02504333. **Results:** Between July 27, 2017, and April 16, 2019, 182 patients were screened and 157 randomised: 78 to *nab*-P/Gem-mFOLFOX and 79 to *nab*-P/Gem. Patients receiving *nab*-P/Gem-mFOLFOX showed a significantly higher 12-month, and 24-month OS (95% CI): 55.3% (44.2-66.5%) versus 35.4% (24.9-46.0%) (p = 0.016), and 22.4% (13.0-31.8%) versus 7.6% (1.8-13.4%) (p = 0.012), respectively. The median OS (95% CI) reached 13.2 (10.1-16.2) months with nab-P/Gem-mFOLFOX and 9.7 (7.5-12.0) months with nab-P/Gem (HR = 0.676, 95% CI 0.483-0.947, p = 0.023). 39.7% patients in the nab-P/Gem-mFOLFOX group and 54.4% in nab-P/Gem group received subsequent anticancer treatments. Safety was comparable except for grade ≥3 neutropenia (46.1% versus 24.1%, p = 0.004) and grade ≥3 thrombocytopenia (23.7% versus 7.6%, p = 0.007) that were higher in the *nab*-P/Gem-mFOLFOX regimen. Two (2.6%) patients died due to adverse events in the *nab*-P/Gem-mFOLFOX arm. **Conclusions:** *Nab*-P/Gem-mFOLFOX showed significantly higher clinical activity than the standard *nab*-P/Gem treatment, with a manageable safety profile. This regimen represents a feasible and efficient new option for first-line treatment of mPDAC. Clinical trial information: NCT02504333. Research Sponsor: Celgene (a Bristol Myers Squibb Company).

4023 **Poster Discussion Session**

Phase 3, multicenter, randomized study of CPI-613 with modified FOLFIRINOX (mFFX) versus FOLFIRINOX (FFX) as first-line therapy for patients with metastatic adenocarcinoma of the pancreas (AVENGER500). *First Author: Philip Agop Philip, Karmanos Cancer Center, Wayne State University, and SWOG, Farmington Hills, MI*

Background: Metastatic pancreatic cancer (mPC) remains a deadly disease with very limited treatment options. FFX is a standard first-line therapy for mPC with a median overall survival (mOS) of 11.1 months. CPI-613 is a stable intermediate of a lipoate analog that inhibits pyruvate dehydrogenase and α-ketoglutarate dehydrogenase enzymes of the tricarboxylic cycle preferentially within the mitochondria of cancer cells. In a phase I study, CPI-613+mFFX was safe and exhibited promising signal of efficacy. **Methods:** A global, randomized phase 3 trial was conducted across 73 sites to investigate the efficacy and safety of CPI-613 in combination with mFFX compared to standard dose FFX in treatment-naïve patients with mPC. Treatment was administered in 2-weekly cycles until progression or intolerable toxicity. In the experimental arm, CPI-613 at 500 mg/m^2 was given intravenously on days 1 and 3. The doses of irinotecan, oxaliplatin, and 5-fluorouracil in the experimental arm were 65 mg/m^2, 140 mg/m^2, and 2,400 mg/^{2}, respectively. Primary endpoint was OS. Secondary endpoints were progression-free survival (PFS), overall response rate (ORR), duration of response, pharmacokinetics, patient reported outcomes and safety. **Results:** 528 patients were randomly assigned (266 in test and 262 in control arm). There were 362 deaths, with a mOS of 11.1 months for CPI-613+mFFX vs. 11.7 months for FFX [hazard ratio (HR), 0.95; 95% CI, 0.77 to 1.18; P = 0.655]; mPFS was 7.8 months vs. 8.0 months respectively [HR, 0.99; 95% CI, 0.76 to 1.29; P = 0.94]; ORR was 39% in the test arm vs. 34% in the control arm [ORR ratio, 1.23 (95% CI, 0.86 to 1.75)]. Grade $\geq$ 3 treatment-emergent adverse events with $\geq$ 10% frequency in CPI-613 plus mFFX vs. FFX arm were diarrhea (11.2% vs. 19.6%), hypokalemia (13.1% vs. 14.9%), anemia (13.9% vs. 13.6%), neutropenia (11.2% vs. 14.0%), thrombocytopenia (11.6% vs. 13.6%) and fatigue (10.8% vs. 11.5%). **Conclusions:** The addition of CPI-613 to mFFX failed to show significant improvements of ORR, PFS or OS. The mFFX in the test arm that had the lowest prospectively tested doses of FFX was without compromise on PFS or OS and may be considered as a reference for future FFX administration. Clinical trial information: NCT03504423. Research Sponsor: Rafael.

4024 **Poster Session**

Molecular characterization of long-term and short-term survivors of advanced pancreatic ductal adenocarcinoma. *First Author: Jesús Fuentes Antrás, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, University Health Network, Toronto, Canada*

Background: Median overall survival (mOS) for advanced pancreatic ductal adenocarcinoma (PDAC) is $\leq$1 year. However, there are patients (pts) who live for >2 years on chemotherapy and those who rapidly progress prior to a first scan, underscoring biological heterogeneity in PDAC subgroups. Understanding these differences is important in clinical trial design and provides prognostic information for pts. **Methods:** Clinical and molecular data (WGS and RNAseq) from pts with a diagnosis of locally advanced or metastatic PDAC enrolled in the COMPASS (NCT02750657) and POG/PanGen (NCT02155621, NCT02869802) studies were available for analysis as part of the TFRI's EPPIC program and Marathon of Hope Cancer Centres Network, a multi-institutional collaborative network aiming to implement precision medicine in Canada. Clinical data were collected prospectively from both cohorts. Pts had an ECOG PS 0-1 and chemotherapy regimen was based on clinician's preference. Profiling was performed on fresh biopsies and homologous recombination deficiency was identified with the HRDetect assay. We compared pts with very short OS (STS; $\leq$3 months, mo) vs long OS (LTS; $\geq$24 mo). **Results:** 341 pts were included in the analysis of which 47 were STS (mOS 1.6 mo) and 42 LTS (mOS 29.7 mo). There was no difference in median age, BMI or sex (p>0.1) between cohorts. STS were more likely to have an ECOG PS 1 vs 0 (p=0.03), higher tumor burden (RECIST) (p<0.001) and higher CA19.9 (p=0.04) at diagnosis. In STS, 71% had non evaluable responses as a result of clinical decline or death before first scan, and 28% PD as best response; in LTS, ORR to chemotherapy was 69%. Sixty-four % and 33% of LTS and 32% and 36% of STS had received mFFX and GA, respectively. There was no difference in the prevalence of *KRAS* mutations (90% vs 98%, ns) or specific mutant alleles, however amplification of mutant *KRAS* was more common in STS (35% vs 65%, p=0.01). The prevalence of inactivating driver mutations in *TP53*, *CDKN2A*, and *SMAD4* (90% vs 98%, ns), and in genes involved in chromatin modification (*ARID1A*, *SMARCA4*, *PBRM1*, *KDM6A*) (17% vs 30%, ns) was similar in both groups. However, STS had a higher prevalence of mutations resulting in activation of the PI3K/AKT/mTOR pathway (*PIK3CA*, *PTEN* loss, *STK11*) (10% vs 26%, p=0.049). Genotypes consistent with HRD were present (17% vs 11%); however, in LTS 6/7 were a result of germline pathogenic variants, compared with only 1/5 in STS. Median structural variant loads, ploidy, TMB and substitution base signatures were similar in both cohorts. More basal-like PDAC were present in STS vs LTS (3% vs 30%, p=0.006). **Conclusions:** Pts who survive $\leq$3 mo with advanced PDAC are characterized by a higher tumor burden and molecular profiles consistent with enhanced RAS signaling, a deregulation of the PI3K/AKT/mTOR pathway, and a basal-like transcriptomic subtype. HRD genotypes are heterogeneous with germline carriers accounting for some of the LTS. Research Sponsor: Ontario Institute of Cancer Research; Pancreatic Cancer Canada; Terry Fox Foundation.

The association of B7-H6 expression to the immune microenvironment in gastric cancer. *First Author: Jian Chen, The Affiliated Yantai Yuhuangding Hospital of Qingdao University, Yantai, China*

Background: B7-H6, also known as NCR3LG1, is a promising molecule in B7 family and a ligand of natural killer (NK) -cell-activating receptor NKp30. B7-H6 can bind NKp30 and induce NK activation and cytokine secretion to exert anti-tumor effects. Studies have reported that the B7-H6 expression is significantly correlated with post-operative prognosis and distant metastasis status in patients with cancer. In patients with gastric cancer, B7-H6 high expression is significantly associated with longer OS. However, the effects of B7-H6 on immunotherapy and immune microenvironment are unknown. Herein, we used the data from TCGA database of gastric cancer to analyze the influence of B7-H6 expression on immune microenvironment. **Methods:** The gene expression profile and clinical data in gastric cancer were extracted from TCGA database (http://cancergenome.nih.gov). According to the previous reported article, 15 was chosen as the cutoff value for the expression of B7-H6, and the expression of B7-H6 is divided into two groups, high group (B7-H6 expression $>$ 15) and low group (B7-H6 expression$\leq$15). Kaplan-Meier analysis was used to verify the influence of B7-H6 expression on OS prognosis. "Cell Type Identification by Estimating Relative Subsets of RNA Transcripts" (CIBERSORT) algorithm was used to analyze the proportion of immune-related cells in the two groups. "Estimation of STromal and Immune cells in Malignant Tumours using Expression data" (ESTIMATE) algorithm was used to analyze stromal and immune scores in the two groups. The differences of immune-related signatures between the two groups were calculated according to previous reports. **Results:** Kaplan-Meier survival analysis showed that high group was significantly associated with longer overall survival (p value = 0.016), which was consistent with previous reports. The result of CIBERSORT algorithm showed that the proportion of activation immune correlation CD8(+) T cells and NK active cells was significantly higher in low group than in high group ($p < 0.05$). Meanwhile, the proportion of immune suppressive correlation CD4 resting memory T cell was significantly lower in low group than in high group ($p < 0.05$). The result of ESTIMATE algorithm showed that the stromal score, immune score, and ESTIMATE score in low group were significantly higher than in high group ($p < 0.01$). The immune-related signatures, including immune signature, expanded immune signature, TLS signature, myeloid cell chemotaxis, tertiary lymphoid structure, were significantly higher in low group than in high group ($p < 0.05$). **Conclusions:** The low B7-H6 expression was correlated with better immune microenvironment. The effect of B7-H6 expression on immunotherapy needs to be further explored. Research Sponsor: None.

Choice of PD-L1 immunohistochemistry assay influences clinical eligibility for gastric cancer immunotherapy. *First Author: Ryan Yong Kiat Tay, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore*

Background: Immune checkpoint inhibitors (ICI) are now standard-of-care treatment for patients with metastatic gastric cancer (GC). To guide patient selection for ICI therapy, programmed death ligand-1 (PD-L1) biomarker expression is routinely assessed via immunohistochemistry (IHC). Regulatory approval for ICIs is granted based on PD-L1 expression status, scored using metrics such as the combined positive score (CPS). However, with an increasing number of approved ICIs, each paired with a different PD-L1 antibody IHC assay used in their respective landmark trials, there is an unmet clinical and logistical need for harmonization. We thus investigated the interchangeability between the Dako 22C3, Dako 28-8 and Ventana SP-142 assays in GC PD-L1 IHC. **Methods:** In this cross-sectional study, samples were obtained via biopsy or resection of gastric cancer at the National University Hospital, Singapore. We scored 362 GC samples for PD-L1 CPS, tumor proportion score (TPS) and immune cells (IC) using a multiplex immunohistochemistry/immunofluorescence technique. 344 samples were developed into a tissue microarray (TMA), while 18 samples were used as whole slides for orthogonal validation. The samples selected for whole slide analysis were obtained from GC patients treated with ICI therapy. **Results:** The percentage of PD-L1 positive samples at clinically relevant CPS $\geq$1, $\geq$5 and $\geq$10 cut-offs (Table) for the 28-8 assay were approximately two-fold higher than that of the 22C3 (CPS$\geq$1: 70.3% vs 49.4%, p<0.001; CPS$\geq$5: 29.1% vs 13.4%, p<0.001; CPS$\geq$10: 13.7% vs 7.0%, p=0.004). The mean CPS score on 28-8 assay was nearly double that of the 22C3 (6.39 $\pm$14.5 vs 3.46$\pm$8.98, p<0.001). At the clinically important CPS$\geq$5 cut-off, there was only moderate concordance between the 22C3 and 28-8 assays. **Conclusions:** Our findings suggest that scoring PD-L1 CPS with the 28-8 assay may result in higher proportion of PD-L1 positivity and higher PD-L1 scores compared to assessment with the 22C3 and other assays. Clinically, this could lead to a larger number of patients eligible and approved for ICI therapy. If assays are viewed and used interchangeability, a substantial number of patients may be inaccurately denied or granted treatment with ICIs based on the assay chosen. As such, until stronger evidence of inter-assay concordance is found, we urge caution in treating the assays as equivalent. Research Sponsor: National Medical Research Council.

The percentage of PD-L1 positive samples at clinically relevant CPS $\geq$1, $\geq$5 and $\geq$10 cut-offs.

Assay	CPS $\geq$1	CPS $\geq$5	CPS $\geq$10
22C3	49.4%	13.4%	7.0%
28-8	70.3%	29.1%	13.7%
SP-142	49.4%	19.8%	9.6%

Combination of oligo-fractionated irradiation with nivolumab can induce immune modulation and replacement of T cell clones in patients with gastric cancer (phase I/II clinical study). *First Author: Koji Kono, Fukushima Medical University, Fukushima, Japan*

Background: Although basic, translational and clinical research suggest a possibility of synergistic effect of radiation-induced immunogenic cell death with immune checkpoint inhibitors, the effectiveness of the combination therapy is not fully established. Therefore, we conducted a single-arm, phase 1/2 trial (ClinicalTrials.gov, NCT03453164) in gastric cancer (GC) patients treated with a combination of nivolumab and oligo-fractionated irradiation (22.5 Gy/5 fractions/5 days). **Methods:** Eligible patients (n = 40) had un-resectable advanced or recurrent GC which progressed after primary and secondary chemotherapy with more than one lesion assessable in diagnostic imaging (one lesion must be ≥2cm). PBMCs from enrolled patients underwent high-dimensional flow cytometry-based, multiplexed MHC multimer analysis using a total of 46 tumor-associated antigens (TAA) and 10 virus epitopes and next-generation sequencing-based repertoire analysis of TCR β-chain. **Results:** The disease control rate (DCR) for the non-irradiated target as abscopal effect as the primary endpoint was 22.5%, and the DCR for the irradiated lesion was 40.0%. The median survival time was 230 days (157-330 days, 95%CI) and probability of 1-year survival rate was 28.6%. Although most TAA-specific T cells could be tracked longitudinally pre- and post-treatment, some several novel TAA-specific CD8 T cells were detected de novo after irradiation, indicating that potential irradiation-driven antigen spreading. Moreover, irradiation was associated with phenotypical changes of TAA-specific CD8 T cells towards higher expressions of KLRG1, HLA-DR, TIGIT and CD160 and lower expression of CD27 and CD127. Furthermore, the T cell clonality evaluated by the inverted Pielou's evenness indicated that longer survival patients had more diverse TCR beta repertoire during treatment in comparison to shorter survivors. Also, we confirmed several new sequence-reads after radiation and nivolumab treatment in the top 30 most frequent clonotypes. **Conclusions:** Taken together, our results suggest that irradiation may induce, through immunogenic cell death, an immune-modulating effect with potential antigen spreading and a more diverse TCR repertoire, ultimately resulting in better survival during combination therapy of radiation with nivolumab. Clinical trial information: NCT03453164. Research Sponsor: Ono Pharmaceutical company.

VOYAGER (KSCC1902): A single-arm, multicenter, phase II study of early induction of nivolumab during second-line treatment with taxane ± ramucirumab for advanced gastric or gastro-esophageal junction cancer. *First Author: Hiroo Katsuya, Division of Hematology, Respiratory Medicine and Oncology, Department of Internal Medicine, Faculty of Medicine, Saga University, Saga, Japan*

Background: Although nivolumab prolonged overall survival in 3rd or later line treatment for advanced gastric cancer in the ATTRACTION-2 study, only a small number of patients respond or achieve stable disease. Previous reports have shown that low tumor burden at the start of treatment was potentially associated with efficacy to immunotherapy in some types of tumors, but it has not been studied in advanced gastric cancer. We conducted a clinical trial to evaluate the early induction of nivolumab. **Methods:** Eligible patients were unresectable advanced or recurrent gastric or gastro-esophageal junction cancer, histologically confirmed to be adenocarcinoma regardless of PD-L1 expression. Patients who were refractory to or intolerant of fluoropyrimidines had a complete or partial response after at least three cycles of taxane ± ramucirumab, and were confirmed to be either of the following conditions; disease progression by imaging tests, an increase of tumor markers, exacerbation of symptoms, and intolerant of pretreatment. Patients received 240mg/body nivolumab every 2 weeks. The primary endpoint was the rate of progression-free survival (PFS) at 6 months (M), and the secondary endpoints included safety, overall survival (OS), response rate (RR), time to treatment failure (TTF), and duration of response (DOR). Based on assuming a threshold PFS at 6M of 16% and an expected PFS of 30% with the early induction of nivolumab, 39 patients were required for a power of 0.8 with a one-sided α of 0.1. **Results:** Between September 2019 and February 2021, 42 patients were enrolled in this study. The characteristics of patients were male/female: 28/14, median age: 71 years (range: 39-87), and performance status 0/1/2: 21/19/2. The PFS at 6M was 35.7% (80% confidence interval 26.4-45.1%), which means this trial met the primary endpoint. The median PFS and OS were 4.0M (95%CI:2.3–5.7) and 10.9M (95%CI:9.9–16.0), respectively. Of 34 patients with baseline target legions, RR was 17.5% (all confirmed partial response) and the rate of stable disease was 41.2%. TTF, and DOR were 3.6M (95%CI:2.2–5.1), and 14.3M (95%CI:3.9–14.3), respectively. No new safety signals were observed. **Conclusions:** This study demonstrated an improvement of PFS at 6M in patients with advanced gastric cancer and might justify the strategy of early induction of nivolumab. Clinical trial information: jRCTs071190025. Research Sponsor: Ono Pharmaceutical.

Durvalumab (D) and PET-directed chemoradiation (CRT) after induction FOLFOX for esophageal adenocarcinoma: Final results. *First Author: Darren Cowzer, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Induction FOLFOX followed by PET-directed CRT prior to surgery demonstrated positive results in the CALGB 80803 study. We investigated the safety and efficacy of adding D, an anti-PD-L1 antibody, to PET-directed CRT. **Methods:** Patients (pts) with locally advanced esophageal/GEJ adenocarcinoma were enrolled. Pts received 2 cycles of mFOLFOX6 prior to repeat PET/CT. PET responders (≥35% reduction in SUV (PETr)) received 5-FU/capecitabine and oxaliplatin with RT to 50.4Gy, while induction PET non-responders (PETnr) received carboplatin/paclitaxel with RT. All Pts received D 1,500 mg q4W ×2 starting 2 weeks prior to CRT. Esophagectomy was planned 6-8 weeks after CRT. Pts with R0 resections received adjuvant D 1,500mg q4W ×6. The primary endpoint was the pathologic complete response (pCR) rate. **Results:** 36 pts were enrolled. Clinical ≥T3 disease was seen in 32 pts (88.9%, cT4 = 3) and ≥N1 in 23 (63.9%) pts. PD-L1 CPS was ≥1 in 25 (71.4%) of 35 tested with 14 (40%) ≥5. Microsatellite instability (MSI) was identified in 3 (8.3%) pts. 25 (70%) pts were PETr. Preop treatment was well tolerated with no new safety signals. Three pts had disease progression prior to surgery. pCR was identified in 8 (22.2%) pts and 22 (64.7%) had major pathologic response (MPR; ypTanyN0 + ≥90% response). Those with MSI tumors had ≥90% treatment response (1 pCR, 1: ypT1aN0 99% response, 1: ypT2N0, 90% response). 17 (73.9%) of 23 cN+ pts had ypN0 disease. MPR was associated with PD-L1 ≥1 (p = 0.03) and with a higher tumor mutational burden (TMB; p = 0.016) on MSK-IMPACT testing. Adjuvant D was commenced in 27 pts, with a median number of 6 cycles. Early discontinuation was due to risks of visits due to COVID19 (4, 15%), progressive disease (3, 11%), late surgical complications (2, 7%) and immune toxicity (1, 4%). With a median follow-up of 30 months, OS rates were 92% [95%CI: 83%-100%] and 85 % [95%CI: 74%-98%] at 12 and 24 months post induction. 12 and 24-month PFS rates were 81% [95%CI: 69%-95%] and 71% [95%CI: 58%-88%] respectively. In the 33 operated pts, 12 and 24-month disease free survival was 82% [95%CI: 70%-96%] and 78% [95%CI: 65%-94%], respectively. In addition to SUV on PET, total lesion glycolysis (TLG) was correlated with pathologic response. In cases with borderline change in SUV, TLG could predict response to treatment. One PETnr with 30.8% reduction in SUV had 88.1% reduction in TLG and pCR. Conversely, a PETr (-36.3%) who had an increase in TLG (39.3%) had only 40% treatment response on pathology. **Conclusions:** The addition of D to induction FOLFOX and PET-directed CRT prior to surgery is safe and appears effective with a high rate of pathologic response, as well as encouraging survival data. PD-L1 CPS≥1 and higher TMB may be associated with MPR. TLG is a novel PET variable that should be studied prospectively. Additional correlatives and comparison to a cohort treated with standard PET-directed CRT will be presented. Clinical trial information: NCT02962063. Research Sponsor: Astra Zeneca, Other Foundation.

Tandem CAR-T cells targeting CLDN18.2 and NKG2DL for treatment of gastric cancer. *First Author: Hui Xu, Nanjing Kaedi Biotherapeutics Co. Ltd., Nanjing, China*

Background: Gastric cancer (GC) is one of most common malignant tumor which is fifth for melanoma incidence and second for mortality rates worldwide. Novel therapeutic strategies are urgently needed. Recently people are exploring the potential of chimeric antigen receptor T (CAR-T) cell therapy in GC, yet the clinical outcome is limited. Reportedly, the bispecific CAR-T cell with tandem scFvs exhibited superior response rates or synergistic response compared with CAR-T cell with single scFv. It's reported that Claudin18.2 (CLDN18.2) is the most potential target of gastric cancer. Here, we construct a novel bispecific CAR-T cells (KD-496), which simultaneously recognize NKG2D ligands and CLDN18.2, to show superior antitumor efficacy and safety *in vitro* and *in vivo*. **Methods:** Gastric cancer cell lines as well as GC patient tissue samples were evaluated for NKG2DL and CLDN18.2 expression. The KD-496 CAR-T cells showed antigen-specific stimulation by cytokine secretion and tumor cell cytotoxicity assay. The patient tumor tissue fragments (8 mm^3) were implanted subcutaneously into B-NDG mice to establish PDX models. When the tumor volume reached 50-100mm^3, the mice received a single treatment of 5 million KD-496 CAR-T cells intravenously. The effect of KD-496 CAR-T *in vivo* was detected by measuring tumor volume twice a week. **Results:** CLDN18.2 and NKG2DL were detected on NUGC4, AGS-18.2 and MKN-28-18.2 cells and most of screened BM patient samples. The bispecific CAR-T cell KD-496 was generated with CD8 hinge region and transmembrane region, 4-1BB costimulatory region and CD3 zeta region. The KD-496 expression was > 50% on the surface of T cells confirmed by flow cytometry. Co-incubation of KD-496 CAR-T cells with NUGC4 and MKN-28-18.2 cell specifically upregulates IFN-γ cytokines and strongly lysis tumor cells even at low E:T ratio (50-60% at 4:1). Strikingly, KD-496 CAR more efficiently eliminated xenograft tumors in vivo and did not exhibit significant treatment-related toxicity in the treated mice. No obvious pathological changes were found in the tested organs. **Conclusions:** Our work construct a tandem CAR molecule targeting two tumor-associated antigens, NKG2DL and CLDN18.2, and found that Tan-CAR-T cells (KD-496) distinctly recognize the antigens and exhibited superior antitumor effect. KD-496 CAR-T cells potently respond to GC and more efficient tumor elimination than single CAR such as KD-025 and KD-182 CAR-T cells in PDX model with no obvious safety issue. The results support future clinical trial of KD-496 CAR in patients with GC, where the need for effective treatment is great. Research Sponsor: Nanjing Kaedi Biotherapeutics Co. Ltd.

Perioperative chemotherapy with docetaxel plus oxaliplatin and S-1 (DOS) versus oxaliplatin plus S-1 (SOX) for locally advanced gastric or gastro-esophageal junction adenocarcinoma (MATCH): An open-label, randomized, phase 2 study. *First Author: Wen Zhang, Department of Medical Oncology, National Cancer Center/ National Clinical Research Center for Cancer/ Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: The optimal perioperative chemotherapy of locally advanced gastric or gastro-esophageal junction (G/GEJ) cancer has not been established in Asia, though FLOT was considered as standard therapy in Europe. Therefore, we aimed to assess efficacy and safety of DOS versus SOX as perioperative treatment in patients with locally advanced G/GEJ cancer in this study. **Methods:** This was a single center, open-label, randomized, phase 2 study. Eligible pts were aged ≥18 years with histologically diagnosed HER2 negative cT3-4 Nany M0 G/GEJ (Siewert II/III type) adenocarcinoma. Pts were randomized (1:1) to receive either 4 preoperative and 4 postoperative cycles of DOS (docetaxel 60mg/m2 D1, oxaliplatin 100mg/m2 D1, S-1 40-60mg bid D1-14 depending on body surface area (BSA), Q3W) or SOX (oxaliplatin 130mg/m2 D1, S-1 40-60mg bid D1-14 depending on BSA, Q3W). Pts underwent D2 gastrectomy after preoperative treatment. The primary endpoint was major pathological response (MPR) analyzed in the modified intention to treat (mITT) population according to Becker TRG criteria. Secondary endpoints included the 3-year progression free survival (PFS), the 3-year overall survival (OS), pathological complete response, R0 resection rate and safety. **Results:** From Aug, 2015, to Dec, 2019, 154 pts were enrolled, 7 pts withdrew consent, 147 pts were included as mITT population (DOS 71; SOX 76). 80.3% and 67.1% of the pts in the DOS and SOX groups accepted surgery respectively. More pts achieved MPR (25.4% vs. 11.8%, p = 0.035) and R0 resection (78.9% vs. 61.8%, p = 0.024) in the DOS group than the SOX group. With a median follow-up of 42.4 months, the 3-year PFS and the 3-year OS were 52.3% vs. 35% (p = 0.065, HR 0.667, 95%CI 0.432-1.029) and 57.5% vs. 49.2% (p = 0.114, HR 0.685, 95%CI 0.429-1.095) in the DOS and SOX groups, respectively. Pts who acquired MPR had a significant longer survival than non-MPR pts. The 3-year PFS were 89.4% vs. 38.6% (p < 0.001, HR 0.076, 95%CI 0.018-0.314). The 3-year OS were 100% vs. 50.1% (p = 0.008, HR 0.024, 95%CI 0.002-0.371). 56.1% and 60.8% of the pts completed at least 6 cycles of the perioperative chemotherapy in the DOS and SOX groups, respectively (p = 0.625). The most common grade ≥3 TRAEs included neutropenia (8.5% vs.10.5%), leucopenia (1.4% vs. 5.3%), thrombocytopenia (1.4% vs 15.8%, p = 0.002), anemia (1.4% vs. 3.9%) and diarrhea (1.4% vs. 2.6%). The incidence of grade 1-2 thrombocytopenia was also significant lower in the DOS group (15.5% vs. 31.6%, p = 0.022). No treatment-related deaths occurred. **Conclusions:** Perioperative DOS improved MPR significantly and tended to have better PFS compared with SOX in locally advanced G/GEJ cancer, might be regarded as a prefered option of perioperative chemotherapy. Clinical trial information: NCT02725424. Research Sponsor: None.

4032 **Poster Session**

Zanidatamab (zani), a HER2-targeted bispecific antibody, in combination with chemotherapy (chemo) and tislelizumab (TIS) as first-line (1L) therapy for patients (pts) with advanced HER2-positive gastric/gastroesophageal junction adenocarcinoma (G/GEJC): Preliminary results from a phase 1b/2 study. *First Author: Keun-Wook Lee, Department of Internal Medicine, Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam, South Korea*

Background: Zani, also known as ZW25, is a novel HER2-targeted bispecific antibody that targets two distinct extracellular domains of HER2. Zani has shown preliminary antitumor activity and tolerability in pts with HER2+ gastroesophageal adenocarcinoma as monotherapy/with chemo in Phase 1/2 studies (NCT02892123, NCT03929666). TIS, an anti-PD-1 antibody, has demonstrated antitumor activity in pts with advanced solid tumors. Combining anti-HER2 therapy with anti-PD-1 therapy and chemo increased tumor response in G/GEJC in a Phase 3 clinical trial. **Methods:** Cohort 2 of this ongoing open-label, Phase 1b/2 study was in pts with untreated locally advanced/metastatic HER2+ G/GEJC (NCT04276493). Cohort A received zani 30 mg/kg IV, Cohort B received zani 1800 mg IV (weight < 70 kg) or 2400 mg IV (weight ≥ 70 kg), both with TIS 200 mg IV and capecitabine/oxaliplatin (CAPOX) Q3W. Primary endpoints were safety and investigator (INV)-assessed objective response rate (ORR) per RECIST v1.1. Secondary endpoints included INV-assessed duration of response (DoR), disease control rate (DCR) and progression-free survival (PFS). **Results:** As of Nov 26, 2021, 33 pts with a median age of 64.0 years (range: 29.0–80.0) were assigned to Cohort A (n=19) or B (n=14). Median study follow-up was 7.7 months (range: 2.1–19.0) and the median number of treatment cycles was 10 (range: 1–28), 20 (60.6%) pts remained on treatment. All pts were efficacy evaluable ([EE], n=33), confirmed ORR was 72.7% (95% CI: 54.5, 86.7). Median PFS was 10.9 months (95% CI: 6.9, NE). Efficacy data are summarized in the Table. All pts experienced ≥ 1 treatment emergent adverse event (TEAE), and 24 (72.7%) pts experienced ≥ Grade 3 TEAEs. All pts experienced treatment related TEAEs (trTEAEs), 20 (60.6%) pts experienced ≥ Grade 3 trTEAEs and trTEAEs leading to death occurred in two (6.1%) pts. Immune-mediated AEs (imAEs) occurred in nine (27.3%) pts, of which seven (21.2%) pts experienced ≥ Grade 3 imAEs. **Conclusions:** Zani, TIS and CAPOX combination demonstrated a manageable safety profile and antitumor activity as 1L therapy for pts with HER2+ G/GEJC. Clinical trial information: NCT04276493. Research Sponsor: This study was sponsored by BeiGene, Ltd. Medical writing support for the development of this abstract, under the direction of the authors, was provided by Victoria Dagwell, MSc, of Ashfield MedComms, an Ashfield Health company, and was funded by BeiGene,.

Summary of efficacy results (EE analysis set).

	Cohort A (n=19)	Cohort B (n=14)	Total (n=33)
Confirmed best overall response, n (%)			
Complete response	1 (5.3)	0 (0)	1 (3.0)
Partial response	13 (68.4)	10 (71.4)	23 (69.7)
Stable disease*	5 (26.3)	4 (28.6)	9 (27.3)
Progressive disease	0 (0)	0 (0)	0 (0)
Confirmed ORR, n (%)	14 (73.7)	10 (71.4)	24 (72.7)

Effect of neutrophil extracellular traps on tumor lymph nodes. *First Author: Xin Su, RI-MUHC, Montreal, QC, Canada*

Background: In most human cancers, regional lymph nodes (LNs) are the first sites of metastasis. In addition to being an important part of the tumor staging system, with the advent of novel therapies, lymph node metastasis has become a crucial clinical intervention point before distant metastasis, the leading cause of cancer-associated deaths. To initiate metastasis, the conditions of LNs need to be optimized for tumor cell deposition and growth. This process is believed to be mediated by the activation of immune cells including polymorphonuclear neutrophils (PMNs). However, the cellular mechanism is not well defined. Our early observations suggest that PMNs and neutrophil extracellular traps (NETs), DNA comprising structures that are extruded in response to inflammatory cues, are associated with adverse oncologic outcomes. Thus, one potential mechanism of increased LN metastasis is that tEVs recruit PMNs and propend NETs formation. **Methods:** Human tissue micro-arrays (TMAs) of gastroesophageal (GEA) cancer patients were stained with PMN and NETs markers and quantified by HALO software. C57BL/6 or *pad4-/-* mice were injected with B16F10 or H59 cells alone or treated with neutrophil elastase inhibitor (NEi) or PMN depletion antibody. LN sections were stained with NETs markers and quantified by ImageJ (NIH). **Results:** In the study of 175 GEA cancer patients, lymphatic NET deposition was observed in both tumor infiltrated lymph nodes and tumor negative lymph nodes. We also demonstrated high LN NETs deposition was associated with reduced survival, even in the absence of overt metastasis (p=0.03). Next, we sought to investigate the dynamic and the consequence of LN NETs deposition using animal models. We found that LN Neutrophil Recruitment and NET deposition happens in a pre-metastatic manner. Moreover, LN metastasis was abrogated through different kinds of NETs inhibition (neutrophil depletion, *pad4* knockout and NEi treatment, n=10, p<0.001), demonstrating the consequences of LN NETs deposition and its potential as a treatment target. Finally, we showed that the LN PMN recruitment and NETs formation was mediated by increased production of IL-8 by Lymphatic Endothelial Cells (LEC). **Conclusions:** Together, we demonstrated that NETs can contribute to LN metastasis, and can serve as a potential therapeutic targets. By further investigating the detailed mechanism, this project will lead to major advances in the management of cancer patients. Research Sponsor: Thoracic Surgery Foundation.

Phase I/II trial of perioperative avelumab in combination with chemoradiation (CRT) in the treatment of stage II/III resectable esophageal and gastroesophageal junction (E/GEJ) cancer. *First Author: Nataliya Volodymyrivna Uboha, UW Carbone Cancer Center, Madison, WI*

Background: Neoadjuvant CRT followed by surgery is the standard of care for patients (pts) with stage II/III E/GEJ cancer, yet recurrence rates remain high. Immunotherapy has demonstrated activity in advanced E/GEJ cancer and was recently approved for adjuvant treatment of early stage disease. This trial evaluated the safety and efficacy of avelumab with perioperative CRT in resectable E/GEJ cancer. **Methods:** This is a two part phase I/II trial. Phase I was a safety run-in of 6 pts. Phase II planned to enroll an additional 18 pts in an expansion cohort. Pts with E/GEJ adenocarcinoma or squamous cell cancer received CRT (41.4 Gy in 23 fractions) with weekly carboplatin and paclitaxel. Three doses of avelumab (10 mg/kg IV, q14 days) were administered starting on day 29 of treatment, to coincide with the last chemotherapy dose. Surgery was performed 8-10 weeks after CRT completion. Pts received 6 doses of avelumab after resection (10 mg/kg IV, q14 days). The primary endpoint of the Phase 1 was safety and tolerability. The primary endpoint of the Phase II was pathologic complete response (pathCR) rate, assessing patients from the safety run in and expansion cohorts. **Results:** Between 6/2018 and 10/2021, 22 pts (20 males, median age 64) enrolled in the study. Enrollment was stopped after 16 patients in the expansion cohort due to accrual delays and changes in standard treatment. 19/22 patients (86%) had adenocarcinoma; 15/22 (68%) had lymph node positive disease at diagnosis. 19 pts underwent successful resection while on study. 3 pts went off study before resection due to grade 3 avelumab-related infusion reaction (1), patient preference (1), and non-adherence (1). There were no unexpected surgical complications. 4 pts (21%) had R1 resection with 3/4 having positive radial margin and 1/4 positive proximal margin. At resection, 5 pts (26%) had pathCR (3/16 adenocarcinomas, 2/3 squamous cell), 4 ypT1N0 disease, and 14/19 were ypN0. 42% had tumor regression score of 0 or 1. The combination of CRT and avelumab had an acceptable toxicity profile. No grade ≥3 immune-related AEs were observed. Immune-related hypothyroiditis was seen in 2 patients (grade 2). Three patients had grade 2 infusion-related reaction, but were able to continue with treatment. 21/22 pts had reversible grade ≥3 lymphopenia; 13/22 grade ≥ 3 wbc decrease; 6/22 grade 3 neutropenia. As of data cutoff on 2/1/2022, 1 patient remains on study treatment, 15 in follow up, 5 expired, 1 off study. Additional efficacy data is being collected. Correlative studies are ongoing. **Conclusions:** Perioperative CRT with avelumab is well tolerated with no unexpected toxicities. Neoadjuvant chemoradiation with immunotherapy is a promising approach for patients with E/GEJ tumors. Additional safety, efficacy and correlative analysis from this study will be presented at the meeting. Clinical trial information: NCT03490292. Nivolumab (NIVO) plus chemotherapy (chemo) or ipilimumab (IPI) versus chemo as first-line (1L) treatment for advanced esophageal squamous cell carcinoma (ESCC): Expanded efficacy and safety analyses from CheckMate 648. *First Author: Ian Chau, Royal Marsden Hospital, London & Surrey, United Kingdom*

Background: NIVO + chemo and NIVO + IPI demonstrated significant overall survival (OS) benefit vs chemo in previously untreated patients (pts) with advanced ESCC in the phase 3 CheckMate 648 study. We report expanded results from the primary analysis with 13-month (mo) minimum follow-up. **Methods:** Pts with previously untreated, unresectable advanced, recurrent, or metastatic ESCC were randomized to NIVO (240 mg Q2W) + chemo (fluorouracil + cisplatin Q4W), NIVO (3 mg/kg Q2W) + IPI (1 mg/kg Q6W), or chemo. Primary endpoints were OS and progression-free survival (PFS) per blinded independent central review (BICR) in pts with tumor cell programmed death ligand 1 (PD-L1) ≥ 1%. Secondary endpoints planned for hierarchical testing included OS, PFS, and objective response rate (ORR) per BICR in all randomized pts. Duration of response (DOR) per BICR and PFS2 per investigator (time from randomization to progression after subsequent systemic therapy, initiation of second subsequent systemic therapy, or death) were exploratory endpoints. **Results:** Among all pts randomized to NIVO + chemo (n = 321), NIVO + IPI (n = 325), or chemo (n = 324), PFS2 favored NIVO + chemo (HR 0.64, 95% CI 0.54–0.77) and NIVO + IPI (HR 0.74, 95% CI 0.62–0.88) vs chemo. ORR (95% CI) was 47% (42–53), 28% (23–33), and 27% (22–32), respectively. More responders with NIVO + chemo or NIVO + IPI vs chemo had prolonged DOR (≥12 mo; 39%, 48%, and 23%, respectively). Efficacy data by tumor cell PD-L1 and PD-L1 combined positive score will be presented. Grade 3/4 treatment-related adverse events with potential immunologic etiology (select TRAEs) occurred in ≤ 6% of pts with NIVO + chemo and NIVO + IPI, and non-endocrine select TRAEs resolved in 57%–95% of pts across organ categories (Table). **Conclusions:** NIVO + chemo and NIVO + IPI demonstrated favorable PFS2 and a higher proportion of pts with prolonged DOR vs chemo, as well as acceptable safety profiles. These results provide further support for each regimen as a new potential 1L standard of care in advanced ESCC. Clinical trial information: NCT03143153. Research Sponsor: Bristol Myers Squibb.

The PRODIGE 59-DURIGAST trial: A randomized phase II study evaluating FOLFIRI plus durvalumab and FOLFIRI plus durvalumab plus tremelimumab in second-line treatment of patients with advanced gastric or gastro-esophageal junction adenocarcinoma. *First Author: David Tougeron, Gastroenterology Department, Poitiers University Hospital, Poitiers, France*

Background: Efficacy of 2nd line chemotherapy in advanced gastric/gastro-oesphageal junction (GEJ) adenocarcinoma remains limited. No study up until now has evaluated the efficacy of immune checkpoint inhibitors combined with chemotherapy as 2nd line treatment of advanced gastric/GEJ adenocarcinoma. **Methods:** DURIGAST PRODIGE 59 is a randomized, multicenter, phase II study designed to assess the efficacy and safety of the combination of FOLFIRI plus durvalumab (anti-PD-L1 until progression) (FD) versus FOLFIRI plus durvalumab and tremelimumab (anti-CTLA-4 for 4 cycles) (FDT). Key eligibility criteria included advanced gastric/GEJ adenocarcinoma, platinum-based first-line chemotherapy and ECOG performance status (PS) 0 or 1. Patients were randomized in a 1:1 ratio to FD versus FDT. The primary endpoint is progression-free survival (PFS) at 4 months, which was expected to be 70% (H_0:50%). With an α risk of 5%, a power of 85% and 5% of non-evaluable patients, 47 evaluable patients are needed by arm. Secondary endpoints included safety, overall survival (OS) and quality of life. **Results:** Between August 2020 and June 2021, 96 patients were randomized, 48 in each arm. The median age was 59.7 years, 30.4% were women and 66.3% ECOG PS 1. All in all, 22.8% had HER2+ tumors and 4.3% dMMR/MSI tumors. The 4-month PFS were 44.7% [90%CI: 32.3–57.7] and 57.8% [90%CI: 44.5–70.3] in the FD and FDT arms, respectively. Primary endpoint was not met. Median PFS were 3.8 and 5.9 months, disease control rates 68.9% and 73.8% and median OS not reached and 10.1 months in FD and FDT arms, respectively. Eight patients in FDT arm had tremelimumab re-introduction at progression. Twenty-one patients, 8 in FD arm and 13 in FDT arm, are still being treated with a median duration of treatment of 7.8 and 10.9 months. All in all, 50.0% and 47.8% of patients experienced at least one grade 3-4 adverse events related to the treatment (neutropenia: 13.0 vs 21.7%, anemia: 10.9 vs 6.5%, diarrhea: 2.2 vs 8.7% and vomiting: 6.5 vs 10.9%), in FD and FDT arms, respectively. In both arms there was no clinically significant deterioration of quality of life superior to 10 points according to EORTC QLQ-C30 global health status. **Conclusions:** The DURIGAST PRODIGE 59 trial demonstrates an acceptable safety profile of immune checkpoint inhibitors plus FOLFIRI in 2nd line treatment for advanced gastric/GEJ adenocarcinoma. FDT combination demonstrates a clinically relevant efficacy never before achieved with a median PFS of 6 months and should be evaluated in a phase III trial. Updated results including PFS according to centralized review and PD-L1 status will be presented during ASCO meeting. Clinical trial information: NCT03959293. Research Sponsor: Federation francaise de cancerologie digestive (FFCD) and Astra Zeneca.

SOURCE beyond first-line: A survival prediction model for patients with metastatic esophagogastric adenocarcinoma after failure of first-line palliative systemic therapy. *First Author: Steven C. Kuijper, Amsterdam University Medical Centers, Amsterdam, Netherlands*

Background: Prediction models for survival may aid shared decision making between physicians and patients. Prior models have been developed that predict survival for patients with potentially curable esophagogastric cancer and patients with metastatic esophageal cancer who start first-line therapy (the SOURCE models). The aim of this study was to develop and internally validate a registry-based clinical prediction model, called SOURCE beyond first-line, for survival of patients with metastatic esophagogastric cancer after failure of first-line palliative systemic therapy. **Methods:** Patients with unresectable or metastatic (synchronous or metachronous) esophageal or gastric cancer who received first-line systemic therapy (N = 1067) between 2015-2017 were selected from the Netherlands Cancer Registry. Follow-up data were retrieved in 2019. Patient, tumor and treatment characteristics at primary diagnosis and at progression of disease, were used to develop the prediction model. A Cox proportional hazards regression prediction model was developed through forward and backward selection using Akaike's Information Criterion. The model was internally validated through 10-fold cross-validations to assess performance on unseen data. Model discrimination (C-index) and calibration (slope and intercept) were used to evaluate performance of the complete and cross-validated models. **Results:** The final model consisted of 10 patient, tumor and treatment characteristics. The C-index was 0.75 (0.74-0.77), the calibration slope 0.99 (0.98-0.99) and the calibration intercept 0.02 (0.01-0.02). Internal cross-validation of the model showed that the model performed adequately on unseen data: C-index 0.79 (0.76-0.80), calibration slope 1.02 (1.00-1.04) and calibration intercept -0.01 (-0.01-0.02). **Conclusions:** The SOURCE beyond first-line model predicted survival with fair discriminatory ability and good calibration, and is a valuable addition to the existing SOURCE prediction models. In the future this model will be integrated in an online decision support tool that can be used in clinical practice to aid personalized treatment. Research Sponsor: KWF Dutch Cancer Society.

Phase II trial of perioperative chemotherapy of esophageal cancer: PIECE trial. *First Author: Motoo Nomura, Department of Clinical Oncology, Kyoto University Hospital, Kyoto, Japan*

Background: Neoadjuvant chemotherapy followed by surgery (NAC-S) is the standard therapy for locally advanced esophageal squamous cell cancer (ESCC) in Japan. The aim of this phase II trial was to assess the efficacy and safety of the addition of adjuvant S-1 after R0 resection in patients treated with NAC-S. **Methods:** Key eligibility criteria were as follows: ESCC of clinical stage IB-III (without T4 disease); aged 20 to 75 years; ECOG performance status 0 or 1; and performed neoadjuvant chemotherapy (5-FU + cisplatin). All patients registered before surgery. Patients received adjuvant therapy with 4 cycles of S-1 (80 mg/m^2/day) that is administered orally for 4 weeks of a 6-weeks cycle. The primary endpoint was three-year relapse free survival (RFS). **Results:** A total of 52 patients were enrolled between January 2016 and January 2019. Two patients (one with small cell carcinoma and the other with synchronous malignancy) were excluded from analysis. Five patients were diagnosed as R1 or R2. Seven patients did not receive adjuvant S-1 due to adverse events of surgery in 5 patients, refusal to adjuvant S-1 in a patient, and forgot to start in a patient. Thirty-eight patients received adjuvant S-1, with 32 patients completing 4 cycles. The median relative dose intensity of adjuvant S-1 was 85.8%. Median follow-up time among survivors after surgery was 4.5 years (range 0.2-5.6). Three-year RFS in intention to treat population was 72.3% (90% confidence interval [CI] 59.9-81.5), suggesting that the primary endpoint was met, and 3-year overall survival was 85.0% (90% CI 73.9-91.6). Grade 3 or higher adverse event with an incidence 10% of greater were neutropenia (13.2%), anorexia (13.2%), and diarrhea (10.5%). There was no treatment-related death. **Conclusions:** Adjuvant S-1 showed promising efficacy with manageable safety profile for patients with resectable ESCC after NAC-S, and warrants further evaluation in larger studies. Clinical trial information: UMIN000020204. Research Sponsor: Taiho Pharmaceutical Co.,Ltd.

The adjudication rates between readers in Blinded Independent Central Review (BICR) of advanced esophageal cancer trials with or without immune checkpoint initiators as first-line therapy. *First Author: Yan Liu, Median Technologies, Valbonne, France*

Background: It is challenging to use RECIST 1.1 for the response assessment in esophageal cancer, because it excludes certain examines such as the use of barium meal and endoscopy. In some esophageal trials, the study protocols also recommend not selecting the primary tumor as a target lesion, because esophageal lesion could be infiltrative in a cavity organ and difficult to measure reliable especially after treatment. Moreover, it can even be more difficult for independent central readers, as they are often blinded to patient clinical symptoms and outcomes. The aim of this study is to analyze a pool of advanced esophageal cancer trials which used RECIST 1.1, and to document the proportion of reader discrepancies, reader performance through monitoring procedures, and to provide suggestions for the reduction of read inconsistency. This study provides benchmarks of reader adjudication rate in novel esophageal cancer therapeutic trials with or without immune checkpoint inhibitors, which will help to trigger corrective actions, such as reader initial training and follow up re-training. **Methods:** We analyzed 4 esophageal cancer BICR trials that included 1,875 patients (8,501 time-points) involving 14 radiologists. We analyzed the adjudication rate of each trial as well as testing inter-trial differences. The analysis of adjudication allowed to compute trial and reader adjudication rate, readers endorsement rate, root causes of adjudications. **Results:** Trials had an average adjudication rate of 45.28% [42.60%-47.99%], while readers endorsement rates ranged [23.1%-81.6%]. The differences of target lesion selection (34.4%) and lesion measurement (40.3%) are the two main reasons that led to discordance per adjudicators' assessment. The difference of new lesion determination and identification of non-target lesion progression contributed 17.8% and 7.5% of the discordance reasons, respectively. **Conclusions:** We provided benchmark performances for monitoring reader performance in trials with double reads. The discordances of baseline lesion selection and lesion measurement in follow up visits are the main reasons triggering adjudications in esophageal cancer central reading. Appropriate reader training and monitoring are solutions which can not only mitigate a large portion of the commonly encountered reading errors and help to reach more consensus on lesion selection and measurement between readers. Research Sponsor: None.

A phase II study evaluating KN026 monotherapy in patients (pts) with previously treated, advanced HER2-expressing gastric or gastroesophageal junction cancers (GC/GEJC). *First Author: Jianming Xu, Department of Gastrointestinal Oncology, The Fifth Medical Center of the PLA General Hospital, Beijing, China*

Background: Outcomes of second or later-line treatment for pts with advanced GC/GEJC remain inferior. KN026 is a novel HER2-targeted bispecific antibody composed of VH regions of trastuzumab and pertuzumab, targeting the HER2 juxtamembrane domain (IV) and the dimerization domain (II) simultaneously. KN026 has shown promising antitumor efficacy in preclinical and phase I studies. Here we present the results of KN026 monotherapy in previously treated, advanced HER2-expressing GC/GEJC. **Methods:** In this multi-center, single-arm, open-label, 2-cohort phase II study, adult pts with previously treated, advanced GC/GEJC were assigned into a HER2 high-level cohort (Cohort 1: IHC3+ or IHC 2+ ISH+) or a HER2 low-level cohort (Cohort 2: IHC 1+/2+ ISH- or IHC 0/1+ISH+). KN026 was given intravenously in 10 mg/kg QW, 20 mg/kg Q2W, or 30 mg/kg Q3W. Primary endpoints were objective response rate (ORR) and duration of response (DoR) assessed by investigators per RECIST 1.1. Secondary endpoints included progression-free survival (PFS), overall survival (OS), and safety outcomes. This trial is registered at ClinicalTrials.gov (NCT03925974). **Results:** At data cut-off (Oct. 29, 2021), 45 pts were enrolled and treated with KN026; 39 were eligible for response evaluation (25 pts in Cohort 1 and 14 pts in Cohort 2). In Cohort 1, ORR was 56% (95%CI 35%-76%) with 14 PR; the median DoR was 9.7 months (mo) (95%CI 4.2-not evaluable (NE)). At a median follow-up of 14.7 mo (95%CI 9.4-16.5), the median PFS was 8.3 mo (95%CI 4.2-11.4), and median OS was 16.3 mo (95% CI 11.0-NE). In Cohort 2, ORR was 14% (95%CI 2%-43%), with median DoR being 6.2 mo (95%CI 3.2-NE). At a median follow-up of 27.5 mo (95%CI 4.1-NE), the median PFS was 1.4 mo (95%CI 1.4-4.1), and median OS was 9.6 mo (95% CI 3.5-14.9). The table shows efficacy in Cohort 1 pts who have progressed on the prior trastuzumab treatment. KN026-related adverse events (TRAEs) were observed in 37 (82%) pts; the most common TRAEs (any grade) were increased aspartate aminotransferase (12, 27%), increased alanine aminotransferase (9, 20%), rash (7,16%), anemia (7,16%), and infusion-related reaction (7,16%). Four pts reported 5 grade 3 TRAEs, including infusion-related reaction, renal hydrocele, ureteral stenosis, increased blood pressure, and abnormal hepatic function (1 each). No grade 4 or 5 TRAEs occurred. **Conclusions:** KN026 monotherapy yielded promising efficacy with mild to moderate toxicities in pts with previously treated, advanced GC/GEJC. Further investigation is warranted. Clinical trial information: NCT03925974. Research Sponsor: Alphamab Oncology Ltd.

The efficacy in Cohort 1 pts who have progressed on the prior trastuzumab treatment (n = 14).

Perioperative chemotherapy with LP002, an anti-PD-L1 antibody, in patients with resectable gastric and gastroesophageal junction cancer: A prospective, open-label, phase Ib trial. *First Author: Jialin Tang, Department of Medical Oncology, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Immune checkpoint inhibitors were effective, either alone or in combination with chemotherapy, in pts with metastatic gastric or gastroesophageal junction (GEJ) cancers, but their role for resectable disease remained unknown. We report the safety and pathological response of gastric/GEJ cancer pts receiving LP002, an anti-PD-L1 antibody, plus chemotherapy as perioperative treatment in a phase Ib trial. **Methods:** We enrolled pts with previously untreated, PD-L1 positive, resectable (cT2-4a, any N, M0) gastric/GEJ cancer. Eligible pts received three preoperative and six postoperative 2-week cycles of intravenous LP002 900mg on day 1, intravenous cisplatin 50 mg/m^2 on day 1, and 2000 mg/m^2 5-fluorouracil as 48-h infusion starting on day 1. The standard surgery was scheduled 4-6 weeks after completion of 3 cycles of preoperative treatment. The primary endpoint was safety. Secondary endpoints included proportion of pts with R0 resection and pathological complete response (pCR), disease-free survival, and overall survival. With pre- and post-treatment samples, we also characterized genomic changes in tumor tissue with next generation sequencing (NGS), and alterations in the tumor immune microenvironment (TIME) using multiplex immunofluorescence staining. **Results:** From September 2020 to July 2021, 30 pts were enrolled into this study. The median age was 64.5 years (range, 50-74). Most primary tumors were in the GEJ (N=28, 93.3%). 29 pts (96.7%) had adenocarcinoma, and 1 had small cell neuroendocrine tumor. The median follow-up duration was 7.9 months (range: 5.1-10.6) as of data cut-off (November 1, 2021). All pts completed the planned preoperative treatment, and 27 pts (90.0%) proceeded to surgery. Reasons for surgery not being performed were metastatic disease in 1 patient, and patient request in 2 cases. 24 pts had R0 resection, while 3 underwent R1 resection. 1 patient achieved pCR (TRG 1 per the Mandard's tumor regression grading system) and 5 pts (18.5%) reached TRG 2-3. Treatment-related adverse events (TRAEs) were observed in 27 pts during perioperative treatment. Most of the TRAEs were of grade 1 to 2. The most common grade 3 toxicities were nausea (23.3%), neutrophil count decreased (16.7%) and anorexia (6.7%). 11 pts had immune-related adverse events, mostly grade 1 hyperthyroidism (45.5%). There were no grade 4-5 TRAEs. NGS analysis revealed that the mutation frequencies of the 733 genes in the sequencing panel decreased after preoperative treatment in pts with TRG 2-3. The analysis of TIME is undergoing. **Conclusions:** LP002 plus cisplatin and 5-fluorouracil was safe in pts with resectable gastric or GEJ cancer, and could be a new perioperative treatment option for PD-L1 positive disease. Pts are followed-up for survival outcomes. Clinical trial information: NCT04755543. Research Sponsor: Taizhou HoudeAoke Biomedical Co., Ltd.

Perioperative ramucirumab in combination with FLOT versus FLOT alone for resectable esophagogastric adenocarcinoma (RAMSES/FLOT7) with high rate of signet cell component: Final results of the multicenter, randomized phase II/III trial of the German AIO and Italian GOIM. *First Author: Thorsten Oliver Goetze, Krankenhaus Nordwest, University Cancer Center Frankfurt and Institut für Klinische Krebsforschung IKF am Krankenhaus Nordwest, Frankfurt Am Main, Germany*

Background: Periop. FLOT has become SOC for resectable, esophagogastric adenocarcinoma. However, patient's outcome is still poor. This trial evaluates the addition of the VEGF-R2 inhibitor ramucirumab (RAM) to FLOT for resectable patients (pts). **Methods:** This is a prospective, international, randomized, investigator-initiated phase II/III trial. Pts with resectable, Her2-negative, adenocarcinoma of the stomach and GEJ type II and III (≥ cT2 or cN+) were enrolled. Pts were randomized to 4 pre-and post-operative cycles of FLOT (docetaxel 50 mg/m^2; oxaliplatin 85 mg/m^2; leucovorin 200 mg/m^2; 5-FU 2600 mg/m^2, q2w) alone (Arm A) or the same regimen with RAM 8mg/kg q2w, followed by 16 cycles RAM (Arm B, FLOT-RAM). Important endpoints of phase II (exploratory) were major pathological (complete and nearly complete) response, centrally assessed acc. to Becker criteria, R0-resection rate, overall survival (OS), disease-free survival (DFS) and safety. GEJ type I tumors and pts requiring trans-thoracic esophagectomy were excluded for safety reasons during the conduct of the study. **Results:** In total, 152 pts were analyzed within the intention to treat population. Baseline characteristics were similar between arms (male, 70%; median age, 60y; cT3/T4, 82%; cN+, 77%; GEJ, 45%). The rate of cancers with signet-ring cell component was at 45%. The FLOT-RAM arm included more unfavorable pts with T4 (8% vs. 5%), impaired ECOG PS of 1 (32% vs. 20%), and concomitant disease (86% vs. 76%). 92% of pts with FLOT as well as with FLOT-RAM completed the 4 pre- cycles. R0-resection could be achieved in 82% of pts with FLOT and 96% of pts with FLOT-RAM ($p = 0.0093$). The rate of major path response was similar in both arms and was 29% for FLOT and 26% for FLOT-RAM. Median DFS was slightly improved in pts with FLOT-RAM (32 months vs. 21 months), while median OS was similar in both treatment arms (FLOT 45 months, FLOT-RAM 46 months). Surgical morbidity was observed in 32% of pts with FLOT and 41% of pts with FLOT-RAM. Mortality at 60 days after surgery was 4.1% with FLOT and 2.8% with FLOT-RAM. There were bit more G≥3 adverse events with FLOT-RAM (76% vs. 92%). **Conclusions:** In this phase II trial, the addition of ramucirumab to perioperative FLOT significantly improved R0-resection rates and slightly prolonged DFS without an impact on path response or overall survival. FLOT-RAM is feasible and safe, when type I tumors are excluded. Clinical trial information: NCT02661971. Research Sponsor: Lilly.

4043 **Poster Session**

FOLFOX versus FOLFOX plus nivolumab and ipilimumab administered in parallel or sequentially versus FLOT plus nivolumab administered in parallel in patients with previously untreated advanced or metastatic adenocarcinoma of the stomach or gastroesophageal junction: A randomized phase 2 trial of the AIO. *First Author: Sylvie Lorenzen, Third Department of Internal Medicine (Hematology/Medical Oncology), Klinikum Rechts der Isar, Technische Universitat München, München, Germany*

Background: FOLFOX plus nivolumab (nivo) has become standard of care for first-line therapy of patients (pts) with esophagogastric adenocarcinomas. The aim of Moonlight trial is to generate signals for whether (a) dual checkpoint inhibition or (b) a triplet chemotherapy is beneficial in the context of nivolumab therapy in this setting. **Methods:** The AIO-STO-0417 trial (Moonlight) is a four-arm investigator-initiated trial. Pts were randomized to FOLFOX alone (Arm B) or FOLFOX plus nivo 240 mg; q2w and ipilimumab (ipi) 1 mg/kg; q6w administered in parallel (Arm A/A1) or sequentially (Arm A2) or pts were treated in a non-randomized fashion with FLOT plus nivo 240 mg; q2w (Arm C). PD-L1 expression was centrally assessed. Primary endpoint is progression-free survival (PFS). **Results:** The study completed enrollment with 260 pts. Arms A1/A2 and C started later and will be analyzed in Mar 2022 and presented at the meeting. The abstract, therefore, focuses on Arms A (n = 60) vs B (n = 60). Baseline characteristics were: median age 62.5y, GEJ, 55%, intestinal type, 36%. Forty-one percent had PD-L1 CPS≥1 (available in 79% of pts). Pts received a median of 10 and 9 cycles Arms A and B. Adverse events of grade 3/4 were seen in 86% for Arm A and 60% for Arm B, respectively, and serious adverse events (SAE) in 78% in Arm A and 50% in Arm B. Median follow-up was 9.7 mo. No difference in PFS (5.7 and 6.6 mo), OS (10 vs. 12 mo) or objective response rate (45% and 48%) was seen in Arms A and B, respectively. The results were similar in the PD-L1+ group. **Conclusions:** FOLFOX plus dual checkpoint inhibition administered in parallel is associated with an increase in toxicity but not activity. This portion of the moonlight trial does not generate a signal for further trials on FOLFOX plus nivo and ipi for adenocarcinoma of stomach and GEJ. Clinical trial information: NCT03647969. Research Sponsor: Bristol-Myers Squibb.

4044 **Poster Session**

Circulating tumor DNA (ctDNA) in predicting residual disease after neoadjuvant chemoradiotherapy (nCRT) for esophageal squamous cell carcinoma (ESCC). *First Author: Zhichao Liu, Department of Thoracic Surgery, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China*

Background: For ESCC patients who receive nCRT, high pathological complete response (pCR) rates could be achieved. An active surveillance strategy has been proposed for patients with clinically complete response (cCR) after nCRT. However, clinical assessment may misclassify non-pCR as cCR. This study aimed to investigate the value of ctDNA in predicting tumor response and residual disease after nCRT in ESCC patients. **Methods:** This was a side study of the prospective, diagnostic pre-SINO trial (NCT03937362). After completion of nCRT, all patients underwent one or two clinical response evaluations (CREs) before planned surgery. The first (CRE-1) was 4–6 weeks after completion of nCRT. A second examination (CRE-2) was 10–12 weeks after nCRT for patients without histological evidence of residual tumor at CRE1. Serial ctDNAs were analyzed by ultra-deep unique molecular identifiers -based next-generation sequencing using 168 cancer-related genes at three time points: at baseline (B0), CRE1, CRE2. pCR was defined as ypT0N0M0. cCR was defined as no evidence of residual tumor during CRE1 & CRE2 in endoscopic biopsies and endoscopic ultrasonography with fine-needle aspiration cytology. We correlated quantitative ctDNA levels and ctDNA presence with pCR and major locoregional residual disease (MLRD) (> 10% residual carcinoma or any residual nodal disease). **Results:** At the time of this initial analysis, 62 consecutive ESCC patients received perprotocol treatments had sufficient sample to test ctDNA. The pCR rate was 32.3% (20/62). ctDNA was detectable in 73.77% at B0, 27.12% at CRE1 and 17.24% at CRE2. Maximum allelic fraction (maxAF) with a > 2-fold decrease post-nCRT (B0-CRE1) was seen in 67% patients with pCR, and 65.2% patients without MLRD. At B0, the high frequency mutated genes detected were TP53 (74%), PIK3CA (13%), CCND1 (11%), FGF19 (11%), FGF3 (11%), and FGF4 (11%). Baseline TP53 mutation status was significantly associated with pathological evaluations. A combining model, which incorporated both CRE1&2 positivity (cCR) and TP53 missense mutation at B0, was developed and demonstrated lower false-negative rate (FNR) in predicting non-pCR (4.9%, 2/41) and MLRD (2.8%, 1/36) compared with clinical assessment only (14.3%, 6/42) and (13.5%, 5/37), respectively. Of note, the FNR of combining clinical assessment and dynamic ctDNA change (continuous drop in maxAF ≥80% [B0-CRE1-CRE2]) was 7.3% (3/41) for non-pCR and MLRD (5.6%, 2/36). **Conclusions:** ctDNA testing combining with clinical assessment further optimized the tumor response and residual disease evaluations after nCRT for ESCC. ctDNA provides complementary information of response to nCRT and might become useful in an active surveillance strategy for the management of ESCC. Tumor-informed ctDNA analysis designed to track patient-specific somatic variants is ongoing. Clinical trial information: NCT03937362. Research Sponsor: National Key Research and Development Program of China (2021YFC2501005).

4045 **Poster Session**

Phase II study of ceralasertib (AZD6738) in combination with durvalumab in patients with advanced gastric cancer. *First Author: Minsuk Kwon, Department of Hematology-Oncology, Ajou University, Suwon, South Korea*

Background: Alterations in DNA damage response (DDR) and repair are associated with genomic instability and increased somatic tumor mutational burden, and modulating DNA repair using specific inhibitors is a promising strategy to boost the efficacy of cancer immunotherapy. Ceralasertib is an oral inhibitor of the serine/threonine protein kinase Ataxia Telangiectasia and Rad3 Related (ATR), which is crucial to the cell's response to replication stress. **Methods**: This phase 2 trial was designed to evaluate the efficacy and safety of ceralasertib in combination with durvalumab in patients with advanced gastric cancer (AGC). The study drug regimen was ceralasertib 240 mg BD days 15 to 28 in a 28-day cycle in combination with durvalumab at 1500 mg day 1 every 4 weeks. The primary end point was overall response rate (ORR) by RECIST (v1.1). Exploratory biomarker analysis was performed using fresh tumor biopsies in all enrolled patients. **Results**: 31 patients (median no. of prior lines, 2; range, 2-5) were enrolled between Jul 2019 and Mar 2020. All enrolled patients had confirmed microsatellite stable tumors, 5 patients were EBV positive, and 24 patients were PD-L1 positive (CPS≥1). Two patients had received prior anti-PD-1 treatment. At the time of data cut-off (Dec 2020), 30 patients were evaluable for response: 7 partial responses (one patient with prior anti-PD-1 treatment), 11 stable disease, and 12 disease progression were observed. The ORR was 22.6%, DCR 58.1 %, median PFS 3.0 months (95% confidence interval (CI), 2.1-3.9), median duration of response 5.7 months (95% CI, 4.9-6.5), and median OS was 6.7 months (95% CI, 3.8-9.6). A subgroup of patients (n = 11) who with loss of ATM expression and/or high proportion of mutational signature attributable to homologous repair deficiency (sig. HRD) demonstrated significantly longer PFS than those (n = 12) who had intact ATM and low sig. HRD (5.60 vs 1.65 months, hazard ratio 0.13, 95% CI 0.045-0.39, long-rank P < 0.001). The most common adverse events of any grade were fatigue (n = 22, 71.0%), nausea (n = 20, 64.5%) and anorexia (n = 19, 61.3%), and the most common adverse events of grade 3 or more were anemia and thrombocytopenia (n = 11, 35.5% each). **Conclusions:** Ceralasertib in combination with durvalumab demonstrated promising anti-tumor activity with durable responses in refractory AGC. Clinical trial information: NCT03780608. Research Sponsor: Korean Health Technology R&D Project, Ministry of Health & Welfare, Republic of Korea (HR20C0025), Pharmaceutical/Biotech Company.

Characterization of *NY-ESO-1* gene expression in gastric cancer (GC). *First Author: Annika Lenz, Keck School of Medicine at USC, Los Angeles, CA*

Background: Tumor specific antigens, such as NY-ESO-1, are emerging as key tumor immune modulating factors with great potential to be used as therapeutic targets to enhance immunotherapy efficacy and expand treatment options for GC. We sought to compare GC tumors expressing high vs low levels of *NY-ESO-1* in terms of immune cell abundance in the tumor microenvironment (TME) as well as distinct molecular features and immune biomarkers. **Methods:** 1967 tumor samples tested with NextGen Sequencing on DNA (592 genes or WES) and RNA (WTS) by Caris Life Sciences (Phoenix, AZ) were retrospectively reviewed. The top quartile of transcripts per million was considered high while the bottom quartile was considered low *NY-ISO-1* expression. Tumor mutational burden (TMB) was calculated based on somatic nonsynonymous mutations. Mismatch repair deficiency/microsatellite instability (dMMR/MSI) status was evaluated by a combination of IHC, fragment analysis and NGS of known MSI loci. Gene fusions were detected based on WTS. X^2, Fisher-exact, and Mann Whitney tests were used for comparison and significance adjusted for multiple testing by Benjamini-Hochberg correction ($q < 0.05$). Cell infiltration in the TME was estimated by quanTIseq. Gene expression profiles were analyzed for a transcriptional signature predictive of response to immunotherapy (T cell-inflamed signature: TIS). **Results:** The analysis was focused on primary tumors (N = 1323) in this initial study. Expression of *NY-ESO-1* was lower in primary/local than metastases (Fold Change FC met vs primary: 1.60, $q < 0.05$). *NY-ESO-1* expression did not appear to be strongly associated with distinct gene mutation profiles in GC. There were no significant differences between low and high expression of *NY-ESO-1* with regards to well established immuno-oncology markers (dMMR/MSI, TMB, PD-L1). However, high *NY-ESO-1* expression was positively associated with immune related gene expression including *CD274*, *CD80*, *CD86*, *CTLA4*, *HAVCR2*, *IDO1*, *IFNG*, *LAG3*, *PDCD1*, and *PDCD1LG2* (FC low vs high: 0.56 to 0.79, $q < 0.0001$). High *NY-ESO-1* expression was also positively associated with cell abundance in the TME including NK cells (FC = 0.87, $q < 0.0001$), monocytes (FC = 0.29, $q < 0.05$), myeloid dendritic cells (FC = 0.66, $q < 0.0001$), CD4+ non-reg T cells (FC = 0.54, $q < 0.0001$), and CD8+ T cells (FC = 0.73, $q < 0.05$). Similarly, tumors with high *NY-ESO-1* expression were associated with higher TIS scores ($q < 0.0001$). **Conclusions:** In our large cohort of GC, tumors expressing high *NY-ESO-1* displayed a distinct landscape of immune cells in the TME and were associated with high expression of immune related genes, as well as high TIS score, which has been reported to predict benefit from anti-PD-1 treatment. The results of our analysis support an association between a more immunologically active tumor microenvironment and *NY-ESO-1* gene expression which may have relevant implications on immunotherapy treatment for GC. A phase II study of perioperative mFOLFOX plus pembrolizumab combination in patients with potentially resectable adenocarcinoma of the esophageal, gastroesophageal junction (GEJ) and stomach. *First Author: Weijing Sun, University of Kansas Medical Center, Kansas City, KS*

Background: Surgical rection is the only potentially curative intervention for locally advanced adenocarcinoma of esophagus, GEJ and stomach. Results from various studies have demonstrated the benefits of perioperative treatment including neoadjuvant and adjuvant chemotherapy or chemoradiation, however, there is lack of universally accepted standard. Recent data demonstrated the benefit of immune checkpoint inhibitor in adjuvant setting in patients who had pre-operative chemoradiation. This single arm phase 2 trial is aimed to evaluate efficacy and safety of pembrolizumab, an immune checkpoint inhibitor, in combination with mFOLFOX in patients with potentially resectable adenocarcinoma of distal esophagus, GEJ and stomach. The primary objective is pathological response rate (ypRR with tumor regression score, TRS ≤ 2). **Methods:** Newly diagnosed locally advanced (T1N1-3M0 or T2-3NanyM0), potentially resectable adenocarcinoma of distal esophagus, GEJ and stomach by PET, EUS, CT C/A/P and staging laparoscopy were treated with pre-operative mFOLFOX6 (oxaliplatin 85mg/m^2, Leucovorin 400mg/m^2, 5-FU bolus 400mg/m^2, and 5-FU 2400mg/m^2 infusion every 2 weeks) for 4 cycles and pembrolizumab (200 mg IV q3week) for 3 cycles. Patients with no evidence of metastatic disease by PET and CT C/A/P who are eligible for resection underwent surgery. Post-operative treatment consisted of 4 cycles of mFOLFOX and 13 cycles of pembrolizumab 4-8 weeks postoperatively. **Results:** Up to 2/10/2021, all 37 patients eligible for the study finished preoperative treatment. 27 had curative intended operations, and all had R0 resection. 5 of 27 (19%) achieved ypCR and 6/27 (22 %) with regression score of 0 in the primary cancer. All except 2 patients (25/27, 93%) had shown pathologic response to the treatment with TRS ≤ 2. 21 patients completed all planned treatment with an average follow-up of 27 months. 2 patients had recurrence/metastatic disease (at 9 and 10 months from the enrollment) with 1 died at 23 months, and the other is still alive at 20 month. The rest patients (19/21) are all free of disease. G3/4 toxicities were reported in 21 of all 37 treated patients. There were no unexpected toxicities. **Conclusions:** The combination of mFOLFOX and pembrolizumab as peri-operative (pre- and post-operative) therapy in patients with locally advanced adenocarcinoma of distal esophagus, GEJ and stomach is safe. The preliminary benefit data are very encouraging with ypRR of 93%, ypCR of 19 %, and the long-time survival. The data support the combination of chemotherapy and Immune checkpoint inhibitor at perioperative setting. In addition, the data supports the staging laparoscopy for peritoneal disease assessment as the standard in resctacbility evaluation. Clinical trial information: NCT03488667. Research Sponsor: Merck.

Claudin 18 (*CLDN18*) gene expression and related molecular profile in gastric cancer (GC). *First Author: Annika Lenz, Keck School of Medicine at USC, Los Angeles, CA*

Background: Claudins are transmembrane proteins which maintain the tight junction between cells. The stomach specific isoform, CLDN18 isoform 2 (CLDN18.2), is emerging as a promising treatment target because of high expression in GC cells, including targeting via adoptive T-cell strategies. We characterized the molecular features associated with *CLDN18* isoform 1 and 2 (*CLDN18.1/18.2*) gene expression in GC. **Methods:** Tumor profiling was performed from 1967 samples by NextGen Sequencing on DNA (592 genes or WES) and RNA (WTS) at Caris Life Sciences (Phoenix, AZ). EBER (Epstein Barr Virus) was tested by CISH. Top quartile transcripts per million for *CLDN18.1/18.2* were considered high while bottom quartile low expression. X2, Fisher-exact, and Mann Whitney tests were used and significance adjusted for multiple testing by Benjamini-Hochberg ($q < .05$). Cell infiltration in the tumor microenvironment (TME) was estimated by quanTIseq. Gene expression profiles were analyzed for a transcriptional signature predictive of response to immunotherapy (T cell-inflamed signature, TIS). **Results:** *CLDN18.2* expression was detected in 97% of the samples and *CLDN18.1* in 63%. Primary tumors had significantly higher expression levels of both *CLDN18.1/18.2* (Fold Change *18.1*: 0.50; *18.2*: 0.65), compared to metastatic tumors ($p < .05$), thus we focused on the comparison of *CLDN18* high and low in primary tumors. *CLDN18.2* high expression group had higher *CLDN18*:*ARHGAP26* fusion positive rate (low vs high: 0.91% vs 5.5%, $q < .0001$), and a trending association with *CDH1* mutation (11.7% vs 20.7%, $p < .01$, $q > .05$) and EBER (2.15% vs 6.31%, $p < .05$, $q > .05$). There were more prevalent *ARHGAP26* fusions in the *CLDN18.1/18.2* high group (18.1: 9.5% vs 3.86%, $p = .001$; 18.2: 10.1% vs 0.9%, $q < .0001$), with the most common fusion between *CLDN18* exon 5 and *ARHGAP26* exon 12. *CLDN18.2* high expression demonstrated an inverse trending correlation with PD-L1 (24.9% vs 18.3%, $p < .05$; $q > .05$) and TMB-H (19.6% vs 12.2%, $p < .05$; $q > .05$). Similarly, *CLDN18.1/18.2* displayed an inverse relationship with M1 Macrophages, NK cells, CD4+ T cells, myeloid dendritic cells in the TME ($q < .05$); with higher *CLDN18* expression associated with fewer immune cells and a colder TME, especially in isoform 2. The TIS score was significantly higher in the *CLDN18.2* high expression group ($q < .05$), but lower in *CLDN18.1* high expression group ($q < .0001$), respectively. **Conclusions:** This is one of the most comprehensive dedicated analyses on *CLDN18* related to tumor molecular features, TME and immunotherapy response in GC. Tumors expressing high *CLDN18*, especially 18.2, displayed distinct genomic and transcriptomic alterations in immune biomarkers and immune cell infiltration in the TME. Anti-CLDN18.2 monoclonal antibodies are being tested in GC and CLDN18 is a target for ADC and CAR-T therapies. Our data suggest that expression may play a role in guiding patient selection and treatment combinations. Research Sponsor: Partly supported by NCI P30CA014089, Dhont Family Foundation, Ming Hsieh research fund, Daniel Butler Research Fund, Victoria and Philip Wilson Research Fund.

A 107-gene Nanostring assay effectively characterizes complex multiomic gastric cancer molecular classification in a translational patient-derived organoid model. *First Author: Daniel Skubleny, University of Alberta, Edmonton, AB, Canada*

Background: Multi-omics profiling of gastric cancer (GC) has produced numerous molecular classification systems. However, widespread clinical implementation and testing of molecular subtypes are currently limited. Here, we develop, validate and implement a custom Nanostring assay capable of allocating GC molecular subtypes to clinical specimens in a translational patient-derived organoid model. **Methods:** Using publicly available whole-transcriptome data, machine learning models were developed to predict GC molecular subtypes from 376 Cancer Genome Atlas (TCGA) and 1797 Tumour Microenvironment Score (TME) patients. Models were generated using feature selection with 10-fold nested cross-validation. GC biopsies from 10 local patients were preserved in paraffin (tumour) and established as an organoid culture (organoid). Gene expression was measured using Nanostring. The allocation of molecular subtypes was internally and externally validated using gold-standard reference features in public databases comprising 2202 GC patients and 10 tumour-organoid pairs, respectively. We evaluated the concordance of tumour-organoid molecular subtypes and explored the correlation between subtype scores and *in-vitro* chemotherapy response. **Results:** Classification models for TCGA (57 genes) and TME (50 genes) predicted subtypes with an accuracy ± standard deviation of 89.46% ± 0.04 and 89.33% ± 0.02, respectively. Subtype assignment of microsatellite instability (MSI) in reference to capillary electrophoresis was found to have 99.3% [95% CI 97.4-99.9, n = 277] internal and 100% [95% CI 83.2-100, n = 20] external accuracy. In reference to Epstein-Barr Virus (EBV) *in-situ* hybridization, EBV type internal and external accuracy was 98.7% [95% CI 97.4-99.5, n = 552] and 100% [95% CI 83.2-100, n = 20], respectively. TCGA Genomically Stable (GS) scores followed a previously characterized enrichment of diffuse-type histology compared to intestinal-type in internal and external cohorts (Dunn's Test, $p < 0.0001$ and $p < 0.05$, n = 1471 and n = 15, respectively). Statistically similar subtype scores (Paired Wilcoxon, $p > 0.05$) were found for tumour-organoid pairs. Discordance occurred in three tumour-organoid pairs. *In-vitro* Drug Sensitivity Score was not statistically efficacious in any molecular subtype, but Pearson correlation identified increasing efficacy with increasing EBV and MSI scores. **Conclusions:** Patient-derived organoids generally recapitulate the molecular subtype of parent tumours; however, in specific cases, subtype discordance occurs. Although additional external validation is required, our 107 gene assay effectively captures multi-omics classification systems in GC and allows future inquiry into the prognostic and therapeutic implications of these molecular subtypes. Research Sponsor: Edmonton Civic Employees, Other Government Agency.

Clinical efficacy of laparoscopic sentinel node navigation surgery for early gastric cancer: Five-year results of SENORITA trial. *First Author: Hoon Hur, Ajou University School of Medicine, Suwon, South Korea*

Background: A phase III multicenter randomized controlled clinical trial (SEntinel Node ORIented Tailored Approach [SENORITA] trial) has been performed to confirm the oncologic safety of laparoscopic sentinel node navigation surgery (LSNNS) for early gastric cancer (EGC). The results did not show the non-inferiority of LSNNS relative to laparoscopic standard gastrectomy (LSG) in terms of 3-year disease-free survival (DFS), the primary endpoint of the SENORITA trial even though the improved quality of life (QOL) in the LSNNS group. However, the long-term oncologic outcomes of LSNNS have not been compared with conventional surgery. This study was planned to investigate the comparison of LSG and LSNNS for EGC in terms of 5 years survival. **Methods:** We collected 5-year follow-up data of 527 patients recruited in the SENORITA trial. The overall survival (OS), disease-free survival (DFS), and recurrence pattern were evaluated in full analysis sets of both LSG (n = 269) and LSNNS (n = 258). **Results:** The mean follow-up period was 58.5 and 57.7 months in LSNNS and LSG groups. There was no statistically significant difference in 5-year OS (p = 0.7403) and DFS (p = 0.0561) between LSG and LSNNS. In terms of DFS, additional five events in the LSG group and 7 in LSNNS occurred after a 3-year follow-up until 5-years. Primary site recurrence in 1 LSNNS, and metachronous gastric cancer occurred in one LSG and two in LSNNS were diagnosed from 3 to 5-year follow-up period. Other organ cancer developed in two *vs.* three and other deaths occurred in two *vs.* one in each group, respectively, from 3 to 5-year follow-up. Overall survival events were 6 in LSG and 7 in LSNNS, and disease-specific death events were two patients in both groups until five years. **Conclusions:** Although the SENORITA trial did not show non-inferiority of LSNNS in the primary endpoint, 3-year DFS relative to LSG, the 5-year DFS and OS did not reveal the statistical difference between the two groups. Considering the benefit of LSNNS regarding the postoperative QOL, LSNNS could be recommended as an alternative treatment option of LSG for EGC. Clinical trial information: NCT01804998. Research Sponsor: National Cancer Center, Korea.

Ramucirumab, avelumab, and paclitaxel (RAP) as second-line treatment in gastro-esophageal adenocarcinoma, a phase II trial of the Arbeitsgemeinschaft Internistische Onkologie (AIO). *First Author: Peter C. Thuss-Patience, Charité–University Medicine Berlin, Department of Haematology, Oncology and Cancer Immunology, Campus Virchow-Klinikum, Berlin, Germany*

Background: Combination of ramucirumab and paclitaxel is a standard second line therapy in gastro-esophageal adenocarcinoma (GEAC) (RAINBOW trial, Wilke et al., 2014). We integrated the PD-L1 inhibitor avelumab into this regimen aiming for synergistic efficacy. **Methods:** In a multicenter phase II trial (NCT03966118) pts with metastatic GEAC, after progression on platinum / fluoropyrimidine based palliative 1st-line, ECOG 0 or 1, were treated with ramucirumab 8 mg/kg (d1,15) + avelumab 10 mg/kg (d1,15) + paclitaxel 80 mg/m^2 (d1,8,15), q4w. Sample size calculation was based on a Simon 2-stage design with overall survival rate at 6 months as the primary endpoint (H0≤50%, H1≥65%). **Results:** 60 pts were enrolled, 59 were evaluable (ITT), median age 64.0 yrs (range 18-81), male 80%, female 20%, primary gastric 52%, GEJ 48%, histology intestinal 59.6%, diffuse 24.6%, mixed 15.8%. Previous treatment with platin/fluoropyrimidine 100%, previous taxanes 66%. At central pathology MSI-H 7%, PD-L1 CPS < 5: 54%; ≥5: 41%, NA 5%. Response by investigator (%) CR 3.4, PR 27.1, SD 49.2, PD 20.3; DCR 79.7%, independent radiology review will be presented. DOR: 8.2 mo (95%CI 6.7-9.7), PFS 5.4 mo (95%CI 4.2-6.6); 6-mo OS rate 71.2%; 12-mo OS rate 45.8%; med OS (ITT) 10.6 mo (95%CI 8.2-13.1), med OS CPS < 5: 9.4 mo (95%CI 7.2-11.2), CPS ≥5: 14.0 mo (95%CI 12.8-15.3), translational data (ct-DNA) will be analysed. Treatment was generally well tolerated and no unexpected toxicities occurred: Grade 3/4 AE above 5%: anemia 5%, leucopenia 12%, neutropenia 22%, diarrhea 5%, pain 10%, peripheral neuropathy 10%, hypertension 5%, non-neutropenic infection 5% including 1 CTC grade 5 due to an esophagotracheal fistula. **Conclusions:** The med OS of 10.6 mo (in a population of 66% pretreated with taxanes) compares very favourably to 8.6 mo in the Western population RAINBOW trial (Shitara et al., 2016) and 7.6 mo in the RAMIRIS trial (Lorenzen et al., 2022). PD-L1 CPS≥ 5 seems to predict for an even better efficacy (med OS 14.0 mo). Second-line RAP is a very efficacious and well tolerated combination. Clinical trial information: NCT03966118. Research Sponsor: This research was financially supported by Merck Serono GmbH, Darmstadt, Germany, an affiliate of Merck KGaA, Darmstadt, Germany, as part of an alliance between the healthcare business of Merck KGaA, Darmstadt, Germany (CrossRef Funder ID: 10.13039/100009.

A randomized, controlled, multi-center, open-label study of adjuvant nab-paclitaxel plus S-1 (AS) versus capecitabine plus oxaliplatin (CapeOX) for stage III gastric cancer after D2 resection. *First Author: Yu Pengfei, Zhejiang Cancer Hospital (University of Chinese Academy of Sciences Cancer Hospital), Hangzhou, China*

Background: There was no prospective randomized study compared taxanes plus fluoropyrimidine versus platinum plus fluoropyrimidine in adjuvant chemotherapy for advanced gastric cancer. Nab-paclitaxel is nanoparticle albumin-bound formulation, showed a potentially efficacy in gastric cancer. We designed this trial to compare the effective and safety of AS and CapeOX regimen for gastric adenocarcinoma adjuvant therapy. **Methods:** Patients with stage III gastric or gastroesophageal junction adenocarcinoma who had D2 surgery and achieved R0 resection were randomized 1:1 to AS group and CapeOX. Randomization was stratified by differentiation type (differentiated vs. undifferentiated) and AJCC/UICC pathological stage (IIIA vs. IIIB, IIIC). AS group: Nab-paclitaxel 100 mg/m^2 on d1 and d8; S-1 80-120mg/d, p.o., bid on d1-d14; repeated every 21 days for 8 cycles. CapeOX group: oxaliplatin 130 mg/m^2 on d1; capecitabine 1000 mg/m^2, p.o., bid on d1-d14; repeated every 21 days for 8 cycles. The primary endpoint is 3-year disease-free survival (3-year-DFS) rate, the secondary endpoints included overall survival (OS), and safety. **Results:** Between March, 2020 to Jan, 2022, 146 subjects were enrolled to receive either AS regimen (n = 71) or CapeOX regimen (n = 75). The baseline characteristics between two arms were generally balanced. The 1-year DFS rate was 95.50% and 72.84% in AS and CapeOX group, respectively. At the cutoff date, 3 patients (the recurrence sites were peritoneum [n = 1], locoregional [n = 1] and distant [n = 1]) in AS group had relapsed, compared with 10 patients (peritoneum [n = 2], locoregional [n = 4] and distant [n = 4]) in CapeOX group. 4 subjects in CapeOX group died compared with 0 in AS group. A total of 42 patients (AS, n = 21 [29.58%]; CapeOX, n = 21 [28.00%]) needed dose reduction main due to hematological toxicity. The median relative dose intensity of Nab-paclitaxel, S-1, oxaliplatin and capecitabine was 82.55%, 91.30%%, 83.16%% and 78.95%, respectively. Treatments were delayed in 82 of 297 (27.61%, 24 due to hematological and 15 due to non-hematological toxicity) cycles at AS group and in 100 of 319 (31.35%, 18 due to hematological and 13 due to non-hematological toxicity) cycles at CapeOX group. There were 34 (47.89%) patients in AS group and 30 (40.00%) patients in CapeOX group occurred treatment-related adverse events (TRAEs), though most of them were grade I-II. Main grade III-IV AEs were neutropenia (28.16% in AS group vs 8.00% in CapeOX group), leucopenia (15.49% vs 1.33%), thrombocytopenia (0% vs 8.00%) and anemia (5.63% vs 1.33%). **Conclusions:** Adjuvant AS regimen showed a trend towards better DFS compared with CapeOX regimen, and is a potentially regimen for stage III gastric cancer after curative D2 gastrectomy, with tolerable toxicity. Long-term survival benefit requires more data. Clinical trial information: NCT04135781. Research Sponsor: CSPC Pharmaceutical Group Co., Ltd.

Tumor microenvironment (TME) dynamics following capecitabine/oxaliplatin (CapeOx) plus pembrolizumab in patients with advanced gastric cancer. *First Author: Minae An, Samsung Medical Center, Seoul, South Korea*

Background: Immune checkpoint inhibition (ICI) has made significant breakthroughs in several tumor types including gastric cancer (GC) in recent years. However, single-agent pembrolizumab demonstrated remarkable and durable response in MSI and EBV GC because they are immune-enriched types. Recently, we reported on-treatment remodeling of the TME during chemotherapy in MSS AGC (*Cancer Discov.* 2021). We defined altered features including decreased tumor-associated macrophages (TAM), M1- macrophages repolarization and recruitment of NK cells, effector T cells. **Methods:** This phase 2, open-label, single-arm study was designed to assess the safety and efficacy of the CapeOx-pembrolizumab combination in advanced gastric cancer patients with HER2-negative. 38 patients were enrolled onto our CapeOx plus Pembrolizumab trial (NCT #04249739). All patients had MSS status with EBV-negative. Endoscopic biopsies were collected at baseline, after 1 cycle of chemotherapy alone and after 4 to 5 cycles of CapeOx + pembrolizumab to understand the impact of treatment to tumor TME. We performed coupling whole exome sequencing and whole transcriptome sequencing. Molecular features were extracted by exonic analysis. TME subtype was estimated by gene expression analysis. **Results:** Between 2020 and 2021, 38 patients were enrolled. There were 2 CR, 25 PR, 11 SD as best response.First, we found a number of somatic mutations (median 157.5, range 7-25,719) in pre-and on-treatment samples. Despite the creation and destruction of somatic mutation, we observed that ancestor mutations including *TP53*, *MUC6* and *APC* previously reported in TCGA GC cohort, were preserved. At baseline (before chemotherapy), patients were classified to 5 immune-enriched (IE) subtye, 21 immune-depleted (D) subtype, ETC. Second, we observed a dynamic change following one cycle of CapeOx before the addition of pembrolizumab to chemotherapy. Nine (23.68%) out of thirty eight patients with immune-depleted or fibrotic pre-treatment TME became immune-favorable during treatment. Interestingly, seventeen (58.62%) out of twenty nine patients with immune-unfavorable pre-treatment TME became immune-favorable following CapeOx plus Pembrolizumab chemotherapy. **Conclusions:** This is the first study to demonstrate TME change during CapeOx plus pembrolizumab at molecular levels and will have clinically meaningful performance in patients with metastatic GC. Clinical trial information: NCT#04249739. Research Sponsor: None.

Circulating tumor DNA and recurrence risk in stage II-III gastric cancer. *First Author: Shu-Qiang Yuan, Sun Yat-sen University Cancer Center, Guangzhou, China*

Background: Circulating tumor DNA (ctDNA) is a promising biomarker for detecting molecular residual disease (MRD) and relapse after definitive treatment in multiple solid cancers. However, the significance of ctDNA is rarely clarified in locoregional gastric cancer (GC). Here, we conducted a prospective and observational study to evaluate the utility of ctDNA in predicting the recurrence risk of GC. **Methods:** From October 2016 to June 2019, 100 patients with stage II/III resectable GC were recruited in this study (NCT02887612). Primary tumors and plasma samples were collected perioperatively and after adjuvant chemotherapy (ACT). Somatic variants were captured via a targeted sequencing panel of 425 cancer-related genes. The plasma of patients was defined as ctDNA positive only if one or more variants detected in the plasma presented in at least 2% of the primary tumors. All the patients received curative-intent standard-of-care therapy. **Results:** Preoperative ctDNA was detectable in 38 (38.0%) patients but showed limited value for predicting recurrence. After surgery (median days, 4), the plasma of 25 (25.0%) patients were still ctDNA positive and they had higher recurrence risk than the non-positive patients (hazard ratio [HR], 2.74 (95% CI: 1.37–5.48); P = 0.003). Forty-one patients had evaluable plasma after ACT and 10 (24.4%) of them who were ctDNA positive had remarkably higher recurrence and death risk compared with ctDNA-negative patients (recurrence-free survival [RFS] HR = 14.99 (95% CI: 3.08–72.96); P < 0.001; overall survival HR, 11.88 (95% CI: 2.38–59.24); P < 0.001). In particular, post-ACT ctDNA achieved better predictive performance (sensitivity, 77.8%; specificity, 90.6%) than both postoperative ctDNA and post-treatment tumor biomarkers (i.e., CEA, CA199, and CA72-4). In all multivariate analyses, ctDNA positivity was an independent factor of RFS. Patients with ERBB4 mutation in their primary tumors had poorer RFS compared to those were ERBB4 wildtype (HR = 3.46 (95% CI: 1.32–9.03); P = 0.007). A comprehensive model incorporating ctDNA status for recurrence risk prediction showed a higher concordance index (0.78; 95%CI, 0.71–0.84) than the model without ctDNA status (0.71; 95%CI, 0.64–0.79; P = 0.009). **Conclusions:** Postoperative and post-ACT ctDNA was associated with MRD and high risk of relapse in patients with stage II/III GC and can be utilized to guide GC management in post-surgical settings. Prognostic role of tumor stroma ratio, tumor-infiltrating lymphocytes, and tumor budding in patients with intestinal-type gastric cancer after radical resection.

First Author: Dan Sha, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China

Background: Tumor microenvironmental (TME) features including tumor stroma ratio (TSR), tumor infiltrating lymphocytes (TILs) and tumor budding (TB), may be associated with tumor metastatic potential. We sought to identify the association of these features with prognosis of patients with resectable intestinal-type gastric cancer. **Methods:** Radical resection of gastric carcinoma (> 15 LNs removed) was performed in 493 patients (stage I, n=225; stage II, n=119; stage III, n=149) at two university hospitals between 2010 and 2016. Cutpoints were as follows: TSR (50%), TILs (median), and TB (Bd0-Bd3). TME features and their association with clinicopathological characteristics, time-to-recurrence (TTR) and overall survival (OS) were analyzed by univariate and multivariate Cox methods.. **Results:** Among 493 patients, high TSR, low TILs and high TB (Bd1-Bd3) were significantly associated with higher histological grade, larger tumor size, and increased T and N stages. Each of these features was significantly associated with poorer TTR and OS at 5 years. In Cox multivariable analysis, N stage and TSR were the only variables that were significantly associated with TTR and OS (Table). The relative contribution (%) of TSR to TTR ranked second (17.5%) behind N stage (49.2%) and ahead of TILs (7.2%) and TB (0.1%). **Conclusions:** Among TME features, TSR was the most robust and was significantly and independently associated with TTR and OS. The relative contribution of TSR to TTR was second only to nodal status. Research Sponsor: the Natural Science Foundation of Shandong Province of China (grant no. ZR2021MH140), the Science and Technology Innovation Development Program of Jinan, Shandong Province, China (grant no. 202019085).

Cox multivariable analysis of TTR and OS.

Features	TTR HR (95%CI)	TTR *P* value	OS HR (95%CI)	OS *P* value
Gender (female vs male)	1.37 (0.89-2.10)	0.16	-	-
Age (>60 years vs ≤60 years)	-	-	1.78 (1.22-2.61)	0.00
Histological grade (moderate vs well)	1.20 (0.71-2.03)	0.49	1.38 (0.82-2.32)	0.23

A biological network approach for mining target genes in EBV-positive gastric cancer.

First Author: Williams Fernandes Barra, Universidade Federal do Para - Nucleo de Pesquisas em Oncologia, Belem, Brazil

Background: Epstein–Barr virus (EBV) discriminates a molecular group of gastric cancer (GC) that seems to have peculiar treatment responses and prognosis. Nevertheless, the gene expression pattern of such tumors needs additional investigations due to the heterogeneity of the tumor microbiome and the small number of studied samples. Biological networks analysis of gene expression patterns, in this complex scenario, might lead to the discovery of putative "hubs" genes, supposed to have important roles in cancer occurrence and consequences. This study aimed to explore the biological value of hub genes in EBV-positive gastric cancer patients. **Methods:** Fresh tumor samples collected during gastrectomies from individuals with gastric adenocarcinoma (n = 41, 59.0±11.0 years) were included. Gene expression of tumor samples was evaluated in the Illumina sequencing platform. A weighted correlation network analysis (WGCNA) was used to find highly correlated gene patterns. The gene's correlation to EBV status was also explored, including eight EBV positive and 33 EBV negative cases. Gene Ontology (GO) term enrichment was performed to predict the involved biological functions. The expression level of the hubs gene was measured by differential expression analysis. **Results:** A gene cluster including 636 genes able to discriminate EBV status (ρ = 0.65, p-value = 6e-05) was identified. GO analysis (padj <0.05) showed that this cluster of genes is related to T cell activation, regulation of immune effector process, and response to the biotic stimulus. In this cluster, 54 genes were differentially expressed (log2FoldChange (FC) >1 and padj< 0.05). The top hub genes were LAPTM5, PTPN22, C1QA, CD84, CD53, ADAMDEC1, DPYD, TYROBP, RARRES3, IFI16, CYBB, CMKLR1, PHF21A, GPNMB, and C1QC, according to cluster significance and gene expression level. In positive EBV-GC, all hub genes were overexpressed (FC 1.24 - 2.49) (Table). The average area under the ROC curve (AUC) for hub genes was 0.9 (0.84-0.99). Overexpression of LAPTM5 (p-value = 0.013) and DPYD (p-value =0.0065) and low expression of ADAMDEC1 (p-value = 0.05) were strongly related to poor survival outcome. **Conclusions:** EBV-positive status was correlated with overexpression of hub genes. Genes found in this investigation have high sensitivity and specificity to discriminate EBV status in GC. Some of them seem to be related to patients' survival, opening an avenue for future scientific explorations in this field. The biological network's approach may be a promising tool for mining target genes for potential clinical applications. Research Sponsor: Ministerio Publico do Trabalho 8a Regiao.

Top 9 hub genes of biological network ordered by log2FC.

Gene	log2FC	padj	AUC

Comparison of four clinical prognostic scores in patients with advanced gastric and esophageal cancer.

First Author: Lucy Xiaolu Ma, Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada

Background: While several clinical scoring systems exist to aid prognostication and patient (pt) selection for clinical trials in oncology, none are standardly used. We compared the ability of four prognostic scores to predict overall survival (OS) in pts with advanced gastric and esophageal (GE) cancer. **Methods:** Pts with advanced (unresectable or metastatic) GE cancer receiving first-line palliative-intent systemic therapy at the Princess Margaret Cancer Centre from 2007 to 2020 were included. High prognostic risk pts were identified using four scoring systems: Royal Marsden Hospital (RMH), MD Anderson Cancer Centre (MDACC), Gustave Roussy Immune Score (GRIm-S) and MD Anderson Immune Checkpoint Inhibitor (MDA-ICI) score. OS was estimated using the Kaplan-Meier method and compared between risk groups (high vs. not-high) for each scoring system using the log-rank test. Cox proportional hazards models were used to analyze the association between each prognostic score and OS, adjusting for baseline clinical factors. Harrell's c-index was used to evaluate predictive discrimination of the models. Time-dependent AUCs were used to measure predictive ability for early death (within 90 days). **Results:** In total, 451 pts with advanced GE cancer were included. The median age was 59 years, 68% were male, 51% had ECOG status 0-1, 63% presented with de novo metastatic disease. The proportion of pts categorized as high risk was: RMH 25% (N=113), MDACC 13% (N=95), GRIm-S 24% (N=109), MDA-ICI 26% (N=117). In all scoring systems, high risk pts had significantly shorter OS (median OS 7.9 versus 12.2 months for RMH high vs. low risk, p<0.001; 6.8 vs. 11.9 months p<0.001 for MDACC; 5.3 vs. 13 months p<0.001 for GRIm-S; 8.2 vs. 12.2 months p<0.001 for MDA-ICI). On multivariable analysis, each prognostic score was significantly associated with OS (Table). The GRIm-S had the highest predictive discrimination (c-index 0.645 [0.612-0.678]) and highest predictive ability for early death (AUC 0.754 [0.675-0.832]). **Conclusions:** All four prognostic scoring systems compared had reasonable accuracy in predicting OS for patients with advanced GE cancer. The higher accuracy for predicting early death may render the GRIm-S as preferable. These tools can aid oncologists in discussions about prognosis, therapeutic decision-making and patient selection for clinical trials. Research Sponsor: None.

Multivariable analyses of association between high risk designation and OS for each prognostic score.[1]

Score	Hazard ratio (95% CI)	p-value
RMH	1.48 (1.08-2.02)	0.013
MDACC	1.64 (1.19-2.25)	0.0022
GRIm-Score	2.61 (2.01-3.38)	<0.001
MDA-ICI	1.53 (1.17-1.99)	0.0019

[1]Each multivariable model adjusted for baseline characteristics: age, sex, histology, ECOG, and number of metastatic sites.

The 27-gene IO score is associated with molecular features and response to immune checkpoint inhibitors (ICI) in patients with gastric cancer.

First Author: Matthew Gordon Varga, 2 International Plaza Drive, Nashville, TN

Background: Gastric cancer (GC) is the 3rd leading cause of cancer-related death worldwide. Unfortunately, most gastric cancer patients are asymptomatic until the cancer has progressed to an advanced stage. ICIs have improved patient outcomes in a variety of cancers, including GC. A variety of biomarkers have been used to identify patients most likely to benefit from ICI therapies such as high PD-L1 expression, MSI-high, Epstein Barr virus (EBV) positive, or TMB . Despite these potential biomarkers, most patients with advanced GC do not respond to ICI treatment Thus, there remains an unmet clinical need for a biomarker that can better predict response to ICI therapies. Herein, we demonstrate that the 27 gene IO score, a tumor immune microenvironment (TIME) classifier is associated with the existing molecular markers of gastric cancer and with objective response to ICI therapy in a clinical cohort. **Methods:** RNA-seq expression data was obtained from 3 independent cohorts including TCGA (STAD), ACRG (GSE84437, GSE84426), and clinical cohort with ICI response data (PRJEB25780, PRJEB40416). The 27 gene IO algorithm was applied to all available patient data to derive IO scores. Fisher's exact test was used to examine the associations between IO score and clinical features and molecular subtypes in each cohort. R (version 4.1.2) was used to calculate ORs with 95%CIs, and ordinal logistic regression modeling. **Results:** From the TCGA cohort, the IO score was associated with the molecular features of EBV, MSI, TMB, and PD-L1 (n = 135, p < 0.05 for all). Similarly, in the ACRG cohorts, the IO score was significantly associated with EBV, MSI, and PD-L1 (n = 294, p < 0.001 for all). To determine whether the IO score was associated with response to ICIs, we examined a cohort of Korean patients with advanced stage GC curated by Kim *et. al.* In this cohort of 59 patients, the IO score was associated with ICI response (Fisher's exact test, p < 0.05). When response was grouped by responders vs. non-responders (CR/PR vs SD/PD), the odds ratio for the association between IO score and response was 5.3 (95% CI: 1.3 to 23.92, p = 0.01). The linearity of continuous value of the IO score was indicative of a direct relationship between IO score and improved objective response (ordinal logistic regression, t = 2.59, p < 0.01). **Conclusions:** PD-L1 and TMB have shown marked levels of both spatial and temporal heterogeneity in GCs, thus there exists a need for a more comprehensive biomarker that can fully assess the TIME. The 27 gene IO score is associated with many existing biomarkers in GC and has now been shown to also be associated with response to ICIs. As such, further studies are warranted to demonstrate that the 27 gene IO score may be a more comprehensive biomarker for assessing the TIME and provide complementary data to tumor-specific biomarkers, which together could aid in clinical decision making for ICI treatment of GCs. Neoadjuvant atezolizumab plus docetaxel/oxaliplatin/capecitabine in non-metastatic gastric and gastroesophageal junction adenocarcinoma: The PANDA trial. *First Author: Yara L. Verschoor, Netherlands Cancer Institute, Amsterdam, Netherlands*

Background: Immune checkpoint blockade improves clinical outcomes for patients with gastric and gastro-esophageal junction (GEJ) cancers, but its efficacy and impact on the tumor microenvironment in non-metastatic, resectable disease remains largely unknown. Peri-operative FLOT, the current standard-of-care, leads to pathologic complete responses (pCR) and major pathologic responses (MPR) in 16% and 37% of patients, respectively. An important open question is whether PDL-1 blockade monotherapy can prime the tumor microenvironment in a favorable manner, prior to combination with chemotherapy. **Methods:** We report results from the phase 2 PANDA trial (NCT03448835) of neoadjuvant atezolizumab (anti-PDL-1) plus docetaxel, oxaliplatin, and capecitabine (DOC) in patients with resectable gastric or GEJ adenocarcinoma. Patients received a single cycle of atezolizumab monotherapy, followed by 4 cycles of atezolizumab+DOC. Tumor tissue was collected at baseline, after atezolizumab monotherapy, the first atezolizumab+DOC, and at resection. The primary endpoints were safety and feasibility in 20 patients, and secondary endpoints included MPR (<10% viable tumor rest) and disease-free survival. **Results:** Twenty patients, of which 18 with mismatch repair (MMR) proficient and two with MMR-deficient tumors, were evaluable for safety and efficacy analyses. MPR was observed in 14/20 patients (70%; 95% CI 46–88%), including 9 pCR (45%; 95% CI 23-68%). Among patients with intestinal type adenocarcinoma, 12/15 (80%; 95% CI 52-96%) had an MPR, with 9/15 (60%; 95% CI 32-84%) pCR. Treatment was well tolerated, with two patients (10%) experiencing a grade 3 immune adverse event. At a median follow-up of 29 months (IQR 16-34), 15 patients (75%) were alive and disease-free. None of the patients with an MPR recurred. All patients underwent resections without treatment-related delays and no unexpected surgical complications were documented. Translational analyses, including baseline PDL-1 CPS score and whole exome sequencing (WES), plus CD8 T-cell infiltration and RNA sequencing at 4 timepoints will be presented at the meeting. **Conclusions:** Our data show that the addition of atezolizumab to neoadjuvant chemotherapy leads to promising pathologic responses in gastric/GEJ adenocarcinoma, which appears to be higher than in historical controls, with no recurrences in responders. These data should be validated in a large randomized controlled trial. Clinical trial information: NCT03448835. Research Sponsor: Roche-Genentech.

REGOMUNE: A phase II study of regorafenib plus avelumab in solid tumors—Results of the oesophageal or gastric carcinoma (OGC) cohort. *First Author: Sophie Cousin, Early Phase Clinical Trials Unit and Thoracic Unit, Institut Bergonié, Bordeaux, France*

Background: Combination VEGF and PD-1/PD-L1 axis blockade has shown benefit in various tumors and is emerging as a promising combination strategy. **Methods:** This is a single-arm open-label multicentric phase II trial assessing the efficacy and safety of regorafenib (R) (160 mg QD 3weeks/4) + avelumab (A) (10 mg/kg every 2 weeks) combination in advanced or metastatic oesophageal or gastric carcinoma (OGC) patients (pts). The primary endpoint was the confirmed objective response rate, based on central review according to RECIST 1.1. Secondary endpoints included: 1-year progression free survival (PFS), 1-year overall survival (OS), and safety using NCI-CTCAE v5.0. Correlative studies were planned from pts tumor samples obtained at baseline. **Results:** Between Dec. 2018 and Mar. 2021, 49 pts were enrolled in 6 centers: 33 adenocarcinoma (ADK), 16 squamous cell carcinoma (SCC). Median age was 63.9 (range 33 – 80). Median follow-up was 14.5 months. Median number of previous treatment lines was: 2 (range 1 – 6). 29 (59.2%) pts experienced at least 1 dose modification or treatment interruption due to an adverse event related to treatment. The most common grade 3/4 adverse events were : Hypertension (12.2% of pts), palmar-plantar erythrodysesthesia syndrome (10.2%), and hypophosphatemia (8.2%). No death was related to the treatment. Among the 42 (29 ADK and 13 SCC) pts who had at least one imaging tumor assessment, 8 (19.1%) achieved a partial response, 5 (17.2%) and 3 (23.1%) in the ADK and SCC group respectively. 12 pts (28.6%) demonstrated stable disease and 22 pts (52.3%) had progressive disease. The median PFS and OS were 1.9 months (95%CI 1.8 – 3.5) and 7.5 months (95%CI 4.5 – 15.7) respectively. **Conclusions:** The R+A combination is associated with encouraging antitumor activity in patients with OGC. Full Biomarkers analyses will be presented at the meeting. Clinical trial information: NCT03475953. Research Sponsor: Bayer/ Merck.

Impact of immune-related adverse events (irAEs) on PD-1/L1 inhibitors efficacy in advanced esophageal cancer. *First Author: Wenru Qin, Department of Radiation Oncology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, China*

Background: The recent development of Immune checkpoint inhibitors (ICIs) has improved treatment outcomes for patients with esophageal cancer, although it may initiate autoimmune-related disorders in some patients. Across disease sites, patients who experience irAEs while on therapy with anti-PD-1 and anti-PD-L1 antibodies have been documented to experience improved outcomes as measured by overall response rate (ORR), progression-free survival (PFS) and overall survival (OS). **Methods:** We reviewed the medical records and the following characteristics of patients were collected: age, gender, Eastern Cooperative Oncology Group performance status (ECOG PS), stage, histology, history of surgery, metastatic sites, therapy line, presence of target lesion according to the response evaluation criteria in solid tumors (RECIST) version 1.1, LDH level before initiating ICIs treatment. We divided the patients treated with ICIs into two groups based on occurrence of irAEs. We compared the efficacy between the irAE - and irAE + groups. **Results:** There were total 295 patients. Of all the patients, 143 patients (50.2%) suffered from irAEs. The median patient age was 60 years (range, 36–84). Baseline characteristics including gender, ECOG PS, tumor location, history of surgery, histology, number of organs with metastases, site of metastases, therapy line, history of drinking, history of smoking between patients with or without irAE were not significantly different. The most frequent irAEs were Anemia(71/295, 24.07%), Pneumonitis (55/295, 18.64%), Cardiovascular toxicities (35/295, 11.86%). There were no grade 5 adverse events related to immunotherapy. Objective response was observed in 92 patients (31.19%), 54 of the 143 patients with irAEs had objective response (37.76%) in contrast with 38 of the 152 cases without irAEs (25.00%). Median PFS in patients with irAEs was 10.27 months and 6.2 months in those without irAEs (p<0.001). Median OS in patients with irAEs was 15.4 months and 9.2 months in those without irAEs(p<0.001).Multivariate analyses identified an ECOG PS ≥2, cycles ≤8, and without irAEs as independent poor prognostic factors (p=0.003, p <0.001 and p=0.011). Multivariate analysis demonstrated that ECOG PS ≥2, Therapy line≥22nd ,without radiation and absence of irAEs were associated with a poor overall survival(p=0.022, p=0.006, p. <0.001 and p=0.002). Multivariable analysis also revealed that Cycles>8, Radiation and Anti-angiogenic therapy were positively associated with occurrence of irAEs(p<0.001, p=0.002, p=0.025). **Conclusions:** In advanced esophageal cancer treated with PD-1/L1 inhibitors., patients with irAEs showed a markedly improved efficacy over patients without irAEs. Research Sponsor: None.

A phase I study of TST001, a high affinity humanized anti-CLDN18.2 monoclonal antibody, in combination with capecitabine and oxaliplatin (CAPOX) as a first-line treatment of advanced G/GEJ cancer. *First Author: Jifang Gong, Department of Gastrointestinal Oncology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/ Beijing), Peking University Cancer Hospital and Institute, Beijing, China*

Background: TST001 is a recombinant humanized IgG1 antibody specifically against human Claudin 18.2 (CLDN18.2) with high affinity and enhanced FcR engaging of NK cells, which can induce strong antibody-dependent cellular cytotoxicity (ADCC) activities. TST001 monotherapy dose-escalation study has been completed (IGCC2022-ABS-1152) and promising anti-tumor activities were observed in advanced gastric cancer patients with CLDN18.2 overexpression who had failed multiple lines of prior therapies. The current study is an open-label, multi-center, multiple cohorts, phase I clinical trial of TST001 monotherapy or in combination with standard treatments in Chinese patients with advanced or metastatic solid tumors (NCT04495296). **Methods:** This cohort is aimed to determine the recommended phase II dose, evaluate safety, tolerability and preliminary efficacy of TST001 in combination with CAPOX as a 1st line treatment of advanced G/GEJ cancer. A 3+3 design was utilized in the dose escalation phase with treatment naïve advanced G/GEJ cancer patients regardless of Claudin18.2 expression. Claudin 18.2 positive G/GEJ cancer patients were planned to be enrolled in the dose expansion phase in selected dose cohorts. **Results:** The TST001/CAPOX combination cohort was initiated in August 2021 and is ongoing in multiple sites in China with a data cutoff date of January 27, 2022. 12 subjects were dosed with TST001 with a dose range from 1 to 8mg/kg Q3W in combination with the standard dose of CAPOX in the dose escalation phase and one subject with central lab tested Claudin 18.2 overexpression was dosed in the expansion phase of TST001 at 6mg/kg Q3W with CAPOX. There was no subject experienced dose-limiting toxicity . Treatment-emergent adverse events (TEAEs) were mostly grade 1-2, including nausea (76.9%), anemia (69.2%), vomiting, AST increased (63.8% respectively), hypoalbuminemia, ALT increased (46.2%, respectively). Treatment related grade 3 AEs were hypertension **(** 15.4%**)** , anemia, hypoproteinemia, WBC count decreased, hypocalcemia aggravated (7.7%, respectively). Among the eight patients from the dose escalation part (with no CLDN18.2 expression selection yet with measurable disease) with at least one post-treatment tumor assessment, four had achieved partial response, three had achieved stable disease and one had progressive disease as the best tumor response per RECIST1.1. **Conclusions:** Conclusion: TST001 in combination with CAPOX in first line gastric cancer patients is safe and encouraging anti-tumor activities have been observed. Additional data from the 6 mg/kg dose expansion cohort will be updated at the meeting. Clinical trial information: NCT04495296. Research Sponsor: None.

SCALE-1: Safety and efficacy of short course neoadjuvant chemo-radiotherapy plus toripalimab for locally advanced resectable squamous cell carcinoma of esophagus. *First Author: Ning Jiang, Department of Radiation Oncology, The Affiliated Cancer Hospital of Nanjing Medical University, Jiangsu Cancer Hospital, Jiangsu Institute of Cancer Research, Nanjing, China*

Background: Adding PD-1 inhibitors to neoadjuvant chemoradiotherapy have shown promising results in treatment of locally advanced esophageal squamous cell carcinoma (ESCC). However, there is a need to explore more effective and safe treatment doses and schedules. The aim of this single arm phase Ib trial is to determine the safety and efficacy of short course neoadjuvant chemo-radiotherapy plus toripalimab following by esophagectomy in patients with locally advanced resectable ESCC. **Methods:** Patients (pts) with histopathologically confirmed thoracic ESCC, diagnosed as clinical stage of cT3-4aN0M0/cT1-4aN+M0 per AJCC 8th and ECOG PS of 0-1 were eligible. Toripalimab (240mg) was given with paclitaxel (135 mg/m^2) and carboplatin (AUC=5) on D1 every 3 weeks for two cycles. Short course neoadjuvant radiotherapy (3000 cGy in 12 fractions on 5 days per week) was administered from D3 to D18. Esophagectomy was scheduled 4 to 6 weeks after the completion of neoadjuvant therapy. Target total enrollment was 20 pts. The primary endpoint was treatment safety. Pre- and post-treatment specimens were collected for PD-L1 expression assay and gene expression profiles (GEPs) analysis using the nCounter platform. **Results:** From Jan 29, 2021 to Nov 3, 2021, 26 patients were screened and 23 met the inclusion criteria. The majority of them were diagnosed with clinical stage of cT3-T4 (95.6%), cN1-2 (62.5%), and cTNM III-IVA (78.2%). All 23 pts finished neoadjuvant radiotherapy, while two of them didn't receive or received reduced dose of the second cycle chemotherapy or toripalimab due to toxicity. Notable grade 3 or higher AEs included leukopenia (n=21), neutropenia (n=21), anorexia (n=19) and nausea (n=18). No treatment related oesophagitis, pneumonia and gastrointestinal hemorrhage above Grade 3 were observed. 20 pts underwent surgery after a median of 7 weeks post neoadjuvant therapy. Reasons for not undergoing surgery were patients' choice (n=2) and tuberculosis reactivation (n=1). 3 pts with Grade III surgical complications were observed during the perioperative period. 11/20 (55%) complete pathological responses (ypT0N0) were observed, 16/20 (80%) pts were major pathologic response (MPR) and the remaining 4 pts achieved partial response. Pre-treatment GEP analysis revealed significantly higher expression levels of CXCL10, CXCL11, OAS2, and lower level of CD209 and KLRB1 in pCR (n=6) than in Non-pCR group (n=4). Moreover, pCR group showed a trend of upregulated signatures of tumor infiltrating leukocytes, cytolytic activity, cytotoxic T cell, T cell markers and Teff score (P= 0.062) after treatment. **Conclusions:** Combining short course nCRT with toripalimab is feasible and effective in patients with locally advanced resectable ESCC, and might be a promising approach for neoadjuvant treatment. Clinical trial information: ChCTR2100045104. Research Sponsor: None.

Cellworks singula therapy response index (TRI) predicts clinical outcomes for esophageal adenocarcinoma: MyCare-004. *First Author: Elizabeth Catherine Smyth, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom*

Background: Computational biological modeling reveals many dysregulated signaling pathways responsible for hallmark behaviors of cancer and variable drug response in the population. A mechanistic model created for each patient using comprehensive genomic inputs can biosimulate downstream molecular effects of cell signaling and drugs for each patient's personalized *in silico* virtual disease model. Singula TRI is designed to predict the outcome of specific therapies with a continuous TRI Score, 0 to 100, for each patient's unique genomic network. **Methods:** TRI's ability to predict Overall Survival (OS), Disease Free Survival (DFS) and Mandard – tumor regression grade (TRG) was prospectively evaluated in a retrospective cohort of gastro-esophageal adenocarcinoma (GEA) from UK OCCAMS consortium. Random sampling stratified by clinical factors was used to split the data into independent training (N = 140) and validation (N = 131) subsets. Multivariate Cox Proportional Hazard (PH) and Proportional Odds models were used to predict survival and pathological response as a function of the pre-defined TRI and clinical thresholds compared with standard clinical factors. **Results:** 271 GEA patients were selected who had pre-chemo treated biopsies with 50x whole genome sequencing from the OCCAMS International Cancer Genome Consortium study. The median age was 65.6 years, 234 male and 30 female, with deceased median OS of 21.9 months and living of 49.9 months. There were 35 T2, 215 T3, 70 N0, 126 N1, 62 N2 and 266 M0. Patients were treated with physician prescribed chemotherapy treatments (PPT) according to UK clinical guidelines (SC). Biosimulation revealed that 99% of these tumors had deficiency in DNA repair genes. Other pathways included amplification of multi-drug resistance pumps, TP53 mutations and aberrations of the PI3K/AKT pathway genes. The table shows that TRI provides additional predictive information for OS and DFS beyond PPT and standard clinical factors. TRI was also predictive of TRG in univariate analysis. TRI scores were also generated for 82 alternate therapies for each patient enabling selection of optimal therapies with estimates of improvements in median OS and DFS compared to SC. **Conclusions:** In this cohort of patients, Cellworks Singula TRI was predictive of survival and TRG beyond clinical factors. These positive results suggest the utility of biosimulation-informed therapy selection to improve survival of GEA and validation in prospective clinical studies is warranted. Research Sponsor: None.

Phase III randomized controlled trial comparing chemotherapy to best supportive care in advanced esophageal and gastroesophageal junction cancer. *First Author: Vanita Noronha, Tata Memorial Centre, Mumbai, India*

Background: Patients with advanced esophageal/gastroesophageal junction (GEJ) cancer have a dismal outcome. No study has unequivocally proven that systemic chemotherapy prolongs survival. Current NCCN guidelines recommend palliative/best supportive care as a first-line option for patients with unresectable locally advanced, recurrent, or metastatic esophageal/GEJ cancers. **Methods**: Phase III randomized controlled study conducted in the Department of Medical Oncology at the Tata Memorial Hospital (Mumbai, India) in patients with advanced unresectable or metastatic esophageal or GEJ cancer, planned for palliative intent therapy. Patients aged 18 to 70 years, with a performance status < 2, were stratified based on histopathology, presence of metastatic disease and receipt of prior curative therapy, and randomized 1:1 to best supportive care alone, or best supportive care with chemotherapy consisting of intravenous paclitaxel 80 mg/m^2 once-a-week, continued until disease progression or intolerable toxicity. Best supportive care consisted of patient education and counselling, non-chemotherapeutic palliative measures like radiation, or stenting, placement of feeding tube, analgesia, antiemesis and other supportive medications, nutritional support, and referral to a patient support group. Primary endpoint was overall survival (OS); secondary endpoints included progression free survival (PFS), response rate, adverse events, and quality of life. **Results**: Between May 2016 and Dec 2020, we recruited 281 patients; 143 to chemotherapy and 138 to best supportive care. Histopathology was squamous in 269 (95.7%) patients. In the 143 patients in the chemotherapy arm, median number of paclitaxel cycles was 12 (IQR, 7-23). The response rate was 32%. Grade > 3 toxicities occurred in 82 (57%) patients who received paclitaxel; commonly hyponatremia (18%), anemia (11%), fatigue (10%), peripheral neuropathy (10%), infection (9%), and neutropenia (7%). Median PFS was 2.1 months (95% CI, 1.98-2.23) in the best supportive care arm, and 4.1 months in the chemotherapy arm (95% CI, 3.54-4.74); HR, 0.51 (95% CI, 0.39-0.64); $P < 0.001$. The 1-year OS was 11.6% in the best supportive care arm, versus 30.8% in the chemotherapy arm. Median OS was 4.2 months (95% CI, 2.93-5.42) in the best supportive care arm, and 8.6 months in the chemotherapy arm (95% CI, 7.56-9.66); HR, 0.52 (95% CI, 0.40-0.66); $P < 0.001$. **Conclusions**: Systemic chemotherapy significantly prolongs survival and should be considered the standard of care in patients with advanced esophageal and GEJ squamous cell carcinoma. Metronomic weekly paclitaxel is an attractive option, especially in LMICs with limited access to newer immunotherapy-based combination regimens. Clinical trial information: CTRI/2016/01/006474. Research Sponsor: Indian Cooperative Oncology Network.

Outcomes in patients undergoing curative surgery for gastric cancer by facility type and socioeconomic factors: An analysis of the National Cancer Database (NCDB). *First Author: Ali Alqahtani, Ruesch Center for the Cure of Gastrointestinal Cancers, Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC*

Background: Surgical and medical treatment for resectable gastric cancer is complex, and multidisciplinary team involvement is essential to provide optimal treatment outcomes. However, socioeconomic disparities influence the quality of medical care patients receive. We hypothesized that facility type, median income, insurance type, and location would impact patients' overall survival (OS). **Methods:** In a retrospective analysis of NCDB data, we identified patients with stage II and III gastric adenocarcinoma who underwent curative-intent surgical resection and chemotherapy between 2004-2018. Demographic and socioeconomic factors were studied, including treatment facility type, median household income, urban/rural residence, and insurance status. Multivariate Cox proportional hazard model was used to evaluate the impact of these variables on overall survival (OS). The Kaplan-Meier method was used to estimate OS. Log-rank test was used to compare the OS between groups. **Results:** Based on the criteria listed above, 36,318 patients were identified: 76.3% were Caucasian, 14.4% black, 7.2% Asian, and 2.0% other. 56.4% lived in large metropolitan areas (LM), 29.9% in small/medium metropolitan areas (SM), and 14.2% in rural areas (RA). Patients who were treated in academic/research programs had significantly better OS (mOS 40.5 months) compared to integrated-network cancer programs (mOS 34.0 months, HR 0.897, $p < 0.0001$), comprehensive community cancer programs (mOS 31.0 months, HR 0.89, $p < 0.0001$), and community cancer programs (mOS 29.5, HR 0.881, $p < 0.0001$). Patients from LM had better OS compared to those from SM and RA (mOS 39.0, 32.1, 29.9 months respectively, $p < 0.0001$). Privately insured patients had improved OS compared to Medicare-insured patients (mOS 40.8 vs 29.7 months, HR 0.758, $p < 0.0001$). Higher annual income (≥ $63,000) was positively associated with improved OS ($p < 0.0001$). **Conclusions:** Outcomes for patients with gastric cancer treated with surgery and chemotherapy are strongly influenced by socioeconomic variables, including place of residence, treatment setting, insurance, and income level. We highlight improved outcomes in patients who resided in LM and were treated at academic/research centers. A potential hypothesis for this trend is increased access to specialized, multidisciplinary care and clinical trials. Research Sponsor: None.

Non-invasive detection of esophageal carcinoma by integrative analysis of low-pass whole methylome sequencing of plasma cell-free DNA. *First Author: Dan Liu, Genecast Biotechnology Co., Ltd., Beijing, China*

Background: Cell-free DNA (cfDNA) methylation, fragmentation patterns, chromosome instability, and chromatin accessiblity have been previously shown to be valid plasma biomarkers for non-invasive cancer detection. However, conventional whole-genome bisulfite sequencing (WGBS) is unable to simultaneously profile all these biomarkers due to bisulfite-induced DNA damages. Here we developed a machine learning approach to comprehensively integrate multiple types of cancer genomic markers from enzyme-conversion-based low-pass whole-methylome sequencing (WMS) of plasma cfDNA to non-invasively detect esophageal carcinoma. **Methods:** Plasma cfDNA sampels from 85 patients and 568 healthy individuals were collected and were split into the discovery and independent testing cohort. The discovery cohort includes 60 cancer patients and 398 healthy individuals and the independent testing cohort includes 25 cancer patients and 170 healthy individuals. Whole methylome sequencing (WMS) libraries were generated from enzymatically converted cfDNA and were subsequently paired-end sequenced at ~2X coverage. The genome-wide methylation density, fragmentation fingerprints, chromosome instability, and chromatin accessibility were extracted from the WMS data and individually modelled via machine learning methods such as SVM, LR, GBDT, random forest. The final predictive model is an ensemble model integrating all uni-modal models. All models were trained and fitted on the discovery cohort. **Results:** Data of different modalities provide complementary information in separating the cancer patients from the healthy individuals. Unsupervised clustering of the individuals showed clear separation between cancer patients and healthy individuals. The final predictive model achieved AUC =96.25% in the discovery cohort and AUC =91.15% in the independent testing cohort. Under a specificity of 95.29% (CI: 87.64% - 100.00%), sensitivity was 72.00% (CI: 56.00% - 92.00%) in the independent testing cohort. Separating the cancer patients into different stages, we found that the detection power is usuaul lower for early-stage cancer patients. **Conclusions:** These results demonstrate the first proof of principle on the feasibility of integrating multiple genomic cancer markers to non-invasively detect esophageal carcinoma from WMS plasma cell-free DNA. A large prospective cohort study is planned to further validate its clinical performance. Research Sponsor: None.

TACE with idarubicin-eluting beads compared with TACE with epirubicin-eluting beads in BCLC B-stage HCC: Interim results of a randomized, double-blind, parallel-controlled, phrase IV multicenter study. *First Author: Jiaping Li, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: The lack of effectiveness of a cytotoxic agent for intra-arterial use in HCC has been a major limitation for improved outcomes. Idarubicin, an anthracycline-based drug, is currently used as the first-line treatment option for acute myeloid leukaemia. Incredibly, a previous study showed that idarubicin has better anti-tumor effects on HCC compared with oxaliplatin and 5-fluorouracil in vitro, and two single-arm studies of idarubicin lipiodol TACE reported good therapeutic outcomes and acceptable adverse drug reactions. **Methods:** This randomized, double-blind, parallel controlled, phrase IV, multicenter trial was conducted from July 2020. Patients with BCLC stage B HCC were randomly assigned in a 1:1 ratio to receive TACE loaded with 10 mg idarubicin (IT group) or 40 mg epirubicin (ET group). The sample size of 120 was needed in each group according to calculation. The primary endpoint was progression-free survival (PFS, defined as the time from randomization until progression or death from any cause). The secondary endpoints were overall survival (OS, defined as the date of randomization to death from any cause), objective response rate (ORR, the proportion of patients with complete response or partial response according to mRECIST), and adverse events. A single interim analysis was planned when appropriately 1/3 (33.3%) of the required 240 patients. To control the type I error rate at the interim analysis, superiority boundaries that were based on Pocock spending function 24 were a P value of less than 0.022 for PFS. The deadline for interim analysis of data is October 1, 2021. **Results:** Overall, 103 patients (mean age: 56.6 years±11.4; 12 women and 91 men) were randomly assigned to receive either TACE with Idarubicin-eluting beads (n = 50) or TACE with Epirubicin-eluting beads (n = 53). The PFS and OS were not mature on October 1, 2021. The median PFS was significantly longer in the IT group than in the ET group (HR [hazard ratio] = 0.32, P < 0.001). PFS rates were 82.4% and 43.9% at 6 months, and 53.7% and 18.9% at 12 months in IT and ET groups, respectively. The median OS was longer but not significant in the IT group than in the ET group (HR = 0.52, P = 0.058). OS rates were 90.2% and 76.5% at 6 months, and 61.6% and 47.3% at 12 months in IT and ET groups, respectively. TACE with Idarubicin-eluting beads did not improve ORR compared to TACE with Epirubicin-eluting beads according to mRECIST (80.0% vs. 62.3%, P = 0.048). The incidence of myelosuppression was higher in the ET group than in the IT group (22.6% vs. 6.0%, P = 0.024). No difference was observed in other treatment related adverse events. **Conclusions:** This study proved that Idarubicin could be a good safety profile and superior PFS and ORR than Epirubicin when used as part of a TACE regimen for BCLC B stage HCC. Longer follow-up is needed to confirm this conclusion. Clinical trial information: ChiCTR2000034758. Research Sponsor: None.

Atezolizumab plus bevacizumab versus lenvatinib or sorafenib in non-viral unresectable hepatocellular carcinoma: An international study. *First Author: Andrea Casadei-Gardini, San Raffaele Hospital, Milan, Italy*

Background: Recently, several evidences have suggested that patients with a no-viral hepatocellular carcinoma (HCC) might be less responsive to immunotherapy and more response to Lenvatinib. **Methods:** The study population derived from prospectively collected retrospectively analyzed data of patients treated with atezolizumab plus bevacizumab (AB) or lenvatinib (L) or sorafenib (S) as first-line treatment for advanced HCC or intermediate HCC deemed not eligible for loco-regional therapies. The overall cohort included Western and Eastern patient populations from 36 centers located in 4 countries(Italy, Japan, Republic of Korea, and United Kingdom) undergoing treatment with L or AB or with S. The primary endpoint was OS of AB versus L; the secondary endpoints were OS of AB versus S. **Results:** 569 patients received L, 190 patients received AB and 210 received S. In the whole population OS was 17.8 months (95%CI:15.8-43.8) for patients receiving L, and 12.1 months(95%CI:11.1-16.8)for patients treated with AB (HR 0.71; 95% CI:0.50-1.06; p=0.1028); multivariate analysis for imbalance patients characteristic highlighted that L is an independent prognostic factor for OS (HR 0.65; 95% CI:0.44-0.95; p=0.0268), compared AB. In the population affected by NASH/NAFLD, 254 patients were treated with L and 82 patients were treated with AB. OS was 21.2 months (95% CI:18.4-30.6) for patients receiving L, and 12.2 months (95% CI:10.0-16.8) for patients treated with AB (HR 0.46; 95% CI:0.25-0.88; p = 0.0181); multivariate analysis for imbalance patients characteristic highlighted that L is an independent prognostic factor for OS (HR 0.46; 95% CI:0.26-0.84; p=0.031),compared AB. In the cohort of no viral and no NASH/NAFLD patients, no statistically significant differences were reported in terms of OS between patients treated with L versus AB. All these results were confirmed following propensity score matching analysis. By comparing patients receiving AB versus S, no significant differences were found in terms of OS in the whole population, in the NASH/NAFLD population and in no viral/no NASH/NAFLD population. **Conclusions:** The present analysis conducted on a large number of non-viral HCC patients showed for the first time a significant survival benefit from lenvatinib over atezolizumab plus bevacizumab, in particular in patients with NAFLD/NASH-related HCC. Research Sponsor: None.

Patient-reported outcomes for the phase 3 TOPAZ-1 study of durvalumab plus gemcitabine and cisplatin in advanced biliary tract cancer. *First Author: Howard A. Burris III, Sarah Cannon Research Institute, Tennessee Oncology, Nashville, TN*

Background: TOPAZ-1 (NCT03875235) is a randomized, double-blind, global, Phase 3 study evaluating the efficacy and safety of durvalumab (D) in combination with (+) gemcitabine and cisplatin (GC) as first-line treatment for patients (pts) with advanced biliary tract cancer (BTC).[1] D + GC significantly improved overall survival (OS) versus placebo (PBO) + GC and represents a new treatment option. **Methods:** A pre-planned secondary objective of TOPAZ-1 was to assess pt-reported outcomes (PROs) for pts receiving D + GC versus PBO + GC. Pts with BTC were randomized 1:1 to D (1500 mg) or PBO, + G (1000 mg/m^2) and C (25 mg/m^2), for up to 8 cycles, followed by D or PBO monotherapy until disease progression, unacceptable toxicity, or other discontinuation criteria were met. PROs were assessed with the European Organisation for Research and Treatment of Cancer 30-item Quality of Life (QoL) Questionnaire, EORTC QLQ-C30 (C30), and the BTC 21-item module, EORTC QLQ-BIL21 (BIL21). Time to deterioration (TTD) was the primary assessment of PROs; defined as the time from randomization to the date of the first pre-specified, clinically meaningful deterioration (e.g. disease progression). The PRO analysis set included all pts from the full analysis set who completed a questionnaire. **Results:** Compliance rates for PROs were high at baseline (>81%) and remained high (majority >70% over 28 cycles) for both treatment groups. Baseline scores were comparable between treatment groups. Addition of D was well tolerated, with no significant difference in TTD in D + GC versus PBO + GC for pt-reported symptoms or functioning using either C30 or BIL21 (Table), or Global Health Status/QoL (hazard ratio [HR], 0.87; 95% confidence interval [CI], 0.69–1.12; p=0.279). **Conclusions:** Addition of D to GC improved OS (Oh D-Y, et al. *J Clin Oncol* 2022;40(suppl 4). Abs 378) and was well tolerated with no difference in TTD of QoL for pts, supporting D + GC as a new treatment option for pts with BTC. Clinical trial information: NCT03875235. Research Sponsor: AstraZeneca.

A phase II study of stereotactic body radiotherapy (SBRT) combined with sintilimab in patients with recurrent or oligometastatic hepatocellular carcinoma (HCC).

First Author: Yixing Chen, Department of Radiation Oncology, Zhongshan Hospital, Fudan University, Shanghai, China

Background: SBRT is an emerging treatment option for oligometastatic cancer disease. Preclinical studies have shown the synergistic effects between the radiotherapy and immunotherapy. Early clinical data also suggested that immunotherapy might augment the local effects of radiotherapy and decrease metastatic recurrence. This study aimed to evaluate the efficacy and safety of SBRT combined with sintilimab (a PD-1 antibody) in patients with recurrent or oligometastatic HCC. **Methods:** In this single arm, phase II study (NCT03857815), eligibility criteria included Pts with recurrent or oligometastatic HCC (defined as ≤5 metastatic/recurrent lesions), Child-Pugh class A, ECOG PS ≤ 1. Pts received sintilimab 200 mg IV Q3W for up to 12 months, progressive disease, unacceptable toxicity, or withdrawal. SBRT to all lesions was started at cycle 1 day 1. Primary endpoint was progression free survival (PFS) per RECIST 1.1. Secondary endpoints included safety, objective response rate (ORR), disease control rate (DCR) and overall survival (OS). **Results:** At data cutoff (Dec 28th, 2021), 25 pts with 32 lesions were treated with SBRT + Sintilimab. SBRT was delivered at a median dose of 54 Gy (range 48-60) in 6 fractions (range 6-10) and the median follow-up time was 16.9 months (range 3.9-32.1). In those 25 evaluable pts, median age was 64 years (range 37-77), 24 (96%) were male, 24 (96%) were HBV+, 6 (24%) had extrahepatic metastasis, most pts had prior ≥2 local therapies. The confirmed ORR was 96% (24/25) according to RECIST 1.1 with 18pts CR and 6pts PR. 6-mo and 12-mo PFS rate was 100% and 70% (95%CI, 52.3%-93.6%), respectively.12-mo local control rate was 100%. Median PFS and OS was still not mature. Treatment-related adverse events (TRAEs) occurred in 14 pts (56%). Most common TRAEs were rash (16%), platelet count decreased (12%), myositis (8%). Grade 3 TRAEs (myositis) occurred in 1pt (4%). There were no grade 4-5 TRAEs. TRAEs led to discontinuation in 6 pts (24%). SAE were myocarditis (1pt Grade1), viral hepatitis (1pt Grade 3, treatment-independent) and upper gastrointestinal haemorrhage (1pt Grade 3, PD related). **Conclusions:** The combination of SBRT with Sintilimab was tolerable and showed an encouraging ORR of 96% in pts with recurrent or oligometastatic HCC. Longer follow up is required to further evaluate the efficacy and safety. Clinical trial information: NCT03857815. Research Sponsor: Innovent.

4072 **Poster Session**

Clinical outcomes associated with tislelizumab in patients (pts) with advanced hepatocellular carcinoma (HCC) who have been previously treated with sorafenib (SOR) or lenvatinib (LEN) in RATIONALE-208.

First Author: Julien Edeline, Department of Medical Oncology, Eugene Marquis Center, Rennes, France

Background: Tislelizumab, an anti-PD-1 monoclonal antibody, demonstrated clinical activity and was well tolerated in pts with previously treated advanced HCC in the Phase 2 RATIONALE-208 study (NCT03419897). At the time of this study, SOR and LEN were recommended first-line treatments for pts with advanced HCC and continue to have an important role in the first-line treatment of HCC despite the recent approval of new immuno-oncology-based combinations (atezolizumab and bevacizumab) in some regions. We report the clinical outcomes of pts with advanced HCC who were previously treated with SOR/LEN. **Methods:** Pts who had received ≥ 1 prior line of systemic therapy for advanced HCC received tislelizumab 200 mg intravenously once every three weeks. Objective response rate (ORR) by independent review committee (IRC) (ORR_{IRC}), duration of response by IRC (DOR_{IRC}), progression-free survival by IRC (PFS_{IRC}), overall survival (OS), and safety were evaluated in pts who had been previously treated with SOR/LEN. **Results:** As of February 2020, 249 pts were enrolled and 235 pts had received prior treatment with SOR/LEN, of whom 126 and 109 pts had received 1 or ≥ 2 prior lines of systemic therapy, respectively. At study entry, 211 (89.8%) pts had BCLC stage C and 187 (79.6%) pts had extrahepatic spread. Median follow-up duration for pts previously treated with SOR/LEN was 12.5 months and ORR_{IRC} was 13.6% (95% CI: 9.5, 18.7), including 2 complete responses and 30 partial responses. Median DOR_{IRC} was not reached. Median PFS_{IRC} and OS of pts previously treated with SOR/LEN was 2.7 months (95% CI: 1.6, 2.8) and 13.5 months (95% CI: 10.9, 15.8), respectively. Tislelizumab was generally well tolerated in pts previously treated with SOR/LEN (Table), and the most common treatment-emergent adverse events were increased aspartate aminotransferase (n=70; 28.1%) and alanine aminotransferase (n=52; 20.9%). **Conclusions:** Tislelizumab was investigated beyond the first-line setting, as effective second- and third-line treatment options are limited for pts with advanced HCC and there is an unmet medical need. This analysis indicates that tislelizumab is clinically active and well tolerated in pts with advanced HCC who have received prior systemic treatment with SOR/LEN. Clinical trial information: NCT03419897. Research Sponsor: This study was sponsored by BeiGene, Ltd. Medical writing support for the development of this abstract, under direction of the authors, was provided by Claire White, PhD, of Ashfield MedComms, an Ashfield Health company, and was funded by BeiGene, Ltd.

Summary of AEs in pts previously treated with SOR/LEN.

	TEAE	TRAE
	N=235	
≥ 1, n (%)	223 (94.9)	147 (62.6)
≥ Grade 3	116 (49.4)	32 (13.6)
Serious	87 (37.0)	15 (6.4)
Leading to discontinuation	26 (11.1)	12 (5.1)

Hepatic artery infusion chemotherapy (HAIC) combined with sintilimab and bevacizumab biosimilar (IBI305) for initial unresectable hepatocellular carcinoma (HCC): A prospective, single-arm phase II trial.

First Author: Dongming Liu, Liver Cancer Research Center for Prevention and Therapy, Tianjin Medical University Cancer Institute and Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin, China

Background: Sintilimab plus IBI305, a bevacizumab biosimilar, showed a significant overall survival and progression-free survival benefit versus sorafenib in the first-line setting for patients with unresectable hepatocellular carcinoma. Hepatic arterial infusion chemotherapy is an intraarterial procedure that has been widely used in Asia, with high response rate. This trial was designed to assess the feasibility and efficacy of HAIC combined with sintilimab and IBI305 in advanced unresectable hepatocellular carcinoma. **Methods:** This is a prospective, single-arm phase II study. Patients with histologically or cytologically diagnosed or clinically confirmed hepatocellular carcinoma, China liver cancer staging (CNLC) stage IIb-IIIb, no previous systemic treatment, Child-Pugh classification A or B, Eastern Cooperative Oncology Group (ECOG) performance status of 0 or 1 were eligible for inclusion. Patients received FOLOFOX-HAIC, followed by intravenous sintilimab (200 mg every 3 weeks, four cycles) and intravenous IBI305 (7.5 mg/kg every 3 weeks, three cycles). The primary endpoint was objective response rate (ORR) per mRECIST. Secondary endpoint were surgical conversion rate, pCR rate and R0 resection rate. The study is registered with Clinicaltrials.gov: NCT05029973. **Results:** Between May, 2021 to Sep, 2021, a total of 30 eligible patients were enrolled: median age 54.5 years (range 37-73); M:F 27:3; CNLC stage IIb/IIIa/IIIb: 3/16/11; Child-Pugh class A/B: 28/2; ECOG PS 0/1: 26/4. There were 23(76.7%) patients with hepatitis B and 5(16.7%) with hepatitis C. The median tumor size was 8.75 cm (interquartile range [IQR], 4.9-10.5), 60.0% pts present vascular invasion, and 36.7% had extrahepatic metastasis. Of 30 pts evaluable for response, 20 (66.7%; 95% CI: 47.2%-82.7%) achieved confirmed partial response, and became eligible for surgical resection. Finally, 14 of them received surgical resection and all (100%) achieved R0 resection, 3 pts completed radiofrequency ablation (RAF), 3 pts refused resection or RFA. The pCR rate in the patients completed pathological examination was 52.6% (95% CI: 28.9%-75.6%). The most common TRAEs included hypertension (23.3%), rash (16.7%), and abnormal liver function (10.0%). No grade 3-4 TRAEs were observed. Of note, in patients received surgery, 1 developed grade 1 biliary fistula, 1 developed hepatic failure and finally lead to death **Conclusions:** HAIC Combined With sintilimab and IBI305 resulted in a promising ORR, R0 surgical conversion rate and pCR rate with a manageable safety for initial unresectable advanced hepatocellular carcinoma. Further follow-up is ongoing. Clinical trial information: NCT05029973. Research Sponsor: National Natural Science Foundation of China (Grant Nos. 81502019).

Patient-reported outcomes from the phase 3 HIMALAYA study of tremelimumab plus durvalumab in unresectable hepatocellular carcinoma.

First Author: Bruno Sangro, Liver Unit and HPB Oncology Area, Clínica Universidad de Navarra and CIBEREHD, Pamplona, Spain

Background: In the Phase 3 HIMALAYA study (NCT03298451) of patients (pts) receiving first-line treatment for unresectable hepatocellular carcinoma (uHCC), a single priming dose of tremelimumab (T; anti-CTLA-4) plus durvalumab (D; anti-PD-L1) in the STRIDE regimen significantly improved overall survival (OS) vs sorafenib (S), and D monotherapy was noninferior to S for OS (Abou-Alfa et al. *J Clin Oncol* 2022;40[suppl 4]. Abs 379). **Methods:** A pre-planned secondary objective of HIMALAYA was to assess pt-reported outcomes (PROs) in pts receiving STRIDE (T 300 mg plus D 1500 mg [one dose] plus D 1500 mg once every 4 weeks [Q4W]; N=393) or D (1500 mg Q4W; N=389) vs S (400 mg twice daily; N=389). The European Organisation for Research and Treatment of Cancer (EORTC) 30-item Quality of Life (QoL) Questionnaire and the EORTC 18-item HCC QoL questionnaire were used to assess disease-related symptoms, physical functioning (PF), and Global Health Status (GHS)/QoL. Time to deterioration (TTD), defined as time from randomization to first clinically meaningful deterioration (worsening ≥10 points) confirmed at a subsequent visit or death, was assessed in pts with baseline scores ≤90 for symptoms or ≥10 for PF and GHS/QoL. **Results:** Across treatment arms, compliance rates for PROs were >77% at baseline and >70% overall. Baseline scores were comparable across treatment arms. TTD in fatigue, appetite loss, abdominal pain, PF, and GHS/QoL were significantly longer for both STRIDE and D vs S (Table). TTD in nausea and abdominal swelling were significantly longer for STRIDE vs S. **Conclusions:** The positive OS outcomes for STRIDE and D in pts receiving first-line treatment for uHCC in HIMALAYA were associated with clinically meaningful, pt-centered benefits, demonstrated by delayed worsening of disease-related symptoms, PF, and GHS/QoL vs S. Median TTD in months (95% CI) in PROs for STRIDE and D vs S. Clinical trial information: NCT03298451. Research Sponsor: AstraZeneca.

Regional subgroup analysis of the phase 3 TOPAZ-1 study of durvalumab (D) plus gemcitabine and cisplatin (GC) in advanced biliary tract cancer (BTC).

First Author: Arndt Vogel, Hannover Medical School, Hannover, Germany

Background: TOPAZ-1 (NCT03875235) is a randomized, double-blind, global, Phase 3 study evaluating the efficacy and safety of D + GC as first-line treatment for patients (pts) with advanced BTC. D + GC significantly improved overall survival (OS) versus placebo (PBO) + GC (Oh D-Y, et al. *J Clin Oncol* 2022;40[suppl 4]. Abs 378). **Methods:** A pre-specified subgroup analysis was performed for efficacy outcomes including OS for pts enrolled in Asia (China, Hong Kong, India, Japan, South Korea, Taiwan, Thailand) or the rest of the world (RoW; Europe [Bulgaria, France, Italy, Poland, Russia, Turkey, United Kingdom], North America [NA; USA], and South America [SA; Argentina, Chile]). Post hoc country level analyses were also performed to better characterize outcomes in different countries and regions. Pts with BTC were randomized 1:1 to D (1500 mg once every 3 weeks [Q3W]) or PBO, + G (1000 mg/m^2) and C (25 mg/m^2) on Days 1 and 8, Q3W, for up to 8 cycles, followed by D (1500 mg Q4W) or PBO monotherapy until disease progression or unacceptable toxicity. Hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated from a Cox proportional hazards model. **Results:** Pt numbers were balanced across regions (Asia, n=374 [54.6%]; RoW, n=311 [45.4%]). Baseline characteristics were balanced between regions with the exception of modest differences in important pre-defined prognostic factors, including disease status: recurrent disease (Asia 23%; RoW 14.5%), ECOG performance status 1 (Asia 59.1%; RoW 41.2%), and metastatic disease (Asia 89.3%; RoW 82%). In the PBO arm, more pts in Asia received subsequent anticancer therapies than pts in RoW (53.6% vs 43.9%). Median duration of follow-up in censored pts was about 2 months (mo) longer in Asia versus RoW (14.8 vs 13.0 mo in D + GC; 13.8 vs 12.1 mo in PBO + GC). Regional level analysis (Table) showed outcomes were similar and approximated the overall population for Asia, Europe, and NA. Grade 3/4 adverse events were similar for Asia (D + GC 78.5%; PBO + GC 78.6%) and RoW (D + GC 72.7%; PBO + GC 76.7%). **Conclusions:** Despite some regional differences in prognostic characteristics, OS trends favored D + GC versus PBO + GC for pts enrolled in both Asia and RoW, supporting the use of D + GC as a potential new treatment option for all pts with BTC. Country-specific and regional outcomes continue to be explored. Clinical trial information: NCT03875235. Research Sponsor: AstraZeneca.

OS outcomes per arm, by region.

Region	D + GC, n/N (%)	PBO + GC, n/N (%)	HR (95% CI)
Overall	198/341 (58)	226/344 (66)	0.80 (0.66–0.97)

Organ-specific responses to atezolizumab plus bevacizumab in patients with advanced hepatocellular carcinoma.

First Author: Jaekyung Cheon, Department of Medical Oncology, CHA Bundang Medical Center, Seongnam, South Korea

Background: Anti-PD-1 monotherapy elicits various organ-specific immune responses. Although advanced hepatocellular carcinoma (aHCC) showed 20–40% objective response rates (ORR) for cases of extrahepatic lesions in sites such as the lungs or lymph nodes (LNs), only 10% of intrahepatic lesions responded to the monotherapy. The organ-specific responses were due to tumor heterogeneity and differential microenvironments, and may have contributed to the failure of the phase III trials of anti-PD-1 monotherapy for aHCC. Recently, the combination of atezolizumab and bevacizumab (Ate/Bev) as first-line systemic treatment has resulted in survival benefits for patients with aHCC. However, the organ-specific response for this treatment has not been explored. We aimed to evaluate the organ-specific response to Ate/Bev combination therapy in patients with aHCC. **Methods:** We enrolled patients who received first-line Ate/Bev treatment for aHCC. Eligible patients included those with Child-Pugh A liver function, measurable tumor lesions, and serial image studies available for response evaluation. An independent radiologist reviewed the tumors located in the liver, lungs, LNs, and other sites. Organ-specific response criteria, adapted from RECIST 1.1 and immune-related RECIST, were used. **Results:** Between May 2020 and June 2021, 124 patients from two Korean cancer referral institutions received first-line Ate/Bev treatment for aHCC. The patient baseline characteristics included: hepatitis B (n = 85, 68.5%), hepatitis C (n = 6, 4.8%), non-viral (n = 33, 26.7%); BCLC stage A/B/C (n = 2, 1.6%/n = 19, 15.3%/n = 103, 83.1%); macrovascular invasion (n = 39, 31.5%); extrahepatic metastasis (n = 75, 60.5%); and AFP >400 ng/ml (n = 39, 31.5%). The median age was 62 years (range: 34–90). With median follow-up duration of 10.1 months, median progression-free survival was 6.8 months (95% CI, 3.6–10.0) and median overall survival was 16.9 months (95% CI, range not available). The ORR was 29.8%. For 260 individual tumor lesions, the liver was the most commonly involved organ (n = 152, 58.5%), followed by the LNs (n = 42, 16.2%) and lungs (n = 24, 9.2%). Ate/Bev treatment induced potent tumor shrinkage in both intrahepatic and extrahepatic lesions: ORR for hepatic lesions was 28.3%; LN lesions, 40.5%; lung lesions, 29.1%; and other metastatic lesions, 19.0%. Further, the organ-specific response rate for intrahepatic tumors decreased as the tumor size increased (36.7%: ≤50 mm, 13.0%: >50 mm). **Conclusions:** Unlike anti-PD-1 monotherapy, Ate/Bev combination therapy showed favorable responses even in intrahepatic lesions, which are comparable to those in extrahepatic lesions. As such, Ate/Bev may overcome an immune-tolerant hepatic microenvironment in patients with aHCC. (NCT04862949). Research Sponsor: Roche.

A phase II study to evaluate the safety and efficacy of anlotinib combined with toripalimab for advanced biliary cancer.

First Author: Jie Shen, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background: To evaluate anlotinib combined with toripalimab for advanced biliary cancer that failed or without the will of standard first-line treatments. **Methods:** Open single arm phase II study were conducted, eligible patients (pts) were advanced biliary without the chance of operation and failed or without the will of standard first-line treatments. Pts received anlotinib 12mg po qd in 21-day cycles and toripalimab 240mg i.v. every 3 weeks. The main outcome measure was the objective response rate (ORR) of the target lesions evaluated by researchers based on the RECIST 1.1 standard, the secondary outcome measures were progress free survival (PFS) and treatment-related adverse event (TRAE). **Results:** As of Jan, 2022, 15 pts were enrolled including 9 the intrahepatic cholangiocarcinoma, 3 hilar Cholangiocarcinoma, and 3 the gall bladder carcinoma. 11 (73.3%) pts failed standard first-line treatments, and 4 pts were without the will of standard first-line treatments. The median follow-up was 254 days and 15 pts were all evaluated. 4PR, 9SD and 2PD were achieved. The ORR and DCR for irradiated target lesions was 26.7% and 86.7%, respectively. PFS for first line treatment was 139 days, and for second line treatment as 171 days. By this strategy, 1 ps was successfully transferred to operation after 3 cycle treatment. TRAEs (all grades) occurred in 14 (93.3%) pts. Grade 3 related AEs were fatigue (13.3%). Grade 1-2 related AEs were white blood cell count decreased (53.3%), hypertension (20.0%), thrombocytopenia (60.0%), fatigue (13.3%), hypothyroidism (6.7%), and fever asthenia (6.7%). **Conclusions:** The combination of anlotinib and toripalimab were demonstrated promising anti-tumor activity in advanced biliary cancer. Clinical trial information: ChiCTR2000037847. Research Sponsor: None.

4078 **Poster Session**

Characterization of tumor responses in patients (pts) with unresectable hepatocellular carcinoma (uHCC) treated with lenvatinib in REFLECT.

First Author: Masatoshi Kudo, Kindai University Faculty of Medicine, Osaka-Sayama, Japan

Background: In REFLECT, lenvatinib was noninferior to sorafenib based on overall survival in pts with uHCC (median 13.6 vs 12.3 mos; hazard ratio [HR] 0.92, 95% CI 0.79–1.06). The objective response rate (ORR) with lenvatinib was 18.8% by blinded independent imaging review (IIR) per RECIST v1.1; ORR was 40.6% by blinded IIR per mRECIST. Here we further characterize the tumor responses in pts with uHCC who were treated with lenvatinib in REFLECT. **Methods:** Assessments of ORR included all pts randomly assigned to lenvatinib treatment (12 mg/day for bodyweight ≥60 kg or 8 mg/day for bodyweight <60 kg). Time to first objective response (TTR) and duration of response (DOR) were calculated among pts who achieved a partial or complete tumor response. Tumors were assessed by IIR per RECIST v1.1 or mRECIST. Median DOR was estimated with the Kaplan-Meier product-limit method; 95% CI was estimated with a generalized Brookmeyer and Crowley method. **Results:** 478 Pts were randomly assigned to receive lenvatinib. Among the 90 pts (18.8%) who achieved an objective response by IIR per RECIST v1.1, median TTR was 2.8 mos (range 1–29) and median DOR was 7.4 mos (95% CI 5.6–9.2). Of the 194 pts who had an objective response by IIR per mRECIST, median TTR was 1.9 mos (range 1–15) and median DOR was 7.3 mos (95% CI 5.6–7.4). ORRs by selected baseline characteristics are reported in the Table. Notably, among responders by IIR per RECIST v1.1 (n=90), median overall survival (by Simon-Makuch method) was 23.4 mos (95% CI 17.6–26.3), median duration of treatment was 10.3 mos, and 65.6% of pts experienced grade ≥3 treatment-related adverse events. **Conclusions:** Pts with uHCC treated with lenvatinib achieved objective responses with a similar frequency to those seen with single-agent immune checkpoint inhibitors. These responses occurred irrespective of baseline characteristics. Tumor responses occurred early and were durable. Clinical trial information: NCT01761266. Research Sponsor: Eisai Inc., Nutley, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Targeting *HER2* mutation–positive advanced biliary tract cancers with neratinib: Final results from the phase 2 SUMMIT basket trial. *First Author: James J. Harding, Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY*

Background: *HER2* mutations are infrequent genomic events in biliary tract cancers (BTCs) and are associated with poor overall survival (OS) in patients with metastatic disease. HER2 overexpression is associated with an increased risk of disease recurrence in patients with resected BTC. There is limited data on targeting HER2 in BTC harboring activating somatic *HER2* mutations. Neratinib, an irreversible, pan-HER, oral tyrosine kinase inhibitor, interferes with constitutive receptor kinase activation and has demonstrated activity in several *HER2*-mutant solid tumors. **Methods:** SUMMIT is an open-label, single-arm, multi-cohort, phase 2, 'basket' trial of neratinib in patients with solid tumors harboring oncogenic *HER2* somatic mutations. The primary objective of the BTC cohort was to estimate objective response rate (ORR). Secondary objectives were clinical benefit rate (CBR), progression-free survival (PFS), OS, response duration, safety, and tolerability. Retrospective central confirmation of locally reported *HER2* mutation (next-generation sequencing on archival or fresh tumor tissue using MSK-IMPACT or in cfDNA extracted from plasma by MSK-ACCESS) and association with outcome was an exploratory endpoint. This trial is registered with ClinicalTrials.gov (NCT01953926). **Results:** 25 treatment-refractory patients with metastatic BTC were enrolled (11 cholangiocarcinoma, 10 gallbladder, 4 ampullary cancers). ORR was 16% (95% CI 4.5–36.1%) and CBR was 28% (95% CI 12.1–49.4%). Median PFS and OS were 2.8 (95% CI 1.1–3.7) and 5.4 (95% CI 3.7–11.7) months, respectively. Median PFS for the gallbladder, cholangiocarcinoma and ampulla cohorts was 3.7 (95% CI 0.8–6.4), 1.4 (95% CI 0.5–9.1), and 1.1 (95% CI 1.1–3.8) months, respectively. Corresponding median OS values in these cohorts were 9.8 (95% CI 2.4–NE), 5.4 (95% CI 0.8–16.2), and 5.0 (95% CI 3.7–10.2) months, respectively. Central mutation confirmation was feasible for 23 of 25 patients; 22 were concordant with enrolment assays. The most common *HER2* mutations were S310F (n = 11; 48%) and V777L (n = 4; 17%). Exploratory analyses suggested worse outcomes for *HER2*-mutant tumors with co-occurring oncogenic *TP53* and *CDKN2A* alterations. Loss of amplified *HER2* S310F and acquisition of multiple previously undetected oncogenic co-mutations were identified at progression in one of four responders. Diarrhea (56% any grade) was the most common toxicity. **Conclusions:** Neratinib is tolerable with modest antitumor activity in patients with BTC harboring *HER2* mutations. Although the primary endpoint was met, future studies should evaluate rational combinations to augment and/or prolong responses. Clinical trial information: NCT01953926. Research Sponsor: Puma Biotechnology, Inc., This work was also supported in part by a Cancer Center Support Grant (P30 CA008748) and Cycle for Survival.

Preservation of liver function with local radiation therapy in patients with metastatic intrahepatic cholangiocarcinoma with extrahepatic disease. *First Author: Rituraj Upadhyay, The Ohio State University Wexner Medical Center, Columbus, OH*

Background: Tumor related liver failure (TRLF) is the most common cause of death in patients with metastatic intrahepatic cholangiocarcinoma (mICC) accounting for up to 72% deaths in patients treated with systemic therapy alone. We present our institutional experience of treating mICC patients with local liver-directed radiation therapy (RT). **Methods:** ICC patients with extrahepatic metastatic disease who received radiation therapy at our center with a biologically equivalent dose (BED) of at least 50 Gy from January 1, 2011 to March 31, 2021 were included in our study. Patient, tumor and treatment characteristics as well as the survival outcomes were recorded. TRLF was considered the cause of death if the patient died due to liver failure; and freedom from TRLF (FFTRLF) at 1 year and 2 years after RT was calculated. **Results:** Sixty-seven patients were included in the study. The median age was 63 years (range 29-83 years) and median RT dose was 60 Gy (range, 40-100 Gy). 73.1% patients received a BED > 80.5 Gy. All except 1 patient were treated with upfront induction chemotherapy, followed by RT to the primary lesion in liver with (71.6%) or without (28.4%) concurrent chemotherapy. The most common induction chemotherapy regimen used was gemcitabine and cisplatin (65.7%) followed by gemcitabine, cisplatin and paclitaxel (22.4%), while the most common concurrent systemic therapy was capecitabine. Out of 43 patients with satellitosis, 29 were treated with RT to the dominant liver lesion while 14 received RT to the primary as well as one or more satellites. Overall, 15 patients (22.4%) had local progression of the radiated lesion, 42 patients (62.7%) progressed elsewhere in liver, and 52 patients (77.6%) had a distant progression. TRLF was the cause of death in 28.4% of patients. Median OS from diagnosis was 25 months while median OS after RT was 11.9 months. The 1- and 2-year rates of FFTRLF were 73.1% and 58.2% respectively, which were significantly higher than 1- and 2-year OS after RT (47.1% and 24.7% respectively, $p < 0.005$). Univariate analysis did not identify significant association of FFTRLF or OS with age, sex, performance status, size of liver lesions, T or N stage, satellitosis, vascular thrombosis, TRLF, timing of metastasis, site of metastasis, RT technique and dose and chemotherapy. **Conclusions:** Liver directed radiation therapy in patients with mICC with extrahepatic disease appears to have favorable rates of TRLF and survival times, compared to historical data. Future prospective studies are warranted to define the survival benefit in these patients attributable to radiation therapy. Research Sponsor: None.

Toripalimab combined with gemcitabine and S-1 in the first-line treatment of advanced biliary tract cancer. *First Author: Wei Li, Department of Oncology, Cancer center, Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Gemcitabine combined with platinum/fluorouracil drugs is the standard first-line treatment for advanced biliary tract cancers (BTCs), but the overall effect needs to be further improved. This study intended to explore the safety and efficacy of toripalimab combined with chemotherapy in the first-line treatment of advanced BTCs. **Methods:** This single-arm, phase II clinical trial enrolled patients with advanced BTCs who had not received systemic treatment. Toripalimab combined with chemotherapy were applied as first-line treatment: toripalimab (240 mg, iv, d1), gemcitabine (1000 mg/m2, iv, d1&d8), and S-1 (40-60mg bid po, d1-14, Q21d). The primary endpoint was progression-free survival (PFS), and the secondary endpoints included overall survival (OS), objective response rate (ORR) , duration of response (DOR) and safety. The study explored the association between response with PD-L1 expression, tumor mutational burden (TMB) and genetic variations identified by next-generation sequencing (NGS) of peripheral blood. **Results:** 50 patients were enrolled from January 2019 to August 2021 with a median follow-up time of 24.0 months (4.3-31.0). The median PFS was 7.0 months (95%CI: 5.0-8.9 months); median OS was 15.0 months (95%CI: 11.6-18.4 months). Of the 49 patients who completed the evaluation for tumor response, the ORR was 30.6% (95%CI: 17.2%-44.0%), and the disease control rate was 87.8% (95%CI: 78.2%-97.3%). The most common treatment-related adverse events (TRAEs) were leukopenia (98.0%), neutropenia (92%), and anemia (86.0%). Grade III/IV TRAEs included leukopenia (38.0%), neutropenia (32%), skin rash (6%), anemia (2.0%), mucositis (2%) and immune-related colitis (2%) .Among them, the Grade III/IV immune-related adverse events irAEs) worthy of attention included were skin rash and immune-related colitis . There was no significant difference in PFS and OS among intrahepatic cholangiocarcinoma, extrahepatic cholangiocarcinoma and gallbladder cancer. Exploratory study showed that patients with CPS≥1 had longer PFS . However, there was no significant correlation between TMB and PFS. **Conclusions:** Toripalimab combined with gemcitabine and S-1 (GS) has shown good safety in the first-line treatment of advanced BTCs. Although the primary endpoint did not reach the preset goal, toripalimab plus GS as first-line treatment has shown encouraging data of PFS and OS in patients with advanced BTC, which is worthy for further verification. Biomarker analysis showed that the expression level of PD-L1 could predict the curative effect. Clinical trial information: NCT03796429. The potential use of blood-based tumor fibrosis markers as diagnostic and prognostic biomarkers in patients with biliary tract cancer. *First Author: Troels Dreier Christensen, Department of Oncology, Copenhagen University Hospital, Herlev, Denmark*

Background: Patients with biliary tract cancer (BTC) have a very poor prognosis. A better understanding of the disease and potential novel biomarkers are needed. BTC is characterized by a collagen-rich desmoplastic extracellular matrix (ECM), and tumor fibrosis is linked to cancer progression and treatment resistance. We tested the diagnostic and prognostic use of seven circulating biomarkers associated with ECM remodeling. We evaluated both pro-peptides (propeptide of collagen type III (Pro-C3), VI (PRO-C6), XI (PRO-C11)) and degradation fragments (matrix metalloproteinase (MMP) degraded collagen type III (C3M) and IV (C4M), granzyme B degraded collagen type IV (C4G), citrullinated and MMP degraded vimentin fragment (VICM)). **Methods:** The study included 269 patients with all stages of BTC (intrahepatic cholangiocarcinoma (CC) (n=124), extrahepatic CC (n=89), and gall bladder cancer (n=56)), and 49 patients with benign biliary tract disease. Serum samples were collected from the patients with BTC before surgery (n=36), 1st line (n=199), and 2nd line (n=56) treatment. A total of 22 patients had samples collected at two timepoints. The seven ECM markers and carbohydrate antigen 19-9 (CA19-9) were analyzed using enzyme-linked immunosorbent assay (ELISA) and electrochemiluminescence immunoassay. **Results:** The levels of C3M, C4M, PRO-C3, PRO-C6, PRO-C11, and VICM were significantly elevated in patients with BTC compared to patients with benign disease (Wilcoxon test, adjusted p-value < 0.05). Area under receiver operating characteristics curve (AUC) identified PRO-C3 (AUC=0.87) as the ECM marker that best discriminated between patients with BTC and controls. A model combining PRO-C3 and CA19-9 further improved the diagnostic accuracy (AUC=0.97). Elevated levels of four markers (C3M, C4M, PRO-C3 and PRO-C6) before 1st line treatment for BTC were associated with short overall survival (OS) in separate multivariate cox regression analyses adjusting for CA19-9, performance status, and stage. Similarly, elevated levels of PRO-C3 and PRO-C6 before 2nd line treatment were associated with short OS (Table). **Conclusions:** We identified specific blood-based collagen fragments as potential novel biomarkers for BTC. Our results indicate that patients with BTC have an elevated collagen remodeling, and that increased collagen turnover is associated with a poor prognosis for these patients. Research Sponsor: Nordic Bioscience A/S, Other Foundation.

Immunogenomic characterization of biliary tract cancers: Biomarker enrichment for benefit to immune checkpoint blockade. *First Author: Wungki Park, Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY*

Background: Several immunomodulatory molecules (PD-L1, B7H4, and CD276) have been associated with biliary tract cancer (BTC) subgroups, suggesting potential value to immune checkpoint blockade (ICB) in this lethal disease. Phase II monotherapy (pembrolizumab or nivolumab), and combination (atezolizumab and cobimetinib) ICB trials reported low response rates in unselected advanced BTC with a wide range of responses. A recent randomized phase III trial (TOPAZ-1) reported an overall survival (OS) benefit among patients (pts) with advanced BTC treated with chemotherapy and anti-PD-L1 ICB. However, no correlation between PD-L1 expression and OS was noted and biomarker enrichment strategy in BTC for immunotherapy remains a key to optimize OS. **Methods**: From our comprehensive clinicogenomic database for BTC at Memorial Sloan Kettering (MSK), a retrospective genomic landscape and neoantigen analysis was performed using MSK-IMPACT. Potential immunogenic subgroups were evaluated: homologous recombination deficiency (HRD) defined by pathogenic alterations in *BRCA1/2, PALB2*, and *BAP1*, microsatellite stability high (MSI-H) defined by MSIsensor score ≥10, and tumor mutation burden (TMB)>10. Clinical outcomes with anti-PD-1 ICB were evaluated. **Results**: Among N=1,190 pts with BTC, N=1,346 samples were sequenced between 03/2014 and 01/2022. Key actionable alterations included (%): IDH1, 2 (13, 3), FGFR2 fusions (9), ERBB2 amplification (5), BRAF V600E (2), RNF43 (2), POLE (2), NTRK1 fusion (<1). There were N=230 (17%) patients with putatively more immunogenic BTC (iBTC) identified by HRD [*BRCA1/2* (1, 2.4), *PALB2* (1), *BAP1* (9)], TMB>10, and MSI-H. Frequency, location (intrahepatic, ICC; extrahepatic, ECC; gallbladder, GBC), TMB, and genomic instability score (GIS) are summarized (Table). Among iBTC subgroup, N=32 pts received ICB. Their median follow up was 29.1 months. Median lines of prior therapy was 3. Median PFS was 5.6 M (95%CI: 1.2-10.1) and OS was 33.4 M (23.1-43.6). **Conclusion**: A subgroup of BTC pts (iBTC) benefit from ICB. Apart from MSI-H and TMB>10, other genomically-defined subgroups such as HRD may benefit from ICB. Prospective studies are needed to evaluate a better biomarker enrichment strategy beyond PD-L1 and TMB, that can represent other immunogenic aspects of tumor neoantigen and microenvironment. ***FGFR2* fusion detection in plasma: A new era in the clinical monitoring of iCCA.** *First Author: Alberto Gonzalez-Medina, Cancer Genomics Group, Vall dHebron Institute of Oncology (VHIO), Barcelona, Spain*

Background: Actionable genetic alterations can be identified in over 50% of intrahepatic cholangiocarcinoma (iCCA). Since EMA approved Pemigatinib, a selective Fibroblast growth factor receptor 1-3 (FGFR1-3) inhibitor for the treatment of CCA with *FGFR2* fusions or rearrangements, the screening of patients who may benefit from such targeted therapies is especially relevant. In addition, novel FGFR inhibitors that are effective for treatment of resistant mutant clones are under development. In patients with no available tissue for genomic profiling or at different timepoints after targeted therapy, NGS testing of circulating cell-free DNA (ccfDNA) would be the most convenient option. Hence, two important issues must be addressed: i) technical set-up and validation of detection of *FGFR2* rearrangements in plasma, and ii) patient shedding in iCCA, in order to consider liquid biopsy for routine clinical care. **Methods:** We conducted a retrospective study in a cohort of 18 iCCA patients with known *FGFR2* fusion or rearrangement events previously identified in tumor FFPE by NGS (FoundationOne CDx test). A custom-designed capture-based NGS panel for use in plasma or tissue (VHIO-iCCA test) was developed to detect *FGFR2* rearrangements and other common altered genes in iCCA. After validating our VHIO-iCCA panel with fusion positive FFPE samples, a concordance study was conducted to evaluate the detection of *FGFR2* fusion and rearrangements in matched-to-tissue timepoint plasmas. Finally, additional serial plasma samples taken during *FGFR* inhibitor treatment were also analyzed. **Results:** From the 18 rearrangement events previously detected with FoundationOne CDx, we were able to identify all 18 in FFPE samples and 15 in the paired plasma using our VHIO-iCCA panel, representing a 100% and 83% concordance, respectively. In the 3 discordant cases, no additional alterations were detected in plasma, indicating a lack of circulating tumor DNA (ctDNA) shedding. Serial sampling of these patients indicated persistent non-shedding. The analysis of fusion allele fraction (FAF) in serial plasma samples revealed that detection of fusion *FGFR2* changed during treatment and correlated with best response. In general, patients with a stable FAF showed a SD, while patients which reduced FAF presented a PR. **Conclusions:** This extremely valuable set of cases has allowed us to validate our VHIO-iCCA panel to be used in tissue and plasma, and to determine that the sensitivity in plasma is >80%, making this a feasible option to avoid tissue biopsies, whenever patients cannot undergo the procedure and even to aid in cancer monitoring. Patient shedding is high in iCCA, yet a fraction of patients may not find a useful resource in liquid biopsy. For those who shed ctDNA, monitoring through the FAF may guide clinical management of iCCA. Research Sponsor: Incyte, Other Government Agency.

Clinical impact of MAPK pathway alterations in advanced biliary tract cancer (BTC): SCRUM-Japan GOZILA and COLOMATE international collaboration. *First Author: Hideaki Takahashi, Department of Hepatobiliary and Pancreatic Oncology, National Cancer Center Hospital East, Kashiwa, Japan*

Background: Abnormalities in the MAPK pathway are potential therapeutic targets in various cancers. However, the clinical impact of alterations in the MAPK pathway in BTC have not been elucidated, especially outside of canonical mutations in KRAS and BRAF. We investigated the clinical outcomes of advanced BTC with MAPK pathway alterations treated with chemotherapy in Japan and the United States. **Methods:** Patients with advanced BTC who received gemcitabine plus cisplatin as first-line therapy were included from the GOZILA study in Japan and Duke Molecular Registry of Tumors in the US. Genetic abnormalities were detected by Guardant360, a cell-free DNA assay, in Japan and by blood or tissue-based next-generation sequencing (NGS) at Duke University. Two hundred and seven patients with BTC from Japan were included in an exploratory cohort to evaluate the association of MAPK alterations with overall survival (OS) according to MAPK alteration status. One hundred and ten patients with BTC from both Japan and the US harboring oncogenic alterations in the MAPK pathway were included in a biomarker selected cohort to assess the association of specific MAPK alterations with OS. Multivariate analysis was performed using a Cox regression model based on a univariate p-value < 0.2. **Results:** MAPK pathway-related oncogenic alterations detected in each cohort are shown in the table below. In the exploratory cohort, median OS was shorter for patients with MAPK alterations vs. no MAPK alteration (15.9 m vs. 24.9 m, log-rank p = 0.001). Based on univariate analysis, the following covariates were selected for multivariate analyses: age, prior resection, and MAPK pathway alteration in the exploratory cohort; country, the timing of NGS, distant metastasis, KRAS amplification, and BRAF class 2 mutation in the biomarker selected cohort. In the exploratory cohort, multivariate analysis identified MAPK pathway alterations as an independent predictor of shorter OS with a HR of 1.92 (95% CI = 1.28-2.87, p = 0.001). In the biomarker selected cohort, multivariate analysis identified BRAF class 2 mutations and KRAS amplification as independent predictors of shorter OS with a HR of 16.2 (95% CI = 3.26-80.8, p = 0.001) and 5.97 (95% CI = 1.74-19.3, p = 0.002) respectively. **Conclusions:** MAPK pathway alterations, especially BRAF class 2 mutation and KRAS amplification, had a significant negative impact on clinical outcomes in BTC receiving first-line chemotherapy. These results are newly confirmed in BTC. Research Sponsor: SCRUM-Japan Funds.

Health-related quality of life (HRQoL) impact of pembrolizumab (pembro) plus best supportive care (BSC) versus placebo (PBO) plus BSC as second-line (2L) therapy in patients (pts) in Asia with advanced hepatocellular carcinoma (HCC): Phase 3 KEYNOTE-394 study. *First Author: Shukui Qin, Jinling Hospital, Nanjing University of Chinese Medicine, Nanjing, China*

Background: In the randomized, double-blind, phase 3 KEYNOTE-394 trial (NCT03062358), pembro + BSC vs PBO + BSC as 2L therapy significantly reduced the risk of death by 21% (HR 0.79, 95% CI 0.63-0.99, *P*= 0.0180), prolonged PFS (HR 0.74, 95% CI 0.60-0.92, *P*= 0.0032), and improved ORR (estimated difference 11.4%, 95% CI 6.7-16.0, *P*= 0.00004) with a manageable safety profile in pts in Asia with advanced HCC and progression on or intolerance to sorafenib or oxaliplatin-based chemotherapy. Here we present the results of prespecified exploratory HRQoL analyses. **Methods:** EORTC QLQ-C30 and EuroQol-5D3L (EQ5D-3L) questionnaires were administered at baseline (BL); wks 3, 6, 9, 12, 18; every 9 wks thereafter up to 1 yr or end of treatment; at treatment discontinuation, and at the 30-day safety follow-up visit. Pts who received ≥1 dose of study treatment and completed ≥1 HRQoL assessment were included in the analyses. Least squares mean (LSM) score changes from BL to wk 12 were compared using a constrained longitudinal data analysis model, including treatment by study visit interaction and stratification factors as covariates. Kaplan-Meier method was used to estimate time to deterioration (TTD) (time to 1st onset of ≥10-point decline from BL/confirmed by a 2nd adjacent ≥10-point decline from BL) for EORTC QLQ-C30 global health status (GHS)/QoL. Stratified Cox proportional hazards model was used to assess the magnitude of the treatment difference (HR) between treatment arms in TTD with nominal, one-sided *P* value calculated. **Results:** The HRQoL population included 450 pts (298 pembro; 152 PBO). HRQoL compliance rate at wk 12 was 95.7% for pembro for both questionnaires and 94.4% for EORTC QLQ-C30 and 95.3% for EQ5D-3L for PBO. There was a statistically significant difference in LSM for change from BL to wk 12, between the two arms for the QLQ-C30 GHS/QoL score and EQ-5D VAS score, with more decline observed in the PBO arm. Difference in LSM for QLQ-C30 GHS/QoL score between pembro (-3.97; 95% CI, -6.38, -1.56) and PBO (-8.40; 95% CI, -11.71, -5.10) arms was 4.43 (95% CI, 0.47, 8.40; *P*= 0.0142). Difference in LSM for EQ-5D VAS score between pembro (-2.74; 95% CI, -4.51, -0.96) and PBO (-6.94; 95% CI, -9.40, -4.48) arms was 4.20 (95% CI, 1.21, 7.19; *P*= 0.0030). GHS/QOL mean scores generally remained stable over time in pembro arm. TTD in EORTC QLQ-C30 GHS/QoL score was similar between arms (HR, 0.85; 95% CI, 0.58, 1.25; *P*= 0.1993). **Conclusions:** Over 12 wks, pts treated with PBO + BSC showed more decline in HRQoL than those receiving pembro + BSC. Combined with the efficacy and safety results from KEYNOTE-394, as well as other global 2L trials with pembro, including KEYNOTE-240 and KEYNOTE-224, our data support the benefit of pembro as 2L therapy for pts with advanced HCC. Clinical trial information: NCT03062358. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Antibiotic therapy and association with oncological outcomes from targeted and immune-based therapy in hepatocellular carcinoma (HCC). *First Author: David James Pinato, Department of Surgery and Cancer, Imperial College, London, United Kingdom*

Background: Immune checkpoint inhibitors (ICI) alone or in combination with tyrosine kinase (TKI) or VEGF pathway inhibitors (VEGFi) are therapeutic options in unresectable HCC (uHCC). Whether exposure to antibiotics (ATB), a consolidated adverse prognostic factor in ICI recipients, affects outcome in HCC remains unclear. **Methods:** FDA analysed patient-level data of 4098 patients receiving ICI (n = 842) either as monotherapy (n = 258) or combinations (n = 584), TKI (N = 1968), VEGFi (n = 480) or placebo (n = 808) as part of 9 international clinical trials submitted to the US Food and Drug Administration in support of marketing applications. Associations for ATB exposure within 30 days before or after initiation of anti-cancer treatment (ATB) with overall (OS) and progression-free survival (PFS) were examined across therapeutic modality. Estimates were weighted by propensity score (PSW) using clinically relevant covariates. **Results:** Out of 4098 patients with uHCC mostly secondary to Hepatitis B (39%) or C (21%) infection, the majority were males (83%) with a median age of 64 (range 18-88), ECOG performance status of 0 (60%) and Child-Pugh A class (98%). Most patients had metastases (68%) but did not have macrovascular invasion (71%). Overall, 620 patients (15%) were ATB+, with comparable rates across placebo (12%), TKI (16%), VEGFi (15%), and ICI (16%). In the overall population, ATB was associated with shorter PFS (2.8 vs 3.9 months [m], HR 1.29, 95%CI 1.22-1.36) and OS (6.4 vs. 8.8 m; HR 1.36, 95%CI 1.29-1.43). In PSW analyses, ATB was associated with shorter PFS in patients treated with ICI (HR 1.52, 95%CI 1.34-1.73), TKI (HR 1.29, 95%CI 1.19-1.39) and placebo (HR 1.23, 95%CI 1.11-1.37). Similar results were observed in PSW analyses of OS in patients treated with ICI (HR 1.22, 95%CI 1.08-1.38), TKI HR 1.40, 95%CI 1.30-1.52), and placebo (HR 1.40, 95%CI 1.25-1.57). Consistent outcomes were observed for ATB+ patients within ICI treatment subgroups, including patients treated with anti-PD-1 monotherapy (PFS HR 1.49, 95%CI 1.22-1.80; OS HR 1.31 1.02-1.68) and ICI combinations (PFS HR 1.50, 95%CI 1.26-1.77; OS HR 1.14 0.99-1.32). **Conclusions:** Unlike other oncological indications where the detrimental effect of ATB may be more prominent in ICI recipients, ATB is associated with inferior outcomes across a broad range of anti-cancer therapies for HCC and placebo. Whether ATB is causally linked to worse outcomes through disruption of the gut liver axis remains to be demonstrated in translational studies. Research Sponsor: None.

Health care resource utilization (HCRU) and costs in patients with biliary tract cancer (BTC) treated with systemic therapy in the United States (US). *First Author: Liya Wang, Merck & Co., Inc., Kenilworth, NJ*

Background: BTC is associated with poor prognosis and limited treatment choices. There is limited evidence on HCRU and costs among BTC patients receiving systemic treatments (ST). This study examined HCRU and total direct cost of care among BTC patients treated with ST to understand the disease burden in management of BTC. **Methods:** A retrospective cohort study of BTC patients who received first line (1L) ST was conducted, using US private payer Cancer Care Quality Program data and administrative claims from the HealthCore Integrated Research Database between 07/01/2014 - 03/31/2021. Patients with ampullary cancer, brain/ CNS metastases, other primary cancer before BTC diagnosis were excluded. Per patient per month (PPPM) costs in 2020 USD were calculated during 1L, 2L, and 3L treatments associated with HCRU from inpatient, emergency room, and outpatient visits as well as outpatient pharmacy dispensing. **Results:** Among 298 BTC patients (biliary tract, n=203; gallbladder, n=65; bile duct, n=30; stage IV, n=231; stage III, n=28; stage I/II, n=39) who received ST, mean (SD) age was 61.7 (9) years at 1L treatment initiation, and the majority were female (58%). Following 1L treatment, 44% received 2L treatment, and 16% received 3L treatment. Median follow-up was 7.6 months. Among 201 (67%) patients who had hospitalization in the follow-up period, mean (SD) number of hospitalizations was 2.5 (2), and the average length of stay was 7.0 (5) days. Total PPPM all-cause costs were the lowest during 1L treatment (mean [SD]: $19,589 [$22,603]), and increased as the treatment advanced (2L: $22,617[$19,302]; 3L: $33,534[$40,588]). Similar trend was observed in BTC-related total costs with $16,237 ($22,452) in 1L, $19,083 ($18,670) in 2L and $27,609 ($39,949) in 3L. The table summarizes BTC-related HCRU and PPPM cost during each line of therapy. **Conclusions:** Study findings suggest significant resource use burden and high total direct medical costs for BTC patients receiving ST. Hospitalizations and outpatient visits represent important HCRU and cost for BTC. These data indicate a need for future newer innovative therapies in the management of BTC. Research Sponsor: Merck & Co., Inc.

BTC-related HCRU and PPPM costs.

Description	During 1L Treatment N=298	During 2L Treatment N=132	During 3L Treatment N=49
Duration of treatment, Mean (SD), months	3.8 (3.2)	4.1 (3.9)	4.6 (5.7)
Number of INP visits, mean (SD)	1.5 (0.9)	1.7 (1)	1.8 (1.2)
Number of ER visits, mean (SD)	1.1 (0.4)	1.3 (0.6)	1.4 (0.5)
Number of outpatient visits, mean (SD)	34.4 (31.7)	36.4 (37.1)	41.3 (34.7)
INP costs, mean (SD)	$7,630 ($20,889)	$6,678 ($13,738)	$13,601 ($39,094)
ER costs, mean (SD)	$247 ($921)	$158 ($534)	$240 ($949)
Outpatient visit costs, mean (SD)	$8,255 ($7,612)	$10,724 ($12,361)	$12,329 ($12,521)
Pharmacy costs, mean (SD)	$104 ($440)	$1,523 ($5,348)	$1,439 ($4,383)

Sequential trans-arterial chemoembolization and stereotactic body radiotherapy followed by immunotherapy (START-FIT) for locally advanced hepatocellular carcinoma: A single-arm, phase II trial. *First Author: Chi Leung Chiang, Department of Clinical Oncology, The University of Hong Kong, Hong Kong, Hong Kong*

Background: Previous studies proposed therapeutic synergy between loco-regional therapies and checkpoint inhibitors in hepatocellular carcinoma (HCC). We aimed to study the safety and efficacy of sequential transarterial chemoembolization (TACE) and stereotactic body radiotherapy (SBRT) followed by Avelumab in patients with locally advanced HCC. **Methods:** Patients with locally advanced HCC not suitable for curative resections were eligible. All patients had HCC ≥ 5cm, tumor nodules ≤3, and child-Pugh A5-B7 liver function. Tumors with distant metastasis, main portal vein (VP4) invasion, or inferior vena cava (VV3) invasion were excluded. Patients underwent single episode of TACE followed by 5-fraction SBRT (28 days afterwards), followed by Avelumab (10mg per kg) 14 days afterwards and every 2 weeks thereafter. The primary endpoint was percentage of patients amendable to curative surgery, defined as R0 resection with sufficient remnant liver volume and function. Secondary endpoints were objective response rate (ORR) per modified Response Evaluation Criteria in Solid Tumors (mRECIST) version 1.1, survivals, and treatment-related adverse event (TRAE). The sample size assumed that around 20% patients amendable to surgery after experimental treatment compared to 5% of historical institutional results after TACE. Modified Simon two-stage optimal design was used (power, 80%; a = 0.05; P0 = 0.05; P1 = 0.20; n1 = 10; n = 29 with an additional four patients to allow for drop-out or other reasons). **Results:** Out of 67 patients screened, 33 patients were enrolled. The median sum of diameter of lesion(s) was 15.1cm (range: 5.3-31.1cm), and 21 (63.6%) had marcrovascular invasion (n=13, hepatic vein, n=3 branched portal vein, n=5 both). After a median follow-up of 17.2 months (range: 3.5-31.6 months), 3 (9.1%) patients had tumor downstaged with curative surgery done. The objective response rate was 62.5% (95% CI, 45.3-77.1%), of whom 15 had complete response (CR) (43.8%) and 6 had partial response (18.7%). The median overall survival (OS) and progression-free survival was 30.3 months (95% CI: 22.7-37.8 months) and 20.7 months (95% CI: 14.6-26.8 months) respectively. All three patients with surgery done were alive at 2 years (100%). For 15 patients had CR, the 2-year OS rate was 92.9% without surgery. Ten patients (30.3%) experienced ≥ grade 3 TRAEs, commonly transient increase in alanine / aspartate aminotransferase (n=4, 12.1%) and bilirubin (n=2, 6%) level after TACE. Five patients (15.2 %) developed ≥ grade 3 immune-related adverse events. **Conclusions:** Although merely 9% of patients were downstaged to receive curative surgery, combined locoregional treatment and immunotherapy is safe and resulted in an unexpectedly high CR rate of 43% and median OS of 30 months in patients with locally advanced unresectable HCC. Clinical trial information: NCT 03817736. Research Sponsor: Merck Pharmaceutical (HK) Ltd., Hong Kong.

4092 **Poster Session**

Bortezomib in PTEN-deficient patients with advanced intrahepatic cholangiocarcinoma: An open-label, prospective, phase II trial. *First Author: Zhen-gang Yuan, Department of Oncology, Eastern Hepatobiliary Surgery Hospital, Shanghai, China*

Background: Intrahepatic cholangiocarcinoma (ICC) is the second-most common primary liver malignancy after hepatocellular carcinoma. Prognosis of cholangiocarcinoma is poor and therapy options are limited. Bortezomib in unselected patients with BTC has been failed in previous clinical trial. Our previous research dedicates that PTEN-deficient facilitates sensitivity to proteasome inhibition in intrahepatic cholangiocarcinoma. In this open-label, prospective, phase II trial, we explore the efficacy and safety of bortezomib in PTEN-deficient advanced intrahepatic cholangiocarcinoma patients who have progressed during Gemcitabine based treatment. **Methods:** Between August 1, 2017, and July 31, 2021, A total of 130 patients were under went PTEN immunohistochemical staining for screening and 15 patients enrolled. Patients with PTEN-deficient advanced intrahepatic cholangiocarcinoma who had progressed after GC/Gemox therapies received bortezomib 1.3 mg/m2 days 1, 4, 8, and 11 of a 21-day cycle. The primary endpoint was objective response rate according to Response Evaluation Criteria in Solid Tumors v1.1. **Results:** The overall response rate was 23.1% (3/13) and disease control rate was 53.8% (7/13). The Median time of follow up was 4.2 months (95% CI: 0.7~17.2 months). median progression-free survival was 2.3 months and the median overall survival was 9.6 months. Adverse events of any grade were reported in 14 patients. Thrombopenia was the most common toxicity. **Conclusions:** Bortezomib provided an encouraging objective response and disease control as second-line therapy for PTEN-deficient Patients with advanced intrahepatic cholangiocarcinoma, and improving the overall survival to 9.6 months. Bortezomib would be a promising treatment option in PTEN-deficient selected patients. Research Sponsor: None.

4093 **Poster Session**

Preliminary results from a phase Ib study of neoadjuvant ipilimumab plus nivolumab prior to liver resection for hepatocellular carcinoma: The PRIME-HCC trial. *First Author: Antonio D'Alessio, Humanitas University, Pieve Emanuele, Milan, Italy*

Background: Early-stage hepatocellular carcinoma (HCC) can be treated with liver resection (LR), but up to 70% of patients experience relapse within two years after surgery. Despite their established use in advanced disease, immune checkpoint inhibitors (ICPI) are still under investigation in the peri-operatory setting. **Methods:** PRIME-HCC is a phase Ib study investigating safety and bioactivity of the nivolumab (3 mg/kg, day 1 and day 22) plus ipilimumab (1mg/kg, day 1 only) combination (Nivo+Ipi) prior to LR in early-stage HCC. The primary safety analysis assessed treatment-related adverse events (trAE) and delays to surgery. Secondary endpoint included objective response rate (ORR) by RECIST v1.1 and pathologic response rate on resection specimens. **Results:** At data censoring on the 27th of January 2022, 17 patients were enrolled, of whom 82% (n = 14) were male, with a median age of 64 years (range 47-76). Performance status was 0 in 88% of patients (n = 15) according to the Eastern Cooperative Oncology Group scale. Liver cirrhosis was found in 65% (n = 11) of the patients, mostly secondary to viral hepatitis (41%, n = 7). All patients were Child-Pugh A, with 53% (n = 9) classified as albumin-bilirubin (ALBI) grade 2, and the rest grade 1. Median tumour diameter was 3.4 cm (interquartile range [IQR] 2.4-4.0), and the median number of liver nodules was 1 (range 1-3). Any-grade trAEs were reported by 73% of the patients receiving at least one dose of treatment (n = 11, tot n = 15). Four patients (27%) reported grade 2 trAEs including hypothyroidism (n = 2), diarrhoea (n = 1), and fatigue (n = 1), and one (7%) grade 3 ALT/AST elevation. After a median follow-up of 6.3 months (IQR 1.9-23.0), no deaths had occurred. One patient had experienced relapse 20.8 months after treatment commencement, and he achieved partial response to subsequent treatment with atezolizumab plus bevacizumab. Median time to LR from screening was 2.5 months (IQR 2.3-3.2). Only one patient had a surgery delay due to liver function worsening (ICPI-unrelated) and experienced disease progression 12.4 months post-screening. One patient was found to have cholangiocarcinoma (CCA) on LR specimen and was excluded from efficacy analyses. Of the 13 patients with an available radiological assessment, ORR was 23%, with two partial responses and one complete response. Disease control rate was 92%, with one patient with mixed HCC/CCA histology showing primary progression. Of the nine pathologically evaluable patients, seven (78%) achieved a pathological response, including two (22%) complete responses. **Conclusions:** Nivo+Ipi can be safely administered in the neoadjuvant setting for HCC and does not delay LR. The combination demonstrates promising evidence of anti-tumour efficacy in terms of radiological and pathological response. Clinical trial information: NCT03682276. Research Sponsor: Bristol Myers Squibb.

4094 **Poster Session**

Phase 1b results of a multicenter, randomized phase 1b/2 study of gemcitabine and cisplatin +/- CPI-613 as first-line therapy for patients with advanced biliary tract cancer (BilT-04). *First Author: Vaibhav Sahai, University of Michigan, Ann Arbor, MI*

Background: Patients (pts) with advanced biliary tract cancers (BTC) have a poor prognosis despite systemic chemotherapy. Gemcitabine (G) and cisplatin (C) is a standard first-line systemic therapy with a reported overall response rate (ORR) of 26% and median overall survival (OS) of 11.7 months (mo). CPI-613/Devimistat (D) is a stable intermediate of a lipoate analog that inhibits pyruvate dehydrogenase and a-ketoglutarate dehydrogenase enzymes of the tricarboxylic (TCA) cycle, preferentially within the mitochondria of cancer cells augmenting chemotherapeutic cytotoxicity. **Methods:** An investigator-initiated, multi-institutional phase 1b/2 trial is underway across 10 sites in the US investigating the combination of G 1000 mg/m^2, C 25 mg/m^2 and D (dose levels: (-1) 500, (1) 1000, (2) 1500 and (3) 2000 mg/m^2) (GCD) on days 1 and 8 every 21 days in pts with previously untreated advanced BTC. The primary objective of the phase 1b portion (n = 20 pts; TiTE-CRM methodology) was to determine the recommended phase 2 dose (RP2D). The primary objective of the ongoing phase 2 portion (n = 48-58 pts; 2:1 randomization with Bayesian control arm) is to determine the best ORR with an alternative hypothesis of 43% (null of 25%); with 80% power and one-sided alpha of 0.05. Secondary objectives include evaluation of progression-free survival (PFS), OS, and safety. Exploratory objectives include targeted exome/ transcriptomic analysis using tissue, and metabolomic analysis using plasma (pre-, on- and post-treatment). **Results**: 20 pts were enrolled on phase 1b; median age 65 years (range 43-75), ECOG PS 0/1 (9/11), male/female (11/9), Caucasian (85%), intrahepatic/hilar/distal cholangiocarcinoma and gallbladder (9/5/3/3), and metastatic/locally advanced stage (15/5). CPI-613 dose level assignments were 1 pt each for (-1) and (1), 2 pts on (2), and 16 pts on (3). Median follow-up was 9.4 mos and median number of cycles was 9. Only 1 pt had dose-limiting toxicity (grade 2 creatinine elevation). RP2D for CPI-613 was 2000 mg/m^2. In phase 1b, ORR was 40% (7 PR, 1 CR). Median PFS not estimable (NE) but probability of PFS at 9 months was 68.1% [95% CI, 38.1%-85.8%]. Median OS is 16.3 months [95% CI, 9.1-NE]. One locally advanced pt was resected with pathologic CR. **Conclusions**: The combination of GCD was well tolerated and demonstrates encouraging efficacy with ORR, PFS and OS in phase 1b. The randomized phase 2 portion of the trial is open and accruing patients. Clinical trial information: NCT04203160. Research Sponsor: Rafael Pharmaceuticals, University of Michigan Rogel Cancer Center.

A multicenter, non-randomized, controlled trial to evaluate the efficacy of surgery versus radiofrequency ablation for small hepatocellular carcinoma (SURF-Cohort Trial): Analysis of overall survival. *First Author: Tatsuya Yamashita, Kanazawa University Hospital, Kanazawa, Japan*

Background: We conducted a multicenter prospective study (SURF trial) to compare the efficacy of surgery vs. radiofrequency ablation (RFA) for small hepatocellular carcinoma (HCC). SURF trial consisted of a randomized controlled trial (SURF-RCT) and a non-randomized prospective observational study (SURF-Cohort), including patients who did not consent to randomization. The initial report of the SURF-Cohort trial showed that recurrence-free survival (RFS) did not differ significantly between patients undergoing surgery and RFA. The focus of the present report was to assess the efficacy for overall survival (OS). **Methods:** The SURF-Cohort trial was a prospective multicenter study conducted in 49 institutions in Japan. Patients (aged between 29 and 79 years) with Child-Pugh scores ≤ 7, largest HCC diameter ≤ 3 cm, and ≤ 3 HCC nodules were considered eligible. Before the enrollment, both liver surgeons and hepatologists who perform RFA confirm that all the patients can be treated using both surgery and RFA. The co-primary endpoints were RFS and OS. OS was assessed at 5 years after the last accrual as per the protocol. Inverse probability of treatment weighted (IPTW) analysis was used to balance the characteristics of the groups. This trial is registered in UMIN000001796. **Results:** During 2009–2015, 782 patients were enrolled. After excluding ineligible patients, the surgery and RFA groups included 382 and 371 patients, respectively. In the surgery group, median platelet count ($13.7x10^4$ vs. $11.5x10^4$, $P< 0.01$) was significantly greater, and the median largest HCC diameter was significantly greater (2.0 cm vs. 1.8 cm, $P< 0.01$) than in the RFA group. The median (range) follow-up period was 6.8 years in the surgery group and 6.7 years in the RFA group. The IPTW-adjusted OS did not differ significantly between the surgery and RFA groups: the 5-year OS, 79.7% vs. 79.3%; HR 0.98; 95% CI 0.75–1.30; $P= 0.906$. The analysis after long-term follow-up in the current report showed that RFS was not significantly different between the surgery and RFA groups: the 5-year RFS, 44.6% vs. 39.3%; HR 0.86; 95% CI 0.71–1.06; $P= 0.155$. **Conclusions:** SURF-Cohort trial revealed that OS and RFS after the IPTW adjustment were not significantly different between patients undergoing surgery and RFA for early stage HCC (≤ 3 cm and 3 nodules). Clinical trial information: UMIN000001796. Research Sponsor: None.

Trastuzumab plus FOLFOX for gemcitabine/cisplatin refractory HER2-positive biliary tract cancer: A multi-institutional phase II trial of the Korean Cancer Study Group (KCSG-HB19-14). *First Author: Choong-kun Lee, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, South Korea*

Background: HER2 over-expression/amplification, which accounts for roughly 15% of total biliary tract cancer (BTC) patients, has been identified as a druggable molecular target by recent genomic profilings, Trastuzumab is a humanized monoclonal antibody against HER2 that has been shown to be effective in patients with HER2-positive breast and gastric cancer, but it has not been studied prospectively in HER2-positive BTC. In the phase III ABC-06 trial, the FOLFOX regimen showed survival benefit as a second-line therapy of BTC. We report the result of a multi-institutional phase II trial of Trastuzumab plus modified-FOLFOX as a second- or third-line treatment for HER2-positive BTC (KCSG-HB19-14; NCT04722133). **Methods**: HER2-positive (defined as IHC3+ or IHC2+/ISH+ or ERBB2 gene copy number ≥6.0 by NGS) BTC (intrahepatic cholangiocarcinoma, extrahepatic cholangiocarcinoma, gallbladder cancer and ampulla of vater cancer) patients who progressed on gemcitabine/cisplatin containing chemotherapy (1 or 2 previous chemotherapy lines permitted) were enrolled. Pts received trastuzumab 4mg/kg (after 6mg/kg load) D1, oxaliplatin 85mg/m^2 D1, Leucovorin 200mg/m^2 D1, 5-FU 400mg/m^2 bolus D1, and 5-FU 2400mg/m^2 infusion D1-2 every 2 weeks until unacceptable toxicities or disease progression. The primary endpoint was ORR per RECIST v1.1. Secondary endpoints included PFS, DCR, OS, safety, QOL and correlative biomarker exploration. **Results:** Total of 34 pts were treated with median follow up of 9.9 months, and 6 pts remained on treatment (treatment duration range: 1.0 to 14.7 months). The primary endpoint was met, with 29.4% (95%CI 15.1-47.5) ORR (PR n = 10), and 79.4% DCR. Median PFS was 5.1 months (95%CI 3.6-6.7) and median OS was not reached (95%CI 7.1-NR; 12-months OS rate 50.6%, 95%CI 29.3-63.6). Pts with HER2 IHC3+ (n = 23, 67.6%) showed tendency for better PFS compared to pts with HER2 IHC 2+/ISH+ (median 5.5 vs 4.9 months, HR 0.52, 95%CI 0.23-1.16). Pts with HER2 3+ tumor cell proportion ≥30% (n = 10) by an artificial intelligence-powered automated HER2 IHC analyzer (Lunit SCOPE HER2) showed significantly better PFS compared to pts without (median 6.67 vs 4.87 months, HR 0.33 95%CI 0.13-0.88). Targeted-panel sequencings were done with tumor tissues from 32 pts and tissue HER2-amplification by NGS did not confer better survival. Treatment-related AE (≥G3) occurred in 29 pts (85.3%) including 19 pts (55.9%) with neutropenia G3-4 and 4 pts (11.8%) with peripheral neuropathy G3-4. No pt showed cardiac AE nor treatment-related study discontinuation. **Conclusions:** For HER2-positive BTC, 2nd- or 3rd-line trastuzumab plus FOLFOX exhibited a promising efficacy with acceptable toxicity, warranting further investigations. Targeted NGS analyses with ctDNAs from pre-treatment and post-progression liquid biopsies are ongoing. Clinical trial information: NCT04722133. Research Sponsor: Korean Cancer Study Group.

4097 **Poster Session**

NEO-GAP: A phase II single-arm prospective feasibility study of neoadjuvant gemcitabine/cisplatin/nab-paclitaxel for resectable high-risk intrahepatic cholangiocarcinoma. *First Author: Shishir K. Maithel, Winship Cancer Institute, Emory University, Atlanta, GA*

Background: Given a high recurrence rate, surgical resection for localized intrahepatic cholangiocarcinoma (IHCC) is curative in only 30-35% of patients. BILCAP has established a standard of care for adjuvant therapy with monotherapy capecitabine. Gemcitabine, cisplatin and nab-paclitaxel combination chemotherapy (GAP) was associated with a response rate of 45% in biliary cancer and 20% of patients who were previously inoperable underwent margin negative resection. Based on these data, we conducted a neoadjuvant study of GAP for resectable but high-risk IHCC. **Methods:** A multi-institutional prospective single-arm phase II trial was conducted for patients with resectable high-risk disease, as defined by tumor size > 5cm, multiple tumors, presence of radiographic major vascular invasion, and lymph node involvement. Patients were administered 4 cycles (3 months) of preoperative GAP (gemcitabine 800 mg/m2, cisplatin 25 mg/m2 and nab-paclitaxel 100 mg/m2 on days 1 and 8 of a 21-day cycle) prior to an attempt at curative-intent surgical resection. The primary endpoint was completion of all therapy, including both preoperative chemotherapy and resection. Secondary endpoints were toxicity, radiologic response according to Response Evaluation Criteria in Solid Tumor (RECIST) criteria, RFS, and OS. Thirty evaluable patients provided 73% power to reject a null therapy completion rate of 50%, with a target completion rate of 70% using a one-sided exact test with a Type I error of 0.05. **Results:** Thirty-seven patients were screened and 30 evaluable patients were enrolled. The trial was sequentially activated at each of the 4 sites from 09/18-02/21 and the final patient was enrolled in 09/21. Median age was 60.5 years and 40% were female. Twenty-three patients (77%, 90% CI: 60.6-88.5%; p = 0.0026) completed all preoperative chemotherapy and underwent surgical resection. Ten patients (33%) experienced grade 3-4 treatment-related adverse events, the most common being neutropenia and diarrhea; 47% required at least one dose reduction. Partial response rate was 23% and disease control rate was 90% (PD: 10%, PR: 23%, SD: 67%). Of the 23 patients who successfully underwent surgical resection, 2 (9%) had minor postoperative complications. Median size of largest tumor was 5.5cm, median number of tumors was 3, and 39% were lymph node positive. Median length of hospital stay was 4 days. There was zero treatment related mortality. **Conclusions:** This study met its primary endpoint and demonstrated that neoadjuvant gemcitabine/cisplatin/nab-paclitaxel is feasible and safe prior to resection of intrahepatic cholangiocarcinoma and does not adversely impact perioperative outcomes. Continued follow-up for RFS and OS with this treatment strategy is underway and larger validation studies are planned. Clinical trial information: NCT03579771. Research Sponsor: Celgene / BMS.

Comparative efficacy of novel combination immunotherapy strategies for unresectable hepatocellular carcinoma (HCC): A network metanalysis of landmark phase III trials. *First Author: Claudia A.M. Fulgenzi, Department of Surgery and Cancer, Imperial College London, Hammersmith Hospital, London, United Kingdom*

Background: After over a decade of stagnation, therapeutic options for unresectable HCC (uHCC) are expanding. In 2020, the results of IMbrave150 established the combination of atezolizumab and bevacizumab (A+B) as the novel standard of care for patients with uHCC. Parallel reporting of novel immunotherapy combinations tested in phase III trials against sorafenib limits therapeutic decision making in clinical practice, given direct comparison between novel first line treatment options does not exist. We conducted a network metanalysis (NMA) to compare A+B with other first line systemic therapies that reached their primary endpoint in phase III trials. **Methods:** After performing a literature review from January 2008 to February 2022, we identified 13709 studies for screening, 70 for revision, and the following 9 phase III trials for the analysis: SHARP, Asia Pacific, REFLECT, CheckMate459, IMbrave150, ORIENT32, HIMALAYA, COSMIC312 and Qin et al.2021, which tested respectively: sorafenib (Sor) vs placebo (SHARP and Asia Pacific), lenvatinib (Len) vs Sor, nivolumab (Nivo) vs Sor, A+B vs Sor, Sintilimab+IBI305 vs Sor, Durvalumab+Tremelimumab (D+T) vs Sor, atezolizumab+cabozantinib (A+C) vs Sor, and Donafenib vs Sor, as first line systemic treatments for uHCC. Hazard ratios(HR) and 95% confidence intervals(95%CI) for overall (OS) and progression free survival (PFS) were extracted for each study. A frequentist network metanalysis, with fixed effect multivariable meta-regression models to estimate the indirect pooled HRs and corresponding 95%CI, was performed. CheckMate459 was the only trial testing PD-1 monotherapy and was included as a reference despite not reaching its primary endpoint. **Results:** In total, 6272 patients were included in the analysis, among them, 5896 received active treatment and 376 had placebo. Amongst analyzed treatment regimens, A+B reduced the risk of death by 60% compared to placebo (HR 0.40; 95%CI 0.28-0.57), and by 42%, 37%, 36% and 32% compared to Sor (HR 0.58; 95%CI 0.43-0.79), Len (HR 0.63; 95%CI 0.45-0.89), A+C (HR 0.64; 95%CI 0.43-0.97) and Nivo (HR 0.68; 95%CI 0.48-0.98), respectively. With regards to OS, D+T was not significantly inferior to A+B (HR 0.74; 95%CI 0.52-1.06) and the efficacy of sintilimab+IBI305 was similar to A+B (HR 1.02; 95%CI 0.67-1.54). Considering PFS, A+B was significantly superior to placebo, Sor, donafenib and Nivo. **Conclusions:** In this network metanalysis comparing 9 landmark phase III trials in uHCC, we confirmed combination of immunotherapy with PD-1 pathway plus VEGF blockade (A+B, sintilimab+IBI305) to be associated to the highest reduction in the risk of death compared to other regimens. Within the methodological limits of this NMA, we provide evidence for the first time of comparable efficacy in terms of OS and PFS for D+T and A+B. Research Sponsor: None.

4099 **Poster Session**

A prospective, multicenter, phase II trial of albumin-paclitaxel plus cisplatin versus gemcitabine plus cisplatin in first-line treatment of advanced biliary tract tumors. *First Author: Xiao Yang, Cancer Center, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*

Background: The prognosis of biliary system tumors is poor, Gemcitabine combined with cisplatin has been the standard first-line treatment for advanced biliary system tumors, but its efficacy and adverse effects are unsatisfactory. Albumin-paclitaxel is a novel paclitaxel with a broad-spectrum anti-tumor effect, which has been widely used in the treatment of digestive system malignant tumors. Therefore, we designed this study to investigate the efficacy and safety of the combination of albumin-paclitaxel and cisplatin compared with gemcitabine combined with cisplatin in patients with previously untreated advanced biliary tract tumors. **Methods:** This is a multicenter, randomized, controlled, investigator-initiated Phase II trial designed to enroll patients with unresectable, recurrent, or metastatic cholangiocarcinoma (including intrahepatic cholangiocarcinoma, extrahepatic cholangiocarcinoma, and gallbladder carcinoma). After enrollment, patients were randomly assigned to the experimental TP group (albumin paclitaxel 125mg/m2 iv, D1, 8 cisplatin 75mg/m2 IV, D1 Q21) or the control GP group (gemcitabine 1000mg/m2 IV, D1, 8 cisplatin 75mg/m2 iv, D1 Q21) and received six cycles of chemotherapy. The primary endpoint was PFS, and the secondary endpoint was OS, ORR, and safety. **Results:** Up to January 2022, 67 patients were enrolled, the 41male and 26 female patients had a median age of 55(range 32-74) years. Of the 67 enrolled patients, 33 were randomly assigned to the TP group and 34 to the GP group. Among the these patients, 47 were diagnosed with intrahepatic cholangiocarcinoma, 7 with extrahepatic cholangiocarcinoma, and 13 with gallbladder cancer. 48 patients had completed at least 2 cycles of chemotherapy and were available for evaluation, mPFS in the TP and the GP groups was 7.7 and 7.5 months, respectively (HR 1.33, CI 0.61 - 2.91,P = 0.469) , mOS in TP and GP groups was 12.1 months and 12.9 months, respectively (HR 1.62, 95% CI 0.67-4.17,P = 0.271). After the first assessment, the ORR was 39.4% and 35.3% in the TP group and the GP group, respectively. In terms of side effects, bone marrow suppression (61% vs 76%) was the most predominant adverse events in both groups, abnormal liver and kidney function (56% vs 67%), gastrointestinal reactions (including nausea, vomiting, diarrhea, constipation, etc.) (46% vs 43%), rash or allergy (44% vs 37%), and other side effects such as fever and influenza symptoms (21% vs 24%) were also observed in the TP group and the GP group. **Conclusions:** The result of this study showed that the regimen of albumin paclitaxel combined with cisplatin was non-inferior to gemcitabine combined with cisplatin in terms of PFS, OS and ORR, and the safety advantages of the combination of albumin paclitaxel and cisplatin make it a potential regiment for first-line treatment of advanced biliary tract tumors. Clinical trial information: ChiECRCT-20180167. Research Sponsor: Beijing Xisike Clinical Oncology Research Foundation.

A phase 2, randomized, open-label, multicenter study of sintilimab and anlotinib in combination with gemcitabine plus cisplatin (GemCis) as first-line therapy in patients (pts) with advanced biliary tract cancer (BTC): SAGC. *First Author: Li Jingjing, Department of Hepato-Pancreato-Biliary & Gastric Medical Oncology, Cancer Hospital of the University of Chinese Academy of Sciences (Zhejiang Cancer Hospital), Institute of Cancer and Basic Medicine (IBMC), Chinese Academy of Sciences, Hanzhou, China*

Background: BTC has a higher incidence in China rather than worldwide, with extremely poor prognosis, and the efficacy of standard first-line therapy (GemCis) is rather limited. TOPAZ-1 study suggested immunotherapy + GemCis as first line in advanced BTC significantly improved OS and PFS vs placebo + GemCis with manageable safety, but the median OS was just 12.8 months. SAGC is the first randomized controlled phase 2 trial to evaluate first-line immunotherapy + antiangiogenic targeted drug + GemCis in advanced BTC. **Methods:** In this randomized controlled study, pts previously untreated for unresectable locally advanced, recurrent, or metastatic BTC were randomized 1:1 to receive sintilimab (200mg every 3 weeks [Q3W]) and anlotinib (10mg po qd, Days 1-14 Q3W) in combination with GemCis (Gem 1000 mg/m2 and Cis 25 mg/m2 on Days 1 and 8 Q3W) for up to 8 cycles, followed by sintilimab (200mg every 3 weeks [Q3W]) and anlotinib (10mg po qd, Days 1-14 Q3W) or GemCis (Gem 1000 mg/m2 and Cis 25 mg/m2 on Days 1 and 8 Q3W) for up to 8 cycles until disease progression or unacceptable toxicity. The primary objective was to assess the 1-year overall survival (OS). Secondary endpoints included OS, progression-free survival (PFS), objective response rate (ORR), and safety. **Results:** At data cutoff for this interim analysis (11 November, 2021), 48 pts were randomized to sintilimab + anlotinib + GemCis (n=26) or GemCis (n=22). The primary objective was not meet: the 1-year OS was 52.5% with sintilimab + anlotinib + GemCis and 36.3% with GemCis (p=0.437), but there was a trend of nominal OS benefit in patients treated with sintilimab + anlotinib + GemCis. PFS was significantly improved with sintilimab + anlotinib + GemCis vs GemCis (6.4m vs 5m; p=0.014). ORR was 37.5% with sintilimab + anlotinib + GemCis and 26.7% with GemCis. Grade 3/4 treatment-related adverse events (TRAEs) occurred in 69.2% of pts receiving sintilimab + anlotinib + GemCis and38.7% of pts receiving GemCis. TRAEs led to discontinuation of any study medication in 7.7% of pts receiving sintilimab + anlotinib + GemCis and 9.1% of pts receiving GemCis. **Conclusions:** In pts with advanced BTC, sintilimab + anlotinib + GemCis could improve OS and PFS vs GemCis with manageable safety, indicating sintilimab + anlotinib + GemCis may be a new first-line standard of care regimen. 4101 **Poster Session**

Genomic characterization and translational immunotherapy of microsatellite instability-high (MSI-H) in cholangiocarcinoma. *First Author: Xu Yang, Department of Liver Surgery, State Key Laboratory of Complex Severe and Rare Diseases, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Microsatellite instability-high (MSI-H) status is a unique genomic state with encouraging effects of PD-1-based therapy in patients with advanced cancer. Cholangiocarcinoma is often driven by genetic mutations. However, the genomic characterization and translational medicine of MSI-H are not clear. **Methods:** In this study, 881 Chinese patients with cholangiocarcinoma (582 intrahepatic cholangiocarcinoma and 299 extrahepatic cholangiocarcinoma) were enrolled and their genomes were investigated using panel sequencing or whole-exome sequencing. Clinicopathological and genomic features as well as PD-1 inhibitor-based immunotherapy were analyzed by MSI status in patients with cholangiocarcinoma. **Results:** Overall, 47 (5.3%) cholangiocarcinoma patients were identified as MSI-H patients after enrichment enrollment. Intrahepatic cholangiocarcinoma (ICC) accounted for 74.47% (35/47) of MSI-H patients. Clinicopathological parameters showed younger, ICC-dominated, and more positive PD-L1 expression in MSI-H patients. In the genome of MSI-H cholangiocarcinoma, ACVR2A (75.00%), ARID1A (75.0%), KMT2D (72.2%), TGFBR2 (63.9%), PBRM1 (58.3%), RNF43 (55.6%), TP53 (52.8%)), ARID1B (47.2%) had a higher mutation frequency. Comparing the SNV and INDEL mutation in the genome, the differential genes between MSI-H and MSS were ARID1A, ACVR2A, KMT2D, TGFBR2, PBRM1, RNF43, LRP1B, ARID1B, etc., respectively. In addition, the differential mutation pathways of MSI-H showed that the mutation rate of DDR, SWI/SNF CeIICycle, HRD and other pathways was significantly higher than that of MSS samples. The tumor mutation burden (TMB) in MSI-H patients was significantly higher than that in MSS (P<0.001). In a cohort of 151 CCA patients who received PD-1 inhibitor-based immunotherapy, 19 patients with MSI-H cholangiocarcinoma were found to have a favorable prognosis (1-year survival rate 68.4%). Compared with 132 MSS cholangiocarcinoma patients, Patients with MSI-H cholangiocarcinoma had significantly prolonged OS (Not reach vs. 13.4m, P<0.001, HR=0.17, P <0.001) and high clinical benefit (CBR) (OR=8.16, P <0.001). In this immunotherapy cohort, ≥2 DDR pathway genes and ≥2 SWI/SNF pathway genes mutations, positive PD-L1 expression and TMB-H were also associated with better OS and CBR (both P<0.05). **Conclusions:** MSI-H cholangiocarcinoma has distinct genomic features, and the effect of PD-1 inhibitors immunotherapy is excellent to these patients. Clinical trial information: NCT03892577. Research Sponsor: CAMS Innovation Fund for Medical Sciences (CIFMS) (2021-I2M-1-061).

Genomic profile of intrahepatic cholangiocarcinoma with *MTAP* loss. *First Author: Tin-Yun Tang, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Recent data suggests a role for immune-checkpoint inhibition in the management of intrahepatic cholangiocarcinoma (iCCA). Chromosomal 9p21 loss with *CDKN2A/MTAP* co-deletion commonly occurs in iCCA and may correlate with poor response to immunotherapy. **Methods:** 2,508 cases of intrahepatic cholangiocarcinoma underwent comprehensive genomic profiling with the FoundationOne CDx assay. PD-L1 expression was measured with IHC using the Dako 22C3 antibody and measured with the tumor proportion score (TPS) method. Prevalence of different selected genomic alterations in tumors with *MTAP* loss was compared against *MTAP* intact tumors using Fischer's exact test. **Results:** In 2,508 cases analyzed, 15.5% of tumors were found to have *MTAP* loss. Of these, 98.7% had concomitant *CDKN2A* and 9p21 loss. No significant difference in immune biomarkers in *MTAP* loss versus wildtype (WT) was seen. PD-L1 low positive at 13.2% vs 19.2%, PD-L1 high positive at 2.9% vs 6.5%, median tumor mutational burden at 2.5 vs 2.5 and MSI high at 0.0% vs 1.6% in *MTAP* loss vs WT, respectively. There were no significant differences between *MTAP* loss and WT in potentially actionable mutations including *FGFR1/2* mutations (12.4% vs 10.7%), *PIK3CA* (6.40% vs 6.60%), *ERBB2* (4.10% vs 5.30%) and *KRAS* G12C (1.20% vs 1.10%) in *MTAP* loss vs WT, respectively. The table depicts significant genomic differences between these subgroups. **Conclusions:** This represents the largest iCCA cohort with *MTAP* loss to our knowledge. Given the historical data regarding 9p21 loss and poor response to immunotherapy, efforts targeting *MTAP* loss through synthetic lethality or other novel combinational therapeutics are justified. Research Sponsor: Foundation Medicine.

Genomic differences between *MTAP* WT and loss in iCCA.

	MTAP Wildtype	*MTAP* Loss	P Value (Fischer's exact)
Number of Cases	2119 (84.50%)	389 (15.50%)	
CDKN2A	19%	99%	<.0001
TP53	36%	31%	0.07
SMAD4	6%	11%	<.0001
BRAF	5%	9%	0.003
IDH1	15%	7%	<.0001
MYC	0%	5%	<.0001
BRCA2	2%	5%	0.001
TERT	7%	4%	0.03

Discovery and clinical validation of cost-effective noninvasive early detection of hepatocellular carcinoma (HCC) through circulating tumor DNA (ctDNA) methylation signature. *First Author: Xin-Rong Yang, Liver Cancer Institute and Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Hepatocellular carcinoma (HCC) is one of the most common and lethal cancers worldwide, especially in Asian counties. Patients can be treated more effectively if detected earlier, however the current screening strategies with alpha-fetoprotein (AFP) or ultrasound it is largely suboptimal. We aimed to develop non-invasive and cost-effective assay to improve HCC early detection. **Methods:** HCC-specific DNA methylation markers were screened from tissue and plasma samples through a modified reduce representation bisulfite sequencing assaay,and optimized by a targeted methylation sequencing assay. The most informative markers were then integrated in a multi-locus qPCR assay, HepaQ. **Results:** Profiling DNA methylation pattern on 61 tissue samples (31 HCC tumor and 30 normal tissues) and 663 plasma samples (276 HCC and 393 control plasma samples) achieved an AUC of 0.99, which corresponds to 91% sensitivity at 94% specificity. The best-performance markers were further screened and analytically verified in additional tissues and plasmas after several rounds of marker selection. A multi-locus qPCR assay, designated as HepaQ, was then developed to incorporate the most effective markers. A cohort of 559 plasma samples including 293 HCC (84% of them at stage 0/A), 60 liver cirrhosis (LC), 36 chronic hepatitis B (CHB) and 170 healthy controls (CTRL), were used to train a classifier for HCC early detection. HepaQ classifier enables to detect 85.3% of HCC under a specificity of 88.3%, 91.7% and 92.4% in LC, CHB and CTRL, respectively. Finally, HepaQ classifier was validated in 374 plasma samples independently collected from multiple clinical centers to confirm its performance of 87.2% sensitivity in HCC and 86.8%,90.5% and 93.4% specificities in LC, CHB and CTRL respectively. **Conclusions:** We have developed and demonstrated a blood-based ctDNA methylation assay, HepaQ, that can detect early-stage HCC at high sensitivity and specificity. We proposed that HepaQ assay, a cost-effective qPCR assay, has the great potential to benefit the population at-risk for HCC early detection and screening. Efficacy and safety of low-dose apatinib in advanced hepatocellular carcinoma. *First Author: Lingbin Meng, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Apatinib, a tyrosine kinase inhibitor, has shown promising effects on advanced hepatocellular carcinoma (HCC) recently. However, studies on its efficacy and safety are limited with controversial findings. Therefore, this study aimed to reveal the efficacy and safety of low-dose apatinib for the treatment of advanced HCC in the real world. **Methods:** Between January 2017 and August 2020, 178 patients with advanced HCC treated with apatinib at three different institutions were included for the present study. 174 patients received oral apatinib 250 mg daily and 4 received 500 mg daily until disease progression. 25 and 103 patients were also treated with immunotherapy and transcatheter arterial chemoembolization (TACE) at least once, respectively. Tumor response and adverse reactions were evaluated according to RECIST 1.1 and CTCAE 5.0 respectively. Survival curves were analyzed using the Kaplan-Meier method. Cox proportional hazards model was used to determine the prognostic value of variables in a univariate and multivariate setting. **Results:** During the 24-month follow-up period, 0 (0%), 28 (15.73%), 103 (57.87%) and 47 (26.40%) patients achieved a compete response (CR), partial response (PR), stable disease (SD), and progressive disease (PR), respectively. The overall response rate (ORR) and disease control rate (DCR) were 15.73% and 73.60% respectively. Interestingly, among the 28 patients with PR, 27 received apatinib as the first or second line treatment and 21 received immunotherapy or TACE as a combined treatment, indicating early application of apatinib and combination treatment could provide better efficacy. Kaplan-Meier analysis revealed the median overall survival (OS) and progressive-free survival (PFS) were 16.0 and 7.0 months respectively, which are significantly higher than previously reported survival of sorafenib in advanced HCC. Univariate Cox analysis indicated medication lines, distant metastasis, aplpha fetoprotein (AFP) level, portal vein tumor thrombus (PVTT) and combination therapy significantly affected OS and PFS. Multivariate Cox analysis confirmed third-line treatment (HR = 3.21; 95%CI = 1.54–6.68; p= 0.002), and PVTT (HR = 1.75; 95%CI = 1.13–2.70; p= 0.011) were independently associated with worse PFS. In contrast, apatinib combined with immunotherapy (HR = 0.52; 95%CI = 0.32–0.83; p= 0.008) or TACE (HR = 0.27; 95%CI = 0.18–0.40; p< 0.001) were independently associated with better PFS. Similar findings were also present on OS. The most common treatment-related adverse events were hypertension (29.21%), fatigue (16.85%), hand and foot syndrome (16.29%), vomiting (14.04%), liver dysfunction (6.18%), and proteinuria (6.74%). No severe (grade ≥3) adverse events were observed. **Conclusions:** Low-dose apatinib is able to provide effective and safe treatment for advanced HCC. Early application of apatinib and combination treatment could provide even better efficacy. Research Sponsor: the National Natural Science Foundation of China[-grant number 82170369].

High atezolizumab antidrug antibody levels are associated with unfavorable clinical outcomes and diminished T cell responses following atezolizumab and bevacizumab treatment in advanced hepatocellular carcinoma. *First Author: Hong Jae Chon, Department of Medical Oncology, CHA Bundang Medical Center, Seongnam, South Korea*

Background: Systemic administration of humanized monoclonal antibodies can be immunogenic and trigger unwanted anti-drug antibody (ADA) responses. In the IMbrave 150 study, 29.6% of advanced hepatocellular carcinoma (HCC) patients developed atezolizumab ADAs after atezolizumab and bevacizumab (atezo/bev) treatment. ADAs could impair the action of the therapeutic antibody by reduction of serum concentration or neutralization. We determined the clinical and immunological implications of high ADA levels in advanced HCC patients after atezo/bev treatment. **Methods:** Advanced HCC patients (n = 132) treated with first-line atezo/bev were prospectively enrolled (discovery cohort: 50 from an institute; validation cohort: 82 from four institutes). Serum levels of atezolizumab ADA at baseline and three weeks (C2D1) and atezolizumab concentrations at C2D1 were measured by competitive ELISA. The effects of ADA on T cell immunity were examined by multiplex flow cytometry. **Results:** Strong ADA (≥ 1000 ng/ml) responses at C2D1 were observed in 17.4% of advanced HCC patients. ADA elevation after atezo/bev at C2D1 was evident in non-responders but not significant in responders. In the discovery cohort, patients with high ADA at C2D1 showed a decreased response rate (ADA-high: 11% and ADA-low: 34%) and shorter progression-free survival (PFS) and overall survival (OS) with atezo/bev compared to those with low ADA levels (P = 0.004 for PFS; P = 0.009 for OS). In the validation cohort, patients with high ADA at C2D1 showed reduced response rate than those with low ADA (ADA-high: 7% and ADA-low: 29%). PFS and OS were worse in ADA-high group than in ADA-low group (P = 0.001 for PFS; P < 0.001 for OS). In multivariate Cox regression analysis, the clinical significance of high ADA levels was independently associated with shorter PFS and OS after adjustment for age, sex, ECOG performance status, Child-Pugh score, AFP, macroscopic vascular invasion, extrahepatic spread, and neutrophil-to-lymphocyte ratio (PFS: HR 2.27, P = 0.006; OS: HR 3.04, P = 0.006). The atezolizumab serum concentrations were 29.8% lower in patients with high ADA levels than in ADA-negative patients. Atezolizumab concentration at C2D1 was inversely correlated with ADA levels. Moreover, patients with high ADA lacked $CD8^+$ T cell proliferative responses to atezo/bev treatment. Furthermore, patients with high ADA had decreased secretion of effector cytokines such as IFN-γ and TNF-α from $CD8^+$ T cells compared to those with low ADA. **Conclusions:** Highly elevated ADA at C2D1 is associated with unfavorable clinical outcomes in advanced HCC patients treated with atezo/bev. High ADA levels were associated with reduced atezolizumab exposure and could limit the drug's anti-cancer efficacy. Research Sponsor: Korea government.

Hepatic artery infusion chemotherapy (HAIC) combined with apatinib and camrelizumab for hepatocellular carcinoma (HCC) in BCLC stage c: A prospective, single-arm, phase II trial (TRIPLET study). *First Author: Yang-Kui Gu, Department of Minimally Invasive Interventional Radiology, Sun Yat-sen University Cancer Center, State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Guangzhou, China*

Background: The combination of anti-angiogenesis and immune checkpoint blockade has been proven to improve clinical outcomes of advanced HCC. We assessed the efficacy and safety of HAIC combined with apatinib and camrelizumab for BCLC stage C HCC. **Methods:** Consecutive treatment-naive patients with BCLC stage C HCC were enrolled in this phase II trial (NCT04191889). Eligible patients were administrated with HAIC (oxaliplatin 85 mg/m^2, leucovorin 400 mg/m^2 and fluorouracil 2500 mg/m^2; q3w), combined with apatinib (250 mg qd) and camrelizumab (200 mg q3w) for 6 cycles, followed by maintenance therapy with apatinib and camrelizumab until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR). Following an optimal Simon 2-stage design, 26 eligible patients needed to be included in the first stage, of whom at least 11 patients had to achieve objective responses to warrant further investigation in the second stage. **Results:** In the first stage, confirmed ORR was achieved in 16 and 20 patients per RECIST v1.1 and mRECIST, respectively, therefore enrollment of the second stage continued. From 4/13/2020 to 1/31/2022, 31 eligible patients were enrolled and 29 evaluable for efficacy analyses. The 31 patients were characterized with median age 45 years (range 30-67), men 96.77%, Child-Pugh A 100%, portal vein tumor thrombus Vp 1-2/Vp 3-4 25.81%/45.16%, and extrahepatic metastasis 12.90%. As of 1/31/2022, with a median follow-up of 18.07 months (95% CI 14.10 to 22.04), the confirmed ORR was 70.96% (95% CI, 53.41%-83.91%) with 22 partial responses (PR) per RECIST v1.1,while 87.10% (95% CI, 71.15%-94.87%) with 3 (9.68%) complete responses (CR) and 24 (77.42%) PR per mRECIST. The disease control rate (DCR) was 87.10% (95% CI, 71.15%-94.87%) whether per RECIST v1.1 or mRECIST. The median time to response (TTR) was 2.67 months (interquartile range (IQR), 1.43-2.96) per RECIST v1.1 and 2.03 months (IQR, 1.37-2.80) per mRECIST. The median progression-free survival (PFS) time was 9.37 months (95% CI 7.00 to 11.73) per RECIST v1.1 and 9.63 months (95% CI 5.82 to 13.44) per mRECIST, in particular, the liver-specific median PFS time was 10.80 months (95% CI 5.88 to 15.72) per mRECIST. The 6-month, 12-month, and 18-month overall survival rate were 93.1%, 85.8%, and 65.8%, respectively. Grade ≥3 adverse events (AEs) occurred in 74.19% of the patients, of which the most common AEs were decreased neutrophils (52.17%), decreased lymphocytes (43.38%), and increased ALT and AST (30.43% and 43.48% for each). **Conclusions:** The triplet treatment of HAIC, apatinib and camrelizumab showed promising clinical benefits and acceptable safety for BCLC Stage C HCC. Further confirmatory randomized controlled trial is about to get underway. Clinical trial information: NCT04191889. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

4107 **Poster Session**

IMMUNIB trial (AIO-HEP-0218/ass): A single-arm, phase II study evaluating safety and efficacy of immunotherapy nivolumab in combination with lenvatinib in advanced-stage hepatocellular carcinoma (HCC). *First Author: Arndt Vogel, Klinik für Gastroenterologie, Hepatologie und Endokrinologie, Medizinische Hochschule, Hannover, Germany*

Background: The field of systemic options in HCC therapy has significantly evolved in recent years, and first line options now include sorafenib, lenvatinib and bevacizumab plus atezolizumab. Nivolumab is a recombinant human IgG4 mAb targeting PD-1 with clinically meaningful activity in about 15-20% of HCC patients, but the confirmatory phase III trial Checkmate 459 failed to demonstrate superiority over sorafenib. VEGF signaling is not only a driver of tumor angiogenesis, but also contributes to the formation of an immunosuppressive microenvironment. Combinations of anti-angiogenic multikinase inhibitors, specifically lenvatinib, and PD-1/PD-L1 inhibitors have demonstrated remarkable antitumor activity and manageable toxicity in several tumor types, including HCC. We therefore aimed to evaluate the efficacy of nivolumab in combination with lenvatinib as first line treatment in patients with advanced HCC. **Methods:** This investigator-initiated single-armed phase II trial (NCT03841201) recruited 50 patients (pts) at 8 sites in Germany between 07/2019 and 05/2021. Primary endpoints were objective response rate (ORR) according to investigator assessed RECIST 1.1 and safety/tolerability. Secondary endpoints included ORR according to iRECIST, time to progression (TTP), progression free survival (PFS) and overall survival (OS). Recruitment of the trial was completed in 05/2021. At the time of analysis, 4 patients remained on treatment. **Results:** 50 pts (24 BCLC B, 24 BCLC C, 2 not evaluable) were enrolled and received at least one dose of the combination treatment. ORR by RECIST 1.1 was 28% (CR: 6.0%, PR: 22.0%, SD: 46.0%, PD: 12.0%). Median PFS was 9.0 mo (26 events). Median TTP was 11.5 mo (0.69 at 6 mo, 0.45 at 12 mo, 0.36 at 18 mo) and median OS was 27.1 mo (8 events). 45 (91.8%) pts experienced at least one TRAE, of which 29 pts (59.1%) encountered at least one TRAE ≥ grade 3. 17 (34.7%) pts had one or more SAE related to the study medication, whereof 15 pts (30.6%) experienced at least one treatment related SAE ≥ grade 3. **Conclusions:** No new safety signals were observed for the combination of nivolumab and lenvatinib. Although the study failed to reach its prespecified ORR of at least 40%, the high activity in all efficacy endpoints with a mOS of 27.1 mo supports the further investigation of the combination in HCC. Clinical trial information: NCT03841201. Research Sponsor: EISAI GmbH and Bristol-Myers Squibb GmbH & Co. KGaA.

Durvalumab (D) plus tremelimumab (T) immunotherapy in patients (Pts) with advanced biliary tract carcinoma (BTC) after failure of platinum-based chemotherapy (CTx): Interim results of the IMMUNOBIL GERCOR D18-1 PRODIGE-57 study. *First Author: Matthieu Delaye, Medical Oncology Department, Curie Institute, Saint-Cloud, France*

Background: D (anti-PDL1) plus T (anti-CTLA-4) combination immunotherapy showed encouraging results in hepato-biliary cancers. Its efficacy in non-Asian Pts with pretreated BTC is unknown. **Methods:** IMMUNOBIL GERCOR-D18-1 PRODIGE-57 was initially a 2-arm, open-label, randomized non-comparative phase II study. Pts with recurrent/advanced pathologically proven BTC (intrahepatic cholangiocarcinoma [iCCA]/extrahepatic CCA [eCCA]/gallbladder cancer [GC]), ECOG PS 0-1, pre-treated with platinum-based CTx were randomized (1:1) to D (1500 mg Q4W) plus T (75 mg Q4W x 4 cycles [T75]) (Arm A) or D plus T in combination with weekly paclitaxel (Arm B). Arm B was closed prematurely for toxicity after inclusion of 10 Pts. The study continued with Arm A only. It was further amended to modify the T schedule (300 mg at cycle 1 [T300], amended Arm A) due to higher efficacy reported in other tumors as compared to T75 mg x 4. The new primary endpoint was the overall survival (OS) rate at 6 months (M6) in amended Arm A (D + T300) with a Fleming two-stage design (H0: 50%, H1: 65%, one-sided alpha: 5%, power: 90%). A total of 100 evaluable Pts were required (efficacy threshold: 59%). We present here the efficacy data of Arm A (D + T75). **Results:** From 12/2018 to 12/2020, 106 Pts were included in Arm A; 103 were evaluable for OS at M6. Median age was 66 years, 47% were male, 46% had ECOG PS 0, 69%/18%/13% had iCCA/eCCA/GC, 76% had metastatic disease, and 28% had prior tumor resection. First-line CTx was GEMCIS/GEMOX/5-FU-based/other in 63%/22%/4%/11%. The M6-OS rate was 59.2%. With a median follow-up of 12 months (95% CI 11.4-14.9), the median OS was 8.0 months (95% CI 5.7-11.7) and median PFS was 2.5 months (95% CI 2.0-3.2). Complete response (CR) was observed in 2 (1.9%) Pts, partial response (PR) in 8 (7.8%), and stable disease (SD) in 32 (31.1%), resulting in an objective response rate of 9.7% and a disease control rate of 40.8%. Absence of progression (PD, iRECIST) after 2 cycles (M6-OS rate: 84% vs 41%, median OS: 17.9 months vs 4.4 months) and CR/PR as a best overall response (M6-OS rate: 100% vs 84% and 39% for SD and PD, respectively) were associated with markedly prolonged OS. 65 (63.1%) Pts had ≥1 grade 3-4 (G3-4) adverse event (AE) and 22 (21.4%) had ≥1 G3-4 treatment-related AE (TRAE). The most commonly reported G3-4 AEs were fatigue (12.6%), abdominal pain (5.8%), and aspartate aminotransferase increase (5.8%) and G3-4 TRAEs were fatigue (4.9%) and diarrhea (2.9%). One death was possibly related to treatment. **Conclusions:** Although no statistical conclusions can be drawn from this exploratory analysis of Arm A, D+T75 reached the pre-defined threshold for efficacy, with no unexpected toxicity. Results from amended Arm A (D+T300, N = 106 additional Pts), quality of life, and ancillary studies are pending. Clinical trial information: NCT03704480. Research Sponsor: Astra Zeneca, GERCOR.

4109 **Poster Session**

Pembrolizumab monotherapy for previously untreated advanced hepatocellular carcinoma (aHCC): 3-year follow-up of the phase 2 KEYNOTE-224 study. *First Author: Ivan Borbath, Cliniques Universitaires Saint-Luc and Université Catholique de Louvain, Brussels, Belgium*

Background: Pembrolizumab monotherapy showed durable antitumor activity and a manageable safety profile in patients with sorafenib-treated (cohort 1) and treatment-naive (cohort 2) aHCC in the open-label, phase 2 KEYNOTE-224 (NCT02702414) study. Longer term data from KEYNOTE-224 after ~3 years of follow-up for patients with treatment-naive aHCC are reported. **Methods:** Eligible patients in cohort 2 had histologically, cytologically, or radiologically confirmed aHCC, Barcelona Clinic Liver Cancer stage C or B not amenable or refractory to locoregional therapy and not amenable to curative treatment, Child-Pugh A liver function, measurable disease per RECIST v1.1 by blinded independent central review (BICR), and ECOG PS 0 or 1. Patients received pembrolizumab 200 mg intravenously every 3 weeks for ≤35 cycles (~2 years). Primary end point was ORR assessed per RECIST v1.1 by BICR. Secondary end points included DOR, DCR, TTP, and PFS, all assessed per RECIST v1.1 by BICR, OS, and safety/tolerability. **Results:** All 51 patients enrolled in cohort 2 received ≥1 dose of pembrolizumab. Median follow-up, defined as the time from first dose to the data cutoff (October 1, 2021), was 35 months (range, 31-37). ORR was 16% (95% CI, 7-29). Median DOR was not reached (NR; range, 3 to 24+ months); 58% of responders were estimated to have a response duration ≥18 months. Best overall response was 8 (16%) PRs, 21 (41%) SDs, and 17 (33%) PDs; no CRs were observed and response was not evaluable for 2 patients (4%) and not assessed for 3 patients (6%). DCR was 57% (95% CI, 42-71). ORR was generally consistent among patients with a viral and nonviral etiology for HCC, although sample sizes were small. The median TTP was 4 months (95% CI, 3-9). Median PFS was 4 months (95% CI, 2-8). Estimated PFS rate at 24 months was 15%. Median OS was 17 months (95% CI, 8-23). Estimated OS rate at 24 months was 34%. No new or unexpected adverse events (AEs) occurred. Treatment-related AEs were reported in 28 patients (55%; grade 3-5, 8 [16%]). **Conclusions:** Updated results from cohort 2 of the KEYNOTE-224 study continued to demonstrate durable antitumor activity, promising OS, and manageable safety for pembrolizumab monotherapy in patients with aHCC and no prior systemic therapy. These data, together with recent positive results from KEYNOTE-394, underscore the broad applicability of pembrolizumab in patients with aHCC both as monotherapy and in combination with other therapies. Clinical trial information: NCT02702414. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Next-generation sequencing (NGS) of circulating cell-free DNA (cfDNA) in patients (pts) with advanced hepatocellular carcinoma (HCC). *First Author: Darren Cowzer, Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: HCC is often diagnosed based on high-quality cross-sectional imaging, and when a biopsy is pursued, acquisition of tissue may be of limited quantity and quality or complicated by underlying medical comorbidities. NGS of tumor derived circulating cfDNA represents an investigational tool for non-invasive molecular profiling, that has the potential to aid in diagnosis, prognosis, and in monitoring disease status. Although prior reports have evaluated such technologies, few studies have included tumor tissues to confirm histology and to explore plasma-tissue gene concordance. **Methods:** The primary objective of this retrospective cohort study was to define genomic alterations in circulating cfDNA and to explore plasma-tissue genotype concordance in HCC pts. HCC pts underwent collection of cfDNA for NGS using the MSK-ACCESS 129-gene assay between August 2019 and February 2021. Matched tissue-based NGS with the FDA authorized MSK-IMPACT gene assay was completed when tumor tissue was available. Clinical actionability of sequence variants was annotated by OncoKB, an FDA recognized knowledge base. Clinicopathologic characteristics were extracted, and all data were reported with descriptive statistics. **Results:** 51 unique patients with 53 plasma samples had an HCC histological diagnosis. Pts were male (39, 76%), median age 69 (42-87), viral hepatitis-related (24, 47%), and advanced stage (Stage III:9, 18%; Stage IV:38, 74.5%). Extrahepatic disease and macrovascular involvement were observed in 28 (55%) and 19 (38%) pts, respectively. 22 (43%) pts had AFP ≥400 ng/mL. 49 (92.5%) of 53 plasma samples had detectable genomic alterations. Median cfDNA yield after extraction was 39.43 ng (range: 7.93-287.68). The most frequently mutated genes occurring in > 10% of patients were *TERT* (57%), *TP53* (47%), *CTNNB1* (37%), *ARID1A* (18%) and *TSC2* (14%). The most common oncogenic pathways that contained alterations were WNT-β-Catenin (45%) and PIK3-AKT-TOR (25%). 37 (73%) pts underwent tissue sequencing with MSK-IMPACT with a median time of 9.0 months to the time cfDNA testing. MSK-ACCESS identified mutations observed in tumor in most cases: *TERT* (20/22; 91%), *TP53* (16/17; 94%), *CTNNB1* (11/12; 92%), *ARID1A* (6/6; 100%) and *TSC2* (6/7; 86%). In 18 (49%) of 37 paired samples, additional mutations in cfDNA not seen in tumor were detected and included *KRAS*, *EGFR*, and *TP53* alterations. Potentially actionable mutations were identified through cfDNA in 37% of cases including *TSC1/2* (18%), *BRCA1/2* (8%) and *PIK3CA* (8%). **Conclusions:** Circulating cfDNA genotyping with MSK-ACCESS identifies previously reported HCC tumor genomic profiles and revealed tumor-associated mutations in 92.5% of plasma samples. Ongoing efforts will explore predictive and prognostic implications of NGS at different HCC stages as well as kinetics of treatment response. Research Sponsor: Society of MSKCC.

Nivolumab and lenvatanib combination for fibrolamellar carcinoma. *First Author: Paul Kent, Rush University Medical Center, Chicago, IL*

Background: Fibrolamellar Carcinoma (FLC) is a rare form of primary liver cancer affecting children and young adults that often presents at an advanced stage and even with surgery has an 80% relapse rate. Unresectable FLC patients are considered incurable and have short life expectancy. Effective neoadjuvant and adjuvant systemic therapies are needed to increase chances at remission and protect against relapse. Because of success as single agents in HCC, we tried the combination of nivolumab (NIV) and lenvatanib (LEN) in FLC patients who had exhausted more common therapies. Our objective is to describe our experience using combination NIV-LEN in FLC patients. **Methods:** Over the last 5 years we have seen over 90 patients with FLC at our institution. After securing IRB approval, (ORA Number: 19071603-IRB01), we collected data in a de-identified fashion for all patients who had received NIV-LEN. **Results:** Twenty patients (6M/14F), median age at diagnosis/start of NIV-LEN 17/20 (7-52) have received at total of 349 cycles of NIV-LEN (NIVO 3mg/kg IV q2 weeks) and lenvatanib 8mg po daily, 5 adjuvant, 14 neoadjuvant and one both. All had cross sectional imaging every 3 months with independent review. The median number of cycles/months of follow up was 19.5 (3-43)/13.5 (3-31) respectively. The median number of prior relapses, systemic therapies, prior abdominal surgeries, and prior radiation (IR ablations, TARE, TACE, SBRT) were 3.5 (0-7), 3 (0-11), 2 (0-6), and 2.5 (0-13) respectively. Three patients had gemcitabine added to NIVO-LEN for part (< 1/3) of their regimen. The best response by RECIST 1.1 of the 14 neoadjuvant patients was 3 CR, 3 PR, 7 SD and 2 PD, for an overall response rate (PR + CR) of 40% and overall control rate (CR + PR + SD) of 87%. Seven of 20 (30%) stopped NIVO-LEN [PD (3), infection (2), or patients' wishes (2)] while 14 (70%) continue, including all adjuvant patients who remain in CR (median follow-up of 10 months). The 6-, 12-, and 24-month progression free survival (PFS) and overall survival (OS) were: (70%,49%,49%) and (94%,94%,73%) respectively. For 14 of 17 (82%) relapsed patients, the PFS was longer than the patients' most recent PFS, and longest ever in 9 (53%). Six of the 14 initial non-surgical candidates (43%) either had surgery (2), or avoided surgery (3 CR, 1 ablation). There were 2 grade 3 toxicities (both infections) and no grade 4 toxicities. The most common toxicities were hypertension and fatigue in 25% and 20% respectively. One patient, after 5 relapses, had more than 120 lung nodules > 1cm that after 14 months of NIVO-LEN achieved CR and has remained in CR for another 14 months. **Conclusions:** Our retrospective experience with the novel immune-chemotherapy combination of NIV-LEN for FLC in an extremely rare disease with no proven systemic therapies is encouraging, especially for those who are not surgical candidates or in a surgical remission. We hope this report can inform future prospective trials in treating this deadly disease. Research Sponsor: None.

Early detection of hepatocellular carcinoma using cfDNA signatures from cirrhotic patients with nodules. *First Author: Rong Fan, Department of Infectious Diseases, State Key Laboratory of Organ Failure Research, Guangdong Provincial Key Laboratory of Viral Hepatitis Research, Nanfang Hospital, Southern Medical University, Guangzhou, China*

Background: Hepatocellular carcinoma (HCC) is the fourth most common cause of cancer-related death worldwide. Early detection of HCC patients is related to favorable survival. Nodules in liver cirrhosis (LC) are at higher risk of developing into HCC. There is an urgent clinical need for development of an accurate and affordable non-invasive method for early HCC diagnosis among LC patients with nodules. **Methods:** We have previously shown that the genome-wide HIFI (5-Hydroxymethylcytosine/motIf/ Fragmentation/nucleosome footprInt) method held a solid diagnostic value in differentiating HCC from LC. In this study, we leverage this knowledge to diagnose early HCC (BCLC 0/A) in cirrhotic nodules using copy number variation (CNV) to replace 5-Hydroxymethylcytosine to simplify NGS protocol and decrease cost. The updated method generates a score that reflects the presence of tumor-derived cfDNA in 10 ml blood via low coverage (2x) whole-genome sequencing (WGS). We applied it in a retrospective cohort (validation set 1, n = 171) and a prospective cohort (validation set 2, n = 156), both of which involved patients with newly diagnosed early stage HCC (BCLC 0/A) as well as individuals with cirrhotic nodules. **Results:** The updated method showed excellent performance for early HCC detection both in the validation set 1 (84 HCC and 87 cirrhotic nodules; AUC: 0.951, 82.1% sensitivity at 90.8% specificity) and validation set 2 (71 HCC and 85 cirrhotic nodules; AUC: 0.958, 81.7% sensitivity at 91.8% specificity) (Table). The AUC values for distinguishing early HCC from cirrhotic nodules could reach 0.951 (80.9% sensitivity at 91.0% specificity) and 0.947 (74.7% sensitivity at 92.1% specificity) among patients with AFP < 400 μg/L and those with nodular size < = 2 cm, respectively. More importantly, our model also maintained consistent performance in detecting very early stage HCC (BCLC 0) with AUC of 0.941 (74.7% sensitivity at 91.3% specificity). **Conclusions:** These findings provide an accurate, affordable, excellent clinical potential model integrating four cfDNA molecular signatures for detecting early stage HCC from cirrhotic nodules using low-coverage WGS of plasma cfDNA samples. Clinical and genomic characterization of *ERBB2*-altered gallbladder cancer. *First Author: Sebastian Mondaca, Department of Hematology and Oncology, Faculty of Medicine, Pontificia Universidad Católica de Chile, Santiago, Chile*

Background: Gallbladder cancer (GBC) is a molecularly distinct entity among biliary tract tumors. *ERBB2* amplification and mutation have been described in GBC, however, clinical and genomic characterization of the *ERBB2*-altered subgroup has been limited. **Methods:** Patients with GBC treated at Memorial Sloan Kettering and Pontificia Universidad Católica de Chile with genomic tumor profiling between 2014 and 2021 were included. Clinical information was retrieved from electronic medical records. Categorical data were analyzed by Fisher exact test and time-to-event data were analyzed by Cox proportional hazards models. **Results:** During the study period 260 GBC patients underwent genomic profiling. The prevalence of *ERBB2* alterations was 14% including 8% with *ERBB2* gene amplification, 4.2% with *ERBB2* mutation, 1.5% with concurrent amplification and mutation and 0.4% with *ERBB2* fusion. There was no age difference between GBC patients with and without *ERBB2* alterations (63.6 vs. 65.4; p = 0.36) and in both subgroups there was a majority of female patients (75% vs. 84%; p = 0.44). Patients with *ERBB2*-altered tumors had a different genomic profile with lower concurrent *KRAS* alterations (2% vs. 12%; p = 0.14) and higher prevalence of *TP53* alterations (81% vs. 59%; p = 0.01). There was no difference in the prevalence of *PIK3CA* mutations (13% vs. 9%; p = 0.38). GBC patients with *ERBB2* alterations had a longer overall survival (22.3 vs. 12.1 months; HR 0.54 95% CI 0.3 to 0.98). **Conclusions:** *ERBB2* amplification and mutation are the most frequent potentially targetable alterations in GBC (14%). *ERBB2*-driven GBC has higher concurrent alterations of *TP53*, while *KRAS* alterations appear to be less frequent. While no particular clinical feature was associated with this subgroup, overall survival was longer. A phase II study combining KN046 (an anti-PD-L1/CTLA-4 bispecific antibody) and lenvatinib in the treatment for advanced unresectable or metastatic hepatocellular carcinoma (HCC): Updated efficacy and safety results. *First Author: Baocai Xing, Beijing Cancer Hospital, Beijing, China*

Background: PD-1 inhibitor with Lenvatinib were reported to improve ORR in patients with metastatic HCC. KN046 was a bispecific antibody that target both PD-1/PD-L1 and CTLA-4/B7 immune checkpoints pathway. Preliminary report already showed good efficacy and tolerable safety of the KN046+Lenvatinib regimen. Here we updated the efficacy and safety results with more enrolled patients and longer follow-up duration. **Methods:** This is an open-label, single-arm, multicenter, phase II trial in pts with unresectable or metastatic HCC. Enrolled patients (pts) with Barcelona Clinic Liver Cancer (BCLC) stage B or C who were not suitable for curative surgery or local therapy had received Lenvatinib 12 mg/day (bodyweight [BW] ≥60 kg) or 8 mg/day (BW<60 kg) orally and KN046 5 mg IV on Day 1 of a 21-day cycle until disease progression or intolerable toxicity or 2-year treatment. Primary endpoints were safety and ORR by RECISTv1.1 per investigators. **Results:** As data cutoff (January 7, 2022) date, 55 enrolled pts received combination treatment with median duration of 25 weeks. For 52 evaluable pts, ORR was 51.9% (95% CI 37.6-66.0) (RECIST v1.1) and DCR was 86.5% (95% CI 74.2-94.4) (RECIST v1.1). Median PFS was 9.3 months (95% CI 7.0–not estimable [NE]), The median OS and DOR of pts were not reached. The overall incidence of KN046 related treatment-emergent adverse events(TRAEs) was 98.2%, with 27.3% Gr3. The most common Grade ≥ 3 TRAEs included platelet count decreased (7.3% of pts) and aspartate aminotransferase increased (3.6% of pts). The immune related adverse events (irAE) occurred in 14.5% of pts (grade ≥3 5.5%). 3 pts discontinued KN046 treatment due to ≥3 Gr TRAE, which was infusion related reaction, platelet count decreased and interstitial lung disease. 4 (7.2%) pts died from KN046 TRAEs (Hyponatremia, n=1; Interstitial lung disease, n=2; Cause of death unknown, n=1). **Conclusions:** KN046+Lenvatinib demonstrated a promising efficacy in ORR and PFS and the manageable safety profile in the first-line advanced unresectable or metastatic HCC treatment. These result support the KN046 plus Lenvatinib as a potential new treatment option for this population. Clinical trial information: NCT04542837. Research Sponsor: None.

IMMUTACE: A biomarker-orientated phase II, single-arm, open-label AIO study of transarterial chemoembolization (TACE) in combination with nivolumab performed for intermediate-stage hepatocellular carcinoma (HCC; AIO-HEP-0217)—Updated efficacy results. *First Author: Anna Saborowski, Hannover Medical School, Hanover, Germany*

Background: Immunotherapy based combinations recently revolutionized the treatment of patients (pts) with advanced HCC, but its significance in earlier stages remains to be determined. TACE is commonly used as first line treatment in intermediate HCC, but outcome of patients treated with TACE in real-life cohorts is still poor with a median overall survival (OS) below 20 months. The aim of this study was to determine the safety and efficacy of TACE combined with nivolumab. **Methods:** This is a phase II trial, that recruited 59 patients at 10 sites in Germany between 06/2018 and 06/2020. Pts received up to two TACE treatments followed by nivolumab (240 mg/ Q2W), initiated on day 2-3 after the first TACE session and continued until progression for a maximum treatment duration of two years. Primary endpoint was ORR (mRECIST; with ORR exceeding 55% (power = 80%; actual beta 0.17) as promising for further investigations). Secondary endpoints include mPFS, mTTFS (median time to failure of strategy), mOS, QoL, and safety/tolerability. Tumor tissue was obtained at baseline and blood samples were collected longitudinally for translational research. **Results:** 49 pts (14.3% HCV and 8.2% HBV) were enrolled and received at least one dose of nivolumab, median tumor size was 4.5 cm (0.9 – 15 cm) and median number 3 (1 – 12). ORR by mRECIST was 71.4% (CR: 16.3%, PR: 55.1%, SD 4.1%, PD: 14.3%). At a median follow-up of 20 months, mPFS was 7.2 mo (95% CI; 5.3 – 11.2; 40 events), mTTFS was 11.2 mo (95% CI; 7.2, 13.5; 42 events) and mTTSST (median time to subsequent systemic therapy) was 24.9 mo (95% CI; 12.2, - ; 21 events). Median duration of Nivolumab was 8.3 months and mOS was 28.3 mo (95% CI; 20 – not estimable; 23 events). Grade ≥3 treatment-related adverse events occurred in 34.7% of patients. Correlative analysis of efficacy with genetic alterations, gene expression signatures and changes of immune cell populations will be reported soon. **Conclusions:** The study met its primary endpoint and provides evidence for the efficacy of TACE in combination with nivolumab without new safety signals in pts with intermediate HCC and no prior systemic therapy. Our findings support further evaluation of nivolumab-based combinations for the treatment of intermediate HCC. Disclaimer: This study was supported with drug and funding by Bristol-Myers-Squibb. Clinical trial information: NCT03572582. Research Sponsor: BMS.

Health-related quality of life in patients treated with gemcitabine/cisplatin and durvalumab ± tremelimumab in chemotherapy-naïve advanced biliary tract cancer. *First Author: Jin Won Kim, Seoul National University Bundang Hospital, Seongnam, South Korea*

Background: In the phase 2 (NCT03046862), gemcitabine/cisplatin (GemCis) and durvalumab (D) ± tremelimumab (T) in chemotherapy-naïve advanced biliary tract cancer (BTC) showed a high objective response rate and durable clinical benefit. Based on this study, phase 3 trial (TOPAZ-1, NCT03875235) has been conducted and the positive result for adding D to GemCis has been reported. Health-related quality of life (HRQoL) for adding immunotherapy to cytotoxic chemotherapy in BTC has not been reported yet. We present HRQoL results from the phase 2 study. **Methods:** In this study, treatment-naïve patients with unresectable or recurrent BTC were enrolled into three cohorts. Patients received one cycle of GemCis followed by GemCis plus D and T (cohort 1) or, starting with the first cycle, received GemCis plus D (cohort 2) or GemCis plus D and T (cohort 3). The EORTC Quality of Life Questionnaire (QLQ)-C30 and BIL21 were administered at baseline and every cycle throughout treatment. Change from baseline to post-2 cycles and deterioration of HRQoL (≥10 points change) were analysed. **Results:** At data cut-off (March 22, 2021), 126 patients (32 in cohort 1, 47 in cohort 2, 47 in cohort 3) were included for this analysis. Compliance for QLQ was very high (> 90 %) at all time points. C30 global health status (GHS) scores remained stable at all time points and from baseline to post 2 cycles (mean [95% CI] change, 2.66 [-1.10–6.42]), with greater improvements observed in patients with responder (a best response of complete response (CR) or partial response (PR)) (3.60 [-1.27 to 8.47]) compared to non-responder (stable disease (SD) or progressive disease (PD) (0.66 [-5.19 to 6.51]). For the overall cohort, functioning scales also remained stable from baseline to post 2 cycles. Nausea/vomiting (8.4 [4.45 to 12.36]), dyspnea (7.28 [2.17 to 12.4]), constipation (9.24 [3.35 to 15.13]), financial difficulties (5.53 [1.65 to 9.41]) in C30 and eating (5.53 [1.65 to 9.41]), tiredness (5.42 [1.23 to 9.6]), treatment side effects (7.98 [1.15 to 14.81] in BIL21 were worse at post 2 cycles. However, pain (-7.14 [-12.24 to -2.04]), diarrhea (-4.48 [-8.86 to -0.1]) in C30 and jaundice (-5.51 [-9.26 to -1.76]), pain (-6.02 [-9.7 to -2.34] in BIL21 were improved and more improvement was shown in responder compared to non-responder. Regarding deterioration of C30 GHS, median deterioration-free survival (months [95% CI]) was 4.14 (2.66-6.47) in all cohorts and there was no difference between responder (3.68 [2.27-7.92]) and non-responder (5.59 [2.73-9.46], Hazard ratio = 1.00 [95% CI, 0.62-1.61], p = 0.997). There was no difference among 3 cohorts. **Conclusions:** GemCis plus D ± T in chemotherapy-naïve advanced BTC generally preserved HRQoL and improved some symptom scales such as jaundice and pain although chemotherapy related symptom scales were worse. Research Sponsor: Astrazeneca.

4118 **Poster Session**

Impact of metformin on clinical outcomes in advanced hepatocellular carcinoma treated with immune checkpoint inhibitors. *First Author: Lana Khalil, Emory University Hospital, Atlanta, GA*

Background: Non-alcoholic steatohepatitis (NASH) is an emerging etiology for hepatocellular carcinoma (HCC) and contributes to the increasing incidence of HCC worldwide. Patients with NASH often have risk factors of metabolic syndrome including hypertension, obesity, and type 2 diabetes (T2DM). NASH induced HCC has been shown to be associated with less response to immune check point inhibitors (ICIs) in HCC. Anti-diabetic agent metformin has been shown to be associated with improved outcomes in patients treated with ICIs in melanoma and non-small cell lung cancer. However, the impact of metformin on the efficacy of ICIs is not well defined in HCC. The main purpose of this study was to examine the effect of metformin on clinical outcomes in patients with advanced HCC treated with ICIs. **Methods:** We performed a retrospective analysis of patients with advanced HCC treated with ICIs in first and later-line settings between 2015 and 2021. The primary endpoints were overall survival (OS), progression free survival (PFS), and objective response rate (ORR) as assessed according to Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1. Patients were stratified based on their usage of metformin. OS and PFS were analyzed using Cox proportional hazard models and Kaplan-Meier analysis with log-rank test. **Results:** A total of 111 patients met inclusion criteria, 18 patients in the metformin group and 93 patients in the non-metformin group. Most common cause of HCC was viral hepatitis (52%), followed by NASH (29%), alcohol (8%) and other (11%). Baseline characteristics between the two groups were similar except all patients in the metformin group had a diagnosis of T2DM. ORR was 5.6%. (1 partial response) in the metformin group vs 22.6% (5 complete responses, 16 partial responses) in the non-metformin group. Median OS was 45.9 months in the non-metformin group vs 10.8 months in metformin group (HR 1.99, 95% CI 0.95-4.21, p = 0.064). Median PFS of 6.6 months vs 2.5 months (HR 1.75, 95% CI 0.93-3.29, p = 0.077). Moreover, metformin usage was associated with shorter median OS of 10.8 months (HR 1.96, 95% CI 0.75-5.09, p = 0.16) vs 20.9 months among patients with T2DM. OS was significantly worse in patients with poor ECOG performance status 2-3, MELD score 10-23, higher grade tumor histology, AFP > = 400, and use of IO in later lines of therapy. **Conclusions:** In this retrospective study metformin use was associated with worse clinical outcomes in advanced HCC patients treated with ICIs. Research Sponsor: None.

Quantitative analysis of spatial distribution of lymphocytes in hepatocellular carcinoma: A biomarker correlated with survival and gene expression in cancer immune system. *First Author: Hong-Seok Lee, VUNO Inc., Seoul, South Korea*

Background: Tumor microenvironment (TME) is known to impact prognosis in hepatocellular carcinoma (HCC). Although digital pathology and artificial intelligence have been adopted in modern medicine and oncology, few quantitative biomarkers have been identified to predict the prognosis and guide treatment for HCC via an automated analysis of TME at the cellular level. **Methods:** Histopathological images and clinical data of 365 cases with HCC were obtained from TCGA (The Cancer Genome Atlas), and 60 of HCC pathology images and cancer lesion annotations were collected from PAIP2019 [1]. DenseNet-based HCC segmentation model (F1-score, 0.904) and Hover-Net-based cell detection model (F1-score, 0.914) were developed using PAIP2019 and MoNuSac datasets, respectively [2,3,4]. Each histopathology image of TME was segmented via the segmentation model into two areas: 1) non-tumoral regions that include the stroma; 2) tumoral regions where HCC cells are concentrated. The cell detection model recognized individual cells on images, specified lymphocytes, and calculated ratios of lymphocyte to total cell count (RLTCC) in segmented regions. RLTCC was then correlated with clinical survival outcomes, HCC primary risk factors, and RNA expression profiles. **Results:** RLTCC in tumoral regions was not significantly associated with prognosis. Patient groups with higher RLTCC in non-tumoral regions (RLTCC in NT) showed better overall survival (OS) than those with lower RLTCC in NT regardless of HCC risk factors (median OS 45.7 vs 18.6 months; log hazard ratio of -1.6 ± 1.1, p=0.006). These patients had significantly enriched expression of genes (p<0.05) related to cancer antigen presentation (higher gene expression by +33.7%), recognition of cancer cells by T-cell (+32.0%), T-cell priming and activation (+32.2%), immune cell localization to tumors (+31.9%), and killing of cancer cells (+24.7%). Those with HCC etiology of hepatitis B and C had more patients in the higher RLTCC in NT (17/21 patients, 81.0%; 23/29, 79.3%, respectively). In comparison, those with alcohol consumption showed equal distribution (26/53, 49.1%). The RLTCC in NT in hepatitis B/C groups was statistically higher than alcohol consumption group (p<0.05). **Conclusions:** A digital prognostic biomarker, RLTCC in NT of TME was identified as a significant prognostic indicator, and it was shown to correlate with RNA gene expression related to T-cell mediated cancer immunity. A retrospective analysis of clinical response from systemic therapy in relation to digital biomarkers is underway and will be reported. References: [1] Kim et al. Med. Image Anal. 67 (2021). Comparative genomic analysis and its prognostic impact on survival between viral hepatitis-related and non-viral hepatitis intrahepatic cholangiocarcinoma. *First Author: Nai-Jung Chiang, National Institute of Cancer Research, National Health Research Institutes, Tainan, Taiwan*

Background: Intrahepatic cholangiocarcinoma (IHCC) is hard-to-treat cancer with a high mortality rate worldwide. Hepatitis B virus (HBV) or hepatitis C virus (HCV) is involved in the development of IHCC, especially in Asian countries. Despite rapidly growing genomic profiling studies of IHCC in Western and Eastern populations in recent years, less on genomic heterogeneity of viral hepatitis-related and non-viral hepatitis IHCC been reported. This study aims to provide a comprehensive genomic analysis of IHCC and its prognostic value in IHCC populations with or without viral hepatitis infection. **Methods:** FFPE tissues from 157 patients with IHCC were subject to next-generation sequencing using the FoundationOne CDx (n = 52) or ACTOnco + comprehensive genomic profiling panels (n = 105). Genomic alterations and features, including single nucleotide variations (SNVs), short insertions and deletions (InDels), copy-number variations (CNVs), fusion genes (only FoundationOne CDx), tumor mutations burden (TMB), and microsatellite instability (MSI) status, were analyzed. The prevalence of genetic mutations and their prognostic values were compared between patients with a history of hepatitis B/C infection (BC; n = 71, 45.2%) and those without hepatitis B/C infection (NBNC; n = 79, 50.3%). Seven patients had no medical record of HBV or HCV infection. **Results:** The most frequently mutated genes in BC- and NBNC-related IHCC populations were TP53, KRAS, and IDH1. The genetic alternations related to PI3K/AKT/mTOR signaling pathway and copy number gain of receptor tyrosine kinase were relatively dominant in BC-related IHCC. In contrast, the Ras/Raf/MAPK pathway alterations were frequently common in NBNC-related IHCC. In addition, we investigated the correlation between commonly altered genes or pathways and overall survival (OS). Interestingly, the prognostic biomarkers in BC- and NBNC-related IHCC were significantly different. The results showed that TP53 DNA-binding domain (DBD) and TET2 mutations were associated with poor prognosis in BC-related IHCC. On the contrary, CDKN2A deletion and Ras/Raf/MAPK pathway alteration were associated with inferior prognosis in NBNC-related IHCC. However, neither the PI3K/AKT/mTOR signaling alteration nor IDH1/2 mutation affected the OS in BC- or NBNC-related IHCC. Notably, we found that SWI/ SNF complex involved in ARID1A, ARID1B, ARID2, PBRM1, and SMARCA4 alterations exhibited a beneficial prognosis in BC-related IHCC patients, which has not been discussed in previous studies. **Conclusions:** This study provides comparative genomic profiling between BC- and NBNC-related IHCC and shows genomic heterogeneity and different dominant prognostic biomarkers and activated signaling pathways. Different treatment strategies should be considered in these two subpopulations based on these results. Efficacy of nivolumab and temozolomide in advanced neuroendocrine neoplasms (NENs) in a phase 2 clinical trial.

First Author: Dwight Hall Owen, Division of Medical Oncology, Department of Internal Medicine, Ohio State University, Columbus, OH

Background: Treatment options are limited in patients with metastatic NEN. Temozolomide (TEM) alone and in combination with capecitabine is active in NEN and has been shown to have immunomodulatory impact. Here we present the final results for the NEN cohort of a phase 2 trial of combination nivolumab and TEM in patients with advanced NEN along with observed peripheral immune changes. **Methods:** NCT03728361 is a non-randomized, two-cohort, open-label phase 2 trial of nivolumab and TEM in patients with metastatic NEN and small cell lung cancer. The NEN cohort enrolled patients with tumors of any WHO grade, location, and line of therapy; all patients had evidence of progression prior to study. Prior immunotherapy was not allowed. Treatment consisted of nivolumab 480 mg IV on day 1 and TEM 150 mg/m2 on days 1-5 of a 28-day cycle. The primary objective was efficacy measured as response rate (RR) by RECIST v1.1. Secondary objectives were progression free survival (PFS) and overall survival (OS), by the method of Kaplan–Meier. The translational objective was to analyze peripheral blood mononuclear cells (PBMCs) collected at screening (baseline) and on cycle 1, day 15 (C1D15) via mass cytometry. **Results:** The RR was 36% (n=10/28, 95% CI: 18.6%-55.9%), including 10 patients (36%) with PR, 16 (57%) with SD, and 2 (7%) with PD (Table). The disease control rate was 93%. Responses occurred across all WHO grades; 44% of patients with tumors with Ki-67 >20% had PR. There was a significant difference in ORR by primary tumor location (bronchial vs pancreas vs other, p=0.004). There was no significant difference in response by Ki-67% (p=0.872), or in patients treated as first line (31%) or beyond (40%, p=0.706). The median PFS was 8.9 months (95% CI: 3.9 – 11.1 months), and median OS was not reached (95% CI: 20.7 – NR months). Two immune related SAE's occurred: myocarditis and diarrhea in one patient each; gr4 toxicities included neutropenia (10%) and thrombocytopenia (7%). Profiling of PBMCs revealed no correlation of baseline MDSC levels with clinical benefit, however significant changes within the T cell landscape, including a decrease in CD4+ T cells (59.6% ±13.08 vs. 56.5% ±13.01, p=0.001) and increase in CD8+ T cells (27.9% ±13.36 vs. 31.7% ±14.57, p=0.03) were observed. **Conclusions:** Combination nivolumab and TEM demonstrated promising efficacy in patients with NENs; median OS has not been reached. Clinical trial information: NCT03728361. Research Sponsor: OSU-BMS Collaborative Research Grant.

Characteristics and efficacy.

Patient Characteristics (N=28)	N (%)	Response Rate (n, %)	PFS (95% CI), months	OS (95% CI), months
Primary Location:				
All patients	28	10 (36%)	8.9 (3.9, 11.1)	NR (20.7, NR)
Bronchial	11 (39%)	7 (64%)	11.1 (3.0, 29.0)	NR (8.8, NR)
Pancreas	3 (11%)	2 (67%)	28.3 (3.8, 28.3)	NR (NR, NR)
Other	14 (50%)	1 (7%)	6.7 (3.6, 10.0)	20.8 (16.8, NR)

Australasian Gastrointestinal Trials Group (AGITG) CONTROL NET Study: ^{177}Lu-DOTATATE peptide receptor radionuclide therapy (PRRT) and capecitabine plus temozolomide (CAPTEM) for pancreas and midgut neuroendocrine tumours (pNETS, mNETS)—Final results.

First Author: Nick Pavlakis, Northern Cancer Institute, St. Leonards, Sydney, Australia

Background: CAPTEM is an accepted regimen for patients (pts) with advanced pNETs. Single agent PRRT is now a standard of care for progressive WHO Grade 1/2 mNETs. High activity was seen with PRRT/CAPTEM in a single arm Phase I/II trial. This study aims to determine the activity of combining CAPTEM with PRRT in mNETs and pNETs pts. **Methods:** Non-comparative randomised open label parallel group phase II trial with 2:1 randomisation to PRRT/CAPTEM (experimental arm) vs. PRRT (mNETs control) and CAPTEM (pNETS control). PRRT/CAPTEM: 7.8GBq ^{177}Lu Octreotate (Lutate) given intravenously (IV) on day 10 every 8 weeks for 4 cycles, with concurrent oral capecitabine 750mg/m^2 b.i.d. days 1-14 and temozolomide 75mg/m^2 b.i.d. days 10-14 every 56 day cycle, up to 4 cycles. PRRT alone: 7.8GBq ^{177}Lu Octreotate (Lutate) given intravenously (IV) on day 1 every 8 weeks for 4 cycles. CAPTEM alone: Oral capecitabine 750mg/m^2 b.i.d. days 1-14 and days 29-42; Oral temozolomide 75mg/m^2 b.i.d. days 10-14 and 38-42 every 56 day (8w) cycle. Primary endpoint: Progression free survival (PFS). mNETS: At 15 months, assuming PFS 66.4% in control arm; target PFS ^{3} 80%; pNETS: At 12 months, assuming PFS 60% in control arm; target PFS ^{3} 75%. Secondary endpoints: Objective tumor response rate (complete or partial) (OTRR), overall survival (OS), adverse events (AEs). **Results:** 75 pts enrolled (Dec 2015 – Nov 2018): mNETs 33 PRRT/CAPTEM, 14 PRRT, median follow up (mFU) 60.3 months; pNETS 19 PRRT/CAPTEM, 9 CAPTEM, mFU 57.5 months (mo). Late Grade 3/4 haematologic AEs: mNETS: 2/32 (6%) PRRT/CAPTEM pts and 4/13 (31%) PRRT pts. Events included myelodysplastic syndrome (40 mo), leukaemia (60 mo), pancytopenia (50 mo), anaemia (32 mo), thrombocytopenia (7 mo). No late haematologic G3/4 AEs were reported in the pNETS cohort. No late renal toxicity was identified in all study arms. **Conclusions:** CONTROL NETs is the first randomized trial to demonstrate efficacy for PRRT in pNETs, in addition to a standard of care. Extended follow up confirms durable CAPTEM/PRRT activity, with superior PFS in pNETs. Late haematologic toxicity was seen in both mNET PRRT arms but was not higher with additional CAPTEM. The activity of CAPTEM/PRRT in pNETs should be tested in the phase III setting. Clinical trial information: ACTRN12615000909527. Research Sponsor: NeuroEndocrine Cancer Australia, University of Sydney, Tour de Cure, Australasian Gastrointestinal Trials Group.

Association of LAG-3 expression in circulating T cells and response to combination temozolomide (TMZ) and nivolumab (NIVO) in advanced neuroendocrine neoplasms (NENs): Results from an investigator-initiated phase 2 trial.

First Author: Vineeth Sukrithan, Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: LAG-3 is an immune checkpoint present on NK cells, activated T cells and myeloid cells that inhibit T cell responses. Recent evidence demonstrating the safety and efficacy of LAG-3 inhibition has increased interest in this pathway for the treatment of multiple malignancies but the role in NEN is unclear. We present results from correlative peripheral blood mass cytometry (CyTOF) performed in a phase 2 trial (NCT03728361) of the combination of NIVO and TMZ in pts with advanced NEN. **Methods:** Patients (pts) with progressive NEN of any grade or primary location and any line of therapy were eligible. Small cell lung cancer was excluded. Clinical results from NCT03728361 will be presented in a separate abstract. Study treatment consisted of NIVO 480 mg IV every 4 weeks and TMZ 150 mg/m2 for 5 consecutive days out of a 28-day cycle. Peripheral blood mononuclear cells (PBMCs) were available from 16 out of 28 patients at screening (baseline) and cycle 1, day 15 (C1D15) and analyzed via CyTOF. Antibody labelling was performed using a 37 marker Maxpar Direct Immune Profiling Assay (Fluidigm). Immune cell populations were compared using two sample t-tests between pts with partial response (PR) and non-partial response (non-PR). **Results:** At screening, no differences were observed in PD-1, TIM3, or KLRG1 positive T-cell populations between pts with PR or non-PR. Patients with a PR had a significantly lower % of LAG-3 expressing T cells (p=0.029). There was a trend towards a lower % CD8+LAG-3+ T cells in pts with PR (p=0.086). At C1D15: The % of CD8+ LAG-3+ T cells were significantly higher in PRs vs. non-PR (p = 0.015). In matched samples comparing T cell populations at screening to C1D15, LAG-3+ CD8+ T cells increased significantly in PRs when compared to non-PRs (p=0.021). **Conclusions:** The % of LAG-3+ T cell population at baseline associates with non-response to TMZ/NIVO in NENs. Among responders, there was a significant increase in CD8+ LAG-3+ T cells by Day 15 compared to baseline indicating a potential mechanism of immune escape and eventual resistance. Clinical trial information: NCT03728361. Research Sponsor: Ohio State University-Bristol Myers Collaborative Research Grant.

Percentage LAG3+ T cell population at screening and during treatment in NEN patients treated with TMZ/NIVO comparing responders (PR) and non-responders (Not PR).

Population	Total (n=16)	Not PR (n=11)	PR (n=5)	P-value
		Mean (SD, min-max)		
1. Screening: Total LAG-3+ (PR=5, not-PR=9)	0.6% (0.55, 0.01–1.98)	0.83% (0.55, 0.13–1.98)	0.18% (0.24, 0.01-0.6)	0.029
2. Screening: CD8+ LAG-3+ (PR=5, not-PR=9)	1.07% (1.04, 0.12-3.66)	1.42% (1.16, 0.12-3.66)	0.43%(0.18,0.14-0.61)	0.086
3. C1D15: CD8+ LAG-3+ (PR=3, not-PR=8)	0.99% (0.72, 0.19–2.57)	0.69% (0.48, 0.19- 1.42)	1.78 % (0.71, 1.2-2.57)	0.015
4.Change from screening to C1D15: CD8+ LAG-3+ (PR=3, not-PR=6)	0.46% (1, –0.7–2.13)	–0.03% (0.73, –0.7–1.3)	1.45 % (0.67, 0.8–2.13)	0.021

Genomic correlates of response to capecitabine and temozolomide (CAPTEM) in pancreatic neuroendocrine tumors.

First Author: Patrick Lee, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Despite the frequent use of capecitabine and temozolomide (CAPTEM) to treat metastatic, well-differentiated pancreatic neuroendocrine tumors (PNETs), no reliable genomic predictors of response currently exist. PNETs commonly harbor mutations in *MEN1*, *ATRX*, *DAXX*, and the PI3K/AKT/mTOR pathway. We sought to determine whether the mutational status of these genes correlates with response to CAPTEM. **Methods:** A retrospective cohort of PNET cases seen at Cedars-Sinai Medical Center or from Perthera's Real-World Evidence Database included 23 patients who were treated with CAPTEM in 1st or 2nd line and had targeted next-generation sequencing (NGS) of their tumors available. Genomic alterations were correlated with progression-free survival (PFS) using multivariate Cox regression analysis. **Results:** We analyzed 23 PNET patients, 4 (17.4%) of whom had documented functional tumors. We identified *MEN1* mutations as positively associated with CAPTEM response, but this effect was less pronounced for the subset with co-occurring *DAXX* mutations, which are commonly found alongside *MEN1* alterations. With and without accounting for line of therapy, we found that PFS on CAPTEM was significantly longer in *MEN1*-mutated, *DAXX*-wildtype tumors compared to other mutation profiles ($P < 0.01$, see Table). *ATRX* (67%) and *PTEN* (33%) alterations were also enriched in the *MEN1*-mutated/*DAXX*-wildtype subset; however, other PI3K/AKT/mTOR alterations were common across all *MEN1*-mutated cases. **Conclusions:** We describe a novel genomic signature (*MEN1* mut/*DAXX* wt) that correlates with PNET response to CAPTEM therapy and is exploratory in nature. Prospective validation of these associations is warranted while taking into account other therapies, histopathologic factors, and other genomic correlates. Research Sponsor: Know Your Tumor PANCAN.

Exploratory PFS analyses on 1st/2nd line CAPTEM comparing *MEN1*-mutated/*DAXX*-wildtype PNETs versus other genomic profiles.

PNET Subset	mPFS (95% CI)	Univariate p-value (HR (95% CI))	Multivariate p-value (HR (95% CI))	Line of Therapy p-value (HR (95% CI))

REGOMUNE: Phase II study of regorafenib plus avelumab in solid tumors—Results of the gastroenteropancreatic neuroendocrine carcinomas (GEP-NEC) cohort. *First Author: Sophie Cousin, Early Phase Clinical Trials Unit and Thoracic Unit, Institut Bergonié, Bordeaux, France*

Background: There is no standard treatment for patients (pts) with advanced extra-pulmonary neuroendocrine tumors (NET) and carcinomas (NEC) after failure of chemotherapy in the metastatic setting. PD-1/PD-L1 expression is frequent in these tumors. Combining anti-PD1/PDL1 agents with anti-angiogenics has been shown to be synergistic in several tumor models. **Methods:** This is a single-arm open-label multicentric phase II trial assessing the efficacy and safety of regorafenib (R) (160 mg QD 3weeks/4) + Avelumab (A) (10 mg/kg every 2 weeks) combination in pts with advanced or metastatic grade 2 or 3 (G2/3) gastroenteropancreatic (GEP)-NET or GEP-NEC. The primary endpoint was the confirmed objective response rate, based on central review according to RECIST 1.1. Secondary endpoints included: 1-year progression free survival (PFS), 1-year overall survival (OS), and Safety using NCI-CTCAE v5.0. Correlative studies were planned from pts tumor samples obtained at baseline. **Results:** Between May 2019 and Apr. 2021, 46 pts were enrolled in 6 centers. Median age was 63 (range 31 – 80). 10 pts presented with a NEC and 36 pts with a G2/3 NET. Median follow-up was 6.5 months (95% CI: 5.3 - 9.6). Median number of previous treatment lines was: 2 (range 0 – 8). 39 (84.8%) pts experienced at least 1 dose modification or treatment interruption. The most common grade 3/4 adverse events were : Hypertension (13% of pts), fatigue (13%), and diarrhea (11%). One death was related to the treatment. Among the 42 assessable pts, 7 (16.7%) achieved a partial response: 6 pts with a G2/3 NET and 1 patient with a NEC. 22 (52.4%) pts demonstrated stable disease, 22 (52.4%) pts had tumor shrinkage and 10 (23.8%) pts had progressive disease. 3 (7.1%) pts were inevaluable as per RECIST. The median duration of response was 15.5 months (95%CI: 3.7 - not reached (NR)). The median PFS and OS were 5.5 months (95% CI: 3.6 – 9.2) and NR respectively. One year OS rate was 69.4 % (95% CI: 45.1 % – 84.5 %). **Conclusions:** REGOMUNE is the largest prospective study ever conducted in pts with grade 2/3 GEP-NET or GEP-NEC refractory to cytotoxic chemotherapy. The R+A combination has significant clinical activity in pts with refractory disease. Full Biomarkers analyses will be presented at the meeting. Clinical trial information: NCT03475953. Research Sponsor: Bayer, Merck.

4126 **Poster Session**

A pooled analysis of surufatinib safety from phase 3 trials in advanced NETs. *First Author: Jie Li, Department of Gastrointestinal Oncology, Key laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital & Institute, Beijing, China*

Background: Surufatinib is a small-molecule inhibitor of VEGFR1, 2, & 3, FGFR1, and CSF-1R. Surufatinib demonstrated prolonged PFS and tolerable safety in two phase 3 studies in advanced neuroendocrine tumors (NETs) of pancreatic (SANET-p; NCT02589821) and extrapancreatic (SANET-ep; NCT02588170) origin (Xu, 2020 Lancet Oncology). Detailed outcomes on safety from these 2 studies are reported here as a pooled analysis. **Methods:** Data is pooled from SANET-p and SANET-ep studies which have similar designs including a 2:1 randomization of surufatinib to placebo in patients ≥18 years with advanced, well differentiated NETs, progressing on or after ≤2 prior therapies. Surufatinib 300 mg or placebo, was administered once daily until disease progression or unacceptable toxicity. Safety outcomes for each pooled treatment group are reported as treatment-emergent adverse events (TEAE) assessed by NCI-CTC 4.03. Patients were included if they had received study treatment during the double-blinded phase of the studies. **Results:** As of 30th June 2020, 396 patients were assigned to the surufatinib (n = 263) and placebo (n = 133) groups. Median treatment duration was longer with surufatinib 7.4 months (range 0.1–41.4) compared with placebo 4.6 months (range 0.1–39.9). 29% of patients reached more than 12 months of treatment with surufatinib group compared to 11% with placebo. The mean relative dose intensity was 87.56% in the surufatinib group and 97.01% in the placebo group. Most common TEAEs (surufatinib vs placebo) were proteinuria 68.8% vs 54.9%, hypertension 68.4% vs 27.1%, and diarrhea 49% vs 22.6%. Most common grade ≥3 TEAE were hypertension 38.8% vs 13.5%, proteinuria 14.8% vs 0.8% and hypertriglyceridaemia 5.3% vs 0%. Deaths due to TEAEs were comparable between groups 2.7% vs 2.3%. TEAEs led to dose reductions in 43.0% vs 6.8% of patients and dose interruptions in 47.1% vs 29.3% of patients. The majority of patients (83.3% vs 93.2%) were managed without discontinuation because of TEAE. Median onset of proteinuria and hypertension were < 1 month in both groups. Median (range) onset was 0.95 months (0.16–30.36) vs 0.95 months (0.23–16.95) for proteinuria and 0.49 months (0.03–31.18) vs 0.89 months (0.03–14.75) for hypertension. Among patients with hypertension, 59% (n = 111) vs 28% (n = 11) received antihypertensive medication. **Conclusions:** Surufatinib was generally well tolerated in this pooled analysis and the safety profile was consistent with its previously reported data. The monitoring and management of hypertension and proteinuria are important for patients receiving surufatinib. Clinical trial information: NCT02589821; NCT02588170. Research Sponsor: HUTCHMED Limited.

Molecular correlates of Delta-like-ligand 3 (DLL3) expression in neuroendocrine neoplasms (NENs). *First Author: Justin Hwang, Division of Hematology, Oncology and Transplantation, Department of Medicine, University of Minnesota, Minneapolis, MN*

Background: NENs can occur in many locations but have limited precision therapy options. DLL3 is a cell surface protein that is emerging as a promising therapeutic target in NENs including neuroendocrine prostate cancer (NEPC) and small cell lung cancer (SCLC). Our recent study indicated that ~77% of NEPCs expressed DLL3, with expression in circulating tumor cells being highly concordant with matched biopsies. While there are ongoing clinical trials of drugs targeting DLL3, the repertoire of clinical and genomic features shared across other DLL3-expressing NEN cancers is ill-defined. **Methods:** We analyzed WES and WTS data from NENs identified across 29 different sites of origin using the Caris Life Sciences platform, excluding SCLC and including neuroendocrine carcinomas and neuroendocrine tumors. We used values above or below median DLL3 expression of all NEN samples to define DDL3-High/Low (H/L). Significance of molecular alterations in DLL3-H vs L was determined using Fisher's-Exact/Mann Whitney/X^2 test with Benjamini-Hochberg correction. **Results:** DLL3 expression across all 2672 NEN samples was observed in 27 of 29 NENs after excluding SCLC. NENs of anus, prostate, lung, bladder, and bile duct exhibited the greatest median DLL3 expression, whereas adrenal gland, small bowel, and nervous system displayed the lowest. Certain tissues of origin displayed more robust DLL3 expression, with 71% (50/66) of NEPC, 75% (87/122) of lung, and 77.3% (51/66) of bladder being DLL3-H compared to 14.4% (13/90) of adrenal and 7.9% (12/151) of small bowel NENs. DLL3-H NENs were associated with TMB-high status (> 10 muts/Mb; 12.1% vs 4.5%, OR 2.7, q < 0.001) and more genomic alterations in several driver genes, including tumor suppressors TP53 (51% vs 23%, OR 2.3, q < 0.001) and RB1 (42% vs 10%, OR 4.2, q < 0.001), and oncogenes KRAS (14% vs 5.4%, OR 2.5, q < 0.001), MYC (5.7% vs 0.9%, OR 6.3, q < 0.001) and CCNE1 (5.3% vs 1.3%, OR 4.0, q = 0.001). Conversely, DLL3-L NENs exhibited more alterations in CTNNB1 (2.2% vs 5.2%, OR 0.42, q = 0.04), MEN1 (3.3% vs 11%, OR 0.30, q < 0.001), and BCOR (1.3% vs 4.1%, OR 0.32, q = 0.02). DLL3-H NENs also had significantly more alterations in PIK3CA (6.4% vs 3.0%, OR 2.1, q = 0.04), chromatin remodeling genes KMT2D (6.7% vs 2.6% OR 2.6, q = 0.005) and CREBBP (3.2% vs 0.9%, OR 3.6, q = 0.03), and WNT signaling gene APC (9.7% vs 5.2%, OR 1.9, q = 0.02). **Conclusions:** We confirmed DLL3 expression in NENs across different tissues of origin, with highest expression in poorly differentiated NENs. DLL3-H expression was associated with genomic features considered "undruggable" based on current precision therapy approaches. Therefore, DLL3-targeted therapies may serve as a promising strategy for NEN patients with functional loss of tumor suppressors TP53 and RB1, as well as increased activity of KRAS, WNT and MYC signaling. Research Sponsor: None.

Targeted alpha-emitter therapy with ^{212}Pb-DOTAMTATE in neuroendocrine tumor subjects who progressed following prior ^{177}Lu/^{90}Y-PRRT. *First Author: Ebrahim Delpassand, Excel Diagnostics and Nuclear Oncology Center, Houston, TX*

Background: Targeted Alpha-Emitter Therapy (TAT) with ^{212}Pb-DOTAMTATE has been shown to be safe and effective in subjects with neuroendocrine tumors (NET) who have not received previous PRRT, however, data is lacking for the use of TAT once progression occurs. Herein, we present the safety and efficacy of ^{212}Pb-DOTAMTATE in subjects with recurrent NETs following prior ^{177}Lu/^{90}Y-PRRT. **Methods:** Subjects with biopsy-proven unresectable or metastatic SSTR expressing NETs from different primary sites with at least one measurable lesion who had received progressed after receiving prior PRRT were enrolled and received up to four 8-week cycles of ^{212}Pb-DOTAMTATE at 67.6 μCi/kg/cycle. Response to treatment was measured per RECIST 1.1 criteria and by ^{68}Ga/^{64}Cu-DOTATATE PET/CT. Safety parameters were also obtained. **Results:** A total of 11 PRRT subjects were enrolled regardless of primary tumor location (pancreas (4), small bowel (3), midgut (1), ileum (1), thymus (1), and lung (1)). 8/11 subjects (73%) completed all four cycles. The mean cumulative dose was 20.9 mCi. As of January 2022, an objective radiological response (ORR) was demonstrated in 30% of evaluable subjects (1CR, 2PR, and 7 SD). In addition, 70% (7/10) evaluable subjects demonstrated a response per ^{68}Ga/^{64}Cu-DOTATATE PET/CT SSTR imaging. One hundred forty-five AEs were reported, with Grade 1 (79%). There were 23 (16%) Grade 2 AEs and 5 (3%) Grade 3/ 4 AEs. Of the AEs reported, 84 (58%) were considered possibly related, and 61 (42%) were considered not related or unlikely related. The most frequent AEs (reported in ≥ 4 subjects) include: alopecia (100%), fatigue (100%), nausea (91%), anemia (36%), alanine aminotransferase increased (36%), aspartate aminotransferase increased (36%) and lymphopenia (46%). Three SAEs were reported (achalasia, asthma exacerbation, and septic shock) one of which resulted in the death of the subject (septic shock). No SAEs were considered related to study drug. **Conclusions:** This is the first clinical trial of ^{212}Pb-targeted alpha-emitter therapy in subjects with NETs who progressed following prior PRRT. The use of ^{212}Pb-DOTAMTATE in the recurrent setting is highly effective with manageable toxicity and warrants further investigation. Clinical trial information: NCT03466216. Analysis of molecular characterization: Pancreatic ductal adenocarcinoma with hepatic metastases. *First Author: Yonggang He, Department of Hepatobiliary, The Second Affiliated Hospital of Army Medical University, Chongqing, China*

Background: Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal solid tumors. Distant metastasis is the leading cause of cancer death. Approximately 50% of PDAC patients are discovered to have distant metastases, mainly in the liver. Chemotherapy is the main recommended treatment for metastatic PDACs, with a median survival time of only 4-6 months and the 5-year survival of 1%. Therefore, deciphering the molecular mechanisms of metastatic PDAC is urgently for exploring effective therapeutic targets. **Methods:** 93 normal-paired samples from patients with PDAC were analyzed using hybridization capture-based next generation sequencing. Somatic and germline mutations were identified including 500 genes associated with tumor development. Sequencing data were analyzed to call tumor specific single nucleotide variants (SNV), small insertions and deletions (InDels), copy number alterations (CNA) and gene fusions and rearrangements. **Results:** A total 93 patients with PDAC were analyzed, including hepatic metastases (15/93), lymph node metastases (1/93), colon metastases (1/93), pelvic metastases (1/93), and no distant metastasis (75/93). In PDAC patients without distant metastasis, the most frequent mutated gene was *KRAS* (72%), followed by *TP53* (60%), *CDKN2A* (21%), *SMAD4* (17%), *ARID1A* (11%), *RNF43* (9%), and *RBM10* (8%). In PDAC patients with hepatic metastases, we found that the most frequent one was *KRAS* (100%), followed by *TP53* (87%), *CDKN2A* (40%), *SMAD4* (40%), *RNF43* (13%), and *RBM10* (6%). Furthermore, four PDAC patients occurred KRAS copy number amplification, including 2 cases of hepatic metastases. And a hepatic metastases PDAC patient had *ERBB2* and *MET* copy number amplification. We also found that seven no-metastasis patients carried pathogenic or likely pathogenic germline variants, including *BRIP1*, *PALB2*, *RECQL*, *ATM*, *RAD50*, *FANCM* and *BRCA1*. **Conclusions:** High frequency mutation genes in PDAC patients with hepatic metastases were highly consistent with those of no-metastasis patients. *KRAS* and *TP53* gene co-mutations were extensively mutated in hepatic metastases patients. Our results revealed the molecular mechanisms driving PDAC hepatic metastases should be considered in further study. Research Sponsor: None.

KRAS wild-type pancreatic ductal adenocarcinoma: Molecular and therapeutic opportunities. *First Author: Aakash Desai, Mayo Clinic Rochester, Rochester, MN*

Background: *KRAS* is mutationally activated in over 90% of pancreatic ductal adenocarcinoma (PDAC). Compared to pts with *KRAS* mutation, *KRAS* wild-type (wt) PDAC seem to have better response to therapy and may harbor potentially actionable molecular alterations. Here, we analyze the molecular profile and clinical outcome of a cohort of pts with *KRAS* wt PDAC. **Methods:** A retrospective review was conducted on pts with PDAC who underwent CLIA-certified Next Generation Sequencing (NGS) testing at Mayo Clinic between December 1, 2018 and December 1, 2021. Pts with *KRAS* wt PDAC with available reports were included. Their genomic drivers, RNA expression, demographics, disease characteristics, therapies offered, and clinical outcome data were collected. The study was approved by the institutional IRB. **Results:** Of the 241 eligible pts, 8% (19) has *KRAS* wt PDAC. Among those, 2 pts had no mutation identified by the gene/molecular panel used. Of the 17 pts (89%) with identified alterations, mutations found in ^{3} 2 pts were TP53 (53%), CDKN2A (16%) and CDKN2B/ERBB2/PTEN/MSH3/RNF43/FBXW7/KMT2D/GNAS (11% each). Chromosomal rearrangements were identified in 5 (26%): CADPS2-BRAF, GP2-ERBB2, PTPRK-RSPO3, EML4-NTRK3 and TFG-MET. RNA expression results were available in 12 pts: common overexpression were ERBB2 (27%) and MET/NRAS/MYC/CCDN1/CCNE1/AR (18% each); and the under-expression MGMT (18%). Among the 13 pts with available MSI status via NGS, 2 (11%) were MSI-high (both had high TMB [28.4 and 23.7 m/MB]) while all others were TMB < 10 m/MB. The median age at diagnosis was 61 years (68% males). 8/19 (42%) were Stage IV at diagnosis with 15/19 (79%) pts ultimately diagnosed with metastatic disease. Among metastatic pts, median lines of treatment received was 2.5 (range:0-4). 4 pts received FOLFIRINOX (FFX), 2 gemcitabine/*nab*-paclitaxel (GP) and tumor response were comparable to previously reported results. 1 received 1st-line pembrolizumab and remained on therapy at the time of analysis. The median length of follow up from diagnosis was 29 months. A patient with TFG-MET re-arrangement previously progressed on FFX and GP was treated using a MET inhibitor, and achieved significant CA19-9 drop and pancreas tumor shrinkage at 1st restaging, with ongoing response. **Conclusions:** The molecular profile of *KRAS* wt PDAC is highly heterogeneous and difficult to generalize. Novel approaches (e.g., basket trials) are needed to develop therapy for this rare PDAC subgroup. Research Sponsor: None.

A descriptive study on the treatment and outcomes of patients with platinum-sensitive, advanced, *BRCA*- or *PALB2*-related pancreatic cancer who have progressed on rucaparib. *First Author: Timothy J Brown, Abramson Cancer Center, Hospital of the University of Pennsylvania, Philadelphia, PA*

Background: We recently reported the results of a single arm phase II study of maintenance rucaparib in patients with platinum-sensitive advanced pancreatic cancer and a pathogenic variant in *BRCA1, BRCA2*, or *PALB2* (NCT 03140670; Reiss, JCO 2021). However, optimal treatment following progression on PARP inhibitors (PARPi) has not been defined. Here, we report a descriptive study of post-progression treatment and outcomes of this patient population. **Methods:** Patients with advanced pancreatic cancer and germline or somatic *BRCA1, BRCA2*, or *PALB2*mutations treated with at least 16 weeks of platinum-based chemotherapy without progression were enrolled and treated with rucaparib until progression or unacceptable toxicity. At the time of progression, patients were treated with physician-choice chemotherapy. Here we evaluate the objective response rates (ORR) by RECIST 1.1. Overall survival (OS) and time to second progression (PFS2) calculated from trial enrollment and progression free survival on chemotherapy (PFS) by regimen were secondary endpoints. Time-to-event was analyzed by the Kaplan-Meier method and censored at date of last clinic visit, with a cutoff date of 12/10/21. **Results:** The trial enrolled 42 patients; 31 patients had progressed. Of these, 22 received second-line chemotherapy: nine were treated with an oxaliplatin-based regimen, nine were treated with a cisplatin-based regimen, and four were treated with non-platinum regimens. Demographics were balanced between those who received platinum versus non-platinum. All patients who received second-line chemotherapy regimens met the PFS2 endpoint and all but one patient had died at time of data cutoff. No patients had a complete response, five patients had a partial response (PR). By regimen, 1/9 patients treated with cisplatin had a PR, 3/9 treated with oxaliplatin had a PR, and 1/4 patients treated with non-platinum had a PR. OS, PFS2, PFS, and ORR results by regimen are shown in the table. **Conclusions:** In this small sample of patients with advanced pancreatic cancer with progressive disease on PARPi, chemotherapy retains some activity. Further study to identify predictors of response and/or resistance to post-PARPi treatment are underway. Research Sponsor: U.S. National Institutes of Health.

Comparison		OS (months)	PFS2 (months)	PFS (months)	ORR (%)
Platinum vs Non-platinum	Platinum (n=18)	14.8 (9.3-21.5)	9.1 (5.4-15.1)	2.9 (2.0-5.9)	22.2 (6.4-47.6)
	Non-platinum (n=4)	20.3 (14.4-NR)	6.6 (5.5-NR)	3.9 (1.0-NR)	25.0 (0.6-81.0)
Platinum Type	Cisplatin (n=9)	13.8 (5.8-21.5)	9.1 (3.1-15.1)	2.9 (1.5-7.4)	11.1 (0.3-48.2)
	Oxaliplatin (n=9)	19.0 (5.0-23.0)	9.4 (3.8-20.7)	3.7 (1.6-8.4)	33.3 (7.5-70.0)

OS is defined from study enrollment until death. PFS2 is time from study enrollment until second progression. PFS is defined as time from chemotherapy initiation (after rucaparib) and progression. NR= not reached.

The impact of HRD in patients with pancreatic adenocarcinoma undergoing surgical resection: An updated analysis. *First Author: Gudbjorg Jonsdottir, University of Iowa Hospitals and Clinics, Department of Internal Medicine, Division of Hematology, Oncology, and Blood & Marrow Transplantation, Iowa City, IA*

Background: Limited data is available regarding which mutations in the homologous recombination repair (HRR) pathway beyond BRCA can be targeted with platinum-based chemotherapy in the perioperative setting in patients with pancreatic ductal adenocarcinoma (PDAC). In this updated analysis, we assess the outcome of patients with homologous recombination deficiency (HRD) in response to platinum vs. non-platinum based perioperative chemotherapy in resected PDAC and have included additional variants linked to HRD. **Methods:** Patients with resectable PDAC, diagnosed between 1999-2020 from the participating members of the Oncology Research Information Exchange Network (ORIEN) were included in the study. Patient's germline and somatic whole exome sequencing (WES) data were analyzed for known pathogenic and likely pathogenic variants according to ClinVar for the following HRR pathway genes: *BRCA1, BRCA2, PALB2, BRIP1, BRAD1, BLM, BAP1, ATM, RAD51C, RAD51, RAD50, RAD54B, CHECK2, NBN, FANCA/B/C/D2/E/F/G, ARID1A, MRE11 and XRCC2.* The Kaplan Meier method was used to compare median overall survival (mOS) between patients with and without HRR pathway mutations in response to perioperative platinum vs non-platinum-based chemotherapy. Multivariate cox proportional hazard model was used to calculate HR and 95% CIs adjusting for age, sex and pathologic stage. **Results:** The ORIEN cohort included 311 patients with resectable PDAC and available WES data. A total of 22 patients (7%) had an HRR pathway mutation. Of these, 8 (36%) received perioperative platinum-based chemotherapy and 9 (41%) a non-platinum based regimen, 4 patients (23%) received no perioperative systemic treatment. Frequency of HRR variants detected: BRCA2 n=8 (2.6%), BRCA1 n=3 (1%), ATM n=2 (0.6%), ARID1A n=1 (0.3%), BRIP1 n=1 (0.3%), CHECK2 n=1 (0.3%), FANCG n=1 (0.3%), PALPB2 n=1 (0.3%), RAD50 n=4 (1.3%), RAD51C n=1 (0.3%). The mOS for patients with HRR mutations exposed to perioperative platinum-based chemotherapy was 3.5 years (95% CI 3.4-NA), patients with HRR mutation but no platinum exposure had a mOS of 1.2 years (CI 0.9-NA). In patients with no HRR mutation exposed to platinum-based chemotherapy mOS was 2.7 years (CI 2.3-3.9) and in those without exposure mOS was 2.9 years, p=0.43. Comparison of risk of death between the 4 groups is demonstrated in the table. **Conclusions:** There was a trend towards improved survival in patients with PDAC who harbored a HRR pathway mutation and were treated with perioperative platinum-based chemotherapy compared to those with no platinum exposure. Our results highlight the importance of identifying patients with HRD beyond BRCA and the need for large prospective studies in the perioperative setting to further assess their predictive role. Research Sponsor: None.

	HR	95% CI	P-value
HRD-, non-platinum	Reference	-	-
HRD+, non-platinum	2.53	0.99-6.5	0.05
HRD-, platinum	1.06	0.69-1.6	0.81
HRD+, platinum	0.78	0.26-2.3	0.65

Perioperative or adjuvant nab-paclitaxel plus gemcitabine for resectable pancreatic cancer: Updated final results of the randomized phase II AIO-NEONAX trial. *First Author: Thomas Jens Ettrich, Ulm University Hospital, Department of Internal Medicine I, Ulm, Germany*

Background: Perioperative chemotherapy (CTX) in resectable pancreatic ductal adenocarcinoma (PDAC) is still not considered standard of care and data are limited. The NEONAX trial examined gemcitabine (Gem) plus nab-paclitaxel (nab-P), in the perioperative or adjuvant therapy of resectable PDAC (NCCN criteria). **Methods:** NEONAX is a prospective, randomized phase II trial with two independent experimental arms. 127 resectable PDAC patients in 22 German centers were randomized 1:1 to perioperative (2 pre- and 4 postoperative cycles, arm A) or adjuvant (6 cycles, arm B) of Gem (1000mg/m2) and nab-P (125mg/m2) on days 1,8,15 of a 28-day cycle. **Results:** We previously reported the primary endpoint disease free survival (DFS) at 18 mo. in the modified intention-to-treat (ITT)-population (defined as R0/R1 resected pts. that either started neoadjuvant (A) or adjuvant (B) CTX. The pre-defined DFS rate of 55% at 18 mo. was not reached in both arms (A: 32.2%, B: 41.4%). Here we present the final results of the secondary endpoints median overall survival (mOS), pN0-resection rate, perioperative morbidity/mortality and safety in the ITT-population. Most common grade ≥3 treatment emergent adverse events in the safety population were neutropenia (arm A 21.1%, arm B 12.3%), fatigue (arm A 8.8%, arm B 5.3%) and anemia (arm A 10.5%, arm B 1.8%). The most frequent post-/perioperative complications of all grades in pts. undergoing resection were infections (arm A: 24.4%, arm B: 8.8%), pancreatic fistulas (arm A: 14.6%; arm B: 13.3%) and bleedings (arm A: 9.7%; arm B: 6.7%). Perioperative mortality was 2.4% in the neoadjuvant and 6.7% in the upfront surgery setting. The median number of resected lymph nodes was comparable in both arms (A: n = 21, B: n = 26). The pN0-resection rate was 33.3% in the neoadjuvant/perioperative arm A and 29.5% in the upfront surgery arm B. R0 resection rates were 87.8% in arm A and 67.4% in arm B, respectively. Median OS as a key secondary endpoint in the ITT population was 25.2 mo. in arm A and 16.7 mo. for upfront surgery, a difference of 8.5 mo. This difference corresponds to a mDFS of 11.5 mo. in arm A and 5.9 mo. in arm B. 91.5% of pts. in arm A started and 84.7% completed neoadjuvant CTX but only 42.4% of pts. in arm B started adjuvant CTX. **Conclusions:** Perioperative treatment with Gem/nab-P was well tolerated and showed an encouraging mOS of 25.2 mo., this is well in the range of the data in SWOG 1505 (23.6 mo.) or PREOPANC (15.7 mo.). The corresponding mOS in the upfront surgery arm was 16.7 mo. The 8.5 mo. difference may be explained by the fact that many pts. in arm B did not receive adjuvant treatment whereas the vast majority of pts. in arm A completed at least preoperative CTX. Neoadjuvant/perioperative treatment is a promising novel option for pts. with resectable PDAC. The optimal treatment regimen is subject of current clinical trials. Clinical trial information: NCT02047513. Research Sponsor: Bristol Myers Squibb GmbH & Co. KGaA.

Resectable pancreatic adenocarcinoma neo-adjuvant FOLF(IRIN)OX-based chemotherapy: A multicenter, non-comparative, randomized, phase II trial (PANACHE01-PRODIGE48 study). *First Author: Lilian Schwarz, Rouen University Hospital, Rouen, France*

Background: Despite the limited number of published RCTs, patients with resectable pancreatic adenocarcinoma (rPAC; NCCN criteria) seem to benefit from neoadjuvant (NAT) with regards to R0 resection rate, downstaging and survivals (PREOPANC-1; Preop-02/JSAP-05; NEONAX, SWOG05-15). Few prospective results are currently available concerning the completion of the full therapeutic sequence and oncological results. **Methods:** In the PANACHE01-PRODIGE48 prospective multicenter controlled non-comparative Phase II trial, 153 patients with rPDAC were randomized 2:2:1 to 4 cycles of NAT chemotherapy (mFOLFIRINOX; Arm1 or FOLFOX; Arm2) or upfront surgery (Ctrl_Arm) in 28 French centers from 02/2017 to 07/2020. Primary objective was to evaluate the safety and efficacy of two regimens of NAT chemotherapy. The main co-primary endpoints were 1y-OS rate after randomization and the rate of patients undergoing the full therapeutic sequence. Event-free survival (EFS) was used to evaluate the time to recurrence between groups. An event being defined as progression before surgery, unresectable or metastatic disease at surgical exploration, recurrence after surgery or death. **Results:** Of the 153 randomized patients, 146 were available for analysis (Arm1,n=70; Arm2,n=50; Ctrl_arm,n=26). In the Arm1 and 2, completion of the 4 planed cycles was 88.6 and 84%, respectively, with a dose reduction in 52% and 24%. The cumulative rates of grade 3/4/5 toxicity were 56.7 and 57.4%, respectively. The resection rates (RR) were 74, 68 and 81% respectively in Arm1, Arm2 and Ctrl_Arm. Respectively, 88.4, 91 and 85.7% of patients started adjuvant chemo. 1y-OS rates were respectively of 84.1, 71.8 and 80.8% in Arm1, Arm2 and Ctrl_Arm with a median follow-up in each group of 25.6, 33, 30.9 months. Following the intermediate analysis, the Arm2 was stopped for lack of efficacy (rejection of the H0 hypothesis for 1yOS). 1y-Event free survival (EFS) rates were 51.4% in Arm1, 43.1% in Arm2 and 41.7% in Ctrl_Arm, with corresponding median EFS of 12.4, 11 and 9.2 months. **Conclusions:** The feasibility and efficacy of the mFOLFIRINOX neoadjuvant chemotherapy is confirmed regarding completion of therapeutic sequence and oncological outcomes. These results confirm the rationale for ongoing clinical trials, PREOPANC3 and Alliance AO21806. Clinical trial information: NCT02959879. Research Sponsor: Programme for Hospital Clinical Research in Cancer - FRANCE.

Socioeconomic factors associated with a late-stage pancreatic cancer diagnosis: An analysis of the national cancer database. *First Author: Jillian Gallegos, Creighton University School of Medicine, Omaha, NE*

Background: Pancreatic cancer is an aggressive, lethal cancer that is the 4th leading cause of cancer death in the United States. It is often asymptomatic until later stages, thus it is critical to assess the socioeconomic factors associated with diagnosis at early vs. late stages. Using the National Cancer Database, we aim to identify associations between socioeconomic factors of patients that present with early stage (0-I) pancreatic cancer in comparison to late-stage disease (stage IV) at diagnosis. **Methods:** In this study, 256,822 patients from the National Cancer Database who were diagnosed with NCDB Analytic Stage Group stage 0-I and stage IV pancreatic cancer were analyzed based on age, race, sex, ethnicity, insurance type, income, geographic location, education and Charlson-Deyo score. Demographic factors of patients that presented with early and late-stage disease were analyzed using chi square and multivariate analysis. All patients included in the study were diagnosed with pancreatic cancer between 2004 and 2018. **Results:** We identified significant (P <0.05) associations between race, sex, insurance status, education, income, and geographic location with diagnosis of advanced-stage disease. A greater percentage of males were diagnosed with late-stage cancer than early-stage (52.8% vs 47.9%). Females were more likely to have an earlier-stage diagnosis and were 15% less likely to have late-stage diagnosis than males (p < 0.001 and 95% CI = 0.839-0.875). African Americans were 10% more likely to have a late-stage diagnosis than Caucasians (p < 0.001 and 95% CI = 1.069-1.144). For insurance status, private and Medicaid insurance had higher percentages of late-stage diagnosis than early-stages, and all types of insurance had lower rates of late-stage diagnosis than patients without insurance (p < 0.001). Patients from a zip-code associated with < $38,000 median household income and zip-codes with lower levels of high school diplomas had higher rates of late-stage diagnosis (p < 0.025). **Conclusions:** Factors associated with increased likelihood of pancreatic cancer presentation at advanced stage compared to early stage include race, sex, insurance status, education, median income, comorbidity score, and geographic location. Research Sponsor: None.

Phase Ib study of anetumab ravtansive in combination with immunotherapy or immunotherapy plus chemotherapy in mesothelin-enriched advanced pancreatic adenocarcinoma: NCI10208. *First Author: Pavlina Spiliopoulou, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: Mesothelin (MSLN) is overexpressed in 80-85% of pancreatic adenocarcinomas (PDAC). Anetumab ravtansine (AR) is a fully human anti-MSLN immunoglobulin G1 antibody conjugated to the anti-tubulin maytansinoid DM4. Through NCI-ETCTN, the North American Star Consortium conducted a phase I study to evaluate the safety/tolerability of AR in various combinations in patients (pts) with PDAC. Here, we report preliminary results of the escalation part. **Methods:** Pts with advanced PDAC after at least one line of treatment were included. AR was combined with nivolumab (ARM1), nivolumab/ipilimumab (ARM 2), or nivolumab plus gemcitabine (Gem) (ARM3), using an integrated biomarker analysis. Two dose levels (DL) of AR were evaluated, DL1=5.5mg/kg and DL2=6.5mg/kg (established RP2D). Key eligibility criterion was MSLN expression in >5% of tumor cells by immunohistochemistry. Pts with prior anti-PD1/anti-CTLA4 treatment were excluded but treatment with prior Gem was allowed. Mandatory blood and paired tumor samples were collected for investigation of the immune microenvironment, genomic/transcriptomic changes and for an in-depth description of AR pharmacokinetics. **Results:** Data cut-off date was 22/01/2022. A total of n=33 pts were enrolled, n=11 (ARM 1), n=13 (ARM 2) and n=9 (ARM3). Median age of pts was 66 (40-83), 33% of PS=0 and 66% of PS=1. Twenty-six pts (79%) had previously been exposed to Gem. Median number of prior lines of treatment was 3 (1-7). Twenty-eight patients were evaluable for DLT. Grade (G)3/4 TRAEs: 0% in ARM1DL1, 5.3% in ARM1DL2, 0% in ARM2DL1, 16.9% in ARM2DL2, 8.6% in ARM3DL1 and 19.5% in ARM3DL2. There were 2 dose-limiting toxicities in ARM2DL2, one G3 upper gastrointestinal haemorrhage, possibly related to AR, and one G3 thrombocytopenia and G3 anaemia, definitely related to AR. Ocular toxicity events were G1/2 blurred vision in 5/33 (15%) and G1 xerophthalmia in 1/33 (3%), related to both AR and anti-PD1; G2 keratitis in 1/33 (3%), related to AR only. Only G1 peripheral neuropathy was observed in 4/33 (12%) pts. Efficacy data is presented in the table. In ARM3, the range of tumor measurement (TM) change was Δ_{TM}=–16.8% to +16.2% and 3/8 (36%) pts with SD had previously been exposed to Gem. **Conclusions:** Based on the observed disease control rate and acceptable toleratbility, ARM3 (both DL1 and DL2) will be tested in the expansion part. A further 20 patients will be recruited for dose confirmation and comprehensive biomarker evaluation. Pharmacokinetic/pharmacodynamic analysis is under way. Clinical trial information: NCT03816358. Research Sponsor: U.S. National Institutes of Health.

Mutational landscape of pancreatic adenocarcinoma identified by prospective clinical sequencing in a nationwide cancer network. *First Author: Katherine E Poruk, Cancer Treatment Centers of America, Part of City of Hope, Newnan, GA*

Background: Curative treatment of pancreatic adenocarcinoma (PDAC) remains a challenge. Improved understanding of the tumor biology is needed to adequately target therapies for individual patients. Tumor genomic profiling is a critical component of precision medicine for these patients to identify potential genomic alterations that can be targeted for therapy. We present a cohort of PDAC patients who underwent prospective comprehensive genomic profiling (CGP) in a national cancer network. **Methods:** Between 2013 and 2021, 731 patients with PDAC underwent CGP with hybrid capture of up to 406 cancer-related genes on tumor tissue for treatment decision-making. Clinically relevant genomic alterations (CRGA) were defined as associated with targeted therapies or mechanism-driven clinical trials. Patient demographics and outcomes were retrospectively reviewed with IRB approval. **Results:** Median patient age at presentation was 58 years (range, 26-87) and a slight majority were male (54%). Most patients presented with stage IV disease (n=457; 63%). Median overall survival (OS) was 26 months for stages I-III and 15 months for stage IV disease. A majority of patients were treated with first line chemotherapy, predominantly gemcitabine or FOLFIRINOX. Surgical resection was performed in 198 patients (27%). Genomic alterations (GA) were identified in 96% of PDAC patients. The most common GA were in *KRAS* (86%), *TP53* (75%), *CDKN2A* (49%), *SMAD4* (21%), *ARID1A* (7.8%), *RNF43* (5%), *BRCA2* (4%), *and BRCA1* (1%). A mutation in one of the four commonly mutated genes (*KRAS*, *TP53*, *CDKN2A*, or *SMAD4*) was identified in 92% (n=675). Common *KRAS* mutations were G12D(43%), G12V (30%), and G12R(16%). Median OS was significantly worse for patients with mutations in *KRAS*, *TP53* and *CDK2NA*, while wild type *RNF43* demonstrated improved OS (all, P<0.05). 206 patients (28%) had a CRGA based on the Know Your Tumor registry trial, including mutations in *BRCA1*, *BRCA2*, *BRAF*, *ATM*, *CHEK2*, and *ATK*. Tumor Mutational Burden (TMB) was known for 345 patients and included: 292 TMB-low (85%), 49 TMB-intermediate (14%), and 4 TMB-high (1%). PD-L1 status was obtained in 33 patients, with 18 PD-L1 positive (55%). MSI status was noted for 345 patients; only 5 patients (1%) were MSI-high. Of the 39 patients with a *BRCA1* or *BRCA2* mutation, 30 (77%) were treated with Olaparib. Other commonly utilized therapies included Niraparib (n=56), Regorafenib (n=8), Everolimus (n=35), Erlotinib (n=8), and Cetuximab (n=7). **Conclusions:** In a large series of PDAC patients assayed with CGP, GA were identified in 96% but only 28% had an actionable mutation. Access to the TAPUR trial allowed for an increase in the patients identified for targeted immunotherapy between 2013 and 2019, although overall use remained low for PDAC. Further research is needed to identify therapies based on the more commonly mutated genes given their association with overall survival. Research Sponsor: None.

A phase I/II study of LOAd703, a TMZ-CD40L/4-1BBL-armed oncolytic adenovirus, combined with nab-paclitaxel and gemcitabine in advanced pancreatic cancer. *First Author: Benjamin Leon Musher, Baylor College of Medicine, Houston, TX*

Background: Due to its low tumor immunogenicity and immunosuppressive microenvironment, pancreatic ductal adenocarcinoma (PDAC) remains an immunotherapeutic challenge. LOAd703, an oncolytic adenovirus with transgenes encoding TMZ-CD40L and 4-1BBL, has been shown to lyse tumor cells selectively, induce anti-tumor cytotoxic T-cell responses, reduce myeloid-derived suppressor cell (MDSC) infiltration, and induce tumor regression in preclinical studies. **Methods:** In this phase I/II trial, patients with unresectable or metastatic PDAC were treated with intratumoral injections of LOAd703 and standard intravenous nab-paclitaxel/gemcitabine (nPG) chemotherapy. Starting on cycle 1 day 15 of nPG, LOAd703 was injected with image guidance into the primary pancreatic tumor or a metastasis every 2 weeks for 6 injections. In the event of sustained tumor control, subjects were eligible to receive up to 6 more injections. Three dose levels of LOAd703 were investigated using a BOIN dose escalation design. Primary endpoints were safety and feasibility. **Results:** Of the 22 subjects enrolled, 21 received at least 1 LOAd703 injection, and 18 received at least 3 LOAd703 injections (the *a priori* definitions of evaluability for dose limiting toxicity [DLT] and efficacy, respectively). Of the 21 subjects injected, median age was 61, 81% had stage IV disease, and 57% had already received chemotherapy for advanced disease. Median CA 19-9 was 1494. Of the 18 response evaluable subjects, 3 were treated at dose level 1 (5x10e10 VP), 4 at dose level 2 (1x10e11 VP), and 11 at dose level 3 (5x10e11 VP). The most common adverse events (AEs) attributable to LOAd703 were fever, chills, nausea, and increased liver enzymes. AEs were short-lived and grade 1/2, except for a grade 3 transaminase elevation in one subject receiving dose level 3 (the only DLT). Objective response rate (ORR) among those treated at the highest dose level was 55% (5/11 subjects), thus meeting the predefined criterion for efficacy. Among all response evaluable patients, overall response rate (ORR) was 44%, and disease control rate (DCR) was 94%. CA 19-9 decreased by ≥50% in 61% of evaluable patients. Median overall survival (OS) among the 21 subjects receiving at least 1 LOAd703 injection was 8.7 months. The proportion of T effector memory cells increased after initiation of on-protocol treatment ($p = 0.0232$) while the proportion of T regulatory cells and myeloid-derived suppressor cells decreased ($p = 0.0410$, $p = 0.0256$, respectively). **Conclusions:** Combining intratumoral injections of LOAd703 with standard nPG chemotherapy was safe and feasible. The target response rate at the highest dose level was met, and treatment-emergent immune responses were observed. A follow-up clinical trial combining LOAd703, nPG, and the anti-PDL-1 inhibitor atezolizumab is underway. Clinical trial information: NCT02705196. Research Sponsor: LOKON Pharma AB, Swedish Cancer Society, Swedish Research Council.

4139 **Poster Session**

Evaluation of stage IV pancreatic adenocarcinomas based on mutational profiling of tumors. *First Author: Katherine E Poruk, Cancer Treatment Centers of America, Part of City of Hope, Newnan, GA*

Background: Curative treatment of pancreatic adenocarcinoma (PDAC) remains a challenge, as most patients present with advanced disease that has spread to other organs. The main opportunity for cure for these individuals remains systemic therapy. An improved understanding of the tumor biology is needed to appropriately target therapies for individual patients. We present cohort of Stage IV PDAC patients who underwent prospective comprehensive genomic profiling (CGP) in a national cancer network to evaluate genomic mutations, treatment patterns and survival. **Methods:** Between 2013 and 2021, 458 patients with Stage IV PDAC underwent CGP with hybrid capture of up to 406 cancer-related genes on tumor tissue for treatment decision-making. Clinically relevant genomic alterations (CRGA) were defined as associated with targeted therapies or mechanism-driven clinical trials. Patient demographics and outcomes were retrospectively reviewed with IRB approval. **Results:** Median patient age at presentation was 59 years (range, 26-84) and a majority were male (55%). Median overall survival was 15 months. Most patients were treated with first line chemotherapy, predominantly gemcitabine or FOLFIRINOX. GA were identified in 98% (n = 447) of PDAC patients. The most common genomic alterations were in *KRAS* (85%), *TP53* (75%), *CDKN2A* (52%), *SMAD4* (21%), *ARID1A* (9%), *BRCA2* (5%), *RNF43* (4%), *and BRCA1* (1%). A mutation in one of the four commonly mutated genes (*KRAS*, *TP53*, *CDKN2A*, or *SMAD4*) was identified in 94% (n = 426). Median overall survival was significantly worse for patients with mutations in *KRAS* or *TP53* (both, $P < 0.05$). 185 patients (40%) had an actionable mutation based on the Know Your Tumor registry trial, including mutations in *BRCA1*, *BRCA2*, *BRAF*, *CHEK2*, *ATM*, *ATK* and *STK11*. MSI status was noted for 226 patients; only one patient was MSI-high. Tumor Mutational Burden (TMB) was known for 228 patients and was split as follows: 199 TMB-low (87%), 27 TMB-intermediate (12%), and 2 TMB-high (1%). TMB status was not associated with OS ($P = 0.21$). PD-L1 status was obtained in 20 patients, with 9 PD-L1 positive (45%); this was not associated with OS ($P = 0.66$). Of the 38 patients with a *BRCA1* or *BRCA2* mutation, 31 (82%) were treated with Olaparib. Other commonly utilized therapies included Niraparib (n = 56), Regorafenib (n = 8), Everolimus (n = 34), Erlotinib (n = 8), and Cetuximab (n = 6). **Conclusions:** In a large series of Stage IV PDAC patients assayed with CGP, GA were identified in 98% of tumors but only 40% had an actionable mutation. Most patients continue to be treated with conventional chemotherapy despite a sizeable group with targetable mutations. Further work is needed to identify targeted therapies for the more common mutations in PDAC given their impact on overall survival. Research Sponsor: None.

4140 **Poster Session**

A study of relacorilant in combination with nab-paclitaxel in patients with metastatic pancreatic ductal adenocarcinoma. *First Author: Erkut Hasan Borazanci, HonorHealth, Scottsdale, AZ*

Background: Pancreatic cancer remains the third-leading cause of cancer-related death in the US. Average overall survival is only one year, and no standard therapies exist beyond second line. Chemotherapy resistance is one reason for the poor outcomes in pancreatic cancer, which can be caused by, among other factors, excess tumor expression of the glucocorticoid receptor (GR). Nonclinical and clinical data indicate that GR antagonism may enhance or restore chemotherapy sensitivity. Here, we report the interim analysis of RELIANT, a trial evaluating the efficacy and safety of relacorilant, a selective GR modulator, with nab-paclitaxel in patients with metastatic pancreatic ductal adenocarcinoma (mPDAC). **Methods:** RELIANT (NCT04329949) was a single-arm, open-label, multicenter study of relacorilant (100 mg QD) + nab-paclitaxel (80 mg/m^2 on days 1, 8, and 15 of each 28-day cycle) in patients with histologically confirmed mPDAC. Based on tolerability, relacorilant doses were escalated up to 150 mg. Patients with 2+ prior lines of therapy, including prior gemcitabine- and fluoropyrimidine-based therapy, were enrolled. Planned enrollment was 80 patients. The study included a planned interim analysis after approximately 40 patients had completed 12 weeks of treatment or discontinued study treatment due to disease progression or toxicity. Objective response rate (ORR) by blinded independent central review was the primary endpoint. At the interim analysis, ORR was assessed by the investigator. **Results:** At the interim analysis, 43 heavily pretreated patients with a median age of 64 years (range: 43–78; 56% male) had been enrolled. 27/43 (63%) patients had received ≥2 prior lines of therapy (range: 2–5), and all but 3 patients had received prior treatment with nab-paclitaxel. Twelve patients (28%) did not have a post-baseline radiographic tumor assessment and were hence not efficacy evaluable. Most common reasons for discontinuation from relacorilant were disease progression (n = 16), adverse event (AE, n = 8), and patient decision (n = 9). Relacorilant + nab-paclitaxel demonstrated antitumor activity with 15/43 (35%) patients showing decreases in target lesion size, 10/43 (23%) achieving disease control for at least 12 weeks, and 17/43 (40%) having decreases in CA 19-9. Of note, one patient has been on study treatment for > 15 months. No confirmed responses by RECIST (CR or PR) were observed, and enrollment was thus stopped after the interim analysis. No new safety signals were identified. The most common AEs were fatigue, nausea, and decreased appetite. Suppression of GR target genes was also observed. **Conclusions:** Modest antitumor activity of relacorilant + nab-paclitaxel was observed in this heavily pretreated patient population, with a safety profile similar to that observed for relacorilant in other oncology studies. Clinical trial information: NCT04329949. Research Sponsor: Corcept Therapeutics.

4141 **Poster Discussion Session**

Phase 1/2a trial of nadunolimab, a first-in-class fully humanized monoclonal antibody against IL1RAP, in combination with gemcitabine and nab-paclitaxel (GN) in patients with pancreatic adenocarcinoma (PDAC). *First Author: Eric Van Cutsem, University Hospitals Leuven, Leuven, Belgium*

Background: Interleukin-1 Receptor Accessory Protein (IL1RAP) is expressed on cancer and stromal cells in PDAC. The IL-1 pathway is active in the pancreatic tumor microenvironment and upregulated in response to chemotherapy. IL1RAP interacts with IL-1R1 and modulates downstream factors (e.g. IL-6, IL-8) and CRP level. Nadunolimab (CAN04), a fully humanized ADCC-enhanced IgG1 antibody, targets IL1RAP and blocks IL-1α and IL-1β signaling. Here, results are reported from the phase 1/2a clinical trial CANFOUR evaluating nadunolimab combined with GN in PDAC. **Methods:** Patients (pts) with previously untreated, unresectable, locally advanced or metastatic PDAC received nadunolimab at 1 (n=20) 2.5 (n=20), 5 (n=28) or 7.5 mg/kg (n=8) Q2W with standard GN. Primary objective was safety; secondary objectives included ORR, iPFS per iRECIST and OS, and exploratory objectives included effects on serum and tumor tissue biomarkers. **Results:** In total, 76 pts were enrolled: median age 63 years (43-89), 42% female, 93% stage IV, 45% PS=0, 9% received adjuvant chemotherapy. Treatment-related adverse events (AE) of grade≥3 were reported in 72% with neutropenia being most frequent. G-CSF prophylaxis was useful in managing neutropenic events. The 7.5 mg/kg dose was above MTD due to neutropenia. Infusion-related reactions were reported in 29% (grade 3 in 3%). Peripheral sensory neuropathy was rare (only two grade 2 events). Common treatment-related grade 3/4 AE are shown below. Seventy-three pts received combination therapy and were included in the efficacy analysis. Three pts did not receive chemotherapy due to consent withdrawal (n=2) or clinical deterioration (n=1). Median iPFS was 7.3 months (95% CI 5.6-8.9) with 15 pts still on treatment, median OS was 13.2 months (10.0-19.1) with 62% of pts alive and 1-year survival of 59% (42-72%). ORR was 33% (22-45), disease control rate 63% (51-74%) and duration of response 5.7 months (3.9-11.1). ORR was similar for all dose levels. Low baseline CRP was favorable for OS; reduction of serum IL-8 and CRP during Cycle 1 correlated with positive impact on OS. Also, neutrophil-lymphocyte ratio was reduced throughout the trial, driven by the reduction in circulating neutrophils. IL1RAP expression on cancer and stromal cells was confirmed in tumor biopsies. **Conclusions:** Nadunolimab combined with GN shows promising iPFS and OS and manageable safety in PDAC pts. A phase 2/3 trial of nadunolimab combined with chemotherapy in PDAC is planned and nadunolimab is also currently evaluated in additional combination trials with chemotherapy or IO. Clinical trial information: NCT03267316. Research Sponsor: Cantargia AB.

The tumor microenvironment and immune infiltration landscape of *KRAS* mutant pancreatic ductal adenocarcinomas (PDAC) compared to colorectal adenocarcinomas (CRC). *First Author: Emil Lou, Masonic Cancer Center/ University of Minnesota School of Medicine, Minneapolis, MN*

Background: The composition of the tumor microenvironment (TME) in PDACs is more heavily driven by mutant (mt) *KRAS* than any other cancer. How genomic alterations of PDAC including *KRAS* status affect the immune cell (IC) landscape remains unclear. Thus, we characterized IC types and the prevalence of immuno-oncologic (IO) biomarkers in PDAC by genomic and transcriptomic analysis, and investigated associations of mt *KRAS* with IC estimates in the TME. Our findings were compared to our previous study in CRC. **Methods:** A total of 4,142 PDAC and 3,727 CRC with *KRAS-mts* were analyzed using next-generation DNA sequencing (NextSeq, 592 gene panel or NovaSeq, WES), IHC, and whole transcriptome RNA sequencing (NovaSeq) (Caris Life Sciences, Phoenix, AZ). MSI/MMR was tested by FA, IHC and NGS. TMB-H was classified based on a cut-off of >10 mutations per MB. ICs were estimated by QuantiSeq (Finotello 2019, *Genome Medicine*) or MCP counter (Betcht 2016, *Genome Biology*). Significance was determined by X^2 and Fisher-Exact and p-adjusted for multiple comparisons (q<0.05). **Results:** Mutant *KRAS* was seen in 81% of PDAC and in 48% of CRC. The most common variant was *G12D*, comprising 43% and 32% of all PDAC and CRC *KRAS* variants, respectively. The therapeutically actionable *KRAS G12C* variant comprises 2% and 7% of PDAC and CRC in this cohort, respectively. In PDAC, *KRAS* mt was associated with lower prevalence of MSI-H/dMMR than *KRAS*-wildtype (wt); 0.9% vs 1.9%, p=0.027). PDL1 expression was significantly lower in *KRAS* wt (12%) compared to *G12D* (19%) and *G13X* (33%), similar to previous observations in CRC. However, when considering TMB, in PDAC, *G12D* (1%), *G12V* (1%) and *Q61* (1%) mutations had significantly lower TMB-H than *RAS* wt tumors (4%); in contradiction to CRC. The immune cell environment of *KRAS* mt PDAC showed significantly higher infiltration with M1 macrophages and cancer-associated fibroblasts (CAFs), as well as lower M2 macrophages, $CD4^+$ & $CD8^+$ T cells, T-reg, NK, myeloid dendritic and endothelial cells compared to *KRAS* wt. In CRC, a similar pattern was observed but more pronounced in PDAC. Immune-regulatory markers, were among multiple genes downregulated in *KRAS*-mt PDAC, including *CTLA-4* and *LAG3*. Overall changes were most pronounced in cases harboring *KRAS G12D*, *G12V*, *Q61*, and rare *KRAS* variants. **Conclusions:** The TME of *KRAS* mt PDAC shows IC patterns similar to *KRAS* mt CRC. Actionable IO-targets, such as PDL1, are enriched in tumors harboring specific variants of *KRAS* mt PDAC including the targetable *G12C* variant. If *G12D* becomes druggable, it could be targetable in 35% patients with PDAC or 15% in CRC. These results demonstrate that the TME of PDAC and CRC shows immune-cold features. Tailored immunotherapeutic strategies would have to overcome these barriers in *KRAS* mt PDAC and CRC, possibly in combination with molecularly targeted treatment strategies. Research Sponsor: Caris LLC.

Gut microbiota composition and outcomes following neoadjuvant therapy in patients with localized pancreatic cancer: A prospective biomarker study. *First Author: Pranav Murthy, Department of Surgery, University of Pittsburgh, Pittsburgh, PA*

Background: The prognostic role of the gut microbiome, which modulates cancer development and therapeutic response, is unknown in patients with pancreatic ductal adenocarcinoma (PDAC). With increasing utilization of neoadjuvant therapy (NAT) prior to pancreatic cancer surgery, identification of patient-specific biologic signatures associated with NAT response *a priori* could help inform PDAC precision medicine. Thus, we assessed the influence of the baseline gut microbiome on clinical outcomes in patients with PDAC receiving NAT. **Methods:** Stool samples were collected at diagnosis from 42 consenting patients with localized PDAC intending to undergo NAT and surgical resection between 2018 and 2020. 16S rRNA sequencing was completed on pre-NAT stool and resected tumor samples. Microbiota alpha diversity and log transformed taxonomic classifications were utilized in multiple regression analyses to predict oncologic outcomes. **Results:** Five patients progressed during NAT and eight of the 37 operated patients were deemed NAT responders, demonstrating pathologic near complete or partial response (CAP 0-2), T1N0 AJCC 8^{th} staging, and ≥ 80% CA 19-9 reduction. Compared to the gut, the tumor microbiota demonstrated remarkably reduced Shannon diversity (2.4±0.5 vs 1.5±0.4, $p< 0.0001$) and distinct taxa (75.2±19.7 vs 8.0±4.5, $p< 0.0001$) and, accordingly, was not associated with clinical outcomes. Overall, several taxa, including *Bacteroides* and *Akkermansia,* were enriched in the gut relative to the tumor ($p< 0.001$). The gut microbiota of NAT non-responders had an increased proportion of the gemcitabine metabolizing *Enterobacteriaceae* (additive log ratio (ALR) -3.4±2.0 vs -8.7±0.8, $p= 0.0004$). NAT responders, by contrast, had an increased proportion of the adaptive immune cell activating *Akkermansia* (ALR -0.9±1.2 vs -6.2±3.3, $p= 0.0004$). The incidence of jaundice or biliary stent placement was associated with relative increases in *Enterobacteriaceae* (+3.3 ALR, $p< 0.01$ and +4.9 ALR, $p< 0.0001$) and decreases in *Akkermansia* (-3.2 ALR, $p= 0.02$ and -2.4 ALR, $p= 0.057$), without altering total gut microbiota diversity. Age, sex, BMI, comorbidities, receipt of pre-NAT antibiotics, diagnostic EUS tumor size, resectability, and pre-NAT CA 19-9 were not predictive of NAT response or survival in a univariate regression model. However, inclusion of gut microbiota data improved the ability of the model to predict NAT response ($p= 0.016$, adjusted R^2 0.76) and survival ($p= 0.001$, adjusted R^2 0.89), with *Enterobacteriaceae* (FDR $p= 0.012$) and *Akkermansia* (FDR $p= 0.015$) being significant negative and positive predictors of NAT response, respectively. **Conclusions:** The baseline gut microbiota could be leveraged as a biomarker of NAT response and prognosis in patients with pancreatic cancer and warrants further investigation. Research Sponsor: University of Pittsburgh Institutional Funds.

A clinical study following phase I/IIa trial of STNM01 to investigate the overall survival and tumor microenvironment in patients with unresectable pancreatic cancer. *First Author: Takayoshi Tsuchiya, Department of Gastroenterology and Hepatology, Tokyo Medical University, Tokyo, Japan*

Background: Carbohydrate sulfotransferase 15 (CHST15) is a proteoglycan biosynthetic enzyme and responsible for tumor matrix remodeling. We reported last year the top-line clinical results of Phase I/IIa (PI/IIa) trial of STNM01, a synthetic RNA oligonucleotide to CHST15, as a second-line (2L) therapy in patients with progressive, unresectable pancreatic ductal adenocarcinoma (PDAC). Here we report the final PI/IIa results and follow-up clinical results investigating the changes of tumor microenvironmental parameters and the correlation with overall survival (OS). **Methods:** An additional clinical study was followed by PI/IIa trial (jRCT2031190055), which was a multicenter, open-label study of locoregional injections with STNM01 three times at 2 week-interval in 4 weeks as one cycle. A total of 3 cycles were repeated at maximum in combination with systemic 2L chemotherapy, oral fluoropyrimidine S-1 in the PI/IIa trial. The primary objective of this additional clinical study was OS. The secondary objectives were relations of tumor microenvironmental parameters evaluated by immunohistochemistry with OS. For comparison analyses, two-tailed unpaired t-test was performed. For correlation analyses, the Pearson coefficient analyses were performed. **Results:** A total of 22 patients were enrolled in the study. The average number of tumor-infiltrating $CD3^+$ (13.8/mm^2) and $CD8^+$ T cells (8.0/mm^2) at baseline in the evaluable population (n = 20) was at most one tenth or less, compared to historical data, indicating 2L population contained more T cell-immune suppressive patients. Baseline $CD3^+$ and $CD8^+$ T cells negatively correlated with tumoral CHST15 expression (p = 0.0051, p = 0.0478, respectively). As the final PI/IIa results, the median OS was 7.8 months with 6 and 12 months-survival rates of 68.2% and 31.8%, respectively. Disease control rate was 76.2% including 1 complete response. STNM01 led to a significant reduction in CHST15 at the end of cycle 1 compared to baseline (p = 0.0095, n = 19), and this was associated with increased $CD3^+$ (p = 0.0331) and $CD8^+$ T cells (p = 0.0146) and reduced $CD33^+$ myeloid-derived suppressor cells (MDSCs) (p = 0.0281) in the tumor. Patient subpopulation who survived over 1 year (n = 5) showed a significant fold increase of $CD3^+$ (p = 0.0033) and $CD8^+$ T cells (p = 0.0147) and decrease of $CD33^+$ MDSCs (p = 0.0403) at the end of cycle 1 compared to another subpopulation who survived less than 1 year (n = 13-14). Higher fold increase of $CD3^+$ T cells (p = 0.0035, n = 19) or fold decrease of $CD33^+$ MDSCs (p = 0.0212, n = 15) at the end of cycle 1 significantly correlated with longer OS. **Conclusions:** Locoregional injection of STNM01 was able to reactivate and augment tumor-infiltrating T cells while repress MDSCs. These changes in tumor immune cell profiles correlate with prolong prognosis in patients with first-line refractory, unresectable PDAC. Clinical trial information: jRCT2031190055. Research Sponsor: Japan Agency for Medical Research and Development.

Responses to immune checkpoint inhibition among MSI-H pancreatic ductal adenocarcinoma: A multi-institutional case series. *First Author: Tucker Coston, Jacksonville, FL*

Background: Pancreatic ductal adenocarcinoma (PDAC) is the 4th leading cause of cancer death. Outcomes remain poor, due to irresectability at diagnosis for many and sub-optimal responses to systemic therapy. Cytotoxic chemotherapy remains the standard of care. High microsatellite instability (MSI-H) predicts response to immune checkpoint inhibition (ICI) in many cancers. Detecting high MSI is rare in PDAC (incidence <2%), but case reports demonstrate potential therapeutic benefit with ICI. Here, we present multi-institutional data to characterize the clinical behavior of MSI-H PDAC, with special attention to response to ICI. **Methods:** Cases of MSI-H PDAC were obtained by reviewing data of all PDAC patients from our tertiary cancer center who had undergone genomic sequencing by one commercially available platform. The resulting cohort was supplemented with MSI-H PDAC cases identified by GI oncology specialists at multiple institutions. De-identified patient data were compiled and analyzed. **Results:** 15 MSI-H PDAC patients were identified. 20% had stage II disease at diagnosis, 27% stage III, and 53% stage IV. 73% of patients received ICI (n=11); 40% as 1st line and 33% as 2nd line. These patients demonstrated 100% overall response rate; 45% complete response (1 pathologic CR, 4 radiographic CR) and 55% partial response. No patient that received ICI had lost response or died after a median follow-up of 18 months (range 6-89 mos). 1 patient had oligoprogression of a single hepatic lesion after 7 mos that was then irradiated; this patient retained radiographic CR for 17 subsequent mos (ongoing). In this cohort, we observe poor responses to cytotoxic chemotherapy. In total, 12 regimens were trialed among 9 patients. Overall response rate was 0%. 42% achieved disease stability, with median duration of response of 2 mos; only 2 cases maintained disease stability for >5 mos. 4 patients did not receive ICI; all patients died, with a median survival of 7.5 mos. **Conclusions:** MSI-H PDAC represents a rare but important subtype of PDAC with unique clinical behavior. Given its rarity, large-scale analyses and trials are unlikely to be performed, making case series such as ours crucial. In our cohort, we observe impressive, durable responses to ICI, along with very poor responses to cytotoxic chemotherapy. Our data argues for consideration of ICI in any patient presenting with MSI-H PDAC, including in the first-line and neoadjuvant settings. Research Sponsor: None.

Phase I dose escalation and expansion study of defactinib, pembrolizumab, and gemcitabine in patients with advanced treatment-refractory pancreatic cancer. *First Author: Andrea Wang-Gillam, Washington University School of Medicine in St. Louis, St. Louis, MO*

Background: Targeting focal adhesion kinase (FAK) renders checkpoint immunotherapy effective in pancreatic ductal adenocarcinoma (PDAC) mouse models. Defactinib is a highly potent oral FAK inhibitor shown to have a tolerable safety profile. We evaluated the safety and recommended phase 2 dose (RP2D) of defactinib in combination with pembrolizumab and gemcitabine for PDAC patients. **Methods:** We conducted a multicenter, open-label, phase I study with dose escalation and expansion phases. In 3x3 dose escalation, patients with refractory solid tumors were treated at five escalating dose levels of defactinib and gemcitabine to identify a RP2D. In expansion phase, patients with metastatic PDAC who progressed on frontline treatment (refractory cohort) or had treatment response or stable disease (SD) on standard gemcitabine/nab-paclitaxel (maintenance cohort) were treated at RP2D. Pre- and post-treatment tumor biopsies were performed to evaluate changes in tumor immunity. **Results:** The triple drug combination was well-tolerated with no dose-limiting toxicities. Among 17 treated patients with refractory PDAC, the disease control rate (DCR) was 58.8% with one partial response (PR) and nine SDs and the median progression-free survival (PFS) and overall survival (OS) were 4.2 months and 9.1 months, respectively. Among the evaluable patients in the maintenance cohort, DCR was 63.6% with one PR and six SD. Three patients with SD came off study due to treatment- or disease-related complications. The median PFS and OS were 5.0 months and 8.3 months, respectively. **Conclusions:** The combination of defactinib, pembrolizumab, and gemcitabine was well-tolerated, had promising preliminary efficacy, and showed increased infiltrative T lymphocytes in post-treatment tumor biopsies. Incorporation of a more potent chemotherapy backbone should be considered to achieve better clinical response in future trial design. Clinical trial information: NCT02546531. Research Sponsor: U.S. National Institutes of Health, Pharmaceutical/Biotech Company.

Phase 2 Quilt 88 trial of DAMP inducers combined with IL15 superagonist, N-803, and anti–PD-L1 NK cell therapy more than doubles historical overall survival in patients with third- to sixth-line advanced pancreatic cancer. *First Author: Tara Elisabeth Seery, Chan Soon Shiong Institute for Medicine, El Segundo, CA*

Background: Pancreatic cancer claimed 48,220 lives in the USA in 2021, with an expected median OS of 3 months after 2nd line. We hypothesize that effective response against pancreatic cancer requires a coordinated approach that orchestrates both the innate and adaptive immune system. We further hypothesize that by inducing DAMPs to expose tumor associated antigens and orchestrating the activation of the entire immune system, we could accomplish immunogenic cell death with durable responses in this disease, previously considered immune therapy resistant. We present results of a novel combination immunotherapy protocol, the NANT Cancer Vaccine: DAMP inducing metronomic low-dose chemoradiation, cytokine-induced NK and T cell activation via N-803 (an IL-15 cytokine fusion protein), and overcoming immune evasion with off-the-shelf PDL1-targeted high-affinity NK cell (PDL1 t-haNK) cell therapy infusion. **Methods:** We report data on 65 patients with > 2 prior lines of therapy (cohort B+C: Quilt 88), with 30 patients at 3rd line, 35 patients ≥4th line. Patients were treated every 4 weeks with low dose DAMP inducing chemo modulating therapy including Nab-paclitaxel (100 mg/ m2 IV), Gemcitabine (600 mg/m2 IV), Aldoxorubicin HCl (150 mg/m2 IV), Cyclophosphamide (50 mg PO BID) and low-dose SBRT. This pre-conditioning therapy induces expression of tumor associated antigens including PDL1 and is followed by cytokine stimulus of endogenous NK and T cells and allogeneic off-the-shelf NK cells to initiate immunogenic cell death via the innate and adaptive system. N-803 is administered at 15 μg/kg SC and PDL-1 engineered off-the-shelf NK cells (PDL1-thaNK) are infused weekly, to induce immune memory. All treatment was conducted as outpatients. **Results:** Follow-up 7 days to 18 months. Median age 62, 95% ECOG 0-1. Well tolerated with mainly low grade AEs [fatigue, chills, injection site reaction (> 50%)]. Treatment related grade ≥3 mainly associated with chemotherapy without prophylactic growth factors: anemia 46%, neutropenia 23%, thrombocytopenia 12%, all others < 10%. Patients with at least 1 Treatment related SAE = 6%; edema, pyrexia, anemia, atrial flutter. No treatment related deaths. In all patients (3rd to 6th line, N = 65) median OS is 5.8 months with 40% still alive; median PFS 2.3 months (95% CI: 2.0, 3.6), 32% not having progressed to date. In 3rd line (N = 30), median OS is 6.3 months (95% CI: 5.0, 9.8). Updated data will be presented. **Conclusions:** Early safety and efficacy is seen in QUILT 88 of the novel immunotherapy combination of DAMP inducers, NK and T cell activation, and PDL1 t-haNK cell therapy in Pancreatic Cancer. OS in 3rd line (6.3 months) exceeds historical results of 3 months across 19 trials (Manax ASCO GI 2019) and compares favorably with the 6.1 months in 2nd line patients in NAPOLI-1. Clinical trial information: NCT04390399. Research Sponsor: ImmunityBio.

4148 **Poster Session**

A randomized, non-comparative, phase II study of maintenance OSE2101 vaccine alone or in combination with nivolumab (nivo) or FOLFIRI after induction with FOLFIRINOX in patients (Pts) with advanced pancreatic ductal adenocarcinoma (aPDAC): First interim results of the TEDOPAM GERCOR D17-01 PRODIGE 63 STUDY. *First Author: Marc Hilmi, Medical Oncology Department, Curie Institute, Saint-Cloud, France*

Background: OSE2101 is a multiple neoepitope vaccine restricted to HLA-A2 positive Pts. This study aimed to assess the efficacy and safety of OSE2101 ± anti-PD1 nivo as maintenance therapy in Pts with aPDAC after FOLFIRINOX induction chemotherapy. **Methods:** TEDOPaM-PRODIGE 63 was initially a 3-arm, open-label, randomized, non-comparative phase II study. Pts with aPDAC, HLA-A2 positive (blood) and no progression after 8 cycles of (modified) FOLFIRINOX were randomized 1:1:1 to receive FOLFIRI (standard Arm A), OSE2101 (subcutaneous injection on D1 Q3W x 6 doses then Q8W until M12 then Q12W up to M24, experimental Arm B) or OSE2101 + nivo (360 mg IV on D1 Q3W x 6 then 480 mg Q4W up to M24, experimental Arm C). FOLFIRI was reintroduced at disease progression in Arms B and C. Primary endpoint was overall survival (OS) rate at 12 months (M12) (Fleming two-stage design, H0: 25%; H1: 50%, one-sided alpha: 2.5%, power: 90%). 156 Pts were planned. **Results:** Following the occurrence of 2 tumor flares in Arm C, an Independent Data Monitoring Committee (IDMC) recommended to continue FOLFIRI as backbone in experimental Arm B and stop Arm C. Interim analysis results refer to 29 randomized Pts: 9/10/10 in Arm A/B/C, respectively. Median age was 63 years, 52% were men, 55% had ECOG PS 0, and 83% were metastatic. Best response to induction FOLFIRINOX was partial response in 48% and stable disease in 52%. With a median follow-up of 23 months, M12-OS rate was 44%, 40%, and 30% in Arm A, B and C. Other efficacy results are summarized in Table below. No OSE2101-related toxicity of grade ≥ 3 (G≥3) were observed in Arm B; 1 G3 cytokine-release syndrome (OSE2101-related) and 2 tumor flares (nivo-related) leading to death were observed in Arm C. **Conclusions:** Maintenance OSE2101 monotherapy showed a favorable safety profile and encouraging time to strategy failure warranting further evaluation. OSE2101 + nivo was associated with poorer outcomes leading to close Arm C. Following IDMC recommendation, the study is ongoing with the new design (maintenance FOLFIRI vs. FOLFIRI + OSE2101). Clinical trial information: NCT03806309. Research Sponsor: OSE Immunotherapeutics, GERCOR.

Comparison of systematic inflammatory prognostic scores in patients with advanced pancreatic adenocarcinoma. *First Author: Lucy Xiaolu Ma, Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada*

Background: Systemic inflammatory scores have been developed as tools to aid clinicians in prognostication and patient (pt) selection for clinical trials. We compared the accuracy of five prognostic scores to predict overall survival (OS) in pts with advanced pancreatic adenocarcinoma (PDAC). **Methods:** Pts with advanced PDAC enrolled on the COMPASS trial (NCT02750657) from 2015 to 2020 were included. All pts had biopsies for whole genome and RNA sequencing prior to standard first-line chemotherapy in the advanced setting. Prognostic risk was calculated using: neutrophil-to-lymphocyte ratio (NLR; >5 = high), platelet-to-lymphocyte ratio (PLR; > 150 = high), Prognostic Nutritional Index (PNI = albumin + 5 x lymphocytes. PNI < 45 = high risk), Gustave Roussy Immune Score (GRIm-S; NLR>6 = 1 point, albumin <35 = 1 point, LDH > upper limit of normal [ULN] = 1 point. GRIm-S ≥2 = high risk), and Memorial Sloan Kettering Prognostic Score (MPS; NLR >4 and albumin < 40 = high risk). OS was estimated using the Kaplan-Meier method and compared between risk groups (high vs. not-high) for each scoring system using the log-rank test. Cox proportional hazards models were used to analyze the association between each prognostic score and OS, adjusting for baseline clinical and genomic factors. **Results:** In total, 263 pts with advanced PDAC cancer were included, with median follow up of 32.9 (95% CI 15.9-64.2) months. Median OS in the intention to treat population was 9.3 months (95% CI 8-10.2). PLR and PNI were not prognostic. High risk NLR (N=85, 32%), GRIm-S (N=47, 18%) and MPS (N=46, 17%) identified pts with poor prognosis. The GRIm-S and MPS were most significant: median OS in high vs low risk pts 6.4 vs. 10 months p<0.001 (GRIm-S) and 6.3 vs. 10 months p=0.002 (MPS). On multivariable analyses, high risk NLR, GRIm-Score and MPS were each associated with poor OS after adjusting for baseline clinical and genomic factors (Table). For all models, ECOG ≥1 (N=165, 63%); the basal-like Moffitt RNA subtype (N=49, 20% vs 80% classical) and low HRDetect scores (N=31, 13%) were significantly associated with poor OS. However these scores did not associate with RNA based classifiers or HRD scores and can therefore provide additional prognostic information. **Conclusions:** Both the GRIm-S and MPS are highly prognostic in PDAC and are scores easily used in the clinical setting and may help in clinical trial selection. Genotypic correlates are being explored. Research Sponsor: Government of Ontario, Wallace McCain Centre for Pancreatic Cancer, Princess Margaret Cancer Foundation, Terry Fox Research Institute, Canadian Cancer Society Research Institute, Pancreatic Cancer Canada Foundation.

Multivariable analyses of association between high risk group and OS for each prognostic score.

Model	Adjusted HR[1]	p-value
NLR	1.39 (1.01,1.90)	0.04
PLR	0.89 (0.66,1.21)	0.46
PNI	0.96 (0.67,1.36)	0.80
GRIm-S	1.85 (1.23,2.77)	0.0029
MPS	1.53 (1.05,2.25)	0.028

Do we need postoperative chemotherapy after preoperative FOLFIRINOX in resected borderline or locally advanced pancreatic cancer? A retrospective analysis. *First Author: Roxane Mari, Medical Oncology Department, Institut Paoli-Calmettes, Marseille, France*

Background: Pancreatic ductal adenocarcinoma (PDAC) has poor outcome and surgical resection remains the only curative treatment. Post-operative (Post-Op) chemotherapy (CT) improves survival and FOLFIRINOX (FFX) regimen is the standard of care. Increasing number of patients with borderline resectable (BL) or locally advanced (LA) disease are treated with pre-operative (Pre-Op) CT with FFX. However, the benefit of Post-Op CT after Pre-Op FFX remains unclear. The aim of this study was to analyze the impact on survival of Post-Op CT in patients with resected BL or LA PDAC after Pre-Op FFX CT. **Methods:** 116 consecutive patients treated at the Institut Paoli-Calmettes comprehensive cancer center between 2014 and 2020 were retrospectively analyzed. All patients underwent pancreatectomy after Pre-Op FFX for a BL or LA PDAC. Patients who progressed or died within 3 months after surgery were excluded from the analysis. We compared median relapse-free survival (mRFS) and median overall survival (mOS) defined by time from surgery to relapse or death in patients who received or not Post-Op CT. **Results:** 116 patients (80% BL, 20% LA) were included: 82 received Post-Op CT (CT+) and 34 did not (CT-). The median number of Pre-Op FFX cycles was 4 in the CT+ group *vs* 6 in the CT- group. 24 (29.3%) patients received Post-Op FFX, 37 (45.1%) received Gemcitabine, 9 (11%) received Gemcitabine + Capecitabine, and 9 (11%) received a 5FU-based CT. Median time between surgery and first Post-Op CT cycle was 63 days. No difference in mRFS nor in mOS were found between CT+ and CT- groups: mRFS 15.0 vs 13.6 months, HR 1.1 [IC95% 0.69–1.77] and mOS 33.8 vs 36.1 months, HR 0.94 [IC95% 0.55–1.60]. Among patients with pathologic node positive disease (N+) (n = 79), mRFS was 13.9 months in the CT+ group vs 6.9 months in the CT- group (HR 0.68 [IC 0.35 – 1.19]), and mOS was 31.8 months in the CT+ group *vs* 16.5 months in the CT- group (HR 0.96 [IC95% 0.51-1.81]). Patients who received peri-operative (Peri-Op) FFX (n = 24) experienced longer mOS compared to patients who received Gemcitabine Post-Op CT: NR vs 33.8 months, HR 0.45 [IC95% 0.25-1.02]. Patients who received Peri-Op CT for a total of six months or more (n = 31) had increased mOS (55 vs 32 months, HR 0.61 [IC 95% 0.37- 1.11] and mRFS (16 vs 14 months HR 0.80, [IC95% 0.50 -1.31]) than patients receiving less than 6 months Peri-Op CT (n = 85) **Conclusions:** Post-Op CT does not clearly impact survival in BL or LA pancreatic cancer pretreated with Pre-Op FFX. We observed a trend in the N+ population for a survival benefit. Peri-Op FFX was associated with longer survival than Gemcitabine Post-Op regimen. Further randomized data are needed to assess the impact of Peri-Op FFX for these patients Research Sponsor: None.

Discrimination of mucinous pancreatic cysts using an enzymatic turnover assay to improve clinical diagnostic accuracy. *First Author: Daniel Sheik, Amplified Sciences, West Lafayette, IN*

Background: One impact of medical imaging technology has been an approximately 3-fold increase in the incidental detection of pancreatic cysts during routine clinical examinations. To reduce burden on the healthcare system and patients, clinicians desire accurate classification of pancreatic cysts into benign non-mucinous or potentially malignant, mucinous populations. Using EUS-FNA, fluid from these cysts can provide molecular biomarkers of predictive value. However, current in vitro diagnostics lack the desired sensitivity and specificity for clinicians to accurately stratify patients for risk of pre-malignant cancers. This situation can be improved by introducing new biomarkers and novel assay platforms. An enzymatic biomarker, pepsin C, has shown high accuracy for diagnosing mucinous cysts. The use of enzymatic activity assays is applicable to clinical workflows without disruption of current standards of care. **Methods:** A pepsin C activity assay using a magnetic bead-based platform was developed, with both fluorescent and surface-enhanced Raman spectroscopy (SERS) readouts. The assay platform utilizes selective peptide substrates, and a dimeric Rhodamine-6G-based dye, which allows ultrasensitive detection and significantly decreases the sample volume requirement for analysis, down to 1 μL of cyst fluid. The dye-labeled substrate is immobilized on magnetic beads and reacted with enzyme-containing samples to produce a quantitative assay signal that is standardized and expressed in true enzyme activity units. **Results:** While both readouts were quantitative and produced linear standard curves, SERS-based analysis was more robust against established biological matrix effects than fluorescence. Nevertheless, both assay modes successfully differentiated mucinous and non-mucinous cysts in a retrospective cohort of 69 cyst fluid samples. Compared with the standard of care CEA assay, this activity-based assay displays much improved sensitivity in diagnosing mucinous pancreatic cysts (Table). **Conclusions:** This pepsin c activity assay differentiates between mucinous and non-mucinous cysts better than the CEA assay and provides a quantifiable standardized readout. This work establishes a path to a true rule-out assay enabling clinicians to better stratify patients into low risk vs. potential malignancy thus impacting treatment and monitoring plans. Research Sponsor: Amplified Sciences.

Assay	Cutoff	Sensitivity	Specificity	AUC	NPV	PPV

Circulating tumor DNA profile in pancreatic ductal adenocarcinoma (PDAC) and potential targeted therapy. *First Author: Francis Esposito, Hospital Clinic de Barcelona, Barcelona, Spain*

Background: Despite huge efforts patients (pts) with advanced PDAC, still have a dismal long-term prognosis. The lack of available good-quality tissue samples for next generation sequencing (NGS) prevents from finding actionable alterations that could guide personalized treatments. Circulating tumor DNA (ctDNA) provides a non-invasive method for obtaining molecular information with therapeutic potential. Here, we present prospective data of ctDNA sequencing in pts with PDAC. **Methods:** We collected a single blood sample from advanced PDAC pts at any line of treatment (Tx) and at least 10 days apart from their last therapy. The samples were analyzed by Guardant360 plasma-based NGS, a standardized assay which covers microsatellite instability [MSI] evaluation and analysis of all four types of somatic alterations in 74 genes. Alterations were reported either as pathogenic or non-pathogenic. We classified each gene alteration according to the different OncoKB therapeutic levels of evidence [LE]. Additionally, we gathered the dates of both blood collection and molecular report. In case the molecular report showed no tumor-related alterations, it was interpreted as either absence of detectable mutations or low ctDNA levels, which would translate low disease burden or pts responding to therapy. Demographic and clinical data have been accessed from the medical records. **Results:** From 08/2019 to 09/2021 we collected blood samples from 94 PDAC pts. 56% of them were male and 53% were >65 years old. At the time of sample collection, nearly all pts were metastatic (98%). Regarding previous lines of Tx, 57% pts were Tx naïve; 10% were receiving active systemic Tx and 33% had experienced disease progression. Molecular reports were available in an average of 9.1 days. A total of 243 gene alterations were detected, having 94% of pts at least 1 genomic alteration, which was pathogenic in 69% of the cases (see Table). There were no pathogenic alterations ranked as OncoKB LE 1-2 (*MSI* or *NTRK*). Seventy alterations (30%) were ranked as OncoKB LE 3A and 4 (*ARID1A, BRAC2, CDKN2A, KRAS).* Three of these pts were treated with PARP inhibitors due to the presence of *BRCA2* mutations. No ctDNA was detected in 15 pts (16%), despite being the sample collected >10 days from receiving their last Tx. Of these, 11 had low tumor burden (only peritoneal or lung metastases) and 4 had documented response to the Tx by the time the samples were collected. **Conclusions:** Real-time and prospective genomic profiling of pts with advanced PDAC using ctDNA is feasible and conveniently fast, which would allow its role in identifying and developing therapeutic targets for approved Tx or clinical trial treatments. Research Sponsor: None.

Lymphocyte to monocyte ratio in metastatic pancreatic ductal adenocarcinoma as a prognostic factor and its potential role in identifying a subset of patients with a favorable response to therapy. *First Author: Andrea Pretta, Medical Oncology Unit, University Hospital and University of Cagliari, Cagliari, Italy*

Background: Despite the most recent therapeutic achievements, pancreatic ductal adenocarcinoma (PDAC) is characterized by poor prognosis and response to treatments. Among the most investigated prognostic biomarkers, the lymphocyte to monocyte ratio (LMr) is gaining increasing interest in literature, mostly in hematological malignancies, breast cancer, bladder cancer, non-small cell lung cancer, colorectal cancer, and resected pancreatic adenocarcinoma. In these settings, a higher LMr allows identifying a subset of patients with a better prognosis. Our study aimed to evaluate the role of the LMr as a prognostic factor in patients affected by metastatic PDAC and to find a cut-off value able to identify a subset of patients with better prognosis and possibly susceptible to other therapeutic options. **Methods:** Data from 228 patients were collected retrospectively from 2014 to 2021. 175 from the Department of Medical Oncology of the University Hospital of Cagliari and 53 from the Oncology Clinic - University Hospital of Ospedali Riuniti of Ancona. All patients had metastatic PDAC and blood samples were collected before starting first-line chemotherapy. The cut-off value for LMr was calculated according to the ROC curves at 6, 12, and 18 months. Kaplan-Meier curves were then obtained for the evaluation of survivals. Finally, multivariate analysis was performed, taking into consideration the following prognostic factors: sex, ECOG-PS, NL ratio, metastatic sites, Ca19.9 and LDH. **Results:** The median age was 68 y.o. (range 39-84 y.o.), 123 (54%) were males. Cut off value obtained for LMR, was 4. 156 (68,4%) patients had an LMr < 4 and 72 (31,6%) patients had an LMR ≥ 4. Patients with a ratio ≥ 4 showed a statistically significant difference in terms of median overall survival compared to patients with a ratio < 4 (23 months versus 11 months, $p < 0.0001$). First-line median progression-free survival was also different in patients with a value greater than or equal to 4 (11 months versus 6 months, $p = 0.005$), suggesting a better treatment response in the first group of patients. Finally, multivariate analysis showed that LMR ≥ 4 is an independent prognostic factor for OS ($p = 0.0005$). **Conclusions:** The results of our study show that the lymphocyte to monocyte ratio could be an important prognostic factor in patients with metastatic pancreatic ductal adenocarcinoma, although the limitations of a retrospective study should be considered. Furthermore, these findings suggest the active role of the immune response in limiting disease progression, indicating a group of patients who could benefit most from a target or combined immunotherapy treatment. Supportive care (SC) utilization for patients with locally advanced pancreatic cancer: Review of the National Cancer Data Base (2004-2018). *First Author: Christopher G Cann, Vanderbilt University Medical Center, Nashville, TN*

Background: Pancreatic cancer is a formidable malignancy, with an estimated 62,000 new cases in 2022 and approximately 50,000 deaths. Five-year overall survival remains low at 11%; 14.4% for locally advanced disease. Nearly one-third of newly diagnosed patients (pts) present with locally advanced pancreatic cancer (LAPC) and only a minority of pts (<25%) are eligible for surgical resection. Given the significant morbidity and mortality associated with LAPC, timely integration of SC into the treatment care plan is vital. **Methods:** Pts diagnosed with Stage II-III LAPC (2004-2018) recorded in the National Cancer Data Base were included, stratified by stage and use of SC (defined as procedures or therapy provided for palliative intent symptom control) from time of diagnosis throughout the disease trajectory. Analyses included tumor characteristics, demographics, and socioeconomic parameters. Multivariate logistic regressions were performed on three sets of data: Stage II, Stage III, and Stage II/III combined. **Results:** 158,340 pts were included in the cohort [stage II (70.6%); stage III (29.4%)]. Only a minority of pts (2.9%) received SC treatment despite > 65% of pts receiving care at an academic program; 95% living in or near a metro area, and nearly 60% living < 20 miles of their primary treatment center (p <0.001). Medicare (58%) and private insurance (32.8%) was consistent across both stages and SC use. The table depicts selected significant factors and the respective adjusted odds of receiving SC from the three logistic regressions. **Conclusions:** Our analysis demonstrates the underutilization of SC in LAPC population over the past decade and potential specific demographic/social areas of unmet need. Future work should focus on practice patterns across cancer centers and the significant impact SC has on both survival and quality of life outcomes for LAPC pts. SC should be an integral component incorporated early on in the care of pancreatic cancer regardless of stage. Research Sponsor: None.

Comparative analysis of the targetable landscape in *KRAS*-mutant and wild-type pancreatic adenocarcinoma. *First Author: Todd C Knepper, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Pancreatic adenocarcinoma (PC) is the fourth leading cause of cancer deaths, with increased incidence among patients (pts) younger than 50 years old (yo). Small cohort studies suggest early-onset PC (EOPC, diagnosis at < 50 yo) tumors may have a unique biology, harboring a higher proportion of *KRAS* wild-type status ($KRAS^{WT}$) and enrichment of targetable mutations/fusions compared to non-EOPC. In addition, therapy targeting oncogenic fusions in $KRAS^{WT}$ tumors has shown meaningful responses in PC pts. Here, we investigate the prevalence of fusions, mutations, and homologous recombination deficiency (HRD) in $KRAS^{WT}$ PC to identify potential targets for therapeutic intervention, and compare EOPC to non-EOPC to better characterize EOPC differences. **Methods:** De-identified records from 4,956 PC pts with tumor biopsies sequenced using the Tempus xT solid tumor assay (DNA-seq of 595-648 genes at 500x coverage; full transcriptome RNA-seq) were retrospectively reviewed. Fusions were detected from RNA-seq data via the Tempus bioinformatics pipeline. Mutations identified included germline and/or somatic single-nucleotide variants and insertions/deletions. HRD status was determined from RNA-seq data by the Tempus HRD test. Significance was determined as FDR-corrected p-values < 0.05. **Results:** Across the entire cohort, 21% tumors were $KRAS^{WT}$. HRD was more frequent in $KRAS^{WT}$ (7.9%) compared to $KRAS^{MUT}$ (3.1%) tumors (P< 0.001). Significant somatic mutational differences between the $KRAS^{WT}$ and $KRAS^{MUT}$ cohorts included *BRAF* (5.0% vs 0.2%), *CDKN2A* (5.4% vs 25%), *ARID1A* (3.6% vs 8.6%), *CTNNB1* (1.3% vs 0.3%), and *TSC2* (1.2% vs 0.1%) (all P< 0.001). Actionable rearrangements were enriched in the $KRAS^{WT}$cohort (10% vs 2.1%, P< 0.001); the most common fusion partners include *NRG1*, *MET*, *RAF1*, *BRAF*, *NTRK1-3*, *FGFR 1-4*, and *RET*. TMB-high (10 muts/Mb) and MSI-high were more common in $KRAS^{WT}$ (2.9% and 1.0%) compared to $KRAS^{MUT}$ (1.7% and 0.4%) tumors (P= 0.015). Additionally, 382 pts were classified as EOPC. $KRAS^{WT}$ tumors comprised 30% of EOPCs, 22% of the 50-70 yo cohort, and 17% of the > 70 yo cohort. Germline (pathogenic/likely pathogenic) alterations in *BRCA1* and *BRCA2* were more frequent in EOPCs (2.0% and 4.5%) compared to the 50-70 yo (0.4% and 1.7%) and > 70 yo (0.4% and 0.8%) cohorts (P= 0.015 and < 0.001, for *BRCA1* and *BRCA2* respectively). There were no statistical differences in actionable genes detected in EOPC vs non-EOPC. HRD was found at higher frequency in EOPC (5.4%) and decreased in age cohorts 50-70 yo (4.7%) and > 70 yo (2.5%) ($P = 0.047$). Rearrangements were more common in EOPC compared to non-EOPC (10% vs 1.1%, P< 0.001). **Conclusions:** HRD, TMB-H/MSI-H and oncogenic rearrangements are more prevalent in $KRAS^{WT}$ PC when compared with $KRAS^{MUT}$. These molecular analyses may provide additional therapeutic options for PC pts, warranting comprehensive genomic and transcriptomic profiling for this population. Research Sponsor: None.

Landscape of homologous recombination reversion mutations in pancreaticobiliary malignancies. *First Author: Brennan James Decker, Foundation Medicine, Cambridge, MA*

Background: Homologous recombination (HR) pathway reversion mutations (REV) are emerging treatment resistance biomarkers for platinum and PARP inhibitor therapy. The wide diversity of REV presents a diagnostic challenge. We implemented an automated computational approach to detect REV and examined the genomic features of REV-positive pancreaticobiliary cancers. **Methods:** Retrospective study of tissue (n = 31,124) and liquid biopsy (n = 3,870) samples from patients undergoing hybrid-capture comprehensive genomic profiling during routine clinical care 11/2012-03/2021. A proprietary algorithm tested samples for seven distinct REV mechanisms in *BRCA1*, *BRCA2*, or *PALB2*. For subjects with multiple samples, the earliest REV-positive sample was used for downstream analyses. **Results:** 5.3% (1,866/34,994) of biliary and pancreatic primary tumors harbored one or more pathogenic variants (PV) in *BRCA1* (1.4%, n = 499), *BRCA2* (3.2%, n = 1,119), or *PALB2* (0.81%, n = 282). Among patients with at least one PV in these genes, 2.4% (45/1,866) had REV. The majority of REV involved *BRCA2* (82%, 37/45), significantly higher than the proportion of *BRCA2* PV in the cohort overall (59%, 1,119/1,900; p = 0.022). The remainder of REV involved either *BRCA1* (8.9%, 4/45) or *PALB2* (8.9%, 4/45). A total of 63 REV pairs were identified. The most frequent REV mechanism was an exonic non-frameshift deletion completely encompassing a PV (36%, 23/63), followed by a frameshift restoring the reading frame of a pathogenic frameshift (23%, 15/63), a benign missense replacing a PV at the same codon (17%, 11/63), and deletion with intronic breakpoints causing loss of a PV (17%, 11/63). REV were approximately equally prevalent in liquid biopsy (2.8%, 5/178) and tissue samples (2.4% 40/1,688; p = 0.72). A range of 1-9 REV were found per sample (liquid biopsy = 1-9, tissue = 1-2), and liquid biopsy samples had a higher median REV per sample compared to tissue (2.0 vs. 1.0; p < 0.001), as well as a higher prevalence of multiple REV per sample (60% [3/5] vs 7.5% [3/40]; p = 0.013). These differences likely reflect stage of disease and sampling of multiple subclones. **Conclusions:** Although REV are uncommonly detected in pancreaticobiliary carcinomas, the presence of REV in *BRCA2*, *BRCA1*, and *PALB2* in patients with pancreaticobiliary neoplasms supports HR as a therapeutic target in these cancers. Diverse REV mechanisms highlight a need for robust detection to incorporate REV in identifying treatment resistance and guiding therapy selection. Research Sponsor: Foundation Medicine.

Neoadjuvant chemotherapy is associated with improved outcomes in patients with stage 1A and 1B pancreatic cancer undergoing surgery: An NCDB study. *First Author: Noah Rozich, Aurora St. Luke's Medical Center, Milwaukee, WI*

Background: The use of neoadjuvant chemotherapy (NAC) for pancreatic ductal adenocarcinoma (PDAC) has shown clear advantages in locally advanced and borderline resectable disease. The benefit in upfront resectable PDAC is debated. Moreover, in early clinical stages IA/IB, potential benefits including improved R0 resection rate, decreased tumor upstaging, and survival, are not clear. We hypothesize that NAC will be associated with improved outcomes and survival compared to adjuvant therapy in patients with clinical stage IA/IB PDAC. **Methods:** The National Cancer Database (NCDB) PUFs (2004-2017) were used to perform a retrospective review of patients with clinical stage IA or IB PDAC undergoing surgery. Treatment groups were selected based on timing of chemotherapy. Patients receiving chemotherapy or surgery alone were excluded. **Results:** We identified 6,613 patients with clinical stage IA or IB PDAC who underwent surgery. The neoadjuvant therapy group (NAT) included 1,533 patients who received neoadjuvant or perioperative chemotherapy, and the adjuvant therapy group (AT) contained 5080 patients who received chemotherapy after surgery. Patients in the NAT had higher rates of T1 and T2 disease and lower rates of T3 pathology compared to the AT (pT1: 18.7% vs 7.8%; pT2: 20.1 vs 18.6%; pT3: 59.3% vs 72.1%, p<0.0001). Additionally, the NAT had significantly higher rates of N0 disease and less N1 pathology (pN0: 54.6% vs 37.5%; pN1: 45.4% vs 62.5%, p<0.0001). The R0 resection rate was higher in the NAT (83.2% vs 62.3%, p=0.0197) and there was less lymphovascular invasion (LVI) compared to the AT (34.8% vs 48.1%, p<0.0001). Using Kaplan Meier estimates, the NAT was associated with improved overall survival (OS) compared to the AT (median OS: 33.4 vs 27.5 months, p<0.0001). On multivariable analysis, R0 resection (HR=0.715, CI: 0.619-0.825, p<0.0001), LVI (HR=1.126, 95% CI: 1.038-1.222, p=0.0043) but not receipt of NAC (HR=0.94, 95% CI: 0.852-1.038, p=0.2229) were independent risk factors for OS. **Conclusions:** NAC is beneficial in patients with stage IA/IB PDAC undergoing surgical resection as it is associated with improved oncologic outcomes including increased R0 resection rate, decreased tumor upstaging, lymph node metastasis, and LVI. Furthermore, patients receiving NAC were found to have improved survival over those getting adjuvant therapy. Based on these results, we recommend all patients diagnosed with PDAC be considered for NAC prior to surgery. Research Sponsor: None.

Phase 2 study of azacitidine (AZA) plus pembrolizumab (pembro) as second-line treatment in patients with advanced pancreatic ductal adenocarcinoma. *First Author: Rachael A Safyan, Columbia University Irving Medical Center, New York, NY*

Background: Pancreatic ductal adenocarcinoma (PDAC) is the third leading cause of cancer-related death with a 5-year survival rate of 10%. Novel strategies for advanced PDAC are a critical need. A DNA hypomethylating agent (HMA) increased tumor-infiltrating effector T cells and significantly prolonged survival in combination with immune checkpoint blockade (ICB) in a PDAC mouse model (Gonda et al 2020). We hypothesized that combining HMA with ICB will lead to therapeutic benefit in pts with advanced PDAC. **Methods:** This is an open-label, single-arm, single-center, Phase 2 trial of AZA plus pembro in pts with unresectable or metastatic PDAC. Pts were treated with AZA 50 mg/m2 subcutaneous daily for 5 days Q4W beginning week 1 day 1 followed by pembro 200 mg IV Q3W starting week 3 day 1. Key eligibility criteria included documented progression on or following first-line systemic treatment, ECOG PS 0-1, and adequate organ function. The primary objective was progression-free survival (PFS). Thirty-one evaluable pts were required to detect an improvement in PFS from 2 mo to 4 mo with a one-sided p-value of 0.05 and 80% power. Secondary endpoints included safety and tolerability, overall response rate (ORR), disease control rate (DCR), and overall survival (OS). Data cut-off was February 10, 2022. **Results:** Between Oct 2017 and Sept 2021, 36 pts were enrolled (median age 62.5, 75% white, 72% male). At data cutoff, 34 and 31 pts received at least 1 dose of AZA and pembro, respectively. Median PFS for ≥1 dose of AZA was 1.48 mo (95% CI: 1.35, 1.74) and for ≥1 dose of pembro was 1.51 mo (95% CI, 1.38, 3.42). The median OS was 4.67 months. Among the 34 pts, 3 (8.8%) experienced a partial response (PR) by RECIST with a DCR of 32.4%. Of the 3 pts with PR, 2 received 35 doses of pembro and continued beyond 2 years with an ongoing PR. One pt remains on pembro 20 months after study completion. None of the pts with a PR were microsatellite instability-high or tumor mutation burden high, and next-generation sequencing of the 3 cancers identified a BRCA1 variant and POLE variant. Treatment-related AEs (TRAEs) occurred in 20/34 pts (59%), the most common of which were diarrhea and fatigue. Grade ≥3 occurred in 7/34 (21%) including 1 immune-related grade 5 event (encephalitis). **Conclusions:** AZA plus pembro demonstrated a tolerable safety profile but no PFS benefit compared to historical controls. Our data suggests combined epigenetic therapy and ICB may expand therapeutic options in a subset of pts with PDAC. Further investigation is needed to identify biomarkers to predict response and elucidate effective timing, sequencing, and combination of epigenetic agents. Follow-up for OS is ongoing. Correlative analysis of epigenetic effects and characterization of the tumor immune microenvironment will be reported. Clinical trial information: NCT03264404. Research Sponsor: Merck & Co.

Evaluation of somatic and germline variants in patients with small bowel adenocarcinoma reveals clinically actionable targets. *First Author: Deng Wei, Department of General Surgery, Beijing Friendship Hospital, Capital Medical University, Beijing, China*

Background: Small bowel adenocarcinoma (SBA) is a rare gastrointestinal cancer with a poor prognosis and limited treatment options. Because the treatments for colorectal cancer showed limited efficacy in SBA, the NCCN guide strongly encourages SBA patients to participate in clinical trials. In this study, we aimed to explore clinically actionable variants in a large cohort of patients with SBA to assist oncologists to select the matched trials for patients. **Methods:** To explore therapeutic targets in 84 Chinese SBA patients, a deep sequencing panel (OncoPanscan, Genetron health) was used to characterize somatic alterations including point mutations, indels, copy number alterations, gene fusions as well as pathogenic germline variants. **Results:** Recurrent somatic mutations included *TP53* (57%), *KRAS* (56%), *APC* (31%), *SMAD4* (21%), *MDM2* (13%), *CTNNB1* (12%), *KMT2C* (12%), *SOX9* (12%), *ARID2* (12%), *FAT3* (11%), *FBXW7* (10%), *SPTA1*(10%) and *PIK3CA* (10%). Of the entire cohort, we observed five activating *PIK3CA* mutations (R108H; G364R; E542K; E545K, n = 2) which may be sensitive to FDA-approved PIK3CA inhibitor alpelisib. Additionally, patients with loss-of-function mutation in *NF1* (n = 2), *STK11* (n = 1) and *PTEN* (n = 1) can be targeted with MEK inhibitor selumetinib and mTOR inhibitor everolimus, respectively. Except for one V600E mutation, all mutations in *BRAF* are either type 2 (L597R, n = 1) or type 3 (N581S, n = 1; D594N, n = 4) which were sensitive to MEK inhibitor trametinib. We also found four type 2 MAP2K1 activating mutations (K57E, K57N, and F53L) which can be targeted by trametinib. Furthermore, oncogenic *ERBB2/HER2* mutations were seen in 4 patients including S310F (n = 1), V842I (n = 2) and V777L (n = 1). We also found one patient harbored *ERBB2/HER2* high magnification amplification. These five patients were candidates for HER2-targeted therapy clinical trials. Interestingly, one IDH1 mutation (R132C) carrier in our cohort might benefit from ivosidenib. In addition, we observed targetable gene amplification of *MDM2* (n = 2) and *FGF3/4/19* (n = 2). There were two patients with *MLH1* loss-of-function germline mutations that may benefit from immunotherapy. Among 78 patients with available MSI status, three were designated as microsatellite instability. The median TMB of microsatellite stable patients was 2.82 mutations/Mb. Lastly, we observed five deleterious germline mutations, three for *SBDS*, one each for *APC* and *ERCC5*. Taken together, at least 33 (39%) patients in our cohort harbored actionable genetic alterations. **Conclusions:** Through comprehensive genomic characterization of Chinese SBA patients, we identified actionable variants of multiple signaling pathways in plenty. NGS profiling results can guide physicians to enroll a significant portion of SBA patients in genomically-matched clinical trials. Research Sponsor: None.

Patient-derived explant model of appendiceal cancer. *First Author: Madeleine Cornelia Strach, Faculty of Medicine and Health, The University of Sydney, Sydney, Australia*

Background: Appendiceal cancers (AC) are rare with 5-year survival of 15% for high grade (HG) adenocarcinomas and 75% for low grade (LG) mucinous neoplasms. There is limited literature on the AC tumour microenvironment (TME) in disease progression and drug resistance. *Ex vivo* cultures, such as patient derived explants (PDEs), have been used for other solid tumours to test anticancer agents, explore the TME, and are being developed as personalised models. The aim of our study was to develop a PDE model of AC, preserve the TME, study the biological profile of AC and test novel therapies. **Methods:** Fresh tissue was collected during cytoreductive surgery (CRS) from consenting patients with AC with peritoneal disease, Jul 2020-Mar 2021. Tissues from 10 patients were dissected and cultured as PDEs under varying conditions of tissue size, media, matrix support and duration (Table). Uncultured Day 0 tissues and PDEs were fixed in formalin prior to paraffin embedding (FFPE). Immunohistochemical staining was performed on sections of FFPE tissue to assess viability with antibodies against the tumour marker, Cytokeratin-20 (CK20), and cell death marker, cleaved caspase 3 (CC3). Tissue architecture was rated on a 4-point scale (MS, J-SS). Cancer cells were counted in 6 Day 0 samples and PDEs from 3 patients using QuPath v0.3.2. Apoptotic index (AI) was calculated as the proportion of cells positive for CC3 divided by the number of total CK20 positive cells. **Results:** The mean proportion of tumour and mucin in the tissues was 3% (0-60%) and 39% (0-95%) respectively. Day 0 samples were viable with mean AI of cancer cells 7% (0-4%). Tissue architecture was maintained, as compared to Day 0 control, for varying sizes of PDE and culture durations up to 4d. More small or medium-sized PDEs had improved architecture compared to large sized PDEs (Table). PDEs at 4d had poorer architecture compared to at 1-3d. There was improved architecture in PDEs using enriched media with support factors compared to base media, and in specimens with matrix support compared to none. The mean AI of PDE cancer cells was 21% (0-92%) and 51% of PDEs had no cancer cell death. **Conclusions:** This is the first study demonstrating that AC tissue is amenable to *ex vivo* culture as PDEs. The optimal PDE model was <10mm tissue placed on a gelatine sponge in enriched media for 1-3d. PDEs had preserved tissue architecture and viability compared to uncultured tissue. Protein expression was in keeping with the original tumour. We plan to use this model to test anticancer agents and explore the TME of AC. Research Sponsor: Philanthropic funding from Chris O'Brien Lifehouse, Sydney, Australia.

TPS4161 **Poster Session**

Phase 2 study of trastuzumab deruxtecan in the neoadjuvant treatment for patients with HER2-positive gastric and gastroesophageal junction adenocarcinoma (EPOC2003). *First Author: Daisuke Takahari, Department of Gastroenterology, The Cancer Institute Hospital of the Japanese Foundation for Cancer Research, Tokyo, Japan*

Background: Trastuzumab deruxtecan (T-DXd) is an antibody-drug conjugate consisting of an anti-HER2 antibody, a cleavable tetrapeptide-based linker, and a cytotoxic topoisomerase I inhibitor. DESTINY-Gastric01 study showed significantly higher objective response rate with T-DXd than physician's choice of chemotherapy (51.3%, vs. 14.3%, Shitara K, et al. NEJM 2020) as well as prolonged overall survival (median 12.5 vs. 8.4 months, hazard ratio 0.59). Considering that high response rate or major pathological response (MPR), which is defined as the proportion of subjects with < 10% residual tumor may be associated with favorable survival outcomes after preoperative chemotherapy, T-DXd could be a promising neoadjuvant treatment for patients with gastric and gastroesophageal junction (GEJ) cancer. However, to our knowledge, there is no currently ongoing study of T-DXd as a neoadjuvant setting for patients with gastric and GEJ cancers. **Methods:** This is an open-label, single-arm, multicenter, investigator initiated phase 2 trial to evaluate antitumor activity of T-DXd as the neoadjuvant treatment for patients with HER2 positive gastric and GEJ adenocarcinoma. Eligible patients should have previously untreated locally advanced gastric and GEJ adenocarcinoma with clinical stage of T2-4 and/or N+ without distant metastasis. The main cohort will enroll patients with HER2 overexpression defined as immunohistochemistry (IHC) 3+ or IHC2+/ in situ hybridization (ISH) + by local assessment. According to the results of exploratory biomarker analysis of DESTINY-Gastric01 study (Shitara K, et al. ESMO-GI2021), patients with HER2-low expression (IHC1+ or 2+ with ISH negative) with HER2-extra cellular domein (ECD) higher than 11.6 ng/ml also will be enrolled into the exploratory cohort. Patients will receive 3 cycles of T-DXd (6.4mg/kg) by intravenous infusion every 3 weeks followed by surgery at 3 to 8 weeks after last T-DXd infusion.The primary endpoint is MPR rate. The threshold in the main cohort is defined as 20%, and the expected MPR rate was set at 45%. The minimum sample size of this trial is 23 patients in the main cohort (α- and β-error probabilities, 0.1 and 0.15, respectively). Total number of patients will be increased up to 27 patients depending on the enrollment. In addition, 10 patients will be recruited into the exploratory cohort. Secondary endpoints are pathologic complete response (pCR) rate, curative resection rate, and adverse event rate. Biomarker analyses including whole exome sequencing, RNA sequencing, proteomics, and ctDNA changes will also be conducted using pre- and post-treatment tumor and blood samples. Enrollment is ongoing at six sites in Japan from November 2021. Clinical trial information: NCT05034887. Research Sponsor: Daiichi-Sankyo.

TPS4162 **Poster Session**

EA2183: A phase III study of consolidative radiotherapy in patients with oligometastatic HER2-negative esophageal and gastric adenocarcinoma. *First Author: Nataliya Volodymyrivna Uboha, UW Carbone Cancer Center, Madison, WI*

Background: Advanced esophageal and gastric adenocarcinomas (EGA) have poor prognosis. Doublet chemotherapy with fluoropyrimidine and platinum agents in combination with nivolumab for PD-L1 positive tumors is now the standard first-line approach, but overall survival (OS) remains < 1.5 years. A subset of EGA patients have limited burden of metastatic disease. There is accumulating evidence that patients with oligometastatic states across disease types may benefit from locoregional ablative therapies during the course of their treatment. EA2183 is the first prospective study to evaluate the potential benefits of consolidative radiotherapy (XRT) in oligometastatic EGA. **Methods:** This is a prospective, randomized phase 3 study evaluating the role of consolidative XRT in oligometastatic EGA. Patients with ≤3 metastases at the time of diagnosis of advanced disease are eligible for enrollment. After completion of 4 months of systemic therapy, patients whose disease has not progressed are randomized to consolidation with XRT to all sites of disease followed by continuation of systemic therapy or continuation of systemic therapy alone. Patients are able to enroll in the study at the time of diagnosis of advanced disease or after completion of induction therapy. Systemic therapy is left to the discretion of the treating physician and can include FOLFOX (5-fluorouracil, leucovorin, and oxaliplatin) or CAPOX (capecitabine, oxaliplatin) in combination with nivolumab. Unless there are contraindications to immunotherapy or a history of prior treatment with immune checkpoint inhibitors, nivolumab use is mandatory if tumor has PD-L1 combined positive score (CPS) ≥5. The goal of radiation is to consolidate gains made by chemotherapy by delivering the highest dose that maintains the greatest tumor control probability that is also safe to deliver given the anatomic and normal tissue constraints. Specific radiation dose and fractionation are recommended in the protocol but is left to the discretion of the treating radiation oncologist to choose the course that is most suitable. Radiation must be administered over a maximum of 15 treatment days to minimize systemic therapy treatment breaks. Primary endpoint is OS from the time of randomization. Secondary endpoints include progression free survival from the time of randomization and safety and tolerability of consolidative XRT. We hypothesize that consolidative XRT will prolong OS from 10 to 15.6 months (an increase in median OS of 55.6%). The study is planning to enroll 314 patients with the goal of randomizing 204 patients in a 2:1 fashion. Stratification factors include number of metastatic sites, choice of immunotherapy with relation to PD-L1 CPS, as well as time of registration to the protocol (before or after systemic therapy initiation). Enrollment to the study is ongoing. Clinical trial information: NCT04248452. Research Sponsor: U.S. National Institutes of Health.

TPS4163 **Poster Session**

Anti-PD1, capecitabine, and oxaliplatin for the first-line treatment of dMMR esophagogastric cancer (AuspiCiOus-dMMR): A proof-of-principle study (AuspiCiOus). *First Author: Joris Bos, Amsterdam UMC, University of Amsterdam, Department of Medical Oncology, Cancer Center Amsterdam, Amsterdam, Netherlands*

Background: Doublet cytotoxic treatment demonstrates survival benefit over single drug therapies in patients with advanced esophagogastric cancer (EGC). Previous clinical data suggests an improved survival outcome in patients with microsatellite instability (MSI) treated with PD-1 inhibitor monotherapy or in combination with chemotherapy in first line palliative treatment. The positive effect of immunotherapy was only seen after a couple of months of treatment. This suggests that the patient might benefit from a short course of chemotherapy at the start of treatment. However, reports on the effects of cytotoxic treatment in MSI-high tumors range from beneficial to detrimental. Thus, the value of cytotoxic treatment, as well as the effect on the tumor immune microenvironment (TME) in MSI-high tumors is unclear. Therefore, in AuspiCious-dMMR we will study the effect of sequential treatment in patients with mismatch repair deficient (dMMR) EGC on the tumor immune microenvironment and, more specifically, the impact on the infiltration of cytotoxic T cells, before and after a short course of chemotherapy, and during treatment with PD-1 inhibition. **Methods:** AuspiCiOus is a multi-center, open-label, single arm (phase 2) study in patients with dMMR irresectable or metastatic EGC adenocarcinoma (NCT05177133). Patients are treated with Capecitabine and Oxaliplatin for two 3-weekly cycles, after which treatment is continued with retifanlimab (PD-1 inhibitor) for 4-weekly cycles up to progression or unacceptable toxicity, with a maximum of two years. Before treatment, after chemotherapy and after two cycles of immunotherapy fresh tumor biopsies are collected to study the primary outcome (T cell infiltration and the interferon-γ signature) as well as for translational research purposes (flow cytometry, nanostring profiling, (multicolor) immunohistochemistry and organoid culturing). Blood is collected at the same time points and on day 3 after the first course of immunotherapy for isolation of peripheral blood mononuclear cell, and determination of cytokine/chemokine profile, circulating stromal markers, and circulating tumor DNA. Also, fecal samples are collected to determine changes in the intestinal microbiome and patient reported outcome measures are used to determine quality of life. (s)AEs are assessed according to CTCAE v5 and tumor response is determined according to (i)RECIST 1.1. Key eligibility criteria are 1) histological confirmed diagnosis of untreated metastatic or irresectable HER2- adenocarcinoma of stomach or junction and 2) dMMR determination by IHC. Study is open for inclusion and three of planned 25 patients have been enrolled. Clinical trial information: NCT05177133. Research Sponsor: Incyte.

TPS4164 **Poster Session**

Trial in progress: Phase 3 study of bemarituzumab + mFOLFOX6 versus placebo + mFOLFOX6 in previously untreated advanced gastric or gastroesophageal junction (GEJ) cancer with FGFR2b overexpression (FORTITUDE-101). *First Author: Elizabeth Catherine Smyth, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom*

Background: Fibroblast growth factor receptor 2b (FGFR2b) is overexpressed in approximately 30% of non-human epidermal growth factor receptor 2 (non-HER2) positive gastric cancer (Wainberg, 2021). Bemarituzumab is a first-in-class monoclonal antibody that specifically blocks FGFR2b, inhibiting downstream tumor proliferation and enhancing antibody-dependent cellular cytotoxicity (Catenacci, 2020; Xiang, 2021). In the phase 2 FIGHT study (Wainberg, 2021; Catenacci, 2021), bemarituzumab + mFOLFOX6 improved progression-free survival (PFS; HR, 0.68; 95% CI, 0.44–1.04; p = 0.07) and led to a 5.7 month longer median overall survival (OS; 19.2 months vs 13.5 months; HR, 0.60; 95% CI, 0.38-0.94) compared with placebo + mFOLFOX6. **Methods:** FORTITUDE-101 (NCT05052801) is a double-blind, placebo-controlled phase 3 study in patients with untreated, unresectable locally advanced or metastatic gastric or GEJ adenocarcinoma not amenable to curative therapy. Approximately 516 patients aged ≥18 years with IHC-confirmed FGFR2b overexpression by central testing will be enrolled and randomized 1:1 to bemarituzumab + mFOLFOX6 or placebo + mFOLFOX6. Additional key eligibility criteria include Eastern Cooperative Oncology Group performance status 0-1, evaluable disease per RECIST v1.1, adequate hematologic and organ function, and no contraindication to receive mFOLFOX6 chemotherapy. Key exclusion criteria include prior treatment for metastatic or unresectable disease except one dose of mFOLFOX6 during screening, positive HER2 status, untreated or symptomatic CNS metastasis and leptomeningeal disease, history or evidence of ongoing ophthalmologic abnormalities, and prior treatment with any FGF-FGFR pathway inhibitor. Patients randomized to bemarituzumab will receive 15 mg/kg every 2 weeks (Q2W) with an additional 7.5 mg/kg dose on cycle 1 day 8. mFOLFOX6 will be administered at a fixed dose Q2W. Patients will receive treatment until disease progression, unacceptable toxicity, withdrawal of consent, or death. The primary endpoint is OS; secondary endpoints include PFS, objective response (defined as best overall response of complete or partial response), and treatment-emergent adverse events. Tumor responses and PFS will be assessed locally per RECIST v1.1. The concurrent phase 1b/3 FORTITUDE-102 study (NCT05111626) will evaluate the efficacy and safety of bemarituzumab + mFOLFOX6 + nivolumab versus placebo + mFOLFOX6 + nivolumab. Clinical trial information: NCT05052801. Research Sponsor: Amgen Inc.

TPS4165 **Poster Session**

Trial in progress: Phase 1b/3 study of bemarituzumab + mFOLFOX6 + nivolumab versus mFOLFOX6 + nivolumab in previously untreated advanced gastric and gastroesophageal junction (GEJ) cancer with FGFR2b overexpression (FORTITUDE-102). *First Author: Zev A. Wainberg, UCLA School of Medicine, Los Angeles, CA*

Background: Fibroblast growth factor receptor 2b (FGFR2b) is overexpressed in approximately 30% of non-human epidermal growth factor receptor 2 (non-HER2) positive gastric cancer (Wainberg, 2021). Bemarituzumab is a first-in-class monoclonal antibody that specifically blocks FGFR2b, inhibiting downstream tumor proliferation and enhancing antibody dependent cellular cytotoxicity (Catenacci, 2020; Xiang, 2021). In the phase 2 FIGHT study (Wainberg, 2021; Catenacci, 2021), progression-free survival (PFS) was improved (HR, 0.68; 95% CI, 0.44-1.04; p = 0.07) and a 5.7 month longer median overall survival (OS) was observed (19.2 months vs 13.5 months; HR, 0.60; 95% CI, 0.38-0.94) with bemarituzumab + mFOLFOX6 vs placebo + mFOLFOX6. Preclinical studies indicate that bemarituzumab modulates the tumor microenvironment to sensitize tumors to anti-PD1 monoclonal antibodies (Powers, 2016; Xiang, 2021) providing rationale for combination with nivolumab. **Methods:** FORTITUDE-102 (NCT05111626) is a phase 1b/3 study in patients (pts) with unresectable locally advanced or metastatic gastric or GEJ adenocarcinoma not amenable to curative therapy. Part 1 is an open-label safety lead-in; Part 2 is a double-blind, placebo-controlled study to evaluate efficacy and safety. Approximately 702 pts ≥18 years will be enrolled (Part 1, ~20; Part 2, ~682). Key eligibility criteria include Eastern Cooperative Oncology Group performance status 0-1, evaluable disease per RECIST v1.1, adequate hematologic and organ function, and no contraindication to receive mFOLFOX6 chemotherapy or nivolumab; for part 2, IHC-confirmed FGFR2b overexpression by central testing is required and no prior treatment for metastatic or unresectable disease allowed except 1 dose of mFOLFOX6 ± nivolumab. Key exclusion criteria include positive HER2 status and untreated or symptomatic CNS metastasis and leptomeningeal disease. Pts on bemarituzumab will receive 15 mg/kg every 2 weeks (Q2W) with an additional 7.5 mg/kg dose on cycle 1 day 8. mFOLFOX6 + nivolumab will be at a fixed dose Q2W. The dose-limiting toxicity (DLT) period is 28 days; observed safety data will influence additional enrollment to Part 1, de-escalation of bemarituzumab, or the recommended phase 3 dose (RP3D). For Part 1, primary endpoints are DLTs and adverse events; secondary endpoints include OS, PFS, and objective response (OR). For Part 2, pts will be randomized 1:1 to mFOLFOX6 + nivolumab Q2W plus either bemarituzumab at RP3D or placebo. Primary endpoint for Part 2 is OS; secondary endpoints include PFS, OR, and safety. The concurrent phase 3 FORTITUDE-101 study (NCT05052801) will evaluate bemarituzumab + mFOLFOX6 vs placebo + mFOLFOX6. Clinical trial information: NCT05111626. Research Sponsor: Amgen Inc.

TPS4166 **Poster Session**

Blood-borne assessment of stromal activation in esophageal adenocarcinoma to guide tocilizumab therapy: A randomized phase II proof-of-concept study (NCT04554771). *First Author: Benthe Doeve, Department of Medical Oncology, Amsterdam UMC, location VUMC, Cancer Center Amsterdam, Oncode Institute, Amsterdam, Netherlands*

Background: The tumor stroma is increasingly acknowledged to harbor tumor-promoting properties. Recently, we found that stroma activity measured by serum ADAM12 predicts response to chemoradiation in esophageal adenocarcinoma (Veenstra et al., Oncogenesis, 2018). Preclinically, the esophageal adenocarcinoma stroma was found to produce interleukin 6, which causes epithelial-to-mesenchymal transition of tumor cells. These mesenchymal tumor cells have a poor response to chemoradiation (Ebbing et al., PNAS, 2019). Therefore, stroma-derived interleukin 6 provides a potential new target to improve the treatment of esophageal adenocarcinoma. Tocilizumab is an interleukin 6 receptor inhibitor clinically used in rheumatoid arthritis and cytokine-release syndrome. In this phase II proof-of-concept clinical trial, we aim to demonstrate that stroma-targeting by tocilizumab in esophageal adenocarcinoma patients with highly activated stroma increases efficacy of chemoradiation measured by pathological response according to the Mandard criteria. **Methods:** BASALT is a multi-center, randomized, open-label phase II proof-of-concept clinical trial in patients with surgically resectable adenocarcinoma of the esophagus or gastroesophageal junction (NCT04554771). To assess efficacy of tocilizumab in addition to chemoradiation, 48 patients will be grouped for serum ADAM12 level with a cutoff of 203 pg/mL. Patients are then randomized in a 1:1:1:1 ratio to receive three cycles of tocilizumab every two weeks in addition to paclitaxel, carboplatin and radiation (Table). The sample size is based on the rule-of thumb estimate of 12 patients per arm. Tocilizumab will be given intravenously at a dose of 8 mg/kg with a maximum of 800 mg per dose. Efficacy will be assessed by pathological response to chemoradiation according to the Mandard criteria. Secondary endpoints are overall and progression free survival, safety and toxicity, feasibility and efficacy of interleukin 6 inhibition with serum interleukin 6 levels, immunohistochemistry and RNA-sequencing. Currently, 28 out of the 48 planned patients have been enrolled. Clinical trial information: NCT04554771. Research Sponsor: Oncode Institute.

TPS4167 **Poster Session**

First-line lenvatinib plus pembrolizumab plus chemotherapy in esophageal squamous cell carcinoma: LEAP-014 trial in progress. *First Author: Jong-Mu Sun, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea*

Background: Recent data from the KEYNOTE-590 study demonstrated the superiority of pembrolizumab plus chemotherapy compared with chemotherapy as first-line treatment for unresectable locally advanced recurrent or metastatic adenocarcinoma or squamous cell carcinoma of the esophagus, or advanced/metastatic Siewert type 1 adenocarcinoma of the gastroesophageal junction. Prior data also suggest promising antitumor activity of lenvatinib plus pembrolizumab in advanced solid tumors. LEAP-014 (NCT04949256) is a randomized, 2-part, open-label, phase 3 study that will evaluate the efficacy and safety of first-line lenvatinib plus pembrolizumab plus chemotherapy versus pembrolizumab plus chemotherapy in patients with metastatic esophageal squamous cell carcinoma (ESCC). **Methods:** Key eligibility criteria include histologically or cytologically confirmed metastatic ESCC, measurable disease per Response Evaluation Criteria in Solid Tumors version 1.1 (RECIST v1.1), and Eastern Cooperative Oncology Group performance status 0 to 1. In part 1 (safety run-in), ~6 patients will be treated for induction with intravenous (IV) pembrolizumab 400 mg every 6 weeks (Q6W) for 2 cycles plus oral lenvatinib 8 mg daily (QD) plus IV 5-fluorouracil (FU; 4000 mg/m^2 on days 1-5) plus IV cisplatin (80 mg/m^2) (FP) for 4 cycles and treated for consolidation with pembrolizumab 400 mg Q6W for ≤16 doses plus lenvatinib 20 mg QD; patients will be closely monitored for 21 days after the first dose of study intervention for dose-limiting toxicities. In part 2 (main study), approximately 850 patients will be randomly assigned 1:1 to induction with pembrolizumab plus lenvatinib plus chemotherapy (FP or mFOLFOX6 [Q2W for 6 cycles {IV oxaliplatin 85 mg/m^2 plus bolus IV 5-FU 400 mg/m^2 plus continuous IV 5-FU 2400 mg/m^2 plus IV leucovorin 400 mg/m^2 or IV levoleucovorin 200 mg/m^2}]) followed by consolidation with pembrolizumab plus lenvatinib (arm 1) or pembrolizumab plus chemotherapy (FP or mFOLFOX6; arm 2). Randomization will be stratified by PD-L1 combined positive score (CPS; ≥10 vs < 10), region (East Asia vs North America and Western Europe vs rest of world), and chemotherapy backbone (FP vs mFOLFOX6). Treatment will continue until disease progression, unacceptable toxicity, or withdrawal of consent. Tumor imaging assessment will be performed Q6W for ≤1 year and Q9W thereafter. In part 1, the primary end point is safety and tolerability. In part 2, the dual primary end points are overall survival and progression-free survival (per RECIST v1.1 assessed by blinded independent central review [BICR]); secondary end points include objective response rate and duration of response (per RECIST v1.1 assessed by BICR) and safety and tolerability. Enrollment in this trial is ongoing. Clinical trial information: NCT04949256. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA and Eisai Inc., Woodcliff Lake, NJ, USA.

TPS4168 **Poster Session**

Phase I trial of CA-4948, an IRAK4 inhibitor, in combination with FOLFOX/PD-1 inhibitor +/- trastuzumab for untreated unresectable gastric and esophageal cancer. *First Author: Haeseong Park, Siteman Cancer Center, Washington University School of Medicine, St. Louis, MO*

Background: Activated NFκB has been linked to aggressive phenotype, poor survival outcomes and resistance to chemotherapy in multiple gastrointestinal cancers including gastroesophageal cancer (GEC). Preclinical studies established that: 1) Genotoxic stress incurred by chemotherapy induces TLR9, which signals through IRAK4 to drive pro-survival NFκB signaling; 2) The survival mechanism through IRAK4 is independent of cancer types and mutational profiles based on colorectal and pancreatic cancer models; and 3) IRAK4 inhibition reduces tumor desmoplasia and revitalizes intratumoral T cells, setting the stage for successful combination with immune checkpoint inhibitors in a highly aggressive autochthonous pancreatic cancer mouse model. These data combined provide a strong rationale to add CA-4948 to systemic therapy for multiple advanced gastrointestinal malignancies, where resistance to chemotherapy is inevitable and benefit of PD-1 inhibitors is limited to small population. CA-4948 is a novel, first-in-class reversible inhibitor of IRAK4. In a phase I trial, patients with relapsed/refractory hematologic malignancies tolerated CA-4948 monotherapy well with mild fatigue, neutropenia, and nausea as most common adverse events. Recommended phase 2 dose (RP2D) was determined as 300 mg orally twice daily. CA-4948 has not been tested in combination with cytotoxic chemotherapy or immune checkpoint inhibitors for solid tumors in clinic. We hypothesize that inhibition of IRAK4 with CA-4948 will potentiate the effect of immune checkpoint inhibitor while deepening the efficacy of cytotoxic chemotherapy in GEC. **Methods:** This is a phase I trial of CA-4948 in combination with FOLFOX/PD-1 inhibitor with or without trastuzumab for unresectable GEC. During Dose Escalation, we will investigate CA-4948 in combination with FOLFOX/nivolumab by BOIN algorithm evaluating 4 different dose levels. Starting dose of CA-4948 for Part A will be 200 mg twice daily. Once RP2D is determined, the study will proceed to Dose Expansion, including Cohorts A and B. Cohort A will enroll up to 12 patients with HER2 negative disease at the RP2D of CA-4948 determined at the Dose Escalation phase. Cohort B will investigate CA-4948 in combination with FOLFOX/pembrolizumab and trastuzumab. The initial 6 patients in Cohort B will be considered safety lead-in to confirm the safety and tolerability at the RP2D, followed by additional patients, up to 12 patients treated at the RP2D. The primary objective is to determine the safety and RP2D of CA-4948 in combination with FOLFOX/PD-1 inhibitor with or without trastuzumab. Secondary objectives are to determine the preliminary efficacy of the combination. Correlative studies to evaluate pharmacodynamic effects and to identify biomarkers associated with disease response are planned. Clinical trial information: NCT05187182. Research Sponsor: None.

TPS4169 **Poster Session**

Multicenter phase II study of abemaciclib and ramucirumab in metastatic esophageal/gastroesophageal junction carcinoma. *First Author: Ronan Joseph Kelly, Baylor University Medical Center, Dallas, TX*

Background: Cyclin dependent kinases (CDKs) are serine/threonine kinases that are responsible for phosphorylating the intracellular proteins that coordinate cell-cycle progression. The Cancer Genome Atlas (TCGA) molecular analysis of esophageal/gastroesophageal junction (E/GEJ) carcinomas has highlighted significant dysregulation of CDKN2A, the gene coding for the tumor suppressor p16, through deletion, mutation or epigenetic silencing in up to 76% of cases and the associated significant upregulation of the CDK4/6-Cyclin D-axis (The Cancer Genome Atlas Research Network. Integrated genomic characterization of oesophageal carcinoma. Nature 2017). Preclinical experiments demonstrated that single agent abemaciclib has potent antitumor efficacy both *in vitro* and *in vivo* in esophageal adenocarcinoma with direct pathway inhibition (Kosovec J et al. CDK4/6 dual inhibitor abemaciclib demonstrates compelling preclinical activity against esophageal adenocarcinoma: a novel therapeutic options for a deadly disease. Oncotarget 2017 Nov 1;8[59]). Significant activity was seen in the OE33 (p=0.048) and FLO1 (p=0.043) esophageal cancer cell lines while western blot revealed downregulation of Cyclin D, phospho-pRb, E2F1, and Cyclin A2 (Kosovec J et al, 2017). *In vivo* experiments, utilizing the Levrat model of end-to-side esophagojejunostomy performed on Sprague-Dawley rats demonstrated that 78.9% of animals given abemaciclib demonstrated >20% tumor volume decrease (placebo 0%). Post treatment comparison between placebo and abemaciclib of qRT-PCR gene expression demonstrated downregulation of pathway correlates, including CDK4 (p=0.023), CDK6 (p=0.068), E2F1 (p=0.005), Rb1 (p=0.067), Cyclin D (p=0.031), and Cyclin A (p=0.039) (Kosovec J et al, 2017). The JPBJ phase 1b study has previously demonstrated the safety of combining abemaciclib with ramucirumab in NSCLC. **Methods:** Subjects with previously treated metastatic esophageal or gastroesophageal junction adenocarcinomas are eligible for this study which is currently open and enrolling patients. Squamous cell and mixed histology with neuroendocrine features are excluded. A total of 30 patients will be enrolled across 3 sites at Baylor University Medical Center in Dallas, The Allegheny Health Network in Pittsburgh and at Johns Hopkins Hospital in Baltimore. The primary objective is to describe the safety profile of abemaciclib (150mg po bid) and ramucirumab (8mg/kg iv every 2 weeks) in this patient population as assessed according to Common Terminology Criteria for Adverse Events version 4.0. Secondary objectives are to assess response rate, progression free and overall survival. In addition, we will determine the rate of stable disease at 3 months post targeted therapy. Correlative studies investigating changes in the expression of selected serum/tissue genomic markers of interest will be performed. Clinical trial information: NCT04921904. Research Sponsor: Eli Lilly.

TPS4170 **Poster Session**

ACCRU-GI-2008: A phase II randomized study of atezolizumab (Atezo) plus a multi-kinase inhibitor (MKI) versus MKI alone in patients with unresectable advanced hepatocellular carcinoma (aHCC) who previously received atezolizumab plus bevacizumab (Bev). *First Author: Wen Wee Ma, Division of Medical Oncology, Mayo Clinic, Rochester, MN*

Background: IMbrave150 is the first study demonstrating the benefit of anti-PDL1 in the frontline treatment of aHCC, and established Atezo/Bev as a new 1st line standard for aHCC. There is currently limited evidence to guide subsequent therapy for aHCC patients progressing on Atezo/Bev. ACCRU-GI-2008 is designed to determine the benefit of continuing Atezo into 2nd line and the safety of Atezo plus a MKI in patients with aHCC who previously received Atezo/Bev. The study is being conducted across 12 centers in the United States (ClincalTrials.gov#: NCT05168163). **Methods:** This study utilizes a 2:1 randomized phase II design where eligible patients will receive either Atezo/MKI (experimental arm) or MKI alone (control). Patients will be stratified according to the MKI choice (cabozantinib or lenvatinib, per physician's decision), etiology of HCC (viral vs. non-viral) and alpha-fetoprotein level (< 400 vs. > = 400 ng/mL). The major eligibility criteria are histological/cytological diagnosis or clinical diagnosis of HCC per the AASLD or WASL 2018 guidelines, has advanced disease not amendable to curative treatment, previously received and progressed on Atezo/Bev, has received only 1 previous line of systemic therapy (2nd line only), ECOG PS 0-1, Child Pugh Class A, adequate organ reserves and RECIST v1.1 measurable disease; previous MKI for advanced disease is excluded. The primary endpoints are overall survival (OS) and progression free survival (PFS). A total sample size of 122, with 89 PFS events, we will have 80% power to detect an improvement in median PFS from 4 to 7 months, assuming a one-sided significance level of 0.05. With approximately 84 deaths, we will have 80% power to detect an improvement in median OS from 10 to 18 months, assuming a one-sided significance level of 0.05. The overall one-sided significance level, for the study, is 0.1. An OS interim analysis will be conducted at 89 PFS events. Secondary endpoints include objective response, duration of response, and adverse events. Archival tumor and serial blood samples will be collected to evaluate for potential prediction biomarkers and mechanisms of sensitivity/resistance. Baseline and on-treatment tumor biopsy specimens will also be collected from the initial 10 patients of each arm. The study is approved by the ethics committee and enrollment to the study will be underway by Q2/3 2022. Clinical trial information: NCT05168163. Research Sponsor: Genentech.

TPS4171 **Poster Session**

PROOF 301: A multicenter, open-label, randomized, phase 3 trial of infigratinib versus gemcitabine plus cisplatin in patients with advanced cholangiocarcinoma with an *FGFR2* gene fusion/rearrangement. *First Author: Ghassan K. Abou-Alfa, Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY*

Background: First-line treatment options are limited for patients with advanced cholangiocarcinoma (CCA). Genetic alterations in the fibroblast growth factor receptor (*FGFR*) gene play an important role in CCA. *FGFR* gene fusions/rearrangements are present in 10–16% of intrahepatic CCA and may predict tumor sensitivity to FGFR inhibitors. Infigratinib (BGJ398) is a potent, orally bioavailable, selective, ATP-competitive, small-molecule tyrosine kinase inhibitor of FGFRs that showed promising clinical activity and a manageable adverse event profile in a phase 2 study in patients with previously treated, unresectable locally advanced/metastatic CCA with an *FGFR2* gene fusion/rearrangement. The multicenter, open-label, randomized, controlled phase 3 PROOF 301 trial is evaluating infigratinib vs standard-of-care gemcitabine + cisplatin as first-line treatment for patients with advanced/metastatic or inoperable CCA with an *FGFR2* gene fusion/rearrangement. **Methods:** Approximately 300 patients ≥18 years of age with histologically or cytologically confirmed, advanced/metastatic or inoperable CCA with an *FGFR2* gene fusion/rearrangement (confirmed by central laboratory) are randomized 2:1 to oral infigratinib 125 mg once daily for the first 21 days of a 28-day treatment cycle vs intravenous standard gemcitabine (1000 mg/m^2) + cisplatin (25 mg/m^2) on days 1 and 8 of a 21-day cycle. Randomization will be stratified by unresectable locally advanced vs metastatic disease, geographic region, prior neoadjuvant/adjuvant treatment vs none, and receipt of up to 1 cycle of gemcitabine-based chemotherapy for unresectable locally advanced/metastatic disease prior to randomization vs none. Treatment will continue until confirmed progressive disease by blinded independent central review (BICR), intolerance, withdrawal of informed consent, or death. Patients on the gemcitabine + cisplatin arm who develop disease progression, confirmed by BICR, can cross-over to receive infigratinib. The primary endpoint is progression-free survival (PFS, RECIST v1.1), confirmed by BICR. Secondary endpoints include overall survival, PFS (investigator determined), overall response rate, best overall response, disease control rate, duration of response (BICR and investigator determined), and the type, frequency, and severity of adverse events (AEs) and serious AEs. PFS after subsequent therapy (PFS2), quality of life, pharmacokinetics and other exploratory genetic alterations/biomarkers will also be evaluated. Trial enrollment is ongoing in the US, EU, and APAC (including Australia). The Data Monitoring Committee last reviewed the trial in December 2021. Clinical trial information: NCT03773302. Research Sponsor: QED Therapeutics, Inc., and Helsinn Healthcare SA.

TPS4172 **Poster Session**

AdvanTIG-206: Anti-TIGIT monoclonal antibody (mAb) ociperlimab (BGB-A1217; OCI) plus anti-programmed cell death protein-1 (PD-1) mAb tislelizumab (TIS) plus BAT1706 versus TIS plus BAT1706 as first-line (1L) treatment for advanced hepatocellular carcinoma (HCC). *First Author: Jia Fan, Fudan University Zhongshan Hospital, Shanghai, China*

Background: Treatment with PD-1/programmed death ligand 1 (PD-L1) inhibitors and anti-angiogenic agents has demonstrated significant survival improvements in patients with untreated HCC. T cell immunoglobulin and immunoreceptor tyrosine-based inhibitory motif domain (TIGIT) is a co-inhibitory immune checkpoint receptor upregulated on T cells and natural killer cells in multiple solid tumors. OCI is a novel, humanized mAb that binds TIGIT with high specificity and affinity, blocking interaction with its ligands on tumor cells. TIS is an anti-PD-1 mAb that has demonstrated clinical activity in patients with previously treated, unresectable HCC (NCT03419897). BAT1706 is a similar biological product to the anti-angiogenic agent bevacizumab. OCI combined with TIS and BAT1706 could further enhance both anti-angiogenic and anti-PD-1 therapies for patients with HCC. **Methods:** AdvanTIG-206 is a Phase 2, randomized, open-label clinical study (NCT04948697). Patients aged ≥ 18 years with histologically confirmed advanced HCC that is not amenable to a curative treatment approach are eligible. Patients must have a Child-Pugh A score, ECOG PS ≤ 1, and have received no prior systemic therapy for HCC. Approximately 90 patients will be randomized 2:1 to OCI 900 mg combined with TIS 200 mg plus BAT1706 15 mg/kg (Arm A) or TIS 200 mg plus BAT1706 15 mg/kg (Arm B), all administered intravenously (once every 3 weeks [Q3W]). The primary endpoint is objective response rate as assessed by the investigator (RECIST v1.1). Radiological assessment of tumor response status will be performed Q6W for the first 48 weeks and Q12W thereafter. Secondary endpoints include duration of response, time to response, disease control rate, clinical benefit rate, and progression-free survival (all by investigator's assessment), overall survival, safety, pharmacokinetics, and immunogenicity. Study enrollment is ongoing. Clinical trial information: NCT04948697. Research Sponsor: This study was sponsored by BeiGene, Ltd. Medical writing support, under the direction of the authors, was provided by Victoria Dagwell, MSc, of Ashfield MedComms, an Ashfield Health company, and funded by BeiGene, Ltd.

TPS4173 **Poster Session**

Phase 2 open-label study of pembrolizumab plus lenvatinib and belzutifan in patients with advanced solid tumors. *First Author: Robin Kate Kelley, University of California San Francisco, San Francisco, CA*

Background: There is an unmet medical need in patients (pts) with advanced/metastatic hepatocellular carcinoma (HCC), colorectal cancer (CRC), pancreatic ductal adenocarcinoma (PDAC), and biliary tract cancer (BTC), that progresses after standard therapy. The combination of pembrolizumab (pembro; anti–PD-1 antibody) and lenvatinib (len; anti-angiogenic multikinase inhibitor) demonstrated antitumor activity and manageable toxicity in many tumor types. Hypoxia-inducible factor-2 alpha (HIF-2α) acts on multiple pathways including cell survival and proliferation, angiogenesis, genomic instability and treatment resistance. Monotherapy with the HIF-2α inhibitor belzutifan (MK-6482) impairs hypoxic signaling in cancer cells and has antitumor activity in clear cell renal cell carcinoma (RCC), von Hippel-Lindau (VHL) disease associated non-RCC tumors such as pancreatic neuroendocrine tumors. Based on the potential role of hypoxia signaling and HIF-2α in tumorigenesis and tumor progression, the combination of belzutifan with pembro and len may improve antitumor activity further in the selected tumor types. **Methods:** This phase 2, single-arm, open-label, multicenter study (NCT04976634) is evaluating pembro 400 mg IV Q6W + oral len 20 mg QD (8 or 12 mg QD for body weight < 60 or ≥60 kg, respectively, for pts with HCC) + oral belzutifan 120 mg QD. Eligible pts: ≥18 y old with histologically confirmed unresectable HCC (Child-Pugh A; 1L); previously treated unresectable, metastatic non–MSI-H/mismatch repair deficient CRC (3L+); metastatic PDAC (2L/3L); or locally advanced/metastatic BTC (includes intra/extrahepatic cholangiocarcinoma and gall bladder cancer; 2L+) with progressive disease (PD); measurable disease per RECIST v1.1 (verified by blinded independent central review [BICR]); ECOG PS ≤1 and archival/new tumor sample for biomarker analysis. All pts should be naïve to prior immune checkpoint inhibitor therapy, len or any HIF-2α inhibitor. The safety lead-in phase is based on the modified toxicity probability interval design with a target dose-limiting toxicity (DLT) rate of 30% and DLT-evaluable period of 21 days (3 wk/1 cycle) in ≤10 HCC pts and ≤15 pts with CRC, PDAC and BTC pooled for each dose level. The study will enroll 120 pts (30/tumor type) to receive triplet therapy for up to 2 y (for pembro) or until PD or discontinuation criteria are met. Enrollment may be expanded by an additional 70 pts/tumor type at the chosen dose level after safety and efficacy review with ≥6 mo follow-up. Primary endpoints are safety (DLTs [safety lead-in], AEs, and treatment discontinuation due to AEs) and ORR per RECIST v1.1 by BICR. Secondary endpoints include DOR, disease control rate and PFS per RECIST v1.1 (and mRECIST for HCC) by BICR, and OS. Efficacy analyses will report binomial proportion or Kaplan-Meier estimates with 95% CIs. Safety analyses will be descriptive. Enrollment began August 2021. Clinical trial information: NCT04976634. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS4174 **Poster Session**

An investigator-initiated phase II trial of a PARP inhibitor niraparib monotherapy for patients with pre-treated, *BRCA*-mutated, unresectable/recurrent biliary tract, pancreatic, and other gastrointestinal cancers (NIR-B trial). *First Author: Yasuyuki Kawamoto, Hokkaido University Hospital, Sapporo, Japan*

Background: Recent comprehensive genomic profiling tests have revealed therapeutic target molecules. However, because many targets are present in only a small fraction of patients, a large number of patients need to be screened for enrollment in a single study. In order to overcome this patient identification barrier, the SCRUM-Japan, nationwide large-scale genomic profiling platform, efficiently has been performed umbrella- and basket-type clinical trials. Among the platforms, we have reported that there are *BRCA1/2*-mutated patients in biliary tract, pancreatic, and other gastrointestinal cancers. Niraparib is an anticancer drug belonging to poly(ADP-ribose) polymerase (PARP) inhibitors. Niraparib has been shown to be selective for PARP1/2, to be more cytotoxic among other PARP inhibitor because of its PARP trapping activity. **Methods:** This is an investigator-initiated, multicenter, three-cohort phase 2 study. Main eligibility criteria are unresectable, advanced or recurrent biliary tract cancers (cohort A), pancreatic cancers (cohort B), and other gastrointestinal cancers (cohort C) with *BRCA1/2* gene mutations identified by germline test or genomic profiling test with either circulating tumor DNA (ctDNA) or tumor tissue, refractory or intolerant to previous treatments, and adequate organ function. Primary endpoint is the investigator-assessed objective response rate in each cohort with a threshold-response rate of 10% and an expected response rate of 35%. Key secondary endpoints are progression-free survival, overall survival, disease control rate, duration of response, and safety. Patients with body weight of 77 kg or more and a platelet count of 150,000 /μL or more receive 300 mg of niraparib, and less than 77 kg or having a platelet count less than 150,000 /μL receive 200 mg of niraparib, orally once daily. Furthermore, pretreatment tumor tissue and serial ctDNA will be collected and analyzed to investigate the resistance mechanisms and provide clinically meaningful biomarker which may be used for identifying and implementing treatment changes. The trial was initiated in January 2021 with enrollment being ongoing. Thirty-three out of planned 60 patients (cohort A/B/C; 25/25/10, respectively) have been enrolled as of December 2021. Funding: Takeda Pharmaceutical Co., Ltd. Clinical trial information: jRCT2011200023. Research Sponsor: Japan Agency for Medical Research and Development, Pharmaceutical/Biotech Company.

TPS4175 **Poster Session**

TALENTop: A multicenter, randomized study evaluating the efficacy and safety of hepatic resection for selected hepatocellular carcinoma with macrovascular invasion after initial atezolizumab plus bevacizumab treatment. *First Author: Hui-Chuan Sun, Liver Cancer Institute and Zhongshan Hospital, Fudan University, Shanghai, China*

Background: Hepatocellular carcinoma **(**HCC) patients with macrovascular invasion are consistently considered to be at an advanced stage of disease. The combination therapy of atezolizumab (atezo) plus bevacizumab (bev) has been the new standard-of-care for those patients. In patients responding to systemic therapy, hepatic resection may provide additional benefit. Here we propose a phase 3 study to investigate whether hepatic resection following atezo/bev can bring more benefits for HCC patients with macrovascular invasion when compared with atezo/bev alone. **Methods:** This is a multicenter, open-label, two-arm, randomized study designed to evaluate the efficacy and safety of surgical resection plus peri-operative atezo/bev compared with regular systemic atezo/bev (Q3W, every three weeks) in HCC patients with macrovascular invasion and without extrahepatic metastasis. Initially eligible patients have enrolled into induction phase, during which they receive 3 cycles of atezo/bev and 1 cycle of atezo alone as primary systemic therapy. Patients who are assessed as partial response or stable disease (RECIST v1.1 criteria) and considered suitable for R0 hepatic resection are randomized in a 1:1 ratio to either Arm A, hepatic resection with post-operative atezo/bev for 1 year (or until loss of clinical benefit or intolerable toxic effects), or Arm B, continuing atezo/bev for 1 year (or until loss of clinical benefit or intolerable toxic effects). The primary endpoint of this study is time-to treatment failure (TTF), defined as time from randomization to the first documented treatment failure (i.e., tumor recurrence or metastasis [Arm A], disease progression [Arm B] according to RECIST v1.1, or death from any cause). We hypothesize that hepatic surgery with peri-operative atezo/bev will improve the TTF from 5.8 months to 9.2 months, with the hazard ratio of 0.63. With 2-sided significance level of 0.05, the sample size for randomization will be 198. The study, registered with clinical trial ID of NCT04649489, started enrollment in Apr 2021. As of Jan 2022, 65 patients have been enrolled and 15 patients have been randomized. Research funding: Shanghai Roche Pharmaceuticals Ltd. Clinical trial information: NCT04649489. Research Sponsor: Shanghai Roche Pharmaceuticals Ltd.

TPS4176 **Poster Session**

Study protocol of an open-label, single-arm, phase II trial investigating the efficacy and safety of trifluridine/tipiracil combined with irinotecan as a second-line therapy in patients with cholangiocarcinoma (TRITICC). *First Author: Linde Kehmann, Charité University Medicine Berlin, Berlin, Germany*

Background: Biliary tract cancers (BTC) currently account for ~15% of all primary liver cancers and ~3% of gastrointestinal malignancies. Gemcitabine/Cisplatin has been the standard of care in the first-line therapy of BTC for a decade. Despite recently some survival benefit has been shown in adding a checkpoint inhibitor, further lines of treatment are only poorly defined. In the ABC-06 phase-3 study, second-line FOLFOX demonstrated a moderate but significant improvement of survival and might be regarded as a standard of care. The combination of liposomal Irinotecan and 5-FU infusion pump also improved survival after first line therapy. Both mentioned second-line regimens are based on limited evidence and questionable generalizability. Thus, there is a high need for novel treatment concepts in patients without targetable genetic alterations. Trifluridine/tipiracil (FTD/TPI) is a orally active, antimetabolite agent comprised of trifluridine, a thymidine-based nucleoside analogue, and tipiracil, a potent thymidine phosphorylase inhibitor. Recent reports provided evidence of an antitumor activity of FTD/TPI plus Irinotecan as well in patients with BTC. Therefore, the TRITICC trial was designed to evaluate the safety and efficacy of FTD/TPI plus irinotecan in patients with BTC refractory to previous Gemcitabine based treatment. **Methods:** TRITICC (NCT04059562) is an interventional, prospective, open-label, non-randomized, exploratory, multicenter, single-arm phase IIA clinical trial that evaluates the safety and efficacy of FTD/TPI (25 mg/m^2 body surface area (BSA), BID, orally on days 1-5 followed by a 9-days recovery period from day 6 trough day 14 of each 14-days treatment cycle) plus irinotecan (on day 1 of each cycle at a dose of 180 mg/m^2) in adult patients with histologically verified locally advanced or metastatic BTC (including cholangiocarcinoma and gallbladder or ampullary carcinoma) with documented radiological disease progression to first-line gemcitabine based chemotherapy. A total of 28 patients is planned to be enrolled in 6 sites across Germany. Study treatment will be continued until disease progression according to RECIST 1.1 criteria or occurrence of unacceptable toxicity. The effect of FTD/TPI plus irinotecan on progression-free survival will be analyzed as primary endpoint. Safety (according to NCI-CTCAE), response rates and overall survival are secondary endpoints. In addition, a comprehensive translational research program is part of the study and might provide findings about predictive markers with regard to response, survival periods and resistance to treatment. Currently, 3 out of the planned 6 German study sites are opened for recruitment and 6 patients have been enrolled. The primary study endpoint is estimated to be evaluated in 2023. Clinical trial information: NCT04059562. Research Sponsor: Servier.

TPS4177 **Poster Session**

An open-label, multicenter, randomized phase II study of atezolizumab and bevacizumab with Y90 TARE in patients with unresectable hepatocellular carcinoma (HCC). *First Author: Aiwu Ruth He, Georgetown University Lombardi Comprehensive Cancer Center, Washington, DC*

Background: The anti–PD-L1 antibody atezolizumab (ATEZO) prevents PD-L1 from interacting with PD-1 and B7.1, thus reinvigorating antitumor T cell activity. Anti-VEGF bevacizumab (BEV) increases dendritic cell maturation, enhances T cell infiltration, and reduces myeloid-derived suppressor cells and regulatory T cells in tumors. ATEZO + BEV is FDA approved for first-line treatment of advanced HCC based on the IMbrave 150 study. Locoregional radiotherapy (e.g., Y90 TARE) enhances the diversity of the intratumoral T cell receptor repertoire and increases tumor antigen release. We hypothesize that the Y90 TARE + BEV + ATEZO combination induces synergistic tumor killing and prolongs progression-free survival in patients (pts) receiving Y90 TARE (HR = 0.6 when compared to Y-90 TARE alone). **Methods:** Eligible pts have HCC that cannot be surgically resected (confirmed by pathology review), is at least BCLC stage B, and is outside Milan criteria. Other requirements include ECOG PS of 0-1 at screening, measurable disease by RECIST 1.1, no prior systemic therapy, and FLR estimated at ≥ 40% post local therapy. Pts must have a pretreatment liver biopsy taken and then be randomized 1:1 to TARE (Arm A) or TARE + ATEZO + BEV (Arm B). Pts will have TARE mapping followed by TARE treatment. In Arm B, pts will begin TARE treatment followed by BEV + ATEZO (4 wks [± 1 wk] later). Pts will have abdominal MRI or CT scans every 12 weeks and CT scans of the chest every 24 wks. The primary study objective is to assess and compare pts' progression-free survival (per mRECIST 1.1) in each study arm. The main secondary objective is to determine the safety and tolerability (CTCAE v5) of pts in Arm B. Exploratory objectives are to define the use of cellular and circulating biomarkers in the prediction of improved clinical outcomes of pts in Arm B. Symptoms experienced by pts in both arms using patient-reported outcomes will be assessed. Disease progression will be captured by both RECIST 1.1 and mRECIST. We plan to assess the safety of Y90 TARE + BEV + ATEZO in the first 10 pts randomized to Arm B for two cycles, and if there are no grade ≥ 3 unexpected toxicities possibly, probably, or definitely related to combined TARE + BEV + ATEZO, continue to accrue 128 pts in total (current enrollment n- = 5). Pts will continue study treatment (Arm B) for a total of 24 months from initiation of TARE or until intolerable toxicity or disease progression occur, whichever is earlier. Enrollment began in September 2020. Clinical trial information: NCT04541173. Research Sponsor: Roche/Genentech, Institutional funding.

TPS4178 **Poster Session**

Methodology of the SORENTO clinical trial: Assessing the efficacy and safety of high exposure octreotide subcutaneous depot in patients with GEP-NETs. *First Author: Simron Singh, Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

Background: Somatostatin receptor ligands (SRLs) are first-line standard of care therapies for gastroenteropancreatic neuroendocrine tumors (GEP-NETs), showing efficacy in tumor/symptom control with an established safety profile. Yet, disease progression may occur despite standard-dose SRL treatment, requiring more aggressive and toxic therapies. Retrospective/non-randomized data suggest higher-dose SRLs may benefit patients with GEP-NETs who do not respond to standard-dose treatment and provide improved disease control. Octreotide depot (CAM2029) is a novel high-exposure, subcutaneous (SC) formulation. Clinical trials showed ~500% higher CAM2029 bioavailability versus octreotide long-acting release (LAR) (Tiberg et al. 2015), and maintenance/reduction of NET symptoms (Pavel et al. 2019). Prospective, randomized data are needed to confirm the efficacy/safety of novel SRLs with higher bioavailability such as CAM2029, vs standard-dose SRLs including octreotide LAR and lanreotide Autogel (ATG). **Methods:** SORENTO is a randomized, multi-center, open-label, active-controlled Phase 3 trial, aiming to enroll 302 adults with GEP-NETs. Key eligibility criteria: advanced, well-differentiated NET of GEP/presumed GEP origin; ≥1 measurable SR positive (by nuclear imaging) lesion according to RECIST 1.1; no or < 6 months consecutive treatment with long-acting SRLs. Notably, patients with Grade 3 GEP-NETs (excluded by CLARINET/PROMID trials) are eligible. Patients will be randomized 1:1 to CAM2029 20 mg Q2W, or active comparator (octreotide LAR 30 mg intramuscular or lanreotide ATG 120 mg SC, Q4W). CAM2029 self/carer administration is allowed after ≥3 successful supervised administrations. Randomization stratified by: histological grade, tumor origin, intended comparator. Primary outcome: progression free survival (PFS; time from randomization to date of first documented disease progression [RECIST 1.1] or death), assessed by a Blinded Independent Review Committee. The study is powered to detect a hazard ratio of 0.65. Key secondary outcomes: overall survival; response rate; rescue medication use; patient satisfaction; adverse events. After primary PFS analysis, patient overall survival will be followed for up to 2 years. If CAM2029 displays superiority in the primary analysis, the comparator group may switch to CAM2029 20 mg Q2W. Patients in any treatment group experiencing progressive disease in the randomized part of the study may proceed to an open-label extension with intensified CAM2029 treatment, to investigate effects of higher frequency dosing. First patient randomized in Nov-2021, with readout (following 194 events) expected by 2024 end. This novel head-to-head superiority trial is anticipated to demonstrate the potential benefits of CAM2029 as a first line-therapy in patients with well-differentiated GEP-NETs. Clinical trial information: NCT05050942. Research Sponsor: Camurus AB.

TPS4179 **Poster Session**

SWOG S2012: Randomized phase II/III trial of first line platinum/etoposide (P/E) with or without atezolizumab (NSC#783608) in patients (pts) with poorly differentiated extrapulmonary small cell neuroendocrine carcinomas (NEC). *First Author: David Bing Zhen, University of Washington/Fred Hutchison Cancer Research Center, Seattle, WA*

Background: Poorly differentiated, extrapulmonary small cell NEC are rare cancers with median overall survival (OS) < 1 year. Treatment is extrapolated from small cell lung cancer (SCLC) with use of P (cisplatin or carboplatin) + E. More effective treatment regimens and predictive biomarkers are needed to improve outcomes. In SCLC, induction therapy with combination of P/E + PD-L1 checkpoint inhibitor atezolizumab and maintenance atezolizumab improved OS (12.3 months vs 10.3 months; HR 0.70, 95% CI 0.54 – 0.91, P = 0.007) vs P/E alone (Horn L, et al. N Engl J Med 2018). No study to date has compared PD-1/PD-L1 inhibition during induction only vs during induction and maintenance therapy. In SCLC, distinct molecular subtypes can be identified by the presence of specific transcription factors (e.g., ASCL1, NEUROD1, POU2F3) or an Inflamed gene signature (SCLC-I), with SCLC-I pts more likely to benefit clinically from the addition of immunotherapy (Gay CM, et al. Cancer Cell 2021). In this study we plan to test the benefit of adding atezolizumab to induction P/E plus maintenance vs P/E alone, as well as the role of adding maintenance atezolizumab vs observation after induction chemo-immunotherapy. We also plan to correlate tumor- and blood-based subtype biomarkers with response to therapy. **Methods:** Eligible pts ≥18 years old have evaluable, histologically confirmed extrapulmonary small cell NEC, Zubrod PS ≤2, and are allowed to have up to 1 cycle of P/E prior to enrollment. P (cisplatin 75 mg/m2 or carboplatin AUC 5, iv) on day 1, E 100 mg/m2 iv on days 1-3, and atezolizumab 1200 mg iv on day 1 of q21 day cycles. Treatment consists of an induction phase x 4 cycles, and if no disease progression, a maintenance/observation phase given until disease progression for up to 1 year. Pts are randomized to 1 of 3 arms: A) Induction P/E + atezolizumab → maintenance atezolizumab B) Induction P/E + atezolizumab → observation C) Induction P/E → observation. The primary endpoint is to compare the OS (from randomization) between arms in a fixed sequence: A vs C → B vs C → A vs B. Secondary endpoints include comparing OS (from start of maintenance/observation), progression free survival, response rate, duration of response, and safety/tolerability across arms. Tumor and blood samples will be banked for future biomarker analyses, including immunohistochemistry of transcription factors on tissue and whole exome sequencing on tumor and circulating tumor DNA. With 189 pts, the study is powered to detect an improvement in 12-months OS from 35% to 57.5% (HR 0.53). Both phase 2 and phase 3 portions include interim analyses. Accrual will not pause for phase 2 analysis, expected early 2024. This study was activated December, 2021 and is open to accrual across the NCI National Clinical Trials Network (NCTN). Clinical trial information: NCT05058651. Research Sponsor: U.S. National Institutes of Health.

TPS4180 **Poster Session**

Trial in progress: Phase I study of SY-5609, a potent, selective CDK7 inhibitor, with initial expansion in adults with metastatic pancreatic cancer. *First Author: Manish Sharma, START Midwest, Grand Rapids, MI*

Background: SY-5609 is an oral, selective, potent CDK7 inhibitor that targets two fundamental processes in cancer: transcription and cell cycle control. Early results from the Phase 1 dose escalation portion in patients (pts) with advanced solid tumors reported improved tolerability of the intermittent 7 days on followed by 7 days off (7/7) schedule with ongoing dose escalation beyond the continuous daily dosing maximum tolerated dose. Single-agent clinical activity was demonstrated with durable stable disease, target lesion regressions, and reduction in tumor markers observed in multiple tumor types, notably in pancreatic cancer with a disease control rate (DCR) of 38.5% (Sharma 2021). Pancreatic ductal adenocarcinoma (PDAC) has a 5-year survival rate of 11% (ACS Cancer Facts and figures, 2022) with limited treatment options and therefore, is a disease in need of novel effective therapies. Oncogenic *KRAS* mutations are prevalent in PDAC. Mutant *KRAS* is a potent stimulator of mitogenic MAPK signaling and downstream transcriptional programs for cell proliferation. Preclinical studies have shown that CDK7 inhibition via SY-5609 inhibits tumor growth in *KRAS* mutant PDAC xenograft models, in many cases leading to regressions. SY-5609 also potentiates gemcitabine (gem) activity in PDAC cells *in vitro* and in xenografts *in vivo* (Henry 2021). Therefore, combining SY-5609 with gem +/- nab-paclitaxel (nab-pac) offers a potential new treatment strategy for metastatic PDAC (mPDAC). The expansion portion of this Phase 1 study will evaluate SY-5609 in combination with gem +/- nab-pac in mPDAC pts. Gem +/- nab-pac will be administered on a biweekly schedule as it has shown better tolerability and similar clinical activity compared to the standard of care (SOC) administration schedule (Rehman 2020). **Methods:** This is an ongoing Phase 1, multi-center study in select solid tumors, amended to open expansion cohorts for mPDAC and expected to enroll approximately 80 mPDAC pts who have progressed on SOC treatments. Objectives of the expansion cohorts include evaluation of safety and efficacy of SY-5609 in combination with gem +/- nab-pac. Key objectives of the two parallel safety lead-in cohorts 1) SY-5609 + gem and 2) SY-5609 + gem + nab-pac are safety and determination of the recommended combination dose of the doublet and triplet for subsequent cohort expansions using a 3+3 escalation design. Key objectives of expansion cohorts are to describe efficacy, defined by progression-free survival, overall response rate, and DCR. Additional objectives include evaluation of pharmacokinetics and pharmacodynamics of SY-5609 in combination with gem +/- nab-pac. SY-5609 will be administered orally once daily on a 7/7 regimen and gem +/- nab-pac will be administered intravenously, in a 4-week cycle. The expansion portion is now open to enrollment. Clinical trial information: NCT04247126. Research Sponsor: Syros Pharmaceuticals.

TPS4181 **Poster Session**

A phase 1b/2, dose-escalation, randomized, multicenter study of maintenance (maint) ivaltinostat (ival) plus capecitabine (cap) or capecitabine monotherapy in patients (pts) with metastatic pancreatic adenocarcinoma (PDAC) whose disease has not progressed on first-line FOLFIRINOX chemotherapy (CT). *First Author: Evan Justin Walker, UCSF, San Francisco, CA*

Background: The mainstay of treatment (TX) for pts with advanced or mPDAC consists of CT, with FOLFIRINOX and gemcitabine (gem)/nab-paclitaxel currently representing the front-line standards of care. TX is generally continued until either dis progression (progr) or cumulative toxicity, with pts often reaching a plateau in response after 4-6 mos. For those who have achieved dis control (stable dis or better) on front-line CT, a maint TX strategy that can effectively delay dis progr while preserving quality of life with minimal cumulative toxicity is highly desirable. However, aside from PARP inhibition in the subset of PDAC pts with gBRCA mutated dis, there is no current standard of care in this maint setting. Ival is a pan-HDAC (histone deacetylation) inhibitor that increases histone acetylation (HA), suppresses PDAC cell proliferation, and promotes apoptosis in PDAC cell lines in a dose-dependent manner. It has demonstrated synergy with 5-FU in cholangiocarcinoma cell lines and shows promising antitumor activity when combined with cap in syngeneic PDAC mouse models. On these bases, we are conducting a ph1b/randomized ph2 trial of ival plus cap vs cap alone in the maint setting for pts with mPDAC who have not progressed on front-line FOLFIRINOX. **Methods:** Key eligibility criteria include pts with mPDAC; no evidence of dis progr following at least 16 wks of front-line FOLFIRINOX at full or modified doses; ECOG PS 0-1; and no known gBRCA1/2 mutation. The study includes an initial dose-esc ph1b evaluating 3 dose levels of ival, (60, 125, and 250mg/m^2 iv weekly on days 1 and 8) in combination (comb) with cap (1000mg/m^2 po BID on days 1-14) of a 21-day cycle, using a standard 3 + 3 dose-esc design. Of note, ival 250 mg/m^2 represents the RP2D identified in prior clinical studies of this agent both as monotherapy in solid tumors and in comb with gem/erlotinib in advanced PDAC pts. In the ph2 portion, pts will be randomized 1:1 to receive either ival plus cap or cap alone, in 21-day cycles, until dis progr, with tumor assessments occurring at 6-wk intervals. Blood will be collected at pre-specified serial timepoints for pharmacodynamic assessments, including HA of PBMCs. Primary endpoint for ph2 is investigator-adjudicated PFS. The primary analysis will compare PFS distributions in the ival/cap and cap alone arms using a one-sided log rank test with an alpha = 0.10. The assumed true 6-mo PFS rates are 35% (cap), based on historic data, and 60% (ival/cap), which corresponds to an HR of 0.487. Assuming an accrual duration of 18 mos and a dropout/lost to follow-up rate of 10%, the estimated total number of pts in the randomized ph2 portion is 52 (26 per arm). Enrollment is expected to being in spring 2022 across 25 U.S. sites. Research Sponsor: CG Pharmaceuticals Inc.

TPS4183 **Poster Session**

Phase II study (daNIS-1) of the anti-TGF-β monoclonal antibody (mAb) NIS793 with and without the PD-1 inhibitor spartalizumab in combination with nab-paclitaxel/gemcitabine (NG) versus NG alone in patients (pts) with first-line metastatic pancreatic ductal adenocarcinoma (mPDAC). *First Author: Li-Yuan Bai, China Medical University Hospital, Taichung, Taiwan*

Background: Overall survival remains low for pts with mPDAC despite approved therapies, highlighting the need for further innovative treatment options. Intra-tumoral fibrosis that characterizes PDAC has been associated with a state of immune exclusion and may constitute a mechanical obstacle to the intra-tumoral penetration of chemotherapy as well as contribute to the lack of efficacy of immunotherapy. TGF-β plays a key role in regulating the tumor microenvironment and emerging evidence points to its role as a pivotal activator of cancer-associated fibroblasts, leading to the development of fibrotic networks. Preclinical data in murine models have shown that TGF-β blockade augmented the antitumor activity of both NG and anti-PD-1 therapy, leading to tumor regression. These data provide the rationale for combining TGF-β-targeting agents with immunotherapy and chemotherapy. NIS793 is a human IgG2 mAb that binds to TGF-β. This study investigates NIS793 with and without spartalizumab (PD-1 antagonist) combined with NG in treatment naïve mPDAC. **Methods:** This is a phase II open-label, randomized, multicenter study (NCT04390763) beginning with a safety run-in period followed by randomization. Eligible pts are adults with previously untreated mPDAC and ECOG performance status score ≤1. Pts are excluded if they have a microsatellite-unstable tumor. The safety run-in data will be analyzed after ≥6 pts have received NIS793 (intravenously [IV] 2100 mg Q2W) + spartalizumab (IV 400 mg Q4W) + nab-paclitaxel (IV 125 mg/m^2 on Days 1, 8 and 15) + gemcitabine (IV 1000 mg/m^2 on Days 1, 8 and 15) for 1 cycle (28 days) to assess the safety and tolerability of the combination. In the randomized part, pts will be randomized 1:1:1 to NIS793 + spartalizumab + NG (n = 50) or NIS793 + NG (n = 50) or NG (n = 50). Treatment will continue until unacceptable toxicity, disease progression, discontinuation by investigator's/pt's choice, or withdrawal of consent. The primary objective is to evaluate the progression-free survival per RECIST 1.1, of NIS793 + NG ± spartalizumab versus NG alone . Secondary objectives include safety and tolerability, antitumor activity, overall survival, change in tumoral CD8 and PD-L1 status, and characterization of immunogenicity and pharmacokinetics. Efficacy will be assessed locally per RECIST v1.1 and iRECIST at screening, every 8 weeks for 1 year and then every 12 weeks until disease progression. Blood and tumor samples will be taken at baseline and during study treatment for pharmacokinetic, immunogenicity and biomarker assessments. This study is ongoing and will enroll pts from 31 sites across 14 countries. The first pt was treated on October 22, 2020. Enrollment for the randomized part of the study started on August 09, 2021. Clinical trial information: NCT04390763. Research Sponsor: Novartis.

TPS4184 **Poster Session**

GRECO-2: A randomized, phase 2 study of stereotactic body radiation therapy (SBRT) in combination with rucosopasem (GC4711) in the treatment of locally advanced or borderline resectable nonmetastatic pancreatic cancer. *First Author: Sarah E. Hoffe, H. Lee Moffitt Cancer Center, Tampa, FL*

Background: While treatment of pancreatic cancer has advanced, survival rates remain low. Stereotactic body radiotherapy (SBRT; high dose per fraction radiation) may exhibit improved clinical outcomes in locally advanced pancreatic cancer but carries potential gastrointestinal toxicity risks (Zhong 2017). Rucosopasem (GC4711) is one of a class of investigational selective dismutase mimetics that rapidly and specifically converts superoxide to hydrogen peroxide (Riley 2006). Studies have shown that normal cells tolerate hydrogen peroxide fluxes better than cancer cells (Doskey 2016). As radiation response modifiers, dismutase mimetics have the potential to increase tumor control of SBRT without compromising radiation safety (El-Mahdy 2020, Sishc 2021). In a pilot phase 1/2 trial in patients with pancreatic cancer, avasopasem, a dismutase mimetic related to rucosopasem, nearly doubled median overall survival in patients receiving SBRT vs placebo plus SBRT. Improvements versus placebo were also observed in local tumor control, time to metastases, and progression-free survival. Altogether, these data support the hypothesis that rucosopasem may improve survival and the benefit-risk ratio of SBRT by improving efficacy without increasing gastrointestinal toxicity. **Materials/Methods:** GRECO-2 is a phase 2, multicenter, randomized, double-blind, placebo-controlled study (NCT04698915) to determine the effect of adding rucosopasem to SBRT on overall survival in patients with borderline resectable or locally advanced, unresectable nonmetastatic pancreatic cancer following initial chemotherapy with a FOLFIRINOX-based regimen or a gemcitabine doublet. Approximately 160 patients will be randomized (approximately 35 sites) to receive rucosopasem 100 mg or placebo via IV infusion over 15 minutes, prior to each SBRT fraction (5 x 10 Gy). Patients judged to be resectable will undergo surgical exploration within 8 weeks after SBRT. The primary endpoint is overall survival. Secondary endpoints include progression-free survival, locoregional control, time to metastasis, surgical resection rate, R0 resection rate, best overall response, in-field local response, and safety (acute and late toxicities). Exploratory endpoints include PRO-CTCAE and CA19-9 normalization. This trial is now enrolling. Clinical trial information: NCT04698915. Research Sponsor: Galera Therapeutics, Inc.

TPS4185 **Poster Session**

A randomized phase II study of gemcitabine and nab-paclitaxel compared with 5-fluorouracil, leucovorin, and liposomal irinotecan in older patients with treatment-naïve metastatic pancreatic cancer (GIANT): ECOG-ACRIN EA2186—Trials in progress. *First Author: Efrat Dotan, Fox Chase Cancer Center, Philadelphia, PA*

Background: Evidence-based data is lacking to guide the care of older adults with newly diagnosed metastatic pancreatic cancer (mPCA). As a result, treatment approach and the selection of chemotherapy regimens are often extrapolated from data from younger patients. Furthermore, vulnerable older adults are often treated with dose adjusted regimens with limited data to support this practice. EA2186 is a phase II randomized controlled trial, and the first prospective study aiming to define the optimal treatment approach of vulnerable older adults with newly diagnosed mPCA. **Methods:** Patients aged 70 years and over with histologically confirmed pancreatic adenocarcinoma, evidence of metastatic disease, ECOG PS 0-2 and adequate organ function, who are considered vulnerable are eligible for this trial (accrual target 184). This study utilizes a screening geriatric assessment which characterize patients as fit, vulnerable or frail by evaluating functional status, cognition and co-morbidities. Vulnerable patients according to this screening assessment are those with mild abnormalities in functional status, comorbidities and/or cognition, or older than 80 years of age. Those patients will be randomized to receive either modified Gemcitabine/Nab-Paclitaxel or dose-reduced 5-Fluorouracil Leucovorin and Liposomal Irinotecan every 2 weeks. A comprehensive geriatric assessment (GA) and quality of life (QOL) evaluation are completed prior to initiation of therapy for all randomized patients. Follow up will continue until disease progression or withdrawal, with repeated GA and QOL assessments at each disease evaluation. Overall survival is the primary objective, with secondary objectives including progression free survival, and response rate. Enrolled patients will be stratified by age 70-74 vs ≥75, and ECOG PS 0-1 vs 2. Additional endpoints of interest for older adults include: evaluation of risk factors identified through GA, and capturing toxicities of interest for this patient population (i.e. hospitalization, deterioration in PS, and falls). Correlative studies include assessment of pro-inflammatory biomarkers or aging in the blood (IL-6 and CRP) as well as imaging evaluation of sarcopenia and body composition as predictors of treatment tolerance. Clinical trial information: NCT04233866. Research Sponsor: U.S. National Institutes of Health.

TPS4186 **Poster Session**

Zolbetuximab plus gemcitabine and nab-paclitaxel (GN) in first-line treatment of claudin 18.2-positive metastatic pancreatic cancer (mPC): Phase 2, open-label, randomized study. *First Author: Wungki Park, Memorial Sloan Kettering Cancer Center, Weill Cornell Medical College, New York, NY*

Background: GN is a first-line treatment option for patients (pts) with mPC. Poor prognosis and low 5-year survival rate (< 5%) of pts with mPC highlight the need for new therapeutics. Claudin 18.2 (CLDN18.2), a tight junction protein expressed exclusively on normal gastric epithelial cells, is maintained during malignant transformation in gastric cancers and is frequently expressed in some carcinomas from organs that do not normally express it, such as pancreatic cancer. Zolbetuximab, a chimeric IgG1 monoclonal antibody, binds to CLDN18.2 and mediates tumor cell death through antibody-dependent cellular cytotoxicity and complement-dependent cytotoxicity. **Methods:** This phase 2 study (NCT03816163), expanded to enroll approximately 369 pts, will assess safety and efficacy of GN alone or with zolbetuximab in pts with histologically confirmed mPC and high CLDN18.2 expression (moderate-to-strong IHC staining intensity in ≥75% of tumor cells). The study included a safety lead-in that enrolled 3-12 pts to assess safety/tolerability of zolbetuximab (n = 3 at 1,000 mg/m^2 on Cycle 1 Day 1 then 600 mg/m^2 Q2W, then expand/de-escalate using a 3+3 design) plus GN. Dose-limiting toxicities (DLTs, defined as a specified zolbetuximab-related toxicity that occurs during DLT assessment period) will be assessed after Cycle 1 (28 days). Based on the recommended phase 2 dose (RP2D), confirmed during the safety lead-in, approximately 357 pts will be randomized 2:1 to zolbetuximab Q2W on Days 1 and 15 plus GN on Days 1, 8, and 15 of each cycle (Arm 1), or GN alone on Days 1, 8, and 15 of each cycle (Arm 2). Randomization will be stratified by ECOG performance status (0 or 1) and liver metastasis (yes or no). At sites in Japan, DLTs (assessed from Cycle 1 Day 1 to Cycle 2 Day 1) will be evaluated in ≤6 pts randomized to the RP2D in Arm 1. Pts will undergo imaging (CT/MRI) at baseline and every 8 weeks until investigator-assessed disease progression (RECIST v1.1) or the start of another systemic anticancer treatment, whichever comes earlier. In addition to confirming the RP2D during the safety lead-in, primary objectives are to assess whether treatment with zolbetuximab plus GN, versus GN alone, improves overall survival (randomization phase) and to establish the safety/tolerability profile of zolbetuximab plus GN (across the study). Secondary endpoints include progression-free survival, objective response rate, disease control rate, duration of response, pharmacokinetics, and health-related quality of life (per protocol amendment). Data will be presented using descriptive statistics for continuous endpoints and frequency and percentage for categorical endpoints. At original protocol enrollment completion (October 2021), 84 sites were actively recruiting; sites are currently reopening for screening/enrollment pending protocol amendment approval. Clinical trial information: NCT03816163. Research Sponsor: Astellas Pharma, Inc.

TPS4187 **Poster Session**

PANOVA-3: A phase 3 study of tumor-treating fields with gemcitabine and nab-paclitaxel for frontline treatment of locally advanced pancreatic adenocarcinoma. *First Author: Vincent J. Picozzi, Virginia Mason Hospital and Medical Center, Seattle, WA*

Background: Tumor Treating Fields (TTFields) are a novel, locoregional antimitotic treatment modality approved for glioblastoma and malignant pleural mesothelioma. Continuous, non-invasive low intensity, intermediate frequency (150–200 kHz) alternating electric fields are delivered to the tumor via skin-placed arrays. *In vitro,* TTFields (150 kHz), with or without chemotherapy, induced antiproliferative and anticlonogenic activity on pancreatic cancer cell lines (Giladi M, et al. Pancreatology 2014;14:54–63). The phase 2 PANOVA study (NCT01971281) demonstrated that the combination of TTFields with nab-paclitaxel and gemcitabine (GnP) is well-tolerated, with promising efficacy in metastatic and locally advanced pancreatic adenocarcinoma (LAPC) (Rivera F, et al. Pancreatology 2019;19:64–72). These data indicate that TTFields with GnP warrant phase 3 evaluation. **Methods:** PANOVA-3 (NCT03377491) is a prospective, randomized, phase 3 trial designed to investigate the efficacy and safety of TTFields concomitant with GnP in patients with LAPC. Planned enrollment is 556 patients. Eligibility criteria include unresectable LAPC (per National Comprehensive Cancer Network guidelines), Eastern Cooperative Oncology Group performance status of 0–2, and no prior treatment. Patients will be stratified by performance status and geographical region, and randomly assigned 1:1 to TTFields plus GnP or GnP alone. Based on a recent protocol amendment, a smaller and lighter-weight (reduced from 6 to 2.7 lbs) TTFields device will be used. Standard doses of nab-paclitaxel (125 mg/m^2) and gemcitabine (1000 mg/m^2) will be administered on days 1, 8, and 15 of a 28-day cycle. TTFields (150 kHz) will be delivered ≥ 18 h/day until local disease progression per Response Evaluation Criteria in Solid Tumors V1.1. Follow-up will be performed every 4 weeks and a computed tomography scan of the chest and abdomen every 8 weeks. After local disease progression, patients will be followed every month until death. The primary endpoint is overall survival (OS). Secondary endpoints include progression-free survival (PFS), local PFS, objective response rate, 1-year survival rate, pain- and puncture-free survival rate, rate of resectability, quality of life, and toxicity. The sample size was estimated per log-rank test comparing time to event in patients treated with TTFields plus GnP with published clinical trial data on patients treated with GnP alone. PANOVA-3 is designed to detect a hazard ratio of 0.75 in OS. Type I error is set to 0.05 (2-sided) and power to 80%. The trial is currently recruiting at 106 sites in Austria, Belgium, Canada, China, Croatia, Czech Republic, France, Germany, Hong Kong, Hungary, Israel, Italy, Poland, Spain, Switzerland, and USA. The DMC last reviewed the trial in August 2021, and suggested that the trial continue as planned. Clinical trial information: NCT03377491. Research Sponsor: Novocure Ltd.

TPS4188 **Poster Session**

Precision Promise (PrP): An adaptive, multi-arm registration trial in metastatic pancreatic ductal adenocarcinoma (PDAC). *First Author: Vincent J. Picozzi, Virginia Mason Hospital and Medical Center, Seattle, WA*

Background: The success rate of drug development in PDAC is disappointingly low.PrP is a transformative, adaptive platform clinical trial designed to continuously evaluate many novel therapeutic options while increasing the probability that patients (pts) are randomized to effective experimental therapies. It cultivates enhanced cooperation among groups representing pts advocacy, pharmaceutical companies, academia, and the FDA. This patient-centric study aims to become the largest Phase 3 registrational study in PDAC and represents a fundamental shift in drug development for PDAC in the United States (US). **Methods:** PrP (NCT04229004) is a platform clinical trial sponsored by the Pancreatic Cancer Action Network (PanCAN), developed based on the FDA 2020 guidance document regarding "complex innovative designs" in registration trials https://www.fda.gov/media/130897/download. It utilizes adaptive randomization and other Bayesian statistical innovations provided by Berry Consultants LLC, including the "time machine" which uses all previously randomized controls for each arm, suitably adjusted for line of therapy and the time period of the arm. Focused on 1st and 2nd line treatment of mPDAC, PrP uses an adaptive platform design with randomization to one of 2 control arms (gemcitabine + nab-paclitaxel (GA) or mFOLFIRINOX, 30% of pts) or experimental therapy (70% of pts). Candidate experimental arms are reviewed by an Arm Selection Committee based on validity of the treatment target and strength of the pre-clinical and clinical data. The primary endpoint is overall survival (OS). Pts undergo pre- and on-treatment biopsies with state-of-the-art genomic, transcriptomic, and immune analysis, along with a serial collection of blood-based research samples. Pts are managed using novel supportive care techniques; PrP contains 3 sub-protocols evaluating quality of life, sarcopenia, and actigraphy. PrP launched in 2020 and has enrolled > 130 pts; 30 US sites have been selected with 17 currently active. Current experimental arms include: (i) GA + Pamrevlumab, an anti-CTGF Ab, (ii) Racemetyrosine monotherapy, a cancer metabolism-based therapy (for follow-up of patients) and (iii) an immuno-oncology arm in activation. Other arms are in the planning stages. Compared to traditional designs, PrP offers several advantages: multiple investigational treatments evaluated in parallel over time; ~175 pts per experimental arm required to initiate a regulatory registration; and continuous learning from every patient, resulting in significant savings of time and resources. PrP has created an entirely new learning environment for accelerating drug development in PDAC. Clinical trial information: NCT04229004. Research Sponsor: PanCAN, Pharmaceutical/Biotech Company.

TPS4189 **Poster Session**

A multicenter, randomized, double-blind phase III clinical study to evaluate the efficacy and safety of KN046 combined with nab-paclitaxel and gemcitabine versus placebo combined with nab-paclitaxel and gemcitabine in patients with advanced pancreatic cancer (ENREACH-PDAC-01). *First Author: Gang Jin, Department of Hepatobiliary Pancreatic Surgery, Changhai Hospital, Navy Medical University (the Second Military Medical University), Shanghai, China*

Background: Pancreatic cancer is biologically aggressive, and the majority of pts was diagnosed as locally advanced or metastatic disease. Nab-paclitaxel and gemcitabine is a frequently used regimen for advanced pancreatic cancer, but chemoresistance is unavoidable. The combination of immunotherapy with chemotherapy have shown efficacy for certain types of cancer, but no similar results have been obtained in pancreatic cancer. KN046, a novel recombinant humanized bispecific antibody, can simultaneously block PD-1/PD-L1 and CTLA-4 pathways and restore T-cell immune response to tumor. In a phase II clinical trial (NCT04324307), as of August 10, 2021, 53 pts with unresectable advanced pancreatic cancer had received one cycle KN046 combined AG regimen treatment and 31 subjects had received post-baseline tumor assessment at least once. Objective response rate (ORR) was 45.2% (95% CI: 27.3%, 64.0%) and disease control rate (DCR) was 93.5% (95% CI: 78.6%, 99.2%), excellent preliminary results have been achieved. Based on this, a phase III pivotal study (ENREACH-PDAC-01) is conducting now in China to verify the efficacy and safety of KN046 plus nab-paclitaxel and gemcitabine as first-line treatment for advanced pancreatic cancer (NCT05149326). **Methods:** This nationwide multicenter phase III clinical trial enrolled pts with histologically or cytologically confirmed unresectable locally advanced or metastatic pancreatic ductal adenocarcinomas with a WHO performance score of 0 or 1 and expected survival period of more than 3 months. Eligible pts will be randomized 1:1 to intervention group or control group and receive 4-6 cycles of KN046 (5mpk Q2W) or placebo combined with nab-paclitaxel (initial dose: 125mg/m^2 D1,8,15 Q4W) and gemcitabine (initial dose: 1000mg/m^2 D1,8,15 Q4W) followed by KN046 (5mpk Q2W) or placebo with gemcitabine (QW × 3, 1 week off) maintenance therapy. Treatment will continue until disease progression or intolerable toxicity, withdrawal of consent, loss to follow-up or death, end of study, whichever occurs first. The primary endpoint is overall survival (OS). Key secondary endpoints are ORR and progression free survival (PFS). PFS and ORR will be assessed independently per RECIST v1.1 at screening, every 8 weeks for 1 year and then every 12 weeks until disease progression. Tumor and blood samples will be collected at baseline and during study treatment for pharmacokinetic, immunogenicity and biomarker assessment. The first patient was enrolled in early February 2022. Clinical trial information: NCT05149326. Research Sponsor: Jiangsu Alphamab Biopharmaceuticals Co., Ltd.

TPS4190 **Poster Session**

Sequential first-line treatment with gemcitabine plus nab-paclitaxel (GA) followed by FOLFIRINOX (FFX) versus FFX alone in patients with metastatic pancreatic cancer (PC): GABRINOX-2 randomized phase 2 trial. *First Author: Fabienne Portales, Institut du Cancer de Montpellier (ICM), Univ Montpellier, Montpellier, France*

Background: PC is a major health concern worldwide and a deadly disease due to its high metastatic behavior. In recent years, incremental progresses have been made with the use of new chemotherapy (CT) regimen in the metastatic setting. Thus, both PRODIGE 4/ACCORD11 (Conroy T, et al. 2011) and MPACT (Von Hoff D, et al. 2013) phase III trials established 2 new standard-of-care in the first line treatment of metastatic PC (mPC), demonstrating a survival benefit over gemcitabine monotherapy, with the use of FFX or GA. In the phase I/II GABRINOX trial (Assenat E, et al. ESMO Open 2021), we reported that sequential GA followed by FFX provided a high overall response rate (ORR) (64.9%) and a promising median progression-free survival (PFS, 10.5 months) and median overall survival (OS, 15.1 months), together with acceptable toxicity and remarkably low severe neurotoxicity rate (gr.3: 5.3%). To follow up these encouraging results in a controlled study, we aimed at comparing our experimental GABRINOX regimen to control FFX in the GABRINOX-2 randomized phase 2 trial (NCT05065801). Our primary objective is PFS, and our secondary objectives are tolerance, ORR, disease-control rate, OS, and Quality-of-life. **Methods:** Main inclusion criteria were as follows: Patients (pts) in good condition (ECOG PS $\leq$ 1), aged from 18 to 75 yo, with histologically or cytological proven mPC and at least one measurable metastatic target. Pts should have not been treated with (adjuvant) chemotherapy in the last 6 months. Eligible pts are randomized (ratio 1:1) either in the standard FFX group or in the experimental GABRINOX group where a GA (gemcitabine 1000 mg/m^2 and Nab-paclitaxel 125 mg/m^2, day 1-8-15) cycle alternates after a 2-weeks rest with a FFX cycle. To detect an increase in median PFS from 6.4 to 10.5 months (HR = 0.61) with a 80% power and a 5% α risk, 130 events are required among a total population of 210 pts. PFS was defined as the length of time between randomization and the onset of 1st documented progression (RECIST 1.1 criteria) or death. The study of quality of life will use the EORTC QLQ-C30 and QLQ-PAN26 self-reported questionnaires at baseline and every 2 months up to 12 months and then at 16, 20 and 24 months. Circulating DNA tests will be carried out at baseline and every 2 months until progression. All numerical variables will be expressed as medians and 95% CI, while PFS and OS will be estimated using Kaplan-Meier method. Multivariate analyses will use Cox proportional hazard model. Enrolment started in late 2021 and 3 patients were included so far. Clinical trial information: NCT05065801. Research Sponsor: None.

TPS4191 **Poster Session**

Sequential treatment with gemcitabine/nab-paclitaxel (GA) and FOLFIRINOX (FFX) followed by stereotactic MRI-guided adaptive radiation therapy (SMART) in patients with locally advanced pancreatic cancer (LAPC): GABRINOX-ART phase 2, multicenter trial. *First Author: Fabienne Portales, Institut du Cancer de Montpellier (ICM), Univ Montpellier, Montpellier, France*

Background: LAPC represents a major challenge with no standardized chemotherapy (CT) and radiotherapy (RT) treatment. Phase 2 studies (LAPACT/NEOLAP) indicated efficacy of FFX and GA, although addition of conventionally fractionated RT remains controversial. Phase 3 LAPO7 trial obtained a reduction of progression free survival (PFS), albeit with no overall survival (OS) advantage. Since in metastatic pancreatic cancer we recently attained with GA/FFX sequential combination (GABRINOX) high objective response rate and promising OS with acceptable toxicity and no limiting neurotoxicity, we proposed in LAPC to complement GABRINOX with SMART, recently recognized beneficial in pancreatic tumors by a retrospective multicenter study (OS at 2 years) and our prospective registry study (dosimetric benefit of adaptation). In a first step (SEQ1), we will evaluate GABRINOX efficacy and select patients without progression for a second step (SEQ2), to evaluate feasibility and tolerance in patients without disease progression after SEQ1. Secondarily we will evaluate CT tolerance (SEQ1), acute toxicities and dosimetric results (SEQ2) and for both SEQ1+2, late toxicities, response to treatment, PFS, OS and quality of life (QoL). **Methods:** Naive patients with confirmed non-metastatic unresectable adenocarcinoma by centralized reading (WHO 0/1) and adequate organ function will receive in SEQ1 two cycles of GABRINOX, GA (1000 mg/m^2, 125 mg/m^2) on days 1, 8, and 15 followed by FFX on day 29 and 43. After 3-4 weeks, patients without progression or unacceptable toxicity will benefit from SMART (5 fractions of 10 Gy/day over 5 consecutive days). Specific dummy-run, contouring quality assurance and dosimetric plans will precede post-treatment monitoring every 6 weeks for 6 months for non-progressive patients and then every 2 months until progression: radiological assessment, biological markers (circulating tumor DNA) and QoL evaluation. Co-primary endpoints include success of SEQ1 (non-progression at 4 months, RECIST v1.1) and that of SEQ2 as absence of acute digestive non-toxicity rate > grade 3 (NCI-CTCAE v5.0) within 90 days. Based on Fleming design with maximal inefficacy (p_0) of 70% and 90% (α = 2.5% and β = 5%) we need 98 and 70 patients (SEQ1 and SEQ2), and total of 103 cases considering those entering in SEQ 2 (70%) and non-evaluable patients. Success rate, toxicities (by treatment sequences) and safety (System Organ Class) by patient and cycle will be considered while dosimetry will be correlated with gastro-intestinal toxicities. Median follow-up, OS and PFS will be expressed as medians and rates with 95% CI while QoL will be explored by QLQ-C30 and QLQ-PAN26 analyses using the time to definitive deterioration. From 2021, we included 5 patients (NCT04570943). Clinical trial information: NCT04570943. Research Sponsor: None.

TPS4192 **Poster Session**

Trial in progress: A randomized phase II study of pembrolizumab with or without defactinib, a focal adhesion kinase inhibitor, following chemotherapy as a neoadjuvant and adjuvant treatment for resectable pancreatic ductal adenocarcinoma (PDAC). *First Author: John Davelaar, Samuel Oschin Cancer Center, Cedars-Sinai Medical Center, Los Angeles, CA*

Background: PDAC is an aggressive cancer. It remains refractory to checkpoint inhibition because of its significant desmoplastic and immunosuppressive tumor microenvironment (TME). Focal adhesion kinase (FAK), a non-receptor tyrosine kinase, is involved in tumor progression in many cancers and appears to be a targetable master regulator of the TME in PDAC. FAK inhibition combined with anti-PD1 antibody has been shown to modulate pancreatic stellate cells and decrease immunosuppressive myeloid and T-reg cells, leading to increased CD8 infiltration and improved survival in PDAC mouse models. A recent single arm phase I study of defactinib, a FAK inhibitor, combined with pembrolizumab, an anti-PD1 antibody, and chemotherapy was shown to be safe, and two confirmed partial responses were observed in patients with microsatellite-stable disease. Furthermore, increased CD8 T cell infiltration was observed in metastatic biopsies. Given the promising preclinical data and efficacy signals, as well as safety of the phase I clinical trial, our current study aims to assess the translational and clinical effects of sequentially combined defactinib and pembrolizumab following neoadjuvant and adjuvant chemotherapy in patients with high-risk resectable PDAC. **Methods:** This study is a multi-center, two-arm, randomized, open label, phase II clinical trial of neoadjuvant and adjuvant immunotherapy with defactinib and pembrolizumab, following neoadjuvant standard of care (SOC) gemcitabine and nab-paclitaxel in subjects with high-risk resectable PDAC. The primary objectives aim to assess changes in CD8 T cell intratumoral infiltration utilizing multiplex IHC and the pathologic complete response rate with defactinib and pembrolizumab or pembrolizumab alone, following neoadjuvant chemotherapy. Secondary objectives include assessment of disease-free survival, overall survival, and safety. Translational exploratory objectives include evaluating stromal and immune signatures among treatment groups via multiplex IHC and RNA/DNA sequencing. 36 subjects will be randomly assigned to receive 400 mg defactinib PO BID and 200 mg pembrolizumab IV every 3 weeks (Arm A) or 200 mg pembrolizumab IV alone every 3 weeks (Arm B). After enrollment, subjects will undergo 2 cycles (~2 months) of standard neoadjuvant therapy of gemcitabine and nab-paclitaxel, followed by 2 cycles (6 weeks) of investigational treatment (Arm A or B) before surgical resection. Following surgery, subjects will receive SOC adjuvant chemotherapy followed by investigational treatment (Arm A or B) for 8 cycles (~24 weeks). Key inclusion criteria include: resectable PDAC, CA 19-9>200, no prior systemic treatment for PDAC, and ECOG PS $\leq$1. As of February 2022, 14 patients have been enrolled. Clinical trial information: NCT03727880. Research Sponsor: Merck, Conquer Cancer Foundation of the American Society of Clinical Oncology, U.S. National Institutes of Health.

TPS4193 **Poster Session**

Phase III study (daNIS-2) of the anti–TGF-β monoclonal antibody (mAb) NIS793 with nab-paclitaxel/gemcitabine (NG) versus NG alone in patients (pts) with first-line metastatic pancreatic ductal adenocarcinoma (mPDAC). *First Author: Eileen Mary O'Reilly, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Despite improving outcomes, current therapies for mPDAC have a modest impact on overall survival (OS) and new therapies are needed. PDAC is characterized by an abundance of intratumoral fibrosis, which may contribute to the lack of treatment efficacy and act as a mechanical barrier to effective penetration of therapeutics. TGF-β has a multifactorial role in tumorigenesis and maintaining an immunosuppressive tumor microenvironment (TME). Emerging evidence points to the role of TGF-β as a pivotal activator of cancer-associated fibroblasts that lead to the development of fibrotic networks. In preclinical models, TGF-β blockade alters the TME to facilitate an antitumor response, reduce stromal fibrosis, and augment the benefit of chemotherapy, providing rationale for combining TGF-β–targeting agents with chemotherapy. NIS793 is a potent, selective, human IgG2 mAb antagonist of TGF-β. This study investigates NIS793 in combination with NG vs NG alone in treatment-naïve pts with mPDAC. **Methods:** This is a phase III, randomized, double-blind, multicenter, two-arm study (NCT04935359) consisting of two stages: an initial safety run-in period followed by two-arm randomization. Eligible pts include adults with previously untreated mPDAC and an ECOG performance status $\leq$1. Pts with a tumor histology other than adenocarcinoma or with microsatellite instability-high tumors are ineligible. The aim of the safety run-in period is to assess the safety and tolerability of NIS793 + NG and confirm the recommended dose for the randomized phase of this study. Data will be analyzed once at least six evaluable pts have received NIS793 (intravenous [IV] 2100 mg every 2 weeks) + nab-paclitaxel (IV 125 mg/m^2 on Days 1, 8, and 15) + gemcitabine (IV 1000 mg/m^2 on Days 1, 8, and 15) for one 28-day cycle. Pts (N = 480) will be randomized 1:1 to NIS793 + NG or placebo + NG. Treatment will continue until unacceptable toxicity, disease progression, discontinuation by investigator or pt choice, death, or withdrawal of consent. The primary objective is to evaluate the OS of pts receiving NIS793 + NG vs NG alone; secondary objectives include assessing progression-free survival, the overall response rate, disease control rate, duration of response, and time to response (assessed locally per RECIST v1.1), as well as safety and tolerability, immunogenicity, pharmacokinetics, and patient-reported outcomes such as health-related quality of life. Efficacy will be assessed at screening, every 8 weeks for 1 year, and then every 12 weeks until disease progression. Blood samples will be taken at baseline and during treatment for pharmacokinetic and immunogenicity assessments. This study is ongoing and will enroll pts from approximately 149 sites across 28 countries. The first pt was treated on October 20, 2021. Clinical trial information: NCT04935359. Research Sponsor: Novartis Pharmaceuticals.

TPS4194 **Poster Session**

A phase Ib/II study of sotorasib combined with chemotherapy for second-line treatment of KRAS p. G12C–mutated advanced pancreatic cancer. *First Author: Devalingam Mahalingam, Northwestern University, Chicago, IL*

Background: Kirsten rat sarcoma viral oncogene homolog(*KRAS*) p.G12C mutation is an oncogenic driver mutation in several solid tumors. Sotorasib is a specific, irreversible, small molecule inhibitor of $KRAS^{G12C}$ that has demonstrated durable clinical benefit in NSCLC, with mild and manageable toxicities. Pancreatic ductal adenocarcinoma (PDAC) remains a leading cause of cancer-related death in the world, although recent advances in chemotherapeutic regimens for metastatic PDAC provide better clinical outcomes. *KRAS* p.G12C mutations are found in 1-2% of PDAC. Modest single agent activity of Sotorasib was observed in chemo-refractory PDAC patients (pts). Combination of Sotorasib with approved PDAC chemotherapy regimens is expected to enhance antitumor efficacy. This study is designed to evaluate safety, tolerability and efficacy of Sotorasib in combination with second line chemotherapy in pts with *KRAS*p.G12C mutated advanced PDAC who have progressed on first-line chemotherapy. **Methods:** This investigator initiated study run through Hoosier Cancer Research Network, is a phase Ib/II study evaluating Sotorasib in combination with either Liposomal Irinotecan/5-Fluorouracil/Leucovorin or Gemcitabine/nab-paclitaxel. Physician choice of chemotherapy based on first line chemotherapy regimen used. Histologically confirmed PDAC pts who have *KRAS* p.G12C mutation identified through tumor or blood based testing, progressed on first-line chemotherapy, adequate organ function and performance status are eligible. A safety lead-in will be conducted to evaluate the safety of Sotorasib at a dose of 960 mg in combination with each of the two chemotherapy regimens. A "3+3" dose de-escalation design will be used for each combination separately. All patients treated at the RP2D in the initial safety cohort will be evaluable for response and included in the first stage of Simon's two stage design. The phase II trial conducted at the RP2D follows Simon's two-stage "minimax" design. The trial is designed to test whether addition of Sotorasib to chemotherapy will improve the objective response rate (ORR), from 16% to 31%. In Stage 1, 22 evaluable patients will be enrolled, and the trial will be stopped if 3 or fewer of the 22 evaluable patients respond. If ≥ 4 responses are observed, an additional 28 patients will be enrolled in Stage 2, for a total of 50 evaluable patients. Up to 59 subjects will be enrolled across 15 academic cancer institutions in order to obtain the required number of 50 evaluable subjects, assuming 15% attrition rate. Primary endpoint is to determine the objective response rate (ORR) by RECIST 1.1. The secondary endpoint to evaluate safety, and further evaluate efficacy in terms of disease control rate, duration of response, progression-free survival and overall survival. Correlative endpoints will determine biomarkers based on analysis of blood and/or tumor on study. Clinical trial information: IND 159412. Research Sponsor: Amgen.

TPS4195 **Poster Session**

Phase Ib/IIa trial of CEND-1 in combination with neoadjuvant FOLFIRINOX-based therapies in pancreatic, colorectal, and appendiceal cancers (CENDIFOX). *First Author: Anup Kasi, University of Kansas Cancer Center, Westwood, KS*

Background: The efficacy of chemotherapy is often compromised due to poor penetration of drugs in solid tumors. The tumor microenvironment, which is characterized by dense extracellular matrix-rich stroma that creates a physical barrier to penetration of anti-cancer drugs, is especially pronounced in Pancreatic Ductal Adenocarcinoma (PDAC) and in peritoneal metastases from Colorectal/Appendiceal Adenocarcinoma. CEND-1 is a tumor-penetrating peptide (scientifically also known as iRGD) that has preclinically demonstrated to enhance the tumor penetration of chemotherapy agents through binding and activation of alphav-integrins and neuropilin-1 (NRP-1). The 2-step mechanism leads to a higher delivery and concentration of chemotherapeutics selectively in the tumor, while sparing normal tissue. Hence CEND-1 therapy has the potential to improve the efficacy of anti-cancer therapies and reduce side effects through increased tumor access, specificity, and sensitivity. We hypothesize that CEND-1 may become a powerful adjuvant that safely enhances standard anti-neoplastic therapy in the neoadjuvant setting for the above populations. **Methods:** A safety lead-in 6-9 patients (Phase Ib) will be followed by an open label, single arm, parallel (3 cohorts) Phase IIa study. A total of 50 patients (20 PDAC, 15 colorectal/appendiceal with peritoneal metastases, 15 oligometastatic colorectal) will be enrolled. A starting CEND-1 dose of 3.2 mg/kg in combination with the standard doses of FOLFIRINOX (+/- Panitumumab if RAS/RAF wild type) will be used for the safety lead-in. CEND-1 dose will be lowered for Phase IIa if > 1/6 patients experienced DLTs. Participants enrolled will receive standard doses of FOLFIRINOX q2w +/- Panitumumab q2w 6mg/kg IV q2w (14-day cycles) for Cycles 1-3. After a subsequent research biopsy, the CEND-1 + chemotherapy combo will be continued at RP2D q2w for cycles 4-6, followed by CEND-1 +/- Panitumumab ~72h prior to resection. Assessment of tumor response using RECIST v1.1 will be done every 3 cycles. Up to 10 patients may receive Panitumumab. Eligible Pts are untreated, newly diagnosed, resectable/borderline resectable PDAC or colorectal/appendiceal adenocarcinoma with peritoneal metastases or oligometastases eligible for cytoreductive surgery, as determined by multidisciplinary evaluation. Inclusion criteria also include ECOG PS 0-1, adequate organ function, measurable or evaluable disease. Primary objectives are safety and biological activity of CEND-1. Secondary objectives include ORR, RO resection rate, DFS, OS. Exploratory objectives include pathologic response, tissue immune response, EGFR expression, tumor tissue-to-plasma concentration of Panitumumab pre and post CEND-1 treatment. Enrollment to the CENDIFOX trial is currently ongoing. Clinical trial information: NCT05121038. Research Sponsor: KUCC IITSC EP Pilot Grant, CEND Therapeutics.

TPS4196 **Poster Session**

A phase II, open-label, pilot study evaluating the safety and activity of liposomal irinotecan (Nal-IRI) in combination with 5-FU and oxaliplatin (NALIRIFOX) in preoperative treatment of pancreatic adenocarcinoma: NEO-Nal-IRI study. *First Author: Sherise C. Rogers, Division of Medical Oncology, Department of Internal Medicine, The Ohio State University Comprehensive Cancer Center, Columbus, OH*

Background: Neoadjuvant treatment for potentially curable pancreatic cancer (PDAC) is increasing in acceptability, but a standard regimen has yet to be established. Multiple studies have demonstrated feasibility and effectiveness of the FOLFIRINOX (5-fluorouracil, leucovorin, oxaliplatin and irinotecan) regimen in the perioperative setting. However, FOLFIRINOX often requires dose modifications, delays and growth factor support due to excessive toxicity which can complicate care delivery when given pre-op. Liposomal irinotecan injection (Nal-IRI) is FDA approved in combination with 5-FU/LV with a well-tolerated safety profile in relapsed, refractory metastatic PDAC. The current study aims to substitute Nal-IRI for traditional irinotecan in the standard FOLFIRINOX regimen (NALIRIFOX) and to demonstrate safe and effective neoadjuvant delivery. **Methods:** This phase 2, open-label, multicenter single-arm study focuses on patients (pts) with operable PDAC without metastatic disease. Other key eligibility criteria include age ≥18 years, resectability confirmed by multiD GI tumor board (resectable vs. borderline), adequate cardiac, renal, hepatic function and ECOG performance status of 0 to 1. Pts receive NALIRIFOX regimen as per the table every 2 weeks for four months followed by disease reassessment. Pts who remain surgical candidates will undergo surgical resection within 4 to 8 weeks following last dose of therapy. The primary endpoint is to assess safety and feasibility of regimen in pre-op setting. Secondary endpoints include RO resection rate, clinical, biochemical and radiological response rate and patient-reported quality of life during treatment as measured by the NCI validated FACT-G scale. Enrollment continues to a maximum of 28 evaluable pts to demonstrate a reduction in historical 30-day post-op complication rate. Clinical trial information: NCT03483038. Research Sponsor: University of Florida Health Cancer Center and Ipsen Biopharmaceuticals, Inc.

NALIRIFOX regimen components given intravenously (IV) every 14 days.

Agent	Dose	Infusion Duration
Nal-IRI	50 mg/m2	90 min
Oxaliplatin	60 mg/m2	120 min

EVEREST: Everolimus for renal cancer ensuing surgical therapy—A phase III study (SWOG S0931, NCT01120249). *First Author: Christopher W. Ryan, Oregon Health & Science University, Knight Cancer Institute, Portland, OR*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

4501 **Oral Abstract Session**

Association between depth of response (DepOR) and clinical outcomes: Exploratory analysis in patients with previously untreated advanced renal cell carcinoma (aRCC) in CheckMate 9ER. *First Author: Cristina Suárez, Vall d'Hebron University Hospital, Barcelona, Spain*

Background: Among patients (pts) with untreated aRCC in the CheckMate 9ER trial, superior progression-free survival (PFS; hazard ratio [HR], 0.56) and overall survival (OS; HR, 0.70) were maintained, and objective response and complete response (CR) rates were doubled for nivolumab plus cabozantinib (N+C) vs sunitinib (SUN) with extended 25.4 mo minimum (32.9 mo median) follow-up. This exploratory analysis evaluated the relationship between DepOR and clinical outcomes in CheckMate 9ER. **Methods:** Eligible pts received N (240 mg) every 2 weeks plus C (40 mg) once daily or SUN (50 mg once daily; 4 weeks of each 6-week cycle). In this analysis, DepOR subgroups were based on best overall response (blinded independent central review [BICR] per RECIST v1.1) and best tumor reduction threshold, as follows: CR; partial response subdivided by a tumor reduction of ≥80%–<100% (PR1); ≥60%–<80% (PR2); or ≥30%–<60% (PR3); stable disease (SD); and progressive disease (PD). PFS (per BICR) and OS by DepOR subgroups were analyzed after a 6-mo post-randomization landmark. Treatment-related adverse events (TRAEs) were assessed in DepOR subgroups. **Results:** Of 323 and 328 pts randomized to N+C or SUN, 236 and 157 pts were progression-free and alive and 293 and 253 pts were alive at the 6-mo landmark and were categorized by DepOR subgroup. Overall, greater proportions of pts receiving N+C had deeper responses vs SUN (CR, PR1, PR2; Table). Deeper responses with N+C were associated with improved 12-mo PFS rate vs SUN for CR (94.9% vs 82.4%), PR1 (81.3% vs 37.5%), and PR2 (72.1% vs 53.2%). In both arms, increasingly deeper response led to better OS outcome; yet OS rates and medians were comparable between arms for CR, PR1, PR2, and PR3 (Table). No meaningful patterns for overall TRAE rates by DepOR subgroup were identified in either arm. **Conclusions:** In CheckMate 9ER, more pts receiving N+C achieved deeper responses vs SUN. Deeper responses were generally associated with improved PFS and OS. Clinical trial information: NCT03141177. Research Sponsor: Bristol Myers Squibb.

4502 **Oral Abstract Session**

The relationship between health-related quality of life (HRQoL) and clinical outcomes in patients with advanced renal cell carcinoma (aRCC) in CheckMate (CM) 214. *First Author: David Cella, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL*

Background: In CM 214, when compared to sunitinib (S), nivolumab plus ipilimumab (N+I) was associated with both clinical benefit and improved HRQoL as first-line treatment for intermediate/poor (I/P)-risk patients (pts). This analysis investigates the direct association between HRQoL and clinical outcomes in aRCC pts. **Methods:** I/P-risk population included 425 and 422 pts in the N+I and S arms, respectively. HRQoL was assessed using the FKSI-19 (Total Score and Disease Related Symptoms [DRS]). Three separate analyses (A, B, and C) were conducted. A: Changes in individual item scores from baseline to last assessment prior to progression were descriptively assessed. B: For each FKSI-19 score, multivariable Cox regression, adjusted for treatment and stratification factors, was used to evaluate the prognostic significance of baseline and time-dependent HRQoL scores in separate models. Hazard ratios (HR) were calculated based on the risk of death per improvement in HRQoL scores, defined using the clinically meaningful change threshold (5 points for FKSI-19 Total and 3 points for DRS). Pts with overall survival (OS) events were censored if their survival event was not within 12 weeks of the last available HRQoL assessment. C: The association between HRQoL change status (ie, improvement or maintenance vs. worsening from baseline in the FKSI-19 Total Score), irrespective of treatment arm, and OS was further assessed using a landmark analysis at the month 6 (mo-6) landmark. Additional landmark time points were explored in sensitivity analysis. **Results:** Items related to fatigue and perceived bother of the side-effects of treatment had the largest percentage of pts worsening prior to progression. In both baseline and time-dependent HRQoL analyses, OS was independently associated with both HRQoL measures. Higher (better) baseline scores were associated with significantly reduced risk of death (HR [95% CI] for FKSI-19 Total Score and DRS was 0.83 [0.80-0.87] and 0.80 [0.76-0.84], respectively). Every 5-point increase (improvement) in FKSI-19 Total Score and 3-point increase in DRS was associated with a 31% decreased risk of death ($P < 0.01$). At mo-6, 301 pts showed improvement or maintenance in HRQoL. Pts with improved/stable HRQoL had a 52% reduction in risk of death compared to pts who had worsened (HR 0.48 [95% CI: 0.39-0.59]). **Conclusions:** Results demonstrate there is an association between HRQoL and clinical outcomes in CM 214. Baseline HRQoL scores are a potential predictor for survival in aRCC, and HRQoL changes are informative for pts' expected survival. HRQoL change status at mo-6 was significantly and positively associated with subsequent survival. Thus, patient-reported outcomes may be useful for both describing pt experience in clinical trials and providing valuable clinical insights during routine practice. Clinical trial information: NCT02231749. Research Sponsor: Supported by Bristol Myers Squibb in collaboration with Ono Pharmaceutical.

CALYPSO: A three-arm randomized phase II study of durvalumab alone or with savolitinib or tremelimumab in previously treated advanced clear cell renal cancer. *First Author: Thomas Powles, Barts ECMC, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

4504 **Oral Abstract Session**

Cabozantinib (C) in combination with atezolizumab (A) in urothelial carcinoma (UC): Results from Cohorts 3, 4, 5 of the COSMIC-021 study. *First Author: Sumanta K. Pal, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: C, a multitargeted receptor tyrosine kinase inhibitor (TKI), promotes an immune-permissive environment that may enhance response to immune checkpoint inhibitors (ICIs). COSMIC-021, a multicenter phase 1b study, is evaluating C + A (anti–PD-L1 therapy) in various solid tumors (NCT03170960). C + A demonstrated encouraging clinical activity in cohort 2 of COSMIC-021 in patients (pts) with UC previously treated with platinum-containing chemotherapy (chemo) (Pal S et al. ASCO 2020. Abstract 5013). Outcomes of C + A from 3 other UC cohorts (C3, C4, C5) are presented. **Methods:** Pts with inoperable locally advanced/metastatic UC with transitional cell histology and ECOG PS 0–1 were eligible. Pts enrolled in C3 and C4 had no prior therapy and were cisplatin-based chemo ineligible (C3) or eligible (C4). C5 enrolled pts with one prior ICI and no prior VEGFR-TKI therapy. Pts received C 40 mg PO QD and A 1200 mg IV Q3W. CT/MRI scans were performed Q6W for first year and Q12W thereafter. The primary endpoint is objective response rate (ORR) per RECIST v1.1 by investigator. Other endpoints: safety, duration of response (DOR), PFS, and OS. **Results:** Thirty pts each were enrolled in C3 and C4, and 31 in C5. Baseline characteristics for C3, C4, and C5, respectively: median age, 74 y, 66 y, 68 y; male, 67%, 73%, 55%; ECOG PS 1, 63%, 57%, 74%; lung/liver metastasis; 33%/17%, 40%/20%, 58%/23%; ≥3 tumor sites, 30%, 43%, 45%; bladder as primary site, 67%, 70%, 71%. As of Nov 30, 2021, the median follow-up for C3, C4, and C5 was 27.9, 19.1, and 32.9 mo, respectively, with 1, 6, and 1 pts on treatment. C + A demonstrated clinical benefit across all cohorts (Table). Most common treatment-related adverse events (TRAEs) of any grade across C3, C4, and C5, respectively, were diarrhea (43%, 33%, 35%), nausea (27%, 17%, 26%), fatigue (27%, 27%, 48%), and decreased appetite (33%, 27%, 39%); grade 3/4 TRAEs occurred in 63%, 43%, and 45%, and there was no grade 5 TRAE. **Conclusions:** C + A demonstrated encouraging clinical activity with manageable toxicity in inoperable locally advanced/metastatic UC as first-line systemic therapy in cisplatin-based chemo eligible/ineligible pts and as second- or later line in pts who received prior ICI. Clinical trial information: NCT03170960. Research Sponsor: Exelixis, Ipsen, Takeda.

4506 **Oral Abstract Session**

Cell-free DNA methylation as a predictive biomarker of response to neoadjuvant chemotherapy for patients with muscle-invasive bladder cancer in SWOG S1314. *First Author: Yi-Tsung Lu, Division of Medical Oncology, Department of Medicine, Keck School of Medicine and Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA*

Background: Neoadjuvant chemotherapy is the standard of care in muscle-invasive bladder cancer patients. However, treatment is intense, the overall benefit is small, and there is no established marker to identify patients who benefit most. The aim of the study is to characterize cell-free DNA (cfDNA) methylation from patients receiving neoadjuvant chemotherapy in SWOG S1314, a prospective cooperative group trial, and to correlate the methylation signatures with pathologic response. **Methods:** Blood samples were collected prospectively from 73 patients before and during standard neoadjuvant chemotherapy. At radical cystectomy, pathologic response was documented. Plasma cfDNA was profiled using Infinium MethylationEPIC BeadChip array. Differential methylation between pathologic responders (≤pT1N0M0) and non-responders was analyzed, and a Random Forest model was used to generate a classifier predictive of treatment response. **Results:** Using pre-chemotherapy plasma cfDNA, we developed a methylation-based response score (mR-score) predictive of pathologic response. The mR-score also could be calculated using plasma samples collected after the first cycle of neoadjuvant chemotherapy, resulting in a similar predictive ability. Furthermore, we used cfDNA methylation data to calculate the circulating bladder DNA fraction, which had a modest but independent predictive ability for treatment response. When we combined the mR-score and circulating bladder DNA fraction, we successfully predicted pathologic response outcomes in 79% of patients based on their plasma collected before chemotherapy and after 1 cycle of chemotherapy. **Conclusions:** Our study provides proof of concept that cfDNA methylation may be used to predict treatment response in bladder cancer patients receiving neoadjuvant chemotherapy. Clinical trial information: NCT02177695. 4507 **Oral Abstract Session**

TRUCE-02: An open label, single-arm, phase II study of tislelizumab combined with nab-paclitaxel for high-risk non-muscle-invasive urothelial bladder carcinoma. *First Author: HaiTao Wang, Tianjin Medical University, Tianjin, China*

Background: Pts with multiple or tumors with large invasion areas which are un-completely-resectable through TURBT would be recommended radical cystectomy in the clinical treatment. The KEYNOTE-057 study has illuminated the efficiency of immune checkpoint inhibitors monotherapy in HR-NMIBC pts, with acceptable adverse events (AEs). However, the role of PD-1/PD-L1 inhibitor in combination with chemotherapy in NMIBC pts remains unclear. We report preliminary treatment efficiency, safety data, and exploratory work of TRUCE-02 trial. **Methods:** TRUCE-02 is a phase II study for NMIBC pts with uncompletely resectable tumour by TURBT. The primary endpoint was complete response(absence of non-muscle-invasive bladder cancer or progressive disease). Pts that meet the criteria would receive tislelizumab 200mg on days 1 plus paclitaxel 200mg on days 2 every 3 weeks (Q3W) x 3 or 4 cycles followed by a comprehensive assessment including pathology, urine cytology, and imageology. Meanwhile, biomarker analyses included programmed death-ligand 1 (PD-L1) expression using the combined positive score (CPS; Dako 22C3 pharmDx assay) and whole transcriptome RNA sequencing of the tumor. **Results:** Between July 2020 and January 2022, 54 pts were enrolled. 42 pts have completed whole 3 or 4 treatment cycles and reached the primary endpoint. 23 pts achieved CR condition (56%, 95%CI, 43.6% and 74.4%). ORR of 60% (N=25/42, 95%CI, 45.2% and 74.8%). As a secondary endpoint, 33 pts remain cystectomy-free condition (78.6%, 95%CI, 66.2% and 91%). Grade 3-4 AEs were lower than 2%. Urine cytology showed its diagnostic efficiency of 68.42% (95%CI, 61.3% and 75.6%), urine FISH showed a diagnostic efficiency of 45.71% (95%CI, 37.7% and 53.4%) before pathological assessment. As for PD-L1 expression, 47.3% (N = 9/19) of response pts (CR+PR) showed positive, 50% (N = 5/10) of un-response pts (PD+SD) showed positive. We also found out through sequencing results that AR, TCF7L2 might be underlying markers that predict adverse outcomes for pts in this crew. HRR mutation may predict a positive prognosis and mutations in NMIBC which might predict the prognosis of this treatment plan. **Conclusions:** Tislelizumab with nab-paclitaxel represents a novel treatment option with a satisfactory benefit in treating NMIBC. PD-L1 expression has no obvious correlation with the efficiency of this treatment plan. WGS result also showed that there are mutation markers that may predict whether pts would benefit from this treatment plan. Clinical trial information: NCT04730232. Research Sponsor: The Natural Science Foundation Project of Tianjin (grant no. 18PTLCSY00010), Other Foundation.

	Grade (counts)

Final clinical results of pivotal trial of IL-15RαFc superagonist N-803 with BCG in BCG-unresponsive CIS and papillary nonmuscle-invasive bladder cancer (NMIBC). *First Author: Karim Chamie, Department of Urology, University of California-Los Angeles, Los Angeles, CA*

Background: Patients with NMIBC CIS unresponsive to BCG have limited treatment options. N-803 (Anktiva) is a mutant IL-15-based immunostimulatory fusion protein complex (IL15RaFc) that promotes proliferation and activation of natural killer (NK) cells and CD8+ T cells, but not regulatory T cells. Phase 1b data in BCG-naïve patients with NMIBC demonstrate that intravesical administration of N-803 with BCG induced complete response in all patients, without recurrences for the study duration of 24 months. Pembrolizumab was approved in 2020 with a 41% complete response (CR) rate in a single arm phase 2 trial of 96 patients. We report data on 160 subjects from an open-label, 3 cohort multicenter study (QUILT 3.032) of intravesical BCG plus N-803 in patients with BCG-unresponsive high-grade NMIBC (NCT03022825). **Methods:** All treated patients received intravesical N-803 plus BCG, consistent with the standard induction/maintenance treatment schedule. The primary endpoint for Cohort A (CIS) is incidence of CR of CIS at any time. The primary endpoint for Cohort B (Papillary) is disease-free rate (DFS) at 12 months. **Results:** To date, we enrolled 160 patients (83 CIS, 77 Papillary). In the overall population, median age is 72.3 years, 81% male, with mean number of prior TURBT = 4. Median number of prior BCG doses = 12. CIS patients have a CR rate of 71% (59/83), with a mediation duration of CR of 24.1 months in responders; 91% avoided cystectomy and 96% 24 month bladder cancer specific progression free survival (defined as progression to MIBC). Papillary patients have a 57% 12 month DFS rate, 48% 24 month DFS rate, and 95% avoided cystectomy. Median time to cystectomy in responders (N = 4) is 12.9 months versus 7.8 in non-responders (N = 8) for a 5.1 month delay in cystectomy. PK data shows no systemic levels of N-803; activity is confined to the bladder. Low grade treatment related AEs (grade 1-2) include dysuria (22%) , pollakiurua (19%), hematuria (18%), fatigue (16%), and urgency (12%), all other AEs were seen at 7% or less. No treatment related grade 4 or 5 AE were seen. No SAE's were considered treatment related. No immune related SAE's have been seen. **Conclusions:** In 160 patients with BCG-unresponsive NMIBC, there is a 99% bladder cancer specific overall survival at 2 years. In CIS patients 71% CR rate with 24.1 months median duration of response, and 53% DFS rate at 18 months in Papillary disease. Cystectomy was avoided in over 90% of patients with 2 years of follow-up. The efficacy and safety profile of N-803+BCG exceeds that of other available intravesical and systemic options for BCG-unresponsive NMIBC. Clinical trial information: NCT03022825. Research Sponsor: ImmunityBio.

4509 **Poster Discussion Session**

Phase 1 LITESPARK-001 (MK-6482-001) study of belzutifan in advanced solid tumors: Update of the clear cell renal cell carcinoma (ccRCC) cohort with more than 3 years of total follow-up. *First Author: Eric Jonasch, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Hypoxia-inducible factor 2α (HIF-2α) is a key oncogenic driver in RCC. Antitumor activity of the HIF-2α inhibitor belzutifan has been observed in RCC and is approved for treatment in patients (pts) with VHL disease who require therapy for associated RCC, CNS hemangioblastomas, or pNETs not requiring immediate surgery. Previous data from the phase 1 LITESPARK-001 trial (NCT02974738) designed to evaluate belzutifan in heavily pretreated RCC showed durable antitumor activity and an acceptable safety profile. After more than 3 years of follow-up for pts with ccRCC still receiving treatment, updated data are presented. **Methods:** Pts enrolled in the ccRCC cohort were previously treated with ≥1 therapy, had RECIST-measurable disease, ECOG PS score of 0 or 1, adequate organ function, and life expectancy of ≥6 months. Pts received oral belzutifan 120 mg once daily. The primary end point was safety. Secondary end points were ORR, DCR (CR + PR + SD), PFS, and DOR per RECIST v1.1 by investigator. The data cutoff date was July 15, 2021. **Results:** Of 55 pts enrolled in the ccRCC cohort, 9 (16%) remain on treatment as of the data cutoff date of July 15, 2021; the primary reason for discontinuation was progressive disease (n = 34; 62%). Pts received a median of 3 prior therapies (range, 1-9); 39 (71%) received prior VEGF and immunotherapy. Pts were followed while on treatment and for 30 days after the last dose for a median of 41.2 months (range, 38.2-47.7). Twenty-two pts (40%) experienced grade 3 TRAEs. The most common (≥10%) grade 3 TRAEs were anemia (n = 13; 24%) and hypoxia (n = 7; 13%). There were no grade 4 or 5 TRAEs. ORR was 25%, with 1 confirmed CR (2%) and 13 PRs (24%); DCR was 80%. Median DOR was not reached (range, 3.1+ to 37.9+ months); 8 of 14 responding pts (57%) remain in response as of the data cutoff date. Per IMDC risk, 4 of 13 pts with favorable risk achieved response (ORR = 31%; all PRs) and 10 of 42 pts with intermediate/poor risk achieved response (ORR = 24%; 1 CR, 9 PRs). DCR was 92% for pts with favorable risk and 76% for pts with intermediate/poor risk. For pts who received prior VEGF and immunotherapy, 8 of 39 pts achieved response (ORR = 21%; 1 CR; 7 PR); DCR was 74%. For the 16 pts who did not receive prior VEGF/immunotherapy, 6 achieved response (ORR = 38%; all PRs); DCR was 94%. Median PFS for the total cohort was 14.5 months (95% CI, 7.3-22.1); PFS rate at 156 weeks (~36 months) was 34%. **Conclusions:** As seen after a median follow-up of > 3 years for pts still receiving treatment, belzutifan monotherapy continued to show a high rate of disease control and durable responses in previously treated pts with advanced ccRCC. Belzutifan exhibited a favorable safety profile, and no new safety signals were observed. In several phase 3 studies, belzutifan is being evaluated as monotherapy and combined therapy for ccRCC. Clinical trial information: NCT02974738. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Characterization of the microbial resistome in a prospective trial of CBM588 in metastatic renal cell carcinoma (mRCC) offers mechanism for interplay between antibiotic (abx) use and immune checkpoint inhibitor (ICI) activity. *First Author: Nazli Dizman, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: The negative association between ICI response and abx therapy is well defined (Derosa *et al* Cancer Discov 2021). Paradoxically, a retrospective assessment of the live bacterial product (LBP) CBM588 in patients (pts) with advanced lung cancer showed improved outcome with ICIs when the combination of CBM588 and abx (as compared to CBM588 alone) was employed (Tomita *et al* Cancer Immunol Res 2020). We postulated that the microbial resistome (genes encoding antimicrobial resistance) could shift in a manner with CBM588 therapy that facilitated ICI response. **Methods:** Pts with newly diagnosed mRCC with clear cell and/or sarcomatoid histology and intermediate/high risk disease per IMDC criteria were randomized to nivolumab/ipilimumab (nivo/ipi) or nivo/ipi/CBM588 in a 1:2 ratio. Stool samples were collected at baseline and week 12. Whole-metagenome sequencing was performed to analyze stool microbiome composition. Abx resistance genes (RGs) were inferred using publicly available database (McArthur *et al*. Antimicrob Agents Chemother 2013), and groups of abx RGs for various classes of abx were characterized. Wilcoxon signed-rank test was used for comparison of abx RG abundance between baseline and week 12 in each treatment arm and in responders (R) and non-responders (NR). **Results:** The study enrolled 30 pts, with the final analysis including 29 eligible pts (median age: 66 years, M:F 21:8, nivo/ipi: 19 pts, nivo/ipi/CBM588:10 pts). Objective response was 20% and 58% in nivo/ipi and nivo/ipi/CBM588 arms, respectively. The overall abundance of abx RGs remained unchanged between baseline and week 12 in pts receiving nivo/ipi alone. In contrast, a decrease in abx RGs was observed in pts receiving nivo/ipi with CBM588 arm from baseline to week 12 ($p = 0.042$ in Rs; $p = 0.078$ in NRs). More specifically, nivo/ipi/CBM588 treatment led to a significant reduction in fosfomycin RGs and nitroimidazole (e.g., metronidazole) RGs in both pts with R ($p = 0.019$ and 0.042, respectively) and NR ($p = 0.031$ and $p = 0.031$, respectively). A multitude of other clinically relevant abx RGs were downregulated in pts receiving CBM588, including those mediating resistance to glycopeptide (e.g., vancomycin) and lincosamide (e.g., clindamycin) abx. **Conclusions:** In the first interrogation of the resistome in mRCC, we demonstrate that CBM588 decreases abx RGs associated with multiple commonly used classes of abx. Abx clear commensals and increase pathogenic (abx resistant) bacteria in the gut. Based on our data, we formulate the hypothesis that combining abx with CBM588 may decrease potentially pathobionts and favor butyrogenic species, thereby improving CPI response. Clinical studies using CBM588 with abx priming may be warranted. Clinical trial information: NCT03829111. Research Sponsor: The Gateway Foundation.

A phase 1b/2 study of batiraxcept (AVB-S6-500) in combination with cabozantinib in patients with advanced or metastatic clear cell renal cell (ccRCC) carcinoma who have received front-line treatment (NCT04300140). *First Author: Neil J. Shah, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: AXL is up-regulated by hypoxia-inducible factor-1 signaling in both VHL-deficient and hypoxic tumor cells and plays a critical role in the metastatic phenotype of ccRCC. Batiraxcept is a recombinant fusion protein containing an extracellular region of human AXL combined with the human immunoglobulin G1 heavy chain (Fc), demonstrating highly potent, specific AXL inhibition. **Methods:** Batiraxcept at doses of 15 and 20 mg/kg, plus cabozantinib 60 mg daily, was evaluated using a 3+3 dose escalation study design. The primary objective was safety; secondary and exploratory objectives included identification of the recommended phase 2 dose (RP2D), overall response rate (ORR), and duration of response (DOR). Correlation of serum soluble AXL (sAXL)/GAS6 with ORR was evaluated. Key eligibility criteria include previously treated (2L+) ccRCC patients; prior treatment with cabozantanib was not allowed. sAXL/GAS6 was evaluated at baseline. **Results:** Data as of 4-February-2022, Phase 1b enrolled 26 patients, 16 patients treated with 15 mg/kg and 10 patients with 20 mg/kg dose of batiraxcept. Baseline characteristics: median age 60 (40-81); male 22 (85%); median prior line of therapy 1 (1-5); IMDC risk group of favorable 6 (23%); prior VEGF inhibitor 15 (58%); 100% with prior immunotherapy. At median follow up of 4.9 months, 92% (n=24) patients remained on the study. No dose limiting toxicities were observed at either 15 mg/kg or 20 mg/kg dose. Batiraxcept and cabozantinib related adverse events (AEs) occurred in 17 subjects (65%). Most common related AE include decreased appetite 31% (n=8), diarrhea and fatigue 23% (n=6). Grade 3 related AEs occurred in 4 patients (15%) including diarrhea, thromboembolism, hypertension, small bowel obstruction, and thrombocytopenia (n=1, 4% each) being most common. No grade 4 or 5 related AEs were observed. The ORR was 46% (n=12, partial response [PR]; Table). No patients had primary progressive disease. Among the patients who had baseline sAXL/GAS6 ratio of ≥ 2.3, the ORR was 67% (12/18). Regardless of baseline sAXL/GAS6 ratio, 3-month DOR was 100%; and 6-month progression free survival was 79%. Batiraxcept PK levels were similar across both doses and GAS6 levels suppressed through the dosing period. **Conclusions:** Batiraxcept plus cabozantinib is well tolerated. The RP2D of batiraxcept was identified as 15 mg/kg. Early efficacy signals were observed including 100% DOR at 3 months. Baseline sAXL/GAS6 may serve as a potential biomarker to enrich the population. Clinical trial information: NCT04300140. Research Sponsor: Aravive, Inc.

	Entire cohort N=26 (%)	Batiraxcept 15 mg/kg cohort N=16 (%)	Batiraxcept 20 mg/kg cohort N=10 (%)

Adjuvant pembrolizumab for postnephrectomy renal cell carcinoma (RCC): Expanded efficacy analyses from KEYNOTE-564. *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: The randomized, double-blind, phase 3 KEYNOTE-564 study (NCT03142334) met its primary end point of disease-free survival with adjuvant pembrolizumab versus placebo after nephrectomy in patients with localized RCC who are at increased risk for recurrence. Extended follow-up (30-month median follow-up) continued to support the benefit of adjuvant pembrolizumab. We describe additional efficacy analyses of time to first subsequent drug treatment or any-cause death (TFST) and time from randomization to progression on next line of therapy or any-cause death (PFS2). **Methods:** Patients with histologically confirmed clear cell RCC, with intermediate-high or high risk for recurrence (pT2, grade 4 or sarcomatoid, N0, M0; or pT3-4, any grade, N0 M0; or pT any stage, any grade, N+ M0) after nephrectomy, or after nephrectomy and resection of metastatic lesions (M1 NED), were randomly assigned 1:1 to receive pembrolizumab 200 mg IV or placebo Q3W for up to 17 cycles (~1 y). Exploratory analyses of TFST and PFS2 were conducted. The Kaplan-Meier method was used to estimate TFST and PFS2. Hazard ratios (HRs) were estimated using a Cox regression model. **Results:** Of 994 patients, 496 were randomly assigned to receive pembrolizumab and 498 to placebo. Median time from randomization to the data cutoff date (June 14, 2021) was 30.1 months (range, 20.8-47.5). Overall, 67 patients (13.5%) in the pembrolizumab group and 99 patients (19.9%) in the placebo group received ≥1 line of subsequent anticancer drug therapy. Of patients who received ≥1 line of subsequent drug therapy, most in the pembrolizumab group (90.0% [60/67]) and placebo group (85.9% [85/99]) received a VEGF/VEGFR-targeted therapy; 23.9% of patients (16/67) in the pembrolizumab group and 59.6% (59/99) in the placebo group received an anti–PD-1/PD-L1 agent. Seventy-seven TFST events were observed in the pembrolizumab group; 110, in the placebo group. Compared with placebo, adjuvant treatment with pembrolizumab delayed TFST (HR, 0.67; 95% CI, 0.50-0.90; medians not reached). A total of 108 PFS2 events were observed, 40 (8.1%; 12 death events and 28 progression events) in the pembrolizumab group and 68 (13.7%; 14 death events and 54 progression events) in the placebo group. PFS2 was also delayed with pembrolizumab compared with placebo (HR, 0.57; 95% CI, 0.39-0.85; medians not reached). **Conclusions:** Treatment with adjuvant pembrolizumab reduced risk for TFST and PFS2 compared with placebo. Results of this exploratory analyses suggest sustained clinical benefit of adjuvant pembrolizumab and support the use of adjuvant pembrolizumab after nephrectomy as standard of care for patients with localized RCC at increased risk for recurrence. Clinical trial information: NCT03142334. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

4513 **Poster Discussion Session**

Pembrolizumab (pembro) plus axitinib (axi) versus sunitinib as first-line therapy for advanced clear cell renal cell carcinoma (ccRCC): Analysis of progression after first subsequent therapy in KEYNOTE-426. *First Author: Thomas Powles, Barts Health NHS Trust and the Royal Free NHS Foundation Trust, Barts Cancer Institute, and Queen Mary University of London, London, United Kingdom*

Background: The randomized, open-label, phase 3 KEYNOTE-426 study (NCT02853331) met its primary and key secondary end points of improved OS, PFS, and ORR with pembro + axi versus sunitinib as first-line treatment for patients with advanced ccRCC. Extended follow-up (42.8-mo median follow-up) continued to show the superior efficacy of pembro + axi versus sunitinib in this patient population. We describe the results of PFS2 for all randomly assigned patients and across IMDC risk categories. **Methods:** Treatment-naive patients with advanced ccRCC, Karnofsky Performance Status Scale score ≥70% and measurable disease per RECIST v1.1 were randomly assigned 1:1 to receive pembro 200 mg IV every 3 weeks for up to 35 doses (~2 y) + axi 5 mg orally twice daily or sunitinib 50 mg orally once daily on a 4-wk on/2-wk off schedule. The end point of this exploratory analysis was PFS2, defined as time from randomization to progression after first subsequent therapy or any-cause death. The Kaplan-Meier method was used to estimate PFS2 and hazard ratios were estimated using a Cox regression model. **Results:** Of 861 patients, 432 were assigned to receive pembro + axi; 429, to sunitinib. Median time from randomization to the database cutoff date (January 11, 2021) was 42.8 mo (range, 35.6-50.6). Overall, 47.2% of patients (204/432) in the pembro + axi arm and 65.5% of patients (281/429) in the sunitinib arm received ≥1 line of subsequent anticancer therapy. For patients who received subsequent therapy, anti–PD-1/PD-L1 agents were the first subsequent treatment for 11.3% of patients (23/204) in the pembro + axi arm and 54.8% of patients (154/281) in the sunitinib arm. In the pembro + axi arm, 82.8% of patients (169/204) received a VEGF/VEGFR inhibitor as first subsequent therapy, as did 43.4% (122/281) in the sunitinib arm. PFS2 results are displayed in the Table. **Conclusions:** In this exploratory analysis, PFS2 was longer for patients randomized to pembro + axi compared to sunitinib. Results were consistent across IMDC risk groups. These data support use of pembro + axi for the first-line treatment of patients with advanced ccRCC. Clinical trial information: NCT02853331. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Impact of subsequent therapies in patients (pts) with advanced renal cell carcinoma (aRCC) receiving lenvatinib plus pembrolizumab (LEN + PEMBRO) or sunitinib (SUN) in the CLEAR study. *First Author: Martin H Voss, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: In the open-label, randomized, phase 3 CLEAR study, LEN + PEMBRO had significant PFS (primary endpoint) and OS (key secondary endpoint) benefits over SUN among pts with aRCC in the 1L setting (Motzer 2021, *NEJM*). We evaluated PFS on next-line therapy ("PFS2") and explored the effect of subsequent anticancer therapy on OS in the LEN + PEMBRO and SUN treatment arms of CLEAR. **Methods:** PFS2 was defined as time from randomization to disease progression (as assessed by investigator) on next-line treatment or death from any cause (whichever occurred first). PFS2 was evaluated in all pts randomly assigned to LEN 20 mg orally QD + PEMBRO 200 mg IV Q3W (n=355) or SUN 50 mg orally QD (4 wks on/2 wks off) (n=357) using Kaplan-Meier estimates, and compared between treatment arms via a log-rank test stratified by geographic region and MSKCC prognostic groups. The HR and corresponding CI were estimated using the Cox regression model with Efron's method for ties, using the same stratification factors. A post hoc analysis accounting for the effect of subsequent anticancer therapy on OS (time from randomization to death from any cause) in the LEN + PEMBRO and SUN arms using 2-stage estimation was conducted. **Results:** Among pts who received subsequent anticancer therapy in the LEN + PEMBRO (n=117 pts) and SUN (n=206 pts) arms (Table), median time to next-line therapy was 12.2 mos (range 1.45–37.36) and 6.4 mos (range 0.39–28.52), respectively. Median duration of first subsequent anticancer therapy was 5.2 mos (range 0.10–30.23) in the LEN + PEMBRO arm and 6.8 mos (range 0.03–30.72) in the SUN arm. Among all pts, PFS2 was longer with LEN + PEMBRO than with SUN (median not reached vs 28.7 mos; HR, 0.50; 95% CI 0.39–0.65; nominal $P<0.0001$); PFS2 rates at 24 and 36 mos are in the Table. The unadjusted OS HR for LEN + PEMBRO vs SUN (from the primary analysis [Motzer 2021, *NEJM*]) was 0.66 (95% CI 0.49–0.88); the HR for OS adjusted for subsequent therapy was 0.54 (bootstrap 95% CI 0.39–0.72). **Conclusions:** LEN + PEMBRO had a statistically significant and clinically meaningful benefit over SUN in the CLEAR study. These findings remained consistent after accounting for subsequent therapies, as evidenced by prolonged PFS2 and adjusted OS. Results further support LEN + PEMBRO as a standard of care in 1L aRCC. Clinical trial information: NCT02811861. Research Sponsor: This study was sponsored by Eisai Inc., Nutley, NJ, USA, and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Perioperative chemoimmunotherapy with durvalumab for operable muscle-invasive urothelial carcinoma (MIUC): Primary analysis of the single arm phase II trial SAKK 06/17. *First Author: Richard Cathomas, Division of Oncology, Cantonal Hospital Graubunden, Chur, Switzerland*

Background: SAKK 06/17 investigated the addition of perioperative immunotherapy with the anti-PD-L1 antibody durvalumab (Durva) in the multimodality treatment of resectable MIUC. While most similar trials had a primary endpoint of pathological complete remission rate, this study evaluated the clinically more relevant primary endpoint of event-free survival (EFS) at 2 years (yrs). **Methods:** SAKK 06/17 was an open-label, single-arm phase II study including 61 cisplatin-fit patients (pts) with stage cT2-T4a cN0-1 operable MIUC. Pts received four cycles of neoadjuvant Cis/Gem q3w in combination with 4 cycles Durva 1500mg q3w followed by complete resection. Adjuvant Durva 1500mg q4w was given for 10 cycles or a maximum of 40 weeks. The primary endpoint was EFS at 2 yrs after neoadjuvant trial treatment (NAT) start. An event was defined as progression during NAT, appearance of metastases, locoregional recurrence after surgery or death from any cause. 58 pts were needed based on one-sided type I error 10% and power 80% for H_1 EFS at 2 yrs ≥ 65% compared to H_0 EFS at 2 yrs ≤ 50%. Secondary endpoints included pathological response, recurrence free survival after R0 resection (RFS), overall survival (OS) and safety. We report the primary analysis of the full analysis set (FAS, received at least one dose of Durva). **Results:** 61 pts were included between July 2018 and September 2019 at 12 sites. Median follow up is 28.1 months (95%CI 27.8-28.4). FAS consisted of 58 pts (79% male, median age 68 yrs) with bladder cancer (95%) or upper urinary tract/urethral cancer (5%). Clinical T2, T3, T4 stage was present at diagnosis in 69%, 21%, 10%, respectively, and 17% had cN1. Resection was performed in 53 pts (91%; 4 refused, 1 unresectable) with R0 resection in 52 pts (98%). 48 (91%) of resected pts started adjuvant Durva and 32 (67%) completed it. Pathological response < ypT2 ypN0 was achieved in 32 pts (18 pts ypT0 and 14 pts ypT1/a/is), corresponding to 60% of resected pts and 55% of the FAS. EFS at 2 yrs was overall 76.1% (one-sided 90% CI (lower bound): 67.6%; 95% CI 62.3% - 85.3%), for ypT1/a/is 92.9% and for ypT0 100%. RFS at 2 yrs after R0 resection (N=52) was 83.5% (95% CI 69.6% - 91.4%) and OS at 2 yrs for the FAS population was 87.3% (95% CI 73.8% - 94.1%). Grade 1, 2, 3, 4 adverse events attributed to Durva during overall treatment were 14%, 35%, 19%, 7%, respectively. **Conclusions:** The addition of perioperative Durvalumab to the standard of care for pts with resectable MIUC results in a high EFS, RFS and OS at 2 yrs, especially for pts with downstaging to <ypT2. The null hypothesis for the primary endpoint was clearly rejected. More in-depth analyses for biomarkers (PD-L1, ctDNA) will be presented at the meeting. Clinical trial information: NCT03406650. Research Sponsor: Astra Zeneca, SERI: Swiss State Secretariat for Eduction Research and Innovation.

Long-term outcomes in EV-301: 24-month findings from the phase 3 trial of enfortumab vedotin versus chemotherapy in patients with previously treated advanced urothelial carcinoma. *First Author: Jonathan E. Rosenberg, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Enfortumab vedotin (EV), an antibody-drug conjugate directed against Nectin-4, demonstrated longer overall survival (OS) and progression-free survival (PFS) in the confirmatory phase 3, randomized, open-label EV-301 trial at the prespecified interim analysis. The longer-term clinical profile of EV is unknown. Data from 12 additional months of follow-up in EV-301 are presented. **Methods:** In EV-301 (NCT03474107), patients with locally advanced or metastatic urothelial carcinoma (la/mUC) who had received a prior platinum-containing chemotherapy and had disease progression during or after PD-1/L1 inhibitor treatment were randomized 1:1 to receive either EV 1.25 mg/kg on Days 1, 8, and 15 of each 28-day cycle or investigator-chosen standard chemotherapy with docetaxel, paclitaxel, or vinflunine. The primary endpoint was OS; secondary endpoints included investigator-assessed PFS per RECIST v1.1, as well as safety and tolerability. Efficacy and safety findings from July 30, 2021, approximately 1 year after the interim analysis (July 15, 2020), are reported. **Results:** Overall, 608 patients with la/mUC were randomly assigned to EV (n = 301) or chemotherapy (n = 307). As of July 30, 2021, 444 deaths had occurred (EV, n = 207; chemotherapy, n = 237). After a 23.75-month follow-up, median OS was significantly prolonged by 3.97 months with EV compared with chemotherapy (median OS: 12.91 vs 8.94 months, respectively; HR = 0.704 [95% CI: 0.581-0.852], 1-sided P= 0.00015). Additionally, the OS benefit of EV was retained in the majority of prespecified subgroups. PFS also was improved with EV (median 5.55 months) vs chemotherapy (median 3.71 months) (HR = 0.632 [95% CI: 0.525-0.762]; 1-sided P< 0.00001). Rates of treatment-related adverse events (TRAEs; 93.9% vs 91.8%), including serious TRAEs (22.6% vs 23.4%), were comparable between the EV and chemotherapy groups. Rates of grade ≥3 TRAEs were ~50% in both groups. **Conclusions:** EV continues to show significant and consistent survival advantage over standard chemotherapy in patients with treatment-experienced la/mUC. No new safety signals were identified. With robust clinical benefit and a tolerable safety profile, EV maintains its place as a standard of care for this aggressive disease. Clinical trial information: NCT03474107. Research Sponsor: Astellas Pharma, Inc.

Avelumab as the basis of neoadjuvant regimen in platinum-eligible and -ineligible patients with nonmetastatic muscle-invasive bladder cancer: AURA (Oncodistinct-004) trial. *First Author: Nieves Martinez Chanza, Medical Oncology Department, Jules Bordet Institute, Université Libre de Bruxelles, Brussels, Belgium*

Background: Nearly half of the patients (pts) diagnosed with non-metastatic muscle invasive bladder cancer are unfit for cisplatin therapy and no alternative options of neoadjuvant treatment exist. Avelumab (A), a monoclonal antibody directed against PD-L1, showed efficacy in advanced urothelial cancer. We report preliminary data assessing preoperative avelumab associated with paclitaxel and gemcitabine or avelumab alone in the cisplatin ineligible cohort. The results of the cisplatin eligible cohort were reported at ESMO 2021. **Methods:** AURA is a prospective, multicenter, randomized, phase II trial for pts with cT2-4aN0-2M0 bladder carcinoma. Pts were enrolled in two separated cohorts based on eligibility for cisplatin chemotherapy. Cisplatin ineligible pts received 4 cycles of paclitaxel-gemcitabine (PG) plus A every 2 weeks or 4 cycles of A every 2 weeks (1:1). Primary endpoint was pCR rate (ypT0/isN0) with the objective, in each arm, to show pCR rate > 5% (90% power reached in case of pCR rate > 25%). Two-step design was used with planned interim analysis after 12 evaluable pts per arm. Secondary endpoints were pathologic downstaging rate (< ypT2N0) and safety. **Results:** A total of 56 cisplatin-ineligible pts were evaluable. For PG + A arm (n = 28): median age was 72 years (41-80), 93% male. For A alone arm (n = 28): median age was 75 years (49-89), 93% male. One patient did not undergo surgery due to progression in the A arm but was included in intention to treat analysis. Five pts did not receive the 4 cycles of treatment; reasons included toxicity (n = 3) for PG + A arm and patient/physician decision (n = 2) for A arm. pCR was achieved in 5 pts (18%; 95%CI 6%-37%) treated with PG + A and 10 pts (36%; 95%CI 19%-56%) treated with A. Downstaging to < ypT2N0 was achieved in 6 pts (21%; 95%CI 8%-41%) and 11 pts (39%; 95%CI 22%-59%), respectively. Median time from treatment initiation to surgery was 82 days (55-144) for PG + A arm and 67 days (38-89) for A arm. Most common irAEs of any grade were asthenia (15%), skin toxicity and myalgia/arthralgia (each 5%). There were 2 pts in the PG + A arm with grade 3 irAEs (hepatitis and pneumonitis) that caused A discontinuation for 1 patient. No treatment-related deaths were reported. **Conclusions:** Neoadjuvant single agent avelumab resulted in high pCR and was safely administered without compromising surgical resection. Our results suggest that the addition of taxane-gemcitabine regimen to avelumab may reduce avelumab efficacy with low pCR rate. Survival analysis and correlative studies are underway. Clinical trial information: NCT03674424. Research Sponsor: This study is financially supported by Amis de l'Institut Bordet and Merck N.V.-S.A., Overijse, Belgium, an affiliate of Merck KGaA, Darmstadt, Germany, as part of an alliance between Merck KGaA and Pfizer.

4518 **Poster Discussion Session**

Preliminary results of a phase Ib/II combination study of RC48-ADC, a novel humanized anti-HER2 antibody-drug conjugate (ADC) with toripalimab, a humanized IgG4 mAb against programmed death-1 (PD-1) in patients with locally advanced or metastatic urothelial carcinoma. *First Author: Xinan Sheng, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Genitourinary Oncology, Beijing Cancer Hospital, Beijing, China*

Background: RC48-ADC has shown promising data in HER2-positive and even negative patients with metastatic urothelial carcinoma (mUC) who failed with platinum-based chemotherapy. RC48-ADC combined with anti-PD-1 antibody may have a synergistic antitumor effect. **Methods:** This is an open-label, multicenter, phase 1b/II trial to evaluate the safety and activity of RC48 combined with toripalimab in mUC. Patients received RC48-ADC at 1.5 or 2 mg/kg, in combination with 3mg/kg toripalimab every two weeks in a dose-escalation and expansion cohort until confirmed disease progression, unacceptable toxicity, or voluntary withdrawal. The key primary endpoint was safety; secondary endpoints included efficacy and tumor tissue biomarkers. **Results:** As of 17 Jan 2022 (data cutoff), 41 la/mUC pts (19 males; median age 66 y [42-76]) were enrolled since 20 Aug 2020. 61% patients were systemic treatment naïve, and 54% had visceral metastases (mets), including 24% with liver mets. The primary site was in upper tract UC in 54%. HER2 expression was positive (IHC 2+ or 3+) in 59% patients, and PD-L1 positive (CPS ≥ 10) in 32%. No dose-limiting toxicity was observed. The recommended dose was RC48-ADC 2mg/kg + toripalimab 3mg/kg every 2 weeks. With a median follow-up of 8.0 mos, 36 patients had at least one tumor assessment, the best ORR was 83.3%, and the confirmed ORR was 76.7% (95%CI: 57.7, 90.1), including 10% CR. The cORR was 82.4% for 1L previously untreated mUC patients, 100% for patients with HER2 IHC (2+ or 3+) & PD-L1 (+), 92.3% for HER2 (2+ or 3+) & PD-L1 (-), 50% for HER2 (0 or 1+) & PD-L1 (+), and 50% HER2 (0 or 1+) & PD-L1 (-). DCR was 96.7% (95%CI: 82.8, 99.9). The median PFS was immature and 9.2 mos (95%CI: 5.49, 10.32) by the time and the median OS was not reached. The most common treatment-related AEs were ALT/AST increase (65.9%), peripheral sensory neuropathy (58.5%), appetite decrease (56.1%), asthenia (56.1%), hypertriglyceridemia (48.8%). Grade ≥3 TRAEs included γ-glutamyl transferase increase (12.2%), ALT/AST increase (7.3%), asthenia (7.3%), hypertriglyceridemia (4.9%), and neutropenia (4.9%). 9 pts had irAEs (22.0%, 7.3% ≥ G3), including immune-related pneumonitis, hepatitis, and myositis. **Conclusions:** RC48-ADC in combination with toripalimab demonstrated promising efficacy in patients with mUC and a manageable safety profile. A randomized study of RC48-ADC and toripalimab vs. platinum-based chemotherapy in previously untreated la/mUC patients is ongoing. Clinical trial information: NCT04264936. Research Sponsor: Remegen.

Stratification	cORR

A phase II study of RC48-ADC in HER2-negative patients with locally advanced or metastatic urothelial carcinoma. *First Author: Huayan Xu, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education, Beijing), Department of Genitourinary Oncology, Peking University Cancer Hospital & Institute, Beijing, China*

Background: RC48-ADC is a novel humanized anti-HER2 antibody-drug conjugate (ADC). A phase II clinical study showed that RC48-ADC has a good effect on locally advanced or metastatic urothelial carcinoma with HER2-positive expression that failed standard chemotherapy. In the study, some patients with HER2-postive immunohistochemistry (IHC 2+) but negative FISH test still benefited from the treatment of RC48-ADC.This study was to evaluate the activity and safety of RC48-ADC in HER2-negative patients with locally advanced or metastatic urothelial carcinoma. **Methods:** This study is an open-label, single-center, single-arm, phase II trial. Eligibility criteria include: histologically confirmed urothelial carcinoma, HER2-negasitive (IHC 0 or 1+), ECOG PS 0-1,and treated with ≥1 prior systemic treatment. Patients received RC48-ADC 2mg/kg q2w until disease progression, unacceptable toxicity, withdrawal of consent, or study termination. The primary objectives were activity (ORR) and safety. Second objectives included progress-free survival, disease control rate and overall survival. **Results:** As of February 2022(date cutoff),19 patients were enrolled. The median age was 64 years old(-range:36-77). At baseline, there were 6 patients with HER2(IHC 0), and 13 patients with HER2(IHC 1+).Most patients (13/19) had visceral metastasis. 15(79%) patients had received≥2 lines treatment.At date cutoff, 19 patients were assessable for response. The objective response rate was 26.3% (95% CI:9.1%,51.2%) and the DCR was 94.7% (18/19). The mPFS was 5.5months (95% CI:3.9,6.8) and mOS was 16.4months (95% CI:7.1,21.7) .All of the 6 patients with HER2(0) were SD in the study. The ORRs were 38% (5/13) in patients with HER2(IHC 1+),31% (4/13) in visceral metastasis,17% (1/6) in liver metastasis patients,27% (4/15) in patients post to ≥ 2 lines of treatment. Common treatment-related AEs were leukopenia (52.6%), hypoesthesia (47.4%),alopecia (47.4%), AST increase (42.1%), ALT increase (42.1%), and neutropenia (42.1%), fatigue (42.1%),nausea (26.3%), vomiting (15.8%).Most of these AEs were Grade 1 or 2. The AE of Grade 3 was neutropenia (10.5%). The SAE was CPK increased (5.3%). **Conclusions:** This study showed that RC48-ADC was safe and the ORR was 26.3% in HER-negative patients with locally advanced or metastatic urothelial carcinoma. The enrollment was completed and data will be updated later. Clinical trial information: NCT04073602. Research Sponsor: RemeGen,Ltd.

4520 **Poster Discussion Session**

RC48-ADC for metastatic urothelial carcinoma with HER2-positive: Combined analysis of RC48-C005 and RC48-C009 trials. *First Author: Xinan Sheng, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Genitourinary Oncology, Beijing Cancer Hospital, Beijing, China*

Background: RC48-ADC (Disitamab Vedotin) is a novel humanized anti-HER2 antibody-drug conjugate (ADC). RC48-ADC demonstrated a promising efficacy with a manageable safety profile in HER2-positive locally advanced or metastatic UC patients who failed to platinum based chemotherapy in RC48-C005 and RC48-C009 trials. Here are the pooled results of the two studies with the supplementary efficacy, safety and updated OS data. **Methods:** Both of the two trials are single-arm, multi-center, phase II trials. Eligible patients were 18~80 years old, with central-laboratory confirmed, histologically HER2-postive (IHC2+,3+), unresectable mUC. Patients had at least one line of systemic chemotherapy. The primary endpoint was objective response rate (ORR). Progress-free survival (PFS), overall survival (OS), and safety were also assessed. **Results:** RC48-C005 and RC48-C009 enrolled HER2-positive locally advanced or metastatic UC patients from Nov 2017 to Sep 2020. 107 mUC patients (80 males; median age 63 y [40-79]) were enrolled. 64.5% patients had received ≥ 2 lines systemic chemotherapy. 90.7% patients had visceral metastases. As of 04 Sep 2021 (data cutoff), The overall confirmed ORR as assessed by the BIRC was 50.5% (95% CI: 40.6%, 60.3%). Similar responses were observed in prespecified subgroups. cORR was 52.1% (25/48) for patients with liver metastasis and was 55.6% (15/27) in patients with previous PD-1/L1 treatment. The cORR was 62.2% (28/45) for HER2 IHC2+&FISH+ or IHC3+ patients, 55.6% (5/9) for HER2 IHC2+&FISH unknown patients, and 39.6% (21/53) for HER2 IHC2+&FISH- patients respectively. DCR was 82.2% (95% CI:73.7%, 89.0%). The mPFS was 5.9 (95% CI:4.2, 7.2) months. The mOS was 14.2 (95% CI:9.7, 18.8) months. The median OS follow up time was 19.1 months. Most common treatment-related AEs were hypoaesthesia (50.5%), Leukopenia (49.5%), aspartate aminotransferase increased (43.0%), neutropenia (42.1%), alopecia (40.2%), asthenia (39.3%), alanine aminotransferase increase (35.5%), decreased appetite (31.8%). The grade ≥3 TRAEs (≥5%) only included hypoaesthesia (15.0%), neutropenia (12.1%) and r-GT increased (5.6%). **Conclusions:** RC48-ADC showed continuously a promising efficacy with a manageable safety profile in HER2-postive mUC patients who had failed at least one line systemic chemotherapy. Clinical trial information: NCT03507166, NCT03809013. Research Sponsor: Remegen Ltd.

4521 **Poster Session**

Association of DNA damage repair (DDR) mutations (mts) and clinical outcomes in CALGB 90601 (Alliance). *First Author: Gopa Iyer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Platinum-based chemotherapy is the standard 1st-line therapy for metastatic urothelial cancer (mUC). C90601 was a randomized phase III trial testing gemcitabine and cisplatin (GC) with bevacizumab (B) or placebo (P) in patients (pts) with untreated mUC. Median overall survival (OS) for GCB vs GCP was 14.5 months (mo) vs 14.3 mo (p=0.14) and median progression-free survival (PFS) was 8 vs 6.7 mo, respectively. DDR mts have been implicated in response and survival in mUC and were investigated in this negative trial. **Methods:** C90601 enrolled 506 pts randomized 1:1 to GCB or GCP from 7/15/09-12/2/14, with stratification for prior chemotherapy and visceral metastases. Consenting pts submitted archival FFPE tumor specimens and blood for matched germline (g)DNA. Tumor and gDNA were sequenced by MSK-IMPACT, a 468-gene exon capture assay, to detect mts in select DDR genes. The proportional hazards model was used to correlate mts in the DNA helicase ERCC2 (pre-specified hypothesis) and additional DDR gene panels being explored in prospective trials in muscle-invasive disease with OS and PFS, adjusting for tumor mt burden and stratification factors. Mts were categorized as deleterious (del) or non-del using pre-defined published criteria. **Results:** 208 pts underwent DNA sequencing. Clinical features and PFS/OS were comparable to the 506-pt cohort. Median sequencing coverage was 497X. Median mutation count was 13.2 and 8.8 for DDR mt and wild-type tumors, respectively. A non-significant improvement in OS and PFS was seen in pts with ERCC2 mts (HR 0.70), but the 5.3% frequency of ERCC2 mts was lower than in historical series. Neither del mts (table) nor any mts in DDR genes were associated with PFS/OS. **Conclusions:** DDR mts were not associated with improved outcomes in C90601. The reliance on archival specimens, lower-than-expected ERCC2 mt frequency, small sample sizes, and tumor genomic heterogeneity may have influenced the predictive capacity of DDR mts in this cohort. Similar analyses are underway in pts who received neoadjuvant chemotherapy prior to cystectomy from completed prospective trials. Support: U10CA180821, U10CA180882, Genentech. Research Sponsor: U.S. National Institutes of Health, Department of Defense grant funding.

Association of DNA damage response (DDR) gene mutations (mts) and response to neoadjuvant cisplatin-based chemotherapy (chemo) in muscle-invasive bladder cancer (MIBC) patients (pts) enrolled onto SWOG S1314. *First Author: Gopa Iyer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Neoadjuvant cisplatin-based chemo followed by radical cystectomy (RC) is a standard of care treatment for pts with MIBC. DDR gene mts, including within ERCC2, a DNA helicase implicated in cisplatin sensitivity in MIBC, have been associated with higher pathologic (path) downstaging (< pT2) and complete response (pT0) at RC and improved overall survival (OS) in retrospective series. S1314 randomized pts to one of 2 chemo regimens (dose dense MVAC or Gem/Cis) followed by RC. We sought to correlate ERCC2 and other DDR gene mts with response and survival in MIBC pts enrolled onto this prospective trial. **Methods:** Tumor and matched germline DNA from evaluable pts enrolled onto S1314 underwent exon capture sequencing of 505 cancer-associated genes (MSK-IMPACT). Both deleterious (del) mts and any mts in 9 DDR genes (ERCC2, ERCC5, BRCA1, BRCA2, RECQL4, ATM, ATR, RAD51C, FANCC) were correlated with clinical outcomes. The prespecified analyses included the association of mts with < pT2 and pT0 by logistic regression analysis and with progression-free survival (PFS) and OS by Cox proportional hazards regression. **Results:** 179 patients (median 61 years, 85% male, 87% white, and 87% clinical stage T2) who received >2 cycles of chemo and were evaluable for path response were included in the analysis. The pT0 rate was 28% and < pT2 was 41%. Del mts in ERCC2 were detected in 26 (14%) pts followed by ATM (n = 12, 7%), ATR (n = 3) and BRCA2 (n = 2). ERCC2 mts were associated with statistically significantly higher path responses with a 54% pT0 rate and 62% downstaging rate. Patients with any del mts had higher path response rates (51% pT0, 56% < pT2) and better PFS (Table) with a median follow-up of 53 months. There was a non-significant trend towards improved OS. **Conclusions:** In pts managed with neoadjuvant chemo and RC on S1314, both ERCC2 mts and del DDR gene mts correlated with pathologic response. Any del DDR gene mt was associated with improved PFS. These results are in line with retrospective analyses displaying a correlation between DDR gene mts and neoadjuvant chemosensitivity in MIBC and support ongoing genomically-informed organ sparing trials. Research Sponsor: U.S. National Institutes of Health.

Landscape analysis of urothelial carcinoma (UC) by telomerase reverse transcriptase (*TERT*) alterations. *First Author: Tyler F. Stewart, University of California San Diego Health, La Jolla, CA*

Background: TERT is a catalytic subunit of telomerase, the unique enzyme that confers immortality to cells and is expressed in >90% of cancer cells. Mutations in the *TERT* promoter region (pTERTmut) are the most prevalent noncoding mutations in cancer. Recent data suggest pTERTmut are associated with improved outcomes in patients with UC treated with immune checkpoint inhibitors. We evaluated the molecular and immune landscape of UC with and without pTERTmut. **Methods:** UC tissue samples were analyzed for DNA alterations (NextSeq, 592 Genes; NovaSeq, WES) and mRNA expression (NovaSeq, WTS). Immune cell fraction was calculated by QuantiSeq (Finotello 2019, Genome Medicine). PD-L1 expression was assessed by immunohistochemistry (IHC) (Caris Life Sciences, Phoenix, AZ). MSI/MMR was tested by fragment analysis, IHC and NGS. TMB-H was based on a cut-off of > 10 mut/MB. We compared alterations between samples with and without detected pathogenic pTERTmut. Significance was determined by Mann–Whitney U, X^2, and Fischer-Exact and p adjusted for multiple comparisons (q) was < 0.05 using Benjamini-Hochberg. **Results:** Overall, 1686 UC samples were analyzed, 1166 from primary lesions and 499 from a lymph node or metastatic site. pTERTmut was present in 68% of primary and 61% of metastatic tumors, and correlated with modest increase of TERT expression (1.18 fold, p=0.015). pTERTmut was associated with less frequent alterations in TP53, KMT2D, CCND1, MYC, KEAP1 and less MSI/dMMR. By contrast, pTERTmut was associated with more frequent alterations in ARID1A, TSC1, PIK3CA and TMB-H (all q<0.05). Over 41% of pTERTmut were TMB-H. TERTp mutations were not associated with FGFR alterations. The frequency of co-occurring mutations was similar by specimen site. In evaluating the immune landscape (Table), pTERTmut was associated with higher expression of PD-L1 (IHC, mRNA), PD-L2 (mRNA) and TIM3 (mRNA) in tumors from primary sites (all p and q<0.05), but not in metastatic sites. Investigation of tumor-associated immune cells demonstrated that pTERTmut correlated with higher percentage of M1-macrophages and CD8+ T cells in primary tumors, and was inversely-correlated with NK cells in metastatic sites (all q<0.05). **Conclusions:** This is the largest analysis looking at the molecular and immune landscape of pTERTmut UC tumors. We observed differential patterns of DNA alterations and tumor immune microenvironment based on pTERTmut status. Further work is needed to understand differences in these molecular cohorts and the association of these data with clinical outcomes. Research Sponsor: None.

Monitoring efficacy of neoadjuvant sunitinib in metastatic renal cell carcinoma using a personalized and tumor informed ctDNA assay. *First Author: Christine B. Peterson, University of Texas MD Anderson Cancer Center, Houston, TX*

Background: Approximately 30% of renal cell carcinoma (RCC) cases present as stage IV at the time of diagnosis. Metastatic RCC (mRCC) is associated with poor outcomes, with a five-year survival rate below 50%. Tools to evaluate the efficacy of novel systemic regimens are needed. Biomarkers like ctDNA can accurately and non-invasively assess molecular residual disease (MRD) in response to therapy and monitor disease status over time to predict disease progression. Here, we aimed to determine the feasibility of performing personalized and tumor-informed ctDNA testing in mRCC patients enrolled on a study integrating systemic therapy with surgical cytoreduction, as well as to measure patient response to sunitinib by assessing ctDNA dynamics. **Methods:** We analyzed a cohort of 21 mRCC patients with median age of 59.5 (43-76) years who were treated with sunitinib, and had planned cytoreductive nephrectomy during their second cycle of therapy. Baseline and post-first cycle ctDNA levels were measured using a personalized and tumor-informed ctDNA assay (SignateraTM bespoke mPCR NGS assay). Changes in ctDNA levels from baseline to the best response time point were correlated with disease status as assessed by radiological imaging. **Results:** In this cohort, baseline ctDNA was detected in 81% (17/21) of patients, with higher ctDNA concentrations observed in patients who presented with multiple distant metastases (n = 11) compared to the 10 cases with a single metastatic mass (median 5.8 vs 1.3 mean tumor molecules/mL , not statistically significant). Of those with baseline ctDNA measurement, 12% (2/17) cleared their ctDNA, 24% (4/17) had a decrease in ctDNA, and 59% (10/17) had an increase in ctDNA after 4 weeks of sunitinib. During the course of treatment, patients whose ctDNA concentration increased from baseline were more likely to experience a disease progression (HR: 3.9 95% CI 1.13-13.7; p = 0.032) compared to those whose ctDNA decreased. In addition, higher ctDNA concentration before surgery after initial treatment with sunitinib correlated with shorter time to progression (p = 0.04). **Conclusions:** Our results demonstrate the feasibility and prognostic value of personalized and tumor-informed ctDNA testing for determining response to systemic therapy in patients with mRCC. Early signs of unfavorable ctDNA kinetics can provide rationale for modification of systemic therapy in order to enhance response. Future work exploring the clinical utility of ctDNA testing in larger mRCC cohorts is warranted. Research Sponsor: None.

Molecular profile and clinical outcomes of renal cell carcinoma brain metastases treated with stereotactic radiosurgery. *First Author: Jennifer Ma, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Molecular profiles of renal cell carcinoma (RCC) tumors are associated with systemic treatment (ST) responses and clinical outcomes. However, the molecular profiles of RCC brain metastases (BM) and their correlation with ST response and clinical outcomes are not well characterized. Effective management of BM with locoregional therapies including stereotactic radiosurgery (SRS) is critical as ST advances have improved overall survival (OS). Therefore, we sought to identify the clinical and genomic features of RCC BM in a large cohort of patients treated with SRS. **Methods:** We performed an institutional retrospective analysis of RCC BM patients treated with SRS and evaluated corresponding genomic next generation sequencing (NGS) data via a targeted sequencing panel (MSK-IMPACT). A comparison cohort of all institutional patients with available NGS data was utilized to investigate genes enriched in our BM cohort using Fisher exact testing. Kaplan Meier analyses were performed for OS and intracranial progression-free survival (iPFS). Clinical factors and genes mutated in ≥ 10% of samples were assessed per patient using Cox proportional hazards models, and per individual BMs using clustered competing risks regression with a competing risk of death. **Results:** From 2010-2021, 91 RCC BM patients underwent SRS for 212 BMs, including 86% clear cell and 14% non-clear cell RCC. NGS data was available for 76 patients (84%), including 18 resected BMs, 26 extra-cranial metastatic lesions (EM), and 32 primary kidney tumors (Table 1). Median follow-up was 3.2 years with median OS of 21 months (m) and median iPFS of 7.8m. Karnofsky performance status ≥80 and extracranial disease control were significantly associated with improved OS on multivariable analyses (MVA; p=0.049 and 0.01, respectively). No clinical variables were significantly associated with iPFS on MVA. At the BM level, *SETD2* alterations approached significance for improved iPFS (HR=0.35; 95%CI 0.11, 1.05; p=0.06). Enrichment in *SMARCA4* alterations was seen in the BM cohort as compared to primary kidney and EM samples from patients without BM (17% vs 1% vs 2%, p<0.05). **Conclusions:** To our knowledge, this is the largest study investigating mutational profiles of RCC BM. *SMARCA4* alterations were enriched in BM samples and a trend towards improved iPFS was seen in *SETD2* variant BMs, warranting further investigation. Research Sponsor: None.

Targeted sequencing results of the five most frequently mutated genes in our BM cohort compared to an institutional cohort of genomic NGS data of all patients with primary RCC or with extracranial lesions without BM.

Association between decline of neutrophil-to-eosinophil ratio (NER) at week 6 after ipilimumab plus nivolumab initiation and improved clinical outcomes in metastatic renal cell carcinoma (mRCC). *First Author: Yu-Wei Chen, Vanderbilt Ingram Cancer Center, Nashville, TN*

Background: Low baseline NER has been associated with improved response to immunotherapy in mRCC (PMID:34732251). The current study aimed to investigate the early decline of NER at week 6 after ipilimumab/nivolumab (ipi/nivo) initiation and treatment responses in mRCC. **Methods:** Retrospective chart review of ipi/nivo-treated mRCC patients at Vanderbilt-Ingram Cancer Center and Duke Cancer Institute was conducted. Landmark analysis at week 6 after ipi/nivo initiation was performed to assess the association between change in NER and clinical responses [progression-free survival (PFS)/overall survival (OS)]. **Results:** There were 150 mRCC patients included in the analysis: 78% had clear cell histology, 78% were IMDC intermediate/poor risk, and 74% were male. The median follow-up time was 11.9 months. After ipi/nivo initiation, the median NER decreased from 23.8 (interquartile range: 15.0-57.1) at baseline to 19.8 (10.6-40.8) at week 6; 102 (68%) patients had decreased NER. The NER at week 6 was grouped by percent change (≥ 50% decrease vs <50% decrease vs increase). In multivariable regression analysis after adjustment for age, sex, race, IMDC risk group, baseline NER, histology, prior systemic therapy, and prior nephrectomy (Table), decreased NER ≥ 50% was associated with improved PFS [adjusted hazard ratio (AHR): 0.55, p-value: 0.03] and OS (AHR: 0.38, p-value: 0.02) (Table). Stratified analysis was conducted by baseline NER [≥vs < baseline median NER (23.8)]: decreased NER ≥ 50% was associated with improved PFS (AHR: 0.46, p-value: 0.048) and OS (AHR: 0.29, p-value: 0.01) in the subgroup with high baseline NER. These associations were not observed in the subgroup with low baseline NER (p-value for PFS: 0.25; p-value for OS: 0.61). **Conclusions:** The decline of NER ≥50% at week 6 after ipi/nivo initiation was associated with improved PFS/OS in mRCC patients with high baseline NER. Prospective studies are warranted to validate NER change as a biomarker to predict response to ICIs in mRCC. Research Sponsor: U.S. National Institutes of Health.

Association between change in NER at week 6 and clinical responses.

	ORR %	PFS		OS	
		Median (95%), months	AHR (95%)	Median (95%), months	AHR (95%)

Healthcare resource utilization (HCRU) and costs for patients (pts) with metastatic renal cell carcinoma (mRCC) receiving first-line (LOT1) pembrolizumab plus axitinib (P+A) or ipilimumab plus nivolumab (I+N). *First Author: Neil J. Shah, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Approval of immuno-oncology (IO) agents have changed treatment paradigm for mRCC pts. While IO-based therapies have demonstrated improved survival, these can be associated with considerable HCRU and costs necessitating their examination in real-world practice. **Methods:** This retrospective claims analyses utilizing Optum Research Database included adult pts with mRCC diagnosis from July-2017 to Aug-2020 and received P+A or I+N as LOT1 from Jan-2018 to May-2020 (first claim=index date). All eligible pts required continuous enrollment for minimum of 6-months prior and 3-months post the index date unless death occurred. All-cause HCRU counts, and associated costs were examined during the first 90 days (LOT1-90) and entire LOT1 duration and reported as overall and per-pt-per-month (PPPM) estimates. **Results:** The study identified 507 pts (P+A=126, I+N=381). Average age of the entire cohort was 67 years, 71% were male, mean NCI Charlson score was 2.4, and lung (55%) and bone (33%) were the most common metastatic sites. Mean (SD) distance from mRCC diagnosis to index date was 97 (172) days. Pts with P+A and I+N had similar baseline characteristics. Total % of pts with ambulatory visits was similar for P+A and I+N for LOT1-90 and entire LOT1 (99.2 vs. 100.0%, p=0.082 for both). During LOT1-90, we observed a lower % of pts on P+A with ER visits and inpatient (IP) stay compared to I+N (34 vs. 48, p=0.008; 19 vs. 38, p<0.001, respectively). We also observed a shorter mean (SD) IP stay for P+A vs. I+N during LOT1-90 (1.9 (6.5) vs. 5.6 (13.24) days, p<0.001). Similarly, P+A had lower mean PPPM ambulatory visits, IP stay, and ICU stay during both LOT1-90 and entire LOT1 (Table). In addition, mean PPPM total (medical + pharmacy) and mean PPPM medical costs were lower for P+A compared to I+N, but mean PPPM pharmacy costs were higher for P+A for both LOT1-90 and entire LOT-1 (Table). **Conclusions:** This study noted significantly higher HCRU with I+N including higher mean PPPM ambulatory visits, IP stays, and ICU stays compared to P+A. Although, P+A had higher mean PPPM pharmacy costs, the total medical plus pharmacy costs were significantly lower compared to I+N. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Phase II randomized double blind trial of axitinib (Axi) +/- PF-04518600, an OX40 antibody (PFOX) after PD1/PDL1 antibody (IO) therapy (Tx) in metastatic renal cell carcinoma (mRCC).

First Author: Sarmad Sadeghi, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA

Background: Immune checkpoint blockade has revolutionized mRCC Tx, but primary and acquired resistance continues to result in poor patient outcomes. OX40 (CD-134) mediates IO resistance. Co-stimulatory OX40 (CD-134) activates exhausted T-cells. OX40 activation in dendritic cells increases the proliferation, effector function, and survival of T cells. PFOX is an agonist for OX40. We hypothesized that PFOX + the VEGFR inhibitor Axi would improve outcomes vs. Axi in patients (pts) with mRCC after IO Tx. **Methods:** Pts with predominantly clear cell mRCC were stratified for MSKCC risk groups then randomized 1:1 to Axi 5mg po bid plus PFOX 0.3mg/kg iv (Arm 1) or placebo (PL) iv (Arm 2) on Day 1 of a 2-week cycle. The primary endpoint was progression free survival (PFS); secondary endpoints included overall survival (OS), objective response rate (ORR), duration of response (DOR) per RECIST v1.1, and safety/tolerability. A prespecified interim analysis (IA) tested PFS at a 1-sided $P < 0.02$ when ≥ 33 events were observed. **Results:** Between February 2018 and October 2021 a total of 59 pts were randomly assigned and treated with Axi+PFOX (N = 29) or Axi+PL (N = 30). Pt and disease characteristics are summarized in the table. As of October 2021, 38 PFS events had occurred, 19 on each arm. The IA rejected the hypothesis of added efficacy for PFOX with a *p* of 0.0089. Subsequently the study was closed to new accrual. At a median follow up of 13.4 mo, median PFS was 13.1 (6-15.8) months (mo) for Arm 1 and 8.5 (5.5-11) mo for Arm 2 (HR = 0.85 [95% CI: 0.45-1.60] p = 0.61). After adjusting by MSKCC risk group and prior lines of Tx, HR = 0.74 [95% CI: 0.38-1.46] p = 0.39. Median OS was not reached (adjusted HR = 0.71 [95% CI: 0.24-2.12] p = 0.54). ORR Arm 1: 31% PR, 52% SD, 14% PD, and Arm 2: 37% PR, 50% SD, 13% PD. Median DOR 9.1 (3.3-23.9) mo for Arm 1, and 7.5 (1.8-32.7) mo. for Arm 2. Rates of any grade Tx related adverse events (TRAEs; 93% vs 100%), including grade 3 or 4 TRAEs (66% vs 47%), in Arm 1 and Arm 2, respectively. 4 pts discontinued Tx due to TRAE, 3 in Arm 1 (1 grade 3 hypertension, 1 grade 2 stroke, 1 grade 3 bullous dermatitis) and 1 in Arm 2 (grade 4 ALT elevation). The most common TRAEs were diarrhea 52%, hypertension 52%, fatigue 41%, nausea 41% for Arm 1 and hypertension 67%, diarrhea 53%, fatigue 50% for Arm 2. **Conclusions:** In IO-pretreated mRCC pts, Axi + PFOX did not improve outcomes compared to Axi alone. Clinical trial information: NCT03092856. Research Sponsor: Pfizer.

Impact of steroid use among patients with renal cell carcinoma (RCC) who develop immune-related adverse events (irAE).

First Author: Peter Zang, LAC+USC Medical Center, Los Angeles, CA

Background: Immune checkpoint inhibitor (ICI) therapy has become a standard therapy in the treatment of advanced renal cell carcinomas (RCC). This has led to a proportional increase in the frequency of immune related adverse events (irAE), however. While increasing evidence suggests that irAE may be correlated with benefit from ICI, the impact of steroids to mitigate irAE's remains unclear. **Methods:** We analyzed records of patients with RCC treated with an ICI at the USC Norris Comprehensive Cancer Center, Keck Hospital of USC, and LAC+USC Hospital from 2015-2021. Statistical analysis was performed using R. The Kaplan-Meier model was used to calculate progression free survival (PFS) and overall survival (OS). A log-rank test was used to determine if differences in PFS/OS were statistically significant. **Results:** Out of a total 841 cancer patients treated with ICI, 107 RCC patients were identified. The median age was 60 (range 20-91). The two most common represented ethnicities were 48 Hispanic/Latino (44.9%) and 37 Caucasian (34.6%). The patient population include 64 male patients (59.8%) versus 43 female patients (40.2%). Most had metastatic disease (74.8%) versus local disease (25.2%), and most patients (80.4%) received ICI therapy as initial therapy. Only 6 patients (5.6%) were given combination ICI therapy. The three most common systems affected by irAE were endocrine (18.7%), dermatologic (16.8%), and renal (14.0%). Of the irAE that occurred, 21.5% were categorized as CTCAE grade III or higher. The median PFS of the irAE group was 51.8 months (95% CI 10.0 – 51.8) versus 11.2 months (95% CI 2.7 – 13.8) in the no irAE group. The median OS of the irAE group was 55.0 months (95% CI 23.9 – 55.0) versus 15.6 months (95% CI 13.5 – 23.5). The occurrence of irAE was associated with both statistically significantly increased PFS (p = 0.02) and OS (p = 0.007). The median PFS of patients receiving steroids to treat irAE was 6.5 months (95% CI 3.9 – 9.2) compared to 12.5 months (95% CI 10.4 – 12.5) in the group with irAE who did not receive steroids. The use of steroids was associated with statistically significant worse PFS (p = 0.04) and worse OS but not at statistical significance (p = 0.2). **Conclusions:** The occurrence of irAE was associated with improved PFS and OS in RCC patients treated with ICI. Furthermore, the use of steroids among patients with irAE was associated with worsened PFS, but not OS. Although steroids should still be used as clinically indicated for the management of irAE, clinicians should be judicious as they may blunt tumor response to ICI treatment. Research Sponsor: None.

Cross-trial validation of molecular subtypes in patients with metastatic clear cell renal cell carcinoma (RCC): The JAVELIN Renal 101 experience.

First Author: Renee Maria Saliby, Dana-Farber Cancer Institute, Boston, MA

Background: Vascular endothelial growth factor (VEGF) and immune checkpoint inhibitors (IO) combinations are a standard in mRCC. Molecular clusters of patients have been identified and correlated with outcomes in the phase 3 IMmotion151 (IM151) trial of atezolizumab + bevacizumab (IO+VEGF) vs. sunitinib (Sun) (Motzer, *Cancer Cell* 2020 & *JAMA Oncol* 2021). Avelumab+axitinib (AA) is an approved IO+VEGF combination in mRCC. This work aims to evaluate these clusters in patients from the phase 3 JAVELIN Renal 101 (JR101; NCT02684006) trial of AA vs. Sun. **Methods:** Bulk RNA-sequencing of primary and metastatic samples and clinical data (data cutoff: 28 January 2019) from JR101 were obtained. A random forest model designed to predict molecular clusters based on transcriptomic data was trained on the IM151 dataset. Using this model, patients from JR101 study were categorized into previously defined molecular subgroups. We then evaluated treatment outcomes including progression-free survival (PFS), objective response rate (ORR), and overall survival (OS) from JR101 in relation to molecular subgroups. **Results:** The proportion of patients in each molecular subtype and across MSKCC risk groups were largely comparable between the 2 trials (accuracy: 81.6%; p=0.2). AA was generally superior to Sun. for PFS and ORR across all molecular subsets, including angiogenic and immune-based clusters (Table). Combining immune and/or cell cycle-enriched clusters 4+5 resulted in improved PFS (HR: 0.65; 95% CI: 0.44-0.97) for AA vs. Sun. **Conclusions:** We were able to largely validate the molecular clusters classification and some of the associations with survival outcomes from IM151 in the JR101 clinical trial cohort. Biomarkers of specific VEGF+IO combinations in mRCC should be prospectively validated in randomized trials. Research Sponsor: None.

Treatment outcomes from the JR101 trial in relation to previously defined molecular clusters.

Molecular Clusters	N AA/Sun	PFS median AA/Sun	PFS HR (95% CI)	2-year OS AA/Sun	OS HR (95% CI)	ORR % AA/Sun

First-line therapy for elderly patients with advanced renal cell carcinoma (aRCC): A systemic review and network meta-analysis.

First Author: Yu Fujiwara, Department of Medicine, Icahn School of Medicine at Mount Sinai, Mount Sinai Beth Israel, New York, NY

Background: Multiple regimens incorporating tyrosine kinase inhibitors (TKI) or immune checkpoint inhibitors (ICI), either alone or in combination, confer a significant OS benefit in 1L metastatic clear cell RCC. However, guidance for optimal treatment selection in elderly patients remains limited. A network meta-analysis (NMA) was performed to compare the efficacy of 1L treatments for elderly patients with aRCC. **Methods:** Database search was performed through Pubmed, Embase, Web of Science, and Scopus. Eligible studies were randomized controlled trials (RCTs) evaluating first-line regimens for patients with aRCC older than 65 years old. The primary outcomes were progression-free survival (PFS) and overall survival (OS). Indirect comparisons of available regimens were estimated using a random-effects NMA. **Results:** 14 RCTs with more than 2,100 patients and 5 RCTs with 1,529 patients were eligible for PFS and OS analyses, respectively. Compared with sunitinib (Sun), the pembrolizumab (Pem) + axitinib (Axi) (HR 0.68, 95% CI 0.48-0.97) and Pem + lenvatinib (Len) (HR 0.61, 95% CI 0.4-0.94) regimens were associated with significantly improved OS. In comparing the TKI-ICI combinations with dual ICI nivolumab (Niv) + ipilimumab (Ipi), no significant OS differences were observed (Pem + Len: HR 0.71, 95% CI 0.40-1.27; Pem + Axi: HR 0.79, 95% CI 0.47-1.34; Avelumab (Ave) + Axi: HR 1.03, 95% CI 0.58-1.85; Niv + cabozantinib [Cab]: HR 1.03, 95% CI 0.57-1.93, using Niv + Ipi as a reference). Pem + Len, Niv + Cab, Pem + Axi, and Cab alone each showed improved PFS over Sun (Table). Among these, Pem + Len showed a PFS advantage compared to Pem + Axi (HR 0.58, 95% CI 0.37-0.91), but no PFS difference compared with the other regimens (vs Niv + Cab: HR 0.63, 95% CI 0.39-1.03; vs Cab alone: HR 0.84, 95% CI 0.40-1.77). **Conclusions:** Pem + Len and Pem + Axi provided the largest OS benefit in elderly patients for 1L aRCC. Pem + Len showed improved PFS compared with Pem + Axi, but no difference compared with Niv + Cab or Cab alone. Further validation using real-world data is needed to confirm the efficacy and safety of first-line regimens for the geriatric population with aRCC. Research Sponsor: None.

The HR of OS and PFS using Sun as a reference with treatment rankings.

Estimating clear cell renal cell carcinoma transcriptomic signatures using machine learning and histopathology images. *First Author: Saeed Hassanpour, Geisel School of Medicine at Dartmouth, Hanover, NH*

Background: Gene expression signatures derived from RNA sequencing data have been associated with treatment outcomes for renal cell carcinoma (RCC) patients. Incorporating these RNA biomarkers into clinical practice is promising, yet its real-world applicability is heavily limited as RNA profiling is expensive, time-consuming, and requires specialized expertise for data analysis. In this study, we applied a deep neural network framework to identify the correlation between standard pathology images and underlying RNA signatures using hematoxylin and eosin (H&E) stained formalin-fixed paraffin-embedded (FFPE) whole slides of clear cell kidney tumors from The Cancer Genome Atlas (TCGA). **Methods:** We collected 496 H&E stained FFPE clear cell RCC whole-slide images and the RNA gene signatures for 496 patients from the TCGA database. We partitioned 496 slides into training (N = 245, 50%), development (N = 49, 10%), and test (N = 202, 40%) sets. We used this dataset to train and evaluate our weakly-supervised deep learning model. The model was iteratively trained using extracted patches from a slide and processed the patches through a convolutional neural network (CNN), pretrained for the RCC subtypes classification task, to represent features. The features were aggregated and summarized to predict angiogenesis, myeloid infiltration, and adenosine gene signature (AdenoSig) scores. Performance was assessed by computing Pearson's correlation coefficients. 95% confident intervals (CI) are computed using the Fisher Z transformation. **Results:** The median angiogenesis score was 6.98 (range: 1.77-8.40), the median myeloid score was 0.54 (range: -4.59-5.96), and the median AdenoSig score was 268.31 (range: -4988.71-7621.57). A total of 202 slides were included in the test set. On this test set, the results of our weakly supervised method achieved a Pearson's correlation of 0.65 (95% CI: 0.57-0.73), 0.10 (95% CI: -0.04-0.23), and 0.10 (95% CI: -0.04-0.23) with angiogenesis, myeloid, and AdenoSig scores from gold-standard RNA sequencing data, respectively. **Conclusions:** We proposed using deep learning-based AI techniques to process digitized histopathological images and estimate actionable signatures of angiogenesis, myeloid, and AdenoSig from H&E stained slides. Our model showed promising results for predicting angiogenesis scores compared to myeloid and AdenoSig scores. These results suggest the feasibility of this approach for estimating digital biomarkers from H&E histopathology images and offering a rapid and cost-effective alternative to conventional RNA sequencing. The prognostic value of peripheral blood inflammatory indices early variation in patients (pts) with metastatic renal cell carcinoma (mRCC) treated with nivolumab (Δ-Meet-URO analysis). *First Author: Sara Elena Rebuzzi, Department of Internal Medicine and Medical Specialties (Di.M.I.), University of Genova, Genova; Medical Oncology Unit, Ospedale San Paolo, Savona, Italy*

Background: Immunotherapy has improved the treatment landscape of mRCC pts and identifying biomarkers for patients' selection is clinically needed. Inflammatory indices from peripheral blood showed a prognostic value in different tumors and therapies, including immunotherapy. These biomarkers are inexpensive and readily available in clinical practice. We aimed to assess the prognostic role of the dynamic evaluation of these indices in immunotherapy-naïve pretreated mRCC pts. **Methods:** The Meet-URO 15 multicentric retrospective study enrolled 571 pretreated mRCC pts receiving nivolumab. The Δ-Meet-URO was a secondary analysis on the early variation through the first four cycles of therapy compared with baseline (difference, delta - Δ) of white blood cells, platelets and inflammatory indices, including neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR) and systemic immune-inflammation index (SII, platelets x NLR), their comparison with baseline values and correlation with treatment response, overall (OS) and progression-free survival (PFS). The baseline and Δ cut-offs were identified by ROC curves for OS. **Results:** The analysis was performed on 422 mRCC pts (74% of the entire cohort). Patients with ΔNeutrophils < 730 at 2nd, 3rd and 4th cycles were more responders ($p < 0.001$, $p = 0.003$ and $p < 0.001$) with longer mPFS (11 *vs* 6.1 months, $p = 0.033$) and mOS (46.9 *vs* 20.8 months, $p = 0.046$) compared to ΔNeutrophils ≥ 730. There was a significant interaction between baseline and ΔNeutrophils on PFS ($p = 0.047$). Pts with baseline neutrophils ≥ 4330/mm^3 had longer mPFS when ΔNeutrophils < 730 ($p = 0.002$), whilst no difference was observed in those pts with baseline neutrophils < 4330/mm^3 according to ΔNeutrophils ($p = 0.46$). Similar non-significant trends were observed in mOS. Patients with ΔNLR < 0.5 at 3rd and 4th cycles were more responders ($p = 0.004$ and $p = 0.001$, respectively) with doubled mPFS (12.1 vs 6.4 months, $p = 0.007$) and mOS (46.9 vs 21.7 months, $p = 0.062$) compared to ΔNLR ≥ 0.5. No significant interaction between baseline NLR and ΔNLR was observed in PFS and OS, suggesting a similar association between ΔNLR and PFS or OS, regardless of the baseline NLR cut-off of 3.2. The multivariable analyses confirmed all these results. **Conclusions:** The early assessment of NLR and neutrophils variations during immunotherapy for mRCC pts is a promising, affordable and non-invasive prognostic tool. Prospective and external validation analyses are warranted. Research Sponsor: Italian Ministry of Health (Ricerca Corrente 2018–2021 grants).

The prognostic role of nephrectomy in patients (pts) with metastatic renal cell carcinoma (mRCC) treated with immunotherapy according to the novel prognostic Meet-URO score: Subanalysis of the Meet-URO 15 study. *First Author: Sara Elena Rebuzzi, Department of Internal Medicine and Medical Specialties (Di.M.I.), University of Genova, Genova; Medical Oncology Unit, Ospedale San Paolo, Savona, Italy*

Background: Most of mRCC pts with favorable and intermediate prognosis, according to the IMDC classification, are offered a nephrectomy. However, in the immunotherapy era, the role of nephrectomy is still unclear. In the Meet-URO 15 study we reported the higher prognostic accuracy of the Meet-URO score compared to the IMDC score, by the addition of the neutrophil-to-lymphocyte ratio (NLR) and the presence of bone metastases to the IMDC score, identifying five categories with progressively worse prognosis. For this reason, we aimed to explore the prognostic impact of the previous nephrectomy (PN) on mRCC pts receiving immunotherapy and according to the Meet-URO score groups. **Methods:** The Meet-URO 15 study was a multicentric retrospective analysis on 571 pretreated mRCC pts receiving nivolumab. Univariable analysis of the correlation between PN and overall survival (OS) and multivariate analysis adjusted for IMDC score, therapy line, NLR and metastatic sites were performed. The interaction of PN with the Meet-URO prognostic groups was then evaluated. **Results:** 503/571 pts (88%) underwent PN. A reduced risk of death (HR = 0.44; 95% CI: 0.32-0.60; $p < 0.001$) and higher mOS and OS rate were observed in pts with PN than without (mOS: 36 vs 13 monhts; 1-year-OS 72% vs 52% and 2-year-OS 57% vs 24%, respectively). The reduced risk of death for pts who underwent PN was confirmed at the multivariate analysis (HR = 0.69; 95% CI: 0.49-0.97; $p = 0.032$). The percentage of pts receiving PN progressively reduced through the five Meet-URO prognostic groups (PN: group 1: 98%, group 2: 95%, group 3: 84%, group 4: 79%, group 5: 59%). No significant interaction was observed between the PN and Meet-URO score when all the five groups were considered ($p = 0.17$). A significant interaction was observed when the Meet-URO groups 1,2 and 3 were taken together (HR = 0.40; 95% CI: 0.25-0.63; $p < 0.001$), highlighting the significant protective role of the PN on OS for these three groups. For the Meet-URO groups 4 and 5, the interaction was indeed not significant (HR = 0.81; 95% CI: 0.51-1.30; $p = 0.39$). **Conclusions:** PN has a favourable prognostic impact on pretreated mRCC pts receiving immunotherapy. This benefit may be limited to mRCC pts with more favorable diseases as belonging to Meet-URO prognostic groups 1, 2 and 3. Further analysis of the type of PN (i.e., radical vs cytoreductive) is ongoing and confirmatory prospective evaluations are warranted. Research Sponsor: Italian Ministry of Health (Ricerca Corrente 2018 - 2021 grants).

Progression-free survival after second line of therapy (PFS-2) for metastatic clear cell renal cell carcinoma (ccRCC) in patients treated with first-line immunotherapy combinations. *First Author: Kelly N. Fitzgerald, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Front-line therapy with immunotherapy combinations is standard of care for metastatic ccRCC, with ipilimumab/nivolumab (IO/IO) and several combinations of a VEGFR-targeted tyrosine kinase inhibitor with a PD-1 inhibitor (TKI/IO) showing superior efficacy to TKI monotherapy. PFS-2 evaluates the ability to be salvaged by 2nd line therapy and is a surrogate for overall survival (OS). PFS-2 was compared in patients receiving 1st line IO/IO vs TKI/IO for metastatic ccRCC. **Methods:** A retrospective analysis was performed on patients with ccRCC treated at Memorial Sloan Kettering Cancer Center between 1/1/2014 and 12/30/2020, in cohorts defined by 1st line: IO/IO or TKI/IO. PFS-2 is defined as time from start of 1st line to progression on next therapy, or death. Patients without a PFS-2 event were censored at a prespecified cutoff date. Objective response rate to 1st (ORR_{1st}) and 2nd (ORR_{2nd}) line are compared with the Fisher's exact test. OS, PFS-2, and time on therapy are estimated with the Kaplan-Meier method and compared with the log-rank test. **Results:** One hundred seventy-three patients received 1st line IO/IO (N = 90) or 1st line TKI/IO (N = 83); respectively, 52 and 40 patients had a PFS-2 event. 1st line TKI/IO regimens included: 34% axitinib/pembrolizumab, 29% lenvatinib/pembrolizumab, 25% axitinib/avelumab, 11% other. More IO/IO patients had brain metastases and intermediate/poor MSKCC risk category (respectively $p = 0.007$, $p < 0.001$). ORR_{1st} and median months on 1st line were higher with TKI/IO vs IO/IO (65% vs 39%, $p < 0.001$; 16.1 vs 5.1, $p < 0.001$). ORR_{2nd} was higher with IO/IO vs TKI/IO (47% vs 13%, $p < 0.001$), and median months on 2nd line was not significantly different (7.7 vs 7.1, $p = 0.30$). Median PFS-2 for TKI/IO was 44 months (95% CI: 27, 53) vs 23 months (95% CI: 16, 47) for IO/IO, $p = 0.13$. For TKI/IO and IO/IO groups, respective PFS-2 at 12 months was 86% (95% CI 77, 92) and 74% (95% CI 63, 82); PFS-2 at 36 months was 51% (95% CI 39, 63) and 42% (95% CI 30, 53). OS was not significantly different (p = 0.32; 3 year OS: IO/IO 60%, 95% CI 47, 71; TKI/IO 62%, 95% CI 49, 73). (Table) **Conclusions:** In patients receiving 1st line IO/IO or TKI/IO, ORR_{2nd} was higher with IO/IO and median PFS-2 was numerically higher with TKI/IO, but no statistically significant difference in PFS-2 or OS was seen. These findings suggest that IO/IO and TKI/O are both acceptable 1st line treatment strategies in ccRCC. Research Sponsor: Memorial Sloan Kettering Cancer Center Support Grant/Core Grant P30 CA008748, National Institute of Health Clinical and Translational Science Awards Program, grant number UL1TR00457.

Sequential immunotherapy in rare variant renal cell carcinomafinal report of UNISoN (ANZUP 1602): Nivolumab then ipilimumab + nivolumab in advanced nonclear cell renal cell carcinoma. *First Author: Ciara Conduit, Australian & New Zealand Urogenital and Prostate (ANZUP) Cancer Trials Group, Camperdown, Australia*

Background: Immune checkpoint immunotherapy (ICI) is active against many cancers. Many people are failed by PD1 inhibition alone, but not all patients benefit, nor require combination ICI treatment. UNISoN (NCT03177239) previously reported outcomes in people with nonclear cell renal cell carcinoma (nccRCC) receiving nivolumab (N) monotherapy, and N plus ipilimumab (I) in those whose cancers progressed after N alone. We present the final planned report. **Methods:** Population, Intervention, Analysis: Participants (pts) with advanced nccRCC with good performance status (ECOG 0/1) received N 240mg q2w alone (Part 1). Those with cancers refractory to N at 3 months were offered combination I (1mg/kg) + N (3mg/kg) q3w for up to 4 doses, followed by N 240mg q2w for a maximum total of 12 months of N (Part 2). UNISoN was powered to identify a clinically-relevant objective tumor response rate (OTRR) of 30% (assuming 15% was not relevant) among people receiving I+N in Part 2. **Results:** 85 pts with a representative spectrum of nccRCC histologies were enrolled and received N. Amongst the total population enrolled to UNISoN Part 1/2, mOS was 24 (16-28) months and 12m OS was 65% (54%-74%); of those proceeding to Part 2, the mOS was 10 (6-17) months only. Overall, 17% (10%-27%; 14/83) and 10% (3%-23%; 4/41) of pts experienced a response from N alone or I+N, respectively. 41 pts refractory to N received I+N. Overall in Part 2, the median time on treatment was 2.1 (95% CI 1.8, 2.8) months, the median number of cycles was 3; median follow-up at final analysis was 22 (16-30) months. In this population, the median PFS was 2.6 (2.2-3.8) months and 12m PFS was 11% (4%-23%). 13% (7%-22%) of patients were free of progression or death at 24 months. The primary endpoint was not met; only 80% of pts failed by N were assessable for response in Part 2. Overall tumor responses from N alone or I+N were more common in pts with papillary histology; pts with chromophobe histology had poor outcomes. No late toxicity safety signals were observed. **Conclusions:** Some pts with nccRCC benefit from N alone, or addition of I when disease is inadequately controlled by N alone, however most pts have limited benefit from ICI. More effective therapeutic options are needed for the majority of people with rare variant renal cell carcinomas. Novel markers of response are required to more rapidly predict pts who will progress on N. Translational research to identify predictive biomarkers of response is ongoing. Clinical trial information: NCT03177239. Research Sponsor: Bristol Myers Squibb, Other Government Agency, Australian and New Zealand Urogenital and Prostate Cancer Trials Group (ANZUP).

Prognostic value of the lung immune prognostic index in patients with untreated advanced renal cell carcinoma (aRCC) receiving nivolumab plus ipilimumab (N+I) or sunitinib (SUN) in the CheckMate 214 trial. *First Author: Lucia Carril-Ajuria, Gustave Roussy, Villejuif, France*

Background: The Lung Immune Prognostic Index (LIPI), defined by lactate dehydrogenase (LDH) and derived neutrophil to lymphocyte ratio (dNLR), has been shown to correlate with outcomes of immune checkpoint inhibitor therapy in patients (pts) with lung and other cancers, including pts with previously treated aRCC receiving nivolumab in the phase 2 NIVOREN GETUG-AFU 26 trial. We report an analysis of LIPI in pts with previously untreated aRCC receiving N+I or SUN in the randomized phase 3 CheckMate 214 trial with 5 years minimum follow-up. **Methods:** Data were used from CheckMate 214 comparing N+I (N 3 mg/kg + I 1 mg/kg) vs SUN (50 mg) for untreated aRCC (N = 1096). Pts with available LIPI data were categorized into 3 LIPI groups (good [LG], dNLR ≤ 3 and LDH ≤ upper limit of normal [ULN]); intermediate [LI], dNLR > 3 or LDH > ULN; and poor [LP], dNLR > 3 and LDH > ULN). This analysis focused on the prognostic value of LIPI using overall survival (OS) outcomes. Univariable analyses (UVAs) were conducted to evaluate LIPI groups alongside known risk factors including age, sex, IMDC risk, baseline PD-L1 status, prior nephrectomy, and baseline tumor burden. Variables that were statistically significant in UVAs ($P < 0.1$) were included in the full multivariable analyses (MVAs), from which a reduced model was generated. **Results:** A total of 1085 pts were evaluable for LIPI (N+I, n = 542; SUN, n = 543). Pts were distributed evenly between treatment arms for all 3 LIPI groups, but distribution between LIPI groups was unbalanced, with most pts grouped as LG (Table). OS outcomes were improved with N+I over SUN across all LIPI groups. Moreover, pts in the LG group had better OS outcomes vs pts in the LI or LP groups regardless of treatment, but with more distinct differences between LIPI groups in the SUN arm (Table). Final MVA results showed the LIPI correlated with OS for LI vs LG in the N+I arm and for LI vs LG and LP vs LG in the SUN arm (Table). **Conclusions:** These results from CheckMate 214 indicate the potential prognostic value of the LIPI in pts with untreated aRCC receiving N+I or SUN. Additional analyses are ongoing to further investigate the prognostic value of LIPI in this pt population and its impact on other clinical outcomes. Clinical trial information: NCT02231749. Research Sponsor: Bristol Myers Squibb.

Real-world treatment patterns in von Hippel-Lindau (VHL) disease-associated renal cell carcinoma (RCC): Costs of tumor reduction procedures and their complications. *First Author: Murali Sundaram, Merck & Co., Inc., Kenilworth, NJ*

Background: VHL disease is an inherited condition associated with tumors in multiple organs; RCC may affect up to 70% of patients with VHL. Patients often need many tumor reduction procedures (TRP) to manage renal neoplasms. This study evaluated TRP treatment patterns, costs, and complications among patients with VHL-RCC. **Methods:** Using an algorithm based on VHL manifestations, patients with VHL were identified from the Optum Clinformatics claims database. Patients were then selected with a prior RCC diagnosis. Minimum continuous enrollment of 12 months before and 3 months after first observed RCC diagnosis was required. TRPs for RCC included nephrectomy, renal ablation, and cryotherapy. Time to first TRP from initial observed RCC diagnosis was estimated using Kaplan-Meier analysis. Mean hospitalization costs per TRP type were estimated. Costs associated with TRP complications were estimated via linear regression; the explanatory variable was the presence of a given complication. Short-term complications were evaluated for 4 weeks post-TRP; long-term ones were evaluated over 6 months. Renal function was evaluated using chronic kidney disease (CKD) stages before and after TRPs, using diagnosis codes and eGFR lab values. **Results:** 160 patients with VHL-RCC were identified; mean follow-up time was 34.1 months. 115 (71.8%) patients incurred ≥1 RCC TRP over their study period. 68.4% had a TRP in the first year after RCC diagnosis and 76.5% had TRPs by year 5. Of the 125 observed TRPs, 97 (77.6%) were nephrectomies and 28 (22.4%) were ablation/cryotherapy. The mean costs for nephrectomy were nominally higher vs. ablation/cryotherapy ($29,313 vs. $18,290). The most common short-term complications were respiratory related (20.8%) and vascular injury/anemia (13.6%). The most common long-term complications were CKD stage 1-5 (24.0%) and end-stage renal disease (chronic dialysis dependence) (4.0%). The most expensive complications were related to impaired renal function: acute renal failure ($21,013 over 4 weeks), CKD ($26,032 over 6 months) and end stage renal disease ($65,338 over 6 months). At baseline, the proportion of patients with a diagnosis of CKD ≥ stage 3 was similar between patients who had TRPs (n = 115) and those who did not have TRPs (n = 45): 24.3% and 24.4%, respectively. After the first TRP, the proportion of patients with CKD ≥ stage 3 increased from 24.3% to 41.7%. **Conclusions:** Patients with VHL-RCC incur a significant clinical and economic burden related to TRPs for managing their renal tumors. This is in addition to the burden that VHL-RCC patients incur from the management of other VHL tumors. This study underscores the need for novel effective therapies to prevent or delay the recurrence of VHL-related renal neoplasms to mitigate the burden of morbidity and long-term medical management related to VHL. Research Sponsor: Merck & Co., Inc.

Prostate-specific membrane antigen (PSMA) positron emission tomography (PET) compared to computed tomography (CT) for advanced renal cell carcinoma (RCC). *First Author: Shivanshan Pathmanathan, Department of Oncology, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia*

Background: There is emerging role of the use of PSMA PET in RCC. Herein, we report our experience in use of PSMA PET in recurrent or metastatic RCC in Brisbane, Australia. **Methods:** Patients (pts) who underwent PSMA PET and conventional diagnostic CT for metastatic or recurrent RCC between 2015 and 2020 at three institutions were identified. Retrospective chart reviews were conducted using standardized collection template. The outcomes included percentage of patients who had a change in management secondary to PSMA PET findings, comparison of metastasis detection for PSMA PET vs. CT, and biopsy histology of PSMA avid sites. **Results:** 42 PSMA PET were performed in 40 patients. 10 pts (25%) and 30 pts (75%) had PSMA PET in the metastatic disease and recurrent disease setting, respectively. Table 1 highlights demographics. Overall, 12 pts (30%, n=3 metastatic, n=9 recurrent) had a change in management following PSMA PET. In the metastatic disease group, 2 pts (20%) underwent initial systemic therapy (after histological confirmation) due to higher burden of disease shown with PSMA PET than CT, while systemic therapy was changed for 1 pt (10%). In the recurrent disease group, PSMA improved delineation of suspected recurrence (compared to CT) resulting in resection rather than surveillance (n=4; 13%) or change in surgical approach for resection (n=1; 3%). PSMA PET distribution showed more metastatic sites than CT leading to systemic therapy rather than resection of recurrence (n=2; 7%), while absent PSMA activity for suspected recurrence on CT led to surveillance rather than resection (n=2; 7%). PSMA PET detected more sites of metastases compared with conventional scan in 6 pts (60%) with metastatic disease and in 9 pts (30%) with recurrent disease. 26 pts had biopsy of PSMA avid sites. Majority of pts had confirmed recurrence of clear cell renal carcinoma (n= 22; 85%). Other histology included sarcomatoid renal cell carcinoma (n=2; 8%), carcinoid (n=1; 4%), and urothelial cancer (n=1; 4%). In 2 instances, biopsy/resection was performed of a suspected recurrence on CT that was not PSMA avid, and neither showed malignancy. **Conclusions:** PSMA PET detected more accurately metastatic and recurrent disease, with high pathological concordance, to result in change in management for 30% of patients. Prospective study is warranted to further investigate the utility of PSMA PET scan in advanced RCC. Research Sponsor: None.

Baseline characteristics.

	Metastatic N=10	Recurrence N=30

Association between tumor burden and response to immunotherapy in patients with metastatic renal cell carcinoma. *First Author: Hesham Abdallah Yasin, Vanderbilt Ingram Cancer Center, Nashville, TN*

Background: Immunotherapy (IO) has become the standard of care in patients with metastatic renal cell carcinoma (mRCC), yet clinical biomarkers of outcome remain elusive. Preclinical and clinical studies have demonstrated that a lower tumor volume burden is associated with better response to IO in melanoma and lung cancer. **Methods:** Retrospective chart review of mRCC patients treated with Immunotherapy/Immunotherapy or Immunotherapy/Tyrosine kinase inhibitors (TKI) combinations at Vanderbilt Ingram Cancer Center was conducted. Baseline target tumor lesions including primary kidney tumors and treatment response were assessed by RECIST 1.1 criteria. The association between baseline tumor burden and outcomes of interest [progression-free survival (PFS) and overall survival (OS)] were assessed with multivariable Cox regression model. **Results:** 79 patients with mRCC were included in the cohort. The median age was 64, 80% were male, 82% had clear cell histology, and 73% were IMDC intermediate/poor risk group. 53% received IO/IO and 39% received IO/TKI. 71% had prior nephrectomy and 14% had prior systemic therapy. The median baseline tumor burden was 87 mm (range: 16-363 mm). After adjusting for age, gender, histology, prior nephrectomy/systemic therapy and IMDC risk, baseline tumor burden was not associated with either PFS (p-value: 0.42) or OS (p-value: 0.99). At the initial follow-up scan (median time of 3.1 months from treatment initiation) 22 (28%) patients had an objective response and 41 (52%) patients had stable disease. Among patients with tumor shrinkage, every 10% decrease seen in the sum of the target lesions was associated with improved PFS (AHR: 0.77, 95%CI: 0.63-0.94, p-value:0.009) and OS (AHR: 0.62, 95%CI: 0.42-0.93, p-value:0.02). **Conclusions:** While baseline tumor burden volume was not associated with clinical outcome to immunotherapy-based therapy in patients with metastatic RCC; however, the degree of early tumor shrinkage was significantly associated with better outcomes. Large tumor burden does not preclude response and good outcome to immunotherapies. Research Sponsor: None.

Activity of tivozanib in non-clear cell renal cell carcinoma (nccRCC): Subgroup analysis from a phase 2 randomized discontinuation trial. *First Author: Pedro C. Barata, Tulane University Medical School, New Orleans, LA*

Background: Non-clear cell renal cell carcinoma (nccRCC) is a blanket term for a collection of heterogenous and biologically diverse RCC histologies including (but not limited to) papillary, chromophobe and unclassified subtypes. Tivozanib is a selective VEGFR tyrosine kinase inhibitor with demonstrated activity in RCC with clear cell component. Here we report efficacy of tivozanib in a histologically diverse nccRCC subset included in a phase 2 study. **Methods:** We conducted a subgroup analysis of patients with nccRCC enrolled in the study 201 (NCT00502307), a phase 2 randomized discontinuation trial of tivozanib in patients with RCC who had no prior VEGF targeted treatment. Clinical outcomes including overall response rate (ORR), disease control rate (DCR, defined by CR+PR+SD), and progression free survival (PFS) were examined. Safety outcomes for all patients are reported in the original publication (Nosov, JCO 2012). **Results:** Of the 272 patients enrolled, 46 (16.9%) patients had nccRCC. [11 (4%) papillary, 2 (0.7%) chromophobe, 2 (0.7%) collecting duct, and 31 (11.4%) unclassified/mixed]. Of the 46 nccRCC patients, the ORR was 17.4% by investigator (INV) review and 15.2% by independent radiology review (IRR). The DCR was 80.4% by INV and IRR. The median PFS was 6.7 months (204 days) (95%CI: 125-366 days) by IRR (Figure 1). Of note, 14 patients with SD after 16 weeks on tivozanib were randomized to 12 weeks of placebo and may have progressed during that timeframe before unblinding and resuming tivozanib. Safety was not analyzed by histology but there were no new safety signals and was consistent with tivozanib labelling in the ITT population. **Conclusions:** Tivozanib demonstrated activity and a favorable safety profile in patients with nccRCC. This data adds to the body of evidence supporting VEGFR TKI use in advanced RCC including in non-clear cell histologies. Clinical trial information: NCT00502307. Research Sponsor: AVEO Oncology.

Variation in recurrence rate and overall survival (OS) outcomes by disease stage and incremental impact of time to recurrence on OS in localized renal cell carcinoma (RCC). *First Author: Naomi B. Haas, Abramson Cancer Center, University of Pennsylvania, Philadelphia, PA*

Background: Prior research shows that post-nephrectomy recurrence is correlated with significantly increased mortality in patients (pts) with intermediate-high (int-high) risk and high risk RCC. However, no study has quantified the incremental OS associated with increased time to recurrence (ToR). Additionally, limited evidence is presented on the variation of recurrence rate and OS by stage of RCC. **Methods:** The SEER-Medicare database (2007–2016) was used in this retrospective observational study. Post-nephrectomy pts with newly diagnosed, int-high risk (pT2 N0 high grade, pT3 N0 any grade) or high-risk (pT4 N0 any grade, pT any N1 any grade) RCC were identified and stratified based on tumor stage and grade. Grade was defined based on Furhman grading system and was reported in SEER Registry. Post-nephrectomy recurrence free rates and OS by disease stage were described using Kaplan-Meier analyses. OS from nephrectomy in pts with recurrence vs pts without recurrence was compared by disease stage. Multivariable regression analysis was used to quantify the incremental OS associated with increased ToR post-nephrectomy in all pts with recurrence. **Results:** 643 pts met the inclusion criteria (269 with vs 374 without recurrence; median follow-up: 23 months). The mean age was 75.5 years (yrs), 61% male, and 86% white. Results presented in the table showed wide variance in 5-yr recurrence-free rate in int-high risk group (28%-63%) and indicated substantial risk of disease recurrence in all subgroups of int-high risk pts. Among those with T3 Grade 1-2, T3 Grade 3, and T3 Grade 4 disease, pts with recurrence had significantly higher risk of death than those without (all ps<0.05;). Results for pts with T2 and T4 disease were not presented due to small sample size. Multivariable regression analysis indicated that 1 additional yr of ToR was associated with 0.73 additional yrs (8.8 additional months) of OS post nephrectomy (95% CI: 0.40, 1.05 yrs; p<0.001). **Conclusions:** The non-trivial recurrence rates observed in pts with T3 Grade 1-2 and T3 Grade 3 RCC highlighted the substantial risk of recurrence and unmet needs in the int-high risk RCC patients. This study also confirms the incremental nature of the association of ToR and OS in patients with int-high and high risk localized RCC. These findings highlight the need for effective early intervention with adjuvant treatments in int-high and high risk post-nephrectomy RCC pts. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Prognostic factors for patients with advanced renal cell carcinoma (aRCC) in the era of first-line (1L) treatment with immune checkpoint inhibitors (ICIs). *First Author: Charlene Mantia, Dana-Farber Cancer Institute, Boston, MA*

Background: The most commonly used prognostic models in aRCC, the Memorial Sloan-Kettering Cancer Center (MSKCC) and the International Metastatic Renal Cell Carcinoma Database Consortium (IMDC) risk scores, were developed when cytokines and VEGF targeted monotherapies were standard of care, respectively. aRCC 1L treatment now includes combination therapy with 2 ICIs or ICI+VEGF receptor inhibitor. Re-evaluation of the MSKCC and IMDC prognostic models in the era of ICI therapy and identification of additional prognostic factors are overdue. **Methods:** Data from 1052 patients with aRCC treated on the CheckMate-214 (CM214) clinical trial with 1L nivolumab/ipilimumab (NIVO/IPI) or sunitinib (SUN) were analyzed retrospectively at median follow-up 5 yrs. For each treatment group, multivariable Cox model hazard ratios (HR) were compared to the published MSKCC and IMDC model HRs. Discrimination (c index) was assessed based upon the continuous scores obtained as the weighted combination of regression parameters from the published MSKCC & IMDC models. **Results:** KPS < 80% remained highly prognostic in both treatment groups (HRs > 2.5). With the exception of high calcium, the other factors of time from dx to treatment < 1 yr, hemoglobin < lower limit of normal (LLN), neutrophils > upper limit of normal (ULN), platelets > ULN and LDH > 1.5xULN consistently retained prognostic value for SUN (HRs ≥ published model HRs) but had diminished prognostic value for NIVO/IPI (each HR < published model HR). High calcium had diminished prognostic value for SUN and retained prognostic value for NIVO/IPI. The c-indices for discrimination were 0.61 and 0.64 for the MSKCC model in the NIVO/IPI and SUN treatment groups, respectively, and were 0.63 and 0.67 for the IMDC model in the NIVO/IPI and SUN treatment groups compared to reported IMDC c-index of 0.73 (Heng 2009). (Table) **Conclusions:** The prognostic ability of the MSKCC and IMDC risk models is reduced with combination ICI treatment. Evaluation of additional prognostic factors and development of new risk scores are needed and this work is ongoing. Research Sponsor: BMS.

Outcomes with novel combinations in nonclear cell renal cell carcinoma (nccRCC): ORACLE study. *First Author: Deepak Kilari, Department of Medicine, Froedtert Cancer Center, Medical College of Wisconsin, Milwaukee, WI*

Background: Despite recent advances in the treatment of clear cell RCC, there is a paucity of data to guide management of nccRCC due to the heterogeneity and rarity of these tumors. The clinical activity of combination therapies (including IO-IO, IO-VEGF, VEGF-mTOR) in subtypes of advanced nccRCC is unknown. **Methods:** In this multicenter retrospective analysis, we evaluated the efficacy of combination systemic therapies in patients with nccRCC. Eligible patients included those with nccRCC as determined by local genitourinary pathology review and receipt of one of three combination regimens during any line treatment (IO-IO, IO-VEGF, mTOR-VEGF). The primary endpoint was objective response rate (ORR) assessed by investigator review. Secondary endpoints were progression- free survival (PFS), disease control rate (DCR), and overall survival (OS). **Results:** Among 128 included patients, median age was 57 years; 66% were male and 65% white. Histologies included papillary (37%), unclassified (33%), chromophobe (16%), translocation (9%), and other (5 %). Among all patients, 69% had prior nephrectomy; 80% were IMDC intermediate/poor risk; 20% had sarcomatoid and/or rhabdoid differentiation, 27% and 29% had liver and bone metastasis respectively and 63% received combination treatment as first line. Comparison of outcomes based on treatment regimen, line of treatment and subtype is shown in the table. Median PFS and OS were longer with IO/IO and IO/VEGF compared to VEGF/ mTOR at 8.5, 9.5 and 3.7 months and 24.4, 18.2 and 15.4 months respectively. **Conclusions:** Antitumor activity was observed with novel combinations in nccRCC in both frontline and later line setting. Optimal management of nccRCC remains an unmet need and prospective data is warranted to guide treatment selection for this population. Research Sponsor: None.

		First line		Second or later line	Papillary	Chromophobe	Unclassified/ other	Sarcomatoid component present	
	n	ORR (%)	Median PFS (mo.)	ORR (%)	ORR (%)	ORR (%)	ORR (%)	ORR (%)	OS (mo.)
IO/IO	68	24	8.5	5	8	20	24	39	24.4
IO/VEGF	44	28	9.5	0	7	0	35	37	18.2
VEGF/ mTOR	16	17	3.7	10	0	33	NA	NA	15.4

n- number of patients; mo.-months; NA-not available. IO/VEGF (pembrolizumab + axitinib/ atezolizumab + bevacizumab /avelumab + axitinib); IO/IO (Ipilimumab and nivolumab); VEGF/mTOR (lenvatinib plus everolimus).

LITESPARK-004 (MK-6482-004) phase 2 study of belzutifan, an oral hypoxia-inducible factor 2α inhibitor (HIF-2α), for von Hippel-Lindau (VHL) disease: Update with more than two years of follow-up data. *First Author: Eric Jonasch, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: VHL disease is associated with malignant or benign tumors, including renal cell carcinoma (RCC), pancreatic neuroendocrine tumors (pNETs), and hemangioblastomas. Alterations in the *VHL* gene cause aberrant stabilization and accumulation of HIF-2α, leading to activation of genes associated with tumor growth. Antitumor activity observed in the ongoing open-label phase 2 study, LITESPARK-004 (NCT03401788), led to the approval of belzutifan for the treatment of patients (pts) with VHL disease who require therapy for associated RCC, CNS hemangioblastomas, or pNETs not requiring immediate surgery. Updated results are presented after > 2 years of follow-up. **Methods:** Pts (≥18 years) with germline VHL alterations, ≥1 measurable nonmetastatic RCC tumor, no tumor of > 3 cm that necessitated immediate surgery, no prior anticancer systemic treatment, and an ECOG PS score of 0 or 1 received oral belzutifan 120 mg once daily until disease progression, unacceptable toxicity, or pt withdrawal. The primary end point was objective response rate (ORR) in VHL disease–associated RCC per RECIST v1.1 by independent central review (ICR). Secondary end points were safety, ORR in non-RCC neoplasms, and duration of response (DOR) in renal and nonrenal neoplasms, per RECIST v1.1 by ICR. **Results:** Of 61 pts, 50 were on treatment as of July 15, 2021; the primary reasons for discontinuation were disease progression in RCC neoplasms (n = 4) and pt decision to withdraw (n = 4). Twenty pts (33%) had ≥1 pNET and 50 (82%) had ≥1 CNS hemangioblastoma evaluable by ICR at baseline. At baseline, 97% of pts (n = 59) had prior VHL-related surgery; 38 pts had ≥1 VHL-related surgery within 3 years before starting belzutifan. Median time from first dose to database cutoff date was 29.3 mo (range, 27.6-37.5). ORR in RCC was 59% (n = 36), with 2 CRs (3%) and 34 PRs (56%). Median DOR was not reached (range, 8.3+ to 27.6+ mo). ORR in CNS hemangioblastomas was 38% (n = 19; 3 CRs; 16 PRs); median DOR was not reached (range, 3.7+ to 28.0+ mo). ORR in pNETS was 90% (n = 18; 3 CRs; 15 PRs); median DOR was not reached (range, 11.0+ to 31.0+ mo). Three pts (5%) underwent VHL-related surgeries after starting belzutifan. Grade 3 treatment-related adverse events (TRAEs) were reported in 10 pts (16%); the most common was anemia (n = 6 [10%]). No pt had a grade 4 or 5 TRAE. Two pts (3%) stopped treatment because of TRAEs (grade 1 dizziness and grade 2 intracranial hemorrhage). **Conclusions**: After a median follow-up of 29.3 mo, belzutifan continued to show antitumor activity in VHL disease–related neoplasms, including RCC, pNETs, and CNS hemangioblastomas, whereas the safety profile remained consistent with that of previous reports. These results support the use of belzutifan as a systemic treatment for VHL disease. Clinical trial information: NCT03401788. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Individualized prediction of post-surgical pathologic T3a (pT3a) upstaging risk in localized renal tumors undergoing nephrectomy (UroCCR 15 study). *First Author: Astrid Boulenger de Hautecloque, Bordeaux University Hospital, Bordeaux, France*

Background: Surgery is the standard of care for localized kidney cancer. Diagnostic imaging plays a critical role in disease staging and informs the extent of surgical resection (partial or radical nephrectomy, extended resection). In clinical routine, up to 15% of the tumors initially assessed as T1-T2 on imaging is upgraded to pT3a status post-surgery, implying a higher risk of relapse. The ability to correctly predict pT3a status pre-surgery would inform the surgical approach. An individualized prediction of the risk of clinical T1 or T2 tumors to be upstaged to pT3a is thus of high surgical interest. **Methods:** UroCCR is a French national network of 37 multidisciplinary teams for kidney cancer management that collects longitudinal data on the routine clinical care of its patients. A retrospective cohort of 4,395 cases of clinical T1-T2 kidney tumors was analyzed to develop a machine learning-based algorithm predictive of post-surgical pT3a upstaging risk at the individual patient level. For each patient, pre-surgical data were collected, including gender, age, symptoms, tumor size, tumor location, RENAL score, ECOG performance status, ASA score, and post-surgical pathological status. Sites were randomly assigned to the training or testing cohort, and their respective patient cases split between cohorts in a 60/40 ratio. Missing values were addressed through imputation performed with a k-nearest neighbor algorithm. Algorithms were trained on a data set of 2,636 patients and hyperparameters were optimized using a Bayes cross-validation (10-fold) approach . The area under the precision-recall curve (prAUC) was used as optimization metric. The performance of the algorithms for pT3a status prediction was then evaluated on the test dataset of 1,759 patients using precision-recall curves. **Results:** A logistic regression algorithm reached an AUC of 0.77 and a prAUC of 0.41. Higher values of the tumor size or age at surgery, the hilar location and the presence of symptoms at diagnosis were all associated with an increase of the predicted probability of pT3a upstaging. For each patient, Shapley values graphs were generated to display the pT3a upstaging probability and the relative contribution of each feature to the prediction. Three risk groups were defined based on the relative computed probability of pT3a upstaging, which displayed a statistically significant difference in Disease-Free Survival (DFS) ($p < 0.0001$), suggesting that pre-surgical multimodal data analysis could help predict long-term outcomes. **Conclusions:** This study suggests that machine learning applied to pre-surgical multimodal data can predict the risk of pT3a upstaging of a localized kidney tumor and inform long-term outcomes at the individual patient level. The results have been validated on an external cohort of 1,759 patients with data from the clinical routine. Research Sponsor: None.

Racial differences in treatment patterns and outcomes of first-line (1L) therapies for advanced renal cell carcinoma (aRCC) in the real-world (RW) setting. *First Author: Daniel M. Geynisman, Fox Chase Cancer Center, Philadelphia, PA*

Background: In 1L therapy for aRCC, nivolumab plus ipilimumab (NIVO+IPI) and pembrolizumab plus axitinib (PEM+AXI) have demonstrated significantly improved clinical outcomes versus sunitinib in phase III trials. African American/Black (AA) patients are grossly underrepresented in all aRCC trials. Little is known about the impact of racial differences on the use of 1L therapies and clinical outcomes in the RW setting. **Methods:** This retrospective chart review included AA and White American (WA) patients diagnosed with International Metastatic Renal Cell Carcinoma Database Consortium (IMDC)/Memorial Sloan Kettering Cancer Center (MSKCC) intermediate/poor (I/P)-risk aRCC who initiated on 1L NIVO+IPI, PEM+AXI, or tyrosine kinase inhibitor (TKI) monotherapy with sunitinib, pazopanib, or cabozantinib. Patients' demographic/clinical characteristics and outcomes were abstracted from medical charts by treating oncologists. Use of 1L therapy, treatment discontinuation, and clinical outcomes including disease response, landmark progression-free survival (PFS), landmark overall survival (OS), and treatment-related adverse event (TRAE) rates were assessed descriptively by race. **Results:** Of 473 patients, 95 (20.1%) were AA, and 378 (79.9%) were WA patients. Median follow-up was 10.9 months. A higher proportion of AA vs. WA patients had received 1L TKI monotherapy (21.1% vs. 16.1%). Treatment discontinuation rate was higher in AA vs. WA patients (49.5% vs. 43.4%). Treatment response was lower in AA than WA patients (overall response rate [ORR]: 58.8% vs. 74.8%; complete response [CR]: 8.2% vs. 11.4%). The TRAE rate was slightly lower in AA vs. WA patients (25.3% vs. 32.5%). Stratified clinical outcomes including landmark PFS and OS rates at 6 and 9 months are shown in the Table. **Conclusions:** In this RW I/P-risk aRCC cohort, fewer AA patients were treated with standard of care immune-oncology (IO)-based therapy vs. WA patients, which may contribute to differences in therapy discontinuation and survival outcomes. Also, even with short follow-up, clinically meaningful ORR differences are noted in AA and WA patients. Research Sponsor: Bristol Myers Squibb.

Clinical outcomes after 1L therapy, stratified by racial groups.

	Overall		NIVO+IPI		PEM+AXI		TKI mono	
(N)	AA (95)	WA (378)	AA (41)	WA (202)	AA (34)	WA (115)	AA (20)	WA (61)

Molecular characterization of the tumor microenvironment in chromophobe renal cell carcinoma (ChRCC) and related oncocytic neoplasms. *First Author: Chris Labaki, Dana Farber Cancer Institute, Boston, MA*

Background: ChRCC represents about 5% of all kidney cancer and has a dismal prognosis in the metastatic setting, with limited response to immune checkpoint inhibitors (ICI) and targeted therapy. We evaluated the molecular properties of ChRCC and related oncocytic neoplasms to define the tumor immune microenvironment and identify potential therapeutic strategies. **Methods:** ChRCC, renal oncocytoma (RO) and low-grade oncocytic tumor (LOT) samples with matched normal kidney specimens were evaluated using single-cell RNA sequencing (scRNA-seq) and single-cell T-cell receptor sequencing (scTCR-seq). T-cell antigenic specificities from scTCR-seq were inferred using a comprehensive database of annotated T-cell receptor sequences (VDJdb). The infiltration of CD45+ immune cells in renal oncocytic tumors and ccRCC samples was quantified using immunohistochemistry (IHC). Bulk RNA-sequencing (RNA-seq) data of clear cell RCC (ccRCC) and ChRCC were further analyzed using The Cancer Genome Atlas (TCGA) KIRC and KICH cohorts, respectively, with immune cell fractions calculated using CIBERSORTx. **Results:** After quality-control, 46,817 cells from 5 tumor (ChRCC: n = 3, RO: n = 1 and LOT: n = 1) and 4 normal samples were isolated for scRNA-seq analysis. Renal oncocytic tumors (ChRCC, RO, and LOT) had a low density of CD45+ cells (mean: 739 ± 114 cells/mm^2; n = 5) compared to ccRCC (mean: 3,420 ± 1,979 cells/mm^2; n = 5) ($p < 0.05$). Across all tumors, CD8+ T-cell clusters displayed a low expression of immune exhaustion markers (i.e. *PDCD1* [PD-1], *CTLA4*, *LAG3*, *HAVCR2* [TIM-3], and *TIGIT*). Analysis of TCGA bulk RNA-seq data after adjustment for CD8 T-cell fraction showed no difference in the expression of most immune exhaustion markers (i.e. *PDCD1*, *CTLA4*, *LAG3*) in ChRCC compared to normal samples ($p > 0.05$), contrasting with a substantially higher expression in ccRCC versus normal kidney ($p < 0.05$). Analysis of the T-cell repertoire (scTCR-seq) of ChRCC, RO and LOT samples did not identify a pattern of clonal expansion, and a considerable proportion of clonotypes were inferred to have specificity for viral antigens (range: 1.3 to 34.4% among all samples; 11.3 to 34.4% after filtering out two samples with a low (< 300) number of T-cells). **Conclusions:** Renal oncocytic tumors, including ChRCC, exhibit a low infiltration of immune cells, a non-exhausted immune phenotype and, a lack of clonally expanded tumor-specific T-cells. These findings may partially explain the molecular basis for the lack of response to ICIs in advanced ChRCC and outline the unique exhaustion phenotype of renal oncocytic tumors. Research Sponsor: US DOD Kidney Cancer Research Program KC180079.

Comprehensive genomic profiling (CGP) of chromophobe renal cell carcinoma (chrRCC) compared with non-chromophobe RCC (nonchrRCC): Impact of *FLCN* genomic alteration (GA) status. *First Author: Gennady Bratslavsky, SUNY Upstate Medical University, Syracuse, NY*

Background: *FLCN* is a tumor suppressor gene associated with cutaneous hair follicle development. *FLCN* germline mutations are linked to inherited chrRCC in the Birt-Hogg-Dube (BHD) syndrome. We queried whether clinically sporadic chrRCC featured *FLCN* mutations by comparing the genomic profiles of chrRCC with nonchrRCC. **Methods:** 109 chrRCC and 5,862 nonchrRCC underwent hybrid-capture based comprehensive genomic profiling (CGP) to evaluate all classes of genomic alterations (GA). Tumor mutational burden (TMB) was determined on up to 1.1 Mb of sequenced DNA and microsatellite instability (MSI) was determined on 114 loci. PD-L1 expression was determined by IHC (Dako 22C3). **Results:** Patients (pts) with chrRCC were more frequently female (37 [34%] vs. 1,817 [31%]) and younger than pts with nonchrRCC (median age 58 vs 62 years, $p < .0001$). None of the submitted clinical records in the chrRCC cases listed signs of BHD syndrome. *FLCN* GA were identified in the nonchrRCC cases only at 2.3% with 37% of the GA being germline. 1/109 (0.9%) of chrRCC featured a germline *FLCN* GA. GA/tumor were slightly higher in nonchrRCC vs chrRCC (3.6 vs 2.4; NS). There were no significant differences in gLOH, genomic signatures or ancestry between the groups. GA more frequent in chrRCC included *TP53*, *RB1*, *PTEN*. GA more frequent in the nonchrRCC included *VHL*, *BAP1*, *PBRM1*, *SETD2*, *CDKN2A/B*, *ARID1A*, *NF2*, *PIK3CA* and *TERT*. Biomarkers of immune checkpoint inhibitor (ICPI) drug response revealed higher mean TMB, TMB ≥10 mutations/Mb and *PBRM1* inactivating mutation frequencies in the nonchrRCC than the chrRCC indicating possible differences in IO drug response. **Conclusions:** *FLCN* mutations that are associated with familial incidence of chrRCC are rarely associated with sporadic chrRCC. Sporadic chrRCC has a substantially different genomic profile from nonchrRCC and appears to harbor fewer opportunities for both targeted and immunotherapies. Research Sponsor: Foundation Medicine Inc.

	chrRCC (109 cases)	nonchrRCC 5,862 cases)	P Value

Phase Ib trial of selinexor (SEL) in combination with nivolumab (NIVO) alone or nivolumab plus ipilimumab (NIVO+IPI) in patients (pts) with advanced malignancies: The renal cell carcinoma (RCC) experience. *First Author: Omar Alhalabi, The University of Texas MD Anderson Cancer Center, Houston, TX*

Background: SEL is a first-in-class nuclear exportin 1 inhibitor, which blocks the transport of several proteins involved in cancer-cell growth from the nucleus to the cytoplasm. A syngeneic RENCA mouse model showed that SEL combined with checkpoint blockade resulted in increased effector and activated T cells, and NKT cells and reductions in myeloid cells and Tregs. We hypothesized that SEL+NIVO and SEL+NIVO+IPI are well tolerated and improve the overall response rate (ORR) observed with anti-PD1/CTLA-4. **Methods**: NCT02419495 is an open label, single center phase IB study of SEL with multiple standard chemotherapy or immunotherapy regimens in pts with advanced malignancies using 3 + 3 design in dose escalation. For SEL+NIVO+IPI, SEL was 60 mg (N = 4) or 80 mg (N = 6) given P.O. weekly with NIVO 3 mg/kg x 4 cycles then 480 mg Q4W plus IPI 1 mg/kg Q3W for 4 cycles only. For SEL+NIVO, SEL was 40 mg twice a week (N = 8), or 60 mg twice a week (N = 11) given with NIVO 240 mg Q2W or 480 mg Q4W. Primary objective was to establish the safety and tolerability of SEL+NIVO and SEL+NIVO+IPI. Secondary objectives included ORR and progression free survival (PFS). **Results**: 29 pts with RCC (25 males) were enrolled (table), including 3 pts with nonclear cell RCC (nccRCC), with a median age of 64 years (IQR 56-69). 21 patients (72%) had prior systemic therapies. Most common SEL or NIVO/IPI treatment-related ≥ grade (G) 3 adverse events (AEs) included endocrine disorders (N = 3), hyponatremia (N = 3), leukopenia (N = 3), transaminitis (N = 3), thromboembolic events (N = 2), asymptomatic lipase increased (N = 2), anemia (N = 1), pneumonitis (N = 1), nephritis (N = 1), colitis (N = 1), fatigue (N = 1). Two pts discontinued therapy due to AEs (G3 pneumonitis from SEL+NIVO+IPI and G3 transaminitis from SEL+NIVO, respectively). At a median follow up of 17.5 months, 5 (17%) pts achieved a PR, and 17 (59%) achieved a stable disease (SD). The median PFS for the entire cohort was 17.5 months (SEL+NIVO+IPI: 7.2 months, SEL+NIVO: 17.5 months). Among the patients with clear cell RCC who received SEL+NIVO+IPI as first line (1L) therapy (N = 4), all (100%) achieved SD as best overall response. Among the patients with ccRCC who received SEL+NIVO as 1L (N = 2), one patient achieved confirmed PR and the other achieved SD. The median overall survival (OS) was 27.8 months (SEL+NIVO+IPI: unreached, SEL+NIVO: 21.3 months). **Conclusions**: Treatment with SEL in combination with NIVO or NIVO+IPI is well-tolerated and shows modest clinical activity as compared to historic NIVO or NIVO+IPI activity. Clinical trial information: NCT02419495. Research Sponsor: Karyopharm.

Baseline circulating soluble factors as predictors of response to nivolumab in metastatic clear cell renal cell carcinoma (mRCC): A validation study within the NIVOREN GETUG-AFU 26 translational study. *First Author: Lucia Carril-Ajuria, Gustave Roussy, Villejuif, France*

Background: The NIVOREN GETUG-AFU 26 study launched a translational research program to quantify baseline circulating soluble factors levels and correlate them with outcomes to nivolumab in mRCC pts. We previously identified on a training set (n = 80, 40 responders/40 progressors) several soluble factors significantly associated with worse overall survival (OS), progression-free survival (PFS) and response (IL-8 and VEGF), or with worse OS only (IL-6, IL-7) (Carril-Ajuria et al. ASCO GU. 2022). Our aim was to confirm these findings using an independent validation set. **Methods:** The remaining pts (n = 233) included in the translational-program of the NIVOREN study were included in this validation set. Based on previous results (training set), a panel of 7 different soluble factors (VEGF, VCAM-1, IL-6, IL-7, IL-8, BAFF, CXCL13) were quantified for each plasma sample using the MSD electrochemiluminescence assay. The association between baseline soluble-factors levels and response, PFS and OS was evaluated using previously identified cut-off values. **Results:** Two hundred thirty-three pts were included in the validation set. Baseline characteristics were similar to the overall trial population. The IMDC risk score breakdown was 17.7% good, 57.3% intermediate and 25.0% poor. With a median follow-up of 21.8 months (mo), the OS rate was 69.6% at 12 mo and median PFS was 3.0 mo. IL-8 (cut-off: 17.9 pg/ml) and IL-6 (cut-off: 8.7 pg/ml), involved in inflammation, confirmed an association with worse OS (IL8: HR = 2.57, $p < 0.0001$, IL-6: HR = 3.28,$p < 0.0001$) and worse PFS (IL-8: HR = 1.61,$p = 0.0008$, IL-6: HR = 1.68, $p = 0.0021$). VEGF (cut-off: 48.3 pg/ml) confirmed the association with worse OS (HR = 1.56, $p = 0.0176$), but not with PFS ($p = 0.2068$). IL-7, involved in T and B cells development, did not show a significant association with OS or PFS when using 8.6 pg/ml (training set) as cut-off ($p = 0.0675$ and $p = 0.7818$, respectively). IL-7 was the only cytokine to show an association with response ($p = 0.044$). Interestingly, circulating CXCL13 (cut-off: 106.4 pg/ml) and BAFF (cut-off: 1122.6 pg/ml), involved in B cell differentiation/survival, were significantly associated with worse OS (HR = 2.09, $p = 0.0001$ and HR = 2.34, $p = 0.0001$, respectively); BAFF showed a trend for worse PFS (HR = 1.29, $p = 0.0920$). **Conclusions:** Using the cut-off values previously identified in the training set, we confirmed a significant association between baseline blood concentration of IL-6/IL-8 and worse OS/PFS, and of VEGF with worse OS. Non-responders presented lower baseline circulating IL-7 concentrations. CXCL13 and BAFF were significantly associated with worse OS. Multivariate analyses are ongoing. Research Sponsor: PRT-K16-181 and Bristol-Myers Squibb.

Preventing adverse events in patients with renal cell carcinoma treated with doublet immunotherapy using fecal microbiota transplantation (FMT): Initial results from perform a phase I study. *First Author: Ricardo Fernandes, London Regional Cancer Program, Western University, London, ON, Canada*

Background: The treatment landscape of metastatic renal cell carcinoma (mRCC) has evolved with the advent of either dual immune checkpoint inhibition (ICI) or in combination with Vascular Endothelial Growth Factor Receptor Tyrosine Kinase Inhibitor. Gut microbiota plays a central role in developing local and systemic immunity, with potential influence in controlling antitumor immune response in cancer patients treated with ICI. We hypothesize that FMT from healthy donors given before immunotherapy will establish a more resilient gut microbiota, reducing the treatment toxicity and improving response to therapy. PERFORM is an ongoing phase I study evaluating the safety of FMT and immunotherapy combination in first-line (1L) mRCC, and assessing whether FMT will prevent or mitigate immune-related adverse events (irAE). **Methods:** Eligible patients with untreated mRCC received a full dose and 2 supportive FMT procedures prior to the first 3 cycles of doublet ICI or in combination with VEGF-TKI. Primary endpoint is the feasibility and safety of combining FMT using intestinal bacteria existing in the stool of healthy donors with immunotherapy. Secondary endpoints include incidence of irAEs, objective response rate (ORR; RECIST v1.1), and changes in pts microbiome and immune profile post-FMT. We included a preliminary analysis of the first 10 patients. **Results:** 10 patients received FMT and doublet ICI therapy (10 ongoing). 8/10 (80%) patients were male. Median Age: 59.5 (53-71) years-old. Most common histology was clear cell RCC (90%) and all patients had an intermediate or poor-risk disease. 93.3% of planned FMT were administered. No dose-limiting toxicities due to FMT were observed. Median (range) follow-up was 5.5 (1–22) months. 4 patients (40%) discontinued treatment due to irAEs: colitis (n = 3), arthritis (n = 1). IrAEs were reported in 8 (80%) patients, including diarrhea (n = 6; 60%) and skin rash (n = 2, 20%). Grade 3/4 AEs were experienced by 6 (60%) patients, including colitis (n = 4, 40%). ORR was confirmed in 4/9 patients (44%; 95% CI, 30–60); 1 (11%) partial response. Microbiota and immune analysis data to be presented. **Conclusions:** The role of microbiome modification in preventing immune-related toxicities by adding FMT to ICI therapy was associated with a safety profile in unselected 1L mRCC and promising clinical efficacy data. Further prospective studies to examine the changes in the immune and microbiota profiles to determine biomarkers related to healthy outcomes/less frequent toxicities in patients receiving immunotherapy are warranted. Clinical trial information: NCT04163289. Distinct outcomes in Hispanic/Latinx and non-Hispanic/Latinx patients with metastatic renal cell carcinoma (mRCC) treated with first-line ipilimumab plus nivolumab (ipi/nivo). *First Author: Sana Ali, Harbor-UCLA Medical Center, Torrance, CA*

Background: Subgroup analyses have reported differences in clinical outcomes by ethnicity in patients (pts) receiving immune checkpoint inhibitors (Cheng *et al* Ann Oncol 2019; Peravali *et al* World J Clin Oncol 2021). We sought to compare real-world outcomes between Hispanic/Latinx and non-Hispanic/Latinx mRCC pts treated with first-line ipi/nivo within a safety-net healthcare system and at a tertiary care center in Southern California. **Methods:** We performed a retrospective analysis of mRCC pts who received ipi/nivo within the Los Angeles County Department of Health Services (a safety-net healthcare system) and the City of Hope Comprehensive Cancer Center (a tertiary oncology center) between Jan 1, 2015 and Dec 31, 2021. Pts were identified using institutional databases and clinical data were compiled from electronic health records. Pts with pathologic diagnosis of stage IV mRCC, age > 18 years and receipt of ipi/nivo as first-line therapy were included. Progression-free survival (PFS) was analyzed using the Kaplan-Meier method and covariates were adjusted using multivariate Cox proportional hazards regression. **Results:** Of 96 pts, 67 (70%) were male, 90 (94%) had clear-cell histology, and 89 (93%) had intermediate/poor IMDC risk. Forty-two pts (44%) were Hispanic/Latinx while the remainder were non-Hispanic/Latinx (44 pts [46%] White, 7 pts [7%] Asian, and 3 pts [3%] Other). Fifty (52%) and 46 (48%) pts received their care at a tertiary care center and within a safety-net healthcare system, respectively. Median age, IMDC risk classification, BMI, and number of comorbidities were similar between both groups. Pooled analysis by ethnicity revealed significantly shorter PFS in Hispanic/Latinx vs non-Hispanic/Latinx pts (HR 1.60, 95% CI 1.04-2.48, p = 0.03). At 12 months, 19% of Hispanic/Latinx pts (95% CI, 9-32) and 35% of non-Hispanic/Latinx pts (95% CI, 23-48) were alive and progression-free. There was no difference in PFS between pts at the safety-net hospital system vs tertiary care center (HR 1.32, 95% CI 0.87-2.02, p = 0.19). **Conclusions:** Our real-world analysis of mRCC pts demonstrated poorer outcomes with ipi/nivo in Hispanic/Latinx pts. We are currently interrogating multiple social determinants of health that may contribute to these concerning disparities. Research Sponsor: None.

Transcriptomic profiling identifies genomic markers associated with benefit from stereotactic body radiation therapy (SBRT) in oligoprogressive metastatic renal cell carcinoma (mRCC). *First Author: Zeynep Busra Zengin, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Addition of SBRT to systemic therapy in oligoprogressive mRCC has been shown to prolong the duration of systemic treatment (Cheung *et al* Eur Urol 2021; De *et al* BJUI 2021). To date, the genomic predictors of benefit are unknown. We hypothesized that hypoxia-related genes would be associated with lesser benefit from SBRT. **Methods:** We retrospectively identified patients (pts) with mRCC who had oligoprogressive disease (progression of < 5 sites) while on systemic treatment and received SBRT without any systemic treatment change or interruption. Clinicopathologic characteristics, whole exome and transcriptome sequencing (Ashion Analytics) data were collected. Duration of systemic therapy (DOT) was quantified as systemic treatment duration prior to oligoprogression (DOT[P]) and after completion of SBRT (DOT[S]). The ratio of DOT[S]/DOT[P] was calculated and patients with a ratio ≥ 1.0 were considered to derive greater benefit from SBRT. The frequency of specific DNA alterations and RNA expression of pts above and below a DOT[S]/DOT[P] threshold of 1.0 was compared using a two-tailed Fischer's exact and student's t-test, respectively. **Results:** In this study, 23 mRCC pts who had oligoprogression during systemic treatment and received SBRT were identified. Within this cohort 16 pts (69.6%; M:F, 12:4) had available genomic data. Median age was 70 years and the most common histology was clear cell (87.5%). At the time of oligoprogression 11 pts (68.8%) were on immunotherapy, 4 pts (25.0%) were on targeted therapy. Median DOT[S] and DOT[P] were 12.6 months (range,0.7-46.3) and 13.4 months (range, 0.5-26.9), respectively, with a median DOT[S]/DOT[P] ratio of 1.4 (range,0.01-3.8). The most commonly mutated genes were *VHL* (56.3%), *PBRM1* (37.5%), and *SETD2* (37.5%). Alterations in *VHL, PBRM1* and *SETD2* were seen in 66.7% vs 42.9%, 33.3% vs 43.9%, and 44.4% vs 28.6% in patients with greater vs lesser benefit from SBRT, respectively (p≥0.05for each). Transcriptomic analysis was available in 9 pts and 1580 genes were noted to be differentially expressed between the groups (p < 0.05). Limiting scope to cancer genes in the COSMIC database, pts with lesser benefit from SBRT had higher expression of *CDKN1B, CNBP*, and *FOXO3* whereas pts with greater benefit had higher expression of *RNF43, POLD1* and *PBRM1* (p < 0.05 for each). Gene set enrichment analysis showed a trend towards increased expression of hypoxia related genes in pts with lesser benefit. **Conclusions:** Our data align with existing studies supporting the role of SBRT in oligoprogressive mRCC. In addition, while clinical benefit from SBRT appears to be independent of DNA-level alterations, transcriptomic analysis revealed significant differences in gene expression. Hypoxia-associated signatures may be associated with lesser benefit from radiotherapy. Research Sponsor: None.

Association of antibiotic therapy and treatment efficacy in patients with renal cell carcinoma receiving immune checkpoint inhibitors. *First Author: Avery Braun, Einstein Healthcare Network, Philadelphia, PA*

Background: There is growing evidence indicating that gut microbiome content is associated with the effectiveness of immune checkpoint inhibitory (ICI) therapy in various cancer types. Antibiotic therapy (ABT) induces significant changes in gut microbiota; however, the effects of ABT on oncologic outcomes with ICI therapy has only been explored in small, single-institution studies. We aimed to investigate the relationship between ABT on overall survival (OS) and real-world progression free survival (rwPFS) in subjects with advanced renal cell carcinoma (RCC) treated with ICI utilizing a national database. **Methods:** We queried the nationwide electronic health record (EHR)-derived de-identified FlatIron Health (FIH) database after Institutional Review Board approval was obtained and included a waiver of informed consent to select 1809 subjects who received ICI therapy. Patient characteristics were described and compared between those with known ABT use and without known ABT use (in the 3 months pre/post ICI initiation) using ANOVA and Chi-square tests. rwPFS and OS were calculated from date of initiation of ICI to date of real-world progression/date of death. Three-month landmark Kaplan Meier and log-rank tests were used to compare rwPFS and OS between groups defined by ABT use (any ABT, and ABT in 3 months pre-ICI vs 3 months post-ICI initiation). Cox proportional models were used to investigate the association between rwPFS, OS, and antibiotic use, adjusting for patient characteristics. **Results:** Patients receiving ABT group were younger (p = 0.007) and more likely female (p = 0.024) but similar in other measured demographic variables. rwPFS (median: 9.03 vs 11.6 months; p = 0.015) and OS (median: 23.7 vs 31.8 months; p = 0.019) were significantly shorter in the with-ABT group than in the without-ABT group. When assessing ABT use 3 months prior to initiation of ICI (vs ABT during/no known ABT use), neither rwPFS (median: 9.53 vs 11.66, p = 0.38) nor OS (median: 23.7 vs 22.6 months; p = 0.38) were significantly different. However, rwPFS (median: 23.5 vs 14.0 months vs not reached; p = 0.004) and OS (median: 36.2 vs 22.5 vs 31.8; p = 0.007) were statistically significantly different when stratifying based on exposure and timing of ABT amongst pre-ICI initiation ABT, post-ICI initiation ABT and no ABT groups, respectively. Multivariable analysis identified as a significant predictor of rwPFS (HR = 0.725, CI = 0.579-0.908; p = .005) and OS (HR = 0.722, CI = 0.573-0.911; p = 0.006). **Conclusions:** This study identifies a significant negative prognostic association of ABT administration on survival in advanced RCC treated by ICI in the first line setting. These results are consistent with the growing body of evidence suggesting that alterations in gut microbiome secondary to antibiotics appear to blunt efficacy of ICI treatment and emphasize the importance of antibiotic stewardship. Maturation of overall survival (OS) in TIVO-3 with long-term follow-up. *First Author: Brian I. Rini, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: Maturity of survival data is a consideration in the value assessment and confident clinical application of oncology drugs based on trial evidence. TIVO-3 supported FDA-approval of tivozanib (TIVO) in relapsed/refractory (R/R) advanced RCC, meeting the primary endpoint of significantly improved PFS over sorafenib (SOR) (HR: 0.73, 95% CI, 0.56-0.95). Long-term follow-up analyses demonstrate that the PFS rate at 3-years with TIVO is >5x higher than with SOR (12% vs 2%, respectively), yet a significant OS benefit for TIVO has not been observed to date. Here we report the contribution of event accumulation and data maturation on the stability of KM survival estimates. **Methods:** Intent-to-treat analyses of Cox proportional hazards and log-rank statistics were used to estimate the HR and 95% CI for OS in the TIVO-3 trial at pre-specified (2-years after last-patient-in [LPI]; ≥251 events) and exploratory extended follow-up timepoints (≥270 events; database closure). Patients were followed for survival until death, consent withdrawal, or loss to follow-up. **Results:** 350 patients were randomized 1:1 to TIVO (n=175) or SOR (n=175). 2-years post LPI and a mean follow-up of 17.9 months (data cut-off August 2019), 65% of patients experienced an event (HR: 0.99, 95% CI, 0.76-1.29). Subsequent analyses are reported at 20.3 (May 2020), 21.9 (January 2021), and 22.8 (May 2021) months follow-up. Accumulation of events and HR over time is shown in the Table. After almost 23 months of follow-up and realization of 80% of events, OS HR has decreased to below 0.90, in favor of TIVO. **Conclusions:** Serial OS analyses using KM estimates are subject to increased curve reliability with decreased censoring and limited residual patients at risk for death. Long-term follow-up of TIVO-3 suggests early and consistent PFS benefit with TIVO over SOR is associated with an OS HR decline over-time with more events. Clinical trial information: NCT02627963. Research Sponsor: Aveo Oncology.

TIVO-3 OS HR with extended follow-up.

Data cut-off date	Follow-up, months mean (95% CI)	Events, n	HR (95% CI)
August 2019	17.9 (16.7–19.1)	227	0.99 (0.76–1.29)
May 2020	20.3 (18.8–21.8)	251	0.97 (0.75–1.24)
January 2021	21.9 (20.2–23.6)	270	0.91 (0.72–1.17)
May 2021	22.8 (20.9–24.6)	280	0.89 (0.70–1.14)

A robust, trial-agnostic gene signature for response to tyrosine kinase inhibition in ccRRCC. *First Author: Sari Khaleel, Memorial Sloan-Kettering Cancer Center-Fellowship (GME Office), New York, NY*

Background: Combination systemic therapies (ST) including immunotherapy (IO) and Tyrosine Kinase Inhibitors (TKI) have become the standard of care for management of metastatic clear cell carcinoma (ccRCC). Several expression (GE) signatures have been reported to predict TKI response with the aim of identifying the optimal ST regimen (IO/IO or IO/TKI) per patient. However, these gene signatures were developed and evaluated using data from individual trials with clinically distinct patient cohorts, fundamentally impeding their general application to diverse and heterogeneous patient populations. We therefore sought to identify genes consistently and directly associated with progression-free survival (PFS) with TKI ST across several trials. **Methods:** We applied a stratified, weighted concordance model to identify genes consistently demonstrating statistically significant association with PFS in the sunitinib TKI arm in four large randomized controlled trials (RCTs) of ST in ST-naïve ccRCC patients: COMPARZ (Motzer et al, 2013), Checkmate 214 (Motzer et al, 2018), IMmotion 151 (Rini et al, 2019), and Javelin 101 (Motzer et al, 2019). Concordant genes with Benjamini-Hochberg adjusted p-value (pAdj) ≤ 0.01 were selected. Of these, genes significantly associated with PFS on Cox proportional hazard regression (pAdj ≤ 0.05) in at least 3 of the 4 datasets were selected. Ontologic process and pathway enrichment analyses (OPPEA) against several ontologic databases were peformed using Metascape (Zhou et al, 2019). **Results:** We identified 2,794 statistically significant genes demonstrating concordant association with PFS across all 4 datasets (1087 patients); 71 genes were significantly associated with PFS on univariate *post-hoc* analysis in ≥3 of the datasets. OPPEA of these results identified significant enrichment in genes associated with cell cycle, cell division, and VEGFA-VEGFR2 pathways (Table 1). Although 5 genes in our set overlapped with published angiogenesis GES, the majority of these genes constitute entirely novel transcriptomic correlates of response to sunitinib. **Conclusions:** We developed a robust meta-gene signature consisting of genes directly and consistently associated with TKI response using data from several clinical trials. This gene signature is readily applicable to heterogeneous patient populations treated with anti-VEGF therapies. Research Sponsor: U.S. National Institutes of Health.

Top 5 enriched processes on OPPEA using Metascape platform against several ontologic databases including Gene Ontology (GO) and Reactome.

Ontologic Database	Entry ID	Process Description
GO	GO:0000278	Mitotic cell cycle
Reactome	R-HSA-194315	Signaling by Intracellular Rho GTPases
GO	GO:0001944	Vasculature Development
Reactome	R-HSA-1640170	Cell cycle
GO	GO:0010564	Regulation of cell cycle process

Avelumab first-line (1L) maintenance for advanced urothelial carcinoma (aUC): Long-term outcomes from JAVELIN Bladder 100 in subgroups defined by response to 1L chemotherapy. *First Author: Begoña Pérez-Valderrama, Hospital Universitario Virgen del Rocío, Seville, Spain*

Background: In the phase 3 JAVELIN Bladder 100 trial (NCT02603432), avelumab 1L maintenance + best supportive care (BSC) significantly prolonged overall survival (OS) vs BSC alone in patients (pts) with aUC that had not progressed with 1L platinum-based chemotherapy. We report exploratory analyses in subgroups defined by response to 1L chemotherapy (complete response [CR], partial response [PR], or stable disease [SD]) after ≥2 years of follow-up. **Methods:** Eligible pts had unresectable locally advanced or metastatic UC without progression with 4-6 cycles of 1L gemcitabine + cisplatin or carboplatin. Pts were randomized 1:1 to receive avelumab + BSC (n = 350) or BSC alone (n = 350), stratified by best response to 1L chemotherapy (CR/PR vs SD) and visceral vs nonvisceral disease at start of 1L chemotherapy. **Results:** At data cutoff (June 4, 2021), median follow-up in both arms was ≥38 months. OS and PFS were longer in the avelumab + BSC vs BSC alone arm in all subgroups (Table). Median duration of study treatment and incidence of grade ≥3 treatment-emergent adverse events (TEAEs) in subgroups are shown in the Table. In the avelumab + BSC vs BSC alone arm, respectively, subsequent second-line anticancer drug therapy was received by: CR subgroup, 50.0% vs 74.2%; PR subgroup, 58.3% vs 71.8%; and SD subgroup, 46.4% vs 70.4%. **Conclusions:** Long-term follow-up from JAVELIN Bladder 100 continues to show prolonged OS and PFS with avelumab + BSC vs BSC alone irrespective of response (CR, PR, or SD) to 1L chemotherapy and despite a higher proportion of pts in the BSC alone arm receiving subsequent therapy. Long-term safety was consistent across subgroups. These findings further support avelumab 1L maintenance as standard of care for all pts with aUC that has not progressed with 1L platinum-based chemotherapy. Clinical trial information: NCT02603432. Research Sponsor: Pfizer, Pharmaceutical/Biotech Company.

Long-term outcomes in patients with advanced urothelial carcinoma (UC) who received avelumab first-line (1L) maintenance with or without second-line (2L) treatment: Exploratory analyses from JAVELIN Bladder 100. *First Author: Joaquim Bellmunt, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA*

Background: Avelumab 1L maintenance + best supportive care (BSC) significantly prolonged overall survival (OS) vs BSC alone in patients (pts) with advanced UC that had not progressed with 1L platinum-based chemotherapy (median OS, 23.8 vs 15.0 months; HR, 0.76 [95% CI, 0.631-0.915]; 2-sided p = 0.0036). Avelumab 1L maintenance is now considered standard of care per international guidelines. However, data on outcomes in pts who receive 2L treatment after avelumab 1L maintenance are limited. We report a descriptive analysis of outcomes in pts enrolled in the avelumab + BSC arm of the JAVELIN Bladder 100 trial based on receipt of 2L treatment. **Methods:** In the phase 3 JAVELIN Bladder 100 trial (NCT02603432), eligible pts had unresectable locally advanced or metastatic UC without progression with 4-6 cycles of 1L gemcitabine + cisplatin or carboplatin. Pts were randomized 1:1 to receive avelumab + BSC or BSC alone. Exploratory analyses of time from randomization to end of 2L treatment and OS were performed in the avelumab + BSC arm in subgroups defined by 2L treatment administered by investigators after discontinuation of study treatment. **Results:** In the avelumab + BSC arm (n = 350), median follow-up at data cutoff (June 4, 2021) was 38.0 months. 185 pts (52.9%) had discontinued avelumab 1L maintenance treatment for any reason and received 2L treatment, whereas 122 (34.9%) had discontinued avelumab and did not receive 2L treatment. Median OS (95% CI) in subgroups is shown in the Table. In 43 pts (12.3%) who were still receiving avelumab, median treatment duration was 154.6 weeks (range, 106.7-216.0). Among pts who received 2L treatment, median time from end of avelumab 1L maintenance to start of 2L treatment was 1.35 months (range, 0.3-30.9) and median time from randomization to end of 2L treatment was 11.7 months (95% CI, 9.7-13.8). 2L treatment comprised rechallenge with platinum-based chemotherapy in 75 pts (21.4%) or other 2L treatment in 110 pts (31.4%), including 2L anti–PD-(L)1 therapy in 11 pts (3.1%). Additional data based on different types of 2L treatment will be presented. **Conclusions:** In this exploratory analysis from the JAVELIN Bladder 100 trial with extended follow-up, approximately 60% of pts (185/307 pts) who had discontinued avelumab received 2L treatment. Long-term OS was observed in pts who received avelumab 1L maintenance with or without 2L treatment. Clinical trial information: NCT02603432. Research Sponsor: Pfizer, Pharmaceutical/Biotech Company.

	n	Median OS (95% CI), mo

Health-related quality of life (HRQoL) for patients with advanced/metastatic urothelial carcinoma (UC) enrolled in KEYNOTE-052 who are potentially platinum ineligible. *First Author: Rafael Morales-Barrera, Vall d'Hebron Institute of Oncology, Vall d'Hebron University Hospital, Universitat Autònoma de Barcelona, Barcelona, Spain*

Background: Frontline cisplatin-based chemotherapy improves survival in patients (pts) with UC, but ~50% are cisplatin-ineligible owing to poor performance status or comorbidity. The definition of platinum ineligibility is not standardized; hence, treatment decisions are almost solely made by clinical judgment. Pembrolizumab (pembro) showed antitumor activity and manageable toxicity as frontline therapy in 370 cisplatin-ineligible pts in the single arm, phase 2 KEYNOTE-052 trial (NCT02335424). We present effects of pembro on HRQoL of pts in KEYNOTE-052 who were potentially platinum ineligible in this exploratory analysis. **Methods:** Eligible pts for KEYNOTE-052 were adults with no prior systemic chemotherapy for advanced/metastatic UC, ECOG PS ≤2, and measurable disease per RECIST v1.1 by blinded independent central review. Pembro 200 mg IV was administered Q3W for up to 2 y. Clinical characteristics of frail pts (platinum ineligible) were identified by extensive review of real-world treatment patterns and relevant literature. Consequently, platinum ineligibility was defined as having an ECOG PS ≥2 plus ≥1 of the following: visceral disease, creatinine clearance < 60 mL/min, or age ≥80 y. HRQoL was assessed using the EORTC QLQ-C30 and EQ-5D-3L during the first 4 cycles, then every 2 cycles for 1 year or until treatment discontinuation (whichever occurred first), and at least 30 days after treatment discontinuation. Key end points were change from baseline per the QLQ-C30 global health status (GHS)/QoL score, QLQ-C30 physical functioning subscale, and EQ-5D visual analog scale (VAS). The minimum important difference (MID) was 10 for QLQ-C30 score change (improved: ≥10; stable: −10 to 10; deteriorated: −10 or less); MID for VAS score change was 7 (improved: ≥7; stable: −7 to 7; deteriorated: −7 or less). **Results:** Median age for 143 pts was 75 y (range, 34-91); 129 pts (90.2%) had visceral disease; 142 (99.3%) had ECOG PS 2; 1 had ECOG PS 3 (enrolled in error). Compliance rate for HRQoL questionnaires was 93.7% at baseline. At the prespecified analysis time of week 9, 77.6% of pts had improved (n = 51) or stable (n = 60) QLQ-C30 GHS/QoL scores, 64.3% had improved (n = 35) or stable (n = 57) QLQ-C30 physical functioning scores, and 62.2% had improved (n = 56) or stable (n = 33) EQ-5D VAS scores. These scores were stable throughout the HRQoL assessment period for pts who continued pembro. **Conclusions:** In this exploratory analysis, pembro maintained HRQoL for pts with advanced/metastatic UC in KEYNOTE-052 who were potentially platinum-ineligible per the above criteria. Together with the efficacy and safety data from KEYNOTE-052, these data suggest that pembro monotherapy is a valuable treatment option for select pts with advanced UC who are more senior and/or deemed medically frail. Clinical trial information: NCT02335424. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

Association between molecular subtype membership or hypoxia-associated gene expression signatures and clinical outcomes in the CALGB 90601 (Alliance) phase 3 clinical trial of gemcitabine and cisplatin (GC) plus bevacizumab (B) or placebo (P). *First Author: David James McConkey, Johns Hopkins Greenberg Bladder Cancer Institute, Baltimore, MD*

Background: Our previous work showed that basal tumors were associated with the best clinical outcomes in a Phase 2 clinical trial of neoadjuvant dose-dense MVAC plus B, and in other work we showed that basal tumors were enriched with hypoxia-associated gene expression signatures. Here we attempted to validate these findings in the C90601 Phase 3 clinical trial of GC plus B versus GC plus P. **Methods:** Whole transcriptome RNAseq was performed on all available tumors using Ion Torrent's Ampliseq platform (n = 189). Tumors were assigned to molecular subtypes using 3 different classifiers - BASE47 (k=2), MDA oneNN (k=3), and the Consensus classifier (k=6). Tumor hypoxia signature enrichment was determined using 2 different gene expression signatures and gene set variation analysis (GSVA). The proportional hazards model was used to correlate molecular subtype calls and hypoxia signature enrichment with overall survival (OS) and progression-free survival (PFS) adjusting for stratification factors and treatment arm (for PFS). **Results:** The median OS & PFS by different signatures and the hazard ratios (HR) are presented in the Table. **Conclusions:** Predefined signatures associated with clinical benefit in the Phase-2 neoadjuvant clinical trial were not associated with benefit in C90601. Possible explanations include the lack of strong therapeutic effects of the treatments, potential heterogeneity ("subtype plasticity") between the profiled tissue samples and the metastatic lesions under treatment pressure, and differences in biology associated with the disease states (muscle-invasive vs advanced/metastatic disease). Support: U10CA180821, U10CA180882, Department of Defense (CA160312), Genentech; ClinicalTrials.gov Identifier: NCT00942331. Research Sponsor: US Department of Defense Peer-reviewed Cancer Research Program, U.S. National Institutes of Health.

Phase Ib study of anti-PD-L1 monoclonal antibody socazolimab in combination with nab-paclitaxel as first-line therapy for advanced urothelial carcinoma. *First Author: Rong Duan, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Department of Renal Cancer and Melanoma, Peking University Cancer Hospital & Institute, Beijing, China*

Background: PD-1/PD-L1 immune checkpoint inhibitors (ICIs)Ohave demonstrated activity in the postplatinum and platinum-ineligible settings for advanced urothelial carcinoma (aUC). As only around 30% of patients with aUC can tolerate platinum standard treatment, first-line ICIs combined with non-platinum drugs have certain research value. Therefore we assessed the safety and efficacy of anti-PD-L1 monoclonal antibody Socazolimab in combination with nab-paclitaxel as first line therapy in aUC (NCT04603846). **Methods:** This is a multi-center,single-arm, phase Ib study which enrolled aUC patients with treatment-naive or first recurrence more than 6 months after the end of adjuvant chemotherapy in China. Eligible patients received Socazolimab (5mg/kg) and nab-paclitaxel (260mg/m^2) every 3 weeks. Primary endpoint was to investigate the safety and tolerability of nab-paclitaxel in combination with Socazolimab. Second endpoints were the objective response rate (ORR) and progression-free survival (PFS). **Results:** 20 patients were enrolled, including 5 renal pelvis urothelial carcinoma, 8 bladder urothelial carcinoma, and 7 ureteral carcinoma. The median age was 69 years. As of January 14, 2022, the median follow-up time was 5.49 months. Median number of treatment cycles was 6.5 cycles. No patients had dose limiting toxicity. Among the 17 patients who had received at least one tumor assessment, 8 patients achieved partial responses. ORR was 52.94% (95% CI, 27.81-77.02). DCR was 88.24% (95% CI, 63.56-98.54). Median PFS was 8.18 months (95% CI, 5.32-13.60). Adverse reactions related to the study drug were mainly Grade 1-2. Common adverse reactions included rash (6/20,30%), increased alanine aminotransferase (6/20, 30%), increased γ-glutamyltransferase (4/20, 20%),sinus bradycardia (4/20, 20%), increased aspartate aminotransferase (4/20, 20%),pruritus (3/20, 15%). Grade 3 or higher treatment-related adverse events occurred in 4 (20%) patients, mainly Grade 3 increases in alanine aminotransferase (2/20, 10%). No confirmed treatment-related deaths occurred, and no treatment-related deaths occurred, and no new safety signals were observed. **Conclusions:** Socazolimab combined with nab-paclitaxel as first-line treatment was effective and well-tolerated in Chinese patients with advanced urothelial carcinoma, warranting phase II trials. Clinical trial information: NCT04603846. Research Sponsor: Funded by Lee's Pharmaceutical Holdings Limited, Hong Kong SAR.

Prognostic impact of bone metastasis in patients with metastatic urothelial carcinoma (mUC) treated with durvalumab (D) with or without tremelimumab (T) in the DANUBE study. *First Author: Carlos Stecca, Division of Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada*

Background: In mUC, bone metastases (BM) are associated with significant morbidity and mortality, but their independent impact on outcomes is not well established, especially in the current era of immune checkpoint inhibitors (ICIs). This post-hoc analysis assessed the impact of BM, as well as PD-L1 status (within the same BM category) on outcomes of patients with mUC treated with ICIs. Data was derived from the Phase 3 DANUBE study, which compared D, D+T, and standard chemotherapy (SoC). **Methods:** Patient characteristics, disease characteristics, treatments, and outcomes were collected. Patients were categorized as having BM or no BM. Outcomes included median overall survival (OS) and median progression-free survival (PFS) (in months [mo]), estimated by the Kaplan-Meier method. PD-L1 expression was assessed using the VENTANA PD-L1 (SP263) Assay. **Results:** Overall, 1032 patients were included; 266 had BM (D, 80; D+T, 97; SoC, 89), and 766 had no BM (D, 262; D+T, 249; SoC, 255). Among all patients, those with BM had a lower OS than those with no BM (HR, 1.67; 95% CI, 1.43-1.92; nominal P< 0.0001) when controlling for cisplatin eligibility, PD-L1 expression, presence of visceral metastases, and treatment. Similarly, patients with BM had lower PFS compared to those without BM (HR, 1.52; 95% CI, 1.30-1.75; nominal P< 0.0001) Within each treatment arm, median OS was lower for patients with BM compared to patients with no BM for all patients, regardless of PD-L1 status (Table). Patients with BM and PD-L1–high expression, treated with either D or D+T, had numerically higher median OS compared to those with PD-L1 low; this difference was also seen in patients with no BM. In contrast, there was no difference in median OS, for BM or no BM, based on PD-L1 expression for patients treated with SoC (Table). **Conclusions:** In this post-hoc analysis, presence of BM was significantly and consistently associated with worse outcomes in patients with mUC across all treatment arms of the DANUBE study. PD-L1–high expression was associated with higher median OS in patients treated with D or D+T, regardless of presence of BM. These data reinforce the negative prognostic impact of BM in mUC and the role for PD-L1 expression in predicting benefit for patients treated with ICIs. Funding: AstraZeneca. Clinical trial information: NCT02516241. Research Sponsor: AstraZeneca.

	D (N = 342)	D+T (N = 346)	SoC (N = 344)

Real-world treatment patterns and clinical outcomes with first-line therapy in cisplatin-eligible and ineligible patients with advanced urothelial carcinoma. *First Author: Guru P. Sonpavde, Dana Farber Cancer Institute, Boston, MA*

Background: Advanced urothelial carcinoma (aUC) has a poor long-term prognosis. Despite new clinical trial data for novel therapies including PD-1/L1 inhibitors, data on real-world (RW) treatment patterns and overall survival (OS) in aUC patients (pts) treated with first line (1L) therapy are limited. **Methods:** This retrospective observational study describes the contemporary RW 1L treatment patterns and OS in aUC pts stratified by cisplatin (cis)-eligibility (based on accepted criteria) and treatment. Data were from the nationwide Flatiron Health longitudinal electronic health record-derived database, comprising de-identified patient-level structured and unstructured data. Eligible pts were adults diagnosed with aUC from May 2016-Oct 2020 and followed until death or end of data availability in July 2021. OS was estimated using Kaplan-Meier methods and compared via multivariable Cox proportional-hazard models adjusted for clinical covariates. **Results:** Of 4,300 aUC diagnosed pts, 3,311 (77.0%) received 1L treatment; 1836 (55.5%) cis-ineligible, 1475 (44.5%) cis-eligible. Differences between cis-ineligible and cis-eligible pts were observed, with cis-ineligible more likely to be older (mean age, 75.0 vs 69.0 yrs), have lower CrCl (median, 45.3 vs 80.7 mL/min), and worse ECOG-PS (2+, 29.2 vs 0%). Only 44.4% received 2L therapy: 38.3% cis-ineligible vs 52.0% cis-eligible. Median OS in all 1L treated pts was 11.0 (95% CI, 10.3 – 11.5) mo and was shorter in cis-ineligible than cis-eligible pts (8.6 [95% CI, 8.1 – 9.2] vs 14.4 [95% CI, 13.4 – 16.4]; hazard ratio [HR], 0.8 [0.7 – 1.0]). A number of cis-ineligible pts received cis, and many cis-eligible pts did not (Table), suggesting physicians consider clinical factors beyond conventional criteria to determine cis-eligibility. Cis + gemcitabine (gem) or MVAC was associated with longer OS vs other treatments regardless of cis-eligibility (Table). **Conclusions:** Clinical outcomes in 1L aUC pts were poor, particularly for cis-ineligible pts, which may be partly driven by the specific regimen administered. Many aUC pts did not receive 1L treatment and among those who did, less than half received 2L therapy. These data highlight the need for more effective and tolerable 1L therapy for all aUC pts. Research Sponsor: Seagen Inc. and Astellas, Inc.

Toripalimab (anti-PD-1) monotherapy as a second-line treatment for patients with metastatic urothelial carcinoma (POLARIS-03): Two-year survival update and biomarker analysis. *First Author: Haige Chen, Department of Urology, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China*

Background: Patients with advanced metastatic urothelial carcinoma (mUC) who experience disease progression after standard therapy have limited treatment options. Toripalimab was approved for the 2nd line treatment of mUC based on a phase II clinical study (POLARIS-03) in Chinese patients with mUC (NCT03113266). Here we report the two-year efficacy update and biomarker analysis of the study. **Methods:** Metastatic UC Patients received toripalimab 3 mg/kg Q2W until disease progression, unacceptable toxicity or voluntary withdrawal. Clinical response was assessed every 8 weeks by independent review committee (IRC) per RECIST v1.1. Tumor PD-L1 expression, tumor mutational burden (TMB), and other biomarkers were evaluated for correlation with clinical response. **Results:** From May 2017 to September 2019, 151 patients were enrolled from 15 participating centers. By cutoff date of September 8, 2021, no emergent of new safety signal was identified compared with the previous one-year report. By the cutoff date, 3 CR, 37 PR and 28 SD were observed among the ITT population for an ORR of 26.5% and a DCR of 45.0% as assessed by the IRC. The response was durable as the median duration of response was 25.8 months. The median OS was 14.6 months. Whole exome sequencing (WES) was performed on tumor biopsies and paired PBMCs and the results were available from 135 patients. The median TMB value was 4.1 mutations per million base pairs (Mb) in the cohort. Using 10 mutations/Mb as the cut off, TMB-high patients (n = 27) had better ORR than TMB low patients(n = 108) (48% versus 22%, p = 0.014). The TMB-high group also showed better PFS (12.9 versus 1.8 months, HR = 0.48 [95% CI:0.31-0.74], p < 0.001) and OS (not reached versus 10.0 months, HR = 0.53 [95% CI:0.32-0.88], p = 0.013) than the TMB low group. Patients with mutations in chromatin remodelers SMARCA4/PBRM1 or tumor suppressor RB1 were associated with better responses to toripalimab than patients with wild-type genes. The ORR was 30% (6/20) in patients with FGFR2/FGFR3 mutations or FGFR2/FGFR3 gene fusions, and 42% (5/12) in patients with NECTIN4 genomic alternations. The mutational signature characterized by exposure to aristolochic acid (A:T to T:A transversion) is present in both upper tract urothelial carcinoma (UTUC) and lower tract urothelial carcinoma (LTUC), but enriched in UTUC (p = 0.003). Similar clinical responses were observed in UTUC and LTUC. **Conclusions:** Toripalimab has demonstrated a manageable safety profile and encouraging clinical activity in metastatic UC patients refractory to 1st line chemotherapy. WES analysis identified divergent mutations in the study. We report the utility of TMB to predict not only the response rate but also the PFS and OS benefits in patients with mUC in response to an ICI monotherapy. Clinical trial information: NCT03113266. Research Sponsor: Shanghai Junshi Biosciences.

A prospective exploratory clinical study of penpulimab plus anlotinib as first-line treatment for locally advanced or metastatic urothelial carcinoma. *First Author: Bo Yang, Department of Oncology, The First Medical Center of Chinese PLA General Hospital, Beijing, China*

Background: A high unmet need remains for first-line cisplatin-ineligible patients with locally advanced or metastatic urothelial carcinoma (la/mUC).Immune checkpoint inhibitors have been implemented in the management of cisplatin-ineligible la/mUC. Penpulimab is a programmed death 1 (PD-1) inhibitor which had approved by the Chinese National Medical Products Administration (NMPA) on August 2021. Anlotinib is a novel oral multi-target tyrosine kinase inhibitor and primary targeted to VEGFR, FGFR, PDGFR and c-Kit. The current prospective single-arm phase II clinical trial (ChiCTR1900028022) aimed to assess the efficacy and safety of penpulimab plus anlotinib as first-line therapy for la/mUC. **Methods:** Patients (pts) who had no prior systemic therapy and at least one measurable lesion according to RECIST v1.1 with histologically or cytologically confirmed locally advanced unresectable or metastatic urothelial carcinoma (including unresectable or metastatic urothelial carcinoma of the bladder, urethra, ureter, or renal pelvis), 18-75 years, ECOG 0-2, were considered eligible for enrollment. Patients received 200 mg penpulimab intravenously on day 1 plus anlotinib, 8 mg oral daily for days 1-14 of a 21-day cycle until confirmed disease progression, intolerable toxicity, physician/patient decision to withdraw, or completion of 24 months of treatment. The primary endpoint was objective response rate (ORR), and the secondary endpoints included disease control rate (DCR), progression-free survival (PFS) and safety. **Results:** As of Dec. 2021, 10 pts were enrolled, 9 pts had the best overall response assessments which inferred the ORR of 66.7% (95% CI, 29.9-92.5) and the DCR of 88.9% (PR in 6 pts and SD in 2 pts; 95% CI, 51.8-99.7). The median PFS was 8.2 months ((95% CI, 8.0-8.4). Any grades of adverse events (AEs) were observed in 90% (9/10) of pts, containing hyperthyroidism (33%), Creatinine increased (33%),haematuria (22%), anaemia (22%), hypertension (11%), fatigue (11%). High grade AEs of grade IV liver dysfunction were observed in one patient (11%). **Conclusions:** An effective treatment strategy for cisplatin-ineligible patients and for patients unable to receive chemotherapy is an important unmet clinical need. Penpulimab in combination with anlotinib in pts with la/mUC showed encouraging efficacy and satisfactory safety. Clinical trial information: ChiCTR1900028022. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd.

Landscape of fibroblast growth factor receptor (*FGFR*) genomic alterations (GA) in urothelial bladder cancer (UBC). *First Author: Maroun Bou Zerdan, Cleveland Clinic Florida, Weston, FL*

Background: Urothelial bladder carcinomas (UBC) with genomic alterations (GA) in the Fibroblast Growth Factor Receptor (*FGFR*) genes have been postulated to be less responsive to immune checkpoint inhibitors (ICI). Immune microenvironment of these tumors could be altered due to suppression of interferon signaling pathways. Here, we present comprehensive genomic profiling (CGP) of *FGFR* altered UBC to study the underlying immunogenomic mechanisms of response and resistance. **Methods:** 4,035 UBC underwent hybrid capture based CGP. Tumor mutational burden (TMB) was determined on up to 1.1 Mbp of sequenced DNA and microsatellite instability (MSI) was determined using 114 loci. Programmed death ligand (PD-L1) expression in tumor cells was assessed by IHC (Dako 22C3). **Results:** 894 (22%) of UBC featured *FGFR* GA (*FGFR1* 3.7%; *FGFR2* 1.1%; *FGFR3* 17.4%). Gender and age distribution was similar in all groups. *FGFR3* cases had lower GA/tumor and 14.7% GA were fusions. *ERBB2* amplification was significantly higher in *FGFR1/2* altered UBC compared with *FGFR3* altered UBC. MTOR pathway GA were highest in *FGFR3* altered UBC. *FGFR3* altered UBC featured significantly higher frequencies of biomarkers predicting resistance to ICI including lower TMB, lower PD-L1 expression and higher frequencies of GA in *MDM2. FGFR3* driven UBC also features significantly higher frequencies of *CDKN2A/B* loss and *MTAP* loss which have also recently been linked to IO drug resistance. **Conclusions:** UBC harboring *FGFR* GA have increased frequency of alterations that have been linked to ICI resistance. Further evaluation of FGFR-based biomarkers in UBC clinical trials focused on the assessment of the patient response to ICI appears warranted. Research Sponsor: Foundation Medicine Inc.

Germline variants across self-reported racial populations with urothelial carcinoma (UC). *First Author: Amin Nassar, Brigham and Women's Hospital, Boston, MA*

Background: Prior studies of the UC germline landscape centered around White patients with minimal representation of other racial populations. Herein, we examine the frequency of germline pathogenic and likely pathogenic (P/LP) variants in 2,582 patients with UC from various racial populations. **Methods:** 2,582 patients with UC underwent germline testing of 1 to 126 genes using massively parallel sequencing with customized capture bait-sets to analyze exonic regions, flanking intronic regions, and copy number alterations (CNAs). P/LP variants including single nucleotide variants, indels and CNAs were reported. Fisher's Exact test and multivariable logistic regression were used after accounting for the number of genes tested, age at diagnosis, site of disease (upper versus lower tract), gender, family history of UC, and personal history of any cancer. **Results:** Among the 2,582 patients with UC, median age at diagnosis was 63 years (range, 4-90) and 1158 (44.8%) were female. There were 58 Asians (2.2%), 110 Blacks (4.3%), and 2,414 Whites (93.5%). Overall, 1,639/2,582 (63.5%) patients had a personal history of another cancer and 284/2,393 (11.9%) had history of UC in a family member. 465 P/LP variants were identified in 18% of patients, among whom 286 (11.1%) harbored ≥1 clinically actionable variants. P/LP in cancer-associated genes were most frequently reported in *MSH2* (72/2,512, 2.9%), monoallelic *MUTYH* (45/2,136, 2.1%), *BRCA2* (44/2,299, 1.9%) and *MSH6* (47/2,511, 1.9%). Patients with upper tract UC had significantly more P/LP (72/247, 29.1%) compared to lower tract UC (332/2,076, 16%, $p = 1.3x10^{-5}$). Age at diagnosis, gender, personal history of other primary cancers, or family history of UC were not significantly associated with the prevalence of P/LP variants. There were no significant differences (p= 0.33) in P/LP variants across Asians (11/58, 19.0%), Blacks (14/110, 12.7%), and Whites (440/2,414, 18.2%) although a trend towards lower P/LP in Blacks is notable. Compared to Whites, Blacks and Asians harbored significantly more variants of unknown significance (VUS, Whites vs Blacks: 241/2414 vs 25/110, p= 0.0015; Whites vs Asians: 241/2414 vs 17/58, p= 4e-7). Asians with UC harbored significantly more P/LP variants in *ATM* (2/50, 4%) compared to Whites (30/2122, 1.4%, OR = 1.1 [95% CI, 1.0-1.2]) and Asian controls from the gnomAD Database. There were no significant differences across racial populations for other highly altered genes (*BRCA1/2, CHEK2, FH, MSH2/6, MUTYH*) or for actionable variants. **Conclusions:** Germline P/LP variants were identified in 18% of patients with UC and were enriched in upper tract tumors. Although no significant differences in P/LP prevalence were noted among patients of different racial populations, a trend towards lower P/LP in Blacks and a higher rate of VUS in Asians and Blacks suggest that ongoing analysis by genetic ancestry may provide richer admixture data and insights. MRG002-006: A multicenter phase II clinical trial of MRG002-ADC for unresectable locally advanced or metastatic urothelial cancer. *First Author: Wang Qu, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Overexpression of HER-2 is associated with poor prognosis of urothelial cancer, and anti-HER-2 antibody-drug conjugate (ADC) has shown a promising efficacy among the UC patients (pts) in recently studies. MRG002 is a novel HER2-targeted ADC being investigated in the MRG002-006 trial to evaluate the efficacy and safety in HER2 positive UC pts. **Methods:** This is a single-arm, multicenter phase II study. Eligibility criteria included: histologically HER2-positive (IHC 2+ or 3+) UC pts confirmed by a central-laboratory, ECOG PS 0-1, prior received ≥1 standard treatment. Approximately 40 pts will be enrolled. In the initial dose finding stage, pts were assigned to receive MRG002 at a dose of 2.6 mg/kg or 2.2 mg/kg administered by intravenous infusion every 3 weeks. The dose expanding stage was subsequentially performed based on preliminary results. The primary endpoint was ORR per RECIST 1.1, secondary endpoints are safety, DOR, PFS and, OS. **Results:** As of December 31, 2021, a total of 39 pts were enrolled. Enrollment is estimated be completed in February 28, 2022, and results are expected to be updated before publication. Nine pts were dosed at 2.6 mg/kg and 26 pts were dosed at 2.2 mg/kg. Based on safety analysis, 2.2 mg/kg was adopted as the recommended dosage. At baseline, 80% pts (28/35) had visceral metastasis. Most pts (28/35) received ≥ 2 lines of treatment and 29 (83%) pts had prior immune checkpoint inhibitor (ICI) therapy. By the cut-off date, 23 pts were evaluable and the ORR was 65% (15/23, 95% CI: 44.9%–81.2%), with 9% CR, and the DCR was 91% (21/23, 95% CI: 73.2%–97.6%). The estimated median PFS for the 23 pts was 5.5 months (95% CI: 2.7–NR). Among the evaluable pts, 1 CR responder achieved a response duration of more than 9.5 months. Subgroup analysis indicated that the ORR was 65% among the 17 pts post ≥ 2 lines of treatment, and 78% among the 18 pts failed platinum-containing chemotherapy and ICI treatment. Most common treatment-related AEs determined by investigators were anemia (34%), alopecia (34%), AST increased (31%), neutrophil count decreased (26%), neuropathy peripheral (23%), constipation (17%), decreased appetite (17%); most were grade 1 or 2 per CTCAE 5.0. The incidence of SAE was 17% (6/35). At the dose of 2.6mg/kg, 1 pts discontinued the treatment due to hypotension and 1 pts experienced ileus, which was considered caused by neurotoxicity of MRG002. There were no similar events described above happened among the pts at the dose of 2.2mg/kg. **Conclusions:** Preliminary results of MRG002 demonstrated a clinically meaningful response in pretreated HER-2 positive unresectable locally advanced or metastatic UC patients, especially in those progressed after platinum-containing chemotherapy and ICI therapy. MRG002 at 2.2mg/kg showed a manageable safety profile in these pts. Further evaluation is ongoing. Clinical trial information: NCT04839510. Research Sponsor: Shanghai Miracogen Inc.

Genomic and immunologic profiles of concurrent RB1 and CDKN1A/p21(WAF1) truncating mutations (RW+) in bladder cancer. *First Author: Wafik S. El-Deiry, Cancer Center at Brown University, Providence, RI*

Background: p53 target and cell cycle inhibitor CDKN1A/p21(WAF1) was initially not found to be mutated in cancer. TCGA analysis identified CDKN1A mutations are present but rare with frequencies of < 1%, but enrich in bladder cancer (~8%). Truncating WAF1 mutations are associated with sensitivity to cisplatin and are associated with truncating Rb mutations in bladder cancer (RW+). We hypothesized RW+ bladder cancers may represent a unique subgroup with sensitivity to therapeutics. **Methods:** A total of 1104 urothelial tumors underwent molecular profiling at Caris Life Sciences (Phoenix, AZ) utilizing NGS of DNA (592 Gene Panel, NextSeq, or WES, NovaSeq) and RNA (NovaSeq, WTS). Wilcoxon, Fisher's exact were used for statistical significance (p value without and q value with multi comparison correction). Immune cell fraction (QuanTIseq) and pathway analysis (ssGSEA) were assessed by mRNA analysis. Immune epitope prediction was performed using the NetMHCpan v4.0 method in the Immune Epitope Database. **Results:** Concurrent truncating mutation (frameshift, nonsense) for RB1 and WAF1 were detected in 47 tumors (RW+, 4.25%) and tumors with wild-type status for both RB1 and WAF1 genes were classified as RW- group (54.08%). Tumors harboring only one RB1 or WAF1 mutation were excluded for further analysis. When compared to RW- group, RW+ tumors showed lower mutation rate of TP53 (54.5% vs 80.9%, q < 0.05), ARID1A (23.5% vs 38.3%, p < 0.05), and PIK3CA (18.4% vs 31.9%, p < 0.05). Interestingly, RW+ was mutually exclusive with FGFR3 mutation (18.0% vs 0%, p < 0.05). We further evaluated RNA expression of DNA repair and checkpoint arrest pathways. Notably, E2F pathway (Normalized Enrichment Scores, NES: 0.89 vs 0.86, q < 0.01) and DNA G2M checkpoint (NES: 0.89 vs 0.86, q < 0.01) were found to be the most enriched in RW+ with respect to RW- group. In addition, mRNA levels of FANCC/A, CHEK1, WEE1, CDC25A/C, PALB2 and BRCA1/2 were found to be overexpressed in RW+ group (q < 0.05). RW+ tumors also displayed a distinct immunological profile: They were associated with higher PD-L1 status (63.8% vs 37.3%, q < 0.01), higher median TMB (11 mut/Mb vs 8 mut/Mb, q < 0.01) and with less frequent loss of heterozygosity for HLA-DPA1 (51.1% vs 66.7%, p < 0.05), with more high-binding-affinity neoantigen load (4.78 vs 3.89, p < 0.05) to MHC proteins, consistent with the significantly more myeloid dendritic cells in in RW+ group (0.3 vs 0.04, q < 0.001). **Conclusions**: Concurrent truncating mutation in RB1 and WAF1 (RW+) bladder carcinomas have fewer p53, ARID1A, and PIK3CA mutations but are enriched for E2F targets, G2/M checkpoint genes, FANCC/A, CHEK1, WEE1, CDC25A/C, PALB2 and BRCA1/2 and have a distinct immunological profile. The findings suggest therapeutic strategies for RW+ bladder cancers including Chk1/Wee1, PARP inhibitors, -/+ immunotherapy that may impact on clinical outcomes. Research Sponsor: None.

Assessment of a HER-2 scoring system and its correlation of HER2-targeting antibody-drug conjugate therapy in urothelial carcinoma. *First Author: Lei Lei, Department of Pathology, National Cancer Center/National Clinical Research Center for Cancer /Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

Background: Human epidermal growth factor receptor 2 (HER2) overexpression is related to many tumor treatments. RC48-ADC, a novel humanized anti-HER2 antibody conjugated with monomethyl auristatin E, has shown a promising efficacy in patients with HER2-positive locally advanced or metastatic urothelial carcinoma (mUC). The characteristic expression and scoring systems of HER2 have existed in breast cancer, gastric cancer for many years, but not in UC. We aimed to explore the expression pattern of HER2 in UC and develop a validated HER2 scoring system. **Methods:** A total of 137 patients and 43 patients in two studies of cohort 1 and cohort 2 were enrolled, respectively. The patients of the cohort 2 were enrolled in the open-label, multicenter, phase II study of RC48-ADC. Formalin-fixed paraffin-embedded urothelial cancer samples were tested for HER2 status using the fluorescence in situ hybridization (FISH) PathVysion HER2 DNA probe kit (PathVysion, Abbott Molecular, USA). Immunohistochemistry (IHC) was performed using the Ventana Benchmark XT (Ventana Medical Systems, USA). The 2018 ASCO/CAP HER2 scoring system of breast cancer was adopted and modified to score HER2 expression level in UC. **Results:** The expression rate of HER2 (IHC 2+/3+) was 24.1% (33/137). In HER2 IHC status 3+ or 2+ patients, the *HER2* amplified rate was 31% (13/42). The objective response rates in RC48-ADC treatment patients with IHC 3+, IHC 2+ and FISH +, IHC 2+ and FISH - were 58.8%, 66.7% and 40%, respectively. Heterogeneity of HER2 protein expression was 55.5% (15/27) and the objective response rate had no significant difference between patients with tumor heterogeneity and homogeneity. **Conclusions:** The modified HER2 testing scoring system could be applied to UC to determine which patient might benefit from anti-HER2-ADC treatment. There was a trend towards a better benefit for patients with *HER2* amplification and the tumor heterogeneity did not influence the drug efficacy. Research Sponsor: None.

Outcomes of patients with advanced urothelial cancer who develop infection while on treatment with pembrolizumab.

First Author: Ryan Blair Kieser, Houston Methodist Cancer Center, Houston, TX

Background: Over the past decade, studies have shown the benefit of immune checkpoint inhibitors (IO) in patients with advanced urothelial cancer. These agents work by reconditioning the adaptive anti-cancer immune response within the tumor microenvironment. Immune-related adverse events have been well documented, but there is limited data evaluating infections in patients treated with IO. We performed a retrospective analysis to assess the incidence of infection and its effect on morbidity and mortality in patients treated with pembrolizumab for advanced urothelial cancer. **Methods:** Data was collected from a network of 7 hospitals for patients who received pembrolizumab for advanced urothelial cancer from 1/1/2017-8/1/2021. Date of last follow up was 12/1/2021. Covariates compared among infected and non-infected cohorts included age, gender, race, comorbidities, ECOG, anti-infective therapy at IO initiation, and line of therapy (1L, 2L, > 2L). Univariable analysis with reported odds ratio (OR) and 95% confidence interval (CI) was used to assess risk factors for infection. Outcome measures included all-cause emergency department (ED) visits, inpatient and intensive care unit (ICU) admissions, median number of IO cycles, and overall survival (OS). OS was evaluated using the Kaplan-Meier model. All analyses were deemed statistically significant if the p-value was < 0.05. **Results:** A total of 51 patients were identified. Of these, 34 (66.7%) had at least one documented infection and 17 (33.3%) had no reported infections. Baseline characteristics were similar across cohorts. Compared to non-infected patients, infected patients received fewer cycles of IO (median 4 vs 8, p = 0.016). At last follow-up, 20 (58.8%) patients in the infected cohort and 4 (23.5%) in the non-infected cohort died (p = 0.017). Median OS was 7.4 months (95% CI: 3.4-24.9) among patients with infection while not reached in those without infection (p = 0.014). ED visits (p = 1.00), inpatient admissions (p = 0.21), and ICU admissions (p = 0.17) did not significantly differ between cohorts. Univariable analysis did not identify significant risks among covariates. **Conclusions:** The incidence of infection in patients treated with pembrolizumab for advanced urothelial cancer is high and associated with fewer cycles of IO therapy and shorter OS. Further study of infectious process prevention is of value to maximize immunotherapy benefit. Research Sponsor: None.

Preliminary results from phase Ib/II neoadjuvant CG0070 and nivolumab (N) for cisplatin (C)-ineligible muscle invasive bladder cancer (MIBC).

First Author: Roger Li, Department of Genitourinary Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL

Background: CG0070 is a replication-competent oncolytic adenovirus engineered to target RB deficient tumor cells and to express GM-CSF. CG0070 has previously demonstrated safety and efficacy against BCG-exposed high risk non-muscle invasive bladder cancer through tumor lysis and anti-tumor immune activation. We tested the safety and efficacy of CG0070 in combination with N as neoadjuvant therapy for MIBC in C-ineligible patients in this study (NCT04610671). **Methods:** C-ineligible pts with MIBC (cT2-4a, N≤1) were enrolled. Pts received 6 weekly intravesical CG0070 ($1x10^{12}$vp) and 2 doses of N at wks 2 and 6, followed by radical cystectomy (RC). The primary objective is safety of CG0070+N as measured by CTCAEv5.0. Secondary objective is to assess pathologic response (PaR) (pTON0). Exploratory objectives include the assessment of correlation between PaR with baseline 1) E2F expression; 2) immune infiltration; 3) PD-L1 expression; and 4) TLS expression. Results from a prespecified interim analysis following accrual of 15 patients is reported herein. **Results:** Between Nov 2020 and Jan 2022, 15 pts were enrolled with median age 75.5yrs, 73% male, 47% > cT2; 1 patient refused RC but was included in the ITT population. No DLTs were encountered. The overall rate of grade 3-4 AEs was 10/15 (75%), and the vast majority were related to RC (90%). Immune related AEs were seen in one pt, who had grade 2 autoimmune thyroiditis. There was no delay in time to RC and no unexpected surgical complications from treatment. PaR was observed in 6/13 (46%) evaluable pts, and an additional pt had negative post-treatment biopsy but refused RC. **Conclusions:** Neoadjuvant CG0070+N is safe and effective in C-ineligible pts with MIBC. This combination was well tolerated without any delays in RC and induced an overall response rate of 54%. Clinical trial information: NCT04610671. Benchmarking maintenance therapy survival in first-line advanced urothelial carcinoma using disease modeling.

First Author: Matt D. Galsky, The Tisch Cancer Institute, Mount Sinai, New York, NY

Background: First-line (1L) maintenance avelumab (maintA) in patients with advanced urothelial carcinoma (aUC) prolonged overall survival (OS) in the JAVELIN Bladder 100 trial. JAVELIN measured OS from the initiation of maintA among a subgroup of the overall aUC 1L treated population, including only patients who did not progress with 1L platinum-based therapy (PBT) and remained progression free during a 4-10 week treatment-free interval following completion of 1L PBT. As such, patients who progressed on or immediately following PBT were not included in the trial. To address this, we used disease modeling to estimate maintA OS measured from initiation of 1L PBT to align maintA OS with the common initiation point to benchmark with other 1L clinical trials. **Methods:** We developed a simulated cohort to estimate OS from initiation of 1L PBT in all aUC patients including those who received maintA. Eligibility for maintA (PBT progressed vs not progressed) was assessed at 5.6 months post-initiation of 1L PBT, accounting for 6 PBT cycles and a nominal 6-week treatment-free interval. Median OS of 14.3 months from the 1L PBT arm of a recent 1L trial, KEYNOTE-361, was used to represent the OS of the simulated cohort of 1L aUC patients. The simulated cohort was stratified by eligibility for maintA. Among the 1L treated population, 57% were projected to be progression-free and eligible for maintA based on progression-free survival (PFS) from KEYNOTE-361. Among those eligible, 85% were assumed to receive maintA based on expert clinical input. OS of maintA eligible patients was 21.4 months from JAVELIN. Our disease model estimated OS among a maintA ineligible simulated cohort, which was combined with the maintA eligible cohort to yield an estimated OS in the overall aUC population measured from initiation of 1L PBT. **Results:** Approximately 50% of the 1L modeled population receive maintA (i.e., 57% eligible x 85% treated). Our approach estimated a median OS of 9.9 months for the maintA ineligible cohort and 27.0 months for the maintA eligible cohort. Combined, the estimated median OS with maintA, measured from initiation of 1L PBT, in all 1L-treated aUC patients was 15.8 months (vs 14.3 months with PBT only in 1L). **Conclusions:** MaintA improves OS for eligible patients, however our simulation model suggests a significant proportion of patients will not receive MaintA. The estimated OS of 15.8 months for the population-level impact of maintA, accounting for patients ineligible for 1L maintA, demonstrates remaining unmet need in the overall 1L aUC population. Digital score of lymphocytic infiltration in tumor-associated stroma in relation to overall survival in bladder cancer.

First Author: Robert Jewsbury, University of Warwick, Coventry, United Kingdom

Background: Bladder Urothelial Carcinoma (BLCA) is the most common type of bladder cancer and the sixth most frequent cancer in the US. High numbers of lymphocytes colocated with tumour-associated stromal (TAS) tissue has demonstrated prognostic significance for overall survival in multiple cancers. Our goal in this study was to explore the prognostic significance of an automated score to quantify the colocalisation of lymphocytes and TAS for overall survival (OS) in BLCA patients from Haematoxylin & Eosin (H&E) stained Whole Slide Images (WSIs). **Methods:** Two cohorts of BLCA patients were included in this study. From the UK, a cohort of 67 BLCA patients constituted cohort A. We also evaluated our method on The Cancer Genome Atlas (TCGA) bladder cancer cohort of 453 cases, which we refer to as cohort B. We developed a two-stage method for digital quantification of lymphocytic infiltrates in TAS. First, we employed an AI algorithm to recognise and classify different regions as areas of high concentration of tumour, lymphocytes and stroma for each WSI creating a segmentation map of the different tissue types. For patients with multiple WSIs, we used the slide with the highest percentage of tumour to predict survival. This algorithm had been pre-trained on a cohort of Oral cancer and was fine-tuned using annotations from 4 BLCA WSIs, 3 from cohort A and 1 from cohort B. These WSIs were excluded from the final survival analysis. Using the segmentation maps, a statistical measure for the colocalisation of TAS and lymphocytes termed the tumour-associated stroma infiltrating lymphocytes or (TASIL) score was computed. Finally, for each cohort, data was right-censored at 10 years and the digital BLCA-TASIL (BT) score's prognostic significance for OS was investigated by fitting a Kaplan-Meier estimator and Cox proportional hazard (PH) analysis, stratifying patients into two groups based on the BT score. In each cohort, two thirds of the data was used as the discovery set to determine the best cut-off for the TASIL Score and the remaining third was used as the validation set. **Results:** Our classification algorithm achieved high average F1-score of 0.88 on a held-out set of unseen data for the classification of tumour, lymphocytic and stromal regions. In cohort A, higher BT score was strongly associated with better OS (P= 0.00906) on the unseen validation data. This significant association was also found in the validation data of cohort B (P< 0.001). Using the BT score as the only covariate, a Cox PH model for the validation data resulted in a C-index of 0.73 for cohort A and 0.57 for cohort B, respectively. **Conclusions:** The digital BT score showed significant prognostic value for overall survival in both BLCA cohorts, reinforcing the findings of prior work. We intend to further validate these findings on another cohort. To the best of our knowledge, this is the first attempt to predict survival solely from H&E slides in BLCA. Research Sponsor: University of Warwick.

Defining "platinum-ineligible" patients with metastatic urothelial cancer (mUC). *First Author: Shilpa Gupta, Taussig Cancer Institute, Cleveland Clinic Foundation, Cleveland, OH*

Background: Treatment (tx) landscape has evolved significantly for cisplatin-ineligible mUC patients (pts). Carboplatin and gemcitabine followed by avelumab (Av) maintenance is the current preferred standard. Although pembrolizumab (P) and atezolizumab (At) were approved as 1L therapy for these pts in 2017, the FDA has now restricted the use of 1L P to "platinum ineligible" mUC pts. We previously suggested a consensus definition for "platinum-ineligible" pts with mUC (Gupta et al. ASCO GU 2019). We now updated the consensus definition for standard therapy and clinical trial eligibility in the current tx era. **Methods:** We surveyed 60 genitourinary medical oncologists in the US (similar cohort to 2019) using an online tool consisting of several clinical parameters used in our initial survey with additional questions related to current available tx options. Different age and creatinine thresholds in combination with ECOG PS along with other clinically relevant established criteria were analyzed. We compiled the responses to generate a consensus definition. **Results:** All 60 respondents provided 100% responses. Respondents (94%) reported using a carboplatin-based regimen followed by Av and 6% reported using carboplatin-based regimen followed by P for cisplatin-ineligible mUC pts. 17/60 (28.3%) and 29/60 (48.3%) checked PD-L1 status prior to using P or At respectively. Survey results for the most common responses are presented in the Table. **Conclusions:** Based on the survey, any mUC pt meeting one the following 5 parameters should be considered "platinum-ineligible": ECOG PS > / = 3; Cr Cl < 30 ml/min; peripheral neuropathy > / =Grade 2; NYHA Heart Failure Class > 3; ECOG PS 2 AND Cr Cl < 30 ml/min. These criteria are proposed to guide treatment recommendations and standardization of eligibility criteria. Research Sponsor: None.

What threshold ECOG PS should be used to define "platinum-ineligibility"?	ECOG PS > / = 3	# Responses 41/60 (68.3%)
What threshold Cr Cl should be used for "platinum-ineligibility"?	< 30 ml/min	# Responses 41/60 (68.3%)
What grade of peripheral neuropathy would you consider for "platinum-ineligibility"?	> / = Grade 2	# Responses 32/60 (53.3%)
What class of Heart Failure do you consider to define "platinum-ineligibility"?	NYHA Class III	# Responses 48/60 (80%)
In a patient with ECOG PS 2, what Cr Cl cut-off would you use to define "platinum-ineligibility" differently of what is used for "cisplatin-ineligibility"?	< 30 ml/min	# Responses 29/60 (48.3%)

Association of antibiotic therapy and treatment efficacy in urothelial cell carcinoma patients receiving immune checkpoint inhibitors. *First Author: Avery Braun, Einstein Healthcare Network, Philadelphia, PA*

Background: The content of gut microbiome has been linked to the effectiveness of immune checkpoint inhibitory (ICI) therapy in various cancer types. Antibiotic therapy (ABT) induces significant alterations in gut microbiota; however, only a limited number of single-institutional studies have examined the impact of ABT on ICI treatment. Utilizing a national database, we sought to provide 'real world outcomes' by investigating the association between ABT and ICI on overall survival (OS) and real-world progression free survival (rwPFS) in advanced urothelial carcinoma (aUC). **Methods:** We used the electronic health record (EHR)-derived de-identified FlatIron Health (FIH) database after Institutional Review Board approval was obtained, and included a waiver of informed consent to select 1491 subjects with aUC who received ICI therapy. Patient characteristics were described and compared between those with known ABT use and without known ABT use (in the 3 months pre/post ICI initiation), using ANOVA and Chi-square tests. rwPFS and OS were calculated from date of initiation of ICI to date of real-world progression/date of death. 3-month landmark Kaplan Meier methods and log-rank tests were used to estimate and compare rwPFS and OS between patients with-ABT and without-ABT, as well as patients with ABT use pre-ICI initiation, post-ICI initiation, and no known ABT use. Cox proportional models were used to investigate the association between rwPFS, OS, and antibiotic use, adjusting for patient characteristics. **Results:** In patients who received ICI, we included 407 patients who received ABT and 1084 who did not. Those who received ABT were younger ($p < 0.001$), more likely Caucasian ($p = 0.046$) and insured by Medicare ($p < 0.001$). rwPFS (median: 9.0 vs 10.0 months; $p = 0.41$) and OS (median: 14.0 vs 16.0 months; $p = 0.073$) were not significantly different between the with or without ABT subgroups. We included 101, 182, and 715 patients who received ABT prior to ICI, after ICI initiation, or did not receive ABT. When assessing timing of ABT, there was a significant difference in OS amongst pre-ICI initiation ABT, post-ICI initiation ABT and no known ABT groups (median: 17.0 vs 10.9 vs 16.0; $p = 0.005$). However, rwPFS (median: 10.1 vs 7.5 vs 10.0 months; $p = 0.22$) was not statistically different. Multivariable analysis identified no antibiotic use as a significant predictor of improved OS (HR 0.733, CI 0.598-0.898; $p = 0.003$). Other factors associated with OS were male gender (HR 1.158, CI 1.005-1.335; $p = 0.043$) and receipt of extirpative surgery (HR 0.785, CI 0.684-0.900; $p < 0.001$). **Conclusions:** This study identifies a potential negative association of ABT and OS, particularly after starting ICI. These results support the relevance of the gut microbiome on the efficacy of ICI treatment, may guide future efforts to improve the efficacy of ICI, and emphasize the importance of antibiotic stewardship. Phase Ib study of avelumab and novel AXL inhibitor avb-S6-500 in patients with metastatic urothelial carcinoma (mUC). *First Author: Abhishek Tripathi, Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK*

Background: AXL is a member of the mammalian Tyro3/AXL/Mer (TAM) receptor tyrosine kinase family, which upon binding to its ligand Gas6 promotes immunosuppression in the tumor microenvironment. AVB-S6-500 (AVB) is a novel AXL pathway inhibitor which binds to circulating Gas6 and inhibits ligand-dependent AXL signaling. In this phase Ib investigator-initiated trial (NCT04004442), we evaluated the safety, tolerability, pharmacodynamics, and preliminary antitumor efficacy of AVB with the anti-PD-L1 antibody avelumab in mUC. **Methods:** Patients with PD-1/L1 inhibitor naïve locally advanced unresectable or mUC with measurable disease were eligible if they were either in-eligible for, refractory to, or declined platinum-based chemotherapy. Employing a 3+3 dose escalation design, patients were treated with AVB 5mg/kg weekly (dose level; DL1), or 10 (DL2), 15 (DL3), or 20 (DL4) mg/kg every two weeks along with avelumab 800 mg every 2 weeks administered intravenously. The safety and tolerability of the combination as measured by the incidence of dose limiting toxicities (DLTs) was the primary endpoint while objective response rate (ORR) per RECIST 1.1 was key secondary endpoint. Pharmacodynamic studies evaluated baseline and on therapy (C2D1) Gas6 levels. **Results:** To date, a total of 15 patients have been enrolled (DL1: n = 3, DL2: n = 7, DL3: n = 3 and DL4: n = 2). Among the 13 evaluable patients, DLT was observed in 1 patient (grade 3 fatigue; DL2). Grade ≥3 adverse events irrespective of attribution were seen in 6 patients which included UTI (n = 3), hyponatremia (n = 1), elevated creatinine (n = 1), and anemia, thrombocytopenia, hematuria, anorexia and sepsis (n = 1 each; all in same patient). No treatment related deaths were noted. While enrollment on DL4 is ongoing, the maximum tolerated dose for AVB has not been reached. Treatment with AVB effectively suppressed circulating Gas6 levels from baseline (median: 28.4 ng/mL; range: 20.4-54.0 ng/mL) to below threshold of detection in 85% (n = 11/13) of patients. Median follow up was 10 months (95% CI: 3.9, 18.55). Confirmed ORR was 38% (n = 5/13) while 1 patient had stable disease as best response. Durable responses lasting > 6 months were seen in 3 patients (7, 19 and 21 mos) who continue to be on treatment without disease progression. Additional correlative studies investigating AXL, Gas6, PD-L1 expression and gene expression signatures are currently underway. **Conclusions:** Concurrent avelumab and AVB was safe and AVB effectively neutralized circulating Gas6 across DLs. Albeit small sample size, the efficacy of the combination was encouraging and ORR compares favorably to that previously reported with PD-1/L1 inhibitor monotherapy. Updated safety, efficacy and biomarker data will be presented. Clinical trial information: NCT04004442. Research Sponsor: This research was financially supported by EMD Serono CrossRef Funder ID: 10.13039/100004755), as part of an alliance between the healthcare business of Merck KGaA, Darmstadt, Germany and Pfizer. Interim results from a multicenter clinical study of tislelizumab combined with gemcitabine and cisplatin as neoadjuvant therapy for patients with cT2-T4aN0M0 MIBC. *First Author: Tianxin Lin, Department of Urology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*

Background: To evaluate the efficacy and safety of tislelizumab combined with gemcitabine and cisplatin as neoadjuvant therapy for patients (pts) with clinical T2-T4aN0M0 (cT2-T4aN0M0) muscle-invasive bladder urothelial cancer (MIBC). **Methods:** This multicenter, open-label, single arm phase II study enrolled pts tolerated with the cisplatin therapy. Eligible pts received tislelizumab 200 mg in day 1 (D1), cisplatin 70 mg/m^2 D2, and gemcitabine 1000 mg/m^2 D1 and D8 every 21 days for four cycles. Radical cystectomy (RC) was performed within 6 weeks after last dose treatment. The primary end point was pathologic complete response (pCR, pT0N0M0). Secondary end points were pathologic downstaging (≤pT1N0M0), EFS, OS and safety. Simon two-stage design was used. If > 5 pts achieved pCR in the first stage (n = 22), study would proceed to the second stage and enroll 33 additional pts. If > 18 of 55 pts achieved pCR, we would deem the study to have met the primary endpoint. **Results:** We reported the results in the first stage. By Oct 2021, 23 eligible pts were enrolled. Eighteen pts have completed neoadjuvant therapy, with median age of 62 (48-72) years and 8 (44.4%) pts of PD-L1 positive, among whom 17 pts underwent RC and one declined RC. At the data cut off time of 14th Jan 2022, among 17 evaluable pts (12 cT2, 3 cT3, and 2 cT4a), 10 (58.8% [95% CI, 32.9-81.6]) pts achieved pCR and 13 (76.5% [95% CI, 50.1-93.2]) achieved pathologic downstaging. No significant differences were found in pCR (62.5% vs. 55.6%) and downstaging (75.0% vs. 77.8%) rates between pts with PD-L1 positive versus PD-L1 negative. Eighteen pts completed 71/72 cycles of tislelizumab, 68/72 cycles of cisplatin and 135/144 cycles of gemcitabine therapy. The rate of dose reduction (all due to AEs) of cisplatin and gemcitabine therapy was 25.0% (17/68 cycles) and 23.7% (32/135 cycles), respectively. The relative dose intensity of tislelizumab, cisplatin and gemcitabine were 93.6%, 84.5% and 85.9%, respectively. Most common neoadjuvant therapy related AEs of any grade were hematologic toxicities (94.4%), nausea (72.2%), vomiting (61.1%), decreased appetite (55.6%), fatigue (27.8%), pruritus (22.2%) and ALT/AST increased (22.2%). Grade ≥3 neoadjuvant therapy related AEs were neutropenia (n = 6), thrombocytopenia (n = 4), anemia (n = 2) and lymphocyte count decreased (n = 1). Eight pts experienced grade 1-2 immune related AEs, including pruritus (n = 4), rash (n = 2), ALT/AST increased (n = 4), GGT increased (n = 2), CPK increased (n = 1), hyperthyroidism (n = 1), hypothyroidism (n = 1). **Conclusions:** Neoadjuvant tislelizumab combined with gemcitabine and cisplatin showed promising anti-tumor activity with high pCR and well tolerance in MIBC pts. The target of first stage has been achieved, and enrollment is ongoing. At the data cut off 14th Jan 2022, 34 pts have been enrolled. Clinical trial information: ChiCTR2000037670. Research Sponsor: BeiGene (Beijing) Co., Ltd.

S1314 correlative analysis of ATM, RB1, ERCC2, and FANCC mutations and pathologic complete response (pT0) at cystectomy after neoadjuvant chemotherapy (NAC) in patients with muscle invasive bladder cancer (MIBC): Implications for bladder preservation. *First Author: Elizabeth R. Plimack, Fox Chase Cancer Center, Philadelphia, PA*

Background: SWOG S1314 (NCT02177695) was designed to validate the CoXEN classifier as a predictive biomarker in pts undergoing cystectomy after NAC. We repurposed banked DNA samples and prospective trial data from S1314 to further validate the predictive ability of the Philadelphia 4 gene signature (P4GS: any mutation in ATM, RB1, FANCC, ERCC2) to predict pT0 as previously reported (PMID: 26238431) and used in the RETAIN trial (NCT02710734). The RETAIN trial prospectively enrolled pts to receive NAC (DDMVAC) followed by allocation to bladder observation vs. intervention (cystectomy or RT) based on clinical evaluation and presence vs absence of P4GS. The primary objective of this correlative investigation was to determine whether presence of P4GS is predictive of pT0 at surgery. **Methods**: Eligibility for S1314 included cT2-T4a N0 M0 MIBC, cisplatin eligible, with plan for cystectomy; 237 pts were randomized between ddMVAC and gem/cis (GC) using standard dose/schedule. Of 167 pts who were evaluable for the original COXEN analysis (received 3+ cycles of chemo and evaluable for path response) adequate banked DNA was available for 105. Next-generation sequencing using the CARIS 592 Gene Panel (Caris Life Sciences, Phoenix, AZ) was performed. Pathogenic mutation or VUS of ATM, RB1, FANCC or ERCC2 was noted as present or absent for each pt and correlated with pT0 using logistic regression, adjusting for clinical stage. **Results**: Among the 105 pts, 51% ddMVAC, 49% GC. 15% female, 95% white, 15% clinical stage T3/T4a Prevalence of mutations: ATM (24%), ERCC2 (17%), FANCC (4%), RB1 (24%) and any variant 53%. Presence of any mutation correlated with pT0 (p = 0.0006), sensitivity 79%, specificity 59%. This association did not vary by treatment arm (MVAC vs. GC). The table below shows the contributions of each of the 4 genes with the greatest contribution from ATM and ERCC2. FANCC was non-contributory due to low prevalence. **Conclusions**: Patients with a mutation in ATM, RB1, FANCC or ERCC2 (P4GS) have a statistically significantly higher odds of a pT0 with GC or MVAC compared to those who do not have any variant. This signature was used to prospectively allocate patients to bladder observation as part of the RETAIN trial previously reported (ASCO GU 2021). RETAIN completed enrollment, final analysis of the primary endpoint – 2-year metastasis free survival – is expected later in 2022. Clinical trial information: NCT02177695. Study EV-103 Cohort H: Antitumor activity of neoadjuvant treatment with enfortumab vedotin monotherapy in patients with muscle-invasive bladder cancer who are cisplatin-ineligible. *First Author: Daniel P. Petrylak, Yale Cancer Center, New Haven, CT*

Background: Up to 25% of all patients (pts) diagnosed with urothelial cancer present with muscle-invasive disease for whom the risk of progression or metastasis is substantial. Neoadjuvant chemotherapy prior to radical cystectomy and pelvic lymph node dissection (RC+PLND) has been shown to prolong overall survival for patients who are cisplatin (cis) eligible. The standard of care for cis-ineligible pts undergoing surgery does not include neoadjuvant therapy. Therefore, safe and effective neoadjuvant therapies are an unmet need for cis-ineligible pts with muscle invasive bladder cancer (MIBC). Enfortumab vedotin (EV) is an antibody-drug conjugate directed to Nectin-4, which is highly expressed in urothelial cancer, and has been shown to benefit previously treated locally advanced or metastatic urothelial cancer pts in phase 2 and 3 trials, including cis-ineligible pts. **Methods:** Cohort H of the EV-103 phase 1b/2 trial (NCT03288545) enrolled pts with cis-ineligible cT2-T4aN0M0 MIBC who were eligible for RC+PLND and had an ECOG of 0-2. Pts received 3 cycles of neoadjuvant EV (1.25 mg/kg) on Days 1 and 8 of every 3-week cycle prior to RC+PLND. The primary endpoint of the study was pathological complete response rate (pCRR; ypT0N0) by central review. Key secondary endpoints included pathological downstaging (pDS) rate (ypT0,Tis,Ta,T1,N0) and safety. Results from a preliminary analysis are presented. **Results:** 22 pts were treated. Pts had cT2 (68.2%), cT3 (27.3%), and cT4 (4.5%) tumors. 68.2% pts had predominant urothelial cancer; 31.8% had a mixed histology. 19 pts completed all 3 cycles of EV. 21 underwent RC+PLND, and 1 had a partial cystectomy. 36.4% pts had a pCR. pDS was seen in 50.0% pts. The most common EV treatment-related adverse events (TRAEs) were fatigue (45.5%), alopecia (36.4%), and dysgeusia (36.4%). 18.2% pts had Grade ≥3 EV TRAEs. No surgeries were delayed due to EV administration. 3 pts had Grade 5 AEs while on study that were unrelated to EV; in 2 pts these AEs occurred > 30 days after RC+PLND. **Conclusions:** Observed pCRR after neoadjuvant EV showed promising activity in cis-ineligible pts with MIBC who have a high unmet need. Adverse events were consistent with the known safety profile of EV. This first disclosure of data supports the ongoing phase 2 and 3 programs evaluating EV in MIBC. Clinical trial information: NCT03288545. Research Sponsor: Seagen Inc. and Astellas Pharma Inc.

Clinical utility of urine DNA for noninvasive detection and minimal residual disease monitoring in urothelial carcinoma. *First Author: Zhisong He, Department of Urology, Peking University First Hospital, Institute of Urology, Peking University, Beijing, China*

Background: Current methods for the early detection and minimal residual disease (MRD) of urothelial carcinoma (UC) are often invasive and/or possess sub-optimal sensitivity, especially in upper tract urothelial carcinoma (UTUC). **Methods:** We developed an efficient workflow named the urine tumor DNA multidimensional bioinformatic predictor, utLIFE, by using low-coverage whole-genome sequencing and targeted deep sequencing. We identified the UC specific mutations and large CNV in the discovery cohort. The utLIFE-UC model was trained in a bladder cancer retrospective cohort (n = 150) and validated in an bladder cohort(n = 674) and UTUC cohort(n = 22). 31 patients established diagnosis of BC who are on neoadjuvant were also enrolled, including a MRD training cohort (n = 16) with serial urine samples at baseline, during treatment and before surgery; a independent MRD validation cohort (n = 15) with urine samples before surgery. **Results:** The utLIFE-UC model could discriminate UC with high accuracy (94.3%), sensitivity (92.8%), and specificity (96.0%). Furthermore, compared to cytology, the assay achieved a great improvement in sensitivity in the detection of non–muscle-invasive bladder cancer (NMIBC, 94.7% vs. 31.6%,p = 0.0002), and muscle-invasive bladder cancer(-MIBC, 82.6% vs. 69.6%, p = 0.4894). The utLIFE-UC model was also validated in independent BC cohort (sensitivity 94.3%, specificity 92.6%) and UTUC cohort (sensitivity 90.9%, specificity 90.9%). utLIFE-UC score also showed outstanding potential on dynamic surveillance of residual disease in UC as the score showed dramatically decreased in pCR patients. As expected, utLIFE-UC score could classify pCR and non-pCR(PR, SD, PD) with NPV 100% in MRD training and validation cohorts, which showed superior sensitivity over that of urine cytology (100% vs.37.5%, p = 0.0070) and FISH (100 vs. 42.9%, p = 0.0125). **Conclusions:** utLIFE-UC diagnostic model for early diagnosis, residual disease detection in UC is a cost-effective, rapid, high-throughput, noninvasive, and promising approach, which may reduce the burden of cystoscopy and blind surgery. Biomarkers of response to neoadjuvant atezolizumab with gemcitabine and cisplatin in muscle-invasive bladder cancer. *First Author: Michael Lattanzi, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: We previously reported the clinical outcomes of a positive multi-center phase II trial of neoadjuvant gemcitabine (G) and cisplatin (C) plus atezolizumab (A) in patients with muscle-invasive bladder cancer (Funt, et al. JCO 2022). In this and another trial of neoadjuvant GC with pembrolizumab (Rose et al, JCO 2021), PD-L1 positivity by immunohistochemistry was not predictive of non–muscle-invasive downstaging (< pT2N0). Therefore, we investigated other pre-treatment tissue-based genomic and gene expression biomarkers of response and resistance. **Methods:** 36 pts had pre-treatment tissue available for genomic analysis. We performed targeted hybridization capture DNA sequencing using the CLIA-certified MSK-IMPACT platform and whole transcriptome RNA sequencing. We examined genomic and gene expression biomarkers which have been previously investigated in the context of neoadjuvant cisplatin-based chemotherapy or anti-PD-1/L1 immunotherapy for MIBC, including tumor mutation burden (TMB), a DNA damage response (DDR) 9-gene panel (NCT03609216) associated with response to neoadjuvant chemotherapy, and an 8-gene cytotoxic T cell transcriptional signature associated with response to neoadjuvant A (tGE8; Powles et al, Nature Medicine 2019). We also evaluated TGF-β pathway activation, which was associated with resistance to A in pts with metastatic BC (Mariathasan et al, Nature 2018). Putative biomarkers were assessed for correlation with < pT2N0, the trial's primary endpoint. **Results:** DNA was available from all 36 pts, and RNA met quality control metrics for 29 pts. TMB was significantly higher in pts with < pT2N0 (median 16 mut/Mb, IQR 12-25) versus ≥ pT2N0 (median 10 mut/ Mb, IQR 8-10; p < 0.01). A single patient had a TMB > 200 Mut/Mb with a *POLE* hotspot mutation and achieved pT0N0; TMB was still significantly higher in responders after omission of this patient (p < 0.01). Nine of 25 pts (36%) with < pT2N0 had a deleterious DDR mutation versus 1 of 10 pts (10%) with ≥ pT2N0 (p = 0.13). While tGE8 was significantly increased in patients with < pT2N0 compared to those without (p = 0.01), TGF-β pathway activation was not increased in pts with ≥ pT2N0 (p = 0.99). **Conclusions:** TMB and the tGE8 cytotoxic T cell transcriptional signature were associated with response to combination GC+A in muscle-invasive bladder cancer. More detailed molecular analyses will be reported. Clinical trial information: NCT02989584. Research Sponsor: Genentech, Inc., U.S. National Institutes of Health.

Results for patients with muscle-invasive bladder cancer (MIBC) in the CheckMate 274 trial. *First Author: Alfred Alfred Witjes, Radboud University, Nijmegen, Netherlands*

Background: In the CheckMate 274 trial, disease-free survival (DFS) was significantly improved with nivolumab (NIVO) vs placebo (PBO) both in intent-to-treat (ITT) patients (pts) (hazard ratio [HR], 0.70; 98.22% confidence interval [CI], 0.55–0.90; $P < 0.001$) and in pts with tumor programmed death ligand 1 (PD-L1) expression ≥ 1% (HR, 0.55; 98.72% CI, 0.35–0.85; $P < 0.001$). We report results for the subgroup of pts with bladder cancer, the most predominant type of urothelial carcinoma. **Methods:** CheckMate 274 is a phase 3, randomized, double-blind trial of adjuvant NIVO vs PBO in high-risk muscle-invasive urothelial carcinoma (bladder, ureter, renal pelvis) after radical resection. Pts were randomized 1:1 to NIVO 240 mg intravenously every 2 weeks or PBO for ≤ 1 year of adjuvant treatment and stratified by nodal status, prior neoadjuvant cisplatin, and tumor PD-L1 expression. Pts had radical resection ± neoadjuvant chemotherapy and were at high risk of recurrence on final pathologic staging. Primary endpoints were DFS in ITT pts and in pts with PD-L1 ≥ 1%. Non–urothelial tract recurrence-free survival (NUTRFS) was a secondary endpoint, and distant metastasis-free survival (DMFS) was an exploratory endpoint. This exploratory analysis focused on the subgroup of pts with muscle-invasive bladder cancer (MIBC) after radical resection. **Results:** Of 709 randomized pts in the trial, 560 had MIBC (NIVO, n = 279; PBO, n = 281). With a minimum follow-up of 11.0 months, a DFS benefit was observed with NIVO vs PBO in these pts, regardless of tumor PD-L1 expression (Table). DFS probability at 12 months in all MIBC pts was 66% with NIVO and 45% with PBO. DFS was improved with NIVO vs PBO across subgroups according to age, sex, ECOG performance status, nodal status, and PD-L1 expression status. Improvement in NUTRFS and DMFS with NIVO vs PBO was also observed (Table). Grade 3–4 treatment-related adverse events occurred in 17% and 6% of pts in the NIVO and PBO arms, respectively. **Conclusions:** Improvement in DFS was observed with NIVO over PBO in pts with MIBC after radical resection regardless of tumor PD-L1 expression. The DFS benefit was observed in all prespecified subgroups. These results further support adjuvant NIVO as a standard-of-care treatment for pts with high-risk MIBC after radical resection ± neoadjuvant cisplatin-based chemotherapy. Clinical trial information: NCT02632409. Research Sponsor: Bristol Myers Squibb.

Chemotherapy with significant mortality benefit in patients with bladder cancer with variant and non-urothelial histologies (NUVH). *First Author: Stuthi Perimbeti, Roswell Park Comprehensive Cancer Center, Buffalo, NY*

Background: Non urothelial cancers and urothelial cancers with variant histologies(NUVH) have a more aggressive natural history and are at a higher risk of progression to muscle invasive disease(MIBC) when compared to their urothelial counterparts. Although surgical resection is the treatment of choice in localized disease, radiation(RT) is commonly used in patients who are not surgical candidates. The use of chemotherapy has shown modest benefit in some retrospective studies. Considering the low incidence of NUVH, there are no large-scale studies examining the benefits of chemoradiation(CRT) in MIBC with NUVH. **Methods:** The National Cancer Database was queried to identify MIBC patients with NUVH from the years 2004-2018.Inclusion criteria for the study are age > 18 years, Non urothelial or variant histologies and receipt of RT. Patients who underwent cystectomy or had metastatic disease were excluded. The population was divided into two cohorts if they received chemoradiation. Chi-Square test and Mann Whitney U tests were used to compare frequency distributions. Cox proportional Hazard regression was employed to control for confounding factors associated with overall survival. Covariates for confounding included age, race, sex, income, insurance status, charlson-deyo comorbidity index, education. **Results:** Among 1773 observations in the final analysis, 63.05%(n = 1118) received CRT. Small cell, large cell and neuroendocrine cancers composed of the majority of NUVH. 38.01% (n = 641). Other histologies composed of squamous cell cancer 30.34%(n = 538), spindle cell/sarcomatoid cancers10.15%(180), adenocarcinoma 11.44%(203). Patients who received CRT were found to be significantly younger (76 vs 82 years P: < 0.0001) with higher male predominance74.73%. 5 year overall mortality was significaantly lower in the CRT vs RT group (66.47% vs 81.55%, p < 0.001). After controlling for confounding factors, CRT was associated with lower risk of mortality Hazard Ratio(HR)of 0.41(0.36-0.47) p < 0.0001. Added, the survival benefit of CRT continued in the non small cell variant cohort HR: 0.43(0.37-0.51) P < 0.0001. **Conclusions:** In this large retrospective study, CRT was associated with reduced overall mortality among patients with non-urothelial MIBC. The findings suggest the importance of systemic therapy in providing a survival advantage to non-urothelial MIBC, including the non-small cell variants. Research Sponsor: None.

Novel use of ctDNA to identify muscle-invasive and non-organ-confined upper tract urothelial carcinoma. *First Author: Heather L Huelster, Department of Genitourinary Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: Upper tract urothelial carcinoma (UTUC) is an aggressive cancer for which use of neoadjuvant chemotherapy (NAC) is limited by suboptimal clinical staging prior to nephroureterectomy. Detection of circulating tumor DNA (ctDNA) is associated with locally advanced and metastatic urothelial carcinoma of the bladder and may help identify UTUC patients who would benefit from NAC. Here we examine the feasibility and utility of plasma ctDNA in the diagnosis of non-organ confined high-risk UTUC. **Methods:** Patients with high-grade cTa-T2 UTUC without radiographic evidence of metastatic disease undergoing up-front radical nephroureterectomy (RNU) were prospectively accrued for pre- and post-operative plasma collection. Blood was collected preoperatively on the day of surgery, and plasma and buffy coat were processed for extraction of cell-free DNA and genomic DNA, respectively. FFPE tumor samples from RNU were used for tissue genomic DNA extraction. Targeted next-generation sequencing (NGS) was used for variant profiling. ctDNA positivity was defined as the presence of plasma cell-free DNA variants concordant with tissue-based variants. **Results:** NGS analyses of matched FFPE and plasma samples were successfully performed for all 19 accrued UTUC patients. Alterations in the TERT promoter (74%), TP53 (58%), FGFR3 (53%), myc amplification (53%), and ATM (42%) were demonstrated in urothelial tumor tissue. Matched plasma ctDNA showed prevalent alterations in the TERT promoter (42%), TP53 (42%), PIK3CA (37%), ATM (32%) and CD274 (26%). Nine patients (47%) had detectable plasma ctDNA mutations concordant with tumor-specific variants using the targeted NGS panel. All patients with detectable preoperative ctDNA had advanced staging (≥pT2 or ≥pN1) and lymphovascular invasion on final pathology, resulting in a 90% sensitivity. The panel was 100% specific with no patients with pTis, pTa, pT1 and pN0 having detectable concordant ctDNA mutations. Concordant plasma ctDNA was detected in four of nine patients postoperatively. Two of three (67%) who developed metastatic disease had detectable ctDNA while neither of the two who developed non-muscle-invasive bladder recurrences did. **Conclusions:** Prospective ctDNA analysis using a targeted NGS panel can be used to predict muscle-invasive and non-organ-confined UTUC preoperatively. Detectable postoperative ctDNA may indicate residual disease and predate clinical recurrence. Research Sponsor: Predicine Inc.

Efficacy and safety of atezolizumab concurrent with radiotherapy in patients with muscle-invasive bladder cancer: An interim analysis of the ATEZOBLADDERPRESERVE phase II trial (SOGUG-2017-A-IEC(VEJ)-4). *First Author: Sergio Vazquez-Estevez, Lucus Augusti University Hospital, Lugo, Spain*

Background: Combined-modality treatments are bladder-preserving alternatives for patients (pts) who are not candidates for radical cystectomy by medical reasons, refusal, or patient's choice. Immune therapies seem to potentiate tumor-specific immune response induced by radiotherapy (RT). Combination of RT with anti-PD-1/PD-L1 therapy appears safe and there are signs of promising activity. The aim of this study is to assess the efficacy and safety of atezolizumab (ATZ) concurrent with external beam radiotherapy (EBRT) for the treatment of muscle-invasive bladder cancer (MIBC) with bladder preservation intent. Here we present an interim analysis. **Methods:** This is an open, multicenter, and phase II trial, sponsored by SOGUG, in pts with confirmed diagnosis of MIBC in clinical stages cT2-T4a N0 M0 who are not candidates for radical cystectomy. Treatment consists of 6 doses of ATZ 1200 mg IV every 3 weeks, starting on day 1 of EBRT, and 60 Gy of RT in 30 fractions over 6 weeks at 2 Gy/day. The primary endpoint of the study is pathological complete response (pCR) defined as a response of grade 5 according to Miller and Payne criteria, 1 to 2 months after the last dose of ATZ. A planned interim analysis has been performed (data cut-off date: November 2021) on the primary endpoint to avoid exposure to ineffective treatment according to the minimax two-stages Simon's design (stopping rule: 9 out of the first 13 evaluable pts should achieve pCR). Incidence of adverse events (AE) and serious AE (SAE) has been also secondarily assessed. **Results:** From September 2019 to November 2021, 39 pts were screened, of whom 13 were excluded due to non-compliance with eligibility criteria. Thus, the evaluable population consisted of 26 pts. The safety analysis was performed in 22 pts who had received at least one dose of ATZ. 14 pts were assessed pathologically and, thus, included in interim efficacy analysis (median age: 78.6 years; clinical stage: 71.4% T2a, 14.3% T2b, 7.1% T3a, 7.1% T3b). All 14 pts had achieved pCR at the cut-off date. 20/22 (91%) pts experienced at least one AE, with asthenia (11 pts), diarrhea (9 pts), and urinary tract infection (4 pts) being the most common. 9 SAEs were reported in 7 (32%) pts (bacteriemia, COVID-19 infection, depressed LVEF, unknown origin fever, hepatic toxicity, kidney failure, rectorrhagia, respiratory infection, and urinary sepsis). 6 (27%) pts suffered AEs leading to treatment discontinuation. No AEs leading to death occurred. 17 pts with available data on survival were alive at the cut-off date. **Conclusions:** Interim results suggest that ATZ combined with EBRT is a feasible and effective treatment in terms of pCR, with a manageable safety profile. The final results from this trial will provide information about its effects on clinical outcome, including survival and updated safety findings. Clinical trial information: NCT04186013. Research Sponsor: Roche Farma S.A.

Phase II clinical study of tislelizumab combined with nab-paclitaxel (TRUCE-01) for muscle-invasive urothelial bladder carcinoma: Bladder preservation subgroup analysis. *First Author: Yuanjie Niu, Tianjin Medical University Second Hospital, Tianjin, China*

Background: The current strategy for bladder preservation is focused on trimodality treatment, including complete transurethral resection of bladder tumor (cTURBT), with concurrent chemotherapy and radiotherapy. Chemotherapy is usually a cisplatin-based regimen. However, many pts cannot tolerate cisplatin-based chemotherapy and radiation therapy. It fails to meet clinical needs. Meanwhile, the efficacy and safety of checkpoint inhibitors (ICIs) have now been demonstrated. We conduct a study to evaluate ICIs in combination with second-line chemotherapy agents for patients with MIBC. **Methods:** TRUCE-01 is a phase II trial (NCT04730219) of tislelizumab combined with nab-paclitaxel before cTURBT or radical cystectomy. Pts with pure or mixed urothelial bladder cancer (T2-4a Nx M0) received tislelizumab 200mg on days 1 plus paclitaxel 200mg on days 2 every 3 weeks (Q3W) x 3 cycles followed by cTURBT or radical cystectomy. Imaging evaluation is usually done before and after the drug administration using the same tests to assess the efficacy. Pts who choose to preserve bladder usually continue their medication after cTURBT. This abstract focuses on patients with bladder preservation. **Results:** Between July 2020 and November 2021, 47 pts completed at least 2 cycles of treatment, 22 (47%) pts received cTURBT, 16 (34%) pts received radical cystectomy and 9 (19%) pts refuse surgery. As for radiological response, 22 achieved complete response (CR), 16 achieved partial response (PR). In the bladder-preserving subgroup, 13 CR pts and 9 PR pts selected cTURBT, pathology showed 17 pT0, 1 pTa, 3 pT1 and 1 pTis. The median medication cycle is 9 (6-11). There were 3 pts experienced grade 3-4 adverse events (CTCAE), a grade 3 rash, a grade 3 gastric perforation and a grade 4 acute renal failure. In addition, The most common grade 1-2 adverse events include alopecia (86%), fatigue (77%), rash (41%), appetite decreases (41%), hyperglycemia (36%), fever (18%), and creatinine increased (14%). Median follow-up 357 (438-291) days with 3 recurrences and 1 death. The 1-year recurrence-free survival rate was 82%. **Conclusions:** The early efficacy data further support the role of tislelizumab combined with paclitaxel in bladder preservation setting with an acceptable adverse events. Patients with imaging CR or PR after neoadjuvant therapy are preferred for bladder preservation. Enrollment is ongoing. Clinical trial information: NCT04730219. Research Sponsor: The Natural Science Foundation Project of Tianjin (grant no. 18PTLCSY00010), the Tianjin Urological Key Laboratory Foundation (grant no. 2017ZDSYS13) and the Youth Fund of Tianjin Medical University Second Hospital (grant no. 2020ydey09).

Artificial intelligence algorithms for the diagnosis of urothelial carcinoma based on urine cytology: A noninvasive and efficient diagnostic approach. *First Author: Chong Shen, The second hospital of Tianjin Medical University, Tianjin, China*

Background: Urine cytology is a noninvasive and relatively inexpensive approach that plays an important role in both screening/initial diagnosis of urothelial carcinoma, and surveillance of tumor recurrence; However, interpretation of urine cytology is labor-intensive and time-consuming. Artificial intelligence (AI) has been widely used in the field of medically assisted diagnosis, but it is almost blank in the field of urothelial carcinoma diagnosis based on urine cytology. In this study, artificial intelligence (AI) algorithms have been developed to efficiently and automatically analyze urinary cytological specimens stained with Acridine orange fluorescence for screening and diagnosis of urothelial carcinoma with a good clinical application prospect. **Methods:** To develop the algorithms, images of urinary cytological specimens with Acridine orange Fluorescence staining were collected from patients who underwent examination, surgery, or both at the Second Hospital of Tianjin Medical University from August 2015 to August 2021. To standardize the urine cytological determination, the images were determined by 3 certified and experienced cytopathologists in this hospital. Images were collected to establish a dataset containing two major categories: Malignant (Defined as images containing malignant cells) and Benign (Defined as images containing malignant cells). From the acquired database, 2794 malignant and 2787 benign eligible images were selected for AI training/validation/testing. Inception V3, a specific type of neural network optimized for image classification called a deep convolutional neural network was trained based on the database. To prevent the model from over-fitting during training, data augmentation methods, such as rotation and flipping were adopted. The diagnosing performance of the binary classification model was analyzed using accuracy, F1 score, operating characteristic (ROC), and the area under the curve (AUC) generated from the sensitivity and specificity to evaluate. **Results:** A total of 21022 slides of urine cytological specimens with Acridine orange Fluorescence staining were collected. The AI algorithms achieved excellent performance, which showed the best prediction with an accuracy of 92.25%, a sensitivity of *98.50*% along with a specificity of 86.00%, the F1score was 0.9271, and the area under the ROC curve was 0.96. **Conclusions:** Our novel artificial intelligence algorithms could accurately classify urine specimens as malignant or benign efficiently and automatically. The use of AI during cytopathology screening provides a new strategy and technical support for the diagnosis and screen of urothelial carcinoma. A classification system for urothelial carcinoma (UC) defined by genomic drivers and the tumor microenvironment (TME) is predictive of immunotherapy response. *First Author: Konstantin Chernyshov, BostonGene Corporation, Waltham, MA*

Background: UC is associated with high recurrence rates, progression, and resistance to platinum-based therapy. Checkpoint inhibitors (CPIs) are often used for treating UC, but predictive biomarkers that characterize response are lacking in the majority of patients. Defining the TME is essential to understanding patient response to CPIs. Employing a transcriptome-based classification platform, we sought to identify predictive and prognostic subtypes of UC using malignant cell and TME features. **Methods:** We collected a metacohort of 2,418 UC samples from 14 publicly available datasets, one of which had atezolizumab response data (IMvigor210). Using the methodology described in Bagaev et al. 2021, we selected 28 signatures composed of specific gene sets reflecting distinct cellular processes. Analysis of signature expression and unsupervised clustering was performed. **Results:** We identified 7 recurring novel UC subtypes (Table 1) with unique genomic and molecular characteristics. The subtypes and key findings include: an immune desert (D) subtype characterized by genomic instability high HER2 expression; an immune desert, *FGFR*-altered (D-FGFR) subtype with *FGFR* alterations; an immune enriched (IE) subtype with an enriched TME and high CPI response; a fibrotic (F) subtype with a mesenchymal TME, and strong TGFβ signaling; an immune enriched, fibrotic (IE-F) subtype with a mixed TME and a high CPI response rate; a fibrotic, basal (F-B) subtype with a mesenchymal TME and minimal genomic targets, and a neuroendocrine-like (NE-L) subtype with a high CPI response rate. **Conclusions:** UC can be classified into 7 subtypes with distinct prognoses, CPI response rates, and druggable targets using malignant cell and TME profiling. Patients with IE, IE-F, and NE-L UCs may be good candidates for CPIs. D UCs may benefit from HER2-i and PARP-i, while FGFR-i might be more suitable for D-FGFR UCs. TGFβi and PARPi may be effective for F UCs, but F-B UCs have no targetable findings. These findings warrant additional investigation for clinical translation. Research Sponsor: BostonGene Corporation.

Urothelial cancer subtype characteristics.

UC Subtype	n	TME immune composition	Malignant cell features	Alterations	Cisplatin 5-year OS	Atezolizumab CPI response rate
D	382	Desert	Genomic instability	*TP53, RB1* (del), *MCL* (amp), *HER2*	70%	45% (n=37)
D-FGFR	674	Desert	–	*FGFR3, CDKN2A* (del)	58%	43% (n=79)
IE	360	T, B, NK	–	*ARID1B, MCL* (amp)	77%	58% (n=50)
IE-F	251	Macrophage, MDSC, T, NK	Activated NFκB, JAK-STAT	*RB1, EP300*	60%	52% (n=25)
F	381	Mesenchymal, protumor cytokines, angiogenesis	Activated TGFβ, EMT	*TNFRSF14* (del)	48%	39% (n=56)
F-B	337	Mesenchymal, CAF, ECM	–	–	48%	28% (n=49)
NE-L	33	Desert	Neuroendocrine differentiation	*TP53, RB1*	NA	100% (n=4)

CAF - cancer-associated fibroblasts; ECM - extracellular matrix; " – " no significant events.

Efficacy of hyperthermic-intra-vesical chemotherapy in patients with BCG-refractory nonmuscle-invasive bladder cancer. *First Author: Geraldine Pignot, Institut Paoli-Calmettes, Marseille, France*

Background: In Bacillus Calmette-Guérin (BCG) refractory non-muscle-invasive bladder cancer (NMIBC), radical cystectomy is the standard of care. For patients unwilling or unable to undergo cystectomy, alternative intravesical therapies are currently being investigated to minimize the risk of recurrence and progression. Chemohyperthermia by HIVEC (Hyperthermic-Intra-Vesical Chemotherapy) is a therapeutic option in BCG-refractory patients. The objective of our study was to evaluate the 2-year oncological results of HIVEC in BCG-refractory patients. **Methods:** Between June 2016 and September 2021, patients treated with HIVEC (6 weekly instillations) for BCG-refractory NMIBC were prospectively included in our study. These patients had a theoretical indication for cystectomy but were ineligible for surgery or refused it. The primary endpoint was 1-year recurrence-free survival (RFS) rate. Secondary endpoints were 6-month complete response rate for Cis, 1-year overall and cancer-specific survival rates and bladder preservation rate. **Results:** Seventy patients, mean age 70 [42-89] years, were treated consecutively. After a mean follow-up of 20.9 months, 32 patients recurred (mean time of 10.6 months) and 7 patients finally had a cystectomy. The recurrence-free survival rate was 53.1% at 1 year and 20.5% at 2 years. Six patients progressed to a muscle-invasive disease, after a mean delay of 6.7 months. Four of them experienced metastatic progression and died from bladder cancer. Cancer-specific and overall survival rates were 95.1% and 92.9% at 1 year, and 87.5% and 77.8% at 2 years. The bladder preservation rate was 90%. For patients with Cis (34% of the entire series), the 6-month complete response rate was 75%. The presence of Cis was not a predictive factor of response to HIVEC. Tolerance was excellent with 38.2% grade 1-2 adverse events and no grade 3-4 adverse events. **Conclusions:** Chemohyperthermia using the HIVEC device achieved a RFS rate of 53.1% at 1 year and enabled a bladder preservation rate of 90%. While cystectomy remains the standard of care, HIVEC may be discussed cautiously for patients who are not eligible for surgery and well informed of the risk of progression to muscle-invasive disease. Research Sponsor: None.

Prognostic factors and clinical outcomes in patients with upper tract urothelial carcinoma undergoing surgery: The Cleveland Clinic experience. *First Author: Ramsha Ahmed, Cleveland Clinic Foundation, Cleveland, OH*

Background: Upper tract urothelial carcinoma (UTUC) is a rare and heterogeneous disease accounting for approximately 5-10% of UC. While tumor grade and stage are known prognostic factors, data on other factors affecting outcomes in UTUC patients (pts) undergoing surgery is scant. We studied effect of various clinical factors and treatment on outcomes in UTUC. **Methods:** This is a single-institution retrospective study of 607 pts with UTUC undergoing surgery (nephroureterectomy (NU) or ureterectomy (U)) between Jan 2000 and Dec 2020. We studied effect of demographics, clinicopathological features, tumor location, preoperative Neutrophil-to-Lymphocyte ratio (NLR) and Albumin-to-Globulin ratio (AGR) and use of neoadjuvant or adjuvant chemotherapy on overall survival (OS) and recurrence free survival (RFS). **Results:** Of the 607 pts 401 (66.06%) were males and 355 (58.48%) were > 70 yrs; 232 pts (38.22%) had UTUC of renal pelvis, 242 (39.87%) of ureter and 133 (21.91%) of both. 542 pts (89.29%) underwent radical NU and 65 (10.71%) segmental U; 328 patients (54.04%) were diagnosed with muscle invasive UC (MIUC) (> / = pT2) and 276 (45.47%) with non-MIUC (< / = pT2). Only 51 (8.4%) pts had lymph node positive (N+) disease. Lymphovascular invasion (LVI) was identified in 163 (26.85%) and carcinoma- in-situ (CIS) in 163 (26.85%) pts. Surgical margins were positive in 92 pts (15.16%). Median NLR cutoff was 3.25 and AGR cutoff was 1.25 (dichotomized based on literature). 44 pts (7.2%) received Neoadjuvant chemotherapy and 49 pts (8%) received adjuvant chemotherapy. Tumor recurrence occurred in 216 pts (35.58%) of which 65% were at urothelial and 35% at non-urothelial sites. With median follow up of 35.2 mos, median OS was 82.69 mos and 5-yr OS rate was 60%; median RFS was 29.47 mos and 5-yr RFS rate was 40%. High grade, age > / = 70 yrs, high NLR, low AGR, presence of LVI, positive margins, CIS, MIUC, N+ disease were associated with worse outcomes. Pts with only renal pelvis involvement had better OS. **Conclusions:** In this large, long term follow-up series of UTUC pts, we identified several prognostic factors besides grade and stage that impact outcomes. These findings warrant further validation for use in clinical practice. Research Sponsor: None.

Prognostic Factors	Median OS (mos)	Median RFS (mos)
Age, > / = 70 vs < 70 yrs	48.3 vs 130.56 (p < 0.0001)	20.5 vs 70.2 (p < 0.0001)

Quantifying the absolute benefit of neoadjuvant chemotherapy followed by definitive therapy in patients with muscle-invasive bladder cancer: A systematic review and meta-analysis. *First Author: Waleed Ikram, Mayo Clinic, Phoenix, AZ*

Background: Cisplatin based neoadjuvant chemotherapy (NAC) followed by definitive therapy improves survival in patients with muscle invasive bladder cancer (MIBC). However, the clinical benefit of NAC might vary with the choice of definitive therapy. Therefore, we assessed the absolute benefit of NAC followed by radical cystectomy or radical radiotherapy separately using the totality of evidence. **Methods:** MEDLINE and EMBASE were systematically searched to identify randomized trials assessing cisplatin based neoadjuvant chemotherapy followed by either radical cystectomy or definitive radiotherapy in patients with MIBC. Outcomes of interest included overall survival (OS) and disease-free survival (DFS). Treatment effects were expressed as hazard ratios (HR) with 95% confidence interval (CI). Incidence rate ratios were calculated to estimate time to event outcomes for trials not reporting HR. A random-effects DerSimonian-Laird meta-analysis was conducted. Absolute effects were then obtained using baseline risks from the control arm of RCTs. **Results:** Of 4887 studies identified, 13 trials with 2529 patients were included in this meta-analysis. Most trials included patients with T2-4 and N0 patients and only 3 trials included patients with node positive disease. Total of 180 (47%) DFS events were observed with NAC+RC compared to 213 (56%) events in RC alone (HR: 0.72; 95% CI: 0.59-0.89) and 346 (58%) OS events were observed with NAC+ RC compared to 385 (52%) events in RC alone (HR: 0.80; 95% CI: 0.69-0.92). Total of 186 (70%) DFS events were observed with NAC + radiotherapy compared to 205 (71%) events in radiotherapy alone (HR: 0.91; 95% CI: 0.74-1.12) and 263 (58%) OS events were observed with NAC+ radiotherapy compared to 294 (61%) events in radiotherapy alone (HR:0.93; 95% CI: 0.79-1.08). **Conclusions:** The choice of definitive therapy after cisplatin-based NAC impacts survival in patients with MIBC. RC after NAC improved DFS (114 fewer events per 1000 events) and OS (76 fewer per 1000 events) whereas radiotherapy after NAC showed no survival benefit. Research Sponsor: None.

Outcome	Studies (Participants)	Relative effect	Anticipated absolute effects	
			Risk with Radical cystectomy	Risk difference with Neoadjuvant Chemotherapy
OS	8 (1511)	HR 0.80 (0.69 to 0.92)	528 per 1,000	76 fewer per 1,000 (from 124 fewer to 28 fewer)
DFS	5 (765)	HR 0.72 (0.59 to 0.87)	563 per 1,000	114 fewer per 1,000 (from 177 fewer to 50 fewer)
			Risk with Radical radiotherapy	Risk difference with Neoadjuvant Chemotherapy
OS	6 (1018)	HR 0.93 (0.79 to 1.08)	632 per 1,000	27 fewer per 1,000 (from 86 fewer to 28 more)
DFS	2 (520)	HR 0.91 (0.74 to 1.12)	734 per 1,000	66 fewer per 1,000 (from 191 fewer to 88 more)

Evaluating oncologists' practice patterns and decision-making in locally advanced or metastatic urothelial carcinoma (la/mUC): The U.S. physician PARADIGM study (Part 2). *First Author: Frank Liu, EMD Serono, Rockland, MA*

Background: The treatment (tx) landscape for la/mUC has evolved with the use of immunotherapy (IO) for platinum-refractory la/mUC as well as first-line (1L) maintenance therapy (1LM). This cross-sectional survey explored practice patterns for 1L tx/1LM use and clinical decision-making. **Methods:** Community/academic US oncologists (n = 150) completed an online survey (Sept-Oct 2021) on demographics, 1L tx, 1LM use, attributes in 1L tx selection/1LM use, and factors associated with 1L tx/1LM use. Physicians were dichotomized into 4 pre-specified groups using the median percentage (%) as a cutoff: 1) more frequent 1L prescriber 2) less frequent 1L prescriber (% of pts treated with 1L tx in the past 6 months); 3) more frequent 1LM prescriber 4) less frequent 1LM prescriber (% of pts eligible and received 1LM). Descriptive and bivariate analyses assessing attributes (scored out of 100 points across 16 attributes) in 1L tx selection/1LM use were conducted. Multivariable logistic regression was used to assess factors associated with more/less frequent 1L tx/1LM use. **Results:** Median time in practice was 15 yrs (range, 2-31; 63% community vs 37% academic setting). The median % of la/mUC pts who received 1L tx was 46% (range, 25-89%). 72 physicians were categorized as more frequent 1L prescribers, while 78 were less frequent 1L prescribers. The median % of pts eligible and received 1LM was 71% (range, 0-100%). 71 physicians were categorized as more frequent 1LM prescribers, while 75 were less frequent 1LM prescribers. Attributes used in 1L tx selection differed among more vs less frequent 1L prescribers: mean scores for efficacy/overall survival (OS), disease control rate (DCR), or rate of grade 3/4 adverse events (AEs) were 23 vs 17, 10 vs 8, and 10 vs 5, respectively (all $p < 0.05$). Similarly, for more vs less frequent 1LM prescribers, mean scores for efficacy/OS, rate of grade 3/4 immune-mediated AEs, and inclusion in institutional guidelines/pathways were 23 vs 16, 6 vs 4, and 2 vs 4. Oncologists who stated OS, DCR, or rate of grade 3/4 AEs as important factors impacting tx selection were more likely to prescribe 1L tx (all $p < 0.05$). Regarding 1LM use, oncologists based in the academic setting, those who reported using RECIST 1.1 criteria to assess tx response or agreed 1LM is important to prolong OS were all more likely to prescribe 1LM (all $p < 0.05$). Those who reported that their institutional guidelines/pathways impact tx decisions or cited prior IO use before metastatic diagnosis as reason not to prescribe 1LM were less likely to prescribe 1LM (all $p < 0.05$). **Conclusions:** While several factors were found to be associated with offering 1L tx by US oncologists, including impact on OS and practice setting, variability exists in physicians' attitudes to 1L tx/1LM use. Studies and interventions to explore shared decision-making for optimal 1L tx selection are needed. Research Sponsor: the healthcare business of Merck KGaA, Darmstadt, Germany, Pharmaceutical/Biotech Company.

4596 **Poster Session**

EO2401, a novel microbiome-derived therapeutic vaccine for patients with adrenocortical carcinoma (ACC): Preliminary results of the SPENCER study. *First Author: Eric Baudin, Institut Gustave Roussy, Villejuif, France*

Background: In advanced ACC, no significant progress has been made since introduction of mitotane and cisplatin-based therapy. EO2401 (EO) was designed to activate existing commensal memory T cells cross-reacting with tumor associated antigens (TAAs). EO includes microbial-derived, synthetically produced peptides corresponding to HLA-A2 restricted epitopes with molecular mimicry to three TAAs upregulated in ACC, IL13Rα2, BIRC5 and FOXM1, with the CD4 helper peptide UCP2 and the adjuvant Montanide. Pre-clinically EO generates strong immune responses and cross-reactive CD8 cells recognizing the TAAs. **Methods:** This Phase 1/2 trial (NCT04187404) investigated EO + nivolumab (N) (EO + N = EN) in pts with ACC. Cohort 1 lead-in established safety of EN. Cohort 2 includes pts with metastatic ACC, with (C2a), or without (C2b) prior systemic therapy. EN was given 4 times q2 w, followed by boosters q4 w until PD (iRECIST). **Results:** 33 pts with ACC started study treatment: C2a 26 pts (58% 1; 42% 2 prior lines), C2b 7 pts. Median age 47; 24% men; ECOG 0/52%, 1/42%, 2/6%; 61% ≥2 organs involved by metastases (61% liver, 76% lung). EN was well tolerated. The combination safety profile was consistent with the profile of N monotherapy except for higher local administration site reactions (any erythema/pain/induration in 35% of pts). Overall (n = 33), best RECIST response was PR 12%, SD 24%, PD 45%, NE 18%; median PFS was 1.9 mo (range 0.4-7.6+); median survival not reached, and survival rate at 6-mo 63% (median FU 4.9 mo, range 0.9-12.0). Strong CD8 T cell ELISPOT responses against the vaccine peptides (9/9 pts) and cross-reactivity against targeted TAAs (8/8 evaluable pts) was observed. Tetramer staining of specific CD8 cells for all 3 peptides was detected in 7/8 tested. When investigated, positive staining against BIRC5 was detected as early as 4 w after the first vaccination. In C2a, a group of pts (n = 10) with SD at the first CT (incl. 4 pts with PR) seemed to fare well; all investigated tumor samples in this group showed a low level of TMB, low MSI, and low PDL1 expression. In contrast, 10 pts had PD < 2mo and died < 6mo. There was no correlation between clinical benefit and a large panel of cytokines/chemokines. However, post-hoc analysis identified several clinical factors (prior mitotane, ECOG ≤ 1, ACC 1st diagnosis > 9 mo, max lesion ≤125 mm, ≤3 organs involved, lymphocytes ≤ grade 1) that excluded 90% of pts without benefit to EN. In the post-hoc selected group (n = 14) with median FU 6.9 mo (12 pts censored) the DCR was 64% (4 PR, 5 SD), 6-mo PFS was 42% and 6-mo survival rate 93%. **Conclusions:** EO2401 in combination with nivolumab was well tolerated and induced a specific immune response in all tested pts. In addition, efficacy was seen in a subpopulation of pts with ACC defined by clinical parameters in a post-hoc analysis. A randomized phase 2 study based on the findings of Cohort 2a is being planned. Clinical trial information: NCT04187404. Research Sponsor: Enterome.

4597 **Poster Session**

CORE1: Phase 2, single-arm study of CG0070 combined with pembrolizumab in patients with nonmuscle-invasive bladder cancer (NMIBC) unresponsive to bacillus Calmette-Guerin (BCG). *First Author: Roger Li, Department of Genitourinary Oncology, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL*

Background: CG0070, is an Ad5-based oncolytic vaccine engineered to express GM-CSF and replicate selectively in tumor cells with mutated or deficient RB. The CG0070 mechanism of action includes cell lysis and immunogenic cell death which is enhanced in the presence of GM-CSF. In an open label ph. 2 study, an overall CR rate of 62% and a CR at 12 months (m) of 29% have been observed in patients with high risk NMIBC previously treated with BCG. IV pembrolizumab, was recently approved by the FDA for patients with BCG-unresponsive CIS (with or without papillary tumors) with an overall complete RR of 41% and a 12 m CR rate of ~20%. This ph. 2 study will assess the potential synergy of the two agents in the treatment of BCG-unresponsive NMIBC. **Methods:** 35 pts with BCG-unresponsive CIS with or without concurrent Ta or T1 disease will be treated with intravescical CG0070 ($1x10^{12}$ vp) in combination with pembrolizumab at a dose of 400 mg IV q6 weeks. CG0070 will be administered weekly x 6 as induction followed by weekly x 3 maintenance instillations at months 3, 6, 9, 12, and 18. Pts with persistent CIS or HG Ta at 3 m may receive re-induction with weekly x 6 of CG0070. Pembrolizumab will be administered up to 24 m. Assessment of response will include q 3 m cystoscopy with biopsy of areas suspicious for disease, urine cytology, CTU/MRU, and mandatory bladder mapping biopsies at 12 m. Recurrence of HG disease will be enumerated as disease recurrence. The primary endpoint of the study is CR at 12 m. Secondary endpoints will include CR at any time, progression free survival, duration of response, cystectomy free survival and the safety. Correlate assessments will include changes in the tumor immune microenvironment, systemic immune induction,viral replication and transgene expression. Baseline expression of PD-L1, coxsackie adenovirus receptor, E2F transcription factor as well as anti-Ad5 Ab titer will be correlated with tumor response. **Results:** A CR rate of 87.5% (14/16) at the 3 m assessment timepoint has been observed thus far. All patients in CR at 3 m remain in CR at downstream timepoints including: 9/9 at 6 m, 6/6 at 9 m, and 3/3 at 12 m. Treatment related AE have been generally limited to transient grade 1-2 local-regional genitourinary adverse events with no reports of grade 3, 4 or SAE attributed to treatment with CG0070/Pembroluzimab. **Conclusions:** This initial data on the efficacy and safety of CG0070 plus pembrolizumab for the treatment of BCG unresponsive NMIBC is encouraging. Additional data on efficacy as well as safety and biomarker (CAR, E2F, and PDL1) assessment will be presented for at least 25 of the projected 35 patients at the time of the conference. Clinical trial information: NCT04387461. Research Sponsor: CG Oncology.

ALTER-UC-001: Phase II trial of anlotinib plus everolimus as first-line treatment for advanced non–clear cell renal cell carcinoma. *First Author: Hailiang Zhang, Department of Urology Surgery, Fudan University Shanghai Cancer Center, Shanghai, China*

Background: For patients (pts) with recurrent or stage IV non-clear cell renal cancer (nccRCC), the medical treatment guidelines recommend the first choice to participate in clinical trials, or use TKI drugs such as sunitinib, and mTOR inhibitors such as everolimus. Anlotinib is a novel multi-target tyrosine kinase inhibitor (TKI). It's antitumor targets include vascular endothelial growth factor receptor (VEGFR), fibroblast growth factor receptor (FGFR), platelet-derived growth factor receptor (PDGFR) and c-kit. This a single-center, single-arm, phase II trial which will evaluate the efficacy and tolerability of anlotinib hydrochloride plus everolimus as first-line therapy in pts with nccRCC (NCT05124431). **Methods:** Key inclusion criteria are: age ≥18 years; histologically confirmed advanced nccRCC, advanced disease is defined as TNM stage IV, not available for surgery, locally recurrent or metastatic renal cell carcinoma; no prior systemic drug therapy for advanced disease; Eastern Cooperative Oncology Group (ECOG) performance status 0-1. Approximately 30 pts will be assigned to receive anlotinib hydrochloride: 12 mg every 21 days (14 days on treatment from Day 1-14, 7 days off treatment from Day 15-21) by oral, and everolimus 5mg qd, continued for up to 1 year (~17 cycles) or until disease progression, unacceptable toxicity, or withdrawal of consent. The primary endpoint was objective response rate (ORR). Radiographic imaging will be performed every 6 weeks. Secondary endpoints included overall disease control rate (DCR), progression free survival (PFS), and over survival (OS). Adverse events will be monitored throughout the study and graded according to CTCAE V5.0. Recruitment have begun in Jan. 2022. Research Sponsor: Chia Tai Tianqing Pharmaceutical Group Co., Ltd. Clinical trial information: NCT05124431.

TPS4599 **Poster Session**

A phase 1b/2 study of batiraxcept (AVB-S6-500) in combination with cabozantinib, cabozantinib and nivolumab, and as monotherapy in patients with advanced or metastatic clear cell renal cell carcinoma (NCT04300140). *First Author: Katy Beckermann, Vanderbilt-Ingram Cancer Center, Nashville, TN*

Background: In clear cell renal cell carcinoma (ccRCC) the constitutive expression of hypoxia induced factor 1-α leads to increased expression of AXL. AXL overexpression has been associated with the development of resistance to VEGF inhibitors and suppression of the innate immune response through inhibition of macrophage-driven inflammation. Batiraxcept is a recombinant fusion protein dimer containing an extracellular region of human AXL combined with the human immunoglobulin G1 heavy chain (Fc), which demonstrates highly potent, specific AXL inhibition. In preclinical studies using the 786-O, M62, and SN12L1 tumors, batiraxcept monotherapy resulted in a significant reduction of tumor growth compared to control. In healthy volunteer and ovarian cancer clinical studies, batiraxcept was well tolerated with no dose-related adverse events, and a maximum tolerated dose was not reached. Therefore, batiraxcept could be tested as either a monotherapy or in combination with standard of care drugs in patients with metastatic ccRCC. The Phase 1b dose-escalation portion of this study evaluated batiraxcept in combination with standard of care cabozantanib in patients who progressed on or after first line therapy. No DLT was observed at either of two batiraxcept doses evaluated. The recommended Phase 2 dose of batiraxcept has been identified as 15 mg/kg every 2 weeks (q2w) with cabozantinib 60 mg based upon safety, PK/PD, and preliminary efficacy data. **Methods:** This Phase 2, multi-center, open-label study includes three parts: Part A) batiraxcept 15 mg/kg q2w in combination with cabozantinib 60 mg daily for ccRCC subjects who have progressed on or after one line of therapy, n=25. Part B) batiraxcept 15 mg/kg q2w with cabozantinib 40 mg daily and nivolumab at the investigator's choice (240 mg q2w or 480 mg q4w) for first line treatment of advanced or metastatic ccRCC subjects, n=20. If no safety signals are observed in the first 6 subjects enrolled, 10 subjects will be enrolled in the first stage of a Simon 2-stage minmax statistical design. If ≥ 6/10 subjects achieve PR or CR, stage 2 will open to enroll up to 20 total subjects. Part C) batiraxcept 15 mg/kg q2w monotherapy for subjects with advanced/metastatic ccRCC ineligible for curative intent therapies, n=10. The primary objective for each arm is objective response rate by RECIST v1.1. Secondary objectives include safety, duration of response, clinical benefit rate, progression free survival by RECIST v1.1, and overall survival. Exploratory objectives include pharmacokinetic and pharmacodynamic assessments. The Phase 2 portion of this Ph1b/2 study is currently enrolling. Clinical trial information: NCT04300140. Research Sponsor: Aravive, Inc.

TPS4600 **Poster Session**

A phase 1b study (STELLAR-002) of XL092 administered in combination with nivolumab (NIVO) with or without ipilimumab (IPI) or bempegaldesleukin (BEMPEG) in patients (pts) with advanced solid tumors. *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute, Boston, MA*

Background: XL092 is a novel oral inhibitor of receptor tyrosine kinases, including MET, VEGFR2, and TAM kinases (AXL, MER), which are implicated in tumor growth, metastasis, angiogenesis, and immune suppression of the tumor microenvironment. XL092 has a relatively short half-life (~21h) to support convenient daily dosing and help manage tolerability. Preclinical studies of XL092 with an anti–PD-1 immune checkpoint inhibitor (ICI) demonstrated antitumor activity in tumor models, and BEMPEG (IL-2 pathway agonist) showed synergy with anti–PD-L1 and anti–CTLA-4 agents. This phase 1b trial will evaluate the safety and clinical activity of XL092 alone and in combination with NIVO (anti–PD-1 mAb) ±IPI (anti–CTLA-4 mAb) or ±BEMPEG in pts with advanced solid tumors including genitourinary cancers. Presented here is the study design. **Methods:** This multicenter phase 1b, open-label study (NCT05176483) will enroll pts with unresectable advanced or metastatic solid tumors in dose-escalation and expansion stages. In the dose-escalation stage, ~36 pts will be enrolled in three XL092 combination therapy cohorts using a rolling 6 design. Cohort A: XL092 (starting dose [SD] 100 mg PO QD) + NIVO (360 mg IV Q3W); Cohort B: XL092 (SD 80 mg PO QD) + NIVO (3 mg/kg IV Q3W × 4, then 480 mg IV Q4W) + IPI (1 mg/kg Q3W × 4); Cohort C: XL092 (SD 100 mg PO QD) + NIVO (360 mg IV Q3W) + BEMPEG (0.006 mg/kg IV Q3W). The primary objective of the dose-escalation stage is to determine the recommended doses of XL092 with the NIVO regimens to be used in the expansion stage. The expansion stage will include cohorts of advanced genitourinary tumors: Cohort 1, clear-cell renal cell carcinoma (ccRCC), no prior systemic therapy; Cohort 2, ccRCC, 1 prior ICI combination regimen; Cohort 3, metastatic castration-resistant prostate cancer (mCRPC), 1 prior novel-hormonal therapy; Cohort 4, urothelial carcinoma (UC), 1 prior platinum-based regimen, ICI-naïve; Cohort 5, UC, ≤2 prior systemic regimens, ICI-experienced; Cohort 6, non-ccRCC, no prior systemic therapy. In each cohort, pts will be randomized to one of the following treatments (based on tumor cohort): single-agent XL092 (Cohorts 2–6); XL092+NIVO (Cohorts 1–6); NIVO+IPI (Cohort 1); XL092+NIVO+IPI (Cohorts 1, 3, 6); NIVO+BEMPEG (Cohort 1), XL092+NIVO+BEMPEG (Cohort 1, 2, 4–6). Thirty pts will be enrolled in each single-agent XL092 arm and 40 pts in each combination therapy arm. Expansion stage objectives are to assess preliminary efficacy, safety, and pharmacokinetics of XL092 alone or in combination in each tumor-specific cohort. Primary efficacy endpoints include objective response rate by investigator per RECIST v1.1 and progression-free survival by blinded independent radiology committee per Prostate Working Group 3 criteria (mCRPC cohort only). The study is currently enrolling pts. Clinical trial information: NCT05176483. Research Sponsor: Exelixis, Inc.

TPS4601 **Poster Session**

SAMETA: An open-label, three-arm, multicenter, phase III study of savolitinib + durvalumab versus sunitinib and durvalumab monotherapy in patients with MET-driven, unresectable, locally advanced/metastatic papillary renal cell carcinoma (PRCC). *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: Papillary renal cell carcinoma (PRCC) is the most common subtype of non-clear cell RCC and accounts for 10–15% of RCCs. Approximately 80% of PRCC cases are MET-driven, characterized by genomic abnormalities resulting in dysregulation of the MET signaling pathway, making these abnormalities a potential therapeutic target for treatment. Savolitinib is an oral, potent and highly selective MET tyrosine-kinase inhibitor (TKI) demonstrating preliminary clinical activity in advanced solid tumors, including in MET-driven PRCC, defined as presence of any of the following molecular alterations, in the absence of co-occurring fumarate hydratase mutations: chromosome 7 gain, MET amplification, MET kinase domain variations, or hepatocyte growth factor amplification. In the Phase III SAVOIR study, in PRCC, savolitinib monotherapy showed encouraging efficacy vs the multi-targeted TKI, sunitinib. In addition, non-clinical studies suggest a possible synergistic anti-tumor effect of MET-inhibitors and programmed cell death-ligand (PD-L1) inhibitors, such as durvalumab; emerging data from the Phase I/II CALYPSO study investigating savolitinib plus durvalumab shows a notable efficacy signal in patients with MET-driven PRCC. Following these findings, the SAMETA study (NCT05043090) is designed to evaluate the efficacy and safety of savolitinib in combination with durvalumab vs sunitinib and durvalumab monotherapy in PRCC. **Methods:** In this open-label, three-arm, multi-center, Phase III study, adult patients with unresectable, MET-driven and locally advanced/metastatic PRCC are eligible. An estimated 200 patients (25 countries, 165 centers) will be randomized in a 2:1:1 ratio into three treatment arms (A–C) with stratification by International metastatic RCC database consortium risk group & PD-L1 expression tumor status. Arm A: oral savolitinib 600 mg once daily (QD) plus intravenous (IV) durvalumab 1500 mg every 4 weeks (Q4W); Arm B: oral sunitinib 50 mg QD for 4 consecutive weeks, followed by a sunitinib-free interval of 2 weeks Q6W; Arm C: IV durvalumab 1500 mg Q4W. Study treatment continues until RECIST 1.1 disease progression or another discontinuation criterion is met. The primary endpoint is progression-free survival (by BICR; RECIST v1.1). Secondary endpoints include overall survival, objective response rate and duration of response. Safety (adverse events, vital signs, ECG, hematology and biochemistry parameters) will also be reported. The first patient was enrolled onto the study on 28 October 2021. Clinical trial information: NCT05043090. Research Sponsor: AstraZeneca.

TPS4602 **Poster Session**

LITESPARK-022: A phase 3 study of pembrolizumab + belzutifan as adjuvant treatment of clear cell renal cell carcinoma (ccRCC). *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA*

Background: Patients with locally advanced renal cell carcinoma (RCC) may experience recurrence after surgery. In the phase 3 KEYNOTE-564 (NCT03142334) trial, adjuvant pembrolizumab demonstrated significant improvement in disease-free survival (DFS) in ccRCC, leading to FDA approval of pembrolizumab (November 17, 2021) for adjuvant treatment of patients with RCC at intermediate-high or high risk for recurrence following nephrectomy or following nephrectomy and resection of metastatic lesions. Despite benefit of pembrolizumab, there is an unmet need for more effective adjuvant treatment for patients at risk for recurrence after definitive surgery. The HIF-2α inhibitor belzutifan (MK-6482) has shown activity and good tolerability in patients with advanced ccRCC and von Hippel-Lindau (VHL) disease–associated RCC. Combining belzutifan with pembrolizumab may be a therapeutic option as adjuvant treatment of ccRCC. This global, multicenter, double-blind, randomized, phase 3 study LITESPARK-022 (NCT05239728) is designed to compare the efficacy and safety of belzutifan + pembrolizumab with that of placebo + pembrolizumab as adjuvant treatment of ccRCC after nephrectomy. **Methods:** Approximately 1600 patients with histologically or cytologically confirmed RCC (intermediate-high [pT2, grade 4 or sarcomatoid, N0, M0 or pT3, any grade, N0, M0], high [pT4, any grade, N0, M0 or pT, any stage/grade, N+, M0] or M1 NED [patients who present with the primary kidney tumor and solid, isolated, soft tissue metastases that can be resected at the time of nephrectomy or ≤2 years from nephrectomy) with a clear cell component and had not previously received systemic therapy will be enrolled. Patients must have undergone nephrectomy and/or metastasectomy ≤12 weeks before randomization and be tumor free, confirmed by CT/MRI. Stratification factors are tumor grade (1 or 2 vs 3 or 4) and risk type (intermediate-high vs high vs M1 NED). Patients will be randomly assigned 1:1 to receive belzutifan 120 mg orally once daily + pembrolizumab 400 mg IV every 6 weeks (Q6W) or oral placebo + pembrolizumab 400 mg IV Q6W. Pembrolizumab treatment will be administered for up to 9 doses (~1 year); belzutifan and placebo may be continued for a maximum of 54 weeks. Disease recurrence will be evaluated radiologically Q12W from randomization through year 2, Q16W in years 3-5, and Q24W in years 6 and beyond. Adverse events (AEs) will be monitored by NCI CTCAE v5.0 through 30 days (90 days for serious AEs) after cessation of study drug. The primary end point is DFS, as assessed by investigator, defined as time from randomization to first documented event of local recurrence, occurrence of distant kidney cancer metastasis, or death from any cause, whichever occurs first. The key secondary end point is overall survival. Other secondary end points are safety, disease recurrence–specific survival and patient-reported outcomes. Clinical trial information: NCT05239728. Research Sponsor: Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA.

TPS4603 **Poster Session**

STARLITE 2: Phase 2 study of nivolumab plus ^{177}Lutetium-labeled anti-carbonic anhydrase IX (CAIX) monoclonal antibody girentuximab (^{177}Lu-girentuximab) in patients (pts) with advanced clear cell renal cell carcinoma (ccRCC). *First Author: Darren R. Feldman, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: CAIX is a cell surface glycoprotein expressed in > 90% of ccRCC but rarely in normal tissues, providing a target for imaging and therapeutic application. Radiolabeling the anti-CAIX monoclonal antibody girentuximab with ^{89}Zr has shown promise as a novel PET tracer and labeling with ^{177}Lu promise as a therapeutic agent in ccRCC (Muselaers, Eur Urol, 2016). Targeted delivery of radiation to ccRCC cells may prime the immune response by enhancing tumor antigen presentation, providing rationale for combining ^{177}Lu-girentuximab with the anti-PD-1 antibody, nivolumab. This phase 2, open-label, single arm study (NCT05239533) is being conducted to evaluate ^{177}Lu-girentuximab in combination with nivolumab in pts with previously treated ccRCC. **Methods:** Pts with biopsy-proven ccRCC, progressive disease after prior systemic therapy including ≥1 immunotherapy (IO) agent, adequate organ/marrow function, and ≥1 evaluable lesion by RECIST 1.1 that is also avid on ^{89}Zr-girentuximab PET will be enrolled. There is no limit on number of prior lines of systemic therapy, but pts who stopped IO for immune toxicity are excluded. Treatment consists of ^{177}Lu-girentuximab every 12-14 weeks for a maximum of 3 doses plus nivolumab 240mg every 2 weeks until progressive disease (PD) or unacceptable toxicity. Due to expected cumulative myelosuppression, each subsequent ^{177}Lu-girentuximab dose to the same patient is reduced by 25% (dose 2 = 75% of dose 1; dose 3 = 75% of dose 2). Tumor imaging is performed every 12 weeks. Pts will be evaluated in a safety lead-in phase followed by an expansion phase. In the safety lead-in phase, the MTD of ^{177}Lu-girentuximab in combination with nivolumab will be determined with a 3+3 design using a starting dose of 1804 MBq/m^2 (75% of single agent MTD). For cohort 2, dose escalation to 2405 MBq/m^2 (single agent MTD) or de-escalation to 1353 MBq/m^2 will be based on dose-limiting toxicities. In the expansion phase, a Simon 2-stage optimal design is used to evaluate the primary endpoint of response rate by RECIST 1.1 within 24 weeks. With ≥1 response in the first Simon stage (n = 10; includes pts treated at MTD in safety lead-in), a second stage will open (n = 19) for a total of 29 pts with ≥3 responses indicating the regimen worthy of further study. Secondary endpoints include PFS, OS, and toxicity including a continuous safety monitoring rule during expansion. Exploratory imaging with ^{89}Zr-girentuximab PET is performed at baseline and before each ^{177}Lu-girentuximab dose with results correlated with RECIST response on conventional imaging. In addition, whole body planar and SPECT imaging are performed after each ^{177}Lu-girentuximab dose to evaluate distribution, lesion uptake and dosimetry of ^{177}Lu-girentuximab. The trial is currently accruing to the safety lead-in phase. Clinical trial information: NCT05239533. Research Sponsor: Telix Pharmaceuticals.

TPS4604 **Poster Session**

A phase 2 study of bevacizumab, erlotinib, and atezolizumab in subjects with advanced hereditary leiomyomatosis and renal cell cancer (HLRCC) associated or sporadic papillary renal cell cancer (pRCC). *First Author: Gabriela Liliana Bravo Montenegro, Urologic Oncology Branch. National Cancer Institute of the National Institutes of Health, Bethesda, MD*

Background: Papillary RCC accounts for 10-15% of kidney cancers and is the second most common subtype of RCC after clear cell RCC. HLRCC is a familial cancer syndrome characterized by a propensity for developing papillary kidney cancer. HLRCC-associated renal tumors are known to be clinically aggressive, with a paucity of treatment options. The combination of bevacizumab and erlotinib has shown promising activity in patients with HLRCC-associated RCC and sporadic pRCC (Srinivasan et al, ASCO 2020). We hypothesize that the addition of a PDL-1 inhibitor might provide synergistic clinical activity against these tumors. **Methods:** This is an ETCTN-sponsored, open-label, multicenter, phase 2 study evaluating bevacizumab, erlotinib and atezolizumab in adult and pediatric patients with advanced 1) HLRCC-associated RCC or 2) sporadic pRCC. Eligible patients will have cytologically or histologically confirmed advanced HLRCC- associated or sporadic pRCC, age ≥12 years, ECOG PS ≤2, no more than two prior regimens targeting the VEGF pathway, no prior treatment with PD-1 or PD-L1 inhibitors and adequate organ and marrow function. Patients with HLRCC-associated RCC or sporadic pRCC will be enrolled into parallel, independent cohorts. Initially, 12 adult patients with advanced HLRCC-associated RCC or sporadic pRCC will be enrolled into the safety run-in portion of the trial. If ≤ 3 dose-limiting toxicities are observed, enrollment will proceed into both cohorts and pediatric patients will be allowed to enroll. A Simon two-stage phase 2 minimax design will be used to determine accrual to each cohort. In the first stage, 12 evaluable patients will be enrolled into cohort 1) HLRCC-associated RCC or cohort 2) sporadic pRCC. If 0 of 12 patients have a CR, then no further patients will be enrolled in that cohort. If 1 or more of the first 12 evaluable patients enrolled have a clinical response, then accrual will continue until a total of 21 evaluable patients (adult or pediatric) have been enrolled into each cohort for a total of 42 patients. Adult patients will receive a fixed dose of bevacizumab (15 mg/kg IV every 21 days) plus atezolizumab (1,200 mg IV every 21 days) and erlotinib (150 mg PO daily). Pediatric patients will receive bevacizumab (15 mg/kg IV every 21 days) plus atezolizumab 15 mg/kg (max 1,200 mg IV every 21 days) and erlotinib 85 mg/m^2 (max 150 mg PO daily). The primary endpoint is to assess the complete response rate according to RECIST 1.1 in patients with advanced 1) HLRCC-associated RCC and 2) sporadic pRCC. Secondary endpoints include safety and tolerability, objective response rate, disease control rate, progression-free survival and overall survival. Key exploratory endpoints include evaluation of immunologic modulation associated with this regimen. The study has just opened to accrual. Clinical trial information: NCT04981509. Research Sponsor: U.S. National Institutes of Health.

TPS4605 **Poster Session**

TiNivo-2: A phase 3, randomized, controlled, multicenter, open-label study to compare tivozanib in combination with nivolumab to tivozanib monotherapy in subjects with renal cell carcinoma who have progressed following one or two lines of therapy where one line has an immune checkpoint inhibitor. *First Author: Toni K. Choueiri, Dana-Farber Cancer Institute, Boston, MA*

Background: Tivozanib, a highly selective and potent vascular endothelial growth factor receptor tyrosine kinase inhibitor, has demonstrated single-agent efficacy in advanced renal cell carcinoma (aRCC) along with minimal off-target toxicities and a favorable adverse event (AE) profile (Rini et al Lancet Oncol 2020). Tivozanib was approved by the FDA on March 10, 2021, for the treatment of patients with aRCC who had progressed on 2 or more prior systemic therapies. Tivozanib was combined with Nivolumab in the phase 1b/2 TiNivo trial (NCT03136627), showing an objective response rate of 56%, disease control rate of 96%, median PFS of 18.9 months and a tolerable safety profile (Albiges et al Ann Oncol. 2021). **Methods:** TiNivo-2 (NCT04987203) is a phase 3, randomized, controlled, multicenter, open-label study to compare tivozanib in combination with nivolumab to tivozanib monotherapy in subjects with renal cell carcinoma who have progressed following 1-2 lines of therapy including an immune checkpoint inhibitor. Eligibility criteria include age >18 years, clear cell RCC, ECOG PS 0-1, and disease progression during or following at least 6 weeks of treatment with ICI for RCC. Subjects will be stratified by IMDC risk category and whether ICI was received in most recent line of treatment or not. Subjects will receive tivozanib 1.34 mg orally once daily for 21 consecutive days followed by 7 days off, on the monotherapy arm, and tivozanib 0.89 mg at the same schedule in addition to nivolumab 480mg intravenously every 4 weeks on the combination arm. Study assessments include CT scan or MRI of the chest, abdomen, and pelvis every 8 weeks following Cycle 1 Day 1 for 2 years and every 12 weeks thereafter until disease progression is confirmed by independent radiology review (IRR). The primary objective is to compare the progression-free survival (PFS) of tivozanib in combination with nivolumab to tivozanib. A sample size of 326 subjects, with 191 events will provide at least 80% power to detect a 50% improvement in PFS, 12 mos v. 8 mos, as assessed by an IRR. Secondary endpoints include assessment of overall survival (OS), objective response rate (ORR), and duration of response (DoR), as well as safety and tolerability. Exploratory endpoints are to assess the quality of life (FKSI-DRS and EORTC QLQ C-30) and to investigate the pharmacokinetics of tivozanib. TiNivo-2 is actively enrolling and planning to open at 190 sites in the United States, and the European Union. Clinical trial information: NCT04987203. Research Sponsor: Aveo Oncology.

TPS4606 **Poster Session**

A phase I trial to evaluate the biologic effect of CBM588 (*Clostridium butyricum*) in combination with cabozantinib plus nivolumab for patients with metastatic renal cell carcinoma (mRCC). *First Author: Luis A Meza, City of Hope Comprehensive Cancer Center, Duarte, CA*

Background: Combination therapy with the immune checkpoint inhibitor (ICI) nivolumab (nivo) and the tyrosine kinase inhibitor cabozantinib (cabo) is a new standard of care for first line treatment of patients with clear cell mRCC. However, despite the improved clinical benefit obtained with this regimen, a subgroup of patients still presents with progressive disease as best response (Choueiri et al NEJM 2021). There is now evidence supporting the role of the gut microbiome in mediating ICI activity (Routy et al Science 2018) and certain bacterial species, such as *Bifidobacterium spp.* in predisposing clinical response in patients with mRCC receiving ICIs (Salgia et al Eur Urol 2020). Moreover, recent evidence from a phase I clinical trial suggests that the addition of CBM588, a live probiotic comprised primarily of *Clostridium butyricum*, can enhance clinical response in patients with mRCC receiving nivolumab plus ipilimumab without incurring added toxicity (Meza et al ASCO, 2021). Herein we present the study design of an ongoing phase I study evaluating the biological effect of CBM588 in combination with cabozantinib plus nivolumab in patients with mRCC. **Methods:** This is an open label, randomized, single institution phase 1 trial for patients with confirmed mRCC with clear cell, papillary, or sarcomatoid components, who have not received prior systemic therapy for metastatic disease. A total of 30 eligible patient will be randomized 1:2 to receive either cabo/nivo at the standard dose/schedule (40mg PO QD and 480mg IV /4wks, respectively) alone or with CBM588 dosed at 80mg PO bid. The primary objective of the study is to determine the biologic effect of CBM588 with cabo/nivo in the modulation of the gut microbiome. This will be done by assessing the changes in *Bifidobacterium spp.* abundance and Shannon index (a measure of microbiome diversity) in stool specimens. Stool will be collected for bacteriomic profiling at baseline and after 12 weeks of treatment. Metagenomic sequencing will be performed using previously published methods (Dizman et al Cancer Med 2020). Secondary objectives include determining the effect of CBM588 on (1) clinical efficacy, through overall survival, response rate, and progression-free survival; (2) systemic immunomodulation, through assessment of changes in circulating Tregs, circulating cytokines/chemokines, etc; and (3) toxicities. A two-group t-test with a one-sided type I error of 0.05 will be used to assess the study primary endpoint. Clinical trial information: NCT05122546. Research Sponsor: Exelixis is providing funding for this clinical trial.

TPS4607 **Poster Session**

MAIN-CAV: Phase III randomized trial of maintenance cabozantinib and avelumab versus avelumab after first-line platinum-based chemotherapy in patients with metastatic urothelial cancer (mUC) (Alliance A032001). *First Author: Shilpa Gupta, Taussig Cancer Institute, Cleveland Clinic Foundation, Cleveland, OH*

Background: First-line platinum-based chemotherapy followed by maintenance avelumab (Av) is the current preferred standard of care in patients (pts) with mUC who do not progress after platinum-based chemotherapy. There is an unmet need to further improve outcomes by combining Av with an effective, non-cross resistant therapy with non-overlapping toxicity. Cabozantinib (CABO) is an oral inhibitor of MET, VEGFR and TAM family receptors involved in tumor growth, angiogenesis and immune cell regulation and has shown efficacy in UC in combination with PD-1/PD-1L1 inhibitors. We hypothesize that CABO-Av combination will be synergistic in pts with mUC with an acceptable safety profile and will improve upon the benefit seen with Av maintenance in mUC. **Methods:** MAIN-CAV is a phase III randomized, multicenter, international trial for locally advanced/mUC pts (including N3 only disease) who do not progress after 4-6 cycles of any platinum-based chemotherapy (gem-cis, gem-carbo, MVAC or ddMVAC). 654 adult pts will be randomized 1:1 within 3-10 weeks (wk) after last dose of chemotherapy to receive Av 800 mg IV every 2 wk or combination of Av and CABO 40 mg orally daily for up to 2 yrs. Key eligibility criteria include ECOG PS 0-1, no prior use of immunotherapy (exception of BCG), no central nervous system metastases, no major surgery within 4 wk, no uncontrolled hypertension or cardiovascular disorders. Pts will be stratified based on 1) best response to 1L therapy: complete response vs partial response vs stable disease and 2) presence or absence of visceral metastases. The primary endpoint is overall survival (OS) with assumptions of one-sided alpha of 0.025, power of 80%, median OS of 21 months (mo) on Av arm and hazard ratio (HR) of 0.75, thus hypothesizing a median OS of 28 mo on CABO-Av combination arm. Key secondary endpoints include progression-free survival, safety, tolerability, and activity of CABO-Av compared to Av alone based on RECIST 1.1 and iRECIST criteria and PD-L1 status of pts' tumors. Quality of life (QOL) will be assessed using EQ-5D-5L, PROMIS-Fatigue 4a, EORTC QLQ-C30, EORTC QLQ-BLM30 between pts on CABO-avelumab vs avelumab alone. Biomarkers of response and resistance to Av will be assessed using baseline archival tissues, baseline and serial blood, ctDNA, stool and urine. Imaging studies will test correlation of established and new radiomic signatures with OS, adverse events and QOL and incorporate both radiologic and biologic features to predict outcomes. This trial would be the first to systematically address whether adding a multitargeted TKI, CABO to Av leads to improved clinical outcomes compared to Av alone. Support: U10CA180821, U10CA180882, U24CA196171,U10-CA180863 (CCTG); Clinical trial information: NCT05092958. Research Sponsor: U.S. National Institutes of Health.

TPS4608 **Poster Session**

A phase III randomized trial of eribulin (E) with or without gemcitabine versus standard of care (SOC) for metastatic urothelial carcinoma (UC) refractory to or ineligible for PD/PDL1 antibody (Ab): SWOG S1937. *First Author: Sarmad Sadeghi, University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA*

Background: UC is 2nd most common genitourinary cancer. Current SOC offers platinum-based (PB) first line chemotherapy (chemo) with ddMVAC or gemcitabine-cisplatin (GC) regimens. For cisplatin ineligible patients (pts), SOC includes gemcitabine-carboplatin (GCa), and in select pts pembrolizumab. Erdafitinib is approved for pts with FGFR alterations and Enfortumab vedotin (EV) is approved for previously treated pts. A phase I/II CTEP study of eribulin (E) for metastatic UC (mUC) established the activity of E in UC with objective response rate (ORR) of 37.5% and a median progression free survival (PFS) of 4.1 months (mo) and median overall survival (OS) of 9.5 mo (N = 150). A phase II CTEP study of gemcitabine-eribulin (GE) in cisplatin ineligible mUC showed an ORR of 50%, median OS of 11.9 mo and median PFS of 5.3 mo (N = 24). The most common Grade 3-4 toxicities included: neutropenia 63%, anemia and fatigue 29%. Pts with liver metastases benefited from therapy with 5 responders in 7 pts for GE vs 12 out 49 E. **Methods**: This is a phase III, randomized 3 arm study comparing E vs. GE vs. SOC (docetaxel, paclitaxel, or gemcitabine). E is given at 1.4mg/m2 on day (D) 1 and 8 of a 21 D cycle. In the GE arm, gemcitabine is added to E at 1000 mg/m2 dose to D1 and D8. SOC follows standard dosing of the agents. There is no limit to the number/sequence of prior regimens. A simplified summary of eligibility criteria is presented here. All pts must have: received frontline systemic treatment such as PB chemo or a non-platinum regimen. received PD1/PDL1 Ab or be deemed ineligible for PD1/PDL1 Ab. received EV. Assuming a median OS for the SOC arm of 7 mo the study seeks to find at least a 50% increase in median OS to 10.5 mo (Hazard Ratio (HR) = 0.667). One-sided 0.0125 type I error to account for testing of two primary hypotheses (Each arm vs. SOC). 87% power to detect a 3.5 mo improvement in OS. We require 140 eligible (155 total) pts in each arm for a total of 465. The study was activated in Feb 2021 and accrual is ongoing. Clinical trial information: NCT04579224. Research Sponsor: SWOG S1937, National Institutes of Health/National Cancer Institute grants U10CA180888, U10CA180819.

TPS4609 **Poster Session**

^{89}Zirconium-labelled girentuximab (^{89}Zr-TLX250) PET in patients with urothelial cancer (ZiPUP): A phase I trial of a novel staging modality for urothelial carcinoma. *First Author: Dickon Hayne, UWA Medical School, University of Western Australia, Perth, Australia*

Background: Bladder cancer is a lethal disease with a rising incidence. The current standard imaging modalities for staging are either CT of the chest, abdomen and pelvis or FDG PET/CT. However, there are issues with using these modalities for staging. CT is known to have relatively low sensitivity for detecting low volume metastatic disease, while FDG is predominantly renally excreted and therefore has intense activity in the urinary tract, which limits its utility to detect bladder or upper tract lesions, or nodal metastases in close proximity to the urinary tract. Zirconium-89-Girentuximab (89Zr-TLX250) may have utility in the accurate staging of bladder and urothelial cancer, with less renal excretion as compared to FDG, however this has not previously been investigated. ZipUp is an investigator initiated trial. South Metropolitan Health Service WA is the trial sponsor. The study received funding and study drug support from Telix Pharmaceuticals **Methods:** ZiPUP is a single-arm, phase I trial examining the feasibility, safety, and utility of 89Zr-TLX250 PET/CT in patients either undergoing pre-operative staging of urothelial carcinoma or bladder cancer for curative intent, or with known metastatic urothelial carcinoma or bladder cancer. All participants will undergo 89Zr-TLX250 PET/CT and will need to have undergone recent FDG PET/CT for means of comparison. This trial aims to recruit 10 participants undergoing staging and 10 participants with known metastatic disease. The primary endpoint is effectiveness by assessing sensitivity and specificity in detecting lymph node metastases compared to FDG PET/CT; secondary endpoints are safety, tolerability, and feasibility. The first patient was enrolled in this single site study and the study is expected to be completed by December 2022. If 89Zr-TLX250 PET/CT is proven to be feasible, safe, and effective in staging urothelial cancer, it could improve the appropriate selection of treatment for patients with metastatic or primary urothelial carcinoma or bladder cancer. Clinical trial information: NCT05046665. Research Sponsor: Telix Pharmaceutical, South Metropolitan Health Service WA.

TPS4610 **Poster Session**

Trial in progress: A phase II switch maintenance study of live biotherapeutic MRx0518 and avelumab in patients with unresectable locally advanced or metastatic urothelial carcinoma (UC) who did not progress on first-line platinum-containing chemotherapy. *First Author: Amishi Yogesh Shah, MD Anderson Cancer Center, Houston, TX*

Background: Efficacy of avelumab for maintenance treatment of UC was investigated in the JAVELIN Bladder 100 study (NCT02603432), which led to the FDA approval of avelumab for maintenance treatment as the current standard of care for patients with locally advanced or metastatic UC that have not progressed with first-line platinum-based chemotherapy. Outcomes included median overall survival (OS) of 21.4 months (95% CI 0.56-0.86), median progression-free survival (PFS) of 3.7 months (95% CI 3.5-5.5) and objective response rate (ORR) of 9.7% (95% CI 6.8-13). MRx0518 is a novel, human gut microbiome-derived, single-strain, live biotherapeutic. It is a bacterium of the *Enterococcus* genus that was selected for development in solid tumor treatment for its strong *in vitro* and *in vivo* immunostimulatory activity. *In vivo* studies have shown that MRx0518 can inhibit tumor growth in different syngeneic cancer models as both monotherapy and in combination with immune checkpoint inhibitors. MRx0518 has been shown to reduce Treg and increase Th1 and Tc1 lymphocyte differentiation *in vitro* and increase intratumoral CD4+ and CD8+ T cells and NK cells *in vivo*. In clinical studies, preliminary data shows that MRx0518 monotherapy can increase anti-tumor TILs and systemic pro-inflammatory immune signaling molecules. This is a pilot study evaluating whether the addition of MRx0518 to avelumab in the maintenance setting of metastatic platinum-treated UC may improve outcomes. **Methods:** The study will enroll 30 patients with unresectable locally advanced or metastatic UC at multiple US centers. Patients must have measurable disease after a partial response or stable disease on 4-6 cycles of platinum-containing induction chemotherapy. Patients will receive 800 mg avelumab IV infusion every 2 weeks in combination with 1 oral capsule ($10x10^{10}$ – $10x10^{11}$ CFU) MRx0518 twice daily until disease progression, patient withdrawal or unacceptable toxicity. Primary objectives are to assess safety of the combination, and effect on PFS at 6 months. Secondary objectives are to assess other efficacy measures including PFS, ORR, OS, duration of response, time to response, and disease control rate. Collection of paired research biopsies at baseline (after chemotherapy) and on treatment (after 8 weeks of MRx0518 + avelumab), plus longitudinal blood sampling, will allow investigation of immunological changes systemically both in the tumor and as potential predictive markers of response. Stool and urine samples collected before, during and after treatment will allow investigation of changes to the microbiome and metabolome. Recruitment is open, awaiting accrual. Clinical trial information: NCT05107427. Research Sponsor: 4D pharma plc.

TPS4611 **Poster Session**

A phase II clinical trial of neoadjuvant sasanlimab and stereotactic body radiation therapy as an in situ vaccine for cisplatin-ineligible muscle invasive bladder cancer (RAD VACCINE MIBC). *First Author: Raj Satkunasivam, Department of Urology and Center for Outcomes Research, Houston Methodist Hospital, Houston, TX*

Background: The utilization of neoadjuvant immune checkpoint inhibitor (ICI) therapy, including anti-PD1/L1 agents, prior to radical cystectomy (RC), is an emerging paradigm in muscle invasive bladder cancer (MIBC). Pathologic complete responses (pCR) have been observed in 25-40% of patients with neoadjuvant PD1/L1 inhibitor monotherapy for cisplatin-ineligible MIBC. *In situ vaccination* using stereotactic body radiation therapy (SBRT) may augment T-cell responses to tumor-specific antigens through immunogenic cell death. Sasanlimab (PF-06801591) is a humanized IgG monoclonal antibody that targets PD-1 selectively, for which there are both Phase 1 data and ongoing Phase 3 trials in early-stage urothelial carcinoma. There exists a strong rationale to evaluate a novel strategy of combination neoadjuvant ICI therapy with SBRT as an *in situ vaccine* to improve loco-regional control and decrease the risk of distant recurrence in cisplatin-ineligible patients with MIBC. **Methods:** This is a prospective, investigator-initiated, single-arm, single-institution, phase II trial that evaluates neoadjuvant sasanlimab in combination with SBRT as neoadjuvant therapy for patients with MIBC before RC. Eligibility requires patients to be cisplatin-ineligible (one of the following: ECOG-PS=2, creatinine clearance <60 ml/min, or comorbidities such as hearing loss or neuropathy) or those who refuse cisplatin-based chemotherapy. Sasanlimab (300 mg) will be administered subcutaneously on Day 1 of each 28-day cycle for a total of 2 cycles, in combination with SBRT to the primary tumor at a dose of 24Gy given in 3 fractions, starting on Day 1 of Cycle 2 with a 48-hour interval between fractions. The combination treatment will be assessed by using a Simon's 2-Stage design, which the first 10 patients are enrolled as a safety lead-in to evaluate the safety and feasibility. Futility analysis will be performed after a total of 18 patients. The primary endpoint is pCR rate after neoadjuvant sasanlimab/SBRT, followed by RC. If pCR is observed in 4 or fewer patients, further enrollment of patients may be stopped with the conclusion that pT0 cannot be 40% or greater. Otherwise, an additional 15 patients will be accrued in stage II, resulting in a total of 33 patients. Secondary endpoints include adverse events, surgical complication rates, health related quality-of-life, overall survival, and recurrence free survival. Exploratory endpoints include analysis of and association with pCR of the tumor/germline genetic signatures, circulating tumor DNA, tumor PD-L1 expression, blood cytometry time-of-flight analysis to identify immune response. Enrollment opened on February 15, 2022. Clinical trial information: NCT05241340. Research Sponsor: Institutional Funding, Pfizer for Study Drug.

TPS4612 **Poster Session**

A phase II trial evaluating combination pemetrexed and avelumab in patients with MTAP-deficient advanced urothelial cancer. *First Author: Amishi Yogesh Shah, MD Anderson Cancer Center, Houston, TX*

Background: MTAP-deficiency occurs primarily due to homozygous loss in chromosome 9p21 and is seen in approximately 25% of urothelial cancers. MTAP-deficiency portends aggressive biology with poorer outcomes than in MTAP-proficient tumors; for example, in the IMvigor210 data, MTAP-deficient patients had median overall survival of 8.0 months, compared to 11.3 months in MTAP-proficient patients ($p = 0.042$). MTAP-deficient tumors lack salvage nucleotide synthesis pathways and thus are uniquely sensitive to anti-folate agents; however, in prior clinical work with pemetrexed in these tumors, responses are relatively short-lived. In-vivo data has suggested that pemetrexed can increase tumor infiltrating T-cells, macrophages, dendritic cells, and PD-L1 expression in MTAP-deficient tumors and decrease myeloid-derived suppressor cells (MDSCs). As such, it was postulated that sequential treatment with anti-folate chemotherapy (pemetrexed) and immune checkpoint inhibition (avelumab) would improve responses in MTAP-deficient urothelial cancer. **Methods:** A prospective phase II trial of patients with advanced MTAP-deficient urothelial cancer is being conducted under IRB-approved protocol NCT03744793. This study will enroll 25 patients at a single site (The University of TX, MD Anderson Cancer Center). Key eligibility criteria include patients with advanced MTAP-deficient urothelial cancer with measurable disease in second-line or beyond. MTAP-deficiency is confirmed with CLIA-approved IHC or NGS. Patients are stratified as being IO-pretreated versus IO-naïve. All patients receive a lead-in cycle of pemetrexed (500 mg/m2) followed by combination pemetrexed (500 mg/m2) and avelumab (10 mg/kg) IV every three weeks until disease progression, patient withdrawal, or unacceptable toxicity. Three biopsies per patient with tissue collection at trial baseline, on single agent pemetrexed, and on combination pemetrexed-avelumab are performed. The primary objective of this trial is to evaluate response rate with sequential pemetrexed and avelumab in MTAP-deficient urothelial cancer. Imaging response assessment is done via RECIST v1.1. Secondary objectives are to evaluate progression-free survival (PFS) and overall survival (OS), as well as to perform correlative studies evaluating the effect of this therapy on immune cells and tumor microenvironment. This correlative work includes but is not limited to evaluation of peripheral T-cells, tumor-infiltrating T-cells, macrophages, and MDSCs. Interim analyses for futility and safety occur in cohorts of 5 patients and are performed based on Bayesian sequential methods. Fifteen patients have been enrolled thus far. Clinical trial information: NCT03744793. Research Sponsor: EMD Serono.

TPS4613 **Poster Session**

ANTICIPATE: A phase I/II, open-label, multicenter study to evaluate the safety and efficacy of oral APL-1202 in combination with tislelizumab compared to tislelizumab alone as neoadjuvant therapy (NAC) in patients with muscle invasive bladder cancer (MIBC). *First Author: Matt D. Galsky, The Tisch Cancer Institute, Mount Sinai, New York, NY*

Background: Standard treatment for muscle invasive bladder cancer (MIBC) is radical cystectomy (RC) and administration of NAC in patients who are eligible to receive cisplatin. Approximately 50% of patients are ineligible to receive cisplatin as a result of pre-existing contraindications, and some refuse to receive any chemotherapy due to concerns of toxicities. Immune checkpoint inhibitors (ICIs) have been shown to be highly active in metastatic urothelial cancer. APL-1202 (nitroxoline) is a reversible and orally available MetAP2 inhibitor with anti-angiogenic and anti-tumor activities. Synergistic effects of APL-1202 and ICIs have been shown in model systems of bladder cancer. It is hypothesized that APL-1202 in combination with tislelizumab, a humanized IgG4 anti-PD-1 MAb, may be an effective neoadjuvant therapy in MIBC. This trial will evaluate the safety, efficacy, and pharmacodynamic effects of APL-1202 in combination with tislelizumab as neoadjuvant therapy for patients with MIBC who are cisplatin ineligible or refuse cisplatin-based chemotherapy. **Methods:** ANTICIPATE is an open-label, multi-center clinical trial enrolling 79 patients in two phases: Phase I and Phase II. Phase I is a dose escalation study to determine MTD (maximum tolerated dose) and/or RP2D. Phase II is an expanded proof-of-concept study to evaluate the safety and efficacy of APL-1202 in combination with tislelizumab compared to tislelizumab alone as neoadjuvant therapy for MIBC as measured by pathological complete response (pCR). Phase I and Phase II both are divided into 3 periods: screening period of 4 weeks, neoadjuvant therapy comprising 3 cycles (each 21 days) prior to radical cystectomy; and a follow-up period of up to 90 days after surgery. The phase I will determine the RP2D of APL-1202 in combination with tislelizumab as neoadjuvant therapy for MIBC. Eligible patients have newly diagnosed MIBC and are cisplatin ineligible or refuse cisplatin-based NAC and are planned for RC. In phase I, a standard 3+3 dose-escalation design will be used. On day 1 of each cycle, a single dose of 200 mg tislelizumab will be administered intravenously. The daily dose APL-1202 will be escalated in successive cohorts (375 mg à 750 mg à 1,125 mg). The DLT observation window for any dose level will be treatment cycle 1. There will be no intra-patient dose escalation. In phase II patients will be randomly assigned to group 1 (APL-1202 + tislelizumab) or group 2 (tislelizumab only), stratified by PD-L1 expression. The IND has been approved by FDA and NMPA, and the study execution is under preparation both in US and China. Clinical trial information: NCT04813107. Research Sponsor: Asieris.

TPS4614 **Poster Session**

A phase 3 study of the subcutaneous programmed cell death protein 1 inhibitor sasanlimab as single agent for patients with bacillus Calmette-Guérin, unresponsiv,e high-risk, non-muscle invasive bladder cancer: CREST Study Cohort B. *First Author: Neal D. Shore, Carolina Urologic Research Center, Myrtle Beach, SC*

Background: Bacillus Calmette-Guérin (BCG) therapy is the standard of care for high-risk non-muscle invasive bladder cancer (NMIBC) after transurethral resection of bladder tumor. However, disease recurrence or progression is common and patients with BCG-unresponsive disease are unlikely to respond to further BCG therapy. In these patients, the current standard of care is radical cystectomy and bladder-preserving treatment options, limited to intravesical chemotherapy or intravenous pembrolizumab. In a phase 1 study, sasanlimab (PF-06801591), a monoclonal antibody to programmed cell death protein 1 (PD-1), was administered subcutaneously at 300 mg every 4 weeks. Sasanlimab had an acceptable safety profile and showed clinical activity aligned to other anti-PD-1/PD-ligand 1 (PD-L1) agents in patients with advanced urothelial carcinoma and non-small cell lung cancer, while offering the convenience of subcutaneous administration. Therefore, CREST Study Cohort B aims to evaluate sasanlimab administered subcutaneously in patients with BCG-unresponsive NMIBC. **Methods:** CREST Study Cohort B is a non-randomized, multicenter, multinational, open-label, phase 3 study and will enroll ~160 patients with histologically confirmed BCG-unresponsive, high-risk, non-muscle invasive transitional cell carcinoma of the bladder urothelium (high-grade Ta or T1 tumor, or carcinoma in situ [CIS]) in 2 separate Cohorts, B1 and B2 (~110 and ~50 patients, respectively). Cohort B1 will enroll patients with persistent or recurrent CIS with or without concomitant recurrent high-grade Ta/T1 disease, within 12 months of completing adequate BCG therapy. Cohort B2 will enroll patients with recurrent high-grade Ta/T1 disease within 6 months of completing adequate BCG therapy. All patients will receive subcutaneous sasanlimab as a single agent. Efficacy will be assessed at regular intervals by cystoscopy, urine cytology, biopsy, and imaging. The primary endpoint is complete response (CR) and event-free survival (EFS) for Cohort B1 and B2, respectively. Secondary endpoints include duration of CR (Cohort B1 only), EFS (Cohort B1 only), overall survival, time to cystectomy, safety, health-related quality of life, pharmacokinetic parameters, PD-L1 expression, and incidence of anti-drug antibodies. Recruitment of patients in CREST Study Cohort B will be opened in Canada and the United States of America, with other sites in Asia, Australia, and Europe. Clinical trial information: NCT04165317. Research Sponsor: Pfizer.

TPS4615 **Poster Session**

A phase II study of gemcitabine plus cisplatin chemotherapy in patients with muscle-invasive bladder cancer with bladder preservation for those patients whose tumors harbor deleterious DNA damage response (DDR) gene alterations (Alliance A031701). *First Author: Gopa Iyer, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: While a standard approach to muscle-invasive bladder cancer (MIBC) management involves neoadjuvant cisplatin-based chemotherapy (NAC) followed by radical cystectomy (RC), up to 50% of pts recur with metastatic disease. Moreover, removal of the bladder has a significant impact on pts' quality of life. Pathologic downstaging to non-muscle-invasive disease (<pT2) or complete response (pT0) at RC is associated with long-term survival benefit. Somatic DDR gene alterations were shown to be enriched in pts who were pT0 at RC following NAC in multiple retrospective analyses. We hypothesize that MIBC pts with somatic loss-of-function alterations within specific DDR genes and clinical responses to NAC can be uniquely managed with a bladder-sparing approach consisting of close cystoscopic and radiographic surveillance, avoiding the toxicities of definitive local therapy. **Methods:** A031701 is a multicenter phase II trial that will enroll 271 pts with T2-T4aN0/xM0 MIBC diagnosed within 60 days prior to enrollment. Multifocal MIBC, tumors >5 cm by cystoscopic assessment, and Bacillus Calmette-Guérin (BCG)-refractory disease (beyond standard induction and maintenance) are not allowed. Intravesical chemotherapy is allowed. Pts must be eligible for cisplatin chemotherapy. Eligible pts will receive either standard dose or dose dense gemcitabine and cisplatin chemotherapy (investigator's choice) with simultaneous genetic sequencing of pre-treatment transurethral resection specimens. Pts whose tumors contain deleterious alterations in any 1 of 9 pre-selected DDR genes (*ERCC2*, *ERCC5*, *BRCA1*, *BRCA2*, *RECQL4*, *RAD51C*, *ATM*, *ATR*, and *FANCC*) and who exhibit <T1 response on clinical restaging are eligible for organ-sparing management. Pts without deleterious DDR gene alterations or with >T1 disease after NAC will undergo RC or chemoradiation therapy (investigator/patient choice). The primary endpoint is 3-year event-free survival in DDR-altered pts who undergo bladder sparing, defined as the proportion of pts without BCG-unresponsive non-muscle invasive recurrences, any >T2 recurrences, or any metastatic recurrences. Secondary endpoints include clinical response rate (<cT1) in patients with deleterious DDR gene alterations following NAC, bladder-intact survival, overall survival, pT0 rate in DDR-altered pts who elect to undergo RC, pT0 rate in pts without DDR gene alterations, 3-year RC rate in pts with DDR gene alterations, and proportion of pts undergoing intravesical management for in-bladder recurrences. The study opened for enrollment in September 2018. Support: U10CA180821, U10CA180882. Clinical trial information: NCT03609216. Research Sponsor: None.

TPS4616 **Poster Session**

Phase I study of intravesical anti-CD40 agonist antibody 2141-V11 for non-muscle invasive bladder cancer unresponsive to Bacillus Calmette-Guerin (BCG) therapy. *First Author: Jeffrey L. Wong, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: CD40 is an immune-stimulatory receptor centrally involved in activating antigen-presenting cells and downstream anti-tumor immunity. Multiple agonistic anti-CD40 antibodies have been investigated clinically for cancer therapy, but have thus far shown limited efficacy and notable systemic toxicity. Our group has previously demonstrated that the ability of the Fc domain of anti-CD40 agonist antibodies to engage the FcγRIIB receptor, needed for optimal CD40 crosslinking, is critical for CD40 agonist activity. We engineered a fully-human anti-CD40 agonist antibody (2141-V11) with optimized Fc binding to FcγRIIB, which demonstrates significantly enhanced CD40 agonist activity. Non-muscle invasive bladder cancer (NMIBC), which remains an area of significant unmet need, represents an attractive clinical context to pursue CD40 agonist therapy given strong enrichment of CD40 in the bladder tumor microenvironment and routine use of local intravesical delivery as a potential strategy to mitigate systemic toxicity. Our preclinical studies, including in immunocompetent orthotopic murine models of bladder cancer humanized for CD40 and Fcγ receptors, revealed that intravesical delivery of 2141-V11 induced potent and durable anti-tumor immunity in both front-line and BCG-unresponsive settings without associated systemic toxicity (Garris and Wong, et al., *Sci Transl Med*, 2021;13:eabd1346). These data provide rationale to investigate intravesical 2141-V11 for the treatment of BCG-unresponsive NMIBC. **Methods:** This is a phase 1, open-label, dose-escalation study (NCT05126472) to evaluate the safety and tolerability of intravesically-delivered 2141-V11 in patients with BCG-unresponsive NMIBC who are considered ineligible for or have elected not to undergo radical cystectomy. Key inclusion criteria include adults with high-grade NMIBC (Ta, CIS, and/or T1) of urothelial histology that is unresponsive to adequate BCG therapy per consensus 2018 FDA guidelines. The primary objectives are to evaluate the safety and tolerability of 2141-V11 and to define the maximum tolerated dose and/or recommended phase 2 dose. The secondary objectives are to characterize the pharmacokinetics and evaluate the preliminary clinical activity of 2141-V11. Exploratory objectives include assessment of biomarkers of biological activity and disease resistance, their potential associations with clinical outcome measures, and patient-reported outcomes/quality of life measures. The 2141-V11 antibody is administered intravesically once weekly for 3 doses. Depending on disease status at week 13 and week 25 evaluations, patients may be eligible for re-treatment (once weekly for 3 doses) at these time points. Dose exploration utilizes a modified continual reassessment method design. Enrollment began in November 2021 and is ongoing. Clinical trial information: NCT05126472. Research Sponsor: Bochner-Fleisher Scholars Program, Conquer Cancer Foundation of the American Society of Clinical Oncology, Other Foundation, U.S. National Institutes of Health.

TPS4617 **Poster Session**

EA8185: Phase 2 study of bladder-sparing chemoradiation (chemoRT) with durvalumab in clinical stage III, node-positive urothelial carcinoma (INSPIRE), an ECOG-ACRIN/NRG collaboration. *First Author: Monika Joshi, Penn State Cancer Institute, Hershey, PA*

Background: Patients [pts] withlymph node positive (LN+), non-metastatic bladder cancer (BC) have a better prognosis than those with metastatic (M1) disease. However, this population is under-represented in advanced bladder trials and ineligible for bladder-sparing trials. Therefore, there have been no larger prospective trials establishing the standard of care in LN+ BC. Given the promise of immunotherapy in advanced BC and potential synergy between immunotherapy and radiation, INSPIRE was designed to determine the role of concurrent and adjuvant durvalumab (durva) in this patient population when treated with induction chemotherapy (IC) followed by concurrent chemoRT. **Methods:** This is a randomized phase II study that is enrolling BC pts with stage III [N1-3 M0], pure or mixed urothelial cancer. Pts must have received ≥3 cycles of IC [either before or after registration, prior to randomization] without progression. LN+ is defined as radiologically LN ≥1.0 cm in short axis, with or without biopsy prior to IC. As long as pts do not progress on induction chemotherapy, they will be randomized to chemoRT+/- durva using 5 stratification factors (Simon Pocock minimization method) a) IC prior vs. post registration b) cisplatin vs non-cisplatin regimen during RT c) LN size d) response to IC e) extent of TURBT. Pts on the chemoRT+durva arm will get chemotherapy per physician choice + IMRT + 3 x doses of Q3wk durva for 6.5-8 wks, whereas those on the control arm will get chemoRT alone. The primary end point is clinical complete response [CR], defined as no radiologically measurable disease in the LNs and negative cystoscopy and bladder biopsy 8-10 weeks post-chemoRT +/- durva. Pts on the chemoRT + durva arm who have a CR or clinical benefit (> T0 and ≤T2 in bladder per cystoscopy, biopsy + CR/PR/SD in LN by imaging) will get adjuvant Q4wk durva for 9 doses, while those on the chemoRT arm will undergo observation. Secondary end points include OS, PFS, bladder-intact event-free survival, rate of toxicity and salvage cystectomy. This study is designed to detect an improvement of 25% in clinical CR between both arms (37.5% to 62.5%). A total accrual of 114 pts (in order to enroll 92 evaluable pts) will provide 81% power to detect this difference using a Fisher's exact test (assuming 10% drop out + anticipating that 20% chemotherapy-naïve pts will progress post IC). We are banking blood and primary tumor tissue pre- and post-chemoRT in both groups. The study was activated in August 2020 and accrual is ongoing. We expanded eligibility to include N3 in 9/2021. INSPIRE is the first prospective study designed for only LN+ BC and will define both short-term and long-term outcomes for bladder sparing in this patient population and has the potential to define a new treatment strategy for stage III BC. Clinical trial information: NCT04216290. Research Sponsor: U.S. National Institutes of Health, AstraZeneca for sample collection.

TPS4618 **Poster Session**

A phase 2 study of cabozantinib in combination with atezolizumab as neoadjuvant treatment for muscle-invasive bladder cancer (HCRN GU18-343) ABATE study. *First Author: Deepak Kilari, Department of Medicine, Froedtert Cancer Center, Medical College of Wisconsin, Milwaukee, WI*

Background: ABACUS and PURE-01 trials demonstrated the activity of single agent atezolizumab and pembrolizumab respectively as neoadjuvant therapy for muscle invasive bladder carcinoma (MIBC). However, downstaging to non-muscle invasive disease was noted in only 50 percent of patients. Resistance to programmed death (PD)- 1/L1 antibodies is likely to include factors such as impaired dendritic cell maturation/function, infiltration of T-Regs and myeloid derived suppressor cells, impaired T-cell priming and T-cell trafficking in tumors. Cabozantinib is a tyrosine kinase inhibitor which targets MET, AXL, MER, Tyro3 and VEGFR2. Cabozantinib has a unique immunomodulatory profile and has demonstrated clinical activity as monotherapy and in combination with PD-1/L1 antibodies in various solid tumors including urothelial cancer (UC), renal cell, castrate- resistant prostate and non-small cell lung cancer. We hypothesize that the combination of cabozantinib and atezolizumab as neoadjuvant therapy for MIBC would improve rates of pathologic downstaging compared to single-agent checkpoint inhibitors. **Methods:** ABATE is an open-label, single arm, multi-center study to assess the efficacy and safety of cabozantinib with atezolizumab as neoadjuvant therapy for cT2-T4aN0/xM0 MIBC. An estimated 42 patients will be enrolled to obtain 38 evaluable patients, and the study will have over 80% power to declare the investigational combination to be successful using a Bayesian evaluation at 90% posterior probability cutoff, if the response probability is 59%, i.e., 20% higher than the 39% response rate with the single agent atezolizumab. Eligible patients will receive cabozantinib 40 mg PO daily with atezolizumab 1200mg every 3 weeks for a total duration of 9 weeks (3 cycles) followed by radical cystectomy. Adults (≥18 years) with resectable MIBC who are either cisplatin-ineligible or decline cisplatin-based chemotherapy are eligible. Patients are required to have an ECOG PS of 0-2 and provide tumor tissue for PD-L1 expression analysis. UC should be predominant component (≥ 50%). Previous systemic anticancer therapies for MIBC are not permitted. CT/MRI will be performed before investigational therapy and cystectomy. Primary endpoint is pathologic response rate defined as the absence of residual muscle-invasive cancer in the surgical specimen (< pT2). Secondary endpoints are safety and toxicity, pathologic complete response rate and event-free survival. Exploratory end points include patient-reported outcomes and outcome associations with biomarkers. Accrual began May 2020. Clinical trial information: NCT04289779. Research Sponsor: Exelixis and Genentech.

TPS4619 **Poster Session**

CCTG BL13 a randomized phase II trial assessing trimodality therapy with or without adjuvant durvalumab to treat patients with muscle-invasive bladder cancer (NCT03768570). *First Author: Wassim Kassouf, McGill University Health Center, Montréal, QC, Canada*

Background: Immunotherapy improves outcomes in the advanced (Bellmunt 2019; Powles 2020) as well as in the adjuvant setting post cystectomy (Bajorin 2021) for muscle invasive bladder cancer (MIBC) patients. Trimodality treatment (TMT) consisting of transurethral resection of bladder tumor (TURBT) followed by chemoradiotherapy (CRT) may be considered an alternative to radical cystectomy in MIBC. The role of radiotherapy and chemotherapy as immune system stimulants provides a rationale to evaluate the anticancer activity of checkpoint inhibitors in this patient population. Durvalumab, an anti PDL1 inhibitor, administered after CRT leads to improvement in PFS and OS in patients with locally advanced NSCLC, which further supports the rationale for this study (Antonia 2017, 2018). We hypothesized that durvalumab will improve outcomes in patients with MIBC when administered in the adjuvant setting after completion of trimodality therapy. **Methods:** CCTG BL13 is a Canadian Cancer Trials Group, randomized phase II trial in patients with stage T2-T4a N0M0, urothelial carcinoma treated with TURBT followed by radiotherapy with concurrent chemotherapy. Treatment arms consist of durvalumab 1500 mg IV q 4 weeks for 12 months versus surveillance. The primary objective: to compare disease free survival (DFS) between arms (RECIST 1.1, investigator assessed). Secondary endpoints include a non muscle-invasive bladder cancer recurrence rate (< T2); locoregional control rate; overall survival; bladder intact DFS, patterns of disease recurrence; metastasis free survival; safety; quality of life ; economics evaluation. A pilot sub study (BL13F) has been activated and will evaluate the feasibility of electronic real-time patient self-reporting of immunotherapy related symptomatic adverse events using the SYMPTOM-IQ Tool on the uMotif Mobile Health Application (APP). Statistical Design: Randomization 1:1 balanced for stratification factors: ECOG PS; neoadjuvant chemotherapy; radiation field extent; T2 vs T3/T4; centre. Assuming a 2-year DFS rate 65% for patients on the control arm and estimated 12% improvement in the 2-year DFS rate (65% to 77% (HR 0.61)) with 80% power using a 1-sided 10% level test requires a sample size of 190 including 5% drop out rate. Conduct to Date: Study activation Dec 2018. Enrollment as of January 31 2022: 49. The DSMC reviewed and recommended trial continuation in November 2021. Clinical trial information: NCT03768570. Research Sponsor: Canadian Cancer Society, AstraZeneca.

TPS4620 **Poster Session**

Phase 1a/b safety study of intravesical instillation of TARA-002 in adults with high-grade non-muscle invasive bladder cancer (ADVANCED-1). *First Author: Jathin Bandari, Protara Therapeutics, New York, NY*

Background: Bladder cancer is the most common malignancy involving the urinary system, resulting in approximately 18,000 deaths each year in the US. Approximately 70% of new urothelial bladder cancer cases are classified as non-muscle invasive bladder cancer (NMIBC). With the current Bacillus Calmette-Guérin (BCG) shortage and limited effective alternate therapies, there continues to be a significant unmet need for treatment options for patients with NMIBC. TARA-002 is being developed for the treatment of high-grade (HG) NMIBC (consisting of HG Ta, T1, and carcinoma in situ [CIS]). TARA-002 is a lyophilized biological preparation for instillation containing cells of *Streptococcus pyogenes* (Group A, type 3) Su strain treated with benzylpenicillin. TARA-002 is manufactured using the same master cell bank as OK-432 (Picibanil) and is approved in Japan and Taiwan for the treatment of several oncology indications. Nonclinical toxicology studies with TARA-002 and nonclinical and clinical studies with OK-432 (a comparable product to TARA-002) support the starting dose for the planned Phase 1a/b study. **Methods:** ADVANCED-1 is a Phase 1a/b, dose finding, open-label study of intravesical instillation of TARA-002 in adults with HG NMIBC. The study includes a dose escalation phase (Phase 1a) and a dose expansion phase (Phase 1b). The objective of the study is to evaluate the safety and tolerability of TARA-002, to establish the maximum tolerated dose (MTD) and recommended Phase 2 dose (RP2D) in the treatment of subjects with HG Ta or CIS ± Ta NMIBC during Phase 1a, and to further assess the safety and preliminary efficacy of TARA-002 in the treatment of subjects with CIS NMIBC with active disease during Phase 1b. For this first-in-human study, stage T1 is excluded. The study includes eligible male and female subjects ≥ 18 years of age who are unable to obtain BCG or have received at least one dose of intravesical BCG or chemotherapy. Those with current or a history of penicillin allergy or current evidence of any condition, therapy, or laboratory abnormality that might confound the results are excluded. The overall study duration for each subject includes 28 days of screening period, 6-week treatment period, and 6-week follow-up period. During the dose escalation phase (1a), up to 18 subjects with HG Ta or CIS ± Ta NMIBC are enrolled. Up to 3 dose levels are tested sequentially with 6 weekly intravesical doses, starting with the lowest dose using a 3+3 design in a dose escalation manner. At the established RP2D, the dose expansion phase (1b) will enroll approximately 12 new subjects with CIS ± Ta NMIBC with active disease and treat in the same manner to further assess the safety and preliminary efficacy of TARA-002. Phase 1a is currently open for enrollment. Clinical trial information: NCT05085977; NCT05085990. Research Sponsor: Protara Therapeutics.

Subcutaneous nivolumab versus intravenous nivolumab in patients with previously treated, advanced, or metastatic clear cell renal cell carcinoma.

First Author: Matias Rodrigo Chacon, Instituto Medico Especializado Alexander Fleming, Buenos Aires, Argentina

Background: Nivolumab (NIVO), a programmed death-1 immune checkpoint inhibitor, has demonstrated clinical efficacy across patients with different tumor types, including clear cell renal cell carcinoma (ccRCC), when administered via IV infusion. As an alternative to IV infusion, subcutaneous (SC) administration alleviates the need for IV ports, thereby lowering the risk of associated complications such as infections and phlebitis. SC formulation also reduces the time for dose preparation and administration, which may decrease overall treatment burden and reduce patient time in the clinic, benefiting patients and healthcare providers and improving overall healthcare resource utilization. SC-administered NIVO consists of NIVO co-formulated with the recombinant human hyaluronidase PH20 enzyme (NIVO + rHuPH20), which aims to increase the dispersion and absorption of NIVO within the SC space. SC NIVO + rHuPH20 was shown to be safe and well tolerated in a phase 1/2 study, warranting further investigation (Lonardi S et al. *J Clin Oncol* 2021;39(suppl 15):2575). **Methods:** CheckMate 67T is a multicenter, randomized, open-label, phase 3 study that will evaluate the noninferiority of SC NIVO + rHuPH20 versus IV NIVO in patients with advanced or metastatic ccRCC who have progressed after receiving ≤ 2 prior systemic treatment regimens. Key inclusion criteria are age ≥ 18 years, histologically confirmed advanced or metastatic ccRCC, measurable disease by RECIST v1.1 within 28 days prior to randomization, and a Karnofsky performance status ≥ 70. Key exclusion criteria are untreated symptomatic metastases to the central nervous system, other malignancy, autoimmune diseases, HIV-positive status with AIDS-defining infection within past year or current CD4 count < 350 cells/μL, other serious or uncontrolled disorders including severe, acute SARS-CoV-2 infection, and prior treatment with immune checkpoint inhibitors, other T-cell–targeting antibody drugs, or live attenuated vaccines within 30 days of first study treatment. At least 454 eligible patients will be randomized to receive SC NIVO + rHuPH20 or IV NIVO. The primary objectives are to demonstrate pharmacokinetic (PK) noninferiority of SC NIVO versus IV NIVO, as measured by time-averaged serum concentration over the first 28 days (Cavgd28) and trough serum concentration at steady state (Cminss) (co-primary endpoints). Secondary endpoints include objective response rate by blinded independent central review, additional PK parameters, safety, efficacy, and immunogenicity of SC NIVO and IV NIVO. This study is currently enrolling patients globally. Clinical trial information: NCT04810078. Research Sponsor: Bristol Myers Squibb.

TheraP: ^{177}Lu-PSMA-617 (LuPSMA) versus cabazitaxel in metastatic castration-resistant prostate cancer (mCRPC) progressing after docetaxel—Overall survival after median follow-up of 3 years (ANZUP 1603).

First Author: Michael S Hofman, Peter MacCallum Cancer Centre and Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, VIC, Australia

Background: We previously reported that in men with mCRPC progressing after docetaxel randomly assigned LuPSMA vs. cabazitaxel (Lancet 2021), those assigned LuPSMA has significant improvements in PSA response rate (66% vs. 37%), RECIST response rate (49% vs. 24%), progression-free survival (HR 0.63), less G3-4 toxicities (33% vs. 53%) and better patient-reported outcomes. We now report the secondary endpoint of overall survival (OS) with mature follow-up, for trial participants, and also those initially excluded because of low PSMA-expression or discordant disease on imaging with PSMA-PET and FDG-PET. **Methods:** Eligibility for the TheraP trial required mCRPC progressing after docetaxel, PET imaging with ^{68}Ga-PSMA-11 that showed high PSMA-expression (at least one site with SUV-max≥20), and ^{18}F-FDG demonstrating no sites of disease of FDG-positive and PSMA-negative (discordant disease). Participants were randomly assigned treatment with LuPSMA (8.5-6GBq every 6 weeks, maximum 6 cycles) vs cabazitaxel (20mg/m^2 every 3 weeks, maximum 10 cycles). OS was analyzed by intention-to-treat and summarized by restricted mean survival time (RMST) to account for non-proportional hazards. **Results:** 291 patients were screened from 6 Feb 2018 to 3 Sep 2019: 200 were eligible and randomly assigned LuPSMA (99) or cabazitaxel (101); 80 of 291 (27%) registered after initial eligibility were excluded after PSMA/FDG-PET(51 SUVmax < 20, 29 discordant), with follow-up available in 61 of the 80 (76%). After a median follow-up time of 36 months (data cut-off 31 Dec 2021), death was reported in 70/101 assigned cabazitaxel, 77/99 assigned LuPSMA, and 55/61 excluded after PSMA/FDG-PET. Subsequent treatments among those assigned cabazitaxel included cabazitaxel in 21, and LuPSMA in 20; and among those assigned LuPSMA included additional LuPSMA in 5, and cabazitaxel in 32. Overall survival was similar in those randomly assigned LuPSMA versus cabazitaxel (RMST to 36 months was 19.1 vs. 19.6 months, difference -0.5, 95% CI -3.7 to + 2.7). No additional safety signals were identified with longer follow-up. Among 61 men excluded by imaging with PSMA/FDG-PET before randomisation, RMST to 36 months was 11.0 months (95% CI 9.0 to 13.1), following treatment that included cabazitaxel in 29 (48%) and LuPSMA in 3 (5%). **Conclusions:** LuPSMA is a suitable option for men with mCRPC progressing after docetaxel, with lower adverse events, higher response rates, improved patient-reported outcomes, and similar OS compared with cabazitaxel. Median survival was considerably shorter for patients excluded on PSMA/FDG-PET due to either low PSMA expression or FDG-discordant disease who would otherwise be eligible for LuPSMA. Clinical trial information: NCT03392428. [^{177}Lu]Lu-PSMA-617 in PSMA-positive metastatic castration-resistant prostate cancer: Prior and concomitant treatment subgroup analyses of the VISION trial.

First Author: Nitin Vaishampayan, Wayne State University School of Medicine, Detroit, MI

Background: In the phase 3 VISION trial, targeted radioligand therapy with lutetium (^{177}Lu) vipivotide tetraxetan ([^{177}Lu]Lu-PSMA-617; ^{177}Lu-PSMA-617) significantly prolonged radiographic progression-free survival (rPFS) and overall survival (OS) when added to standard of care (SoC) in patients with advanced prostate-specific membrane antigen (PSMA) PET-positive metastatic castration-resistant prostate cancer. Benefits were consistent across most pre-specified subgroups. In this post hoc exploratory analysis, we examined rPFS and OS in the context of prior and concomitant cancer-directed treatments. **Methods:** In VISION, adult patients previously treated with at least 1 androgen receptor pathway inhibitor (ARPI) and 1–2 taxane regimens were randomized 2:1 to ^{177}Lu-PSMA-617 (7.4 GBq Q6W, up to 6 cycles) + SoC or SoC alone. Protocol-permitted SoC excluded cytotoxic chemotherapy, systemic radioisotopes, immunotherapy, or other investigational drugs. Exploratory subgroup analyses of rPFS and OS were performed by: number of prior ARPIs; taxane regimens; non-taxane regimens and immunotherapies; prior treatment with bone-sparing agents; ^{223}Ra and PARP inhibitors; and concomitant treatment with ARPIs, radiation therapy, and bone-sparing agents. **Results:** Prior and concomitant treatments were generally well balanced between study groups (Table). rPFS and OS benefits with ^{177}Lu-PSMA-617 were consistent across all prior treatment subgroups. Notably, there were benefits in patients who had not received a second prior taxane. There were also consistent benefits regardless of concomitant systemic and radiation therapy as part of SoC. **Conclusions:** The clinical efficacy of ^{177}Lu-PSMA-617 was observed regardless of prior treatment or SoC chosen, suggesting that disease biology rather than prior and concomitant treatment context drives outcomes. Small differences in outcomes between subgroups may warrant further study to understand better the predictors of improved clinical benefit. Clinical trial information: NCT03511664. Research Sponsor: Advanced Accelerator Applications, a Novartis Company.

[^{68}Ga]Ga-PSMA-11 PET baseline imaging as a prognostic tool for clinical outcomes to [^{177}Lu]Lu-PSMA-617 in patients with mCRPC: A VISION substudy.

First Author: Phillip Kuo, University of Arizona, Tucson, AZ

Background: In the phase 3 VISION study, gallium (^{68}Ga) gozetotide (^{68}Ga-PSMA-11) PET/CT imaging was used to determine eligibility for lutetium (^{177}Lu) vipivotide tetraxetan (^{177}Lu-PSMA-617). Given that ^{177}Lu-PSMA-617 targets PSMA, we assessed the association between quantitative PSMA imaging parameters and treatment outcomes. **Methods:** In VISION, adults with mCRPC with ≥ 1 PSMA-positive (+) and no PSMA-negative lesions meeting the exclusion criteria were enrolled. In this sub-study, the association between imaging data from pre-enrollment ^{68}Ga-PSMA-11 PET/CT scans of pts in the ^{177}Lu-PSMA-617 group and clinical outcomes was assessed. Imaging data meeting quality requirements were analyzed for 548/551 pts. PSMA expression was quantified by 5 PET parameters: PSMA+ lesions by region, mean standardized uptake value (SUV_{mean}), maximum SUV (SUV_{max}), PSMA+ tumor volume, and tumor load (PSMA+ tumor volume × SUV_{mean}). Parameters were extracted from the whole body and 4 regions. Association between PET parameters and radiographic progression-free survival (rPFS; primary objective), overall survival (OS), objective response rate (ORR), and prostate–specific antigen 50 (PSA50) response was assessed. **Results:** Most pts (92.7%) had PSMA uptake in bone. In both the whole-body and regional analyses, statistically significant associations of PSMA PET parameters to clinical outcomes were observed (whole-body data shown in Table). Higher whole-body SUV_{mean} was associated with improved clinical outcomes; pts in the highest quartile (SUV_{mean}: rPFS, ≥ 10.2; OS, ≥ 9.9) had a median rPFS and OS of 14.1 and 21.4 months, vs 5.8 and 14.5 months for those in the lowest quartile (< 6.0; < 5.7), respectively. Absence of PSMA+ lesions in bone, liver, and lymph node, and lower PSMA+ tumor load, were indicators of good prognosis. **Conclusions:** Higher SUV_{mean} is strongly associated with improved outcomes with ^{177}Lu-PSMA-617; clinical efficacy for different SUV levels vs the SoC arm is being assessed. Data support use of ^{68}Ga-PSMA-11 PET/CT scan to identify pts who will benefit from PSMA-targeted radioligand therapy. Research Sponsor: Advanced Accelerator Applications, a Novartis Company.

A phase 3 trial of SHR3680 versus bicalutamide in combination with androgen deprivation therapy (ADT) in patients with high-volume metastatic hormone-sensitive prostate cancer (mHSPC).

First Author: Ding-Wei Ye, Fudan University Shanghai Cancer Center, Shanghai, China

Background: Both TITAN and ARCHES studies have demonstrated significant clinical benefits of second-generation androgen receptor inhibitors (ARIs) plus ADT versus placebo plus ADT in the treatment of mHSPC. However, first-generation ARIs plus ADT is also widely used in clinic and how superior second-generation ARIs is to first-generation ones remains to be determined. Here, we evaluated the efficacy and safety of SHR3680, a novel oral ARI, versus bicalutamide (Bica) in high-volume mHSPC. **Methods:** CHART is a randomized, open-label, phase 3 study (NCT03520478). Patients (pts) with mHSPC were randomized 1:1 to ADT plus either SHR3680 (240 mg/d) or Bica (50 mg/d). All pts had high-volume disease adapted from the CHAARTED study. The primary endpoints were radiographic progression-free survival (rPFS) assessed by independent review committee (IRC) and overall survival (OS). As of May 16, 2021, 209 rPFS events per IRC and 153 deaths occurred and a preplanned interim analysis for rPFS was done. **Results:** 654 pts were randomized to receive SHR3680 (n = 326) or Bica (n = 328). At data cutoff, the median follow-up duration was 22.1 mo in SHR3680 group and 20.4 mo in Bica group. SHR3680 significantly reduced the risk of radiographic progression or death than Bica (HR, 0.44; 95% CI, 0.33-0.58; p < 0.0001; median, not reached vs 25.1 mo). OS data were immature but an improved OS was observed in SHR3680 group compared to Bica group (HR, 0.58; 95% CI, 0.42-0.80; p = 0.0009). All secondary efficacy endpoints favored SHR3680 plus ADT (Table). Frequencies of adverse events of any cause in any grade were similar between groups. Grade ≥3 treatment-related adverse events occurred in 19.2% and 13.9% of pts in SHR3680 and Bica groups, respectively. No seizure occurred in SHR3680 group. **Conclusions:** SHR3680 plus ADT significantly improved rPFS versus Bica plus ADT in pts with high-volume mHSPC, with a desirable safety profile. New drug application has been submitted to seek approval based on the data presented here. Clinical trial information: NCT03520478. Research Sponsor: Jiangsu Hengrui Pharmaceuticals Co., Ltd.

Updated overall survival outcomes in ENZAMET (ANZUP 1304), an international, cooperative group trial of enzalutamide in metastatic hormone-sensitive prostate cancer (mHSPC). *First Author: Ian D. Davis, Eastern Health Clinical School, Monash University, Box Hill, VIC, Australia*

The full, final text of this abstract will be available at meetings.asco.org on the day of presentation and in the online supplement to the June 10, 2022, issue of the *Journal of Clinical Oncology*.

5006 **Oral Abstract Session**

Assessing intermediate clinical endpoints (ICE) as potential surrogates for overall survival (OS) in men with metastatic hormone-sensitive prostate cancer (mHSPC). *First Author: Susan Halabi, Duke University Medical Center, Durham, NC*

Background: We hypothesized that radiographic progression free survival (rPFS) and clinical PFS (cPFS) are valid surrogates for OS in men with mHSPC and could potentially be used to expedite phase 3 clinical trials. This hypothesis was investigated by the STOPCAP M1 Collaboration. **Methods:** We obtained individual patient data (IPD) from 13/26 eligible randomized trials comparing treatment regimens (androgen deprivation therapy (ADT) or ADT + docetaxel in the control or research arms) in mHSPC. We evaluated the surrogacy of rPFS and cPFS as potential ICEs. rPFS was defined as time from randomization to radiographic progression (defined per protocol) or death from any cause whichever occurred first; cPFS was defined as time from randomization to date of radiographic progression, symptoms, initiation of new treatment, or death, whichever occurred first. OS was defined as time from randomization to death from any cause, if patients had not died they were censored at the date of last follow-up. We implemented a two-stage meta-analytic validation model where conditions of trial level and patient level surrogacy had to be met. We computed the surrogate threshold effect (STE), which is the minimum ICE treatment effect necessary to estimate a non-zero effect on OS. **Results**: IPD from 8592 patients randomized from 1994-2012 from 13 trials were pooled for a stratified analysis. There were 5377 deaths, of which 3971 (74%) were due to prostate cancer. The median follow-up for surviving patients was 75.6 months. In addition, there were 6227 rPFS and 6314 cPFS events. The median OS, rPFS and cPFS were 49.4, 26.8 and 25.2 months, respectively. The STE was 0.82 for rPFS and 0.84 for cPFS. **Conclusions**: Both rPFS and cPFS appear to be valid surrogate endpoints for OS. A surrogate threshold effect of 0.82 or higher makes it viable for either rPFS or cPFS to be used as the primary endpoint as a surrogate for OS in phase 3 mHSPC trials and would expedite trial conduct. Validation of these ICEs in trials with drugs having other mechanisms of action is planned. Clinical trial information: Several. Research Sponsor: Prostate Cancer Foundation.

Defining germline genetics of germ cell tumor: Implications for genetic testing and clinical management. *First Author: Hong Truong, Memorial Sloan Kettering Cancer Center, New York, NY*

Background: Epidemiologic studies on germ cell tumors (GCT) in men have shown GCT has a high heritability. Yet, the genetic mechanisms underlying development of GCT in men remain unknown. We sought to determine the prevalence of pathogenic or likely pathogenic (P/LP) germline variants in cancer predisposition genes in men with GCT and identify clinical and pathologic factors associated with the presence of P/LP variants. **Methods:** We retrospectively identified men with testicular (T) or mediastinal (M) GCT who underwent matched tumor–germline sequencing of ≥ 310 genes as part of an institutional genomic profiling initiative from 04/2015 to 12/2020. Presence of germline variants in clinically actionable genes associated with hereditary cancer syndromes were analyzed. Clinicopathologic characteristics, including primary site, histology and family history were assessed by the presence of P/LP variants and compared using Fisher's exact test. **Results:** The study included 480 men, 70 (15%) with M-GCT and 410 (85%) with T-GCT. The median age of diagnosis was 30 years (interquartile range 24 – 39). A total of 81% had non-seminoma; 5% had localized disease; 46%, 14%, and 34% had good, intermediate, and poor risk advanced disease, respectively; 6% had family history of GCT. Among men with T-GCT, 4% had bilateral T-GCT. P/LP variants in clinically actionable genes were identified in 58 (12%) men in the entire cohort. Men with M-GCT had higher frequency of P/LP variants compared to those with T-GCT (15/70 [21%] vs 43/410 [10%], p = 0.02). A total of 7 (10%) men with M-GCT and 20 (5%) with T-GCT had P/LP variants in moderate or high penetrance cancer predisposition genes (p = 0.09). Most P/LP variants in both M-GCT (11/15, 73%) and T-GCT (33/43, 77%) were in genes involved in DNA damage repair pathways. The spectrum of moderate or high penetrance DNA damage repair genes identified is shown in the Table 1. Family history and histology (seminoma vs. non-seminoma) were not associated with the presence of a P/LP variants in the overall cohort (p = 0.8 and 0.7, respectively). Bilateral disease was not associated with the presence of P/LP variants in men with T-GCT (p = 0.4). **Conclusions:** Approximately 1 in 5 men with M-GCT carried a P/LP variant in a clinically actionable cancer susceptibility gene and 10% had a P/LP variant in a high-risk gene such as TP53 and PMS2. As men with GCT tend to develop disease in early adulthood, identification of germline P/LP variant has significant implications for enhanced cancer screening and surveillance, cascade testing for at-risk family members, and potential preconception genetic counseling. Late relapses in testicular cancer: Results from a national cohort. *First Author: Torgrim Tandstad, St. Olav's University Hospital, Trondheim, Norway*

Background: Late relapses (LR; relapse occurring after disease-free interval of two years) in testicular cancer are relatively uncommon. The limited data published is hampered by selection bias and incomplete data regarding follow-up. We aimed to investigate the frequency of LR and of very late relapses (VLR; relapse occurring after disease-free interval of five years), and the survival of patients with VLR in a cohort treated after 1995, compared to a cohort before 1995. Finally, we aimed to describe the number of missed relapses beyond a 5-year follow-up scheme. **Methods:** A total of 5712 patients, 2978 seminoma and 2734 nonseminoma, were diagnosed with testicular cancer in Norway, with 2207 patients diagnosed 1980-1995 and 5712 patients diagnosed 1995-2009. Data are complete, due to identification by the Cancer Registry of Norway and Norwegian Cause of Death Registry. Details regarding diagnosis, stage, treatment, and follow-up were obtained from medical records. Relapse rates have been estimated using Kaplan-Meyer. **Results:** A total of 472 patients experienced relapse, 186 seminoma and 286 nonseminoma. Of these 109 were LR (51 seminomas, 58 nonseminomas), 50 VLR (22 seminomas, 28 nonseminomas with 17 relapses (4 seminomas, 13 nonseminomas) beyond ten years. The median time to LR was 4.7 years (range 2.0-21.6). In clinical stage I patients, there were 306 relapses (7.9%); with overall 1.9% LR, 1.0% VLR, and 0.5% relapse beyond ten years. Patients followed with surveillance had a higher rate of LR compared to patients receiving adjuvant therapy (4.0% vs 1.0%). Three patients with LR died of testicular cancer, all three had a VLR and initial nonseminoma. In patients with metastatic disease, 166 patients experienced relapse (10.5%); with overall 3.6% LR 1.6% VLR, and 0,8% relapse beyond ten years. In nonseminoma diagnosed after 1995, the rate of VLR was 0.8% compared to 2.3% in the earlier cohort. Eight patients with VLR died of testicular cancer, all with initial nonseminoma, and seven of these were diagnosed in the earlier cohort. Outside a five-year follow-up scheme, 50 patients would be diagnosed with a VLR. Prolonging follow-up to ten years would potentially identify only 33 of these relapses. **Conclusions:** In this first population-based series investigating late relapses of testicular cancer with complete data regarding treatment and follow-up, we find a low rate of VLR in patients treated according to modern guidelines. We believe centralization of treatment, adherence to guidelines, prospective registration of patients, and subsequent reporting of results are key to these improved results. Patients with CS I followed by surveillance will have higher rate of VLR compared to patients receiving adjuvant treatment, resulting in a higher VLR rate in the modern cohort, without affecting survival. In metastatic disease, the VLR rate was drastically reduced in the modern cohort, with a subsequent improved survival. Research Sponsor: Supported by grants from Helse Nord RHF (grant no. SPF1230-15).

Cohort study of patients with oligorecurrent prostate cancer: Oncological outcomes of patients treated with salvage lymph node dissection via PSMA radioguided surgery. *First Author: Sophie Knipper, Martini-Klinik Prostate Cancer Center, Hamburg, Germany*

Background: Prostate-specific membrane antigen (PSMA) positron-emission tomography (PET) allows detection of small and/or atypically localized metastatic prostate cancer (PCa) lesions. In a subset of patients with recurrent oligometastatic PCa salvage surgery with PSMA-targeted radioguidance (PSMA-RGS) may be of value. We aimed to evaluate the oncological outcomes of salvage PSMA-RGS for oligo-recurrent PCa and determine predictive preoperative factors of improved outcomes. **Methods:** In this cohort study within two tertiary care centers, patients with biochemical recurrence (BCR) after radical prostatectomy (RP) and imaging with PSMA PET receiving salvage PSMA-RGS between 2014 and 2020 were analyzed. Kaplan-Meier and multivariable Cox regression models adjusted for various parameters were used to test for BCR-free survival (BFS) and therapy-free survival (TFS) differences. Postoperative complications were classified according to Clavien-Dindo. **Results:** Overall, 364 patients were assessed. At PSMA-RGS, median (IQR) age and preoperative PSA was 67 (61-71) years and 1.0 (0.5-1.9) ng/ml. Metastatic soft-tissue lesions from PCa metastases could be removed in 343 (94.2%) patients. Within three months from surgery, 24 (6.6%) patients suffered from Clavien-Dindo complications grade III-IV. During follow-up, 225 patients experienced BCR and 121 patients received further therapy. Median follow-up for patients who did not experience BCR and who did not receive further therapy was 10.8 months and 10.3 months, respectively. Median (IQR) BFS and TFS was 7.8 (5.4-10.5) and 35.5 months (25.9-45.9 months). At two years of follow-up, BFS rate was 31.9% and TFS rate was 58.0%. In multivariable analyses, higher preoperative PSA (HR: 1.1), higher number of PSMA-avid lesions on preoperative imaging (HR: 1.2) and multiple (pelvic plus retroperitoneal) localizations (HR: 1.9), as well as retroperitoneal localization (HR: 2.0) of lesions in PSMA PET imaging were independent predictors of BCR after PSMA-RGS. Limitations are the retrospective design and lack of a control group. **Conclusions:** As salvage surgery in oligo-recurrent PCa currently constitutes an experimental treatment approach careful patient selection is mandatory based on life expectancy, low PSA values and low number of PSMA PET avid lesions located in the pelvis. Further studies are needed to confirm our findings and define the oncological value of salvage surgical procedures in oligo-recurrent PCa. Research Sponsor: None.

Prostate-specific membrane antigen PET response associates with radiographic progression-free survival following stereotactic ablative radiation therapy in oligometastatic castration-sensitive prostate cancer. *First Author: Philip Sutera, Johns Hopkins University, Baltimore, MD*

Background: Emerging data suggest metastasis-directed therapy (MDT) improves outcomes in patients with oligometastatic castration-sensitive prostate cancer (omCSPC). Prostate-specific membrane antigen positron emission tomography (PSMA-PET/CT) can detect occult metastatic disease and has been proposed as a biomarker for treatment response. Herein we identify and validate a PSMA-PET biomarker for clinical outcomes following MDT in omCSPC. **Methods:** This was an international multi-institutional retrospective study of two completely independent cohorts of men with omCSPC, defined as ≤3 lesions, treated with metastasis-directed stereotactic ablative radiation therapy (SABR) who underwent PSMA-PET/CT prior to and 3-6 months after treatment. Pre- and post-SABR PSMA-PET/CT standardized uptake value (SUV) was measured for all lesions and PSMA response defined discretely using a cutpoint of ≥ 30% decrease in SUV_{max}. PSMA-PET response was correlated with lesion local control (LLC), radiographic progression-free survival (rPFS) defined using conventional and PET imaging, and metastasis-free survival (MFS) defined by conventional imaging alone. **Results:** A total of 131 patients with 261 treated metastases were included in the analysis, with median follow-up of 29 months (IQR 18.5-41.3). Following SABR, 78.4% of lesions experienced a partial or complete PSMA response. Multivariable analysis demonstrated SUV response significantly associated with improved LLC (HR = 9.97, 95%CI 3.92-25.4; $p < 0.01$). Patients with PSMA response in all lesions experienced significantly better rPFS (HR = 0.49, 95%CI 0.26-0.92; p = 0.03) compared to their counterparts and this maintained significance within both the discovery ($p < 0.01$) and validation (p = 0.01) cohorts. Within the discovery cohort, patients with PSMA response in all lesions also experienced significantly improved MFS (HR = 0.24, 95%CI 0.07-0.85; p = 0.03); analysis of the independent validation cohort is ongoing. **Conclusions:** Following SABR, PSMA-PET response is a robust and externally validated radiographic biomarker for rPFS and appears to be associated with MFS pending validation. This approach holds promise for guiding clinical management of omCSPC. Research Sponsor: Prostate Cancer Fundation, Movember, Distinguished Gentlemens Ride.

Phase II, double-blind, randomized study of salvage radiation therapy (SRT) plus enzalutamide or placebo for high-risk PSA-recurrent prostate cancer after radical prostatectomy: The SALV-ENZA Trial. *First Author: Phuoc T. Tran, University of Maryland School of Medicine, Baltimore, MD*

Background: We sought to investigate whether enzalutamide (ENZA) treatment, without androgen deprivation therapy, increases freedom-from-PSA-progression (FFPP) when combined with salvage radiation therapy (SRT) in men with recurrent prostate cancer post-radical prostatectomy (RP). **Methods:** Men with biochemically recurrent prostate cancer after RP were enrolled into a randomized, double-blind, phase II, placebo-controlled, multicenter study of SRT + placebo vs SRT + ENZA. The randomization (1:1) was stratified by center, surgical margin status (R0 vs R1), PSA prior to salvage treatment (PSA ≥0.5 vs < 0.5 ng/mL), and pathologic Gleason sum (7 vs 8-10) using a minimization algorithm. Following randomization, patients received either placebo or ENZA 160 mg PO once daily for 6 months. Following 2 months of study drug therapy, external beam radiotherapy to 66.6-70.2 Gy was administered to the prostate bed (no pelvic nodes). The primary endpoint was FFPP. The trial design was powered for a HR 0.44 FFPP benefit with intended enrollment of 96 subjects and was closed as planned to enrollment on March 2020 short of that goal. Secondary endpoints were time to local recurrence (LR) within the radiation field, metastasis-free survival (MFS), and safety as determined by frequency and severity of adverse events (AEs). **Results:** A total of 86 patients were randomized with a median follow-up of 34 (range 0-52) months. The median pre-SRT PSA was 0.3 (range 0.06-4.6) ng/mL, 56/86 (65%) had extra-prostatic disease (pT3), 39/86 (45%) had Gleason Grade Group 4 or higher and 43/96 (50%) had positive surgical margins. Trial arms were well balanced. FFPP was significantly improved with ENZA vs placebo, for example 2-year FFPP was 87.1% vs 68.1%, respectively, and overall with a HR 0.40 [95% confidence interval (CI), 0.17-0.92, p-value = 0.026]. Subgroup analyses demonstrate differential benefit (p-value of interaction = 0.031) of ENZA in men with pT3 (HR 0.19, 95%CI 0.05-0.67) vs pT2 disease (HR 1.29, 95%CI 0.34-4.81). There were insufficient secondary endpoint events for analysis. The most common adverse events were grade 1-2 fatigue (13% ENZA vs 9%) and urinary frequency (6 % ENZA vs 8%). **Conclusions:** SRT plus ENZA monotherapy for men with PSA recurrent high-risk prostate cancer following RP is safe and delays PSA progression relative to SRT alone. The impact of ENZA on distant metastasis or survival is unknown at this time. Additional molecular biomarker analyses are being pursued. Clinical trial information: NCT02203695. Research Sponsor: Astellas.

Biomarker-directed therapy in black and white men with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Clara Hwang, Henry Ford Health System, Detroit, MI*

Background: Black men have been underrepresented in large-scale molecular prostate cancer (PC) surveys, despite having higher PC incidence and mortality. Since molecular profiling to guide the use of targeted agents is increasingly important in mCRPC, we compared precision medicine data and utilization in a cohort of black and white men with mCRPC. **Methods:** The PROMISE precision medicine database is an academic collaboration to compile clinical and genomic data from men with PC. All patients have had germline and/or somatic genetic testing performed. Eligibility criteria for this analysis included a diagnosis of mCRPC with available race and biomarker data. The primary outcome was the proportion of non-Hispanic black (NHB) and non-Hispanic white (NHW) men with actionable molecular data, defined as the presence of mismatch repair deficiency (MMRd/MSI-H), homologous recombination repair deficiency (HRRd), tumor mutational burden (TMB) ≥ 10 mut/MB, or AR-V7. Secondary outcomes included the proportion of NHB and NHW men with other alterations, the type and timing of genomic testing performed, and the use of targeted therapy. **Results:** A total of 962 mCRPC patients (21.2% NHB; 78.8% NHW) met inclusion criteria of 1619 in the overall database. Median age (NHB/NHW) was 61/63; 77.5/68.8% had Gleason 8-10; 52.5/56.7% presented with de novo metastatic disease (33.8/29.9% LN, 36.2/32.2% bone and 8.3/6.1% viscera). The median time from diagnosis to first molecular result was 56.3 mo for NHB v 58.7 mo for NHW (p = 0.45). Use of blood-based molecular testing was more common in NHB men (48.7% v 36.4%, $p < 0.001$). Overall, 32.8% of NHB men harbored actionable molecular data compared to 30.3% of NHW men (Table). MMRd/MSI-H was more common in NHB men (9.1 v 4.9%, p = 0.04). Other than PTEN (12.7/23.8% NHB/NHW, p = 0.0001), no significant differences were seen in the 15 most frequently mutated genes, including TP53, AR, CDK12, RB1, and PIK3CA. Tumor suppressor co-mutations (PTEN/TP53/RB1) were found in 13.1% of NHB and 18.0% NHW (p = 0.13). Delivery of targeted therapy was reported in 19.6% of NHB and 23.7% of NHW men (p = 0.25) after a median of 2 CRPC lines. Median OS from development of mCRPC was 41.5 mo (95% CI, 34.7-51.3) and 44.7 mo (95% CI, 41.1-51.5) for NHB and NHW men, respectively (p = 0.14). **Conclusions:** In a real-world mCRPC molecular profiling cohort, we found similar overall rates of actionable molecular alterations in NHB and NHW men, but higher rates of MMRd/MSI-H and lower frequency of *PTEN* alterations in NHB men. We did not find differences in delivery of targeted therapy. Research Sponsor: None.

	NHB, N (%)	NHW, N (%)	p-value
Actionable alteration	65 (32.8)	224 (30.3)	0.55
MMRd/MSI-H	18 (9.1)	36 (4.9)	0.04
HRRd	46 (23.2)	179 (24.2)	0.85
TMB high	8 (4)	21 (2.8)	0.53
AR-V7	2 (1)	12 (1.6)	0.76
Targeted therapies	40 (19.6)	180 (23.7)	0.25
PARP inhibitors	12 (19.4)	55 (18.3)	0.98

Racial concordance and trust in health communications: A randomized trial of videos about prostate cancer. *First Author: Stacy Loeb, NYU Langone Health, New York City, NY*

Background: Black men have a significantly higher risk of prostate cancer and more aggressive disease compared to White men. The Internet is a popular source of health information and is commonly used by Black adults. However, Black adults are underrepresented in online content about prostate cancer. Given that medical mistrust is greater among Black compared to White adults, this study sought to evaluate the association between racial representation in online content about prostate cancer and trust in the content. A secondary objective was to identify additional attributes that influence trust in online content. **Methods:** This was a randomized trial of 2904 U.S. adults age ≥40. Participants were randomly assigned to view one of 8 different online videos. Videos used an equivalent script about either prostate cancer screening or clinical trials presented by one of 4 different presenters: Black physician, Black patient, White physician, or White patient. The primary outcome of the study was trust in the information using a Likert scale. Logistic regression models were applied to compare trust in the videos, based upon the characteristics of the speaker and topic of the video. **Results:** Study participants were 1703 (59%) Black and 1201 (41%) White adults. Black adults were 1.5 times more likely to trust a Black presenter compared to a White presenter (p<0.001). For White adults, no significant difference in trust was identified between Black or White presenters (p=0.21). For both Black and White adults, a physician presenting the information was more trusted than a patient, and videos discussing screening were more likely to be trusted than those discussing clinical trials (Table). **Conclusions:** Racial concordance is significantly associated with trust in prostate cancer information among Black adults. Additionally, health information is considered more trustworthy when delivered by a physician. These results highlight the importance of physicians in disseminating health information to the public, and of increasing racial diversity among healthcare providers. They also suggest an ongoing need for public education about clinical trials to prioritize issues of mistrust and distrust. Research Sponsor: Department of Defense.

Targeting B7-H3 in prostate cancer: Phase 2 trial in localized prostate cancer using the anti-B7-H3 antibody enoblituzumab, with biomarker correlatives. *First Author: Eugene Shenderov, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: B7-H3/CD276, a member of the B7 superfamily, is highly expressed in prostate cancer (PCa) and is associated with rapid biochemical recurrence and early metastases. B7-H3 is the only checkpoint candidate to have a presumptive androgen receptor binding site, suggesting interaction with the androgen axis. Enoblituzumab (MacroGenics) is an investigational humanized Fc-optimized B7-H3–targeting antibody that induces antibody dependent cellular cytotoxicity (ADCC). **Methods:** In this phase 2 single-arm biomarker-rich neoadjuvant trial, men with operable intermediate- and high-risk localized prostate cancer (Grade Groups 3-5) were enrolled to evaluate the safety, anti-tumor efficacy, and immunogenicity of enoblituzumab when given prior to prostatectomy. Patients received enoblituzumab (15 mg/kg IV weekly x 6) prior to surgery. Prostate glands were harvested 2 weeks after the last dose, and were examined for pathologic and immunologic endpoints. The co-primary outcomes were safety and PSA0 at 1 year post-op. Pre-planned secondary outcomes were PSA and Gleason grade group change from biopsy to prostatectomy. **Results:** 32 men were enrolled. Grade 3/4 adverse events occurred in 12% of patients. One patient developed a grade-3 infusion reaction, and one had immune myocarditis that improved with steroids. Pre-prostatectomy PSA declines of >10% were observed in 31% of patients (95% CI: 16-50%). PSA0 at 1 year post-op was seen in 66% of men (95% CI: 47-81%). Median time to PSA recurrence was not reached, with a median follow-up of 30 months. Gleason group upgrade, no change, and downgrade was observed in 13%, 37%, and 50% of patients. Gleason grade group changes were significantly associated with enoblituzumab treatment compared to 1:1 matched historical controls (p=0.023). Tumor microenvironment profiling by NanoString GeoMx spatial proteomics and PanCancer IO 360 mRNA expression analysis revealed post-treatment upregulation of CD8+ T cells, PD-1/PD-L1 expression, and immune activation (granzyme B, IFN signaling, myeloid inflammation). There was a significant association between CD8+ T-cell increases and Gleason grade group declines. First-in-human antigen spread profiling revealed no safety concerns. TCR sequencing showed focused peripheral expansion of tumor associated T-cell clones that correlated with PSA0 at 1 year. Whole exome and RNAseq data, and clinical correlations, will be presented. **Conclusions:** In this neoadjuvant trial, inhibition of B7-H3 with enoblituzumab demonstrated favorable safety and encouraging activity in localized PCa patients. Data suggest robust intratumoral induction (adaptive upregulation) of immune checkpoints, T-cell activation, and myeloid inflammation. Enoblituzumab-induced peripheral expansion of tumor associated T-cell clones may be associated with tumor control. Clinical trial information: NCT02923180. Research Sponsor: Macrogenics, Inc, Conquer Cancer Foundation of the American Society of Clinical Oncology, Other Foundation, Other Government Agency.

5016 **Poster Discussion Session**

A phase 2 randomized study of oral docetaxel plus ritonavir (ModraDoc006/r) in patients with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Ulka N. Vaishampayan, University of Michigan, Ann Arbor, MI*

Background: Intravenous (IV) docetaxel and oral prednisone is a standard of care regimen in patients (pts) with mCRPC. ModraDoc006 is an oral formulation of docetaxel. To enhance bioavailability of ModraDoc006, it is co-administered with ritonavir (/r). The ModraDoc006 and ritonavir combination is active in multiple docetaxel and cabazitaxel-resistant prostate cancer cell-lines The oral combination (ModraDoc006/r) was compared to IV docetaxel in a randomized phase 2b study in pts with mCRPC evaluating two doses of ModraDoc006/r (30-20/200-100 mg and 20-20/200-100 mg). Data on outcomes in the larger cohort, receiving the lower dose, are being presented. **Methods:** Eligible pts had mCRPC, performance status of 0-1 and no prior chemotherapy for mCRPC. Sixty-two pts were enrolled in open label 1:1 randomized study comparing ModraDoc006/r 20-20 mg combined with 200-100 mg ritonavir in a bi-daily weekly schedule ("20-20/200-100 mg"), with IV docetaxel 75 mg/m^2 in 21-day cycles. All pts received 5 mg oral prednisone twice daily. Primary endpoint was radiographic progression free survival (rPFS) per PCWG-3 criteria. Secondary objectives included ORR, PSA-PFS, time to skeletal related events, disease control rate, duration of response, and safety assessments. **Results:** 31 pts were enrolled on IV docetaxel 75 mg/m^2 and 31 on ModraDoc006/r 20-20/200-100 mg. Of these, 57 were included in the analysis for rPFS, and 32 pts with measurable disease were included in the ORR analysis. Median PSA was 46 (range 1 to 1460 ng/ml). Prior therapy with enzalutamide in 8 pts, abiraterone in 10 pts. ModraDoc006/r was better tolerated with 0% all grades neutropenia and anemia, as compared to 26% (19% ≥G3) and 16% respectively on IV docetaxel. Neuropathy was significantly reduced at 9.7% G1 only on ModraDoc006/r vs 9.7% G1 and 19.4% G2 on IV docetaxel, whereas alopecia was reduced to 16.1% G1 and 6.5% G2 on ModraDoc006/r vs. 22.6% G1 and 19.4% G2 on IV docetaxel. GI toxicities were broadly comparable with diarrhea 32% (3% ≥G3) vs 29%, nausea 29% vs 13% and stomatitis 3% (G3) vs 13% (3% ≥G3), respectively. **Conclusions:** ModraDoc006/r demonstrated a favorable safety profile and comparable efficacy to IV docetaxel in pts with mCRPC, thus providing a compelling rationale for conduct of an expanded pivotal program. A key clinical program focus is the comparison of ModraDoc006/r to best available therapy in refractory mCRPC. Studies of ModraDoc006/r in other malignancies are also in active development. Clinical trial information: NCT04028388. Research Sponsor: Modra Pharmaceuticals.

Efficacy results.

Results (all 95% CI)	**IV docetaxel**	**ModraDoc006/r**
Overall Response Rate (ORR)	28.6% (CI 8.4, 58.1)	38.9% (CI 17.3, 64.3)
rPFS at 6 months	0.88 (CI 0.66 - 0.96)	0.75 (CI 0.52 - 0.88)
PSA response (≥50% decline)	50.0% (CI 30.6, 69.4)	48.3% (CI 29.4, 67.5)

5017 **Poster Discussion Session**

PRINCE: Phase I trial of ^{177}Lu-PSMA-617 in combination with pembrolizumab in patients with metastatic castration-resistant prostate cancer (mCRPC). *First Author: Shahneen Sandhu, Peter MacCallum Cancer Centre and Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, VIC, Australia*

Background: The VISION and TheraP trials have established the safety and efficacy of ^{177}Lu-PSMA-617 in mCRPC with a 50% PSA response rate (PSA50-RR) of 46% and 66% and median progression free survival (PFS) of 8.7 and 5.1 months, respectively. More effective treatments are required as disease progression remains universal. Immunotherapy has limited single-agent efficacy in mCRPC. We hypothesise that by potentially inducing immunogenic cell death, ^{177}Lu-PSMA-617 may act synergistically with pembrolizumab, an anti-programmed death 1 inhibitor, to enhance the depth and durability of response. PRINCE is a Phase I trial evaluating the safety and efficacy of this combination. **Methods:** mCRPC patients with high PSMA expression (SUVmax ≥ 20 in an index lesion, SUVmax > 10 for all lesions ≥ 10mm), and no FDG+ve/PSMA-ve lesions on paired baseline PET/CT screening, received up to 6 cycles of ^{177}Lu-PSMA-617 (starting at 8.5 GBq, reducing by 0.5 GBq with each cycle) every 6 weeks in conjunction with 200mg of pembrolizumab every 3 weeks for up to 2 years. Response evaluation was undertaken as per PCWG3 and RECIST criteria. Co-primary endpoints were safety and PSA50-RR. Secondary endpoints included PSA-PFS, radiographic PFS (rPFS), overall survival (OS), and patient reported outcomes (PROs). This analysis was undertaken after the last patient had 12 months follow-up. **Results:** 37 patients (median age 72 years; prior docetaxel 73%; prior androgen receptor targeted agent 100%) received a median of 5 cycles (range: 2 to 6) of ^{177}Lu-PSMA-617 and 12 doses (range: 6 to 19) of pembrolizumab. The median follow up was 16 months. PSA50-RR was 76% (28/37 [95% CI 59-88]) and 7/10 (70%) patients with RECIST-measurable disease had a partial response. Median rPFS, PSA-PFS and OS was 11.2 months (95% CI: 5.1-14.1), 8.2 months (95% CI: 5.1-11.2) and 17.8 months (95% CI:13.4-not estimable). 12-month rPFS and OS was 38% (95% CI: 22-54) and 83% (95% CI: 67-92), respectively. Common (≥10%) treatment-related adverse events (TRAE) were mainly Grade (G) 1-2, including xerostomia (78%), fatigue (43%), pruritus (27%), nausea (27%), rash (24%), diarrhoea (14%), anorexia (16%), thrombocytopenia (16%), elevated ALT (11%), arthralgia (11%) and a flare in bone pain (11%). Haematologic TRAEs included G2-3 anaemia (8%), G1-2 thrombocytopenia (16%), and G1 neutropenia (3%). G3 immune-related AEs occurred in 10 (27%) patients with no dominant manifestation. 5 (14%) patients discontinued pembrolizumab due to toxicity. PROs including BPI-SF and FACT-P were stable throughout the study. **Conclusions:** The combination of ^{177}Lu-PSMA-617 and pembrolizumab had promising activity. Toxicities were generally consistent with those of single-agent ^{177}Lu-PSMA-617 and pembrolizumab and were not clearly augmented by combination use. No new safety concerns were observed. Clinical trial information: NCT03658447. Research Sponsor: Victorian Cancer Agency, Pharmaceutical/Biotech Company.

BRCAAWAY: A randomized phase 2 trial of abiraterone, olaparib, or abiraterone + olaparib in patients with metastatic castration-resistant prostate cancer (mCRPC) with DNA repair defects.

First Author: Maha H. A. Hussain, Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL

Background: The PARP-inhibitor olaparib is approved for mCRPC patients (pts) with deleterious germline or somatic homologous recombination repair gene mutations (HRRm). PARP1 interacts with androgen signaling, and castration-resistant tumor cells exhibit increased PARP1 activity. Preclinically PARP1-inhibition synergizes with androgen receptor (AR) targeted therapy. BRCAAway is a biomarker selected, randomized, open-label, multicenter phase 2 trial evaluating efficacy of targeting AR vs PARP vs combination in first line mCRPC patients with germline and/or somatic HRRm in BRCA1, BRCA2, or ATM. **Methods:** Eligible mCRPC pts underwent tumor next generation sequencing and germline testing. Pts with inactivating BRCA1, BRCA2 and/or ATM alterations were randomized 1:1:1 to Arm 1 abiraterone (1000 mg daily) + prednisone (5mg bid) (Abi/pred), Arm 2 olaparib (300 mg bid) or Arm 3 olaparib + Abi/pred. The primary end point is progression-free survival (PFS) analyzed using Kaplan-Meier estimates and Cox regression. Secondary endpoints include measurable disease response rate (RR) by RECIST, PSA-RR, undetectable PSA (≤ 0.2 ng/ml) and toxicity. Arms 1 and 2 pts were allowed to cross over at progression. Pts with other HRRm were treated with olaparib; Arm 4 (ongoing). **Results:** 161 pts were registered and had NGS testing; 60 pts were randomized to Arms 1-3; to date 59 are evaluable for toxicity and 53 are evaluable for PFS. Baseline median age 67 (range 42-85) years; 54 pts were White, 6 were Black; sites of disease: bone only (n=31), soft tissue only (n=18), bone and soft tissue (n=10); median PSA 14.61 ng/ml (range 0.15-4036.8). Mutational status: BRCA1 only n = 2, BRCA2 only n = 39, ATM only n = 8, and > 1 HRRm n = 11. 34 pts had germline and 26 had somatic mutations. Median (range) follow-up time: 8.3 (0.8, 33.3), 12.2 (2.7, 21.8) and 16.8 (2.9, 41.7) months in Arms 1, 2 and 3. 43 pts had treatment-related adverse events; most common were fatigue (23 pts; 1 Grade (G) 3, 22 G1/2), nausea (17 pts, G1/2), and anemia (9 pts, 2 G3, 7 G1/2). ≥50% PSA decline was 79%, 67%, and 85% of pts in Arms 1, 2, and 3, respectively. Median PSA nadir (ng/mL) (95% CI) Arms 1-3: 2.17 (0.44, 49.27), 3.10 (0.83, 12.01), and 0.50 (0.10, 2.13), respectively. Undetectable PSA, median PFS, and 12-month PFS by Arm are listed in the table. **Conclusions:** In mCRPC pts with inactivating BRCA1, BRCA2 and/or ATM alterations Abi/pred + olaparib was well tolerated and resulted in longer PFS and better PSA response vs either agent alone. Clinical trial information: NCT03012321. Research Sponsor: AstraZeneca.

Arm (evaluable pts)	Undetectable PSA n (%)	Median PFS (95% CI) in Months	12-month PFS rate (95% CI)	Unadjusted hazard ratio (Arm 3 vs Arms 1 and 2)
1: Abi/pred (17)	4 (24%)	11.0 (7.4, NA)	42% (0.22, 0.80)	0.19 (95% CI: 0.06, 0.61)
2: Olaparib (17)	4(24%)	11.3 (8.3, 20.6)	44% (0.25, 0.76)	0.14 (95% CI: 0.04, 0.43)
3: Abi/pred + Olaparib (19)	7 (37%)	NR (23.8, NA)	95% (0.85, 1.0)	-

Tolerability of abiraterone (abi) combined with olaparib (ola) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC): Further results from the phase III PROpel trial.

First Author: Antoine Thiery-Vuillemin, CHRU Besançon Hôpital J.Minjoz, Besançon, France

Background: The Phase III PROpel (NCT03732820) trial demonstrated at interim analysis a statistically significant clinical benefit from combining ola + abi in the first-line (1L) mCRPC setting vs placebo (pbo) + abi. Benefit was seen irrespective of a pt's homologous recombination repair mutation (HRRm) status; median radiographic progression-free survival (rPFS) 24.8 for ola + abi vs 16.6 months for pbo + abi (hazard ratio [HR] 0.66, 95% confidence interval [CI] 0.54–0.81; *P*<0.0001). The safety profile of ola + abi was shown to be consistent with that for the individual drugs. We report additional interim safety analysis from PROpel. **Methods:** Eligible pts were ≥18 years with mCRPC, had received no prior chemotherapy or next-generation hormonal agent treatment at mCRPC stage, and were unselected by HRRm status. Pts were randomized 1:1 to abi (1000 mg qd) plus prednisone/prednisolone with either ola (300 mg bid) or pbo. Primary endpoint was investigator-assessed rPFS. Safety was assessed in all pts receiving ≥1 dose of study treatment by adverse event (AE) reporting (CTCAE v4.03). **Results:** 398 pts received ola + abi and 396 pbo + abi (safety analysis set). At data cut-off (July 30, 2021), median total duration of exposure for ola was 17.5 vs 15.7 months for pbo, and for abi 18.2 months in the ola + abi arm and 15.7 in the pbo + abi arm. Anemia (n=183) was the most common AE in the ola + abi arm, and 34% of these 183 events were managed by dose interruption, 23% by dose reduction, and 8% resulted in treatment discontinuation. Anemia and pulmonary embolism (PE) were the only Grade ≥3 AEs in ≥5% of pts (anemia: ola + abi, 15.1% vs pbo + abi, 3.3%; PE: 6.5% vs 1.8%, respectively). Most PEs were detected incidentally on radiographic imaging (69.2% and 71.4% in the ola + abi and pbo + abi arms, respectively) and no pts discontinued. More pts in the ola + abi arm experienced venous thromboembolism (Table). Arterial thromboembolism and cardiac failure AEs were balanced between the treatment arms. No AE of myelodysplastic syndrome/acute myeloid leukemia was reported in either treatment arm. COVID-19 was reported more frequently with ola + abi (8.3% vs 4.5%). **Conclusions:** PROpel demonstrated a predictable safety profile for ola + abi given in combination to pts with 1L mCRPC unselected by HRRm status. AEs of cardiac failure and arterial thromboembolism were reported at similar frequency in both treatment arms. The majority of PEs were asymptomatic. The safety profile of abiraterone was not adversely impacted by its combination with olaparib. Clinical trial information: NCT03732820. Research Sponsor: This study was supported by AstraZeneca and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA, who are codeveloping olaparib.

n (%)	Ola + abi (N=398)	Pbo + abi (N=396)

Gene-by-gene analysis in the MAGNITUDE study of niraparib (NIRA) with abiraterone acetate and prednisone (AAP) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) and homologous recombination repair (HRR) gene alterations.

First Author: Shahneen Sandhu, Peter MacCallum Cancer Centre and University of Melbourne, Melbourne, Australia

Background: NIRA + AAP significantly improved outcomes in pts with mCRPC and HRR gene alterations in the Phase 3 MAGNTUDE study. There is a paucity of data supporting use of PARP inhibitors in pts with HRR gene alterations other than *BRCA1/2*. We report on the efficacy of NIRA + AAP in pts with mCRPC and a qualifying single gene HRR alteration other than *BRCA1/2*. **Methods**: A pre-specified analysis was undertaken of the primary endpoint (radiographic progression-free survival [rPFS] by BICR), secondary endpoints (time to cytotoxic chemotherapy [TCC], time to symptomatic progression [TSP], overall survival [OS]), as well as time to PSA progression (TPSA) and overall response rate (ORR) across 186 pts (91 randomized to NIRA + AAP, 95 to PBO + AAP) with an alteration in the *ATM*, *BRIP1*, *CDK12*, *CHEK2*, *FANCA*, *HDAC2*, or *PALB2* gene (excluding cooccurring alterations). This analysis of individual alterations was not powered for formal statistical inference. Given the rarity of some alterations, groups based on functional similarity are also presented. **Results**: (Table). Pts with *PALB2* or *CHEK2* alterations had consistent improvement across all endpoints. In pts with *ATM* alterations benefit was observed in TCC, TSP, TPSA and ORR. There was benefit only in TPSA and ORR for pts with *CDK12* alterations. When combined into functional groups, pts with an alteration in the HRR-Fanconi pathway (*BRIP1*, *FANCA*, and *PALB2*) as well as pts with a HRR associated alteration (*CHEK2* or *HDAC2*) showed improvement in all endpoints. **Conclusions**: These data support the overall conclusions of the MAGNITUDE primary analysis and support benefit of NIRA + AAP in pts with HRR mutations beyond *BRCA1/2*. Clinical trial information: NCT03748641. Research Sponsor: Janssen Research & Development, LLC.

Long-term predictive value of serum PSA values obtained in clinical practice: Results from the Norwegian Prostate Cancer Consortium (NPCC).

First Author: Jan Oldenburg, Department of Oncology, Akershus University Hospital (Ahus), Lørenskog, Norway

Background: A baseline prostate-specific antigen (PSA) level in midlife is strongly associated with risk of lethal prostate cancer several decades later. In most prior studies, PSA was measured in archived blood from men participating in cohort studies unrelated to prostate cancer. In clinical practice, however, men commonly obtain a PSA test because of lower urinary tract symptoms. Here, we study the association between PSA values when a first PSA test was obtained as part of clinical care – and subsequent risks of prostate cancer diagnosis and death. **Methods:** The NPCC database contained laboratory results from 1995-2006 of the first ("baseline") PSA test below 4.0 ng/mL in 157,836 men aged 40-69 years without prior prostate cancer (PCa) diagnosis. PSA strata were pre-defined: < 1, 1-1.99, 2-2.99, 3-3.99 ng/ml and analyses were split in two age groups based on a prior risk: 40-54 ("younger") and 55-69 ("older"). Predictive accuracy was assessed with Harrell's concordance (C) index. The Kaplan-Meier method was used to visualize risk of PCa death as reported on the death certificate by PSA strata for the two age groups. **Results:** Among 157,836 men with a PSA below 4.0 ng/mL, 83% had < 2.0 ng/mL. Risk of prostate cancer and death from prostate cancer were strongly associated with PSA-levels and age: Harrell's C-index 0.75 and 0.72 for diagnosis of younger and older group, respectively and 0.72 for PCa death for both age groups. In the younger age group 196 deaths among 75,446 men (0.26%) were registered, in the older 943 deaths among 82,390 men (1.14%). The risk of PCa death in lowest (< 1) and highest (3-3.99) strata were 0.23% and 3.22%, respectively (189 deaths among 81,982 vs. 274 deaths among 8517 men). **Conclusions:** This population-based NPCC study shows as strong predictive impact of the different strata of the initial PSA measurement in routine clinical care as prior studies based on cryopreserved blood samples. Research Sponsor: Jan Oldenburg.

PSA	Age in years	n PCa deaths	n Men at risk	Proportion	95% CI

The association of germline *HSD3B1* genotype with outcomes in metastatic hormone-sensitive prostate cancer (mHSPC) treated with androgen deprivation therapy (ADT) with or without enzalutamide (ENZA) [ARCHES]. *First Author: Nima Sharifi, GU Malignancies Research Center, Cleveland Clinic, Cleveland, OH*

Background: A common missense-encoding germline polymorphism in *HSD3B1*(1245A→C) stabilizes the 3βHSD1 enzyme and increases the rate-limiting step for metabolic flux from adrenal precursors to potent androgens. This adrenal-permissive *HSD3B1*(1245C) allele mechanistically drives more rapid progression after ADT in nonmetastatic and low-volume (LV) mHSPC. It is unknown whether upfront treatment with ENZA could improve these poor outcomes. We sought to determine the association between the *HSD3B1* genotype and outcomes in ARCHES, a randomized, placebo (PBO)-controlled, phase 3 global study of ADT with ENZA or PBO in mHSPC. Overall, 31.3% of men on placebo crossed over to ENZA prior to progression. **Methods:** Germline DNA from 660 men (243 LV and 417 high volume [HV]) in ARCHES was genotyped for *HSD3B1*. Radiographic progression-free survival (rPFS), prostate-specific antigen (PSA) outcomes, and overall survival (OS) were compared between men who inherited 0 (adrenal restrictive) vs. 1–2 copies of the *HSD3B1*(1245C) allele (adrenal permissive) using log-rank tests, Kaplan-Meier estimates, and Cox proportional hazards models for hazard ratios (HRs). **Results:** In ARCHES, 340 and 320 men had the adrenal-restrictive and adrenal-permissive *HSD3B1* genotype, respectively. The adrenal-permissive genotype was not associated with worse rPFS, time to PSA progression (TTPP), or OS. Cox model HRs for death in the adrenal-permissive compared with adrenal-restrictive men in the ENZA + ADT and PBO + ADT arms were 1.21 (95% confidence interval [CI] 0.84, 1.74) and 1.48 (95% CI 0.98, 2.25), respectively. Three-year OS was 82% and 73% in men treated with ENZA + ADT with restrictive vs. permissive genotypes, respectively, and 68% and 70% in men treated with PBO + ADT. ENZA significantly improved rPFS, TTPP, and OS, irrespective of genotype. HRs for ENZA + ADT vs. PBO + ADT in models adjusted for genotype were: rPFS, 0.64 ($p < 0.001$); TTPP, 0.27 ($p < 0.001$), and OS, 0.62 ($p < 0.001$). Of OS events in the *HSD3B1*-genotyped men, 48 (23%) and 163 (77%) deaths occurred in the LV and HV groups, respectively. **Conclusions:** In men with mHSPC, ENZA improved OS, rPFS, and TTPP over PBO + ADT, irrespective of *HSD3B1* genotype. Survival analysis of *HSD3B1*-genotyped men in this study is largely driven by men with HV disease. The analysis of men with LV disease was limited by the small number of events. Clinical trial information: NCT02677896. Research Sponsor: Astellas Pharma, Inc. and Pfizer, Inc.
